Nevertheless, some experts opine that this phenomenon entirely explains some crashes, neglecting the messy little details that limit or at least create doubt of the theory's applicability. This study presents the general topic and an example, which includes a matrix of specific calculations pertinent to a fatal rear-end collision involving a pickup truck and a commercial truck.

The study of human vision is an integral part of human-factors engineering, which pertains to the assessment of human capabilities in the real world, and includes physical, sensory, and cognitive elements of our daily performance.

An object approaching the eye projects an image on the retina. Initially, the image size appears constant or slowly increasing, but just prior to a potential contact, the rate at which the retinal image increases rises dramatically (exponentially). The projected image is defined by the subtended angle (in radians θ), and its rate of change over time is dθ/dt. The theory suggests that this retinal image rate of change can be used by the visual system to determine the Time To Collision (TTC) and is independent of other speed-related metrics. This ability has long been observed in animal behavior, including animals as diverse as fiddler crabs, chicks, monkeys, flies, and human infants, who all try to avoid looming patterns.

It is reasonable to believe that, in part, we use this aspect of vision as we run over irregular terrain and adjust our gait, or know when to duck under a branch, or, in the case of a diving bird, when to fold the wings. This looming theory has been popularized as a quick explanation of rear-end accidents, particularly trucks. The argument is that a stopped vehicle is not apparent to a driver closing at speed until they are so close that a crash is unavoidable. This simplistic approach ignores the fact that, as drivers, we use many other cues in the visual field, such as contrast, optic flow, textures, and gradients, and that the criteria (thresholds) for looming detection are highly variable.

The discussion of TTC and looming phenomena is straightforward with respect to simple physics, but is complex, and some say questionable, in its applicability to humans and the relationship to automobile crashes. This discussion will focus on a particular case, Kovalchuck v. System Transport, a Washington state jury case in 2017. The base data for this case are as shown in Figure 1, below.

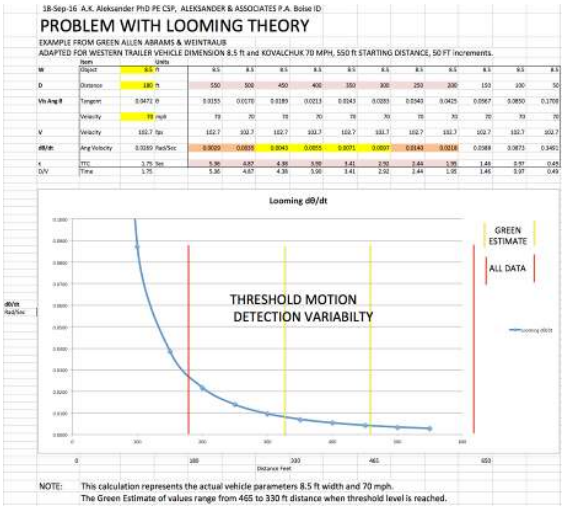

Figure 1. Base Case Parameters, Looming Threshold.

This diagram, the substantiating calculations, and alternative arguments will be presented. Contrasts will be noted for attendees, who will benefit from this discussion by appreciating the complexity of this topic, and the apparent ten-fold variability in the human threshold detection level. Findings of others will also be referenced, and a summary of work in this field will be included. This presentation will conclude with the jury finding.

TAU, Looming, Inattentional Blindness

D8 The Pursuit of a Stolen Patrol Car

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Ste D, Santa Barbara, CA 93111-2326*

The goal of this presentation is to illustrate, by way of examples, how physical evidence can be used together with video analysis to determine vehicle collision parameters in an attempted escape.

This presentation will impact the forensic science community by demonstrating how physical evidence created during a vehicle acceleration maneuver can be analyzed to ascertain useful collision parameters.

Law enforcement officers intercepted a trespassing suspect in progress. The suspect was handcuffed during a routine vehicle search. A sweep of the residence revealed no one was home, but a screwdriver was found near the front door and was presumed to have been used to force entry. The suspect was arrested pursuant to penal code 602.5 (criminal trespass) and placed in the rear of a police car. Further investigation revealed a large amount of cash, a laptop, a portable scale, a .22 caliber pistol, and 11 cell phones.

While the officers were inside the residence processing evidence, the suspect moved his hands from behind his back, around his legs, to the front of his body. The tow truck driver, who was called to remove the suspect's vehicle, was alerted to sounds of the suspect kicking the partition in his attempt to escape (Figures 1 and 2). Turning toward the noise, the tow truck driver's flashlight illuminated the suspect squeezing head-first through the partition window and into the driver's compartment.

Figure 1.

Figure 2.

As the tow truck operator attempted to alert the officers to his discovery, the suspect settled into the driver's seat and shifted the transmission into reverse, spinning the rear wheels as he backed out of the gravel driveway toward the entrance.

In pursuit, the law enforcement officers charged from the residence and sprinted approximately 184 feet toward the accelerating vehicle. At the end of the driveway, the suspect turned the steering wheel and the vehicle yawed clockwise. The brakes were jammed and the vehicle heaved to a stop on the asphalt private drive (Figure 3). The suspect discovered the tow truck and second patrol car were blocking his intended escape route.

Figure 3.

It took approximately seven seconds for the officers to reach the suspect, who was now aware that the sergeant had drawn his service pistol. The suspect ignored his repeated commands to stop, and without further hesitation, slammed the transmission into a forward gear and accelerated the vehicle. Fearing for his safety, the sergeant pulled the trigger continuously, pivoting from his standing position as the vehicle passed.

A ballistics analysis later revealed that all five rounds penetrated the vehicle. Bullets #1 and #2 shattered the driver's tempered glass window (Figures 4 and 5). One bullet passed through the suspect's left arm and exited the right front door. The other bullet tore through the suspect's large intestine and both iliac arteries, requiring extensive surgery. Bullets #3 through #5 entered the vehicle behind the driver's position yet apparently missed striking the suspect.

Figure 4.

Figure 5.

The vehicle impacted the rear of the parked tow truck, halting his attempted escape (Figure 6). The suspect abandoned his escape attempt and was once again apprehended.

Figure 6.

Analysis: Video from an on-board, forward-facing, dash-mounted video camera, photographs, and an incident scene diagram were used determine the vehicle's time-position history during the escape maneuver. It was determined that the patrol car accelerated to approximately 18mph while backing out of the driveway (77 feet long), and the vehicle impacted the tow truck at approximately 15mph.

The vehicle's Restraint Control Module (RCM) recorded a frontal impact event consistent with the subject incident having an algorithm run time of 376ms and longitudinal velocity change of -11.96mph.

Photographs taken during the investigation of the patrol car's instrument panel were compared to an exemplar vehicle to determine the forward gear selected during the escape attempt. The analysis indicates the transmission had been shifted into first gear (Figure 7).

Figure 7.

The subject patrol car was tested to measure its acceleration characteristics on a gravel surface and to evaluate the restrictions imposed on the driver while operating the vehicle wearing handcuffs (Figure 8). The vehicle was instrumented with a Racelogic VBOX II Lite Global Positioning System (GPS) -based data logger and GoPro® Hero3 video camera. Ten reverse-to-forward gear demonstrations were recorded. The reverse demonstrations revealed an average maximum acceleration of 0.252g over a distance of 43.3 feet with a 15.9mph maximum speed. The forward demonstrations revealed a mean maximum acceleration of 0.256g over a distance of 40.2 feet with a 14.4 mph maximum speed.

Figure 8.

The county law enforcement agency and four involved officers reached a settlement with the custody subject prior to trial.

Handcuffs, Coban, RCM

D9 Limit Performance and Controllability Testing of Vehicles Towing Utility Trailers

Robert L. Anderson, MS, Applied Research and Investigations, PO Box 1208, Scottsdale, AZ 85252*

The goal of this presentation is to demonstrate testing procedures for vehicles towing utility trailers and the resulting data from such tests.

This presentation will impact the forensic science community by making known the available standardized test procedures and providing data demonstrating how towing utility trailers limits vehicle performance.

An investigation was conducted to determine how the weight ratio of the tow vehicle to the trailer being towed influences performance.

Two tow vehicles were tested: a 2005 Honda® Pilot®, weighing 5,176 lbs. and a 14-foot U-Haul® Ford® F450, weighing 8,559 lbs.

Two trailers were tested: a 6'x12' utility trailer, weighing 4,008 lbs. and a 5'x8' utility trailer, weighing 2,700 lbs.

Testing instrumentation included a steering machine, cameras, accelerometers, and angle rate sensors. The testing included the following test procedures: (1) braking in a turn, consisting of a turn of either 90° on the steering wheel or 180° on the steering wheel. The speed was increased for each test until a physical limitation, such as jackknifing, occurred; and, (2) sine plus dwell involved a reverse steer of magnitude 180° (similar to a sine wave) with a dwell of one second on the second or corrective steer. The speed was increased for each test until a limit, such as jackknifing, occurred.

The conclusions include: (1) for the 90° steer and braking in a turn, loss of control in the form of extreme jackknifing was experienced at 45mph for the Honda® pulling the 6x12 trailer. Jackknifing was not experienced at that speed with the 5x8 trailer or with either trailer towed by the Ford® truck; and, (2) for the 180° steer and braking in a turn, loss of control in the form of extreme jackknifing was experienced at only 25mph for the Honda® pulling the 6'x12' trailer and was not experienced with the smaller 5'x8' trailer or the Ford® truck with either trailer.

Similarly, the Honda® pulling the 6'x12' trailer experienced jackknifing at 35mph and this was not experienced with the smaller 5x8 trailer or the Ford® truck with either trailer.

In conclusion, vehicles towing trailers in which the vehicle/trailer-weight ratio is close to unity, such as the Honda® towing the 6'x12' trailer, are more likely to lose control than vehicles towing trailers in which the vehicle/trailer-weight ratio is appreciably greater than unity. This presentation benefits the forensic science community by offering a methodology for standardized stability testing for vehicles towing trailers and provides preliminary data detailing how the vehicle/trailer-weight ratio is related to stability in highway-relevant driving activities.

Utility Trailer Towing, Limit Handling, Vehicle Testing

D10 Tow Hitch Failure

Harold Franck, MSEE, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304; and Darren Franck, MSME*, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304*

The goal of this presentation is to introduce attendees to fundamental testing principles to validate or refute an alleged tow hitch failure. The analysis will include calculations and 3D animations of the possible events.

This presentation will impact the forensic science community by describing analytical methods that can be used to evaluate potential events in an alleged tow hitch failure.

On a rainy afternoon that also included strong wind gusts, a boat owner hitched his boat and trailer at a marina complex that performed maintenance on the boat. Personnel at the marina attached the boat-laden trailer to the owner's tow vehicle. The boat owner was cautioned against towing the unit due to the prevailing weather. Eleven miles from the marina, after driving at highway speeds over various roadway surfaces replete with construction activities, various turns and stops, the boat and trailer allegedly became uncoupled. This resulted in the driver losing control, damages to the tow vehicle and boat/trailer combination, and injuries to the driver. These injuries are alleged to be either new injuries to spinal column-based soft tissue or reinjury of such tissue from prior accidents. The loss of control allegation was attributed to improper coupling of the tow vehicle and boat/trailer, categorically implying that the receiver on the trailer was simply placed atop the tow ball on the tow vehicle's hitch. A forensic engineer opined that the physical evidence was consistent with this allegation.

To evaluate the allegation, several basic investigative protocols were employed. The tow ball and hitch were inspected in addition to the receiver located on the boat trailer. An analysis was performed to calculate the forces necessary to cause hitch failure. Analyses were also performed to determine the forces associated with the observed damage on the tow vehicle and the trailer. Additional analyses were performed with an exemplar tow combination. The accident site was extensively photographed to locate physical marks and identify them with accident scene photographs taken by the claimant. The accident was reconstructed and 3D animations were developed to demonstrate the alleged accident scenario as compared to the possible scenario developed from the evidence and supported by established physical laws.

Review and analysis of the physical evidence disproved the opinions of the opposing expert. Damage to the ball on the hitch attributed to loss of control by the opposing expert was shown to be in the wrong position. Other damage attributed to the failure of the ball was instead shown to be attributable to normal wear. The failure of the trailer was shown to be due to material corrosion at a weak location on the trailer. Review of the photographs taken by the claimant conclusively proved that his allegations regarding the cause of the accident were untrue. Testing revealed that if the allegation of the improper coupling of the tow vehicle to the trailer/boat combination had occurred, the unit would have become uncoupled at a speed change of less than five miles per hour and the drive to the accident location was impossible. In fact, the vehicle, boat, and trailer, if coupled as alleged, could not have exited the garage at the marina without having become uncoupled. The accident was proven to have been caused by fishtailing of the unit on wet roads and high winds and that the accident was staged to place blame on the marina.

Forensics, Energy, Testing

D11 The Injury Potential of Fidget Spinners

Sarah V. Hainsworth, PhD, Aston University, School of Engineering and Applied Science, Aston Triangle, Birmingham B4 7ET, UNITED KINGDOM; and Michael E. Fitzpatrick, PhD, The Open University, Materials Engineering, Walton Hall, Milton Keynes MK7 6AA, UNITED KINGDOM*

The goal of this presentation is to highlight the injury potential of fidget spinners, in particular from sharp points or edges that can cause injury when the spinners are used inappropriately as weapons.

This presentation will impact the forensic science community by assisting attendees in understanding the key issues related to the ability of fidget spinners to create stabbing or slashing injuries and other factors that can be relevant to injuries arising from fidget spinner design and manufacture.

Fidget spinners are essentially toys that have a planar multi-lobe structure that spins around a central bearing. Common designs have two or three lobes, and the bearings are contained in a central circular pad or bearing race with a hole through it. The operator either spins the toy while holding the center pad with opposing digits or places the central hole over a finger and spins the device around the digit. These spinners are typically made of metal or plastic, and a wide range of different metal alloys have been used, including brass, titanium, die-cast aluminum, and stainless steel. The bearings at the center of each spinner are made of ceramic or stainless steel and provide exceptionally low friction. As a result, these spinners spin easily and are balanced by weights on the outside that aid balance and retain rotational speed. Fidget spinners reportedly benefit those who have difficulty concentrating or need to relieve nervous energy and/or stress. Some educational institutions have embraced the spinners for aiding attention while others have banned them. There is no scientific evidence that spinners help treat symptoms of autism or Attention-Deficit Hyperactivity Disorder (ADHD).

Fidget spinners have become incredibly popular and retail for low prices (typically <$10). The spinners are typically designed to provide the user with long spin times from an initial impulse, low vibration, and provide a distinctive sensation and noise. Some spinners contain battery-powered Light-Emitting Diodes (LEDs).

While most fidget spinners are designed and intended as toys, there are some issues with the spinners that can potentially lead to injury. Some spinners are now on the market that have sharp points and are marketed as “ninja.” The design of such spinners can be used to inflict injury.

The injury potential of fidget spinners falls into four categories, all of which are related to failure to meet European Conformity (CE) standards or their international equivalents: (1) manufacturing quality — some spinners have manufacturing defects that leave sharp metal burrs; (2) selection of materials of manufacture and the composition of paints, for example; (3) small parts and corresponding age-appropriate warnings (such as whether the spinners contain batteries that could be accessed or swallowed by small children); and, (4) sharpness of the points and blades and whether or not these can create injury.

This presentation reports on an investigation into the sharpness of the points and blades of a range of fidget spinners that are available in the United Kingdom market and their potential for injury. The spinners are marketed as “ninja shuriken” spinners or “dragon blade” spinners. The points on some of the spinners are sharper than that recommended by the European Standard BS EN 71-1:2014 Safety of toys. Part 1: Mechanical and physical properties.

This presentation will illustrate that, although the edges of the spinner blades were dull, the points of some spinners tested are sufficiently sharp to penetrate both tomato and pork skin when used with a stabbing action. Attendees will understand the key issues for fidget spinners that are being designed and marketed to appear threatening and may be used inappropriately as weapons.

Fidget Spinners, Sharpness, Penetration

D12 A Critical Assessment of Cutting — Slicing, Stabbing, Sawing, and Chopping: The Mechanisms of Separating and Penetrating Biomaterials and the Relevance of Sharpness

Sarah V. Hainsworth, PhD, Aston University, School of Engineering and Applied Science, Aston Triangle, Aston B4 7ET, UNITED KINGDOM; and Guy N. Rutty, MD, University of Leicester, Forensic Pathology Unit, Robert Kilpatrick Bldg, Leicester LE2 7LX, UNITED KINGDOM*

The goal of this presentation is to introduce the four main categories of using edged or pointed instruments in forensic cases: slicing, stabbing, sawing, and chopping. Attendees will better understand the way in which biomaterials are divided or invaded by these implements and how this relates to implement edge and tip sharpness.

This presentation will impact the forensic science community by enhancing the competence of forensic scientists and engineers in understanding how each of these four categories of human tissue insult occurs with the various implements retrieved from a crime scene.

Knives, saws, axes, machetes, and other implements are often used in violent crime. Specifically, knives are often used in stabbing attacks in which the depth of the wound is long compared to the injury on the skin or in slashing attacks in which the length of wound on the skin is long, but the depth of the wound into the body is relatively shallow. Saws and axes may be used in dismemberment cases. Other implements (screwdrivers, chisels, etc.) are also used in violent attacks, and the challenge for the forensic scientist or engineer is to relate the particular implement used to the mechanism by which the injury is inflicted. The sharpness, or degree of pointedness, of these implements is a key variable in helping make the link between the implement and the injury. Thus, the goal of this presentation is to define the four different methods in which material can be separated, namely by slicing (or slashing), stabbing, sawing, and chopping, so that the importance of the key features of the implement being used can be investigated and the necessary or controlling forces understood. This presentation will help attendees understand the way in which biomaterials are separated by cutting and how this relates to the sharpness of the implement used.

In cases of slashing, the knife is usually used in a slicing mode in which the blade of the knife is drawn across the body. The lowest cutting force is required when a slice-push action is used. Often in slashing, the blade is presented "obliquely" to the surface being cut.

In stabbing attacks, the sharpness of the tip is important for initial penetration with sharper tips reducing the amount of force required. Once the implement has penetrated clothing or skin, the sharpness of the blade edge is also important for estimation of additional penetration depth. Another parameter that influences the amount of force required for cutting is the friction between the blade and the material being cut. The cutting forces are reduced when the size of the blade is smaller or the material is tougher.

Sawing typically uses a reciprocating motion that engages the series of narrow cutting edges typically found on each tooth of the saw. In contrast to knives, saw blades have parallel sides. Saw teeth are "set," which means the cut is slightly wider than the thickness of the blade; this helps prevent "binding" of the saw blade in the material being cut and diminution (or cessation) of the essential reciprocating motion. Saws are designed with different teeth profiles to optimally cut different materials; however, saws used in crimes are usually those of convenience, not specific design.

Chopping is typically performed by wedge-shaped implements such as axes and machetes that are designed to cut through materials by a single forceful impact rather than a steady or reciprocating push or pull. The force delivered by a chopping impact is generally of greater magnitude than the force delivered by a push. The muscles of the arm and shoulder contribute to accelerating the fall of the implement and add to the total force of impact above what would be obtained by simple free-fall. The material is divided into two parts by driving the wedge-shaped chopping implement into the material, and a crack (or split) forms at the tip of the wedge. The wedge angle of the implement, along with implement weight, velocity, and material resistance, influences the ability to form the crack. The principle motion of implements used for chopping are perpendicular to the cutting edge of the implement.

This presentation will discuss the ways in which different implements cut through or penetrate materials and identify the important characteristics of the blades and edges that are key factors in controlling the separation of these materials.

Cutting, Sharpness, Penetration

D13 Who's Driving?

David Pienkowski, PhD, University of Kentucky, AB Chandler Hospital, Rm MN 564, Lexington, KY 40536-0298*

After attending this presentation, attendees will understand how biomechanics can provide useful information that helps identify operators of motor vehicles involved in accidents.

This presentation will impact the forensic science community by raising awareness that motor vehicle operator identification is sometimes obscure and by illustrating how biomechanics can be used to reduce uncertainty in efforts to identify operators of motor vehicles involved in crashes.

Operator identification of a motor vehicle involved in an accident, while always imperative due to potential criminal and nearly ubiquitous civil consequences, is sometimes obscure due to event circumstances or operator intent to eschew culpability. Correct operator identification is also necessary to prevent wrongful incrimination of innocent passengers.

First responders may report unrestrained occupants in out-of-position interior vehicle locations or outside the vehicle following crash-induced ejection. Operator identification is obscured when such occupants are unable or unwilling to disclose the facts or when uninjured drivers flee the scene before first responders arrive. Forensic investigations seeking operator identification may benefit from the application of biomechanics to analyze the relationships between vehicle damage and human injury.

External vehicle collision analysis quantifies crash force vectors and energy magnitudes. It is an essential prerequisite for application of biomechanical principles seeking driver identification. The principle direction of force is a key parameter established by vehicle collision analysis that, in turn, enables useful information to be obtained from the "second collision" (i.e., occupant collision with the vehicle interior).

Direction of occupant motion is, in the event of a single crash event, parallel to the line of action of the principle direction of force. This line of action determines the trajectory of the body of the unrestrained occupant or the limbs of restrained occupants and the vehicle interior components struck. Information regarding occupant trajectory, considered with first responder-provided data, enables estimation of pre-crash occupant position. Vehicle rollovers and successive crash impacts confound this analysis due to multiple, and sometimes unknown, crash force lines of action. Position identification may also be confounded by occupant ejection due to uncertainties regarding vehicle angle at the time of ejection, escape velocity, and body trajectory.

Consideration of crash force magnitudes may also assist driver identification because these force magnitudes are often proportional to occupant injury severity. Crash force magnitudes may be passenger compartment-specific and are most helpful when considered from two complimentary perspectives: vehicle interior interactions with the human body and human body interactions with the vehicle interior. These interactions require information concerning the mechanical properties of the struck vehicle's interior elements and striking human body components. Quantification of interior component striking force magnitudes begins with peak values established by external collision analyses; these peak force magnitudes are subsequently mitigated due to intervening vehicle structures. Mechanical properties of vehicle components are typically constants with each vehicle design and are amenable to empirical verification. Mechanical properties of human limbs, organs, or tissues are highly variable and depend upon gender, age, genetics, etc. Analysis of the multiple relationships among crash force magnitudes, vehicle interior damage (magnitude, direction, and location), and reported (emergency services and hospital records) type and extent of injury to each vehicle occupant collectively provides data regarding occupant positions at the time of the crash.

Biomechanical analyses of organ damage due to intra-body cavity impact may also provide useful occupant-relevant data. Examples include aortic isthmus injury due to blunt chest impact, femoral head-induced acetabular wall fractures due to knee-dash impact, seat belt-related liver or spleen lacerations, and cranial contusions due to B-pillar impact. Unfortunately, quantitative biomechanical analyses of these injury types are frequently limited by insufficient knowledge of the constitutive mechanical properties of the affected organs and their individual variations with gender, age, genetics, etc. Difficulties performing such analyses are substantially increased when any of the occupants are infants or toddlers.

In conclusion, biomechanical analyses of human injuries relative to vehicle damage can be a useful tool in aiding forensic investigations seeking motor vehicle-operator identification.

Biomechanics, Motor Vehicle Crash, Driver Identification

D14 An Overview of Physical Evidence to Assist With Driver Identification in Vehicle Collisions

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Ste D, Santa Barbara, CA 93111-2326*

The goal of this presentation is to illustrate, by way of examples, how witness marks observed on vehicle interior surfaces and seat belt assemblies and the associated occupants' injury patterns may be collectively used to determine who was operating the vehicle at the time of collision.

This presentation will impact the forensic science community by providing a list of vehicle surfaces to be examined, the physical evidence commonly observed, and the general body regions and injury sites involved in collisions where driver identification is unclear. This presentation will further demonstrate how aligning physical evidence created during frontal, rear-end, lateral, and rollover collisions with observed injury patterns or types may be vital in correctly identifying the occupant's seating position. This presentation will also provide a useful list of vehicle interior components and the associated body regions regularly examined for physical evidence confirming the corresponding impacts. While this list is not intended to be complete, it presents a useful compendium upon which the forensic investigator may rely.

Vehicular collision forces and the resulting occupant motion will often produce impacts between the occupant and vehicle interior surfaces. Impact forces applied to the human body during contact with the vehicle interior may cause injury. An analysis of the resulting interfaces and location of corresponding injuries may be used to correctly identify the driver in a motor vehicle collision. Specifically, an occupant's initial motion during a vehicle collision is toward the velocity change vector. Knowing the collision type (frontal, rear-end, side, or rollover) will help the investigator correctly identify and examine the potential surfaces of interaction. In frontal collisions, these typically include forward surfaces such as the sun visor, header, windshield, roof pillars, steering wheel, airbag fabric, dashboard, glove box, knee bolster, and center console. In rear-end collisions, the surfaces exposed to occupant contact are the front seat assembly, head restraint, rear seat, rear roof pillars, package shelf or cargo area, rear window, and roof header. In side impacts, potential contact evidence may be observed on the door panels, window glass and frames, roof pillars, and center console. In rollover collisions, the headliner, passenger handles, and dome lights must be examined.

Physical evidence often observed on vehicle interior structures includes blood stains, tissue and hair deposits, makeup, fractured glass, steering wheel rim deformation, seat back deformation, and plastic trim deformation, as well as scuffs, abrasions, and cracks on various vehicle surfaces. Close-up examination of interior surfaces may reveal striations to the plastic. Striations are caused by clothing with a coarse fabric weave, such as denim. In these circumstances, knowledge of occupant clothing may be useful in the analysis.

Regions of occupant injury include feet, lower extremities, knees, hips, abdomen and upper torso, neck, head, forehead, face, shoulder, upper extremities, and hands. Commonly observed occupant injuries include abrasions, pattern bruises, lacerations, and fractures, along with a host of internal injuries. The location of these injury sites may be aligned with corresponding vehicle interior evidence of human forcible contact. Medical records may reveal notations of a knee abrasion or a femur or hip fracture. This may be indicative of forcible knee impact into the knee bolster, and this may be verified by vehicle inspection. Abrasions may also result in tissue or hair deposits. The search of the vehicle interior for such a deposit may be instrumental in evaluating the seating position of this occupant. Coloration of hair fibers in particular locations may assist in determining which occupant struck the particular vehicle area.

If the seat belt is worn during the collision, the webbing presents an additional surface of interaction. Restraining forces are applied to the occupant by the seat belt webbing and examination of such webbing may reveal tissue, clothing fiber, or metal transfers arising from the application of these forces. Bruises from the webbing are often observed, though not always expected, when the seat belt is worn during a crash. A diagonally oriented shoulder belt bruise is a telltale indicator of restraint use. The direction of these bruises, crossing upper-left to lower-right or vice versa, is helpful in determining seating position.

Injury, Seat Belt Sign, Forensic Evidence

D15 Determination of Driver Identity: Effective Scientific Investigation, Comparison and Contrast of Forensic Evidence, and Its Spoliation in Various Cases

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015*

After attending this presentation, attendees will better understand the wide range of forensic investigation and analysis techniques employed to identify motor vehicle operators. These techniques include 3D land surveying, accurate measurement of vehicle 3D motion, determination of all significant points of vehicle impact to objects and the ground, photogrammetric analysis to allow accurate replication of vehicle position and trajectory, correct interpretation of vehicle crush and crashworthiness performance relative to occupant ejection, trace evidence recovery, and human factors testing.

This presentation will impact the forensic science community by demonstrating an effective scientific methodology utilized to investigate complex rollovers or other crashes with multiple ejections, both with and without seat belt restraints. Examples provided will illustrate how this methodology can be used to overcome the difficulties faced by forensic investigators studying cases in which driver identification is ostensibly unclear. These difficulties include: lack of witnesses, passage of time, destruction of the subject vehicle (accidental or intentional) or other pertinent physical evidence, gross misinterpretation of facts and evidence by others, and obstruction by insurance companies, tow yards, and police agencies. This presentation will benefit forensic practitioners in engineering sciences, criminalistics, vehicle safety, accident investigation, jurisprudence, and pathology.

Determination of vehicle driver identity during collisions or rollovers with vehicle occupant ejection presents unique challenges in accident reconstruction. Police or insurance company investigations are often inadequate, resulting in failure to observe, measure, and document important facts and physical evidence pertinent to driver identification. This leads to misinterpretation and incorrect conclusions; however, the demand to assign driver identity in a crash with severe or fatal injury serves as a significant motivation to reach rapid and correct conclusions, especially in criminal prosecutions. In several cases, insurance company investigators, police, prosecuting attorneys, emergency services personnel, tow truck operators, wrecking yards, vehicle occupant relatives, auto manufacturers, or other authorities have unwittingly and sometimes intentionally removed or altered critical evidence at crash sites, within vehicles, or even destroyed the subject vehicle before a comprehensive analysis was conducted by a qualified and objective investigator. Destruction of evidence may also occur at the hand of a driver who seeks to avoid responsibility for a serious or fatal crash. All of these corrupting factors can negatively influence a forensic investigation to determine driver identity.

Several cases involving severe vehicle rollovers or collisions with all occupants ejected, usually with one or more killed, and no witnesses will be presented. All of these crashes were examined with adequate time and equipment to properly identify and measure the available facts and forensic evidence and to conduct driving tests pertinent to human factors, visibility, road conditions, and vehicle handling characteristics through the last known path of the subject vehicle. Comparison of current conditions with crash scene photographs and measurements is critical because government agencies have occasionally altered roadways, guardrails, or signage after such a crash. These comparisons also require photogrammetric analysis of 3D land surveys to allow accurate replication of vehicle and occupant positions and trajectories, verification of police measurements and other reported data, determination of all significant points of vehicle impact to fixed objects and various types of ground surfaces, location of all deposited glass and vehicle wreckage components, and vaulting velocity and trajectory of vehicles and ejected occupants. When vehicles are available, analysis of occupant loading of seats, belts, and vehicle interior structures, along with identification and correct interpretation of vehicle damage and witness marks and transfers of fabric, skin, hair, etc., are also conducted.

On occasion, such investigations may not occur until years after the crash. This means that important data may be obscured during the intervening time, and such data may be exposed only by: descending cliffs or climbing trees; electronic metal detection for objects covered by soil or foliage; excavation of vehicle parts and glass fragments from swamps, roadside ditches, culverts, and crop fields; and recovering clothing, personal effects, and hair and other body parts from vehicle interiors and crash sites.

Accurate and thorough forensic examination of evidence at the crash site and subject vehicle are critically important. This analysis includes spatial vehicle-occupant position, determinations using exemplar vehicles and components, review of maintenance and repair records of guardrails and other roadside appliances, procurement and analysis of paint samples, obtaining maps and photographs of body injury sites, video, newspaper, and television reports of the accident, and obtaining all available reliable facts from witnesses and first responders, as well as human factors testing and the application of vehicle crashworthiness knowledge. These are the key elements that comprise a thorough forensic investigation that has the best chance of correctly identifying the motor vehicle operator. In several instances, vehicle safety defects were evident and became crucial factors in determining restraint use and failure, manner of ejection, ejection portal and timing, and pre-crash occupant locations. This includes failures of seat belts, seats, door latches, roof structures, tires, axles, and other vehicle components or safety systems.

Driver Identity, Vehicle Occupant Ejection, Pickup Truck Rollover

D16 Vehicle System Forensics and Determining Who Was Driving at the Time of a Crash

Wesley Vandiver, Collision and Injury Dynamics, Inc, 149 Sheldon Street, Oceanside, CA 90245*

After attending this presentation, attendees will have an appreciation for the vast amount of digital data stored in modern vehicles and how it can be retrieved to assist in identifying the driver of a vehicle following a traffic collision.

This presentation will impact the forensic science community by introducing a new source of data stored in modern automobiles and by illustrating how that data can be used to identify the driver of a vehicle during a collision investigation.

Electronic data being recorded and stored in modern vehicles is an established concept; however, what data are recorded, and where and how to retrieve that data, depend on many variables. Common types of data stored and regularly retrieved from modern vehicles include diagnostic data used in service and repair and crash data used in the investigation of traffic collisions. A more recently discovered source of evidence in motor vehicle incidents is the existence of stored electronic data in vehicle infotainment and telematics systems. The retrieval and analysis of this new data is now commonly referred to as Vehicle System Forensics.

Many collision investigations result in an issue of identifying the driver of a vehicle at the time of the collision. Scenarios in which this issue manifests itself include rollover collisions that have resulted in occupant ejections. It is not uncommon for collision investigators to respond to the scene of a rollover collision where a surviving party states that the driver of the vehicle at the time of the collision was ejected from the vehicle and is now deceased at the scene. There are many approaches to investigating this statement and identifying evidence that would support or refute this party's claim. Analyses involving trace evidence, DNA, biomechanics, and occupant kinematics are common; however, with many modern vehicles, there may be stored electronic data to assist the investigation of this issue.

As an area of focus for this discussion, a hypothetical scenario involving a late-model Ford® vehicle will be examined. The vehicle was equipped with the Ford® SYNC® 3 infotainment and telematics system. The collision scenario being examined is a simple one — a vehicle was driven off the roadway and overturned. One occupant was ejected and killed (Party A). A second occupant (Party B) survived and provided emergency personnel on scene with a statement that included the following claims: (1) Party A was driving at the time of the rollover and Party B was seated in the passenger seat; (2) Party A was ejected out the driver's door as it came open during the rollover sequence; and, (3) after the rollover ended and the vehicle came to rest, Party B exited the vehicle through the passenger door, which he opened.

Data recorded by the Ford® SYNC® 3 infotainment and telematics system in this vehicle can be accessed using the Berla iVe vehicle system forensics tool. This system allows the retrieval of extensive data from this type of vehicle. Example data parameters include vehicle speed, tracking logs, call logs, contact lists, connected devices, and "events," which include the date, time, and location of gear shifts, opening/closing of doors, hard acceleration, and hard braking. In the examined scenario, data related to the opening and closing of doors would be extremely relevant.

Investigators could undoubtedly examine the physical evidence and determine that the vehicle had been driven off the roadway and rolled over, with one party ejected and killed. Furthermore, both vehicle doors may have been damaged and found open during the on-scene investigation; however, finding observable physical evidence of which door came open during the rollover and which door was opened moments after the collision is unlikely. That data may have been recorded by and stored in the SYNC® 3 module. Specifically, this module can record the date, time, and location (Global Positioning System (GPS) – latitude and longitude) when the driver and/or passenger doors were opened or closed. This information could be directly compared to claims of the surviving party. Other data accessible with the Berla iVe system would certainly be useful in the overall investigation as well.

This scenario and depictions of the specific data that can be relied upon in examining the central issue of driver identification will be presented. Specific examples of this data will be demonstrated with a discussion of its availability and retrieval.

Vehicle System Forensics, Infotainment and Telematics Systems, Driver Identification

D17 If the Shoe Fits, Wear It — Using Injury Patterns, Forensic Science, and Impact Biomechanics to Identify the Driver in a Fatal Vehicle Crash

Billy S. Cox, Jr., Billy Cox Group, PO Box 1699, Navasota, TX 77868*

The goal of this presentation is to raise awareness of the problems of identifying the driver of a vehicle in a fatal crash and to highlight the evidence that should be collected and examined when the identity of the driver is in question.

This presentation will impact the forensic science community by informing attendees that in high-speed motor vehicle collisions that result in one or more deaths, identifying the driver of a vehicle can be difficult in situations in which the occupants are unrestrained and ejected from the vehicle or displaced due to the dynamic behavior of the vehicle, post-crash. This presentation will raise awareness of the problems encountered in identifying the driver of a vehicle in a fatal crash and will reveal the key parameters obtained from analytical and forensic science methods that can be used to identify the driver of a head-on crash resulting in vehicle rollover, displacement of the occupants, and multiple fatalities.

In the subject collision, the left front of a Jeep® Grand Cherokee® struck the left front of a Chevrolet® Cavalier® sedan in a wrong-way freeway collision. There were two occupants (A and B) in the Jeep® (the "wrong-way" vehicle). After impact, the vehicles disengaged and the Jeep® rolled over. One Jeep® occupant was found in the right front seat and the other Jeep® occupant in the rear seat after the crash. A jury found that Occupant A was the driver of the Jeep® and was convicted on two counts of Intoxication Manslaughter.

Review of the injuries sustained by Occupants A and B was straightforward and instrumental in determining the Jeep® driver. The driver floor pan and left front hinge pillar exhibited a high degree of collapse and intrusion. The left shoe of the driver was impinged by this crush damage. There was also evidence of heavy knee impact on the left side of the lower dash.

The mechanism of a complex relative movement with multiple energy transmission is influenced by the deformation characteristic of the dashboard and the foot well space.[1] The crush deformation in the foot well can cause the feet to be fixed in the foot space (i.e., the foot as well as the tibia are subjected to bending and compression forces). Lower extremity injuries from the foot to the pelvis are common in offset frontal crashes.

In a set of 1,189 frontal crashes, 23 were identified with ankle or foot fractures of severity Abbreviated Injury Scale (AIS) $\geq$2.[2] Half of the injuries were caused by direct-force application due to entrapment of the leg by passenger compartment collapse.

Occupant A sustained lower extremity injuries, including midshaft fractures of the right tibia and fibula, a left anterior leg wound, and a closed fracture of the left hallux, distal phalanx (big toe). These injuries were photographed. These injuries and the mechanism thereof are well documented in the literature and in exemplar crash tests for drivers of vehicles involved in off-set crashes with foot well intrusion.

Occupant A also reportedly sustained a cervical fracture at the C6 level. The unrestrained driver of the vehicle would have interacted with the vehicle, such as loading of the steering wheel and head contact with the roof, top of the "A" pillar, or sun visor due to the collapse of the "A" pillar on the driver's side.

The laboratory analysis also determined that Occupant A fit the DNA profile obtained from the driver's side airbag. No blood match was obtained. This is an indicator that Occupant A interacted with the airbag during the initial crash phase and not during the rollover event.

The adverse expert speculated that an abrasion on the right-side neck of Occupant A may be related to a seat belt injury from the passenger side belt. This type of abrasion alone is not an indicator of seat belt usage, absent of any other forensic evidence such as diagonal bruising along the torso, left side rib fractures, and forensic markings on the seat belt. Crash tests with exemplar vehicles demonstrate abrasions characteristic of occupant loading on the drivers "D" ring.[3-6] The investigating officer specifically examined the driver and front passenger seatbelts for evidence of occupant loading and found none.

Biomechanics, Crash, Injury

D18 Follow the Broken Bones — Using Injury Patterns, Forensic Science, and Impact Biomechanics to Identify the Driver in a Multi-Occupant, Double-Fatality Vehicle Crash

Billy S. Cox, Jr., Billy Cox Group, PO Box 1699, Navasota, TX 77868*

The goals of this presentation are to raise awareness of the problems in identifying the driver of a vehicle in a fatal crash and to highlight the evidence that should be collected and examined when the identity of the driver is in question.

This presentation will impact the forensic science community by outlining the crash investigation methodology, including the biomechanics used to identify the driver in a single-vehicle crash wherein one occupant was trapped in the wreckage and the other was ejected.

In high-speed motor vehicle collisions that result in one or more deaths, identifying the driver of a vehicle can be difficult. In cases where the damage to the vehicle is catastrophic, the occupants may be crushed in the wreckage or scattered along the crash scene if the vehicle breaks apart. Using excerpts from the forensic autopsy, crash scene photographs, and the seat belts from the vehicle, this presentation outlines the crash investigation and the forensic biomechanics used to identify the driver.

The example presented involves a single-vehicle crash wherein a speeding vehicle struck a tree, two persons were killed, and a third was severely injured. The front of the vehicle separated at the firewall and traveled approximately 160 feet. Damage to the occupant cabin was catastrophic. The vehicle struck the tree near the right front passenger-door mirror. The tree penetrated the vehicle approximately 3.5 feet at an angle of about 65 degrees measured clockwise from the centerline. The force of the impact crushed the occupant cabin such that the right front passenger seat was near the normal position of the driver's seat.

The crushed occupant cabin contained one deceased teenage male and one critically injured juvenile male. Another deceased teenage male was on the ground outside the driver's side of the vehicle. The investigating police agency identified the ejected male as the passenger and the deceased male entrapped in the wreckage as the driver.

The medical examiner's report revealed that the ejected teen male had a ruptured aorta and a massive, displaced skull fracture that extended from right front temporal region through the left parietal bone. The fracture pattern matched the Principal Direction of Force of the collision. There was also a deep laceration on left side of his neck. The ejected male also exhibited diagonal bruising and abrasions on his upper torso, consistent with shoulder belt use. The deceased male located in the wreckage had extensive lower extremity fractures, a basilar ring fracture, and an abrasion on right front side of his head with no skull fracture. There was no evidence of seat belt use on the deceased male located in the wreckage.

Analysis of the seat belts revealed that the shoulder portion of the driver's side seat belt was pulled apart during an extreme loading event. The ends of the belt were frayed and the fibers exhibited evidence that the heat generated during the forced separation created small, melted bubbles on the ends of the fibers. The mounting brackets on the driver's side seat belt retractor were bent. The "D" ring on the driver's side B-pillar of the vehicle displayed evidence of a heavy loading event. The passenger side seat belt was intact and hanging in the retracted position against the passenger side B-pillar. The mounting brackets on the passenger side seat belt retractor were pristine, indicating that the passenger belt was not worn. The forensic pathology identified in the postmortem autopsy, along with the understanding of fundamentals of impact biomechanics and crash reconstruction, confirmed that the ejected male was the driver.

After the independent investigation was complete, the investigating police agency changed the report to reflect these findings. The investigation was previously profiled in a Discovery Channel® program entitled *Crash Detectives*.

Biomechanics, Crash, Injury

D19 A Rollover Off a Cliff With No Witnesses, No Vehicle, and Nothing But Unreliable Information: The Use of Forensic Evidence, Vehicle Crashworthiness, and Human Factors Testing to Prove Driver Identity

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015*

The goal of this presentation is to demonstrate how accurate driver identification can be determined despite a paucity of physical evidence and gross misinterpretation of facts by law enforcement and other key personnel.

This presentation will impact the forensic science community by demonstrating how a complex real-world rollover collision case was solved by the methodical and thorough application of forensic science principles. This presentation will help those involved in forensic engineering sciences, forensic pathology, law enforcement, and jurisprudence gain insight into the correct manner in which to approach difficult cases, such as the case presented.

This case involves an unmodified (since manufacture) two-door compact pickup truck that ran off a highway, travelled over a cliff, and struck a tree as it rolled over on its way to the bottom of a deep canyon. Both occupants were ejected and killed. No witnesses saw the actual crash. The police investigation resulted in multiple misinterpretations of physical evidence and facts, plus gross over-reliance on unreliable statements from others at the scene. The insurance company destroyed the vehicle immediately upon its release by the police, before any investigation of the physical evidence contained within the pickup could be conducted. The insurance company hired well-known, seemingly qualified forensic engineers to determine driver identity. These engineers never went to the crash scene to examine available forensic evidence and facts, take measurements, or perform any of the other typical scientific investigative efforts that are typically made in such cases.

The lack of witnesses, destruction of the subject vehicle, and gross misinterpretation of facts and evidence by others were all difficulties that had to be overcome. Detailed measurements of evidence remaining at the scene, comparison with exemplar vehicles, analysis of available crash and static tests, proper mapping of the involved human trauma, accurate measurement of the crash site and related physical evidence, and consideration of the entire trip history of the two vehicle occupants were all critical factors that had been overlooked or ignored by the police and seemingly qualified forensic engineers hired by the insurance company.

A wide range of forensic investigation and analysis techniques were employed in this investigation, including 3D land surveying, accurate measurement of vehicle horizontal and vertical trajectories, determination of all significant points of vehicle impact to external objects and the ground, photogrammetry permitting accurate replication of vehicle position, correct interpretation of vehicle crush and crashworthiness performance data relative to occupant ejection, trace evidence recovery, and human factors testing.

In conclusion, thorough, methodical, rigorous forensic examination of the crash site, all physical evidence and photographs, coupled with a thorough understanding of crash dynamics and human factors, as well as application of vehicle crashworthiness knowledge, can allow accurate conclusions to be obtained despite the unavailability or misinterpretation of critical evidence.

Driver Identity, Vehicle Occupant Ejection, Vehicle Crashworthiness

D20 Forensic Analysis and Testing to Evaluate Football Helmet Environmental Degradation and the Effects of Repeat Impacts

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661; Mark N. West, BS, Environmental Research & Safety Technologists, 1440 W Bay Avenue, Newport Beach, CA 92661; Luis Frausto, MS, Exova OCM, C/O ERST Inc, 1440 W Bay Avenue, Newport Beach, CA 92661; and Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336*

The goal of this presentation is to present a method for improved scientific evaluation and certification of football helmet head impact potential when used in common, but not currently tested, conditions of both high temperature and humidity, as well as repeat impacts.

Certification and evaluation of new and reconditioned football helmets should include impact performance evaluations under high temperature and high humidity soak conditions that more realistically replicate early season environmental use conditions. This presentation will impact the forensic science community by discussing why this type of evaluation can be beneficial in the early phases of helmet design, and in the reconditioning of used helmets, to assist in the proper selection of energy-absorbing padding that is more resistant to degradation of impact safety performance in high temperature and high humidity environments.

Forensic evaluation of football helmets requires evaluation of factors and variables that can adversely affect the impact-attenuating performance of Energy Absorbing (EA) pad materials as well as helmet shells, face masks, and retention straps. All these safety devices are needed to minimize transmission of linear and rotational forces applied to the head, so that risk of head injury is reduced.

One factor largely ignored by current safety standards is player head heat and contact sweating, which can induce high temperatures (>120°F) and humidity (100%) within a helmet system (Hot-Wet condition) even in moderate environmental weather conditions. This can result in degradation of helmet EA capacity and result in significantly increased risk of head injury.

In this study, adult and youth football helmets of various designs were subjected to a range of varying temperature, humidity, and mechanical impacts (of both varying amplitude and number of load cycles). Quasi-Static (QS) compression testing of commonly used EA materials and dynamic impact testing of full helmet systems were conducted. A long-recognized "multivariable" experimental method was utilized to demonstrate an efficient means for assessment and comparison of currently representative helmets.

The QS tests revealed that a short Hot-Wet soak time of only a few hours noticeably diminished EA levels. The EA pad types that were QS tested included: Thermo-Plastic Polyurethane (TPU) "waffle shaped" EA pad configurations; load-rate sensitive "gel" foam padding; and dual- and single-density elastomeric foam padding.

Dynamic helmet repeat-impact tests were conducted by using a pendulum-impact test device where various helmet designs were mounted to a Hybrid-III head and neck system and impacted against a non-yielding surface after being subjected to ambient and Hot-Wet conditions, at energy levels of 108J and 130J. These energy values are typical of the energy levels resulting from speeds (5.95- to 6.12-second 40-meter dash speeds) of 11-year-old youth players to high school athletes who often run a 40-yard dash in 5.2 seconds, which generates an energy level of approximately 125J. Dynamic full-helmet system testing demonstrated that the "Hot-Wet" condition tended to degrade helmet impact attenuation performance such that, depending on the size and type of EA material provided in the crush zone, head injury risk measures tended to significantly increase.

The Hot-Wet effect was confirmed by testing during a 1992 forensic study of helmet energy-absorbing padding performance and injury risk from only minor to moderate head impacts while wearing a "reconditioned" helmet. It was confirmed that increased helmet temperature and moisture significantly increased head injury severity levels. These earlier forensic studies were recently compared to newer helmet designs, which also showed the likelihood of increased injury risk. Clearly, increasing temperature and moisture in EA padding is an important variable that must be considered in the safe design of any helmet.

Finally, the use and benefits of a "multivariable" experimental method for helmet injury risk assessment, not reported on previously, is provided. QS testing is useful as an economical, effective "first step" to evaluate various EA materials under a range of environmental and loading conditions. Then, "second step" dynamic helmet testing provides reliable evaluation of helmet safety and head injury risk over a wide range of variables, or factors, through the use of only a relatively small amount of test combinations. The multi-variable analysis concept is used to demonstrate how the Head Injury Criteria (HIC) response for a specific helmet design varies over a range of temperature-moisture conditions and impact energy levels generated from "high-low" tests. This two-step test methodology using QS screening of EA loss followed by realistic dynamic test multivariable assessment of the full helmet system as it relates to meeting the defined levels of head injury risk protection provides a valid, cost-effective, and efficient scientific approach for studying the interrelated effects of many variables without resorting to a limited trial-and-error approach examining individual variables in isolation. The implications of this design for helmet testing and analysis may affect most types of helmets since head heat and contact sweat are factors present anytime a helmet is worn.

Football Helmet Testing, Head Injury Severity, Helmet Repeat Impacts

D21 Differential Protective Effects of Motorcycle Helmets Against Head Injury

Michael Singleton, PhD, University of Kentucky, 333 Waller Avenue, Ste 242, Lexington, KY 40513*

After attending this presentation, attendees will understand that motorcycle helmets provide differing degrees of protection against various types of head injury.

This presentation will impact the forensic science community by providing evidence from real-world traffic crashes that motorcycle helmets manage rotational acceleration less effectively than linear acceleration.

Background: Previous observational studies have clearly demonstrated that motorcycle helmets protect riders against head injury; however, the extent to which helmet protection differs across head injury mechanisms remains unclear. Most previous studies of real-world motorcycle crashes considered aggregate protection against head injury. Biomechanical research in cadavers, animals, and computer models has established that head injuries differ in their etiologies. Skull fracture requires a direct impact with a high-amplitude linear component, whereas concussion results primarily from angular acceleration of the head.[1-5] Injuries to the head caused by motorcycle crashes are likely to involve both linear and rotational forces.[2,6,7] This study examined helmet protection versus skull fracture, cerebral contusion, intracranial hemorrhage, and cerebral concussion in a consecutive series of motorcycle operators involved in traffic crashes in Kentucky.

Methods: Anonymized police accident reports, hospital inpatient claims, and Emergency Department (ED) claims for the years 2008 to 2012 were matched by probabilistic record linkage. The study sample included motorcycle operators with known helmet use who were not killed at the crash scene. Police accident reports were used to ascertained operator helmet use. Skull fractures, cerebral contusions, intracranial hemorrhages, and cerebral concussions were identified from the *International Classification of Disease, 9th edition, Clinical Modification* (*ICD-9-CM*) codes on the claims records. Generalized estimating equations were used to estimate the relative risks of each type of head injury for helmeted versus unprotected operators.

Results: Helmet protection against skull fracture (*Risk Ratio* (*RR)*=0.31, 95% *Confidence Interval (CI)=(*0.23, 0.34)), cerebral contusion (*RR*=0.29, 95% *CI*=(0.16, 0.53)), and intracranial hemorrhage (*RR*=0.47, 95% *CI*=(0.35, 0.63)) was substantial. The RR estimates represent the risk of each injury type among operators who wore a helmet, compared to operators who did not. RR<1 indicates a protective effect. The results for uncomplicated concussion (*RR*=0.80, 95% *CI*=(0.64, 1.01)) were inconclusive. The RR estimate (20% risk reduction) suggested a modest protective effect, but the result was not statistically significant.[8]

Conclusions: Motorcycle helmets were associated with a 69% reduction in skull fractures, 71% reduction in cerebral contusion, and 53% reduction in intracranial hemorrhage. This study concludes that current motorcycle helmets do not protect equally against all types of head injury. Efforts to improve management of rotational acceleration in motorcycle helmets should be considered.

Motorcycle Helmet, Concussion, Skull Fracture

D22 Real-World Football Helmet Performance Versus Certification Testing, Refurbishment, and Inspection

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; and Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661*

After attending this presentation, attendees will be familiar with a survey of the current state-of-the-art of sport helmet performance, testing, and real-world usage. Football, rodeo, and equestrian helmet performance, testing, and usage enforcement will be described. This will provide forensic scientists and engineers with new information regarding how football and other sport helmets are performing in relation to the growing field of knowledge regarding the incidence of Chronic Traumatic Encephalopathy (CTE) and other maladies related to youth, high school, college, and professional sports (especially football).

This presentation will impact the forensic science community by enabling those called upon to investigate head and neck injuries in football and other sports, as well as motorcycle helmets, to understand the effects of environmental conditions, certification testing, refurbishment, and real-world usage practices on helmet performance.

Testing and research has proven that significant degradation of football helmet energy-absorption performance occurs due to predictable environmental heat and humidity, as well as unavoidable body heat and contact sweat. New football helmets meeting minimal, antiquated National Operating Committee Standards on Athletic Equipment (NOCSAE) performance standards testing at moderate temperature and humidity repeatedly failed to perform adequately at higher, more realistic levels of heat, humidity, and impact forces consistent with predictable real-world usage conditions. Study testing proved that refurbished football helmets certified fit for safe use demonstrate even greater degradation of protective capacity.

Teams without adequate funds often fail to refurbish helmets adequately, and refurbishment companies often fail to refurbish or test helmets properly to insure reliable safety, leading to potentially insufficient protective performance. Not surprisingly, significant gaps have been discovered between intended or advertised levels of helmet protection, user expectations, and actual user protection. This disparity is likely affected by the proven degradation in protective capacity caused by real-world environmental and usage conditions discovered by this study. It is also predictable that helmet materials will degrade over time and with greater use. Football helmet refurbishment and testing has not always been performed to required standards, resulting in criminal prosecution of refurbishment companies for fraud. Since football helmets can be refurbished for ten years under NOCSAE guidelines with limited testing to determine actual protection performance of this equipment, all with little institutional oversight, this is clearly an even more significant concern.

Research conducted on football helmets to determine real-world, repeat-impact performance demonstrated poor helmet performance. Improper usage, maintenance, fit, damage and refurbishment, and adverse environmental conditions also affect helmet protective capacity. Investigative reports of inadequate helmet refurbishment, as well as evaluation of environmental conditions and inspections of helmets by officials, are described. Despite significant recent efforts to analyze and prevent football-related head injuries, there are far more opportunities for head injuries in practices than in competition because there are fewer trained medical personnel and other observers available to monitor head impacts, proper helmet usage, and potential helmet damage at practices.

In addition to concerns regarding inadequate or misleading helmet refurbishment, effective usage of helmets can be unpredictable and unreliable due to lax enforcement and inspections, poor fit, inadequate maintenance, accumulated helmet damage, basic ignorance, etc. The safety culture of a sport also influences how helmets are utilized and maintained as well as whether injuries are reported or head-injured athletes are restricted from play until medical approval is given for their safe return. Although football has widespread helmet-due-to-rules requirements, other hazardous sports (rodeo rough stock events) often see relatively little helmet use in training despite similar or even greater injury risks. Rodeo competitors in championship events are known to wear helmets without fastening the chin strap, showing a contempt for risks, safety equipment, and rules by competitors and their coaches, and a lack of effort by event officials to insure that safety equipment is in good condition and properly worn.

In contrast to the ten-year refurbishment of football helmets, other sports require that helmets be taken out of use after significant impacts. This is common with bicycle, motorcycle, and auto-racing helmets, but not with football, rodeo, and many other higher head injury-risk sport helmets.

Sport Helmets, Energy Absorption, Environmental Degradation

D23 Does Size Really Matter — Or Is How You Manipulate It More Important? A Review of Data Analysis and Presentation Tips and Tricks

John Nixon, CEng, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation attendees will better appreciate what can go wrong with scientific analyses and testimony, what enabling mechanisms are at work, what motivates practitioners to indulge in unethical and/or illegal behavior, and what strategies may be employed to avoid or minimize such problems.

As the old adage goes, "there are lies, damned lies, and statistics." Some would argue that whoever created that phrase was somewhat myopic — and that it could more correctly be stated as, "there are lies, damned lies, statistics, and government statistics." Experts, judges, and lawyers should be aware of techniques that may be used to misrepresent the facts. This is now more important than ever because in the modern era of digital photography and digital videography, combined with computerized editing, there is ample potential to misrepresent more than just numerical data.

Those indulging in misrepresentation fall into several categories and numerous subcategories. In broad terms, the purveyor of the misleading information may be the devious first-hand manipulator, an unscrupulous messenger who knowingly presents spurious data from a "legitimate and authoritative source" (or otherwise), or merely an innocent, ignorant "victim" who presents bogus data passed along from another source. The latter two categories may be difficult to distinguish — it is amazing how a genius can morph into an absolute imbecile when it comes to interpreting data generated by others. Perhaps this is why courts in some jurisdictions are loathe to allow experts to cite data from studies conducted by others, no matter how prestigious the source: California springs to mind.

When such misrepresentation occurs in the world at large, it can be endlessly debated and debunked (or not); global warming being a good example; however, when misrepresentation occurs in a court, there is less potential for debate — less chance to "get it right" — and the negative consequences may be dire. It usually comes down to one expert contradicting another, and a jury, presumably of limited education and experience in the given specialism, is left to assess credibility based upon unreliable subjective criteria (which expert appeared or sounded most convincing — not always the best indicator of data integrity).

It should be noted that experts are not solely to blame for data misrepresentation. Lawyers see it as their mission to discredit (warranted or not) and mislead. Cross-examination is often used to "debunk" established science by infusing pseudo-science or junk science into an otherwise rational debate. There must be a reason that those lawyers don't operate under oath, right?

Case studies and examples will be used to illustrate the points discussed and speculate as to the motivations of the guilty parties. It will be demonstrated that while some instances of wrongdoing are the acts of individuals, others strongly indicate conspiracy. It is concluded that these practices will continue unabated without systemic reform, and that this reform will take a concerted effort on the part of the legal system and society at large. Perhaps so many key players benefit from these practices that the motivation for change simply does not exist!

Data Manipulation, Misrepresentation, Experts and Lawyers

D24 It's a Fair System, Isn't It? Facts, Alternative Facts, and Other Litigation Influencers

John Nixon, CEng, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will better appreciate what can go wrong with scientific analyses and testimony, what enabling mechanisms are at work, what motivates practitioners to indulge in unethical and/or illegal behavior, and what strategies may be employed to avoid or minimize such problems.

This presentation will impact the forensic science and legal communities by enabling them to identify unethical behaviors, appreciate the diversity of such behaviors, and provide them with ideas for strategies that may be employed to avoid or minimize such problems.

Expert forensic testimony is so widespread that it now often forms the backbone of criminal cases and nearly always plays a critical role in civil litigation. Some disciplines rely on conclusions derived mostly from hard data (test results or recorded observations, for example), while other disciplines rely on subjective opinion that is based upon experience, hypotheses, individual theories, and judgment. Virtually every discipline involves at least some subjective judgment, and that leaves plenty of scope for a well-intentioned process to go awry.

The continuing viability of industries, involvement of huge sums of money, and entire lives are often at stake (death penalty or life without parole). The outcome of trials changes the lives not only of the parties involved, but potentially of huge numbers of people for many years to come. With so much at stake, it is imperative that society ensures the integrity of the system; it should be beyond reproach. Unfortunately, we are falling short of that ideal. The court's role as gatekeeper and the application of *Daubert* and *Frye* standards have helped to keep unreliable expert testimony out of the courtroom, but even these safeguards fall short of desired ideals. *Frye*, for example, requires that testing protocols and underlying scientific principles be accepted by the relevant scientific community — but what objective standards are used to identify the relevant scientific community? The application of a *Frye*-type standard in 16th-century Italy resulted in the incarceration of Galileo because he said the earth was round and rotated around the sun, while the "relevant scientific community" dismissed his work as heresy. How can we be sure that similar errors are not being made in courtrooms today?

Incompetence can largely be overcome by remedial education, training, and stringent staff selection policies. Errors will never be eliminated completely but can be greatly reduced by the adoption of procedures, including independent peer review; however, there are far more sinister forces at work within the system (greed, power grabs, influence peddling, ego aggrandizement, etc.) that motivate humans to lie, commit fraud, intimidate or deceive others, and introduce bias. These can be difficult to detect and extremely difficult to eliminate.

Historically, the legal system appears to have dismissed the aforementioned acts as so rare as to be insignificant; however, a review of cases, and especially criminal cases, reveals that the problem is not as isolated as the layperson may assume. Perhaps there is more motivation to eliminate such acts in civil litigation, where huge sums of money are often involved, and less motivation in the criminal arena, where the high volume of cases and society's perception of criminal defendants as thieves, junkies, rapists, murderers, and general "street scum" results in less scrutiny. The post-conviction process does little to discourage these behaviors. The review system is geared toward errors of process, rather than errors of fact or opinion, and the attitude of the courts is often one of, "tough, the defendant should have hired his own expert and challenged this testimony first time around; he gets only one bite of the cherry." These undesirable expert behaviors have essentially been encouraged by the attitude of the legal community, by experts themselves, by the adoption of poor procedures, and by the creation of innocuous names for unethical or illegal activities. For example, generating fictitious test data (fraud) is often described as "dry labbing," and false and misleading testimony is often described as "he misspoke," even when it leans solely in favor of the hiring party.

Case studies will be used to illustrate the points discussed and perhaps identify the motivations of the guilty parties. It will be demonstrated that while some instances of wrongdoing are the acts of individuals, others indicate conspiracy. It is concluded that the systemic failures that enable these practices to continue will not be changed without significant and concerted effort on the part of the legal system and lawmakers.

Incompetence, Bias, Dishonesty

D25 Ethical Conflicts in Science and Engineering: The Theft of Scientific Records, Marginal Practices, and Breach of Confidentiality in the Peer-Review Process

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; and Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661*

The goal of this presentation is to alert forensic professionals in the ways testing, data, and safety standards have been manipulated and multiple records of taxpayer-supported research and classified information have been intentionally suppressed, stolen, or destroyed. This loss of critical information negatively affects public safety and efforts to improve technology. It also allows defective, dangerous products to continue to be produced, placing the public at risk. None of this could happen if those involved followed the Engineering Code of Ethics.

This presentation will impact the forensic science community by increasing awareness of how automakers, helmet manufacturers, consumer product manufacturers, safety certification groups, government officials, and others who are responsible for generating and maintaining objective and reliable scientific information have failed in many instances to properly carry out this responsibility in an ethical manner. The forensic community and, ultimately, the public will benefit from this presentation.

Many authors have been involved in decades of biodynamics, safety testing, and other engineering research for both the United States Government and the private sector. Several were also associated, before his death, with the legendary Dr. John Paul Stapp of the United States Air Force (USAF) and National Highway Traffic Safety Administration. The theft of scientific records from Dr. Stapp's home and office immediately after his death was briefly described at the 2017 AAFS Annual Scientific Meeting. This presentation expands on that work by providing more detailed contributions from authors, some of whom were actual witnesses to the theft and had early roles in attempts to find the culprits. The author of *Sonic Wind*, a biography of Dr. Stapp published in 2015, later discovered the ultimate fate of these documents.

This presentation will begin with a narrative describing the events preceding re-discovery of the Stapp documents. Legal perspectives and a commentary regarding these documents will then be provided by an aerospace engineer/attorney. Finally, the presentation will conclude with examples outlining the ethical and other pitfalls associated with science and engineering.

One of these examples includes a recently experienced violation of author scientific rights involving a breach of confidentiality by supposedly unbiased, independent peer reviewers. The reviewers acted in collusion so blatant that one copied the review of the other, and submitted it verbatim to an engineering society. It was only after the authors requested and analyzed the comments that the collusion was discovered, then corrected by this engineering society. This is only the latest in a series of similar questionable practices that were encountered from individuals and groups who have lost their ethical compass in conducting science and engineering research.

Another example involves safety standards and test methods for motor vehicles. Specifically, despite objections by the National Transportation Safety Board and other safety professionals, manufacturers have successfully lobbied the United States government to eliminate long-established critical safety standards and test methodologies, with no conceivable benefit to public safety. This has allowed dangerous designs that defeat critical safety systems to be produced, in clear violation of well-established safety principles. Misleading warnings are also provided for consumer products in which, even if the warnings are fully complied with, the hazard is still present and will result in a predictable risk of permanent or fatal injury. The public is given no clue that this is the case, and many permanent disabling injuries and fatalities have resulted. This is a clear violation of well-established safety practices. None of this could happen if those involved, from both the manufacturing and the governmental safety agency aspect, had followed the Engineering Code of Ethics.

Evidently, it is becoming easier and cheaper to roll back or eliminate safety regulations than to actually follow state-of-the-art improvements in science, technology, and knowledge by corresponding safety and performance improvements in products. This is facilitated by suppressing publication of scientific research that exposes flaws in existing designs, which explains the motivation for collusion and other unethical practices in the peer-review process, as well as theft of scientific records.

Theft of Scientific Records, Breach of Confidentiality, Violation of Peer Review

D26 Forensic Microscopy in Determining Historical 1960s and 1970s Asbestos Exposures to Cutting Asbestos/ Cement (A/C) Pipe

James Millette, PhD, Millette Technical Consultants, 220 Cricket Walk, SW, Lilburn, GA 30047*

After attending this presentation, attendees will better understand how Polarized Light Microscopy (PLM), Phase Contrast Microscopy (PCM), and Transmission Electron Microscopy (TEM) were used to determine information regarding the historical asbestos exposure to a worker cutting A/C pipe in the days before proper protection procedures were mandated.

This presentation will impact the forensic science community by providing information to assist in the investigation of asbestos exposures that occurred before exposure monitoring was conducted and where few records exist.

Since the 1920s, A/C pipe has been manufactured from a mixture of asbestos, standard Portland cement, and silica sand. Millions of miles of A/C pipe have been sold around the world to carry drinking water, sewage, telephone duct, and cable conduit. Although not officially banned, A/C pipe is generally not currently used in the United States because of the potential release of asbestos fibers, which are a known carcinogen when inhaled. In the 1960s and 1970s, A/C pipe was cut in the field with a variety of tools, including power saws and abrasive disc cutters. Historical asbestos air sampling data during the cutting of A/C pipe is limited.

To provide more information about the historical asbestos air levels during cutting, a study for possible fiber release was conducted involving the cutting of a piece of A/C pipe in a controlled area while air samples were collected. PLM analysis revealed the pipe contained 20% chrysotile and 2% crocidolite. Air samples were collected in the breathing zone (seven feet distant) of a worker using a gas-powered pipe cutter with a new 14-inch diamond blade. These air samples were collected by a worker with pipe-cutting experience.

The study was conducted in a test chamber that was approximately 9ft high by 10ft wide by 12ft long. The study area had a High Efficiency Particulate Absolute (HEPA) air filtration device that was used to clean the area of particulates before testing activities. The HEPA unit ran at a rate of 177cfm during the testing. While inside the study area, the worker was protected by an air-line supply respirator and complete head and body coverings. The chamber and airline supply intake were monitored for levels of carbon monoxide.

Prior to the testing, an air sample was collected within the chamber. It was apparent that the gas-powered cutter (saw) had been used to cut cement previously. Testing was performed to determine whether the cement residue in the cutter contained any asbestos. An air sample was collected next to the power saw cutter while the cutter was turned on, run briefly, and turned off, and while it was being cleaned and blown out with compressed air at intervals over a one-hour period.

The asbestos level in the breathing zone of the worker during the cutting interval was 182 fibers/cc (PCM National Institute for Occupational Safety and Health (NIOSH) 7,400 value times TEM NIOSH 7,402 percent asbestos). The area sample (seven feet away) during cutting demonstrated a level of 159 fibers/cc. No asbestos fibers were detected in the blank samples or in the sample collected in the chamber before the testing began. No asbestos was detected in the cement residue material contained within the cutter when received. No asbestos was detected in the air when the cutter was running and while compressed air was blown into the cutter in pre-experiment cleaning.

Although the carbon monoxide monitor alarm did go off inside the chamber during the test, the carbon monoxide monitor outside the chamber near the supply air intake did not register above zero during the testing.

The high level of asbestos in the breathing zone of the worker cutting A/C pipe in this study are similar to a level of 170 fibers/cc published in a study of workers cutting A/C pipe in a trench in Japan. Other unpublished studies have also reported air samples more than 100 fibers/cc for cutting A/C pipe with power tools.

Microscopy, Asbestos, Exposure Evaluation

D27 A Forensic Performance Analysis of Load-Limiting Devices in Automotive Seat Belt Retractors

Louis Daulerio, BA, ARCCA, Inc, 2288 Second Street Pike, PO Box 78, Penns Park, PA 18943; Gary Whitman, BS, ARCCA, Inc, 2288 Second Street Pike, PO Box 78, Penns Park, PA 18943; Alan Cantor, BS, ARCCA, Inc, 2288 Second Street Pike, PO Box 78, Penns Park, PA 18943; Larry Sicher, BS, ARCCA, Inc, 2288 Second Street Pike, PO Box 78, Penns Park, PA 18943; and Mike Markushewski, BS, ARCCA, Inc, 2288 Second Street Pike, PO Box 78, Penns Park, PA 18943*

After attending this presentation, attendees will better understand the design and operation of automotive occupant safety restraints. Specifically, attendees will better understand the load-limiting device found in most modern automotive safety belt restraints.

This presentation will impact the forensic science community by providing a key aspect of forensic investigations and analysis of occupant safety belt restraints involved in automotive crashes.

The primary function of an automotive safety belt restraint system is to restrain the occupant within the vehicle's occupant compartment. The primary requirements of any occupant restraint system are: (1) to prevent ejection of the occupant, both partial or total, from the vehicle; (2) to prevent or minimize severe interior impacts of critical body areas with surfaces within the vehicle; and, (3) to control the occupant's kinematics in such a way as to load the body through the strong skeletal structures of the body that are most capable of withstanding the loading.

As such, the safety belt should be designed to apply loads to the body of the occupant through the clavicle, sternum, ribs, and pelvis. By using these robust structures within the body, and by optimizing belt elongation, properly designed lap and shoulder belts have been able to strike a balance between neck loading and the potential for severe interior strikes that body movement can cause in many crashes. The introduction of frontal airbags for front seat occupants, along with pretensioner devices to more effectively couple the occupant to the vehicle, provided an additional opportunity to the safety belt designers to address thoracic injuries that can be caused by the safety belt loading and thus provide added protection for the frailer segments of the population. This led to the introduction of safety belt load-limiting devices, which were intended to reduce belt loading while still maintaining proper restraint protection. Unfortunately, the implementation of these devices in some circumstances increased the potential of injury from head impact, ejection, and submarining.

This presentation focuses on the trade-offs involved in the effective design of such load-limiting devices (i.e., the reduction in maximum loading to the occupant versus the corresponding increase in safety belt webbing and subsequent occupant movement). Obviously, if the additional webbing introduced is not controlled properly, the risk of injury to the occupant is greatly increased and could result in more frequent and severe injuries rather than the reduction intended. This presentation assesses the amount of additional webbing introduced by the activation of the load-limiting device by forensic analysis of the affected safety belt and its components involved in real-world crashes.

Crash, Restraints, Load Limiters

D28 Autonomous Vehicle Control Systems and Human Factors

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; and Laura L. Liptai, PhD*, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556*

After attending this presentation, attendees will better understand the control systems of autonomous vehicles, explore what the future of Highly Autonomous Vehicles (HAVs) will entail, and gain familiarity with some of the legal and ethical issues involving autonomous vehicles. In an increasingly connected world, vehicle control technology has the potential to lead to safer vehicles, once the issues of security, reliability, and ethics are addressed.

This presentation will impact the forensic science community by helping attendees: (1) learn the current capabilities of autonomous vehicles and forecast the future of autonomous vehicles; (2) understand how forensic engineering may contribute to control systems design; and, (3) gain a better understanding of the dynamic relationship between HAV technology and related ethical issues.

The increased integration of technology in vehicles, coinciding with the exponential increase in computing power, has led to the advent of the HAVs. Computers process data substantially faster than humans, leading to decreases in automotive braking times, quicker avoidance of hazards, and generally increasing occupant safety.

In 2014, more than 32,000 people lost their lives on the road in the United States (Figure 1), according to the Fatality Analysis Reporting System (FARS) for 2014.[1] This decline is partially attributable to the numerous safety features automobile manufacturers have added to vehicles to reduce deaths from traffic accidents. The most well-known vehicle safety features are pretensioners and airbags. These two features have reduced mortality in head-on collisions by more than 80%.[2] As the level of technology increased through the turn of the century, additional safety features, such as Blind Spot Detection, Lane Departure Warnings, and even Adaptive Cruise Control, have been added to assist or alert drivers to avoid accidents. The results of a 2008 National Highway Traffic Safety Administration (NHTSA) Crash Causation Survey to Congress revealed that 75% of collisions were due to either recognition or decision errors (Figure 2). Recognition errors were defined as inadequate surveillance, distraction, or general inattention. Decision errors were defined as speeding, illegal maneuvers, following too closely, etc.

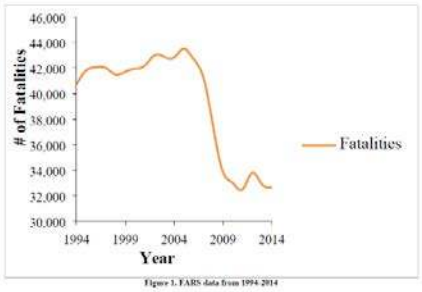

Figure 1. FARS data from 1994-2014

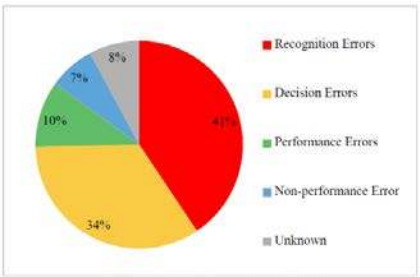

Figure 2. 2008 NHTSA Crash Causation Survey to Congress

Examination of state laws regarding the use of HAVs on public roads reveals a myriad of regulations ranging from permissive to unauthorized use. Such chaos creates issues for the smooth operation of commerce between states and could violate an individual's human rights. The NHTSA's proposal for states to adopt a Model State Policy could create uniformity and partially solve some of these issues.

A major difference between present and future vehicle accident forensics concerns the amount and accessibility of HAV-related data. Two petabytes (10^{15} bytes) of data accompanies processing and responding to the environment around one HAV annually; however, designers of HAV control systems dictate vehicle responses to these input data. This raises new ethical issues because, while human drivers may be "forgiven for making an instinctive but nonetheless bad split-second decision … programmers and designers of automated cars don't have that luxury, since they do have time to get it right and therefore bear more responsibility for bad outcomes."[3] A novel issue is thus raised regarding how will such ethical decision-making be programmed into autonomous vehicles. This will require more thorough dialogue with government, industry, academia, and the public. Other questions will likely also arise from the interface of HAV technology with society. These questions may include: (1) Can HAVs fully replace human drivers?; (2) What will be the socioeconomic impacts of implementing HAVs?; and, (3) Will HAVs disrupt the balance between individual privacy and public security?

This presentation will demonstrate how HAV electronic control systems are tested, including modeling, human simulation, and full-scale experimentation. Exciting and significant performance information will be illustrated with these modeling and testing examples.

Autonomous, Ethics, Controls

D29 What Confidence Do We Have in Confidence Intervals?

Willem A. Schreuder, PhD, Principia Mathematica, Inc, 445 Union Boulevard, Ste 230, Lakewood, CO 80228*

The goals of this presentation are to clarify the correct interpretation of confidence intervals and illustrate how sampling bias and similar factors lead to incorrect confidence limits.

This presentation will impact the forensic science community by informing attendees that confidence intervals are frequently used to ensure compliance with criteria such as maximum contaminant limits. Attendees will learn that sample bias or inappropriate application of upper confidence limits can have significant consequences in evaluating these criteria.

Confidence intervals are widely used to express the certainty with which we can establish that a set of samples exceeds or meets criteria, such as maximum contaminant limits; however, confidence intervals and upper confidence limits are often misunderstood and misapplied.

When considering small sample sets, there may be insufficient information to discern the statistical properties of the data. As a result, many assumptions have to be made regarding important properties, such as the inherent distribution of the data. The situation is further complicated by heterogeneous sample matrices, samples taken at different times, variability introduced by sampling methods, sample preservation, analytical techniques, laboratories, and similar factors that influence data sets encountered in real-world situations.

These sources of uncertainty confound environmental forensic investigations in which investigators often have little control over the data collection efforts. They may be dealing with data sets collected for an event that occurred some time in the past and they can no longer make relevant measurements, or they may be dealing with data collected by another party and they cannot make independent measurements or influence where and how the data are collected. They are simply left with a data set they need to analyze and objectively express the confidence with which they can make various claims.

Further frustrating the establishment of confidence intervals is biased sampling. In some instances, samples are only taken when there is some indication that contaminants are present; for example, staining or when a field instrument such as a photoionization detector indicates the presence of volatile organic compounds. In these instances, forensic investigators have no negative confirmation samples showing background levels. Conversely, sample sets may be biased toward background levels if most of the samples are unrelated to a problem area or there is some other flaw in the sampling protocol, such as sampling too shallow or deep, disturbing the sample, or any number of factors that could cause the samples to be biased low.

Using synthetic data sets for which the statistical properties are known, this presentation explores how these factors contribute to the difficulty of interpreting the data and establishing confidence intervals. This presentation discusses the correct interpretation of the confidence interval, explores how the sample size influences the confidence interval, and illustrates how the distribution of the underlying data is distorted by time, sampling methods, variability in the methods of analysis, and the influence on the confidence intervals. The importance of the sampling protocols is discussed and how sampling bias translates into bias in the confidence interval is demonstrated.

Statistics, Confidence Intervals, Maximum Contaminant Limits

D30 The Effect of Microscopic Surface Coatings and Residues on the Size and Shape of Bloodstains

Samira Shiri, EMA 224 Boston, 730 Commonwealth Avenue, Boston, MA 02215; Kenneth F. Martin, MS, PO Box 1363, 30 County Road, Mattapoisett, MA 01776; and James Bird, PhD, Boston University, 110 Cummington Mall, Boston, MA*

After attending this presentation, attendees will be familiar with how the shape of a bloodstain can be significantly altered if the blood were to impact on a microscopic coating, such as the residue oils and lipids from a latent print.

This presentation will impact the forensic science community by providing results from controlled experiments illustrating how nearly imperceptible surface coatings influence bloodstain size and shape, thereby potentially affecting the results of such analysis. This presentation extends the frontier of research in Blood Pattern Analysis (BPA) to account for alterations in bloodstains due to common coatings that may be encountered at a crime scene.

BPA uses the location, size, shape, and distribution of bloodstains to provide information regarding the events occurring at the crime scene. For example, aspects of the stain can provide insight into the speed at which the blood drop originally hit the surface, which can provide information about the cause of the bloodletting event. Furthermore, when estimating the drop trajectory responsible for a bloodstain, methods that account for gravitational and drag effects rely on an accurate estimate for the impact velocity.[1] Previous research has found a relation between the impact velocity and the number of spines radiating from the dried drop or from the stain size if spines are absent.[2,3] These relations tacitly assume that the drop shape and size would be identical on any smooth surface.[4] The hypothesis presently explored is that microscopic coatings, including residue oil from a latent fingerprint, can also have a significant effect on the size and shape of a bloodstain.

This hypothesis was tested using systematic experiments conducted in a laboratory environment. Four different coatings were prepared on glass slides having a polished non-porous surface. The first set of glass slides was cleaned and left uncoated. The second set of slides was coated with a fixed volume of vegetable oil smeared across the surface to create a uniform microscopic film. The third set of slides was coated with natural sweat secretions deposited by a finger rubbing across the slide, and the final set of slides was coated with a thin layer of soot from a flame, as might occur after a fire. Another group of slides was created using a combination of both clean and coated regions. For each type of slide coating, a single blood drop was released from a given height so that it impacted at a particular velocity. Velocity adjustments were made by changing the height at which the blood drops were released. Impact velocities varied from 1m/s to 18m/s, or terminal velocity for small drops. By recording the drop impact using both high-speed and time-lapse photography, the drop dynamics leading to the final stain could be quantified.

The results demonstrated a significant difference between the shape of a bloodstain on the clean surface and that with a microscopic coating. The size of stains formed on clean glass was larger than those on the glass surfaces with an oily residue. In addition, for the oil-smeared surface, several spines with associated satellite droplets were formed, whereas these did not form on clean glass slides under identical drop impact conditions. By contrast, on the glass surface coated with soot, the blood drop completely recoiled from the surface and, thus, did not leave behind a stain at all.

This study illustrates that commonly found microscopic coatings can alter the way a drop of blood spreads and dries on a smooth surface. This affects the final appearance of the bloodstain upon which BPA examination is based. The results indicate that bloodstain analysts may be able to further reduce uncertainty in forensic reconstructions by noting conditions that might indicate the presence of specific microscopic coatings.

Surface Coating, Bloodstain, Terminal Velocity

D31 Forensic Confrontation in the Engineering Sciences: An International Murder Prosecution Involving American Embassy Military Personnel

Joshua M. Toman, LLM, PLI, 355 W Martin Luther King Boulevard, PH5, Charlotte, NC 28202; and Laura L. Liptai, PhD*, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556*

After attending this presentation, attendees will understand the principal phases of a military court-martial, the critical role of forensic engineering evidence in the pre-trial stages of the case, and their use as "back-stops" to alternative theories.

This presentation will impact the forensic science community by explaining the relationship between the forensic engineer, the military prosecutor, and the expert's ability to inform the military judge or jury.

The Uniform Code of Military Justice (UCMJ) is divided into three phases: pre-trial, trial on the merits, and sentencing (if necessary).

In cases involving serious offenses, including death, two separate entities begin investigating: (1) the law enforcement community; and (2) the chain of command. When cases occur overseas, there is also usually a separate host-nation investigation. These multiple investigations are designed for different purposes and can sometimes be counter-productive. Additionally, there is no organic forensic examiner support in the military outside of a handful of experts. Thus, civilian forensic science experts are usually hired to perform services, often long after the "evidence" has been collected.

The primary goal of this presentation is to present a representative prosecution of a case under the UCMJ involving the death of a Panamanian citizen by a United States Army soldier. The victim's body was discovered in the early morning hours on a Panamanian police training area where the officers were practicing small-arms marksmanship. The victim was the known girlfriend of the accused American soldier, who was receiving training that same day at that training area. The victim died of blunt force trauma. The defendant claimed that she jumped out of the truck and, when he stopped the vehicle, he failed to put it in park, causing it to roll back on top of her. The defendant provided few details and there was no evidence available to determine the location of the actual death. Attempts to collect digital or electronic evidence also failed.

The Panamanian government conducted an autopsy, but no X-rays were taken. At a later date, when the forensic expert was hired, the prosecution was unsuccessful in its efforts to exhume the body for radiographic examination.

At trial, the defense provided expert testimony related to the manner, cause, timing, and location of the death of the victim. The forensic expert hired by the United States Army was essential in challenging that testimony.

Driving, Fatal, Prosecution

D32 Data Center Failures and Outages

Helmut G. Brosz, BASc, PEng, Brosz Forensic Services, 64 Bullock Drive, Markham, ON L3P 3P2, CANADA*

After attending this presentation, attendees will understand the critical importance of preventing data losses in today's information society, the causes of such data losses, and the preventative measures available to avert such losses.

The presentation will impact the forensic science community by: (1) exploring the causes, mitigation, and prevention of power failures and accompanying data losses; and, (2) discussing power failures and outages and the potential for litigation involving data center losses.

Data centers are the hub of communication networks. They are powered by electricity from local utilities, back-up generators, and Uninterruptable Power Supply (UPS) systems. Despite power supply redundancies and proper maintenance, total or partial outages occur and can be a costly disaster for users. Outage costs or penalties in the one-million-dollar-per-minute range have occurred. Litigation can ensue as one or more parties invariably are held responsible. Four cases are presented.

Case 1: Defective switchgear — 480-volt switchgear and circuit breakers are essential components of a UPS distribution system. In-plant inspection at the time of manufacture and proper commissioning are important to achieve the high degree of reliability required. Good electrical connections are necessary to prevent overheating and failure. Thermography is a useful tool for detecting incipient faults and preventing power failures and data losses.

Case 2: Defective Diesel engine overrunning clutches on UPS — Overrunning clutches are used to transfer electro-mechanical power from a motor generator set to a diesel engine during a power failure. Although this transition may last only a few seconds, during this time the clutch is exposed to the harmonic vibrations produced by a large (3,000kw) reciprocating diesel engine. Some types of clutches can fail during these circumstances. This potential source of failure can be averted by proper in-plant inspection and pre-equipment purchase vetting.

Case 3: Improper Maintenance — An establishment's computer and scanners tasked with reading paper credit card receipts were continually failing. The onsite service contractor would replace various printed circuit boards in this equipment using bare-hand handling methods in a service environment that was not designed to safely discharge accumulated static electricity. Upon touching the terminals of the exposed printed circuit board, the technicians would discharge static electricity to sensitive circuit components, ultimately resulting in computer malfunction. Costly arrangements had to be made to have the credit card data read by a competitor.

Case 4: Improper grounding systems — A cold war-era communication center on a hilltop was converted to a data center. The secure 1,000-foot vertical steel well water supply pipe of this center was used as the main building ground. The soil conditions in the vicinity of the center were very dry. The 1,000-foot steel well pipe was connected to the electric utility neutrals and ground. Thus, during utility ground faults, high-fault currents flowed toward the best ground in the area, which happened to be the 1,000-foot well casing. The rise in potential caused failures and outages in the data center. Rearrangement and redesign of the grounding system was necessary.

Data Centers, Failures, UPS Systems

D33 Forensic Image Processing

Marcus Borengasser, PhD, Department of Defense, 3205 Lago Vista Drive, Melbourne, FL 32940*

The goal of this presentation is to provide an overview of forensic image processing techniques and the availability of open source software.

This presentation will impact the forensic science community by providing an introduction to forensic image processing that will raise analyst awareness of an increasingly important technology.

Surveillance video is nearly ubiquitous, from government, institutional, and commercial buildings to outdoor venues and unmanned aerial systems (drones). In many cases, the technology driving the development of video systems has far outpaced the acquisition of resources to aid the analysis of video imagery; however, familiarity with a few image processing concepts can often produce favorable results with video imagery that has been degraded by noise or improper lighting. Other image processing algorithms can be used for feature enhancement or data fusion. Also, open source image processing software is available and has many functions applicable to forensic image processing.

Digital filters are powerful algorithms that can be used for both noise suppression and feature enhancement. Low-pass filters, for example, can block high-frequency image components, such as internal noise or lighting artifacts. High-pass filters behave in the opposite manner, enhancing high-frequency components that produce an edge-sharpening effect. Most open source image processing software includes standardized low- and high-pass filters, plus the capability to design custom filters.

Another powerful image processing technique involves enhancing the pixel brightness histogram. When a video frame has been degraded from adverse lighting, too bright or too dark, pixel brightness values can be redistributed to partially correct for such adverse lighting effects. These histogram enhancement techniques, collectively referred to as a linear histogram stretch, are suitable for both black-and-white and color images. When a video frame has areas that are too dark and also too light, a non-linear histogram stretch can be applied. Almost all open source image processing software includes histogram-stretching functions. In addition to histogram stretching, there are a variety of related histogram-enhancement functions; most of them are easy to understand and implement.

Digital filtering and histogram enhancement can be considered suitable techniques for image restoration. A separate category of forensic image processing is feature extraction. While the process of image restoration is guided by an analyst, feature extraction can be automated to some degree. For example, in a case in which a video surveillance system is used to detect the presence of a feature, such as a vehicle or a person, classification techniques can process a series of video frames to detect the feature of interest. Similarly, image transformations, such as principle components, can be effective for separating image features based on their relative reflectance.

The availability of open source software, coupled with a basic familiarity with image processing techniques, enables analysts to gradually increase their forensic image processing skills. Given the abundance of deployed video surveillance systems, along with law enforcement body cams and drone video, demand for forensic image processing expertise can only increase.

Digital Video, Image Processing, Video Surveillance

E1 The Challenge of Diagnosing Sexual Abuse in Children: A Matter for Experts

Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Caterina Petetta, MD, Sezione di Medicina Legale DSSPP, C So Galileo Galilei N 22, Torino 10121, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. "Città della Salute e della Scienza," Turin, ITALY; and Giancarlo Di Vella, MD, PhD*, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will understand the normal prepubertal female genital anatomy in the absence of abuse, in order to distinguish congenital abnormalities and findings due to sexual abuse.

This presentation will impact the forensic science community by demonstrating the importance of a careful examination of the ano-genital area of children in cases of child abuse in order to avoid communicating wrong or misleading information to a prosecutor.

Female genital anatomy may have different features due to age and hormonal influence. Some authors describe the normal anatomy of the prepubertal population to identify accurate data that can be used for comparison purposes in cases of suspected child abuse.[1,2] Most studies focus on the appearance of hymen. According to Adams, "… the defect in the posterior (inferior) half of the hymen wider than a transection with an absence of hymenal tissue extending to the base of the hymen" is a definitive sign of trauma or sexual contact.[3]

The normal anatomy of prepubertal girls can also vary because of congenital pathologies that involve the urogenital organs. For medical practitioners, it would be useful to recognize these congenital abnormalities in order to distinguish them from the normal and to correctly identify definitive signs of abuse.

This study reports two cases of suspected sexual child abuse. In the first, the diagnosis of abuse was confirmed by the comparison between the findings and the normal anatomy; in the second, thanks to a careful medical examination and the use of imaging, the initial suspicion of abuse was converted to a diagnosis of congenital abnormalities.

Case 1: A 5-year-old girl was hospitalized because of seizure attacks and no response to stimuli. The mother told the doctors that in the past year, the girl had suffered from abdominal pain, genital hyperemia, cystitis, and vaginal hemorrhage. The girl began to talk about strange touches perpetrated by her uncles. The girl was examined in the local ambulatory care facility specializing in multidisciplinary evaluation (pediatrician, medical examiner, and psychologist) of suspected child abuse. The staff identified a certain sign of trauma or sexual contact: *a defect in the posterior half of the hymen wider than a transection with an absence of hymenal tissue extending to the base of the hymen*. The association of this evidence with the stories related by the girl and the clinical findings was fundamental to diagnosing the abuse.

Case 2: Due to vaginal hemorrhage and self-masturbation, a medical examination was conducted on a 9-year-old girl. No hymenal tissue was noted during the examination. Sexual abuse was also suspected because of information from her mother about the father, from whom she was now separated. The mother told the doctor that the father used to sleep with the child every night. The child underwent another multidisciplinary examination (pediatrician, medical examiner, and psychologist) regarding the absence of the hymen, and examining the hood, clitoris, and hypoplasia of the labia minora. The vaginal orifice was clearly visible. The operators diagnosed a congenital pathology. The diagnosis was also confirmed by an ultrasound examination that demonstrated the normality of the urinary tract and the pathological immaturity of the vagina, uterus, and ovaries (the latter were described as two fibrous, ribbon-shaped formations).

These two cases provide strong evidence concerning the modality of how the evaluation of suspected sexual child abuse should be handled. The examiners should be fully educated regarding the genital features that can be observed. In addition, for an accurate diagnosis, utilization of a multidisciplinary analysis based on a combination of pediatrician, medical examiner, and psychologist evaluations is preferred.[3]

This presentation should serve as a stimulus to heighten the importance of an in-depth knowledge of physiological and pathological aspects of child genital anatomy in order to reach a correct differentiation between normal findings and those associated with abuse or congenital abnormalities.[4] In fact, according to the literature, the congenital absence of the hymen is an unlikely occurrence unless there are also concomitant major genitourinary anomalies.[5] Thanks to this information in the second case, considering the absence of the hymen in association with the pathological appearance of the clitoris, labia minora, vagina, uterus, and ovaries, the diagnosis of congenital abnormalities was made.

Child Sexual Abuse, Congenital Abnormalities, Forensic Examination

E2 Cupping Therapy Practiced on Children: Maltreatment or Alternative Therapeutic Procedure?

Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Caterina Petetta, MD, Sezione di Medicina Legale DSSPP, C So Galileo Galilei N 22, Torino 10121, ITALY; Sara Simona Racalbuto, PsyD, Department of Pediatric Emergency, Turin, Piazza Polonia 94, Torino 10100, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. "Città della Salute e della Scienza," Turin, ITALY; and Giancarlo Di Vella, MD, PhD*, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will have increased knowledge of cupping as one of the possible differential diagnoses of bruises in the child victim of suspected maltreatment.

This presentation will impact the forensic science community by providing information concerning the clinical presentation of skin injuries caused by Cupping Therapy (CT).

Two unusual cases, managed in the multidisciplinary unit dedicated to the evaluation of suspected abused children ("Bambi") of the Ospedale Infantile Regina Margherita in Turin, Italy, are presented as illustrations.

Case 1: Two Algerian brothers, three and five years old, were accompanied by their father to the hospital. The parents were separated and the children had previously been with their mother. Upon their return, the father noticed injuries on their backs. The medical examination found the presence of painful, round, and excoriated bruising, approximately 3cm in diameter, on the backs of both children. The patients reported that the mother had produced lesions in order to drive out bad spirits.

Case 2: A 2-month-old Chinese girl was taken to the "Bambi" unit by social workers who had noticed the presence of skin lesions. The little girl actually had a series of round- and oval-shaped reddish bruises, one on the neck, three on the chest, three on the abdomen, and one on the right forearm. The largest measured 3cm in diameter, the others measured 1cm, on average. The parents, who were both very young, did not know the Italian language and were in no way socially integrated.

The lesions observed in these three children were all roundish or oval-shaped bruises and were all produced at the same time as they were of the same color. They were attributable to the domestic practice of CT, one of the oldest traditional procedures in folk medicine around the world. A common element in all cultures that practice CT is the extraction of toxic substances from the body by creating negative pressure in a cup by means of heat or a special suction apparatus. Traditional Chinese medicine and the Arab world both include their own form of CT.[1] It is used to treat many diseases, including painful conditions, nausea and vomiting, urinary tract infections, and respiratory and rheumatic illnesses.[2] After a period of decline, CT has regained popularity over the past six decades by means of its promotion by holistic health care practitioners in China, and also in the Western world. CT was even used during the 2016 Olympic Games in Rio de Janeiro by an extraordinary swimmer who broke the world record.[3]

Some side effects have been reported, especially when practiced at home by inexperienced people; anemia, factitial panniculitis, and herpes viral infections are the most frequent adverse events as well as abscesses, post-inflammatory skin hyperpigmentation, and keloids.[2]

It is essential to be aware of this form of traditional practice and of the characteristics the lesions can leave on the skin in order to avoid the misdiagnosis of traumatic bruises due to a compressive mechanism. Moreover, in similar situations, it is necessary to thoroughly investigate the familiar, psychological, and social context of the child. While CT is configurable as an alternative therapeutic practice when used on an adult subject, it is placed at the limit of maltreatment when performed on a child who cannot consciously express consent.

After attending this presentation, attendees will better understand the necessity of recognizing and promptly reporting a potential child maltreatment situation. Timely intervention may prevent further abuse of a minor and provide protection to safeguard the child's well-being.

This presentation will impact the forensic science community by highlighting that child abuse includes not only child sexual abuse and maltreatment, but also child neglect, which is the most common form of child abuse, although it is not always easy to identify or to prevent.[1]

Cases involving physical violence and sexual abuse typically receive much public attention, but in cases in which minors are not subjected to these obvious signs of injury, they may be overlooked. Without careful assessment and examination, undetected problems and the associated consequences often interfere with the child's psycho-physical development. It is often easier to identify young victims of potential abuse and to facilitate their referrals to a dedicated center for diagnosis and follow up; however, children who live in socially disadvantaged families should be supervised with greater attention by social services, health professionals, or judicial authorities. It is vital to ensure the involvement of special social services who can intervene when parents are unable to properly care for a child, ensuring their development and protecting their well-being.

In literature, child neglect does not have a unanimously recognized definition. It is typically defined as a deficit in meeting a child's basic needs, including the persistent failure to provide health care and to protect the child from exposure to any type of danger which could cause serious, long-term damage or even death. Other examples of neglect include incidents that result in significant health damage or create developmental delays in the absence of organic causes.[2] An unusual type of neglect is the lack of supervision of children who may severely endanger their lives by merely touching or ingesting their parents' drugs or abuse substances.

This presentation will describe two cases of life-threatening child neglect due to acute drug intoxication which were observed in the dedicated child abuse unit called "Bambi," located within Ospedale Infantile Regina Margherita (OIRM), a pediatric hospital in Turin, Italy. Exhibiting severe clinical symptoms, these young patients required hospitalization in the pediatric hospital. The first case involved a 9-month-old boy who was brought to the pediatric emergency unit with hyporeactivity and hypotonia. No circulatory or respiratory problems were observed. Questioning the parents led to a suspicion of the ingestion of a piece of cannabis that had fallen to the ground during a meeting with friends. This was confirmed by the detection of high levels of cannabinoid derivatives in the child's blood and urine. The parents, both unemployed, were shocked because they thought their baby had eaten a dog biscuit while crawling, and had not taken any action.

The second case involved a 4-year-old boy who was transferred from an outside hospital to the Intensive Care Unit of OIRM in a coma with a marked bilateral miosis and intubation due to acute respiratory failure. At first, he showed mild reaction to painful stimuli and hematochimics with increased transaminases. Subsequently, his symptomatology ameliorated; the lethargic baby began to awaken and was discreetly oriented in time and space with spontaneous breathing. Therefore, he was extubated and brought to the pediatric emergency unit where his clinical condition continued to improve. As the child manifested respiratory insufficiency, pin-point pupils, and coma, clinicians immediately suspected an acute opioid intoxication. It was confirmed from a detailed clinical investigation that revealed the young patient had put three transdermal fentanyl patches, used by his grandfather suffering from cancer, on his body while his parents were not present.

Through these two illustrative cases, this presentation underlines the importance of paying attention not only to child maltreatment or sexual abuse, but also to child neglect situations, which may be very dangerous or fatal for children left without supervision.

Child Abuse, Child Neglect, Drug Poisoning

E4 Child Sexual Abuse: The Importance of the Forensic Medical Examination in the Judicial Decisions

Patricia Jardim, Jardim Carrilho Videira, Porto, PORTUGAL; Ricardo Jorge Dinis-Oliveira, PhD, Alameda Prof Hernâni Monteiro, Porto 4200-319, PORTUGAL; and Teresa Magalhães, PhD, Alameda Prof Hernani Monteiro, Porto 4200319, PORTUGAL*

The goal of this presentation is to provide attendees with a perspective of the impact of the forensic medical examination in the legal outcomes in cases of child sexual abuse in Portugal.

This presentation will impact the forensic science community by revealing that medicolegal and forensic intervention significantly contribute to the judicial decision in Portugal and points out the strengths and weaknesses of both the forensic and judicial systems.

Depending on the objectives, studies about sexual offenses may focus on the alleged cases of sexual contact (the number of cases may be overvalued by false claims) or on the legal outcomes (the number of cases may be undervalued because of the filed or acquitted cases due to the lack of evidence or to the unaccountability of the abusers). It is therefore critical to determine the association of both types of studies, as well as the comparison of their results, to highlight the quality of medicolegal and forensic intervention on this subject. Such analysis will certainly help to better understand the effects of medicolegal and forensic interventions on court decisions, as well as assess their strengths and weaknesses. Since such an approach has not yet been consistently measured in both international and national literature, the general objective of this study was to contribute to a better characterization of child sexual abuse in Portugal from a medicolegal and forensic perspective to promote the professionals' abilities in early detection and diagnosis.

An analysis on the forensic medical examination reports of alleged sexual offenses against victims under 18 years of age was performed, concerning cases from the northern medicolegal services of the Portuguese National Institute of Legal Medicine and Forensic Science (INMLCF), between 2004 and 2012. Also obtained were the respective legal outcomes from Public Prosecutor's Offices and Criminal Courts (n=429). A comparison between convicted and non-convicted cases was performed.

The study revealed that 66% of the cases were filed or temporarily suspended and 31% were charged and tried, although in 81% of such cases, the abusers were convicted (26% of all cases). The average time span between the forensic medical examination and the final judicial decision was 9 months in filed or temporarily suspended cases and 14 months in prosecuted and tried cases. Convictions presented were statistically significant ($p < 0.05$) with: (1) the disclosure of the abuse by the victims; (2) the availability of eyewitnesses accounts; (3) the repetition of the abuses; (4) the detection of the suspect's genetic profile on the body and/or clothes of the victim; and, (5) the reference to diagnostic or suggestive sexual contact in forensic medical conclusions.

It therefore follows that medicolegal and forensic intervention significantly contributes to the judicial decision. Regarding the forensic medical examination, the following strengths were identified: the training of the forensic experts, who work at the INMLCF; the existence of an on-call 24/7 activity; and a national model for the forensic medical report. Weaknesses that were determined include: the delay in the disclosure/reporting of cases, which precludes most DNA studies; the limited request of toxicology and microbiology screening; and forensic psychological evaluation.

Sexual Abuse, Children, Forensic Medical Evaluation

E5 An Experimental Evaluation of Participant Recall as One Indicator of the Reliability of Infant Death Doll Reenactments

Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Larissa Ybanez, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; Allison Woody, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Si Gao, MS, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; Stephanie Miller, BA, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; and Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the limitations of individual recollection of the details of a death scene independent of other factors.

This presentation will impact the forensic science community by providing a data-supported evaluation of this commonly practiced infant death investigation tool.

Doll reenactment is a controversial component of the medicolegal investigation of infant death. Its potential utility to the determination of cause and manner of death is often levied against the emotional burden that it places on the family member who is asked to conduct the reenactment.

This presentation will present the results of an experimental evaluation of a key component of the reenactment process, the recollection of the reenactor. The experiment was designed to eliminate other confounding variables, including the acute stress on, effects of drugs/alcohol on, and/or the truthfulness of the person conducting the reenactment.

An empty room in the Harris County Institute of Forensic Sciences (HCIFS) facility in Houston, TX, was configured for the experiment. A portable crib was placed in the room away from other objects and from surrounding walls. An infant-sized doll was placed in the crib in addition to other items, including blankets, stuffed animals, a baby bottle, and a pacifier. A total of 46 members of HCIFS staff were asked to enter the room and to recover the decedent and bring it to the experiment coordinator. They were told the process should take approximately ten seconds and were not given any other experiment details, including the fact that they were going to be asked to conduct a reenactment. The array and arrangement of items placed in the crib varied for each participant. Photos were taken immediately prior to each recovery and immediately after each reenactment. The experiment participants were divided into two groups -- those who conducted their reenactment approximately 2 hours after their recovery and those who conducted their reenactment approximately 24 hours after their recovery. For the reenactment, the crib was cleared out and all items, including the doll, and items that may not have been in the crib during the recovery were placed in a bin next to the crib. Participants were instructed to enter the room and to place the doll and items into the crib as best as their recollection permitted.

Twenty-six binary variables were evaluated for correctness, including body position (supine/prone), direction of face in relation to the body, nose/mouth covered at recovery, and the presence and location (separately) of various items in the crib, including a bottle, a pacifier, blanket(s), and stuffed animals. There was considerable variation in the accuracy of the variables. Participants were able to accurately recall whether the doll was prone or supine (41 of 46 (21 of 23 for the 2-hour group, 91%, and 18 of 20 for the 24-hour group, 90%)). Other variables were less accurately recalled. Whether the nose/mouth were covered at the time of the recovery was accurately recreated 13 of the 23 times by the 2-hour group (57%) and 10 of the 20 times by the 24-hour group (50%).

The effect of time between recovery and reenactment on the accuracy of the reenactment was evaluated statistically by developing a “correct” reenactment score based on a subset of variables. Responses were scored as “correct” if the reenactor correctly scored the following four variables correctly: body position (prone vs. supine), direction of the face in relation to the body, whether the nose and mouth were covered at recovery, and the location of the doll in the crib (correct quadrant). Sixteen (35%) of the 46 participants achieved a “correct” score using this rubric (11 (69%) at 2 hours and 5 (31%) at 24 hours). The difference approaches statistical significance (Wilcoxon p value 0.07). A logistical regression yielded a 66% probability of a “correct” reenactment at 2 hours verses a 52% probability at 24 hours. These results indicate that after 24 hours, a person who is not subjected to the stressors and distractions that are associated with finding an infant unresponsive has a roughly 50% chance at correctly reenacting the core components of an infant death scene.

Infant Death, Doll Reenactment, Death Scene Investigation

E6 A Growth Chart Review in Sudden Unexpected Infant Death

Bailey D. Lyttle, BA, 1357 Island Shore Drive, Memphis, TN; and Marco Ross, MD, West Tennessee Regional Forensic Center, 637 Poplar Avenue, Memphis, TN 38105*

After attending this presentation, attendees will better understand the relationship between infant growth and Sudden Unexpected Infant Death (SUID).

This presentation will impact the forensic science community by exploring potential risk factors related to SUID, adding to the current research regarding the causes and preventive measures that may be taken.

SUID is used to describe the sudden and unexpected demise of an infant less than one year of age. The term expands on the previously common term Sudden Infant Death Syndrome (SIDS), which describes the death of an infant that cannot be explained, even following a thorough death scene investigation and autopsy, to include infant deaths of unknown cause as well as cases of possible asphyxia.[1] While the rates of SUID have declined over the past 30 years, largely attributable to a rise in safe sleep recommendations and campaigns, infant mortality still poses a problem in many parts of the country. For example, the United States national infant mortality rate is estimated to be 5.8 per 1,000 live births in 2016, but as of 2015 infant mortality rates in Shelby County, TN, remained as high as 8.23 per 1000 live births.[2,3] While socioeconomic factors likely play a large role in focally high infant mortality rates, associations with low birthweight and prematurity have been previously made. The objective of this study is to explore the relationship between infant growth and SUID by examining the growth curves of infants dying of SUID in accordance with data provided by the Centers for Disease Control and Prevention (CDC).

Autopsy reports and birth records from 85 cases of SUID from 2014-2016 were reviewed (44 females, 68 African Americans). Average gestational age was 38.64 weeks (*Standard Deviation (SD)*=1.87), excluding cases of prematurity prior to 36 weeks' gestation. Weight, length, and head circumference at both birth and death were recorded and compared to the 2000 CDC 0-36 months growth chart.[4] The average weight, length, and head circumference percentiles at birth were 31% (*z-score*=-0.67), 45% (*z-score*=-0.21), and 20% (*z-score*=-1.16), respectively. When corrected for gestational age, average percentiles were 41% for weight (*z-score*=-0.27), 57% for length (*z-score*=0.27), and 30% for head circumference (*z-score*=-0.71). Average age at death was 91 days (*SD*=56.29). The average weight, length, and head circumference percentiles at death were 45% (*z-score*=-0.39), 36% (*z-score*=-0.79), and 48% (*z-score*=0.05), respectively. When corrected for gestational age, average percentiles were 50% for weight (*z-score*=-0.09), 70% for length (*z-score*=-0.53), and 50% for head circumference (*z-score*=0.35). Of the 85 cases included, 72 were associated with an unsafe sleep environment; 50 were associated with co-sleeping, 18 were associated with covering the decedent with a blanket, and 38 were associated with prone or side sleeping of the decedent.

This preliminary review suggests that while low birthweight and head circumference at birth are associated with SUID, these values tend to normalize over time. It is possible that these associations are artifacts of prematurity, although head circumference at birth remains low even when correcting for gestational age. Additionally, when correcting for gestational age at time of death, infants dying of SUID appear on average to be reaching expected growth targets – even exceeding those targets, in the case of length. Confounding factors that should be further explored include maternal smoking during pregnancy, exposure to secondhand smoke, whether or not the infant was breastfed, and level of prenatal care. Finally, the strong association between SUID and unsafe sleeping conditions cannot be ignored. Education regarding safe sleep practices remains a vital instrument in preventing SUID.

SUID, Growth Chart, Infant

E7 The Sensitivity of Pediatric Organ Donation: Ways to Decrease the Decline Rate From Coroners/Medical Examiners

Tyrish Y. Page, MA, Sharing Hope SC, 3950 Faber Place Drive, Ste 400, Charleston, SC 29405; and Nicholas I. Batalis, MD*, Medical University of South Carolina, 171 Ashley Avenue, Ste 309, MSC 908, Charleston, SC 29425*

After attending this presentation, attendees will understand there are higher rates of organ procurement denials of pediatric cases than adults and the repercussions this has on pediatric patients on the organ waitlist.

The presentation will impact the forensic science community by providing options and process improvements to ensure a thorough death investigation while improving the "organ gap."

Each year, the number of potential organ donors increases while recipients added to the wait list increase astronomically. The "organ gap" is a major concern for all Organ Procurement Organizations (OPOs) and transplant surgeons. The main objective for Coroners/Medical Examiners (C/ME) is to complete a thorough death investigation on behalf of the decedent no matter the cause of death. Higher levels of sensitivity lead to higher denial rates for pediatric cases that are under their jurisdiction. When death investigation and organ donation cannot be accomplished simultaneously, the consequences are serious as one OPO reported that more than 40% of potential organ donors were lost in one year because of medical examiner and coroner denials.[1] An emerging subset of the "organ gap" with a substantial amount of denials are pediatric organ donors.

There are more than 117,000 recipients on the national waitlist, including 2,000 pediatric patients on the organ list.[2] There has been a steady decline in the number of organ procurements from persons under the age of 17 years. Denials in pediatric potential organ donors remain a serious issue because of the inability of many children to receive organs from adult donors.[1] After guardians, C/ME are vital to reducing the denials for potential pediatric donors. From 2014-2016, South Carolina coroners denied 6% of the pediatric organ referrals vetted at the time; this is significantly higher when 0.3% of adults were denied. The "sensitivity" usually occurs when the death is thought to be homicide by child abuse, sudden and unexpected death, or accidental death. When death occurs under these circumstances, C/ME are more likely to decline organ donations. ME/C should permit the recovery of organs and/or tissues from decedents falling under their jurisdiction in virtually all cases, to include cases of suspected child abuse or other homicides and sudden unexpected deaths in infants. It is recognized that blanket approvals may not be possible in every case and may require an "approval with restriction(s)".[3] The final decision after obtaining parental consent lies on the C/ME.

Occasionally, postponing a denial in the case of homicide or accidental pediatric deaths can be beneficial for collecting evidence for the death investigation. The main reason for the refusal is often associated with the death investigation and subsequent legal proceedings. There are very rare instances that organ donation altered the chance of prosecution. The forensic pathologist/ME/C has the responsibility of educating the attorneys regarding the procurement process and assuring them that a complete and accurate examination can be accomplished and all necessary evidence and specimens will be able to be collected.[3]

Death investigation is a priority, and establishing a set of guidelines between coroners, forensic pathologists, and OPOs based on ethics, investigation, and state statues can be effective in creating a good rapport. The "comfort index" of medical examiners, not to say prosecutors and law enforcement officials, would necessarily have to be measured and the proper groundwork laid.[4] The construct of a "comfort index" can be useful in determining approval of donation for cases of child abuse, traffic accidents, natural diseases, and anencephaly. Communication can include educational seminars that highlight the process of the OPO and include photography tutorials that will aid the coroners' investigations. Process improvement and communication will be pivotal in optimizing organ donations and increasing recovery for pediatric recipients on the wait list. Some ME/C offices currently have "zero denials" and this should be the goal of every ME/C office.[3]

A case in which the OPO gained consent from the guardians, but received an initial decline for organs and tissue from the coroner, will be presented. Documentation by the OPO while the coroners gathered witness statements and completed their death investigation was beneficial in this accidental death of a 14-month-old child. The coordination with the coroner, forensic pathologist, and OPO led to a reversal and successful donation of a heart, liver, and kidneys. It is hoped that this case can serve as an example that organ procurement does not obstruct the sensitivity of pediatric death investigation. Conferring with the forensic pathologist to ensure organ procurement will not skew the autopsy was applicable in this case and will be on future cases.

E8 The Expanded Application of Forensic Science and Law Enforcement Methodologies in Army Counterintelligence

Braden Stockham, MFS, US Army Counterintelligence, JFTB Los Alamitos, CA 90720; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Paul Stein, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

After attending this presentation, attendees will understand the importance of forensic science as it applies to Counterintelligence (CI) investigations and that combined with standardized law enforcement methodologies, it is as critical to CI as it is in traditional criminal investigations.

This presentation will impact the forensic science community by identifying the factors involved with why Army CI operates differently in its investigative activities compared to its counterpart organizations. Addressing these factors will make it possible for Army CI to improve their overall case resolution through expansion of the investigative capabilities by adding forensic science resources, training, and personnel.

This presentation should provide insight into the inner workings of Army CI, which reflects an observed lack of investigative capabilities when compared to the other military CI investigative agencies of the Naval Criminal Investigative Service (NCIS) and the Air Force Office of Special Investigations (OSI). This study indicates that the lack of investigative capabilities in Army CI is prevalent in three key areas: (1) forensic science resources and support; (2) law enforcement methodologies and procedures; and, (3) basic investigative training. This presentation will examine this investigative capability gap that seems to exist primarily due to a false belief within the United States Army that a CI investigation is not also a criminal investigation.

This study deals with the capability areas Army CI need to improve. There appears to be a difference in the opinions of Army CI agents compared to NCIS and OSI agents in regard to the investigative capabilities within their respective agencies. The existence of such a difference of opinion would support the idea of a lack of investigative capabilities within Army CI. This study will further support or refute that opinion by utilizing information gathered from published research, professional communications, and 12 years of experience in Army CI and civilian law enforcement.

Current and recently retired special agents from the Army CI, NCIS, and OSI participated in a survey to examine this difference of opinion. The opinions of these agents were noted in the investigative capability areas previously mentioned. The data obtained will reinforce the fact that Army CI conducts investigative activities with a general lack of capabilities in the key areas already identified, creating unnecessary burdens for its special agents in the conduct of their investigations.

The survey results revealed statistically significant differences in the responses by Army CI agents versus NCIS and OSI combined. The responses were divided into three categories related to the three areas of investigative capability previously identified. An analysis was conducted comparing the mean average answers of NCIS+OSI to that of Army CI in each of these categories. In each of the categories of questions asked, extreme statistical significance was present, demonstrating that Army CI agents tended to agree that a lack of investigative capability in each of these areas was present in their organization. This did not appear in a majority of the answers of the NCIS and OSI agents in any of the categories. This statistical difference is further evidence of the disparity between these CI investigative agencies and indicates that Army CI may be less effective by comparison. The findings are consistent with published data. These results further point to a systemic problem within the current investigative culture of Army CI that could be corrected if forensic science and law enforcement methodologies are expanded in a manner similar to that which already exists in other organizations.

Counterintelligence, Investigation, Forensic Sciences

E9 Crime Fear Comparison Based on Residence Selection: Gated Communities vs. Apartments

Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY; Kadri Dalgic, Krav Magen Academy, Istiklal Cad No 108 Aznavur Pasaji Kat 5 Beyoglu, Istanbul 34330, TURKEY; Betul Kilinc, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY; and Oktay Cavus*, Krav Magen Academy, Istiklal Cad No 108 Aznavur Pasaji Kat 5 Beyoglu, Iitanbul 34674, TURKEY*

The goal of this presentation is to focus on the prevention of types of crime that are based on routine activities due to changes in life styles as a result of industrialization and urbanization movements.

This presentation will impact the forensic science community by focusing on the importance of private security in crime prevention in neighborhoods.

Crime has been one of the major problems of urban life. Hence, fear of crime and suspicion of urban places are among the costs of the increasing crime rate. This fear has been the driving force in the rise of private security businesses. The basic services that gated communities' private security task force supply are access controls, vehicle and/or foot patrol, extra lightening in dark corners, Closed-Circuit Television (CCTV) screening of the site and delivering briefs, and place signals at the site for emergency situations.

This research focuses on the fear of crime of people who live in different types of residences in urban areas. The sample group of the research consisted of individuals 17 to 79 years of age who reside in Istanbul. The purpose of the study was to make a comparison between the housing priorities of residents who choose to live in gated communities and those who choose to live in downtown apartments with no security personnel and/or agents. The first sample group of 100 people (78 male, 22 female; 17 to 79 years of age) was randomly chosen from a gated community where approximately 1,600 people are living in 420 households. The comparison group consisted of 100 people (51 male, 49 female; 17 to 76 years of age) who were randomly chosen from people living in non-secured apartments in 12 different neighborhoods of Istanbul.

The method used in this study, in order to measure the level of crime fear of attendants is similar to Ferraro's The Fear of Crime Scale.[1] The standard questionnaire consisted of 22 open-ended questions, divided into four different categories and grading was based on the four grade Likert scale.

The questionnaire used in this study was pre-tested on ten randomly chosen respondents and no cultural biases were observed. The questionnaires were distributed to all participants after delivering an introductory explanatory presentation and were collected one week later. The purpose of the seven-day time span was to provide adequate time and privacy to the participants to answer the questions carefully and comfortably.

The obtained data were quantitatively analyzed with SPSS. A standard *t*-test was used to analyze the data. The results obtained were scientifically impressive. The study reveals that the crime fear of the residents who live in gated communities is significantly lower than those who live in unsecured apartments. The research also reveals that the need for security is the third-most important criteria in home selection for people who live in gated communities. Surprisingly, building supportive and lasting neighborhood relations is significantly higher among these residents. Also, a significantly higher majority of unsecured apartment residents claimed that the main crime prevention method is to live in secured sites.

Crime Fear, Crime Prevention, Private Security

E10 The Spanish Police Intervention Unit Inside the Chaos: Crime Scene Protection Cases

Carlos J. Lopez-Gobernado, PhD, Policia Nacional, UCSP, Calle Rey Francisco 21, Madrid 28008, SPAIN*

After attending this presentation, attendees will better understand the concepts of rioting and police crime scene protection used by the Spanish National Police and how the evidence is protected and collected by the crime scene investigators at public disturbances and after terrorist attacks.

This presentation will impact the forensic science community by illustrating how the Spanish National Police Intervention Unit (UIP) operators are trained to protect dangerous crime scenes, thus allowing investigators to perform their job safely. This presentation will highlight a number of actual cases and explain a new way to investigate complex crime scenes.

While a number of different studies have looked into the different scenes between the military and civilians, there are few studies regarding the protection of crime scenes in civilian disorders, such as riots. The Spanish National Police UIP is responsible for protecting public safety in case of riots, crowd control, and after a terrorist attack. Also, Crime Scene Investigation (CSI) personnel must be protected in such chaotic scenarios, providing them a guaranteed environment in which to work. The UIP training provides the operators with the guidelines to work side-by-side with forensics in dangerous scenes. There will be an in-depth focus on the significant challenges faced during a number of actual UIP cases, including special crime scene issues and the urban "combat" environment.[1]

This presentation will present three high-profile investigation cases in which Spanish National Police UIP operators played a key role in protecting crime scene investigators and will explore the interaction of multiple forensic disciplines of the ForLab Project, in which UIP operators are trained to protect themselves and the crime scene.

In May 2002, before the Champions League Semifinal match between Real Madrid and Barcelona, there was a bomb attack near the Torre Europa building, forcing UIP operators to protect the football match and the work of forensic investigators while angry hooligans flew into a rage. In March 2004, several commuter trains were blown up after the worst terrorist attack on Spanish soil, and UIP operators were deployed to protect the scene as soon as the first call arrived. In November 2014, two clubs' hooligans fought at Manzanares riverside, resulting in one man dead after the clash. The ForLab Project (Forensic Laboratory for *in situ* Evidence Analysis in a Post-Blast Scenario), in which the Spanish National Police Forensic branch is involved, depend on UIP operators to seal and protect the crime scene until forensics arrives.[2]

The opinions or assertions contained herein are the private view of the authors and are not to be construed as official or as reflecting the views of the Spanish Ministry of the Interior or Spanish National Police.

E11 A Usual Cause of Hospitalization and an Unusual Cause of Death

Giuseppe Bertozzi, MD, Deptartment of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71121, ITALY; Francesca Maglietta, MD, Viale degli Aviatori, Foggia 71121, ITALY; Giuseppe Davide Albano, Viale degli Aviatori, 1, Foggia 71121, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Viale degli Aviatori, 1, Foggia 71121, ITALY; Gabriela Perilli, MD, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori, 1, Foggia 71100, ITALY; and Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY*

The goal of this presentation is to illustrate how a traffic accident, which is one of the most frequent causes of morbidity and mortality in the general population, can lead to death following a microtrauma such as a metatarsal fracture.

This presentation will impact the forensic science community by informing attendees that although car accidents are a well-known cause of death, they are usually associated with multiple injuries to various organic structures, making it difficult to decide which was the most serious and mortal wound. Even a simple metatarsal fracture can act as a co-cause of death. Thus, the importance of recognizing typical and atypical patterns of injury associated with traffic accidents could provide a tailored measure for the initial assessment and management of trauma patients in order to improve outcomes.

This case dealt with a patient who came to the emergency room following a car accident. Upon arrival, he complained of right foot trauma that was treated with a temporary immobilization device; however, at the physical examination, the physicians diagnosed a respiratory and cardiac insufficiency with acute pulmonary edema in the patient who had a history of hypertensive cardiac disease and chronic atrial fibrillation in pharmacological therapy.

Due to clinical conditions, urgent hospitalization in the cardiology ward was provided with a diagnosis of respiratory failure and severe respiratory acidosis. Thus, mechanical ventilation was performed, with a subsequent improvement of the clinical parameters. The next morning, the doctor in charge was alerted because of a worsening of clinical conditions. A thoracic Computed Tomography (CT) scan was performed and documented several areas of parenchymal consolidation of the left lung base associated with diffuse fibrosis, including widespread chronic bronchopathy, no pneumothorax, no fractures. At the end of this investigation, the patient presented with a loss of consciousness and the disappearance of the peripheral and carotid pulse; a cardiopulmonary resuscitation was performed with negative results and the patient died. During autopsy, an increased heart size of 700gr was documented; the left lung, which also increased in size, weighed 850gr and the right lung weighed 610gr. The bronchi displayed the release of a foamy reddish-colored material instead of blood fluid released from the great pulmonary vessels. In addition, an incision was made on the right foot dorsal region, highlighting the presence of a hemorrhagic infarction of the soft tissues, which revealed the presence of a fracture of the fourth metatarsus. Histologic examination demonstrated trivasal coronary artery stenosis, interstitial and perivascular fibrosis, numerous necrotic contraction bands, interstitial edema, mild disarray of the right ventricle, chronic emphysema, endoalveolar edema, interstitial fibrosis, areas of atelectasis, massive embolization, and partial fat. In conclusion, the cause of death was attributed to the concatenation of pathophysiological events, following a stress-induced event (represented by the car accident), which caused a ventricular tachyarrhythmia and massive pulmonary embolization from the fracture of the right fourth metatarsal, resulting in respiratory failure from acute pulmonary edema.

This seems to be the first case in which these multiple mechanisms are described acting together as co-causes of death. A review of the literature revealed that the occurrence of Deep Vein Thrombosis (DVT) and Pulmonary Embolism (PE) after foot surgery is generally believed to be low. The National Trauma Data Bank data set (2007-2009) was used to evaluate the incidence of thromboembolism in foot trauma, identifying risk factors associated with the thromboembolic complications. Significant risk factors statistically associated and clinically relevant to both DVT and PE in foot trauma were older age, obesity, and a higher injury severity score. Each of these existed in this case. On the other hand, only one case dealing with a 42-year-old healthy male patient who suffered fractures of the calcaneus, navicular, talus, and metatarsal bone caused by an accidental gunshot wound while hunting was associated with a cerebral fat embolism.

Due to the low incidence, routine pharmacologic thromboprophylaxis might be contraindicated in foot trauma; however, careful, individualized assessment of the risk factors associated with DVT and PE is important in order to prevent embolic complications.

Car Accident, Metatarsal Fracture, Massive Pulmonary Embolization

E12 Examining the Heritability Effects of Latino Youth Violence

Elvis Sevilla, 16914 Camberwell Green Lane, Houston, TX 77070; and Ashraf Mozayani, PharmD, PhD, Texas Southern University, 3100 Cleburne Avenue, Houston, TX 77004*

After attending this presentation, attendees will be better informed regarding the relationship between genetic and environmental influences associated with behavioral traits. Furthermore, attendees will learn about cultural and/or genetic effects on Latino youth violence.

This presentation will impact the forensic science community by demonstrating how violent behavior associated with minorities — specifically Latinos — has become a problem in the United States. Moreover, violence is one of the major effects of the Latino community. The substantial heritability and environmental issues surrounding violence indicate that the underlying genetics can help explain at least some features related to these behaviors.

Human behavior is a complicated process influenced by both genetics and the social environment. A growing body of knowledge has shown the relationship between genetics and environmental influences on humans. The key to understanding the roots of criminal behavior is through the genetic method. One avenue of research for the genetic foundation to behavior is through twin studies. The twin study design allows researchers to break down phenotypic variance into three components: heritability, shared environment, and non-shared environment; however, there exists no literature considering the genetic and environmental influences on culture groups, such as Latinos, using the twin study design.

The focus of this study was to test whether there is a statistical relationship between gene and environmental interaction of Hispanic and non-Hispanic twins and self-reported violence. The sample size (N=97) derived from the first wave of data from The National Longitudinal Study of Adolescent to Adult Health.[1] This data will provide a glimpse of understanding those twins who identify as non-Hispanic male and Hispanic male participants and the differences of behavioral outcome using a Chi-square analysis.

The results suggest there exists a relationship between genetic and environmental effects that play a role in Latino youth violence. The results in the analysis revealed that, overall, there was no significant relationship between Hispanic and non-Hispanic twin youth on violent outcome; however, the identical twins had statistically significant relationships on violent outcomes and fraternal twins had no statistically significant relationships on violent outcomes. In conclusion, Latino youth violence has a significant genetic effect, while the environmental effects were insignificant.

This research concludes that culture such as identifying as Latino may be limited in having effects on self-reported youth violence. There seems to be more of a genetic effect when reporting Latino violence. This evidence provides an understanding of the complexity of human nature and behavior such as violence should be further examined with genetic models.

Latino Violence, Genetics, Biosocial Criminology

E13 Dog Bite-Related Accidents: A New Forensic Approach

Francesco Sessa, MS, Deptartment of Forensic Pathology, University of Foggia, Viale Degli Aviatori, 1, Foggia 71100, ITALY; Vera Filetti, MSc, Deptartment of Forensic Pathology, University of Foggia, Viale Degli Aviatori, 1, Foggia 71100, ITALY; Fabrizio Iarussi, DVM, University of Bari, Bari, ITALY; Valerio Iarussi, MD, Viale Ofanto, Via, Foggia 71122, ITALY; Marcello Rendine, Department of Forensic Pathology, University of Foggia, Ospedale Col D'Avanzo - viale degli Aviatori, 1, Foggia 71100, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Viale degli Aviatori, 1, Foggia 71121, ITALY; Giuseppe Davide Albano, Viale degli Aviatori, 1, Foggia71100 , ITALY; and Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY*

After attending this presentation, attendees will be able to apply a new forensic approach to offending dog identification when dog bite-related accidents occur. The interaction between domestic animals and humans has not been free of conflicts, and dog attacks represent a real problem, not only for health consequences, but also for possible crimes and can affect legal or financial outcomes.

This presentation will impact the forensic science community by providing scientific data from a well-controlled experiment, thus increasing gathered information. An appropriate forensic approach should include an exhaustive analysis of the scene, the victim, and the dog.

The alarming statistics reported around the world have shown that dog attacks today represent a health hazard in cases in which prevention strategies have not always been successful.[1,2] Most dogs involved in these events are known to or belong to the victim. This study found 19 dog bite-related fatalities in Italy from 2009 to 2016 (2.37 cases per year); these data have sharply increased from a previous study that described 32 dog bite-related fatalities between 1984 and 2009 with a frequency of 1.28 cases per year.[3]

A scientific inclusion/exclusion of the involved dog is possible and recommended because of possible consequences for the animal's owner that could have civil consequences (or criminal consequences, in the most serious cases). Since dog bitemark analysis should involve different forensic professionals, such as pathologists, odontologists, veterinarians, biologists, and police investigators, a review focused on this type of evidence from a multidisciplinary point of view is presented.

There are different approaches for the identification of an offending dog when an attack on a human occurs. Forensic investigations in dog attacks usually involve the examination of bitemarks, tooth prints, the dog's stomach, and other pathological methods. For the identification of the offending dog, the best approach is to evaluate the canine Short Tandem Repeat (STR) typing in saliva traces of the dog bitemarks. Generally, it is possible to obtain a canine-specific STR profile from the dog's saliva on the wounded area, even when a high background of human DNA is present (blood).

This approach is often a problem because the surface of the wound may have already been treated (for example, by first aid workers), removing the canine cells. This approach is less successful in obtaining useful STR results than before medicolegal techniques are applied. Furthermore, dogs appear more frequently in human social life, so it is not rare for canine DNA to be present on the hands, arms, legs, or feet of humans.

A new forensic approach was described for offending dog identification beginning with dog buccal swabs: the target is the identification of a human profile beginning with this sample. An additional goal of this presentation was to determine the latency time of this biological trace in the dog's mouth.

In this study, ten different dog breeds were used to bite a beef meat sample that was previously typed (internal control profile). At different minute intervals (30, 45, 60, 90, 120, 150, 180, and 240), two dog buccal swabs were taken (a swab for each dental arch). One hundred and sixty samples were collected. Subsequently, DNA was extracted and a bovine genotyping kit was used. In all samples, a complete profile of the internal control was found for 45 minutes and a partial profile of the internal control for 150 minutes.

These data are very important to confirm the possibility of using buccal swabs to identify an offending dog. Human STR typing kits are much more specific and sensitive compared to cattle kits, so one can suppose that a complete human STR profile could be obtained from the dog buccal swab, after an aggressive act, for at least 150 minutes. This is usually enough time for a medicolegal team arrive.

This study may offer a model that could always be applied to identify offending dogs; furthermore, dog bite-related accidents can provide concrete cases, even when fatal, making it possible to develop, refine, or validate medicolegal techniques.

Dog Attacks, Cattle Genotyping, Dog Identification

E14 Science Matters: Putting Light on Facial Approximations

Sandra R. Enslow, BA, Los Angeles County Sheriff's Department, 1 Cupania Circle, Monterey Park, CA 91755*

After attending this presentation, attendees will understand the fundamentals of a forensic art facial approximation. These images are created for a detective to obtain a better understanding of what a suspect may look like. Detectives and investigators often request a facial approximation from the forensic artist in their agency.

This presentation will impact the forensic science community by raising awareness of the work that forensic artists perform for detectives and investigators. A large majority of this work goes beyond drawing a simple composite of a suspect. In this presentation, adjudicated facial approximation cases will display various angles and situations that often perplex a detective who is trying to determine what someone may look like. This informative presentation will include illustrations of the lighting of the human face.

The presence of light is how we are able to see the environment around us. It is a crucial source of information in producing a facial image for an investigation. How light bounces off a face and illuminates facial planes or features is critical information for the forensic artist. Light assists with the comprehension of what is seen and illuminates facial features, bad skin, or unusual marks. Specifically, the dynamics of direct light, indirect light, highlights, and reflected light on the various features within the face can provide indications of how those structures are built. This information can reveal itself even with grainy, blurry photos or video, to an extent.

The dark — an absence of light — also has a story to tell, one to which the forensic artist pays close attention. Dark areas can mean many things — an overhanging brow with deep-set eyes, skin discolorations, or facial hair, for example. The lack of light motivates the forensic artist to search for corroborating evidence in the various stills or video provided that will illuminate that particular area of the face. Looking through stills that show that specific area, under different angles and positions, may provide more information and "fill in the blanks" that were obscured by the dark.

Understanding the environment as a contributing factor is also vital. Cast shadows can influence an image or completely obscure the information that is sought. So, looking at the environment as part of the whole picture helps to understand what is being seen. The lighting is different if it comes from a modern street lamp rather than an older vintage street lamp. Not all lighting is equal; the lighting is different in a convenience store than a private residence. All these factors assist in or interfere with the forensic artist's efforts to interpret the face. The camera angle in the environment also plays a huge part; distortion is often a problem and must be factored in. In many environments, the camera angle is from above and captures not only the face but many other factors in the scene.

Forensic art is a rapidly expanding discipline that requires specialized training, above and beyond advanced drawing skills. The forensic artist is called on for many different skill sets that assist in the identification process. Applications relate closely with those of other disciplines of the forensic sciences, especially forensic anthropology, forensic odontology, and forensic psychology.

Forensic Art, Facial Approximations, Forensic Imaging

E15 Accuracy Assessment of Korean Craniofacial Reconstructions Applying the Face Pool Comparison Method

Su-Min Kim, Dongcheon-ro 18beon-gil, Seo-gu, Gwangju, SOUTH KOREA; and Won-Joon Lee, MD, National Forensic Service Seoul Institute, 139, Jiyang-ro, Yangcheon-gu, Seoul 08036, SOUTH KOREA*

The goal of this presentation is to inform attendees how the accuracy of Craniofacial Reconstruction (CFR) can be assessed and how the reliability would be sufficient to be utilized in forensic identification.

This presentation will impact the forensic science community by demonstrating the procedure of evaluating the accuracy of CFR and the availability of CFR in the field of forensic sciences.

CFR is a method of rebuilding a living facial appearance onto a skull based on both scientific standards and artistic skill. This technique is used to recognize or identify an individual in the field of forensic sciences, especially when other forensic approaches are not possible or available. The accuracy of CFR has been of primary importance in maintaining the reliability of its applications to forensic investigation. Therefore, many studies have been conducted to evaluate the accuracy of CFRs. A number of methods are used to assess the accuracy of CFR; face pool comparison is considered to be one of the most reliable methods.[1]

In this study, 3D skull images from six living Korean adult subjects were taken by computerized tomography. Six CFRs employing the skull images were produced by utilizing a 3D computerized modeling program. The completed six CFRs were divided into two groups: one group of three CFRs applied out-of-date Korean average facial skin thickness data and the other group of three CFRs applied recently studied Korean average facial skin thickness data. The recognition accuracies of the six CFRs were measured by a face pool comparison method. For accuracy assessment, six face pool sets were made that targeted for each CFR. A face pool set consisted of ten frontal facial photographs, including an actual face for the target CFR. For the accuracy survey, 167 assessors were recruited who were asked to compare the target CFR with the ten faces on the face pool, and they then determined which face should match with the CFR.

The results revealed that the CFRs using the recently studied Korean average facial skin thickness data demonstrated higher accuracy (the average hit rate of 30.74 %) than the other CFRs (the average hit rate of 22.35%) using out-of-date Korean average facial skin thickness data. Additionally, the results were compared with the results from quantitative accuracy measurements by using geometric morphometrics surface comparisons.[2,3] The comparison demonstrated that the results from the geometric morphometrics analysis correlate positively with the results from the face pool comparison method.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT & Future Planning.

E16 Forensic Awareness of Emergency Service Nurses in Turkey

Merve Eyüp, BSc, Üsküdar University, Altunizade Mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; Inci Yagmur Tezbasan, BSc, Üsküdar University, Altunizade Mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; Hatice Yilmaz, BSc, Üsküdar University, Altunizade Mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; and Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY*

After attending this presentation, attendees will better understand the forensic cases most frequently encountered by emergency services staff in Turkey. This presentation will detail the necessary level of knowledge needed by the nurses intervening in these cases as it pertains to keeping records and guarding and preserving evidence.

This presentation will impact the forensic science community by examining the awareness of the emergency service nurses, who are the first medical staff encountered during forensic cases, and by emphasizing the knowledge levels of the emergency service nurses in Turkey, the deficiencies in the area, and the required improvements, thus affecting forensic studies.

Emergency services have special importance because they are involved in forensic cases and their contributions have the potential to change the course of an investigation. It is a legal obligation to provide required emergency medical care for every individual who applies to the emergency service. The acts of the emergency team, which consists of physicians, nurses, and emergency medical technicians, during this care are even more important in forensic cases. The priority of medical personnel is the care and treatment of the patient; however, it is also quite important to guard the evidence because the detection of the crime and the criminal, the relief from the victimization, and the role of the medical staff as patient's advocate are the nature of the task. The emergency team should ensure the collection and guarding of evidence in forensic cases while providing life-saving health care.[1] In such cases, the awareness and knowledge of the health care personnel will prevent failure to preserve evidence and ensure correct collection. This can only be achieved by training the medical staff.[2]

It is known that nurses cannot perform the necessary tasks in forensic cases in Turkey because of their inadequate knowledge and experience in forensic studies, although they frequently encounter such forensic cases. Proper evaluation of forensic cases will contribute to the resolution of the case. This can be ensured by the presence of emergency department nurses who have been specially trained in forensic studies.[3,4] There are forensic nurses in emergency services in many countries; however, forensic nurses who have had training after graduation cannot as yet be employed in emergency services in Turkey. For this reason, emergency services nurses perform tasks such as preserving, keeping, and recording of the belongings of the patient, which should be performed by a forensic nurse.[5,6]

Health care personnel at emergency services need training in forensic cases to ensure avoiding decay of biological materials that may be evidence and to collect them properly. Nurses with different education levels work in emergency services in Turkey. The differences between nurses cause some disadvantages. One of these disadvantages is the assignment of nurses to the emergency services who do not have adequate training support regarding forensic cases. Some nurses working at emergency services do have training in the field, through vocational training, in-service training, or certification programs, in the collection and safe-guarding of evidence, the creation of chain of evidence, and keeping records, but other nurses have no training on these issues.[1,2,6,7]

By examining studies conducted on this issue in Turkey, it is observed that some emergency nurses do not perform these tasks, and some conduct these tasks incompletely or incorrectly. Examples of such shortcomings determined in this study will be presented.

This presentation will illustrate the forensic cases most frequently encountered by staff at emergency services in Turkey and the level of knowledge of nurses intervening in these cases who are responsible for keeping records and guarding and preserving evidence.

Forensic Nursing, Emergency Nursing, Training

E17 Forensic Science in Austria: Insights on Working Processes and Result Communication Concerning DNA, Fingermarks, and Handwriting

Aline Girod-Frais, Schenkenstrasse 4, Vienna 1010, AUSTRIA; and Christian Grafl, Department of Criminal Law and Criminology, University of Vienna, Schenkenstrasse 4, Vienna 1010, AUSTRIA*

The goals of this presentation are: (1) to provide insight on working methodologies and processes used to communicate forensic results in Austria, particularly concerning DNA, fingermarks, and handwriting; and, (2) to promote practice-oriented measures regarding the general appraisal of traces in inquisitorial justice systems, mainly based on expert opinions collected through anonymous surveys.

This presentation will impact the forensic science community by proposing optimized working methodologies and communication processes concerning physical traces, particularly DNA, fingermarks, and handwriting, thus promoting a better use of the information obtained by the analysis of physical traces.

Forensic science is commonly defined as the use of scientific methods and techniques to search for, collect, analyze, and interpret traces left by criminal actions to understand crime and aid justice. This scientific endeavor is interdisciplinary by nature and forensic science is thus widely considered as a "patchwork" of different scientific disciplines. This concept, as well as the privatization of many laboratories, has led to a hyper-specialization and a "sectorization" of forensic science in different specialized fields (e.g., forensic chemistry and forensic biology).[1] Forensic scientists are mostly chemists or biologists who have received some form of additional training. This lack of proper identity has grown larger during the past decade and causes the model of forensic science to be scrutinized and challenged worldwide.[2-4] Debated errors (for example, the controversial identification of Mayfield's fingerprint in the train bombing assault in Madrid in 2004) also shook forensic science to its very foundations by prompting interrogations concerning its scientific nature rand causing distrust in forensic methodologies.[3,5-8] In summary, as perfectly expressed by Roux et al., "Forensic science is at the crossroads [and] its future largely depends on if and how a consensus can emerge about its own nature."[9]

Numerous authors agree that research must be conducted worldwide on the (re)definition of forensic science.[9-10] A solid research culture must be developed through the promotion of educational programs and training for forensic experts and their main partners (e.g., investigators and justice actors). The ability to communicate about the meaning of forensic results should be particularly considered. Communication is indeed an important topic in forensic science, most particularly the interpersonal communication among forensic experts and between forensic experts and their main partners.

This study is aimed at observing, analyzing, and understanding the current application of forensic science in Austria. Particular attention was given to the identification of strengths and weaknesses of the processes used to communicate on the value of DNA, fingermarks, and handwriting results, mainly based on the opinions of forensic experts. The choice to focus on Austria has been made because it is historically interesting to study the situation in this country more than a century after the work of Hans Gross, Austrian pioneer of the discipline. Furthermore, as a country working in an inquisitorial tradition, Austria can be used as an example for most European criminal justice systems. The decision to focus on the selected traces — DNA, fingermarks, and handwriting — was taken because these traces are often encountered on criminal cases and possess characteristics allowing interesting comparisons: they are usually processed by different experts in different institutions, appraised with various degrees of confidence, and evaluated and reported using different methodologies.

In order to identify the main experts of forensic science in Austria and to understand their working processes, the Austrian police and justice systems were studied based on literature and reports, particularly concerning the three selected traces. Surveys were then developed and submitted to the identified experts to further deepen the obtained knowledge and to collect the opinions of the tenants of the discipline relating to the following concepts: (1) examination and analysis of traces; (2) usability and registration of traces; (3) comparison traces — prints; (4) evaluation and interpretation of results; and, (5) communication of results.

This research is crucial and timely for the discipline, as it allowed obtaining interesting insights into the working processes of the Austrian forensic community, most particularly concerning DNA, fingermarks, and handwriting. The obtained results, mainly based on the opinions of the experts of the selected traces, helped to propose practice-oriented measures regarding the appraisal and communication of traces in Austria, and, as an extension, in any inquisitorial justice system. This research will be further developed to include surveys and interviews of other forensic experts as well as judiciary members. This will allow expanding the scope of the proposed measures and promoting a better forensic communication, which is necessary to rehabilitate forensic science as a proper scientific discipline.

Forensic Results, Physical Traces, Communication

E18 Raman Microspectroscopy and Advanced Statistics for Detection and Characterization of Gunshot Residue (GSR)

Igor K. Lednev, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Shelby R. Khandasammy, BS, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; and Justin Bueno, MS, State University of New York at Albany, 1400 Washington Avenue, Albany, NY*

After attending this presentation, attendees will have a better understanding of the recent advancements of the application of Raman microspectroscopy for GSR analysis, identification, and discrimination. This presentation will describe the development of a novel and alternative method for GSR detection and analysis.[1] The implementation of advanced statistics to differentiate experimental Raman spectra collected from non-equivalent GSR samples will be discussed.

This presentation will impact the forensic science community by demonstrating whether this method can already be used for practical purposes. This research has the potential to greatly impact the accuracy and effectiveness of shooting incident investigations. This study has generated significant interest among the scientific community and practitioners. *Journal of Analytical Chemistry*, the top journal in the field in the world, highlighted the article on the journal cover. *Chemical & Engineering News*, the top news magazine of the American Chemical Society, released press coverage. Canada Discovery Channel made a piece on the daily *Planet* program about this discovery. Several emails have been received from police detectives.

Raman spectroscopy has numerous applications in forensic chemistry.[2] Raman analysis is a technique that can obtain confirmatory class identification of analytes through low intensity laser light scattering. The technique is non-destructive, rapid, sensitive, and requires little or no sample preparation. Furthermore, portable Raman spectrometers are readily available, allowing for crime scene accessibility. Raman spectroscopy offers several advantages over the current methodology for GSR analysis. The technique has been shown to detect components from both the organic and inorganic constituents of GSR on adhesive tape.[3,4] This is contrary to current GSR elemental analysis methods, which rely solely on the detection of the heavy metals (lead, barium, and antimony). This is problematic since environmental concerns have led to the increased popularity in heavy metal-free or "green" ammunition. It has been found that in the absence of heavy metals, current elemental analysis techniques are severely hindered when making accurate identification of GSR samples. Additionally, the probability of environmental and manufacturing particles assigned (incorrectly) as being GSR has increased with the onset of "green" ammunition. Until recently, the application of Raman spectroscopy for GSR analysis was largely unexplored, although this approach is not dependent on detecting metals, and is more capable of differentiating environmental contaminants and GSR. Therefore, a Raman spectroscopic method displays numerous advantages in specificity when compared to current techniques.

The firearm discharge process could be considered analogous to a complex chemical reaction. Therefore, the chemical composition of the products (GSR particles) is directly related to the chemical nature of the reagents (firearm-ammunition combination) and the conditions of the reaction. Preliminary results reveal that Raman data collected from GSR particles originating from different firearm-ammunition discharges were successfully classified according to caliber. Using a 785-nm Raman excitation, 0.38-inch and 9mm caliber firearm discharge samples were probed. Resulting data was treated with statistical methods (performed using MATLAB® with the PLS_Toolbox), such as Principle Component Analysis (PCA) and Support Vector Machines (SVM). The results demonstrate a high probability of this method to correctly classify data from the two examined calibers. Preliminary results illustrate that the variations between non-equivalent GSR samples can be detected through this method. Since GSR is often collected from a suspect, the application of this method to forensic investigations would provide a link between GSR collected from the shooter and the crime scene.

This emerging technique illustrates the possibility for an on-scene, non-destructive identification and chemical characterization method for GSR. This method has the potential to greatly impact the forensic science community by increasing the accuracy (and discriminatory power) of GSR detection. The most direct application for this research is a method to exclude a specific firearm-ammunition combination as producing an evidentiary GSR sample. The comparison of a laboratory-generated GSR sample discharge and an evidentiary GSR sample can be made without extensive preliminary studies.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. Gunshot Residue, Raman Spectroscopy, Chemometrics

E19 Analysis of Blood Traces by Attenuated Total Reflection (ATR) Fourier Transform Infrared (FTIR) Spectroscopy for Species Identification

Ewelina M. Mistek, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; and Igor K. Lednev, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222*

The goals of this presentation are to demonstrate: (1) the advantages and disadvantages of current methods for bloodstain analysis during forensic investigation; (2) the importance of species identification from blood traces found at a crime scene; (3) the significance of a non-destructive method for examination of trace evidence at a crime scene; (4) the advantages of FTIR spectroscopy in forensic investigation; (5) the FTIR spectroscopy for bloodstain examination; and, (6) the use of chemometrics for distinguishing between human and animal blood and species identification.

This presentation will impact the forensic science community by demonstrating that a non-destructive, quick, and confirmatory method for species identification based on blood traces found at a crime scene would be of great help to law enforcement. This study reveals great potential of FTIR spectroscopy combined with statistical data analysis for differentiating between species based on bloodstains.

In a forensic investigation, biological evidence can be very helpful for identifying a victim or suspect, as well as for solving a criminal case. Blood identification is typically based on the following steps: visual examination, a presumptive assay, a confirmatory assay, and lastly, the stain can be subjected for species identification before DNA profiling is performed. Presumptive and confirmatory assays are utilized for confirming a stain to be blood. The disadvantage of presumptive tests is the amount of potential false positive reactions with some environmental contaminants. Both presumptive and confirmatory assays require reactants to initiate a chemical reaction and therefore damage the sample. Once a trace found at a crime scene is identified as a bloodstain, it can be subjected for further analysis. Determining the origin of blood is critical in forensic casework since it can streamline the investigation process by including or excluding non-human stains. Immunochromatographic assays are an example of tests for confirming human origin of a stain. The ultimate goal for analyzing blood is DNA profiling, which requires DNA extraction from the sample. Therefore, current standard methods employed for the analysis of blood samples are destructive and time consuming. Another inconvenience for all current types of blood examination, besides DNA analysis, is the limited sample size found at a crime scene. Therefore, it would be highly advantageous to implement a method which is quick, non-destructive, and requires only a small sample with little to no preparation for the identification of a species' blood at a crime scene.

In this study, Attenuated Total Reflection (ATR) FTIR spectroscopy was used as a confirmatory, non-destructive, and rapid method to distinguish blood from different species.[1] Bearing in mind forensic purposes, differentiation of human and non-human blood samples was targeted, and the Partial Least Squares Discriminant Analysis (PLSDA) model that was made demonstrated complete separation between human and animal donors. In addition, the models revealed complete distinction between blood spectra from three species, namely human, cat, and dog. The method was subjected to external validation using samples that were not a part of the training dataset. Classification predictions of unknown blood donors performed by the model resulted in 100% accuracy. This study demonstrated ATR FTIR spectroscopy's great potential for bloodstain analysis and species discrimination. Furthermore, the commercial availability of portable ATR FTIR instruments affirms the potential for the implementation of such bloodstain analyses, at a crime scene as well as in the lab.

This project was supported by awards from the National Institute of Justice, Office of Justice Programs, United States of America, Department of Justice (I.K.L.).

ATR FTIR Spectroscopy, Blood, Human Origin

E20 Universal Detection of Body Fluid Traces *In Situ* With Raman Hyperspectroscopy for Forensic Purposes

Gregory Mclaughlin, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Marisia A. Fikiet, MS, 3 Leach Avenue, Apt A, Albany, NY 12205; Masahiro Ando, PhD, Spectroscopic Science Laboratory Co, 3-22-9 Ozenji-higashi, Kawasaki 215-0018, JAPAN; Hiro-o Hamaguchi, PhD, Spectroscopic Science Laboratory Co, 3-22-9 Ozenji-higashi, Kawasaki 215-0018, JAPAN; and Igor K. Lednev, PhD, University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222*

The goal of this presentation is to demonstrate the difficulties of separating Raman spectra of a sample from that of a substrate and to present a brand new way to deal with this problem.

The presentation will impact the forensic science community by familiarizing attendees with the progress made on a new method for body fluid identification that is non-destructive, fast, easy, and can be used regardless of substrate.

Raman spectroscopy has been a boon to the field of forensic science. One area in which this technique exhibits exceptional promise is body fluid identification and characterization. Previous research has demonstrated that Raman spectra combined with advanced statistics can reliably differentiate body fluids. This is an improvement on current methods that are destructive to the evidence, specific to a single body fluid, and have numerous false positives and cross reactants; however, substrate interference remains a major impediment to its practical implementation.

The new approach outlined in this presentation has immediate application for body fluid detection and allows for a universal, automatic, non-destructive, on-field method for confirmatory identification of body fluid traces at a crime scene. To overcome substrate interference, previous research has been performed using different laser excitation wavelengths, spectral background subtraction, and statistical modeling; however, no one method was able to be used for every substrate tried. Here, an approach for the universal detection of body fluids, regardless of the substrate, is presented. This approach is based on Raman hyperspectroscopy and Multivariate Curve Resolution (MCR) and a new program called Hypothetical Addition Multivariate Analysis With Numerical Differentiation (HAMAND). These techniques were applied to datasets representing simulated semen evidence. Raman spectra of the target body fluid, semen, was first decomposed using MCR and standards were picked from the resulting components. These standards were used to train the program HAMAND. The HAMAND program was then applied to experimental spectra of a semen on substrates. HAMAND then extracted the standards from the experiment spectra, if they were present. Two experimental conditions were tried, one of semen on glass, and the other of semen on blue polyester. In every instance, the signal of the body fluid was extracted and matched to a reference spectra of semen. This approach is applicable to any analyte that is either a minor contributor or spatially distributed on a strongly interfering substrate.

Body Fluids, Raman Spectroscopy, Chemometrics

E21 Bioaffinity-Based Concepts in Forensic Serology

Jan Halámek, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Juliana Agudelo, BSc, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Erica K. Brunelle, BSc*, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Crystal Huynh, BS*, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; Lenka Halamkova, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222; and Leif McGoldrick, BS*, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will understand that bioaffinity-based methods for the analysis of body fluids offer simplicity to traditional forensic analyses of such samples. In addition, attendees will also understand the concept of using such body fluids to identify originator attributes in a quick and straightforward manner.

This presentation will impact the forensic science community by providing new methods for the analysis of body fluids in order to generate essential information directly at a crime scene. Ultimately, these systems can be incorporated into field-deployable devices (similar to glucometers) or connected to hand-held Smart Devices, which will allow for the rapid analysis of body fluids that can be used and interpreted by operators with no scientific training, and thus revolutionizing the "front end" of forensic science.

The analysis of biomarkers has been used in the field of forensics for many years in the form of DNA (usually from blood) for identification purposes; however, the process of matching DNA samples is very time consuming and has caused backlogs in many states. While this is a useful tool, it may not be the best method of analysis during an active criminal investigation. There are many other biomarkers present in blood that can be analyzed in a much shorter amount of time by utilizing bioaffinity-based cascades. The lab at the State University of New York at Albany has developed and is in the process of developing more cascades for the purpose of identifying personal attributes from individuals, such as age, biological sex, and general health conditions. These cascades have been developed for both blood and fingerprint analysis. The cascades created for blood analysis have focused on the determination of the age of the originator and the time since deposition of the sample.

Fingerprint analysis has been focused on pictorial comparisons since the process was adapted for forensics. Advances in this area have only progressed to the point where automated fingerprint identification systems can be used in certain cases (with an expert checking the results). Because of this, a fingerprint may be determined to be too smudged or smeared to be of use; however, what is often overlooked is that the patterns used to match fingerprint samples are created by sweat/sebum emulsions excreted from the fingertips. Like all bodily excretions, the emulsions have their own unique chemical composition, meaning there are biomarkers present for analysis. One of the cascades developed in the lab has focused on the analysis of amino acids in the samples. The cascades developed for fingerprint analysis have focused on the determination of biological sex. There is also ongoing research aimed at the development of a larger variety of cascades able to determine other attributes from blood and fingerprint samples.

Bioaffinity, Serology, Biomarkers

E22 DNA in the Air: The Recovery of DNA Samples From Residential HVAC Air Return Filters Using the Single 4N6FLOQSwab™ Method

Maher Noureddine, PhD, ForensiGen LLC, PO Box 250, Oak Ridge, NC 27310; and James A. Bailey, PhD, Minnesota State University Mankato, 8418 New Sandy Hill Church Road, Bailey, NC 27807*

After attending this presentation, attendees will be familiar with collecting DNA samples from residential Heating, Ventilation, and Air Conditioning (HVAC) air return filters and the potential of using such samples to aid in forensic investigations.

This presentation will impact the forensic science community by demonstrating that the single-swab method is effective in collecting DNA samples from residential HVAC air return filters. It explores this source of biological material as an indicator of living habits and evaluates the cumulative deposition of ambient DNA within the household.

The recovery of DNA samples from various surfaces and objects is of significant value to forensic investigations. The forensic science community has engaged in vibrant discussions and medicolegal debates over topics pertaining to "touch" DNA evidence, such as the modes of DNA transference from person to person, person to object, and vice versa. This important debate continues in the backdrop of heavier reliance on DNA data with varying degrees of complexity and, sometimes, the dangerously creative interpretation thereof. When it comes to explaining "touch" DNA evidence in particular, the foundational understanding of what is reasonable (and what is not) must be reconciled with the simple fact that DNA is all around us. Humans are constantly shedding skin cells -— thousands of them every day. Although a proportion of dead skin cells will have lost nuclear DNA content in the process of keratinization, some will still contribute nuclear, as well as extra-nuclear (free) DNA template sufficient for typing. Recent research has demonstrated that common house dust contains an appreciable amount of the occupant's DNA. This study evaluates whether the common house dust that is captured by HVAC air return filters will yield useful DNA profile data (e.g., missing person searches) and whether any observable differences exist in the representation of DNA profiles from multiple occupants in different vents distributed around a dwelling.

A three-story single-family home (basement, ground level, and second floor) was volunteered as the sample collection site. Built in and continuously occupied since 1999, the current four occupants (one male and three females) have lived in this home on a regular and continuous basis for the past four years. The home is serviced by two independent HVAC systems: HVAC #1 circulates air between the first floor (zone 1, fitted with two ceiling-mounted air return vents) and the basement (zone 2, fitted with one wall-mounted air return vent). HVAC #2 circulates air on the second floor only (zone 3, fitted with four air return vents). A set of seven HVAC filters (Filtrete® Basic, 3M®), one from each vent, was sampled after being in service for 15 days. A section measuring 5cm x 2cm on the inflow surface of each filter was swabbed for DNA using the COPAN® crime scene 4N6FLOQSwabs™ that were pre-wetted with 15uL of sterile water (single-swab method). The samples were extracted using the COPAN® Nucleic Acids Optimizers (NAO), a semi-permeable basket that retains fluid until centrifuged with the PrepFiler® Express™ on the AutoMate Express™ DNA Extraction. DNA was quantitated using the Quantifiler® Human DNA Quantification Kit. The AmpFℓSTR® Identifiler® Plus Polymerase Chain Reaction (PCR) Amplification Kit was used for DNA amplification. The amplified fragments were separated on the Applied Biosystems® 3130 Genetic Analyzer. Data analysis was performed with GeneMapper® ID-X v1.4.

Useful DNA profiles were obtained from all seven vents. Samples from wall-mounted vents revealed slightly higher DNA quantities than ceiling vents with the one exception of the zone 3 vent positioned above the work desk of one of the female occupants. Although zone 2 (basement) is the least occupied space in the house, the associated filter revealed more dust and the highest DNA quantitation value (0.037ng/ul) among all samples, possibly due to that vent being closest to the HVAC unit and drawing a larger parcel of circulating air in comparison. The allelic data reveal consistencies with dwelling/sleeping arrangements, whereas common areas show mixture profiles originating from all four occupants. No foreign alleles were detectable.

Residential HVAC DNA, Touch DNA, Air Filter DNA

E23 A Universal Method for Biological Stain Characterization Using Raman Spectroscopy: From Body Fluid Identification to Phenotype Profiling

Igor K. Lednev, PhD, State University of New York at Albany, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will better understand the potential forensic application of Raman spectroscopy. The implementation of advanced statistics for the analysis of spectroscopic data and the evaluation of the accuracy and reliability of the conclusions made will be discussed.

This presentation will impact the forensic science community by demonstrating the accuracy and effectiveness of biological stain analysis for forensic purposes.

This presentation will report on the development of a novel, non-destructive, and confirmatory method for characterizing biological stains. The all-in-one method has a capability to identify the body fluid, determine human or animal origin, time since deposition, phenotype profile, race and sex, specifically.

Traces of body fluids discovered at a crime scene are a potential source of DNA, which is a major individual evidence in the modern forensic investigation. The application of Raman spectroscopy for non-destructive, confirmatory identification of biological stains at a crime scene, including dry traces of sweat, vaginal fluid, semen, saliva, and blood, have recently been reported.[1] The method allowed for differentiating animal and human blood as well menstrual and peripheral blood.[2,3] Most recently, the method was further developed for determining the time since deposition for bloodstains for up to two years.[4] The theory behind Raman spectroscopy is based on the inelastic scattering of low-intensity, non-destructive laser light by a solid, liquid, or gas sample. Very little or no sample preparation is needed, and the required amount of material tested with a Raman microscope can be as low as several picograms or femtoliters. A typical Raman spectrum consists of several narrow bands and provides a unique vibrational signature of the material. Typically, non-resonance Raman spectroscopy is not destructive for the sample. A portable Raman spectrometer is now a reality that should allow the identification at the crime scene.

It would be of great help for criminal investigations to develop a phenotype profiling immediately at a crime scene based on a rapid analysis of biological stains. With this goal in mind, the possibility of race differentiation based on Raman spectroscopy of blood traces has been investigated.[5] Specifically, advanced statistical analysis of spectroscopic data was used to discriminate between Caucasian (CA) and African American (AA) donors based on dry peripheral blood traces. Spectra were collected from 20 donors varying in gender and age. Support Vector Machines-Discriminant Analysis (SVM-DA) was used for differentiation of the two races. An outer subject-wise Cross-Validation (CV) method evaluated the performance of the SVM classifier for each individual donor from the training dataset. The performance of SVM-DA, evaluated by the Area Under the Curve (AUC) metric, demonstrated 83% probability of correct classification for both races, and a specificity and sensitivity of 80%. This initial work was followed by further proof-of-concept studies demonstrating the differentiation of donor's sex based on bloodstains and saliva traces, as well race differentiation based on traces of semen.[6-8] Overall, the developed method has great potential for crime scene investigation, providing rapid and reliable results with no sample preparation, destruction, or consumption.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. Biological Stain, Raman Spectroscopy, Chemometrics

E24 The Rapid Online Wildlife Identification Network (ROWIN): A Bioinformatic Analysis Pipeline Developed for Wildlife DNA Forensics

James P. Creecy, PhD, University of Central Oklahoma, Forensic Science Institute, 100 N University Drive, Edmond, OK 73034*

After attending this presentation, attendees will have a detailed understanding of the issues associated with wildlife forensics and the efforts being made to combat wildlife crimes.

This presentation will impact the forensic science community by revealing greater focus on the importance of wildlife forensics.

The black market trading of illegally poached wildlife is estimated to generate $20 billion in annual revenues. The travesty associated with the illegal trade of wildlife is two-fold. First, the dramatic decline of biological diversity has resulted in irreparable damage to the ecology of affected environments. Second, the black market trade of illegal wildlife products has been directly linked to funding terrorism. For more than 15 years, the field of wildlife DNA forensics has utilized the principles and tools of conservation genetics and forensic genetics to investigate wildlife crimes. Currently, the state-of-the-art technology in forensic wildlife DNA analysis utilizes Sanger sequencing to determine the genetic sequence of "marker genes." These "marker genes" are often located on the mitochondrial genome and are sequenced and analyzed one at a time.

While current techniques are effective, advances in high-throughput DNA sequencing offers the wildlife DNA forensic community an opportunity to dramatically improve the process of forensic species identification. This improvement requires the development of two key components: (1) a single method for the extraction, sequencing, and analysis of an entire mitochondrial genome; and, (2) a database consisting of forensic vouchered reference DNA samples. The wildlife DNA forensics community is therefore offered ROWIN, the first bioinformatic pipeline developed for wildlife forensics. ROWIN utilizes DNA sequencing data obtained from mitochondrial DNA (mtDNA) -specific extraction methods. ROWIN was been developed with the wildlife forensic scientist in mind and for the specific goal of eukaryotic species determination. Forensic species identification by ROWIN is independent of Polymerase Chain Reaction (PCR) and is completely controlled by the forensic scientist submitting the data. Prior knowledge of computer programming is not required and results are courtroom-ready. Implementation of ROWIN provides the wildlife forensics community with a powerful analytic tool that will result in a reduction of time and cost.

Wildlife Forensics, Bioinformatic, Next Generation Sequencing

E25 A Different Kind of DNA Casework: When It Barks or Purrs

Teri Kun, BS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616; and Christina D. Lindquist, MS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will understand the application of routine forensic genetic tools to casework involving domesticated animals, specifically dogs and cats. Cases involving trace companion animal biological evidence (for example, a shed hair or piece of feces) will be presented to provide an overview of breadth of casework completed by the Veterinary Genetics Laboratory-Forensic unit (VGL-Forensics) at the University of California at Davis (American Society of Crime Laboratory Directors/Laboratory Accreditation Board (ASCLD/LAB) -International accredited since 2010).

This presentation will impact the forensic science community by increasing awareness of the field of wildlife forensics. This presentation is intended to be part of a set of presentations from forensic science practitioners in the wildlife forensics community. Wildlife species have often been the basis for research presented at the American Academy of Forensic Sciences (AAFS); however, the work of wildlife forensic laboratories has, in the past, been underrepresented in the AAFS scientific sessions. By presenting multiple talks, highlighting the breadth of the work that is completed in this community, a valuable resource will be provided to the forensic science community at large.

While committing a sexual assault in a residential backyard, Rusfus Sito Nanez III rolled in some canine feces, which later helped link him back to the victim's home, resulting in his conviction. VGL-Forensics played a key role in the trial and conviction of this serial rapist. As the only crime laboratory in the country accredited for analysis of DNA from domestic animals, VGL-Forensics has been serving federal, state, and local law enforcement agencies, as well as the general public, for more than a decade. The laboratory receives a wide variety of cases from all over the world, with sample types and species unlike those encountered by its human counterparts. Cases range from human-on-human crimes in which dog or cat biological evidence links a suspect to the crime, to large-scale dog fighting, species identification, and animal cruelty cases. Recent case examples will be presented in addition to other high-profile and cold cases.

Because domesticated animals share such a close relationship with humans, the work of the VGL-Forensics routinely intersects with the work of human crime labs and is used as an investigative tool in traditionally "human" law enforcement cases, such as homicide or sexual assault; however, dogs and cats are not "human," which means that working with these species includes some of the same challenges as working with wildlife species in wildlife crime laboratories. In order to meet the demands of courts that are accustomed to hearing human DNA evidence, VGL-Forensics has modelled our laboratory system after that of a "human" DNA crime lab, dealing mainly in match comparison and mitochondrial haplotyping methods. Details of these methods as applied to dogs will be presented as well.

Wildlife Forensics, Canine DNA, Non-Human Forensics

E26 A Different Kind of DNA Casework: When It Has Fangs or Antlers

Kimberly Frazier, MS, Department 3312, 1000 E University Avenue, Laramie, WY 82071; and Christina D. Lindquist, MS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will have a better understanding of wildlife forensics at the state level. Case histories will be highlighted from several states covering a variety of species and testing methods. These case histories will include: bighorn sheep cases from New Mexico and Colorado; an elk case from Colorado; grizzly bear, black bear, white-tailed deer, mule deer, and pronghorn cases from Wyoming; and an elk case from Yellowstone National Park. These cases involve species identification using protein analysis and mitochondrial DNA sequencing, sex identification, and matching using microsatellites.

This presentation will impact the forensic science community by increasing awareness of the field of wildlife forensics. This presentation is intended to be part of a set of presentations from forensic science practitioners in the wildlife forensics community. Wildlife species have often been the basis for research presented at the American Academy of Forensic Sciences (AAFS); however, the work of wildlife forensic laboratories has, in the past, been underrepresented in the AAFS scientific sessions. By presenting multiple talks, highlighting the breadth of the work that is completed in this community, a valuable resource will be provided to the forensic science community at large.

These histories will provide background information of each case, from the law enforcement perspective to the analyses performed in the laboratory to the results of each case. This background information will include information on the discovery of the violation, how officers determined the suspect and collected evidence, and the evidentiary items that were submitted to the laboratory for analyses. For the analyses performed, a brief overview of the testing procedures and results will be provided. The presentation of the cases will also include charges filed, expert witness testimony, if applicable, sentencing, and fines.

It is hoped that these case histories will help explain the diversity of the field of wildlife forensics and while analyses, in some cases, is very similar to that in the human field, they can also be very different. In wildlife forensics, it is most often the animal that is the victim.

Wildlife Forensics, DNA, Non-Human Forensics

E27 A Different Kind of DNA Casework: When It Has Antlers

Brandt G. Cassidy, PhD, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; James Anstead, PhD, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Kelsy Lowther, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Erica Reynaga, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Elizabeth O'Bannon, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Sherri Deaton, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; and Christina D. Lindquist, MS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will better understand the application of forensic principles to the area of wildlife forensics. The development and application of a system for the unique identification of white-tailed deer used for the prosecution of suspects who may have committed crimes involving white-tailed deer will be presented. A multiplex Short Tandem Repeat (STR) marker system was used to confirm the identity of the stolen deer and offered in court to help prosecute an individual charged with the theft of the trophy white-tailed deer buck. The presentation of the development and validation of the white-tailed deer STR marker system will reinforce the parallels between human and wildlife forensics.

This presentation will impact the forensic science community by increasing awareness of the field of wildlife forensics. This presentation is intended to be part of a set of presentations from forensic science practitioners in the wildlife forensics community. Wildlife species have often been the basis for research presented at the American Academy of Forensic Sciences (AAFS); however, the work of wildlife forensic laboratories has, in the past, been underrepresented in the AAFS scientific sessions. By presenting multiple talks, highlighting the breadth of the work that is completed in this community, a valuable resource will be provided to the forensic science community at large.

The unique challenges of wildlife forensics will be discussed as they relate to the prosecution of the individual for the theft of the trophy buck and in general. In this case, a comparison between the DNA profile from the animal and the DNA profile from shed antlers from the original owner were presented in court and contributed to the conviction of the suspect. Methods for the extraction of DNA from typical white-tailed deer samples, multiplex Polymerase Chain Reaction (PCR), and capillary electrophoresis will be discussed. The validation conducted included processing deer samples from substrates such as deer hair and antler material, blood on rope, wood, leaves, dirt, leather boots, tarps, denim, arrows, and concrete; this will be discussed. This database of white-tailed deer DNA profiles was processed using the Cervus computer program to determine if the makers were in Hardy-Weinberg equilibrium and to identify the Polymorphic Information Content (PIC) at each locus. Allele frequencies for each marker were calculated to determine the match probability in this case.

Many other examples of the application of forensic DNA testing for the successful prosecution of suspects in wildlife crimes will be mentioned. Current efforts to produce a tetra-nucleotide STR multiplex system for Sable antelope will also be discussed. At the conclusion of the presentation, attendees should have a good understanding of the application of well-established human forensic principles to the challenging area of wildlife forensics.

Wildlife Forensics, White-tailed Deer, Multiplex STR

E28 A Different Kind of DNA Casework: When It Has Fins

Piper Schwenke, MS, NOAA Forensic Laboratory, 2725 Montlake Boulevard, E, Seattle, WA 98112; Kathy Moore, MS, NOAA/NMFS/Northwest Fisheries Science Center, 219 Fort Johnson Road, Charleston, SC 29412; Trey Knott, MS, NOAA Forensic Laboratory, 219 Fort Johnson Road, Charleston, SC 29412; Linda Park, PhD, NOAA Forensic Laboratory, 2725 Montlake Boulevard, E, Seattle, WA 98112; and Christina D. Lindquist, MS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will better understand the similarities and differences in the application of forensic genetics to humans and marine wildlife species. Two cases, one involving seafood fraud and the other trafficking in prohibited shark fins, will be used to illustrate the legal framework, difficulties in sampling large shipments, and genetic challenges in wildlife analyses.

This presentation will impact the forensic science community by increasing awareness of the field of wildlife forensics. This presentation is intended to be part of a set of presentations from forensic science practitioners in the wildlife forensics community. Wildlife species have often been the basis for research presented at the American Academy of Forensic Sciences (AAFS); however, the work of wildlife forensic laboratories has, in the past, been underrepresented in the AAFS scientific sessions. By presenting multiple talks, highlighting the breadth of the work that is completed in this community, a valuable resource will be provided to the forensic science community at large.

The National Oceanic and Atmospheric Administration (NOAA) Fisheries Forensic Laboratory supports the NOAA Fisheries Office of Law Enforcement (OLE) with forensic analyses. OLE upholds more than 35 statutes regulating commercial and recreational fishing and protecting endangered species, marine mammals, and marine sanctuaries. OLE also enforces laws that focus on harvest, processing, and trafficking of marine resources. As such, cases that the forensic laboratory routinely analyzes fall into two broad categories: major criminal cases of seafood fraud involving false labeling and trafficking in protected species. Both types of cases require definitive knowledge of the species in evidence to determine whether a violation has occurred. Because processing of seafood and protected species early in the supply chain often removes easily identifiable physical characteristics, identification of evidence is often via mitochondrial DNA sequencing. The first case involves large-scale mislabeling of salmon. In 2007, NOAA OLE seized more than 15,000 pounds of frozen, processed salmon fillets believed to be mislabeled as Chinook salmon. DNA analysis of samples collected from the seizure confirmed that the majority of the fillets were not Chinook salmon, but were other, less valuable species of Pacific salmon. The government estimated that the market value of the falsely labeled fish was in excess of $1.3 million. The owner of the processing company was sentenced to a year in prison and fined a $347,000 community service payment. The company has since gone out of business.

The second case involves trafficking in protected species of shark. Shark fins are highly valued for shark fin soup and are subject to a lucrative worldwide trade. Because of the fin trade and other fishing pressures, sharks have come under increased protection in an attempt to stem population declines. Before 2014, only three shark species that were rare in trade were protected under international treaty, but 2014 saw nine relatively common shark species added to this list. These new protections have led to increased enforcement efforts and resulted in several large shark fin shipments seized in the United States. This case presentation will focus on a recent United States West Coast seizure of 21 metric tons of shark fins and share some lessons learned about dealing with large heterogeneous shipments containing mixed legal and illegal product, prosecutions involving foreign defendants, and species with challenging population genetics.

Wildlife Forensics, Species Identification, DNA Sequencing

E29 A Different Kind of DNA Casework: When It Has Horns or Tusks

Mary K. Burnham-Curtis, PhD, USFWS National Fish and Wildlife Forensic Lab, 1490 E Main Street, Ashland, OR 97520; Barry Baker, MA, USFWS National Fish and Wildlife Forensic Lab, 1490 E Main Street, Ashland, OR 97520; Gabriela Chavarria, PhD, USFWS National Fish and Wildlife Forensic Lab, 1490 E Main Street, Ashland, OR 97520; Edgard O. Espinoza, PhD, USFWS National Fish and Wildlife Forensic Lab, 1490 E Main Street, Ashland, WA 97520; and Christina D. Lindquist, MS, UC Davis, VGL-Forensics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will understand the mission of the United States Fish and Wildlife Service (USFWS) - National Fish and Wildlife Forensic Laboratory (NFWFL) and the role that forensic scientists play in providing scientific support for law enforcement investigations of wildlife crimes domestically and internationally. This presentation will raise awareness of an active and diverse field of forensic science that focuses on crimes that involve non-human and non-domestic animals, with an overview of laboratory operations and selected case studies. Crimes that involve wildlife vary widely, such as illegal hunting and fishing violations, events that result in the harm to or death of threatened and endangered species, or activities of sophisticated illegal black markets connected to international wildlife trafficking networks. Often, the primary investigative activity in a wildlife crime case is to determine whether a crime has actually been committed as sometimes both the victim and the suspect may be animals or trees.

This presentation will impact the forensic science community by increasing the awareness of the field of wildlife forensics. This presentation is intended to be part of a set of presentations from forensic science practitioners in the wildlife forensics community. Wildlife species have often been the basis for research presented at the American Academy of Forensic Sciences (AAFS); however, the work of wildlife forensic laboratories has, in the past, been underrepresented in the AAFS scientific sessions. By presenting multiple talks, highlighting the breadth of the work that is completed in this community, a valuable resource will be provided to the forensic science community at large.

The NFWFL is a fully accredited forensic laboratory located in southern Oregon and is the science support arm of the USFWS Office of Law Enforcement, assisting more than 300 special agents, wildlife inspectors, and several K-9 teams in the United States, special agent attachés in nine foreign countries, 50 State Fish and Game Commissions, and more than 170 foreign countries who have signed the United Nation's Convention on International Trade in Endangered Species Treaty. The mission of the NFWFL is to identify the species or subspecies of pieces, parts, or products of an animal; to determine the cause of death of an animal; to help wildlife officers determine if a violation of law has occurred; and to identify and compare physical evidence in an attempt to link suspect, victim, and crime scene. The NFWFL's forensic program has been accredited through the American Society of Crime Laboratory Directors/American National Standards Institute-American Society of Quality (ANSI-ASQ) National Accreditation Board (ASCLD/ANAB) since 1997, and NFWFL forensic scientists participate in regular proficiency testing.

The NFWFL's scientific staff includes experts in morphological identification, genetic analysis, chemical analysis, and veterinary pathology. Cases processed by the NFWFL are primarily focused on compliance with criminal law, and analyses of non-wildlife cases, such as animal abuse or food contamination, are rare. NFWFL scientists conduct cause-of-death determinations, class character analyses (morphology, chemistry, and genetics), and source evaluation of individuals (genetics). Often, individual cases are processed by multiple disciplines. In 2016, the NFWFL analyzed 2,605 individual items of evidence that were part of 732 investigations. NFWFL forensic scientists provided additional support in the form of 1,525 photo identifications to assist field agents in determining if suspected infractions warranted investigation.

One example of casework conducted at the NFWFL is the investigation referred to as "Operation Crash," an ongoing nationwide criminal investigation led by the USFWS Office of Law Enforcement. The investigation focused on the illegal trade in rhinoceros horn and elephant ivory involving international poaching and smuggling syndicates. Charges against defendants included violations of the Endangered Species Act and Lacey Act, conspiracy, smuggling, money laundering, mail fraud, tax evasion, bribery, and false documentation. NFWFL scientists conducted chemical analyses to determine if evidence items were of animal origin, morphological analyses to determine if horns originated from rhinoceros and if ivory originated from extant elephant or extinct mammoth, and genetic analysis to determine the species source of rhinoceros horn (Black or White rhinoceros) and ivory (African or Asian elephant). To date, this operation has secured the arrest and successful prosecution of numerous individuals and businesses and the disruption of several smuggling networks. A total of 34 years of prison and $7.5 million in fines and restitution have been imposed by the courts.[1]

Additional examples of the diversity of forensic analyses conducted at the NFWFL will provide attendees with a greater understanding of the breadth of scientific expertise provided by Wildlife Forensic Scientists at the USFWS-NFWFL.

Wildlife Forensics, Wildlife Trafficking, Non-Human Forensics

E30 The Risk for Immersion Pulmonary Edema (IPE) From Scuba Diving

Benjamin Mokdad, IML CHU Rouen 1 Rue de Germont, Rouen, Normandie 76000, FRANCE; Isabelle Leblanc, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; Gilles Tournel, PhD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; Sophie Thureau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; and Anne-Claire Lhoumeau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76031, FRANCE*

The goal of this presentation is to reveal how risk factors for IPE are still poorly understood and how this study investigated a diver's susceptibility.

This presentation will impact the forensic science community by making people aware of the danger of IPE, which differs from drowning accidents.

IPE occurs when the alveolar capillary barrier fails due to the constraints on a diver's lungs during a dive in which obstructing fluid entering the lungs can resemble symptoms of drowning. IPE can induce death in 1.1% of descents, which is higher than the risk associated with decompression sickness. Some advance figures even put IPE as high as 15%. The onset of IPE generally begins 15 to 20 minutes into a dive with symptoms of dyspnea, coughing, laryngeal sounds, and a feeling of chest tightness without genuine pain. Due to these symptoms, a diver may interrupt decompression breaks during an ascent, thus increasing chances of decompression sickness and hypoxia, which is found in 15%-20% of reported cases. Divers experience sensations of suffocation, coughing up blood, or if serious enough, the diver dies upon resurfacing. This report examines two fatal accidents that occurred during cold sea diving trips.

A 55-year-old man died from cardiac arrest a few minutes after beginning his dive into cold water (5°C). Heavily weighted and swimming against a strong current, fatigue eventually occurred and the diver quickly descended to a depth of 28 meters. During his quick descent, he attempted to resurface, but failed. Another diver made an emergency descent to rescue the failing diver. When the rescuer made it to the individual, he was conscious, but quickly lost consciousness during the ascent. Upon resurfacing and after removing the diver's breathing equipment, a bloody mass came out of his mouth. Unfortunately, the diver died after attempts to resuscitate him at the hospital, where pulmonary X-rays were determined to be normal.

Another unfortunate diving incident occurred in cold water at a depth of 20 meters when a 25-year-old soldier spent 25 minutes in the water. During his ascent, his partner felt a dead weight at the end of the attached rope and noticed that his partner withdrew his regulator as a distress gesture. After resurfacing, the soldier was found unconscious and a blood mass was discharged upon resuscitation attempts. The autopsy revealed no macroscopically visible cardiac lesions, as did a pathology examination. This soldier had regular medical exams and was considered able to perform his duties.

Neither autopsy found signs of macroscopically visible cardiac abnormalities. Hearts were not found to have coronary network obstructions or calcifications and exhibited perfect permeability of the coronary artery; likewise, toxicology examinations did not find any anomalies. No failures were found upon examination of the dive equipment for the two victims.

Both individuals lost consciousness during their ascent and coughed up a bloody mass when they emerged from the water, a sign of pulmonary edema. These two accidents reveal the danger of IPE, which can happen to all divers, even experienced ones. The occurrence of IPE in diving has multiple factors. Incidence and severity increase with age and cardiopulmonary comorbidities. Forensics and the diving community should be aware of the danger of IPE, which differs from drowning accidents; therefore, these events should not be ruled as a drowning accident.

Immersion Pulmonary Edema, Drowning, Swelling

E31 A Study of Death by Firearm Injury

Mobin Ul Islam, MD, MPH, Shaheed Ziaur Rahman Medical College, Bogra-5800, Bogra, Dhaka 5800, BANGLADESH*

The goal of this presentation is to present a retrospective study of cause of death, manner of death, and nature of death.

This presentation will impact the forensic science community by presenting the results of a study of death by firearm injury, which was conducted in a forensic medical college in Bogra, Bangladesh. The period of study was from 2006 to 2014.

In this study, cause of death, manner of death, and nature of death were examined. The total number of deaths in that period were 11. Manner of death (homicidal, suicidal, or accidental) were mentioned. Firearms (rifles or smooth bore) were mentioned. The results revealed that in these firearm injuries, causes of death were ten homicides and one suicide.

A firearm is any instrument that discharges a missile by the expansive force of the gases produced by burning of an explosive substance. Forensic examiners deal with the investigation of firearms, ammunition, and the problems arising from their use. There are generally two types of firearms: rifled weapons (e.g., military rifle, air rifle, revolvers, pistols), and smooth bore weapons, such as shotguns (e.g., cylinder bore, choke bore, breech loader, muzzle loader).

Cartridges are used in both shotguns and rifles. Cartridges consist of a short metal cylinder case that is continuous with a cardboard or plastic cylinder.[1]

Firearm wounds are identified by following the findings: an entrance wound, an exit wound, the presence of gun powder, the presence of gun powder smoke, singeing of hair, blackening of the skin around the wound, the presence of cardboard, the presence of a felt wad, the presence of a bullet, a collar abrasion in the wound, a grease abrasion in the wound, and X-ray revealing the presence of a bullet.

The character of a wound depends on the distance from which the weapon is discharged: - contact and near contact wound; close-range wound, up to 1 meter; short-range (medium) wound, 1-2 meters; intermediate-range wound, 2-4 meters; and long- or distant-range wound, more than 4 meters.[3]

Postmortem examinations of the dead bodies were conducted in Shaheed Ziaur Rahman Medical College Morgue. Prerequisites for autopsy include inquest report, Chillan, commanding certificate and requisition prepared by investigating police officers, and a magistrate sent for the autopsy. External examination and detail dissection of the bodies was conducted with the help of a mortuary attendant.

Eleven firearm-wounded, dead bodies were autopsied from 2006 to 2014. The manner of death, nature of death, age, and sex were mentioned. Bullets, cartridges, and cardboard were collected.

Distribution of death by sex. (*N*=11)

Sex	No	Percentage
male	11	100%
Female	0	0%

Distribution of death by age. (*N*=11)

Age	No	Percentage
20-49	7	63.63%
40-60	4	36.36%

Distribution of death by manner. (*N*=11)

Manner of death	No	Percentage
Homicidal	10	90.90%
Suicidal	1	9.09%
Accidental	0	0%

In this study, death due to 11 firearm wounds were deemed as ten homicides and one suicide. Homicidal firearm wounds are common in Bangladesh, whereas suicidal wounds are rare. Homicidal firearm wounds occur because of terrorism, political issues, struggle for rights, adultery, and in exchange for money and properties. Cartridges and bullets were recovered from dead bodies after dissection and given to the police. All bullets and cartridges were from shotguns. Two firearm wounds were found in the chests in two dead bodies, and firearm wounds were found in temporal and occipital regions of the head in nine dead bodies. In America, two-thirds of homicides are caused by firearm injuries; people commit suicide by firearms, drugs, and hanging; 54% of all suicidal deaths are caused by firearms.[4]

Homicidal firearm wounds are common in Bangladesh. Most are declared as an encounter or cross fire. Incidence of death due to firearm injuries are increasing gradually day by day because of terrorism and the availability of firearms without registration. Deaths were due to shock and hemorrhage resulting from firearm wounds.[2]

Firearm Injuries, Homicidal, Entrance Wound/Exit Wound

E32 Revisiting the Question of Yellow Discoloration of the Skull Bones and Diabetes Mellitus in an Autopsy Population

Angeline Eliasson, MD, Solvegatan 25, Lund, Scania 22362, SWEDEN; and Carl Johan Wingren, PhD*, National Board of Forensic Medicine, Sölvegatan 25, Lund, Scania 22362, SWEDEN*

The goal of this presentation is to illustrate if there is an association between yellow discoloration of the skull bones and diabetes mellitus in the deceased.

This presentation will impact the forensic science community by providing conclusive results that are in line with previous research. The clinical implication for noting a yellow discoloration may guide the physician to order an analysis of insulin and glucose and/or review the patient's history.

This presentation addresses the association between a yellow discoloration of the skull bones and diabetes in the deceased.[1-5] Recognition of diabetes during the autopsy serves to guide the pathologist as to which cases require further toxicological screening to look for glucose and insulin.

The study included 77 autopsy cases, prospectively, at the Unit for Forensic Medicine in Lund, Sweden, during 2016-2017, and the bones of the skulls were evaluated for a yellow discoloration. As a secondary goal, the study evaluated if a possible observed association is confounded by age or sex, or if these characteristics have an isolated effect from that of diabetes mellitus.

The forensic pathologist who evaluated the color of the skull had no background information on the case. Cases with severe decomposition and severely burnt cases were excluded. Discoloration of the skull bones was evaluated by a forensic pathologist using a Chromascop® Shade Guide used in dentistry to evaluate bleaching of the teeth. From this shade guide consisting of 20 shades, two shades were selected, one representing white and one representing yellow.

Information regarding diabetes mellitus in the deceased was obtained either from the police report or patient charts. Diabetes was considered to be present if medication such as oral anti-diabetic medication or insulin was prescribed, or if the diagnosis was mentioned in the police report or in patient journals. Information regarding age at death and sex was collected from the police reports.

Of the 77 cases, 36 (46.8%) were considered to have a yellow discoloration of the skull, and, in total, 11 (14.3%) cases had diabetes mellitus. Of those with a yellow discoloration of the skull, there were n=9 (25%) cases with diabetes, and in those with a normal color of the skull n=2 (4.9%). Using unadjusted logistic regression models, one could observe a conclusive association between a yellow discoloration of the skull bones and diabetes mellitus: *Odds Ratio (OR)*=6.5 (95% Confidence Interval (CI) 1.3, 32.5). The overall sensitivity of a yellow discoloration of the skull bones to detect diabetes mellitus was *9/11*=81%, and the overall specificity *39/66*=59%.

The model was adjusted for sex, and the observed association between a yellow discoloration of the skull and diabetes mellitus remained: *OR*=6.6 (95% CI 1.3, 33.5). The association between a yellow discoloration of the skull bone and diabetes mellitus was still conclusive after having adjusted for age: *OR*=6.8 (95% CI 1.3, 37.2). Age by itself was also conclusively associated with a yellow discoloration of the skull bones: *OR*=4.6 (1.7, 12.8).

In this study, there was a positive association between a yellow discoloration of the skull and diabetes mellitus in a medicolegal autopsy population; however, the study suffers from low statistical power, but the results are still conclusive and in line with previous research; however, the yield of the approach needs to be discussed using the sensitivity (about 80%) and specificity (59%). The test may be useful for identifying cases with diabetes mellitus, but the specificity is low, implying that a large proportion of cases free of diabetes mellitus would not be identified as such. The uncertainty concerning the true association is large, as indicated by the wide CIs.

Discoloration, Skull Bones, Diabetes Mellitus

E33 Standardizing a Large-Scale, Whole Body Computed Tomography (CT) Image Database

Heather J.H. Edgar, PhD, Anthropology, MSC01 1040, 1 University of New Mexico, Albuquerque, NM 87131; and Shamsi Berry, PhD, University of Mississippi Medical Center, 2500 N State Street, Jackson, MS 39216*

After attending this presentation, attendees will understand the benefits of standardizing data and limiting or eliminating free text answers in databases used in medicolegal investigation. Attendees will also be informed of the process by which standards are chosen and created.

This presentation will impact the forensic science community by exploring the benefits of standardized data formats, especially in medicolegal investigations. While data standardization meets several challenges in medicolegal studies not encountered in many other fields, standardization improves potential applications of large-scale data in epidemiology.

The Office of the Medical Investigator (OMI) is a state-wide, centralized medical examiner's office for New Mexico. In 2010, 5,249 deaths were routed to the OMI; 51% of those underwent autopsy, accounting for 35% of the deaths within the state.[1,2]

In 2010, the National Institute of Justice (NIJ) awarded the Center for Forensic Imaging at the OMI a grant to evaluate whether CT scans can supplant or supplement the traditional autopsy. To this end, every decedent that underwent an autopsy received a high-resolution, head-to-toe CT scan. Scanning has continued as standard practice at the OMI, even after the end of this project. So far, more than 11,000 whole body CT images have been created; however, as the original scanning was performed to address specific research projects, and not to create a general research resource, there are no indexes or tags associated with the images that might allow additional research.

In 2016, an NIJ grant was awarded to create a free-access Decedent CT Database, which will make these 11,000 whole body CTs available to the research public. Work is currently underway to contact next of kin and query the OMI's database to populate the new database. This query presents numerous challenges in that the majority of fields within the database are free text fields without any limitations. As a result, even sex can be recorded in multiple ways (e.g., Male, male, M, m), limiting the ability of future researchers to query efficiently. This is especially true as the complexity of the metadata increases. In order to combat this issue, the CT database being developed will utilize data standards, terminologies, and classification systems. Using a modified Delphi technique, experts from varying fields determined the 59 metadata variables to associate with each image.[3] This data is being captured from the OMI investigations database as well as next-of-kin interviews.

A step-by-step process is currently underway to determine the best standards to implement. First, Unified Medical Language System (UMLS) is searched to identify all of the standards for a particular concept (e.g., race) that exist. Each standard is then identified and compared for usefulness in this particular database. A standard can be implemented as is, modified, or all can be rejected. If all current standards are rejected for use in the database (or none are found), a new standard will be proposed and implemented.

A wide range of terminologies, standards, and classification systems may be implemented. This includes LOINC, SNOMED CT, CDISC, and multiple nursing standards. By comparing the standards and determining the best fit, we will eliminate duplication of standards, utilize current health care, and research terminologies will be eliminated.

For example, one of the variables included in the Decedent CT Database is medical diagnoses. This field is often recorded as free text in medicolegal investigation; however, this limits the value of this data in later research because the same condition could have hundreds of synonyms and abbreviations. Standards exist for recording actual data (Logical Observation Identifiers Names and Codes (LOINC), Clinical Data Interchange Standards Consortium (CDISC)), but the responses are of importance here. Systematized Nomenclature of Medicine – Clinical Terms (SNOMED CT) and the International Classification of Diseases (ICD) both record diagnoses; however, one standard is used to identify medical problems (SNOMED CT) within electronic health records, while the other is used for billing (ICD-10). Both standards require coding the response from next of kin or the information from the OMI database as a computer-readable number. Due to the vast number of SNOMED CT codes and the lack of everyday use of them by physicians and researchers, ICD-10 was chosen to represent the medical diagnoses of the decedents for this project.

The free-access Decedent Database is currently under development and is slated to be available by the end of 2018.

Data Standardization, Computed Tomography, Research Database

E34 Stabbing Exploration: An Essential Duality

Anne-Claire Lhoumeau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76031, FRANCE; Sophie Thureau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; Cyril Gricourt, 1 rue de Germont, Médecine Légale, Rouen 76000, FRANCE; Benjamin Mokdad, IML CHU Rouen 1 Rue de Germont, Rouen, Normandie 76000, FRANCE; Isabelle Le Blanc, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; Florence Vincent, CHU Charles Nicolle, 1 rue de Germont, Rouen 76000, FRANCE; Jean-Nicolas Dacher, CHU Charles Nicolle, 1 rue de Germont, Rouen 76000, FRANCE; and Gilles Tournel, PhD, CHU Charles Nicolle - Institut Médico-Légal, 1 Rue De Germont, Rouen 76000, FRANCE*

After attending this presentation, attendees will have learned about a stabbing case in which both a Computed Tomography (CT) scan and autopsy were essential to detect all the lethal injuries and explain the absence of defensive wounds on the victim's skin.

This presentation will impact the forensic science community by confirming the necessity of collaboration between radiologists and forensic pathologists, the importance of a systematic approach, and expanding the range of CT scan indications in stabbings.

Medical imaging investigations, such as a CT scan, have their own place in forensic medicine today, particularly in thanatology (postmortem imaging). They enable the constitution of an acceptable database of pictures for juries at the Assize Court, but are also a wonderful diagnostic tool thanks to the exploration of wounds, which are hardly accessible during a surgical autopsy.

Rouen Forensic Institute was requested following the homicide of a 54-year-old man, stabbed while he was standing in his workplace, where stigmata of an externalized hemorrhage were observed.

External examination brought to light seven cervical wounds, one of which was on the left side of the neck, facing cervical blood vessels, and six of which were on the right posterior side of the neck and were not initially suspected of being potentially lethal. No defensive wounds were visualized on the hands or the forearms, surprisingly, considering the number of blows which should have led the victim trying to fend off his aggressor.

The postmortem non-contrast CT scan, taken before the autopsy, showed a fracture of the fifth cervical vertebra's right lamina and lesions of the pedicle and vertebral body on the left side of the vertebra. The presence of air bubbles in the spinal canal was highly suspect of an associated spinal damage. Exploration of the cerebral and cervical vessels was impossible due to the absence of contrast.

During the autopsy, the left cervical wound was shown to have caused a left jugular vein injury, and one of the posterior cervical wounds was transfixing, associated with a right subclavian vein injury. Exploration of the wound, which caused vertebral and medullar injuries, was very difficult because of its location and its trajectory.

If a postmortem CT scan is actually recognized as the essential additional examination in some cases, in particular for putrefied bodies or ballistic trauma, its place in stabbing exploration is not totally defined. Indeed, a non-contrast CT scan doesn't allow the distinguishing of vascular lesions but provides a good detection of bone lesions, with the possibility of a non-invasive exploration of inaccessible areas at autopsy.

In this case, a non-contrast CT scan did not reveal the two serious vascular injuries; however, it highlighted vertebral and medullar injuries, which would have gone unnoticed or would have needed very damaging explorations during the autopsy because of their location. The absence of defensive wounds were also discovered as a result of vertebral and medullar injuries, which probably caused at least a tetra paresis with difficulty in moving the four limbs.

Thus, it seems to be crucial to systematically couple a CT scan and surgical autopsy, which are actually complementary and shall not, under any circumstances, substitute for each other, particularly in stabbings.

CT Scan, Forensic Autopsy, Stabbing

E35 A Case Report of a Peculiar Bullet Track: Trajectory Making the Defense Unfeasible

Ivan D. Miziara, MD, PhD, Sao Paulo University School of Medicine, Rua Teodoro Sampaio, 352-22, Sao Paulo 05406000, BRAZIL; Nelson Bruni, MD, Legal Medical Institute of the State of São Paulo, Av Dr Enéas de Carvalho Aguiar, 600, São Paulo 05403-000, BRAZIL; and Carmen Silvia M. Miziara, MD, PhD, Rua Capote Valente, 127/111, São Paulo 05409000, BRAZIL*

After attending this presentation, attendees will understand an unusual case of trajectory within the skull and trajectory from the firearm to the body of the victim. This presentation will demonstrate how it was possible to determine the path and trajectory of projectile and determine the location of the shooter.

This presentation will impact the forensic science community by highlighting the importance of carefully analyzing the path of the projectile in cases in which it is not located in the body of the victim and the how the single gunshot wound can reveal the true story.

A 33-year-old man was found dead inside the garage of his house. No apparent bloodstain, gun, or projectile were found at the crime scene. The wife's version, who was accused of committing the crime, was that the victim was drunk and physically assaulted her, then pointed a firearm and threatened to kill her. They began to physically fight and the gun fired. The wife wrapped the corpse in a blanket and transported it from the bedroom to the garage, then she cleaned up the crime scene.

External inspection of the decedent revealed a man of apparent age compatible with chronological age, White, 173cm tall, and weighing 75kg. Wounds in the left frontal region, upper lip, and left arm were present.

An external head examination (after hair in this area has been shaved) revealed a gunshot entrance wound, 1.5cm in size in the right parietooccipital regions of the brain with slightly oblique angle and contusion and an abrasion ring.

Gunshot entry wound to the skull: outer table of the skull exhibited cone-shaped and fractures of the parietal and base of the skull. Bullet track and trajectory: it was envisaged that the projectile's trajectory was from top to bottom, backward, at an angle of 30 degrees, from right to left and at a distance. These data show a discrepancy between the information provided by the perpetrator of the crime and the autopsy findings.

In this case report, the external examination of the cadaver did not identify the exit wound of the projectile, which made a path inside the skull, exiting through the nasal cavity without leaving an external wound. The path of the projectile inside the skull of the victim made it possible to demarcate the trajectory of the shot, contradicting the version given by the possible perpetrator of the crime.

Penetrating Head Injuries, Wound Ballistics, Gunshot Wounds

E36 When a Man Kills a Woman — Femicide in Clark County, Nevada: An Overview of Intimate Partner Homicide (IPH) and Intimate Partner Homicide Followed by Suicide (IPHFS)

Cristina Tica, MA, University of Nevada, Las Vegas, Dept of Anthropology, 4505 S Maryland Parkway, Mailstop 455003, Las Vegas, NV 89154-5003; and Caryn E. Tegtmeyer, MA, University of Nevada, Las Vegas, 4505 S Maryland Parkway, Box 455003, Las Vegas, NV 89154-5003*

The goal of this presentation is to demonstrate how women are more likely to be killed by their intimate male partner than by any other type of perpetrator. Attendees will gain valuable insight into the patterns of female IPH and female IPHFS affecting Las Vegas and its metropolitan environs.

This presentation will impact the forensic science community by explaining femicide -— the killing of a woman by a known perpetrator. In the United States, approximately one-forth of murders committed annually are perpetrated against women. Every week, there is at least one case in the media in which the female is killed by her male intimate partner. In 2011, Nevada ranked number one in the rate of women killed by men. This presentation seeks to highlight the impact fatal domestic violence has had in Clark County.

Data was collected from the Clark County Office of the coroner/medical examiner for all female homicides for seven years (2010 to 2016), with a total of 240 victims. The investigation reports, autopsy reports, the case notes, and case images were consulted.

Of the 240 total female homicides, 148 were intimate violence, in which the attacker knew the victim. Of these 148 intimate violence cases, 84 were perpetrated by a romantic partner, 36 by a relative, 23 by other, 2 by a friend, 2 by a roommate, and in 1 case, the relationship could not be established.

For the 84 romantic relationship victims, “romantic” was defined as the offender being the husband, boyfriend, partner, ex-husband, ex-partner, or ex-boyfriend of the decedent. All of these offenders were male.

Out of the 84 cases, 73 females killed by intimate partners were adults (18 to 65 years old), 10 were older adults (more than 66 years old), and one was less than 18 years old. Of the 84 victims of fatal romantic partner domestic abuse, 44 were White, 18 were Black, 14 were Hispanic, 7 were Asian, and 1 was Multi-Cultural.

In the current sample, most females killed by a romantic partner died of gunshot wounds (47 of 84, or 56%), followed by stabbing (15 of 84, or 17.9%), and blunt force trauma (14 of 84, or 16.7%). Additionally, most of them (66 of 84, or 78.6%) had both cranial and postcranial injuries. Of those who were shot, the majority (33 of 47, or 70.2%) also had both cranial and postcranial trauma.

Out of 84 cases, 31 (36.9%) perpetrated by a romantic male partner were homicides, followed by suicide. This study found that most female IPHFS incidents were perpetrated by White males (20 out of 31, or 64.5%). Most homicide-followed-by-suicide victims were adult White females, followed by adult Hispanic females. Twenty-eight of 31 (90.3%) of the IPHFS victims were killed by firearms, and 23 of 31 (74.2%) had both cranial and postcranial trauma.

According to the Center for Disease Control, intimate partner violence is a serious, preventable public health problem affecting millions of Americans. Violence against women has reached epidemic proportions in many societies, estimated by the World Health Organization (WHO) to account for between 5%-20% of healthy years of life lost in women aged 15 to 44 years. WHO has also stated that “the overwhelming burden of partner violence is borne by women at the hands of men.” That is why studies such as this are needed to help determine patterns and to understand them, in order to prevent, but also better help, the victims of domestic abuse.

Femicide, Intimate Partner Homicide, Homicide Followed by Suicide

E37 A Homicide by Shotgun: The Other Side of a Widespread Weapon

Mauro A. Ciavarella, University of Foggia, Forensic Department, Viale degli Aviatori, 1, Foggia 71121, ITALY; Giuseppe Davide Albano, Viale degli Aviatori, 1, Foggia 71121, ITALY; Giuseppe Bertozzi, MD, Dept of Forensic Pathology, Viale Degli Aviatori, 1, Foggia 71121, ITALY; Francesca Maglietta, MD, Viale degli Aviatori, Foggia 71121, ITALY; Benedetta Di Battista, MD, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Furio Martino Patete, Viale degli Aviatori, 1 C/O Medicina Legale, Ospedale C.D'avanzo, Foggia 71121, ITALY; and Monica Salerno, MD, PhD, Department of Forensic Pathology, Osp. Col. D'Avanzo, Viale degli Aviatori, 1, Foggia 71121, ITALY*

The goal of this presentation is to underline how a very careful external examination of the cadaver, as well as a detailed analysis of the crime scene, can shed light on the manner of death in a case of an unusual use of a common firearm.

This presentation will impact the forensic science community by emphasizing the necessity of a careful crime scene reconstruction and a complete methodological external examination of the cadaver in an attempt to reach a certain unusual manner of death.

Shotguns are used in a large number of homicides and suicides, and gunshot wounds are widely reported in the literature. This particular case exhibits circumstances and pathological findings that brought to recognition an unusual use of a common firearm.

This case is of a 50-year-old man, murdered in the garden of his countryside cottage in Gargano, in southern Italy. The forensic team was alerted by the local prosecutor for an "evident" case of shotgun homicide. The man was found at the crime scene lying on the ground, on his right side, with his head partially submerged in a large pool of blood. Several small pellets surrounded the victim and some had targeted the wall of the warehouse. Five plastic cases and one plastic wad were found. A plastic wad was found in the anterior side of the victim's shoulder bag.

The external examination revealed an abrasion on the left side of the face that seemed to reproduce the herringbone-shaped stone floor of the garden, and, on the right zygomatic area, a small quadrangular honeycomb grid abrasion was also present. "Raccoon eyes" with bilateral bleeding from the ears and several firearm wounds on the left shoulder were observed. Postmortem radiological study conducted with a Computed Tomography (CT) scan of the total body revealed a basal skull fracture, a spider web fracture complex of the left side of skull from the frontal to the occipital bone, a fracture of the right zygomatic bone, and five metallic fragments exclusively in the left shoulder.

At the autopsy, five pellets were found under the skin and in the fat layer of the soft tissues of the shoulder. A careful observation of the honeycomb grid abrasion allowed the examiner to connect it to a specific part of the shotgun stock -— the so called "recoil pad." A massive subdural, intraparenchymal, and intraventricular hemorrhage, diffuse to the basal cisterns, was found. No histological-specific evidence was reported, except for encephalic samples that exhibited perineuronal and perivasal edema and the presence of a massive hemorrhage of gray and white matter.

Death was attributed to a traumatic brain injury as the result of repeated blows to the head by a blunt instrument; the skin on the right side of the face reproduced the pattern of recoil pad, and on the left side, the herringbone-shaped drawing of the stone floor where the man had been lying. In conclusion, the detailed and careful examination of the injuries and other autopsy findings contributed significantly to arriving at the cause and unusual manner of death due to the back side of a shotgun.

Shotgun Deaths, Firearm Homicides, Crime Scene Investigation

E38 The Characterization of Volatile Organic Compounds (VOCs) Present in the Headspace of Decomposing Animal and Human Remains

Hyun Jee Kim, 33-14 Hoguk-ro, Waegwan-eup, Chilgok, Gyeongbuk 39872, SOUTH KOREA; Seh Yeon Park, 33-14 Hoguk-ro, Waegwan-eup, Chilgok, Gyeongbuk39872 , SOUTH KOREA; and Jisook Min, PhD, National Forensic Science Daegu Institute, 33-14, Hoguk-ro, Waegoan-up, Chilgok-gun, Gyungsangbuk-do 39872, SOUTH KOREA*

After attending this presentation, attendees will better understand a pretreatment method used for analyzing decomposition odor and VOCs identified in human remains.

This presentation will impact the forensic science community by stressing the importance of odor in evidence.

Locating human graves is important for crime solving and archaeological purposes. The development of tools and methods that can expedite locating clandestine graves has been of keen interest in the scientific community. The efforts focused on establishing the volatile chemical signature of compounds that could indicate the presence of buried human remains where surface clues are lacking and where the content of a potential grave is unknown.

The VOCs present in the headspace above partially decomposed animal tissue samples were analyzed and directly compared with results from decomposed human tissues using established Solid-Phase Micro Extraction (SPME) and Gas Chromatography/Mass Spectrometry (GC/MS) methods. The source of variation between samples was evaluated using the Analysis of Variance (ANOVA). ANOVA can assess whether altering the controlled factor, such as flow rate or material, produces a significant difference in the amount of compound collected compared with the differences found in replicate samples.

Specifically, five class prediction methods were employed, including Partial Least Squares Discrimination (PLSD), Support Vector Machine (SVM), Decision Tree (DT), Naïve Bayes, and Neural Network. VOCs present in the headspace of different animal tissue samples (muscle, fat, and skin) from a cow, a pig, and a fish were identified and compared with human samples. Although there were compounds common to both animal and human remains, the VOC signatures of each of the animal remains differed from those of humans. Of particular interest was the difference between fish and humans, because it is economically easy to obtain fish rather than beef and pork in Korea. Five fish VOC signatures (3-Udecen-2-one, Pentadecane, 3,5-Octadien-2-one, (1) 2(3H)-Furanone, dihydro-5-(2-pentenyl)-, (Z)-(.+ -.)-, 1,4-Cyclohexanedione) were not found to be a subset of animal and human; in addition to detecting only two ((1) 2-(2-Methylpropyl)-3,5-di(1-methylethyl)pyridine, (1) Benzene propanoic acid) of eight human-specific compounds, an additional one unique VOC (1,4-Dimethyltetrasulfane) was recorded from cow, pig, and human samples, which were not present in fish samples. Best decomposition odor class discrimination outcomes have been achieved by PLSD, SVM and DT.

Identifying VOCs that are unique to humans may be useful to investigate human-specific scent and may eventually lead to an instrument that can detect clandestine human burial sites. Further studies are required to routinely retrieve forensic information that is imprinted in VOCs of human decomposition, such as a variety of part of the body, including large-scale sampling of decomposed animal and human remains, to support criminal investigations. The last step of this study is to determine which compounds are generalized decomposition by-products and which are human-specific.

Decomposition, Odor, VOCs

E39 Collaboration of Forensic Disciplines Used to Solve a 13-Year-Old Homicide

Sandra E. Jones, Office of the Chief Medical Examiner, 501 Indian Hill Road, Holly Springs, NC 27540; Deborah Radisch, MD, Office of the Chief Medical Examiner, 3025 Mail Service Center, Raleigh, NC 27699-3025; and Clyde B. Gibbs, Office of the Chief Medical Examiner, 3025 Mail Service Center, Raleigh, NC 27699-3025*

After attending this presentation, attendees will understand the importance of having multiple disciplines available to assist law enforcement with a thorough death investigation. These disciplines assist law enforcement by allowing them to utilize their equipment, knowledge, and expertise. Attendees will also recognize that non-forensic experts should be considered in complex cases in which the skills or equipment necessary are beyond law enforcement's capabilities.

This presentation will impact the forensic science community by illustrating the value of multi-agency cooperation and is intended to encourage communication between law enforcement and all forensic disciplines.

This presentation looks at a death investigation from 2004 resulting in the excavation of a homicide victim who was reported missing in 1991. A tip led law enforcement to believe that his body was buried on property that was once owned by another man. After a warrant was obtained, several disciplines were contacted to assist with locating, excavating, and identifying the remains: the archaeologist with the Office of State Archaeology Research Center; a geologist with Geo Solutions Limited, Inc.; an anthropologist and forensic pathologist with the North Carolina Office of the Chief Medical Examiner (OCME); the Fayetteville Police Department; and the State Bureau of Investigation.

To scan the area for possible burial sites, the yard was separated into smaller zones. These zones were also searched by cadaver dogs, then by the geologist, using a multifrequency electromagnetic profiler and ground-penetrating radar, to identify areas that would be consistent with a burial site. A noticeable depression was observed beside a storage building that was erected during the time that the potential suspect owned the property. The archaeologist carefully removed soil to be sifted for skeletonized remains. He also determined that the perimeter of the grave had markings consistent with two types of digging tools. Studying the soil and chunks of cement, and with the limited number of bones found, suggested that most of the remains had been removed and the grave refilled.

The anthropologist and forensic pathologist were in attendance to assist with recognizing and identifying bones and bone fragments. All the remains were sent to the OCME for processing and identification. A portion of the maxilla was discovered within a chunk of cement and was carefully removed. Also recovered was the left portion of the mandible, containing teeth with restorations and a wire from surgery for a mandibular fracture. Several other small bones and fragments were recovered.

The teeth within the mandible and maxilla were used for identification. The bones retained a total of 11 teeth, 6 of which contained restorations. The written antemortem dental chart, which included a diagram of restorations, was compared to the decedent's teeth and postmortem dental chart. The repair wire from the mandible was also used for identification by comparing antemortem and postmortem radiographs. These findings confirmed that the remains were that of the missing man.

The suspect was charged with first-degree murder and pleaded guilty to voluntary manslaughter, claiming he shot the decedent in self-defense. On April 24, 2006, a judge sentenced him to three years in prison. The rest of the victim's remains have yet to be found.

When law enforcement establishes connections to agencies possessing a variety of specialized resources, they can request assistance with difficult cases, expediting the recovery of human remains. In this example, the thorough investigation led to the recovery of remains, a conviction, and closure for a family.

Excavation, Homicide, Cooperation

E40 Suture Embolism to the Left Superior Lobar Pulmonary Artery: A Case Report and Review of the Literature

Janice S. Ahn, MD, West Virginia University, 1 Medical Center Drive, Rm 2187 HSN PO Box 9203, Morgantown, WV 26506; Joy Grise, MS*, West Virginia University, 2187 HSCN, #1 Medical Center Drive, Morgantown, WV 26506; and Joseph A. DelTondo, DO*, West Virginia University, One Medical Center Drive, Dept of Pathology, PO Box 9203, Morgantown, WV 26506*

After attending this presentation, attendees will be familiar with the various types of exogenous emboli that may be encountered at autopsy. Furthermore, attendees will gain an understanding of the clinical situations that are associated with the presence of exogenous emboli.

This presentation will impact the forensic science community by increasing awareness of a rare and often bewildering autopsy finding. Moreover, knowledge of the mechanisms of embolization will enhance appreciation for and encourage familiarity with modern surgical techniques, which inescapably impact the forensic science community.

While sources of endogenous emboli, such as thrombus, fat, and tumor are well known, exogenous substances are less commonly encountered and, therefore, less frequently discussed. Modern surgical techniques, both invasive and minimally invasive, allow for the introduction of foreign material into the bloodstream. For example, iatrogenic emboli, such as Inferior Vena Cava (IVC) filters, guidewires, stents, and embolization coils, have been encountered in the surgical literature.[1] These types of emboli may or may not result in patient symptomatology. Other rarer causes of exogenous emboli include percutaneous closure devices, biological glue, and surgical suture.[2-6] When involving critical vessels, emboli cause symptoms and may be, as in this case, fatal.

This case report recounts the autopsy findings of a 58-year-old man with a history of prolonged surgical immobilization provoking deep vein thrombosis and bilateral pulmonary emboli. He had undergone an exploratory laparotomy following a fundoplication complicated by splenic injury and challenging vascular hemostasis. Autopsy revealed a large cavity within the splenic bed filled with turbid fluid consisting of clotted blood and surgical gel-foam. The cavity was lined by omental adipose tissue studded with surgical suture demonstrating fat necrosis. Within the pulmonary vasculature were extensive pulmonary arterial thromboemboli of varying chronicity as well as surgical suture emboli within the left superior lobar pulmonary artery.

Of the handful of existing reports on exogenous emboli, even fewer of which are postmortem evaluations, this is the first case of suture embolus to the pulmonary arterial system. Though the cause of death was not directly influenced by the suture embolus but rather the extensive pulmonary thromboemboli, the presence of the suture embolus was a surprising and an initially perplexing finding; however, an understanding of the clinical, namely surgical, situations around which previously reported exogenous substances were introduced into the vasculature elucidated the likely mechanism of entry.

In conclusion, embolism of exogenous material is a rare but potential finding at autopsy of which pathologists should be aware. A familiarity with modern surgical techniques enhances understanding of potential mechanisms of embolus formation.

E41 The Risk of Selfie-Related Deaths: A Case Report on the Dangerous "Daredevil Selfie" Phenomenon

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Valerio Riccardo Aquila, Via Dante Alighieri, Crotone, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Paola Frati, PhD, Dept of Anat Histol Forensic and Orthop Sciences, University of Roma, La Sapienza, Viale Regina Elena 336, Roma 00161, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Forensic Pathology Dept, Ospedale Colonnello D'Avanzo, Foggia I-71100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the term "daredevil selfie" and the phenomenon of selfie-related deaths.

This presentation will impact the forensic science community by describing this phenomenon as it is publicized on the internet and represents an emulative, dangerous trend.

"Daredevil selfie" represents a trend of recent development. It deals with taking a selfie in places at high elevation (i.e., skyscrapers, roofs) or in dangerous places such as railway tracks during the passage of the train. The phenomenon gained fame on social networks and was copied by others. Contrary to its broadcasting by mass media, it is a phenomenon insufficiently described in literature. From 2014 to the first half of 2016, 75 persons died of selfie-related accidents. The medium age of victims was approximately 23 years and the 82% were male. Forensic cases of selfie-related death have not been reported in literature until recently. The last case that occurred in Italy will be discussed.

This is the case of a boy found dead on the railway track after being run over. A judicial inspection was checked in a raised iron railway bridge. On the way from Taranto to Reggio Calabria, the mutilated body of a boy was found. Photographic surveys were conducted and due to the railway police and forensic investigators, the entrances and exits were recorded. A cellphone and a left shoe were found approximately two meters from the victim. The cellphone was given to detectives to conduct an investigation of its contents. The body presented a very extended laceration with the exposition of cerebral matter and skullcap fragments spread over the point of impact. Cerebral matter fragments were also found 15 meters from the point where the body was found, delimiting the "primary impact point" where the train collided with the body.

By reconstructing the accident, information emerged that the boy impacted the iron piers of the bridge on the railway track, was dragged forward up to the point where the body hit against another iron structure and stopped. Found during the autopsy were traumatic brain injuries with fractures of the skull cap on the right of the occipital bone; multiple ecchymosis from the left mammillary region to the right haunch; fracture of the right tibia and perone; and a cut wound on the back with soft tissue exposure. A psychological autopsy was conducted to better reconstruct the motivations linked to the event. The method involved thorough structured interviews and the collection of all available information concerning the deceased. After informed consent, face-to-face and structured interviews with family members of the victim were conducted. A survey was conducted on the victim's phone to analyze messages, photos or videos, and conversations via WhatsApp and his Facebook® account. By comparing data, it emerged that the victim had his back to the train trying to take an extreme selfie by holding the phone in his hand; when the boy noticed the closeness

This case report represents the last registered account regarding the phenomenon of the daredevil selfie. Unfortunately, the practice of extreme selfies is now rampant and represents an imitative, dangerous phenomenon as it is publicized on the internet. It is important to watch minors, who represent the most affected age bracket, with the help of social, scholastic, and family assistance to inform them that this is a very dangerous phenomenon in terms of mortality.

Forensic Science, Daredevil Selfie, Death

E42 A Nunchaku Strangled Woman: A Case Report

Giuseppe Davide Albano, Viale degli Aviatori, 1, Foggia, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Viale degli Aviatori, 1, Foggia 71121, ITALY; Francesca Maglietta, MD, Viale degli Aviatori, Foggia, ITALY; Giuseppe Bertozzi, MD, Dept of Forensic Pathology, Viale Degli Aviatori, 1, Foggia 71121, ITALY; Natascha Pascale, MD, Viale Degli Aviatori, Foggia 71100, ITALY; Benedetta Di Battista, MD, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; and Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY*

The goal of this presentation is to provide a multidisciplinary approach to the crime scene and the reconstruction of the facts requested. The time between death and the discovery of the body can make it difficult to understand external injuries correctly.

This presentation will impact the forensic science community by demonstrating a multidisciplinary approach to the crime scene and the reconstruction of the facts, especially when the manner of death is not clear.

This case report concerns a murder by strangling, in which the murderer tried to simulate a domestic accident. The device used was quite unusual, a nunchaku, a traditional weapon common in East Asian countries, consisting of two short wooden clubs connected by a chain or rope. This weapon usually inflicts blunt force against different parts of the victim's body but, in this case, it was used as an improvised noose placed around the neck of the victim. The macroscopic characteristics of cutaneous compression sulcus, its vital characteristics illustrated by immunohistochemistry, and the discovery of the weapon of which detailed investigations of forensic genetics were performed, confirmed the homicidal occurrence.

A middle-aged man alerted the police and the health emergency service, stating that his wife fell from a ladder a few days before while cleaning and died. The man reported to the police that, in view of his state of shock, he did not have the strength to ask for help before, so he stood next to his wife's corpse for at least two days. At the crime scene, investigators found an overturned armchair in the bedroom and many opened furniture drawers. The prosecutor ordered a detailed crime scene investigation. The body was laying in a prone position on the floor, near a metal ladder, in an advanced stage of putrefaction; however, a transverse, complete cutaneous compression sulcus, presenting multiple rectangular excoriated areas along its course, was observed around the neck. No evident cranio-facial injuries were detected. The apartment was thoroughly searched. During this operation, a homemade broken nunchaku was found, with hairs on it. The prosecutor requested an autopsy to determine the manner and cause of death. A postmortem Computed Tomography (CT) scan was performed. Bone and visceral injuries were excluded. The autopsy exhibited mild pulmonary edema, as well as the presence of white foam in the main airways. The histological examination of skin specimens taken from the ligature mark revealed intra-epidermal mild erythrocytes reactions and musculature alteration such as "Zenker's necrosis." In addition, the immunohistochemical staining method on skin samples was performed utilizing anti-tryptase antibodies, IL15 and CD15, which confirmed the vitality of the sulcus. Genetic investigation revealed a match between the DNA extracted from the hairs found on the nunchaku and the DNA of the dead woman. The cause of death was attributed to acute asphyxia due to strangulation by the nunchaku metal chain. The prosecutor interrogated the husband of the deceased, who confessed to the homicide as well as the supposed modality. The husband also confessed that he waited for putrefactive process to mask the signs of strangulation.

It seems evident that a multidisciplinary approach to the crime scene and the reconstruction of the facts should be requested, especially when the manner of death is not clear, or the time between the death and the discovery of the body can make it difficult to understand external injuries correctly.

Nunchaku, Strangulation, Homicide

E43 The American Board of Forensic Taphonomy (ABFTaph): A Multidisciplinary Approach to Decomposition

Amanda L. Roe, PhD, College of Saint Mary, 7000 Mercy Road, Omaha, NE 68106; Leon G. Higley, PhD, 7320 Raven Circle, Lincoln, NE 68506; Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; and Neal H. Haskell, PhD, 425 Kannal Avenue, Rensselaer, IN 47978*

After attending this presentation, attendees will have a better understanding of forensic taphonomy, the ABFTaph, and the benefits of joining the ABFTaph.

This presentation will impact the forensic science community by introducing an inclusive organization that helps bring the smaller forensic science disciplines together, by recognizing the need for a multidisciplinary approach to research, and by providing, in the interest of the public and the advancement of the science, a program of certification, procedures, best practices, and protocols in forensic taphonomy.

Forensic taphonomy " … refers to the use of taphonomic models, approaches, and analyses in forensic contexts to estimate the time since death, reconstruct the circumstances before and after deposition, and discriminate the products of human behavior from those created by the earth's biological, physical, chemical, and geological subsystems."[1] This includes, but is not limited to, the forensic disciplines of physical anthropology, botany, climatology, entomology, geology, pathology, and soil science.

Because there is a need to identify forensic scientists qualified to provide essential professional services for the judicial and executive branches of government and because many of the disciplines listed above have a small number of practitioners without parent organizations available for stating and verifying their competence or their scientific standards, we have established a multidisciplinary board called the ABFTaph This is a non-profit, incorporated professional board which establishes, enhances, and revises as necessary standards of qualification for those who practice forensic taphonomy, and to certify as qualified specialists those applicants who comply with the requirements of the Board. Certification is based upon the candidate's personal and professional record of education, training, experience, and achievement, as well as the results of formal examinations. There are two examinations: a general exam for entry into the organization, and a discipline-specific exam to demonstrate competence in an individual's field.

The membership tiers are based on experience and include many of the same levels as the American Academy of Forensic Sciences, including a student category as a means to educate new generations of forensic scientists in an inclusive organization that is focused on the teamwork generally involved in forensic science research and cases.

Additionally, to maintain the integrity of the organization, the Board has requirements for members to provide copies of all case reports (after adjudication of associated case) and will maintain an open database of these reports with post-hoc review as a requirement for re-certification.

Taphonomy, Decomposition, Forensic Science

E44 The Application of Eukaryotic Community Succession on Porcine Remains for Postmortem Interval (PMI) Estimation

Luisa Forger, 701 Saint James Street, Apt 206, Richmond, VA 23220; Michael Shane Woolf, MS, 1023 Tupelo Court, Charlottesville, VA 22903; Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, 907 Floyd Avenue, Richmond, VA 23284; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Harris Hall, S, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will understand how changes in the structure of eukaryotic communities found on decomposing remains may aid in the estimation of the PMI.

This presentation will impact the forensic science community by increasing their understanding of methodology currently in place and their awareness of emerging forensic techniques. This presentation will also provide recommendations as to how investigators may better approach crime scenes to preserve and collect evidence for use in necrobiome sequencing. Finally, this presentation will highlight how the application of next generation sequencing may change the way in which postmortem interval is determined by providing a supplemental technique to traditional estimation methods. This presentation will also highlight a novel area of research that provides a useful alternative to traditional PMI estimation techniques by employing next generation sequencing. Furthermore, this study explores the use of eukaryotic communities for such estimations, an area which has not yet been fully explored.

Every cadaver is the host to a complex mixture of prokaryotic and eukaryotic communities, collectively referred to as a necrobiome. Since necrobiomes respond to environmental changes in predictable patterns during the decomposition process, it is possible to use necrobiome succession as a "microbial clock" for PMI estimation.[1] Several recent studies have used bacterial and eukaryotic community succession on murine, porcine, and human remains for PMI estimation; however, these studies either had limited replications or were conducted in a laboratory environment.[2-5]

The main goal of this study was to determine eukaryotic community succession associated with skin of porcine remains for long-term PMI estimation (>1,500 Accumulated Degree Days (ADD) or >60 days) in well-replicated (n=6) field conditions. To accomplish this goal, six sets of porcine remains were allowed to decompose in field conditions for 62 days. Samples were collected by swabbing the surface of the skin at the lateral thoracic and lateral abdominal regions every day for the first week, every alternate day for the second week, and once every week after the second week, for a total of 96 samples. Microbial DNA was extracted using the Cetyl Trimethyl Ammonium Bromide (CTAB) bead-mill extraction process. Sufficient DNA yields for all samples were determined using a Qubit® 2.0 Fluorometer.

Hypervariable region V9 of the 18S recombinant DNA (rRNA) gene was amplified according to the Earth Microbiome Project protocol (http://www.earthmicrobiome.org/protocols-and-standards/18s/) and amplified products will be sequenced on the Illumina® MiSeq® FGx platform using a dual-index strategy. Sequence data will then be used to perform taxonomic identification and applied to a statistical model for PMI prediction. It is expected that the changes in eukaryote community structure seen during decomposition on a porcine model may parallel those seen in a human model, given the similarities between the two organisms.

Necrobiome, Postmortem Interval, Next Generation Sequencing

E45 The Taphonomic Effects of Differential Burial Practices and Environment in Recently Discovered World War II Cemeteries

Hillary R. Parsons, PhD, Bozeman, MT; and Heather Backo, PhD, History Flight, Houston, TX 77009*

After attending this presentation, attendees will: (1) gain further knowledge concerning the postmortem taphonomic effects of differential interment practices on human remains recently discovered in a coral atoll burial environment from World War II cemeteries; (2) view and learn the taphonomic effects of field-expedient trench burials and burial box interments on human skeletal remains due to environmental factors, such as ground water fluctuations and bioturbation; and, (3) gain a better understanding of the challenges faced by archaeologists and anthropologists dealing with the two largest independent recoveries to date of missing World War II United States servicemen (*MNI*=59).

This presentation will impact the forensic science community by describing unusual taphonomic effects on human remains in variable environments associated within and between burial interment practices in the historical context of World War II. This presentation will contribute to the overall knowledge of the forensic science community by describing *in situ* field discoveries and laboratory analyses documenting unique effects of taphonomic variables on human remains in a battlefield context.

Description of the site and sample: During the Second World War, the Battle of Tarawa was a costly victory for the United States military. More than 1,100 United States Marines and Navy sailors were killed, while approximately 500 were recorded as missing and their bodies believed "unrecoverable." Due to the speed of military operations at the time, the locations of the hasty post-battle cemeteries were lost or misplaced. Additionally, a number of Army Air Corps servicemen flying missions from Hawkins Field on Betio Island, Tarawa, perished in the months after the initial invasion. These servicemen were buried in individual burial boxes and placed in burial rows at a variety of depths and were subsequently affected by various taphonomic factors. In 2015 and 2017, two of the missing cemeteries containing United States Marines, Navy sailors, and Army Air Corps servicemen were discovered and systematically excavated by History Flight, a Non-Governmental Organization (NGO). As of July 25, 2017, History Flight's efforts have led to the repatriation of more than 59 lost United States servicemen from these cemeteries.

The unique coral atoll environment creates taphonomic factors that cause differential preservation of human remains within and between cemeteries and burial interment practices. Specifically, the types of interment practices, differential burial depths, impact of a constantly fluctuating water table, proximity to military-issued equipment (particularly the rubberized canvas poncho), containment within burial boxes, and tree root disturbance contribute to diverse states of skeletal preservation. Combined with historic and modern post-burial disturbances and an absence of scavenger activity, the burial contexts from these cases demonstrate unprecedented and valuable information for the forensic science community.

Taphonomy, Burial Practices, WWII

E46 Veteran Suicides in Harris County, Texas

Bethany L. Bless, MS, 1861 Old Spanish Trail, Houston, TX 77054*

This goal of this presentation is to examine patterns of veteran suicides in Harris County, TX, and compare those patterns to existing veteran suicide publications.

This presentation will impact the forensic science community by demonstrating that accurate data regarding veteran suicides is critical to the development and improvement of suicide prevention programs.

The Department of Veterans Affairs (VA) has published a series of Suicide Data Reports beginning in 2012. The data presented in these publications is in part intended to inform the development of a suicide prevention program. The VA enlisted assistance from state governments to obtain the data presented in these reports. The 2016 report estimates that, in 2014, 20 veterans died each day by suicide, and that veterans account for 18% of suicide deaths in the United States (8.5% of the population). More than 200,000 veterans live in Harris County, making it one of the largest populations of military service members in the nation. This county averages approximately 450 suicides per year, but there is no current means to readily account for the fraction of those suicides that are committed by veterans, and whether that number aligns with the data presented by the VA.

Historically, the Harris County Institute of Forensic Sciences (HCIFS) did not track the military/veteran status of its suicide (or other) cases; however, in July 2016, the HCIFS began: (1) actively tracking the military/veteran status of all reported fatalities; and; (2) comparing HCIFS suicide data to data maintained by the Department of Defense (DOD) veteran database and the Texas Electronic Death Registry. This presentation will provide descriptive statistics regarding the discord between the various agencies that either generate or maintain veteran suicide statistics and its impact on the comparison of a large urban center (Harris County) with a large veteran population to other locations, and/or national statistics.

A cross-comparison of all HCIFS suicides between 2010 and 2016 to the Texas Electronic Death Registry and the DOD veteran database yielded a total of 497 suicide cases that were identified as veterans in one or both. Of those cases, 332 were identified in both databases, the remaining 165 were listed in one or the other, but not both. Four hundred twenty-six of HCIFS suicides during the same interval were listed as veterans in the DOD veteran database; however, veteran status of 94 of these deaths was not recorded on the death certificate. Similarly, 403 cases were reported as veterans by the Texas Electronic Death Registry, 71 of which were not included in the DOD database. The total number of known veteran suicides in Harris County between 2010 and 2016 (497) represents 15% of all suicides in Harris County during that interval. The number of suicides recorded on death certificates (without comparison to the DOD data) during the same interval who are veterans is 13%. The percentage of Harris County suicides recorded on the death certificate and who are listed as veterans in the DOD database is 10%. Each of these percentages is below the national average reported by the VA. Data from other counties and states would need to be collected and verified using this method in order to generalize the findings to the larger population.

A system for accurately detecting and tracking suicides among all veterans needs to be developed. In order to assess the effectiveness and improve suicide prevention programs for veterans, a more accurate reflection of the number of veteran suicides is imperative in order to assess effectiveness of the prevention programs. This would provide the capability of analyzing more current data as well as other characteristics of veteran deaths. Although much research has been completed on veteran suicides, the statistical data measuring the number of suicides is inadequate.

Veterans, Military, Suicide

E47 A Multidisciplinary Search for Missing People: Psychology, Canine Units, and Forensic Archaeology

Simone Montaldo, Ophir Criminology, via maria Luigia Tancredi 10, Rome 00132, ITALY; Luca Daveri, Nemesi Italia, Podere Forest sn, Castel Franco di Sopra, Arezzo 52100, ITALY; and Matteo Borrini, PhD*, Liverpool John Moores University, School of Natural Science & Psychology, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will understand how the search for missing people is a challenging task that could be solved with a multidisciplinary approach involving the cooperation of different disciplines.

This presentation will impact the forensic science community by presenting a case report that demonstrates the potential of the cooperation between psychology, canine units, and forensic archaeology during different steps of the search for missing persons.

Missing persons cases demonstrate several levels of criticality and the police have limited resources; if the person (or the body) is not recovered in a short period of time, protracted searches are not sustainable. These cases pose complex challenges that need to take into consideration the background of the disappearance, the physical and psychosocial conditions of the missing, and the environment in which the event occurred. Therefore, a multidisciplinary approach is crucial to improve existing methodologies and develop operative protocols to both optimize investigation time and cost and to increase the number of successful recoveries.

This study will present an exemplar case from Sardinia, Italy, that involved a 78-year-old male affected by Alzheimer's disease and diabetes. In May 2015, the individual left home in his car. The vehicle was found abandoned on a mountain road, and this location was designated as the Initial Planning Point (IPP).

The survey was organized by two associations: Ophir Criminology and the National and European Multidisciplinary Equipe for Scientific Investigation (NEMESI). The operative units have been remotely coordinated by a forensic anthropologist from Liverpool John Moores University.

Ophir Criminology is a scientific association devoted to the development of forensic sciences and the dissemination of good practices for investigation. NEMESI is a multidisciplinary team that applies archaeo/anthropological techniques for a comprehensive survey of the area in conjunction with inspection by canine units (man-trailing and cadaver dogs).

The first step of the investigation was data collection from the missing person's family. Testimony psychology was used to evaluate both the reliability of witness statements and the interviews on the period surrounding the disappearance. The collection of the preliminary information is the most critical aspect that can influence the entire investigation. A shallow approach during these early stages of the investigation can jeopardize the search for evidence, losing, in some cases, possible links to major offenses (e.g., kidnapping or murder). The most useful details must be recorded and screened according to the reliability of each witness. The acquired data were, therefore, carefully evaluated to immediately assess the risk level of the case and to plan the field search by selecting the most appropriate tools.

The first set of searches with man-trailing dogs was performed from the IPP immediately after the disappearance. According to international protocols, the possible distance from the IPP was evaluated by considering the environment (farmland vs. urban) rather than the psychological condition of the individual. In addition, the physical condition of the individual, as evaluated through witness statements as opposed to medical records, was taken into account.

According to the data processed, the first search performed with NEMESI's canine units allowed some areas to be excluded, thus narrowing the search areas to be covered by the subsequent walking surveys.

The discovery of some personal belongings allowed the team to pinpoint a large area of interest that was accordingly checked with cadaver dogs. The canine unit ruled out the majority of the area, and only a small number of zones were not processed due to environmental conditions (dense vegetation and impervious surface). In the remaining areas, an extensive grid search was planned and performed with volunteers trained in field walking. The search was successful and the remains of the missing person were discovered, demonstrating the potential of a multidisciplinary and planned search that involved psychology, forensic archaeology, and canine units.

This study proposes an innovative and multidisciplinary approach that utilizes dog/handler units in the search of a missing person in conjunction with archaeological survey and testimony psychology. Therefore, this contribution also stresses the need for training on-foot volunteers in basic field walking techniques and the correct approach to the *scena criminis* (i.e., preserving potential evidence, use of PPE) to prepare operative units supporting the judicial authority in the search for the missing.

Missing People, Man Trailing Dog, Cadaver Dog

E48 The Current State of Illicit Drugs, Counterfeit Pharmaceuticals, and New Psychoactive Substances in West Asia — Particularly Turkey

Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY*

After attending this presentation, attendees will better understand: (1) the influence of developments in the opiate market in Afghanistan on the drug control situation in West Asia, particularly in Turkey; (2) the importance of the Balkan route as one of the main trafficking routes of opiates out of Afghanistan; and, (3) the main issues of concern for the region and for Turkey.

This presentation will impact the forensic science community by providing an update on the current state of illicit drugs, counterfeit pharmaceuticals, and new psychoactive substances in West Asia, particularly Turkey.

Nearly all heroin available on the illicit drug markets in Europe originates in Afghanistan. Despite the diverse trafficking routes, the main one remains the so-called Balkan route, with Turkey serving as a starting point of the main corridor for trafficking bulk quantities of Afghan heroin via the Islamic Republic of Iran to Bulgaria and through countries in the western Balkans to Western and Central Europe, or from Bulgaria through Romania and Hungary to Western and Central Europe.

In 2014, seizures of heroin and morphine along the Balkan route amounted to 48 tons, an increase compared with the quantity seized in previous years. The largest quantities were seized in the Islamic Republic of Iran (24.4 tons) and Turkey (8.3 tons). Recent reports indicate that other routes are gaining in importance. In 2015, Turkey observed the emergence of a second route, encompassing Iraq and the Syrian Arab Republic, in addition to the countries traditionally lying on the Balkan route.

Turkey reported a significant amount of seizures involving MDMA or “ecstasy” -type substances, namely more than five and one-half million tablets in 2015, as well as seizures of LSD.

A substantial challenge with respect to psychotropic substances in the region and Turkey remains the supply of the so-called counterfeit “captagon” tablets that continue to be seized in large quantities, especially in countries in the Gulf and Middle East. “Captagon” was originally the official trade name for a pharmaceutical preparation containing fenethylline, a synthetic stimulant. The substance currently known as “captagon” are tablets similar in appearance containing amphetamine cut with multiple adulterants, such as caffeine and other substances. In 2015, Turkey reported seizures of more than 15 million tablets. There is no other synthetic drug seized as regularly in such quantities. Other countries that reported large so-called “captagon” seizures include Lebanon and Saudi Arabia.

Turkey was also one of the few countries in West Asia reporting large seizures of synthetic cannabinoids often advertised as legal replacements for cannabis (more than 500kg) in 2015.

More than 200,000 persons are estimated to be in need of treatment for drug abuse in Turkey. In 2015, Turkey reported an increase in the residential treatment of methamphetamine addicts, a slight decrease in the overall number of persons injecting drugs (mainly heroin), some increase in the use of amphetamine-type stimulants and tranquillizers, as well as opioid-containing pharmaceuticals. More than half of overdose deaths involved polydrug use, with half associated with opioid and one-third with amphetamine-type stimulants and/or cannabis use.

Illicit Drugs, New Psychoactive Substances, Turkey

E49 Medicolegal Death Investigation in the Changing Face of Drug Overdoses

Erin M. Worrell, BSc, Cuyahoga County Medical Examiner's Office, 11001 Cedar Avenue, Cleveland, OH 44106; and Thomas P. Gilson, MD, Cuyahoga County Medical Examiner's Office, 11001 Cedar Avenue, Cleveland, OH 44106*

After attending this presentation, attendees will have a new understanding of the impact of the current opioid/opiate crisis on Medicolegal Death Investigation (MDI) and evolving investigative paradigms involving scene responses, decedent history evaluation (including internet and social media use), and safety concerns.

This presentation will impact the forensic science community by illustrating the rising number of overdose deaths and that the increasing potency of the drugs involved has caused a paradigm shift in MDI in Cuyahoga County, OH.[1] The basic investigative elements of history collection, scene investigation, and scene safety have all been impacted. The resulting developments have involved both the public safety and public health roles of the office.

Cuyahoga County (metropolitan Cleveland), OH, has a population of approximately 1.3 million people. The Medical Examiner's Office (MEO) investigates all sudden, unexpected, suspicious, and violent deaths, including all deaths by intoxication with drugs. In 2006, there were 250 total Drug-Related Deaths (DRDs), primarily involving cocaine and prescription opioids. Over the following years, heroin played an increasing role in overdose mortality and this trend peaked in 2014 when there were 353 DRDs, with the majority involving heroin. Following this, the drug crisis in Cuyahoga County acutely worsened with the appearance of fentanyl and the fentanyl analogues (e.g., carfentanil). Mortality reached 666 DRDs in 2016 and is currently projected to continue rising in 2017. In the majority of DRDs, the decedent is pronounced dead at the scene and an MEO investigator responds to the scene. All investigators are certified by the American Board of Medicolegal Death Investigators.

The initial telephone report is now approached with a higher index of suspicion for the possibility of a DRD. Scene details, including body position, items presently at scene, and circumstances, determine whether jurisdiction will be accepted and a scene visit is required. Apparent natural deaths require adequate follow-up questions and some jurisdictions have even adopted universal checks of the prescription drug-monitoring program data prior to releasing a case.

Scene visits have evolved in important ways too. Because of the increased prosecution of DRDs, a task force was created to process the overdose death scenes as potential crime scenes. This has required the collaboration of the MEO death investigator, narcotics detectives, and prosecutors. The handling of evidence has also been transformed with increased focus on chain of custody as well as safety concerns. The changes in drug potency have led to mandatory use of personal protective equipment at scenes (minimum of gloves and face mask), as well as investigators carrying naloxone (the opioid antagonist) in the event of an untoward exposure. These safety concerns extend into CCMEO itself when drugs previously undiscovered may place receiving personnel at risk.

History collection at the death scene has expanded. Routine questions regarding types of drugs used and routes of administration have been supplemented by inquiries regarding recent sobriety, incarcerations, or rehabilitation in a treatment facility.

Family are asked about recent purchases and shipments (especially from overseas or from the internet), social media, and cellphone data that may also provide valuable information and must be evaluated.

The role of MDI in opiate/opioid deaths is evolving and expanding. As the drug overdose crisis worsens, medicolegal investigators need to adapt practices to emerging trends and to collaborate with other investigative partners to produce optimal results.

Designer Fentanyl Analogues, Death Investigation, Opioid/Opiate Crisis

E50 Attacking the Epidemic: Methods and Considerations for Detection of Fentanyls and Novel Psychoactive Substances (NPS) by Thermal Desorption Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899*

After attending this presentation, attendees will have a better understanding of the strengths, limitations, and safety concerns of employing ambient ionization MS techniques, such as DART®-MS, to the screening of evidence for fentanyl, fentanyl analogues, and other NPS. Attendees will be presented with typical spectral signatures for these compounds, instrument optimization parameters to consider, methods for identifying the limitations posed by competitive ionization (to minimize missed detections), and considerations for analyst safety.

This presentation will impact the forensic science community by providing necessary information for the implementation, strengths, and weaknesses of ambient ionization MS techniques, such as DART®-MS, for the analyses of hazardous chemicals, such as fentanyl.

The increasing prevalence of fentanyl, fentanyl analogues, and other NPS in the community poses significant challenges to law enforcement, first responders, and forensic practitioners. Because of the significant hazards these compounds present, current methods of presumptive screening may no longer be practical. Methods such as color tests that require visible amounts of material have been deemed too dangerous by some agencies (due to inhalation exposure hazards), leaving a gap in the typical analysis chain.

One technique that may fill this gap is Ambient Ionization-MS (AI-MS). These instruments, namely DART®-MS, are being increasingly employed in forensic casework because of their ease of use, minimal sample preparation, and speed of analysis. While these instruments are not ready for deployment into the back of a police cruiser or crime scene van, they have been critical in providing rapid presumptive analyses in forensic labs.

While DART®-MS and other AI-MS techniques show promise as rapid screening tools, the manner in which sampling is commonly completed poses potential risks to examiners. Inhalation of aerosolized samples and the potential for contamination of the instrument are distinct possibilities with techniques such as DART®-MS. This study will address measures that can be taken to limit exposure of the analyst and minimize contamination of the surfaces, providing a safer means of analysis.

This study focuses on identifying the capabilities of Thermal Desorption (TD) -DART-MS, an ambient ionization MS technique, for the detection of fentanyl, fentanyl analogues, and other NPS. More than 20 fentanyl analogues and 25 additional NPS were studied. Using pure compounds and a design-of-experiments approach, a method was created to evaluate analytical metrics of the technique. As observed with many other narcotics, protonated molecular ions are the predominant ions formed, and limits of detection are commonly in the tens to hundreds of picograms. Additionally, considerations for the detection of realistic samples, which commonly exist as multi-component mixtures, will be discussed. Since real-world samples commonly consist of multiple components (i.e., multiple drugs, analogues, and cutting agents), it is necessary to understand how the presence of these compounds will affect detection of the target compounds, given their small weight percentages. Using a combination of prepared and street samples, the limitations of TD-DART®-MS in detection of these minor components and as potential scenarios when detection may not be possible (false negatives) will be presented. Work toward creating a library of these compounds based on representative spectra will also be discussed.

Fentanyl, DART®-MS, Drug Analysis

E51 Side Effects of Anabolic Androgenic Steroids Abuse: What About Necrotizing Fasciitis?

Giuseppe Bertozzi, MD, Dept of Forensic Pathology, Viale Degli Aviatori, 1, Foggia 71121, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Viale degli Aviatori, 1, Foggia 71121, ITALY; Francesca Maglietta, MD, Viale degli Aviatori, 1, Foggia 71121, ITALY; Giuseppe Davide Albano, Viale degli Aviatori, 1, Foggia 71121, ITALY; Santina Cantatore, Viale degli Aviatori, 1, Foggia 71100, ITALY; Francesco Sessa, MS, Dep. of Forensic Pathology, University of Foggia, Viale Degli Aviatori, 1, Foggia 71100, ITALY; and Monica Salerno, MD, PhD, Department of Forensic Pathology, Osp. Col. D'Avanzo, Viale degli Aviatori, 1, Foggia 71121, ITALY*

The goal of this presentation is to illustrate how widespread Anabolic-Androgenic Steroid (AAS) consumption can lead to the development of a wide spectrum of side effects, including necrotizing fasciitis, even if it is rare. Thus, in suspected cases, an autopsy should be performed with a complete biological sampling because of the substantial role of toxicology to define the cause of death and serve justice.

This presentation will impact the forensic science community by demonstrating the impact of the widespread AAS abuse in the world. This presentation will also stress the importance of developing the knowledge of pathological processes and mechanisms of organ damage related to AAS consumption, which can lead to death. Toxicological investigations can identify AAS use in suspected patients and should be performed routinely. This allows physicians to perform tailored treatments.

Previously used by elite athletes, currently AAS use has developed among the general population. The Centers for Disease Control and Prevention (CDC), in their thirty-third report on the health status of the United States, reported that approximately two million individuals use or have used AASs during their life only in the United States. In Italy, AAS consumption began to affect social sensitivity. Last year in Foggia, the death of a sports figure led police investigations into the requisition of substances in many gyms in town.

This case reports a 31-year-old weightlifter who went to the emergency ward referencing an accidental fall with left thigh trauma. Radiologically, a hematoma was detected at the left thigh level with no fractures. The patient refused further investigation. Two days later, this sports figure went to another emergency ward for lower limb edema and hyperpyrexia (38°C). A new imaging evaluation revealed extended dermal emphysema into the left gluteal. Lab results suggested a diagnosis of Multi-Organ Failure (MOF) and septic shock from traumatic left thigh necrotizing fasciitis. Surgical removal of necrotic tissues and fasciotomy were provided. Although surgery and hyperbaric therapy were performed, the man died.

Before the autopsy was performed, a review of the literature had been conducted: (1) necrotizing fasciitis may develop in the site of skin biopsy, lacerations, insect bites, acupuncture, surgical wounds, skin abscesses, burns, closed bruising trauma, and drug extravasation zones; (2) over the past years, only a few cases of athletes who developed pyomyositis or soft tissue infections were described in association with AAS abuse; (3) during the same period, several studies evidenced a wide range of AAS side effects on organs and systems with supra-physiological doses and immunosuppressive effects; and, (4) in AAS abusers, the use of non-sterile needles or frequent injections has been related to local infections at the injection site.

Thus, the autopsy of the weightlifter was performed with a complete biological sampling for toxicological purposes. Not surprisingly, keratin matrix (hair), approximately 1cm long, showed positivity for propionate testosterone, clembuterol, stanazolol, trembolone, oxandrolone, and tamoxifen, indicative of the intake of the substances detected over a period of 4-5 to 30 days prior to the date of the autopsy. Serum samples, collected during the second hospitalization, detected positivity for stanzolol and tamoxifen; however, the multi-organ dysfunction made it impossible and difficult to quantify the rate of recruitment due to a slowdown in the metabolism of these substances and a reduction in the elimination rate. Police investigation led to the seizure of six propionate testosterone vials at the man's home; subsequent analysis showed it to be the same molecule as the testosterone keratin sample.

This scenario was reconstructed: positivity in the keratin matrix expressed a chronic use of these substances; and chronic use resulted in a state of immunodeficiency, which favored the development of necrotizing fasciitis, from the site of inoculation of the substances, confirmed by histological examination.

This analysis highlights the narrow relationship between AAS abuse and immunodeficiency and is the basis for further studies; however, it should be taken into account that among all dangerous effects produced by AAS use, necrotizing fasciitis is not an unusual consequence.

AASs, Necrotizing Fasciitis, Toxicological Examinations

E52 High Order Trace Transfers: Considerations for the Analysis of Sub-Visible and Nanoparticles

Christopher S. Palenik, PhD, Microtrace, 790 Fletcher Drive, Ste 106, Elgin, IL 60123-4755*

The goal of this presentation is to illustrate both the strengths and considerations that must be taken into account as the size of particles being analyzed decreases to sub-visible and, ultimately, nanoscale evidence.

This presentation will impact the forensic science community by providing a framework upon which increasingly smaller traces can be analyzed and interpreted.

As trace evidence analysts begins to exploit the evidentiary value in finer particles, particularly those that would be considered sub-visible (<1µm-100µm) and nanoparticles (<1µm), the traces become more difficult or impossible to visually monitor. To this end, evidence collection teams, examiners, and evidence custodians must be aware of the potential that collecting, sampling, analyzing, and even packaging may have on the transfer of evidence. In addition, those responsible for the interpretation of such traces must also be aware of the potential for secondary, tertiary, and higher order cross transfers. Maintaining this awareness becomes challenging when the particles are invisible to the unaided eye and even more challenging when the particles cannot be resolved by stereomicroscopy. The use of sample blanks, purpose-built laboratory environments, and more rigorous environmental monitoring represent a few of the factors that must be considered when dealing with smaller particles and finer features. Such considerations are presently less significant when dealing with typical trace evidence samples since current traces can be visually located and tracked throughout an analysis, using either an unaided eye or low-magnification stereomicroscopy.

As a means by which to study the transfer of subvisible particles, a commercially available fluorescent detection spray was examined. This substance is composed of 2µm-5µm particles of zinc sulfide in a light hydrocarbon oil. Zinc sulfide is a fluorescent indicator component that is used as a visual illustration of contact transfers between two objects. Such evidence of contact between objects may be visualized through illumination by long-wave ultraviolet light, which stimulates luminescence in the powder. This research provides a microanalytical characterization of the zinc sulfide particles and offers multiple independent approaches by which this powder (or other fine particles) may be detected and specifically identified in quantities from major to trace.

This definitive identification provides a means by which a field test that presently provides a presumptive result (one that is largely limited to investigative work and is based on a relatively crude visualization scheme) can be converted into a court-acceptable result by providing a specific identification. This identification process can be adapted to the detection of microscopic particles of zinc sulfide, thus increasing not only the specificity of the identification but also the sensitivity of the method. Using an adapted Gunshot Residue (GSR) sampling method and automated Scanning Electron Microscopy (SEM) analysis routine, individual particles of the fluorescent detection spray are readily detected.

While such approaches can increase the sensitivity of a test by three orders of magnitude, they also raise significant questions about cross contamination and higher order transfers (e.g., tertiary and quaternary transfers). This research will provide a demonstration of a tenth-order trace transfer using this detection powder. The potential for such transfers raises significant considerations that become particularly relevant to the analysis of increasingly smaller particles as well as the trace evidence of the type and size presently analyzed in a typical crime laboratory.

Nanoparticle, Clue Spray, High-Order Transfer

E53 Teaching Forensic Image Processing

Marcus Borengasser, PhD, Department of Defense, 3205 Lago Vista Drive, Melbourne, FL 32940*

After attending this presentation, attendees will understand the benefits of designing an online program for training in forensic image processing.

This presentation will impact the forensic science community by illustrating how surveillance video is nearly ubiquitous, but many analysts are not adequately trained for forensic image processing.

Video surveillance is widely used and it is expected to increase in the coming years. Not too long ago, only banks had video surveillance and the video was typically acquired with low-quality cameras, recorders, and media. Presently, surveillance video is widely used by many businesses and institutions, in addition to video from law enforcement body cams, Unmanned Aerial Vehicle (UAV) systems, cell phones, and more. Forensic image processing is rapidly becoming a critical skill for the criminologist.

Education in forensic image processing has not nearly kept pace with the ubiquitous video systems. Unfortunately, many criminalists and crime scene analysts have only basic skills in forensic image processing. A challenging situation is often compounded by a lack of proper software, and criminalists find themselves at a technological disadvantage.

Either online or in a traditional classroom setting, forensic image processing can be offered as a suite of specialized courses within an AA or BS program or as a certificate program. Open source software is available that is suitable for forensic image processing, relieving the educational institution of a software acquisition expense plus a wide range of logistical challenges.

As with any specialized curriculum, courses in forensic image processing would have prerequisites. The most important prerequisite is linear algebra, and courses such as undergraduate physics and computer science would be needed. With the extensive course offerings from Massive Online Open Courses (MOOCs), a student can easily satisfy prerequisites.

Like many other forensic sciences, forensic image processing is procedural and can be dissembled into a series of operations. This process can be presented in a data flow context and courses in the curriculum can be designed and offered to reflect this data flow perspective. This data flow would be based on the operations needed to correct or suppress the typical video image flaws. These flaws result from internal and/or external noise that is superimposed on a video image, improper lighting that causes saturated or dark images, and improper camera calibration and/or emplacement.

Noise suppression or removal can be accomplished with digital filtering. An understanding of this important technique is critical for a video image analyst. An entire course could be dedicated to this topic and include both theory and practice.

One of the methods for minimizing the effect of improper lighting is modifying the pixel brightness histogram. This topic, which would include a variety of techniques, is as important as digital filtering and, similarly, an entire course would be needed to ensure analyst competency.

The other major topic, suppressing or removing the effects of improper camera calibration and/or emplacement, can partially be addressed with digital filtering and histogram modification; however, a third course could be designed for specialty topics, such as feature identification, classification, sensor and data fusion, and more.

Education, Video Surveillance, Image Processing

E54 The Opportunity of a Lifetime: The Educational Outreach Program at the Defense Forensic Science Center (DFSC)

Rachel Creager, 4930 N 31st Street, Bldg 925, Forest Park, GA; and Henry P. Maynard III, MSFS, 277 Edison Drive, Stockbridge, GA 30281*

After attending this presentation, attendees will learn about the DFSC's Educational Outreach Program. This presentation will inform students of the opportunities to participate in cutting-edge research at the DFSC.

This presentation will impact the forensic science community by informing future forensic scientists about options to advance their careers while furthering forensic science capabilities at the DFSC.

The Educational Outreach Program is an integral part of enhancing current and developing future forensic science capabilities at the DFSC. The Educational Outreach Program allows students to participate in meaningful research and highlights careers in the military, while building partnerships between DFSC and academia. Students receive a wealth of experience in experimental design, test and evaluation efforts, validations, and analysis of complex data. The Office of the Chief Scientist participates in various programs that allow students to work at DFSC; including the Department of Defense Science, Mathematics, and Research for Transformation (SMART) program and the Research Associate program. This presentation will benefit prospective students as it will highlight these career-developing opportunities (a brief summary of each is provided below).

The Office of the Chief Scientist coordinates the Department of Defense-funded SMART program. The goal of the SMART program is to increase the number of civilian scientists and engineers who are employed by Department of Defense laboratories. To accomplish this, students at any level within their academic career (Bachelor's, Master's, or PhD) can apply to the SMART program to receive a full academic scholarship and employment at a Department of Defense laboratory upon degree completion.

Through the Research Associate program, undergraduate students can come to DFSC to work on research projects for a summer, a semester, or a year. The paid Research Associate program differs from traditional internship programs in that the Office of the Chief Scientist has the students participate directly on a research project under the guidance of a DFSC scientist. The Research Associate program allows students to gain valuable knowledge, skills, and abilities in experimental design, testing, and analysis from dedicated forensic mentors.

Since 2011, 101 Research Associates have worked more than 51,000 hours on 85 DFSC-led research projects and 15 SMART scholars have contributed more than 3,800 hours to 15 research projects. The Educational Outreach Program at DFSC has been growing annually and these numbers will continue to rise. Come learn more about the opportunities at DFSC and join the research team!

Education, Outreach, Intern

E55 Fingerprint Analysis: Determination of Biological Sex Via Enzymatic Assay

Crystal Huynh, BS, University at Albany, State University of New York, 1400 Washington Aveune, CHEM 329, Albany, NY 12222; Erica K. Brunelle, BSc*, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Mindy Hair*, 81 Ten Broeck Street, Albany, NY 12210; Lenka Halamkova, PhD, *, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222; and Jan Halámek, PhD*, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will understand a new bioaffinity-based method for fingerprint analysis and that fingerprint samples can be used for more than pictorial comparison. These cascade-based assays can be applied in multiple areas so other researchers could apply this methodology to their own research.

This presentation will impact the forensic science community by establishing that fingerprints can be used as a biological sample like blood and sweat. It will also introduce a more rapid method of fingerprint analysis that can one day be applicable for on-site usage. The new method presented here will also spur other researchers to place more efforts on creating techniques usable by personnel without scientific training.

Fingerprint analysis traditionally refers to the process of comparing fingerprint patterns by an expert and/or an automated fingerprint identification system. Currently, the analysis ends with this matching methodology, causing the field to be dependent on the presence of a stored matching print or a matching print from an individual that is physically present. Due to this limitation, a latent fingerprint may be judged to be too smudged or smeared to be of use. What is often overlooked is that those latent prints are created by sweat and sebum emulsions excreted by the fingertips. Those emulsions have their own unique chemical compositions for each individual, making them possible biological samples for analysis. The University at Albany's lab has developed a bioaffinity-based cascade for the determination of biological sexes from the chemical composition of the sweat/sebum left as the latent prints.

The research presented here addresses the current limitations in fingerprint analysis using a bioassay system that focuses on the components of fingerprints. Bioaffinity-based assays have been developed for the determination of biological sexes from those components. In one assay, L-amino acid oxidase was used to target the amino acids present in the sebum and sweat left on latent fingerprints. Further research has led to the testing of authentic fingerprint samples collected from various surfaces as well as the development of other bioaffinity-based assays capable of differentiating between biological sexes via less complex systems. Other bioaffinity-based assays will also be developed in the future for the determination of other physical attributes, such as age group and ethnicity.

While these assays will not be able to clearly identify a person of interest, they will be extremely useful for quickly narrowing suspect pools when identification is not possible. The assays will also be useful in cases in which there is not enough time for the process of identification (possibly via DNA) to be completed. The assays that have been developed and are currently in development have the potential to become a portable method that can be used for on-site analysis. Also, due to the ease with which the assay can be performed and interpreted, specialized training for the execution of the analysis is unnecessary, unlike most currently available techniques. These assays could become a very powerful tool for forensics.

Fingerprint Analysis, Enzymes, Bioaffinity

E56 Data-Driven Decisions in Latent Print Examination to Improve Quality

Anthony Koertner, MS, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will be familiar with some of the limitations of the subjective methodologies traditionally applied to latent print examinations and with a path forward to a more objective data-driven approach.

This presentation will impact the forensic science community by discussing the steps taken by the United States Army Criminal Investigation Laboratory (USACIL) to move its latent print branch from a primarily subjective-based approach to a more defensible, data-driven process using more objective methods and pre-defined criteria at many stages of the latent print examination process.

This demonstrative presentation is designed so forensic science practitioners and technical leaders can better visualize and therefore understand these practices in the flow of typical latent print casework. Attendees will be provided with the resources to utilize these tools better and more objectively inform decisions in their latent print examinations.

Latent print examination has been subject to much criticism regarding its scientific standards and validity, specifically due to the lack of objective data utilized in decision making to arrive at conclusions. Many highly publicized reports, such as the *Report to the President. Forensic Science in the Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods* by the President's Council of Advisors on Science and Technology (PCAST), continue to critique the field's shortcomings in an attempt to elicit change by moving latent print examination to a place where all decisions and conclusions are fully supported by empirical, robust, and reproducible data.[1] From reporting latent print findings without the term "identification" to a statistical model that represents the strength of an association, this presentation will introduce some of the data-driven practices utilized by latent print examiners at the USACIL to inform their decisions during casework examinations. These practices not only attempt to satisfy the criticisms set forth by these various reports, but more importantly function as additional quality control measures applied to casework. Specifically, this presentation will describe how "suitability for comparison" claims are supported utilizing empirical measurements from software designed to estimate the quality/clarity of a friction ridge impression area and other software to quantify the similarity between two fingerprints and provide a statistical estimate of the likelihood they were made by the same source rather than by different sources. Together, these methods provide a means of moving away from the previous methodology's reliance on the examiner's subjective opinion for determining the significance of latent print evidence.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Data, Subjective, Latent Print

E57 3D Imaging Technology to Uncover Changes in Latent Fingerprint Topography in Four Dimensions

Josep De Alcaraz-Fossoul, PhD, Arizona State University, West Campus, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; Michelle Mancenido Mancenido, PhD, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; Jennifer Broatch, PhD, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; Emmanuel Soignard, PhD, Arizona State University, LeRoy Eyring Center for Solid State Science, PO Box 871704, Tempe, AZ 85287; Lindsey J. Porter, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; Brandon Shelton, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; Nathaniel Silverman, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908; and Sara R. Anderson*, Arizona State University, School of Mathematical and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306-4908*

After attending this presentation, attendees will be familiar with latent fingerprint degradation patterns and ridge topography changes in 3D, including a phenomenon known as ridge drift. Additionally, attendees will be introduced to the statistical methods used in the analysis of fingerprint aging under different environmental conditions.

This presentation will impact the forensic science community by demonstrating statistical evidence of fingerprint degradation patterns without sample manipulation.

Fingerprints have been used for identifying suspects and victims at crime scenes; however, the issue of "when" a latent fingerprint was deposited is a recurring concern in courts of law. Currently, there is no accepted methodology for estimating the time of deposition of a latent fingerprint. No method has yielded yet reliable results, neither has it been fully approved by the scientific community to be used in a court of law. To address this gap in forensic science knowledge, researchers have been studying visual methods to determine fingerprint age or to model fingerprint degradation patterns.[1] Estimation of the age of fingerprints could prove useful to crime scene investigations by excluding potential suspects if the estimated time of deposition is inconsistent with the time of the crime.

Previous studies have observed topographical changes and individual ridge movements as fingerprints aged, such as the discovery of ridge drift.[2] Other researchers, including Popov et al., have detected a "horizontal migration of components" of fingerprint ridges.[3] Dorakumbura et al. reported that individual fingerprint "droplets" vary in their adhesion to certain surfaces.[4] Merkel et al. demonstrated that 3D optical capturing devices could potentially solve the problem of determining fingerprint age.[5] In accordance with these and other previous research findings, this project investigates the causes of ridge drift that cannot be explained in 2D rendering of a fingerprint.

In 2D rendering, only the length and width of fingerprint ridges can be observed. In traditional analytical methods, fingerprints are usually manipulated using destructive or invasive procedures, such as powdering, exposure to reactive chemicals/metals, or swabbing. In this study, non-destructive 3D optical profilometry is used to examine the aging of a latent fingerprint without manipulating it. This imaging technology provides reliable information on the x, y, and z axes of fingerprint ridges. The ridge heights, widths, and lengths across a fingerprint are measured and analyzed over time using established statistical methods.

The experiment involved aging sebaceous-rich latent fingerprints from six donors (three males and three females) in various environmental conditions: "exposure to natural light" (direct sunlight and darkness); "substrate type" (glass and plastic); and "finger" (index and middle fingers). These were stored indoors and allowed to age. Exposure to light, temperature, and relative humidity were not controlled but monitored to closely mimic field conditions. Samples were randomly drawn over a period of three months and directly observed and captured using 3D imaging without any pre-treatment. The equipment used was a ZeScope™ Optical Profilometer from Zygo® Corp, which provided high-quality images and mathematical data in 3D space and time.

Over the course of the study, 1,296 fingerprint images and statistical data were collected for analysis. Each 3D fingerprint image was measured to acquire two metrics: *Sa* (average surface roughness) and *Sq* (standard deviation of the surface roughness). These values were aggregated to create a statistical model to explain the change in a fingerprint's *Sa* and *Sq* over time. Preliminary data demonstrated that both *Sa* and *Sq* measurements decreased over time, strongly suggesting that fingerprint ridges were also degrading in height.

This study proposes a methodology to track the physical changes in a latent fingerprint's ridge length, width, and height over time. This study provides evidence that degradation can be monitored and measured. Lastly, this study contributes to the ongoing research of determining the age of a fingerprint and provides a basis for future research.

3D Imaging, Latent Fingeprint, Aging

E58 Score-Based Likelihood Ratio

Elham Tabassi, MS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; and Larry Tang, PhD, NIST, 100 Bureau Drive, MS 8940, Gaithersburg, MD 20899*

After attending this presentation, attendees will better understand score-based likelihood ratio, what it is, how to compute it, factors affecting its computation, and when and how it may be used.

This presentation will impact the forensic science community by advancing quantitative methods for assessing the weight of fingermark evidence. This presentation discusses important details that shall be considered when computing score-based likelihood ratios and provides empirical data on repeatability and reproducibly of different methods for computation of score-based likelihood ratios.

Friction ridge patterns of fingerprints exhibit vast information and are the most widely used forensic evidence for solving crimes. During the analysis, fingerprint examiners visually compare the latent marks from a crime scene with one of the retrieved candidate fingerprints from a database, or compare the latent marks with the prints from a known source. Methods to quantify the weight of evidence are useful in assisting fingerprint examiners with reaching correct conclusions with a higher confidence.

Likelihood Ratio (LR) provides one the of commonly used quantitative approaches to weigh the evidence, which, combined with prior belief, provides the posterior odds of determining the same source versus different sources. Two of the most commonly used LRs are feature-based LR and score-based LR. Whether and how to use these LRs has generated great interest in the forensic community. Feature-based LR relies on large dimensional fingerprint features and has been studied more widely than the score-based LR. The methods for computing feature-based LR are complex, difficult to interpret, and are not readily interoperable because of its dependence on accurate extraction of features and types of features. Score-based LR relies on estimating the distribution of comparison scores from fingerprint comparison algorithms and has recently brought attention to forensic scientists. Score-based LR is considerably simpler to compute because the comparison scores are one-dimensional. Moreover, it borrows strength from repeatability and reproducibility of comparison algorithms which are becoming more accurate. Computing score-based LR values require estimation of the comparison score distribution functions for mated and non-mated groups from a well-established database using an accurate fingerprint recognition algorithm.

This presentation first briefly explores the difference between feature-based and score-based LRs, explains both LRs mathematically and visually, and explains how the LRs are related to the population parameters, such as the population mean and population variabilities. This is followed by a detailed discussion on the calculation of score-based LR using parametric methods and non-parametric methods, namely kernel density estimation and logistic regression estimation. This presentation then discusses their performance as well as their repeatability and reproducibility by comparing score-based LR values generated by those methods using various sample size ratios, various total sample sizes, and various probability distributions.

This study reveals that values of score-based LR depend on sample size and the ratio of mated to non-mated groups. Furthermore, it highlights the importance of careful consideration on selecting an appropriate dataset both in terms of size and representativeness of the background information of the particular forensic case.

This study was performed using operational and laboratory-collected fingerprints and fingermarks. Mated and non-mated comparison scores were generated using automated recognition algorithms. Results are reported separately for each dataset and recognition algorithm.

Score-Based Likelihood Ratio, Repeatability, Reproducibility

E59 The Impact of DNA Swabbing Collection Methods on Latent Print Evidence

Monica J. Kupsco, MS, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297*

The goal of this presentation is to highlight a processing sequence that will optimize latent print and DNA yield on paper items of evidence. Attendees will have a greater understanding of how DNA collection methods and latent print processes on porous substrates impact one another and how these data may provide a foundation for improving laboratory policy and procedures.

This presentation will impact the forensic science community by discussing: (1) the impact of DNA collection methods (wet and dry swabbing) on subsequent latent print processing of paper items; and, (2) the impact of porous latent print processing on subsequent DNA analysis.

Currently, unless a fold or some type of creased area exists on a paper item where targeted DNA swabbing can be performed, investigators have been encouraged to choose between latent print testing and DNA testing, rather than attempting both. This decision is largely anecdotal with little data available demonstrating the impacts and significance to one another. In an effort to gain more empirical insights into this issue, preliminary research was performed using six different types of paper: manila envelope, manila folder, plain white envelope, index card, lined notebook paper, and plain white paper. Two prints were deposited on each sample and were processed in one of the following ways: latent print processing followed by either dry swabbing or wet swabbing, wet or dry swabbing followed by latent print processing, or latent print processing followed by direct DNA analysis.

The data collected indicates insignificant differences in the DNA yield or number of suitable latent prints developed between wet and dry swabbing either before or after latent print processing; however, direct DNA analysis of the impression resulted in the highest DNA yield and most success in obtaining a full profile. Wet swabbing prior to latent print development will obscure parts of the print, but oftentimes clear areas can still be used to support the latent print examination.

This study provides preliminary data related to the impact of DNA collection methods and latent print examinations. Although further research is advised using different latent print processing techniques, this data suggests that laboratories may not need to require investigators to choose one method over another.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Latent Prints, DNA, Documents

E60 Size Variations Associated With the Different Methods of Recording Outsole Impressions of Reference Footwear for Comparisons

Anthony Koertner, MS, 4930 N 31st Street, Forest Park, GA 30297; and Jeremy J. John, MS, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have a better understanding of the amount of size variation tolerances that should be given for test impressions when performing footwear comparison examinations.

This presentation will impact the forensic science community by describing and quantifying the potential size variations observed in the creation of test impressions of known shoes.

Size determinations of footwear impressions are an important aspect of the general footwear examination scheme, as significant differences in size can instantly exclude a shoe as having been the donor of a particular footwear impression. There are several common methods and procedures for recording test impressions to permit a thorough comparison of the questioned impression with a known shoe.

Across agencies, policies and procedures regarding the creation of test impressions for known shoes may not be available and/or are not very prescriptive, thus allowing the footwear examiner to resort to personal preference in how these impressions are created. Test impressions are generally created on various types of surfaces with some degree of force applied to ensure a thorough recording of the outsole characteristics. The examiner will typically create a shoe's test impressions by wearing the known shoe and walking over a substrate, which creates a known reproduction of the shoe's outsole using a transfer medium such as ink, powders, inkless chemical treatments, and oil-based mediums. Variables such as substrate composition, method of generating the test impression (e.g., walking, jumping, stomping), weight of individual, size of the foot in relation to the shoe, material composition of outsole, etc., may cause variations in the overall appearance and perceived size of the impression. These size variations may be more or less prevalent in different portions of the outsole (e.g., heel, outsole, and ball).

Although such variations are understood by the practitioner community, significant effort has not yet been directed toward quantifying the extent by which footwear impressions may vary. Thirteen new pairs of shoes that were representative of outsoles commonly observed in footwear examination casework were obtained for purposes of testing these variables. This presentation will discuss the variations observed and lay a foundation for further research regarding the significance of these findings and how they may impact footwear examination conclusions.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Footwear, Test Impressions, Size Variation

E61 Bradford Reagent and Ninhydrin: Chemical Approaches for Biological Sex Identification From Fingerprints

Erica K. Brunelle, BSc, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Anh M. Le, BSc, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Crystal Huynh, BS*, University at Albany, State University of New York, 1400 Washington Aveune, CHEM 329, Albany, NY 12222; Kelly Wingfield, University at Albany, State University of New York, 1400 Washington Avenue, CHEM 329, Albany, NY 12222; Lenka Halamkova, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Mindy Hair*, 103 Guilder Lane, Apt 10, Guilderland, NY 12084; and Jan Halámek, PhD*, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will understand that fingerprints can be used as more than just a picture for comparison and can be used for identifying certain attributes of the fingerprint originator based solely on the composition of the fingerprint content. Attendees will also learn that this concept is possible even when the target analyte population is narrowed from 23 amino acids to 6.

This presentation will impact the forensic science community by providing new methods for the analysis of fingerprints in order to generate essential information about suspected individuals directly at a crime scene. This concept will provide a simple YES/NO response within minutes to confirm originator attributes. In addition, these systems can potentially be incorporated into field-deployable devices (similar to glucometers) or connected to hand-held Smart Devices, which will allow for rapid analyses that can be used and interpreted by operators -— in a manner similar to water test kits and the VOCkit system, which is a small strip that has a grid of several dozen indicator chemicals imprinted on it that is used by the Army for the detection of threat agents such as anthrax, sarin, and mustard gas -— with minimal scientific training.

It has been established that the contents of fingerprints are produced by multiple hormone-based control mechanisms and are, thus, a function of physical properties such as age, ethnicity, or biological sex. It has been demonstrated that fingerprints have the potential to generate much more information because they are samples of biological origin analogous to other body fluids. One of the greatest setbacks in fingerprint analysis is that if a matching fingerprint is not saved in a database or if the person of interest is not physically present for comparison, the print is reduced to merely exclusionary evidence, despite being stored in a separate database for future use with newly obtained fingerprints. The same can be said about DNA. Even though DNA can provide the most significant information about the fingerprint originator, DNA analysis can take weeks or months, not to mention that only a few nanograms of DNA at most can be recovered from a fingerprint as the majority is lost during collection and extraction. Ultimately, even if DNA was collected, it is possible that a matching profile may not exist. The research displayed here investigates the use of fairly well-known chemical assays for the purpose of identifying the biological sex of the fingerprint originator.

The ninhydrin method is the most well-known and widely used. Federal, state, and city crime laboratories have been implementing this technique for nearly 50 years. This method has proven to be durable and reliable because of the stability of amino acids — ninhydrin has been used to detect and develop fingerprints that are more than 30 years old. Ninhydrin is a chemical that reacts with amino acids in the fingerprint content to produce the blue-purple color known as Ruhemann's purple. Here, a modified approach to the traditional ninhydrin method for fingerprint development is combined with an optimized extraction protocol and the concept of determining biological sex from fingerprints.

Despite the success of the ninhydrin method, this group's intentions are to establish a method in which only one metabolite corresponds to one originator attribute. Multianalyte assays that target a larger number of amino acids are not completely reliable because more than one attribute can ultimately affect the output of the assay. This convolutes the intentions of the assay altogether since it would be difficult to identify which attribute is ultimately responsible for causing the difference in the assay's response. For example, if attribute A causes amino acid 1 to increase, but attribute B causes the same amino acid to decrease, the change is negated and neither attribute can be identified. To eliminate this possibility, it is important for systems to be restricted to one analyte (amino acid) or a specific combination of analytes that are correlated to the desired originator characteristics. To do so, a chemical assay involving the Bradford Reagent (traditionally used for protein quantification) used to target a small group of amino acids was developed to begin the transition toward focusing on a single amino acid.

Fingerprints, Chemical, Identification

E62 The "CSI Effect": Is It Relevant to You?

Brittany Borzych, 836 Elk Lane, Westville, IN 46391*

The goal of this presentation is to inform attendees of the controversial issue of the "CSI Effect" and the different ways it can affect each person.

This presentation will impact the forensic science community by informing attendees of how they are affected by the "CSI Effect" and what they can do to adapt to it.

The "CSI Effect" is a controversial issue in the fields of forensic science and criminal justice. It is commonly called the "CSI Syndrome." The "CSI Effect" can be defined as "the influence of media, mainly television shows, on the people in juries, studies, and the general idea about how the field operates and its environment."[1] The theory is said to affect everyone, even when they don't know it. It is closely related to two possible theories. The first is the cultivation theory. This is defined as "the theory that the more television you watch, the more likely you are to believe that the world is exactly like it is in the media."[2] The second is the "Perry Mason Syndrome." This is based on the crime show *Perry Mason* and is said to be the first show that could have sparked the idea of altering perceptions of the United States legal system among defendants and jurors.[3] These are also controversial issues and there is research that supports and contradicts the existence. This will open the eyes of many people to the obstacles they may face in the field and will give them the knowledge they need to overcome it.

The effect has become a major issue in the field and has been brought to attention due to the juries' new knowledge in courtrooms. The research presented will be of a survey conducted to a handful of citizens who are jury eligible. The results are currently inconclusive, with more research to be conducted over the next few months. After extensive research, the "CSI Effect" may exist based on opinion but most researchers agree that the "Tech Effect" has more influence on th people and may be the primary cause of the theory due to the rapidly changing technology that we experience every day. The "CSI Effect" may exist with both positives and negatives coming from the theory. In the opinion that it does exist, the benefits outweigh the negatives.[4] It becomes more beneficial to acknowledge the possibility of its existence and learn how to work with it. This presentation seeks to acknowledge the possibility of the "CSI Effect" and to help people of all interests learn and understand the ways it can affect them.

E63 Comparing the Degree of Force in Infants With Suspected Abusive Head Trauma to Traffic Accidents or High-Altitude Falls Is Not Viable

Jacob Johannes Andersson, MS, Uppsala University, PO Box 1024, Uppsala, Uppland 75140, SWEDEN; and Ingemar Thiblin, PhD, Uppsala University, Box 1024, Uppsala 75140, SWEDEN*

After attending this presentation, attendees will have learned to be cautious when comparing injury mechanisms in suspected abusive head trauma with little external damage to traffic accidents or high-altitude falls when testifying in court.

This presentation will impact the forensic science community by informing attendees of the few similarities between infants with suspected abusive head trauma with little external injuries and infants involved in traffic accidents or high-altitude falls. This presentation will demonstrate that when rib fractures occur, they have extensive concomitant injuries to the organs of the trunk.

In the Swedish national guidelines on infant abuse and in prolific international infant abuse literature, there are statements that have influenced professionals testifying in suspected abusive head trauma cases that the forces applied during shaking are equivalent to an unrestrained traffic accident or a high-altitude fall. In certain studies, rib fractures have been considered to be specific for abusive head trauma due to compression of the rib cage; however, the occurrence of concomitant injuries to internal organs are rare.

Infants deceased from traffic accidents or high-altitude falls have few injury characteristics in common with children with suspected abusive head trauma. When rib fractures occur in traffic accidents or high-altitude falls, there are always concomitant injuries of the internal organs of the trunk.

Infants deceased after traffic accident or high-altitude falls (3 m) between 1994 and 2016 were identified in the computer registry of the Swedish National Board of Forensic Medicine. Cases identified were scrutinized regarding mechanism of injury, external signs of injury, and internal injuries.

Twelve cases were identified in which access to autopsy protocols were possible in ten. Eight cases were involved in traffic accidents, of which three were hit by cars while in strollers, and two were involved in high-altitude falls. All ten cases had extensive skull and/or scull base fractures, sometimes with open wounds and fractures of the orbita or spine. All six infants suffering thorax/abdominal trauma had injuries of the organs of the trunk. Only two infants had rib fractures and both had extensive injuries to the organs of the trunk. One case lacked a proper description of external signs of injuries. All nine cases with information had external injuries to the head and five cases had bruising or injuries to the trunk or extremities.

Professionals should avoid comparing abusive head trauma without massive external and internal injuries to traffic accidents or high-altitude falls when testifying in court. Rib fractures are rare in infants deceased after traffic accidents and when they occur, there is damage to the internal organs of the trunk. Infants with trauma to the trunk can suffer extensive internal injuries to the organs of the trunk without contracting concomitant rib fractures.

Abusive Head Trauma, Traffic Accident, Infant

E64 Expert Decision Making and Visual Analysis: An Empirical Approach to Understand and Advance Examination in the Human Identification Sciences

Sherry Nakhaeizadeh, University College London, 35 Tavistock Square, London WC1H 9EZ, UNITED KINGDOM; Nadine Smit*, University College London, 35 Tavistock Square, London WC1H 9EZ, UNITED KINGDOM; Helen Earwaker, PhD, University of Portsmouth, Institute of Criminal Justice Studies, Ravelin House, Portsmouth, Hampshire PO1 2QQ, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, Centre for the Forensic Sciences, 35 Tavistock Square, London WC1H 9EZ, UNITED KINGDOM; and Tim Thompson, PhD, Teesside University, School of Science & Engineering, Borough Road, Middlesbrough, Cleveland TS1 3BA, UNITED KINGDOM*

After attending this presentation, attendees will better understand how experts approach forensic tasks and analyze evidence within the laboratory, and how this can be conceptualized and translated into decision-making maps. These findings draw important parallel processes between domains previously considered to be unconnected, with implications across the forensic domain.

This presentation will impact the forensic science community by illustrating that there are gaps in the understanding of the decision-making tasks required when drawing inferences, making it challenging to fully assess expert performance.

The goal of this presentation is to demonstrate to attendees the judgments, decisions, and visual processes within two key domains of the forensic identification sciences, and how procedural similarities between these can be exploited to drive empirical research, which seeks to improve these judgements and decisions through the use of state-of-the-art technology. In order to do so, this presentation presents the decision maps of experts undertaking analysis processes within the fields of forensic anthropology and fingerprint analysis. These maps have been developed by combining independent information concerning visual comparison tasks present in both fields and the potential for exchanging knowledge on decision strategies and challenges involved.

Human decision making is a key component of the forensic science process (e.g., the recognition, collection, analysis, and interpretation of evidence) and it has been shown that factors can influence those decisions, affecting the investigative process and subsequent legal outcomes, with the potential for significant societal impact at a global scale.[1,2] It is clear that the concerns raised over expert decision making, including the vulnerabilities of cognitive processes and inappropriate weight assigned to evidence, have not only been highlighted in recent key governmental reports, but created debate and heated controversy.[3,4] Specific criticism has been directed at comparison and human identification processes, as many of the forensic methods used within the identification fields (e.g., fingermark comparison, bitemark comparison, morphological hair analysis, and forensic anthropology) are based on visual comparison tasks. Within the human identification field, the challenge of combining and interpreting analyses of different characteristics of evidence, and achieving transparency in decision-making and evidence-based conclusions, needs to be tackled. This includes a better fundamental understanding of the decisions being made and the visual processes being undertaken within the forensic identification sciences. Therefore, this study takes an empirical approach to provide a comprehensive understanding of the decisions made by expert decision makers in the laboratory, allowing for further targeted empirical studies investigating visual attention within these key decision processes common to both forensic identification fields.

Two experimental studies were designed whereby experts within the fields of fingerprint analysis and forensic anthropology were observed during casework analysis in the laboratory. Forensic anthropologists were asked to assess skeletal remains and develop biological profiles, documenting their decisions throughout this process. Similarly, fingerprint experts were asked to conduct the analysis process of Analysis, Comparison, Evaluation-Verification (ACE-V) on fingermarks recovered from crime scenes. A hierarchical task analysis approach was utilized to collect and analyze data, and decision trees were produced for each process observed. The resulting decision trees from both experimental studies were then compared and contrasted at a process and decision level.

These results will be used to discuss how the method can be applied to other forensic identification sciences, and the importance and possibility of taking both a holistic and detailed approach to understanding the judgments and decisions made during the forensic identification processes, in order to address and overcome the criticisms facing forensic visual analysis and comparison tasks.

Decision Making, Identification, Visual Analysis

E65 Testing Unsubmitted Sexual Assault Kits: The National Institute of Justice-Federal Bureau of Investigation (NIJ-FBI) Sexual Assault Kit Partnership Successes and Lessons Learned

Heather E. Waltke, MS, 810 7th Street, NW, Washington, DC 20531; and Heather LaSalle, MS*, FBI Laboratory, DNA Casework Unit, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand how federal support through the NIJ-FBI Sexual Assault Kit Partnership has assisted in investigations and helped reduce the number of Sexual Assault Kits (SAKs) awaiting testing in the nation's law enforcement agencies.

This presentation will impact the forensic science community by conveying information the Partnership has garnered with regard to the collection, processing, and testing of SAK evidence from law enforcement agencies across the country.

NIJ, the research, development, and evaluation agency of the United States Department of Justice, leads the nation in supporting the forensic sciences through research and by providing state and local crime labs with funding to help process and test evidence more efficiently. This presentation will provide information on the NIJ-FBI Sexual Assault Kit Partnership initiative designed to help inform evidence collection, processing practices, and testing protocols for SAKs. This Partnership begun accepting SAKs from law enforcement agencies in September 2015 and has been helping to address a major need in the nation's forensic science and criminal justice communities: to support state and local law enforcement agencies in their efforts to reduce the number of unsubmitted SAKs. The effort has yielded valuable knowledge related to the processes associated with the intake of sexual assault evidence into the lab, as well as screening, testing, and analysis specific to the processing of large quantities of unsubmitted SAKs. For instance, knowledge gained from this initiative has contributed to the *National Best Practices for Sexual Assault Kits: A Multidisciplinary Approach* report developed in response to the Sexual Assault Forensic Evidence Reporting (SAFER) Act of 2013, which focuses on the accurate, timely, and effective collection and processing of DNA evidence in sexual assault investigations.[1] This initiative has supported the goal of carrying out analyses of samples from untested unsubmitted SAKs so DNA profiles can be developed and placed in the National DNA Index System (NDIS), considered one part of the Combined DNA Index System (CODIS), the FBI's program of support for criminal justice DNA databases and the software used to run these databases. The Partnership has generated hundreds of CODIS hits throughout the nation, and the upload of hundreds of eligible profiles generated from DNA analysis as a result of this research has provided direct aid in the investigation and apprehension of sexual assault perpetrators.

Sexual Assault, Sexual Assault Kit, Unsubmitted Sexual Assault Kit

E66 A Case Study: From Maternal Instinct to Staged Domestic Homicide

Eric R. Ruiz Hernandez, MD, Calle 23D 86 28, Torre 6 Apto 303, Bogota, Cundinamarca 110911, COLOMBIA*

After attending this presentation, attendees will understand, through a process of comprehensive analysis of a crime scene, the criminal behavior and the driving motivation of a murder of two children perpetrated by their own mother.

This presentation will impact the forensic science community by illustrating how the criminal conduct of staged domestic homicide has some repetitive patterns or common characteristics in terms of planning and execution, regardless of location, without being influenced by sociocultural or economic factors of their executors.

In the early hours of September 20, 2010, a mother told the city police Mocoa, the capital of the department of Putumayo in southern Colombia, that an unknown individual attacked her when she opened the front door of her residence, and she was attacked until she lost consciousness. After regaining consciousness, she observed that the children were in bed in the master bedroom and, when she approached them, believing them to be asleep, noted they were wet and without signs of life.

At the beginning of the investigation, the woman´s injuries were consistent with blunt trauma and the apparent coherence of her story the authorities to think there was a perpetrator who murdered her two children and left the mother seriously injured. The high social impact produced by a case of two killed children killed and the assaulted mother activated law enforcement, at both the local and national level; the Criminal Behavior Special Unit of the Attorney General's Office was called to support the investigation through a process of crime scene analysis and possibly developing a criminal profile.

On the basis of the processes of the crime scene analysis, the bloodstain patterns found, the comprehensive study of the evidence related to the victims, the assessment of the versions provided by the surviving mother and other witnesses, and the structural characteristics and safety of the building, the investigation team re-evaluated the hypothesis of an external aggressor and redirected their attention toward the crime being committed by the mother.

This change in the case offered the team a clear vision regarding the dynamics of the events that led to the deaths of the two children. With the support of the analysis of forensic evidence at the scene, the Criminal Behavior Special Unit was forced to focus their attention of finding the motivation that drove this woman to kill her own children. Therefore, the line of investigation focused on probing deeper into all areas of the mother's life and found an intricate world of love, frustration, and abandonment from a mentally unhealthy woman, egocentric and possessive, with strong intentions to overcome any obstacle to achieve all her personal desires.

After gathering and fitting together all parts of this criminal and forensic puzzle, the prosecutors demonstrated definitively and beyond reasonable doubt that the crime was committed by the mother in the form of staged domestic homicide.

Mothers Who Kill, Children, Staged Domestic Homicide

E67 Utah Quick Kit (UQuiK): A Collaborative Program on the Sexual Assault Kit Analysis Process

Julie L. Valentine, PhD, Brigham Young University, 532 SWKT, Provo, UT 84064; and Suzanne Miles, BS*, Utah Bureau of Forensic Services, 4451 S Constitution Boulevard, Taylorsville, UT 84129*

The goals of this presentation are: (1) to describe the UQuiK program to streamline the DNA analysis process in sexual assault kits; and, (2) to identify the research findings on the effectiveness and reliability of the UQuiK program. After attending this presentation, attendees will better understand the importance of collaboration and communication between forensic medical providers/Sexual Assault Nurse Examiners (SANEs) and forensic scientists on sexual assault evidence collection. In addition, attendees will learn about a novel, collaborative approach in selecting most probative DNA evidence swabs to streamline the DNA analysis process in sexual assault cases.

This presentation will impact the forensic science community by providing data on a collaborative approach uniting forensic medical providers/SANEs and forensic scientists at the state crime laboratory. This presentation will add to research as findings from a study analyzing the effectiveness of this new approach will be shared.

Crime laboratories across the United States are receiving higher amounts of sexual assault kits for analysis. The rise in numbers is likely due to more sexual assault victims reporting the crime and an increase in law enforcement submission rates of sexual assault kits. Many crime laboratories have moved to a direct-to-DNA analysis approach consistent with improved Short Tandem Repeat (STR) and Y-chromosomal Short Tandem Repeat (Y-STR) analysis methods and to streamline the analysis process, bypassing serology testing prior to DNA analysis. In an effort to additionally improve the throughput of the crime laboratory analysis process, the Utah state crime laboratory collaborated with a forensic nursing team to pilot a program entitled UQuiK.

The UQuiK program involves educating forensic nurses in identifying the most likely probative swabs collected during a forensic sexual assault examination. The forensic nurses select up to three probative swabs and a reference sample, buccal swab from the victim, and package these swabs in a separate container from the full sexual assault kit. Law enforcement in this jurisdiction also received information and education regarding the UQuiK process. Law enforcement agencies were encouraged to submit the UQuiK evidence envelope to the state crime laboratory. The full sexual assault kit was also submitted, although the evidence contained in the UQuiK envelope was analyzed first. Swabs contained in the full sexual assault kit could be analyzed following evidentiary swabs in the UQuiK envelope, if deemed necessary.

The UQuiK program shortened DNA analysis time for the forensic scientists as they did not need to open a full sexual assault kit, sort and catalog the evidentiary swabs, read the history of the assault, perform body fluid testing, and select the most likely probative swabs for DNA analysis. Prior to launching the program, a pilot study found the time was decreased from 120 days to 25 days for DNA analysis.[1] As the forensic medical providers/SANEs collect the history of the sexual assault directly from the patient/victim, they are prepared with the information to select the most likely probative swabs for DNA analysis. A training program was developed to educate the SANEs participating in the study on how to select the most probative swabs. The training program consisted of three training sessions with the SANEs where studies were shared on DNA analysis findings. The SANEs were then given scenarios and asked to determine which swabs would most likely result in a probative DNA profile.

Research on the DNA analysis results from a sampling of cases under the UQuiK program and cases prior to the UQuiK program will be shared to provide data on the effectiveness and reliability of the UQuiK approach. A key component of this program is the collaborative relationship between forensic scientists and forensic medical providers/SANEs. One study found that only 53% of crime laboratories in the United States have a communication feedback mechanism in place between forensic scientists and forensic medical providers/SANEs.[2] This program underscores the need for improved communication between the professions to improve practice and outcomes.

In conclusion, this project and research study provide information on a program based upon communication and collaboration between forensic scientists and forensic medical providers/SANEs to improve the process of DNA analysis of sexual assault kits.

Sexual Assault, Forensic Scientists, SANEs

E68 Big Business, Big Brother, and Genetic Genealogy

Colleen M. Fitzpatrick, PhD, 18198 Aztec Court, Fountain Valley, CA 92708*

After attending this presentation, attendees will better understand the three-way relationship between Direct-To-Consumer (DTC) DNA testing companies such as Ancestry.com®, those involved in forensic identification, and the genetic genealogy community. The growing size of the DTC companies has been an exciting prospect to genetic genealogists due to an increasing success rate of finding adoptee birth parents and long-lost family members; however, this same growth has been an issue for the forensic community. Although those same databases have the potential of solving crimes, DTC DNA testing databases are unavailable for forensic identification due to Fourth Amendment search and seizure issues. There is also the concern that DTC companies wish to protect access to those databases as their primary financial assets. Genealogists, on the other hand, seem comfortable with relinquishing their rights to how their DNA can ultimately be used by DTC companies for drug development and various research purposes, while at the same time regarding law enforcement as "Big Brother," ready to exploit their DNA for who knows what purpose.

This presentation will impact the forensic science community through an open discussion of how to overcome the challenges that currently limit collaboration with both DTC companies and the genetic genealogy community. Such a discussion will lead to a better appreciation of the issues facing all three communities, with suggestions as to how they can work together toward the common goal of developing strong working relationships based on trust.

The need for this discussion is compelling. At present, there are approximately three hundred thousand Y-chromosomal Short Tandem Repeat (Y-STR) profiles posted online in thousands of large and small public genetic genealogy databases. At the same time, databases of autosomal Single Nucleotide Polymorphism (SNP) testing results controlled by the DTC testing companies have grown to include millions. The database for AncestryDNA™ has now topped four million, while the 23andMe® database has passed the two million mark. While Y-chromosomal DNA (Y-DNA) can only provide information about the direct male line of a family, autosomal SNP testing can provide information not only about the individual who was tested, but also about his immediate relatives. Therefore, the size of each autosomal SNP database is virtually much larger, considering that each person tested shares an average of 50% of his autosomal DNA with his parents and siblings. If, as expected, AncestryDNA™ will top ten million members in a couple of years, based on a typical family of four, the database could represent four hundred million virtual members — larger than the United States population. Unfortunately, unlike Y-STR databases, autosomal SNP databases are not available to the public, but are controlled by Big Business.

The potential of both Y-STR and autosomal SNP databases for solving crimes and identifying John Does must be recognized and a means found for the three communities — the DTC companies, the forensic practitioners, and the genetic genealogy community — to work toward resolution of the issues preventing collaboration. This presentation will explore ways of making this happen.

Direct-to-Consumer, Genealogy, Identification

E69 Child Abuse in Northwest Italy: A Five-Year Retrospective Analysis

Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Francesco Lupariello, MD, University of Turin - Legal Medicine Section, C So Galileo Galilei N 22, Torino 10121, ITALY; Caterina Petetta, MD, Sezione di Medicina Legale DSSPP, C So Galileo Galilei N 22, Torino 10121, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. Città della Salute e della Scienza, Turin, ITALY; Sara Simona Racalbuto, PsyD, Department of Pediatric Emergency, Turin, Piazza Polonia 94, Torino 10100, ITALY; Silvia Murdocca, DSW, Dep. Quality Appropriateness of Diagnosis and Care, A.O.U. Città della Salute e della Scienza, Turin, ITALY; and Giancarlo Di Vella, MD, PhD*, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, C So Galileo Galilei N 22, Torino 10121, ITALY*

After attending this presentation, attendees will understand the characteristics of child abuse in northwest Italy through the analysis of the data collected in one of the larger specialized centers in Italy.

This presentation will impact the forensic science community by providing information about the factors useful for early identification of suggestive cases of abuse.

A survey of the Italian Childhood and Adolescent Guarantee Authority published in 2015, involving a quarter of the population of Italian children, revealed that 4.7% of minors are followed by social services.[1] Among them, a fifth are victims of some form of abuse. The prevalence of minors who are receiving social services grows directly with age. This data highlights poor development of these early-warning services as social services only become involved later when the children have already grown up.

Early identification of the cases of child abuse is crucial for health and social professionals as well as ensuring prompt reporting to the judicial authority. For this reason, a retrospective analysis of the cases managed by the multidisciplinary unit dedicated to the evaluation of suspected abused children ("Bambi") of the Ospedale Infantile Regina Margherita (Turin) was conducted.

From January 2012 to December 2016, the unit dealt with 816 cases: 46% concerned Sexual Abuse (SA), 39.7% Physical Maltreatment (PM), 4.2% neglect, 5.1% were mixed forms, and, in 5% of the cases, the type of abuse was not available. In regard to gender, females were the majority in SA (81.6%), neglect (52.9%), and mixed forms of abuse (64.3%), while males predominated in PM (52.5%). The mean age of the patients was 7.5 years; 7.6 years in SA, 7.7 years in PM, and 5 years in neglect; the age distribution was significantly lower in cases of neglect (p-value 0.00024 and 0.0025, in comparison to SA and PM). The geographical origin of the family and, consequently, the child's cultural growth environment have been taken into account. Italian children were numerically predominant (63.6%), followed by African (14.5%), east European (12.9%), Latin American (5%), Asian (2%), and European (0.2%). The family status analysis observed a slight predominance of divorced parents (28.7%) vs. not divorced (27.2%), while a small percentage of children resided in community (3.9%) or with a foster family (0.5%). In 36.2% of the cases, the visit was required by the hospital ward where the patient was hospitalized and in only 14.1% was the visit required by social workers. In most cases, sexual offenders were fathers (25%), extra-familial people (24.7%), and other components of the family (20.5%), such as the mother (3.6%) or brother (3.3%). In cases of PM, perpetrators were predominantly fathers (44.8%), then mothers (33.1%), then extra-familial people (7.9%). Neglect was associated most to mothers (64.3%), followed by fathers (44.6%). In the mixed forms of abuse, the most frequent perpetrators were fathers (41.2%), mothers (36.5%), or other family members (22.2%). The percentage of the maltreated children (70.3%) did not present any kind of injury. In the remaining cases, bruises were observed in 41.9% of the children, excoriations in 26.2%, scars in 11.2%, bone fractures in 8.4%, burns in 4.2%, non-accidental head trauma in 3.6%, lacerated injuries in 3.3%, cutting wounds in 0.9%, and gunshot injury in one case.

The criterion "localization of injuries," which contributes decisively to differentiate accidental and abuse-related wounds, was also considered. For example, injuries localized at the forehead, tip of the nose, and chin are typically due to accidental falls, while injuries involving eyes, lips, and outer ears are abuse related.[2] In this series, physically maltreated children presented injuries in locations typical for non-accidental trauma in 86.5% of cases. In the cases of confirmed SA (about two-thirds of the visits for suspected SA), 67.1% of the children presented some form of anogenital findings, non-specific (e.g., erythema of the genitals) or specific (e.g., perianal scars) for genital trauma.[3] Among the cases of unconfirmed suspected abuse, 55.1% had non-specific genital findings.

For these reasons, the clinical assessment must be performed by a health care professional with specialized training in child abuse evaluation who is able to correctly identify the specific features of the different forms of abuse. This presentation provides attendees with a greater awareness of the importance of knowing the red flags indicating a situation of child abuse.

E70 Keeping Safe: Understanding Violence Against Law Enforcement by Youth Street Gangs

Cliff Akiyama, MPH, MA, Akiyama and Associates, LLC, 540B S 48th Street, Philadelphia, PA 19143*

After attending this presentation, attendees will be able to understand the signs and symptoms of the ever-growing problem of gang violence against law enforcement and the forensic science community so they may keep themselves safe while investigating the deaths of youth street gang members.

This presentation will impact the forensic science community by educating and ultimately keeping the forensic science and law enforcement community safe out on the streets while investigating the deaths of youth street gang members.

Within the past 13 months, violence toward law enforcement has increased by 85%, according to the Department of Justice. In some metropolitan areas of the United States, this figure is nearly 115%. One cannot turn on the television or radio without hearing about another officer-involved shooting in this country. In Los Angeles County, CA, alone, the Los Angeles Police Department (LAPD) and the Los Angeles County Sheriff's Department (LASD) have increased helicopter patrols and 911 screenings in wake of the recent police ambushes.

Youth street gangs throughout the United States still continue to terrorize the neighborhoods they claim as their own, causing the citizens in these gang-infested neighborhoods to live in constant fear of their lives every single day; however, a new trend on the streets is making a fake 911 call, then ambushing law enforcement as they respond to these fictitious calls for help. As law enforcement responds to the location of the scene, youth gangs are now using urban style tactical warfare learned from the military, using that training against law enforcement as they respond to the scene, seriously injuring or killing officers. Whereas in the past, youth gangs would retreat when confronted by law enforcement, they are now advancing toward law enforcement while shooting, using the same tactics as the officers themselves use, such as "slicing the pie" or "button hook." There are other various forms of urban tactical warfare learned in the military and the police academy that the gang members are learning on a daily basis and using against the police.

In 2016 in Los Angeles County, there were a total of 465 shots fired at police, and between January 1, 2017, and July 1, 2017, there have been a total of 688 shots fired at police. Of those shots fired so far in 2017, 93% were "gang related," yet in the year 2016, only 88% were "gang related." This is a serious "officer safety" concern for law enforcement who respond to these gang-related violence calls on a daily basis. Why are these gang members shooting at police?

This study interviewed 150 Los Angeles gang members on the streets and in the jails between January 2016 and July 2017 as to why they would decide to shoot at law enforcement. This study identified 10 distinct manifestations of these shootings against police and 12 solutions to help keep officers safe while out on the streets investigating these gang-related shootings. A sample of the findings include: distinct cultural differences between African American, Latino, and Asian American gangs as to why they engage violently with the police; state of mind (motivation) of the various gangs; disrespect felt toward police while being questioned, detained, or arrested; covert and overt racism experienced by the gang members; a "getting even" mentality; and being male or female in the gang.

All of these findings culminate in the recent influx of violence against law enforcement by gang members. In Los Angeles County alone, there are 1,351 documented gangs with a gang membership of more than 800,000. Across the country, similar results have been seen, according to the National Gang Crime Research Center in Peotone IL. There are more than 28,800 gangs in the United States with a total gang membership of 975,000. Of those, 90% are male and 10% are female. The ethnic composition nationwide include: 47% Latino, 31% African American, 13% Caucasian, 7% Asian, and 2% "mixed race," according to the Office of Juvenile Justice and Delinquency Prevention of the United States Department of Justice.

Youth Street Gangs, Law Enforcement, Officer Safety

E71 Trauma, Cognition, and the Investigators

Amanda L. Farrell, PhD, Marymount University, School of Education and Human Services, 2807 N Glebe Road, Arlington, VA 22207; and Timothy J. Ainger, PhD*, University of Kentucky, 2720 Burnt Mill Road, Lexington, KY 40511*

After attending this presentation, attendees will be more aware of the various types of trauma that investigative personnel routinely encounter and the potential impacts this may have, not only on the individual, but on the investigation. Paths forward and the development of Evidence-Based Policy (EBP) will also be addressed, so attendees can examine what policies and assistance are available in their own agencies.

This presentation will impact the forensic science community by opening discussion on a topic that is not only often considered to be taboo, but also by highlighting the potentially different trauma experiences that investigative personnel face and how, while more attention is being placed upon first responder exposure to trauma and their subsequent resilience, this focus may mask or overlook specific needs of investigators who are likely to experience trauma for a longer duration and in a different manner.

While there has been increased discussion about trauma and resilience among first responders in the past decade, this discussion has often been limited in scope and scale. There has been a focus on those immediately responding to critical incidents, as noted by Fetterman, with advances made in how we address first responder mental health in the aftermath of a traumatic experience; however, like Henry noted in his research, different positions involved in dealing with death in particular, but ostensibly also those involved in other types of cases, experience trauma differently.[1,2] This includes a variety of factors, such as time spent at the scene, and acknowledges that repeated exposure to trauma has a cumulative, rather than additive, effect. O'Hara notes that, unlike clear critical incident-related traumas, cumulative trauma can be more insidious and difficult to treat.[3] This suggests that best practice would necessitate addressing how participating in difficult or traumatic cases, especially as an investigator or as a member of a crime scene unit, impacts those personnel and provide appropriate services. Traumatic or troubling cases may also impact investigative personnel and lab personnel that were not immediately on scene as a form of vicarious trauma, which has recently been addressed among first responders by the Office of Victims of Crime.[4] Further, cognitive implications subsequent to traumatic exposure are varied in presentation and warrant further exploration. Amnestic complications associated with dissociation, as well as shifts in cognitive schemas, following traumatic exposure have implications for both subsequent cognitive functioning and possible applications of insight-based treatment approaches.[5,6] It has been suggested that the cognitive impact of trauma can be seen in both primary and vicarious/secondary trauma exposure (e.g., peers, treating clinicians).[7] Furthermore, some research has suggested a negative impact on executive functioning and memory, which may even be compounded by repeated exposure to trauma[8-11]. Additional research, especially in order to synthesize findings across trauma research, is indicated.

This presentation draws on research conducted with various law enforcement personnel who had been involved in an officer-involved shooting, to include the shooter and investigative personnel, and clinical experience, as well as current literature and other sources discussing EBP, with the dual goal of both opening and furthering discussion on a sensitive but vital topic, as well as beginning to identify paths forward toward a balanced approach that acknowledges mental health and resilience of the investigators and other investigative personnel.[12]

E72 A Case Study: A Comparative Analysis of Common Behavioral Evidence in Three Columbian Cases of Domestic Homicides

Eric R. Ruiz Hernandez, MD, Calle 23D 86 28, Torre 6 Apto 303, Bogota, Cundinamarca 110911, COLOMBIA*

After attending this presentation, attendees will understand how, through a comprehensive process of analysis of the evidence collected at the crime scenes of three domestic homicides, a reconstruction of criminal behavior was made, demonstrating common patterns of behavioral evidence.

This presentation will impact the forensic science community by illustrating how good practices in crime scene processing, and the effective interpretation of the context of the evidence, reveal that crimes can have behavioral evidence in common, as described by the specialized literature in offender profiling.

Case 1: From September 9-12, 2009, body fragments of a female were found in different vacant lots on the outskirts of the city of Ibague, Tolima.

Autopsies Revealed: Blunt force trauma killed the victim; postmortem dismemberment; disembowelment; removal of the uterus and mutilation of the genitals; and the attempted destruction of fingerprints. All these actions sought to avoid identification of the victim and to mislead investigators as to the link between the victim and his aggressor.

Case 2: Occurred on the morning of September 20, 2010, in the town of Mocoa, Putumayo; the deaths of two children were reported and their mother was seriously injured. In the family's house, the bodies of two drowned children were found and their mother had marks of blunt and sharp force trauma. There was no evidence that an external perpetrator had entered the property.

Case 3: On the morning of February 6, 2014, the police of Villa del Rosario, an upscale neighborhood of Cúcuta, received a report of a break-in in an exclusive residential area where a female homeowner was killed. The autopsy revealed that the victim died because of strangulation with a rope and mechanical suffocation caused by the obstruction of the upper airways with a plastic element that covered her face. Household appliances and the homeowner's personal items were scattered on the floor of other bedrooms and social areas of the house. The victim's husband reported that approximately ten thousand dollars (US) were missing, along with his wife's cell phone.

After a comprehensive process of analysis of the three crime scenes and the effective interpretation of the behavioral evidence in common, as described by the specialized literature in offender profiling, the prosecutors could show conclusively and beyond reasonable doubt that the crimes were committed by the husbands and the mother. All offenders were sentenced.

Crime Scene Investigation, Behavioral Evidence in Common, Criminal Behavior Analysis

E73 3D Reconstruction of Shooting Incidents Using Laser Scanning and Computer Modeling

Parris Ward, JD, Biodynamics Engineering, Inc, 1011 Swarthmore Avenue, Ste 1, Pacific Palisades, CA 90272; and Frank P. Sheridan, San Bernardino Sheriff-Coroner, 385 Summit Avenue, Redlands, CA 92373*

After attending this presentation, attendees will understand how laser scanning and computer modeling can aid in the reconstruction of bullet trajectory analysis in shooting events.

This presentation will impact the forensic science community by demonstrating how a 3D computer model based on high-resolution laser scans of a scene was used in conjunction with ballistics evidence to analyze an unusual shooting event in which a bystander was struck and killed by a deflected bullet.

3D modeling and animation software is often used to analyze shooting events because of their ability to demonstrate the interaction between objects and projectiles in terms of time and space. An accurate computer model of the scene is necessary to achieve the best results. Point clouds generated by laser scanners can be imported into the software and used as they are or as a template to create the geometry in the scene. Once a scene is constructed, mannequins are placed in the scene to represent the individuals involved. Bullet paths can be depicted as lines through space from their point of origin to the objects they strike. Bullet deflections can be calculated based on the evidence. If a person is hit, the path of the bullet through the body can be depicted with lines placed through the mannequin, the same way a pathologist places rods through a body. Those paths are typically placed according to descriptions and measurements noted in the autopsy report, as well as photos of the wounds.

In this shooting incident, sheriff's deputies responded to a report of two men in a Sports Utility Vehicle (SUV) driving around a neighborhood with the passenger threatening residents with a handgun. One person who was threatened obtained the license number of the vehicle. The deputies were unable to find the suspects, so they watched the residence that the car was registered to. Late in the evening, the vehicle with the two suspects arrived at the location. The passenger, who had been brandishing the gun, immediately exited the vehicle and confronted the deputies. The driver of the vehicle then parked the SUV in a driveway approximately 20 feet down the road, exited the vehicle, and observed the confrontation between his passenger and the deputies.

The deputies had their weapons drawn and pointed at the passenger. They noticed that the driver was standing in their backdrop and ordered him to move. As the deputies ordered the passenger to show his hands and get on the ground, they lost sight of the driver. When the passenger reached inside his jacket and started to extract a gun, multiple officers simultaneously fired multiple shots at the passenger and he fell to the ground. One bullet struck the hand with which he was holding the gun, penetrating both his hand and the handle of the gun.

After the shooting, the body of the driver was found approximately 40 feet south of the passenger's location, lying on the sidewalk behind a car in a pool of blood. The question in this case was how and why was he shot?

The autopsy revealed that the driver was struck by a single round to the left side of the neck, severing the left carotid artery and left jugular vein. Macro photography of a fragment of bullet jacket and core recovered from the wound exhibited striations and deformation consistent with striking a hard, abrasive surface.

The shooting site was laser scanned and the resulting point cloud data was imported in a 3D modeling program. The position of all the deputies and the suspect passenger were determined at the time of the shooting. The locations of bloodstains and bullet strikes were identified. The trajectory model revealed that a stray bullet fired at the suspect passenger had deflected off the concrete driveway and struck the bystander driver as he was crouched behind the front end of a parked car. The path of the bullet through the neck was consistent with this position. Also, the lack of a blood trail was consistent with him collapsing where he was shot. The computer modeling also demonstrated that in that position, he would not have been visible to the deputies at the time they fired.

Shootings, Laser Scanning, 3D Modeling

E74 Bulletproof: Two Incidents of Non-Penetrative Bullet Strikes Inflicted on Soldiers Without Armor During Operation Iraqi Freedom

Ryan P. Brokaw, MFS, US Army CID, Fort Rucker CID Office, 5430 Raider Street, Fort Rucker, AL 36362; and Keith M. McCullen, MFS*, PO Box 624, Black River, NY 13612-0624*

After attending this presentation, attendees will have a greater understanding of the effects of unintentional intermediate substrates on would-be victims of gunfire. The substrates were circumstantial to each incident and were not intended or designed for protective purposes or to defend against firearm projectiles. The intermediate substrates likely saved the lives of both victims in the two case studies presented.

This presentation will impact the forensic science community by providing two case studies of rare, anomalous gunshot incidents by the United States Army special agents who investigated them. The case studies presented are in a category of unique and compelling incidents that often become anecdotal "legends" within law enforcement circles. This presentation will formally establish them within the academic community as a resource for future research and possible practical application.

While serving as two forward deployed special agents in the United States Army Criminal Investigation Command during Operation Iraqi Freedom (OIF) in 2005-2006, the two agents each worked a separate, unusual firearm incident involving soldiers being struck by firearm projectiles, but with little to no injury. Both incidents occurred on United States Army bases in Iraq. United States soldiers supporting OIF were issued Individual Body Armor (IBA) at this time in the conflict; however, neither of the victims in the incidents were wearing their IBA as they were located in office or residential settings with presumably little to no enemy threat. The bullet projectiles struck both victims, but failed to penetrate or otherwise break their skin due to the intervention of substrates circumstantial to each incident. As a result, both victims suffered minimal to no injury from the gunshots.

Case 1: In April 2006, a United States Army soldier committed suicide with his rifle in his quarters. The rifle's projectile passed through the soldier, the wall of his quarters, and the wall of an adjacent quarters, striking a second soldier in the back with almost no injury.

Case 2: In December 2005, an Iraqi national interpreter attacked a United States Army intelligence soldier with a pistol. The pistol's projectile struck the soldier in his uniform's chest pocket over his left chest, where he kept his unit standard operating procedure booklet and his official badge and credentials. The bullet penetrated the booklet and lodged in his badge. The soldier was able to overcome his attacker and survived the incident. The soldier received minor bruising below the impact site, but was otherwise uninjured.

Firearm Incidents, Unique, No/Minimal Injury

E75 A Unique Capstone Experience to Assess Student Learning in a Bachelor of Science (BS) Forensic Science Program

Lori J. Wilson, PhD, Eastern Kentucky University, Dept of Chemistry, NSCB 4126, Richmond, KY 40475*

After attending this presentation, attendees will better understand how student learning is assessed in a BS Forensic Science degree program at Eastern Kentucky University. In FOR 499: Forensic Science Capstone, forensic faculty identify whether students have acquired the central knowledge and skills that are the expected learning outcomes of the program.

This presentation will impact the forensic science community by providing assessment measures and criterion for producing the next generation of forensic scientists who are prepared with the skills and knowledge to be leaders in the field. This presentation will add to educational research being conducted in forensic science undergraduate programs.[1]

Using a capstone experience to assess learning in an academic program first requires a set of program learning objectives that are the same as the capstone course learning objectives. Below are the program and course learning objectives:

Student Learning Objective 1: Students will employ the theoretical and practical principles of chemistry, biology, physics, and mathematics to perform the work of forensic scientists. Specifically, given a specific type of evidentiary material, students will demonstrate the ability to: (1) recognize, collect, package, and store evidence commonly found at crime scenes; (2) evaluate analytical requirements and design an appropriate analytical scheme to obtain desired results; (3) properly prepare and analyze the material to generate relevant data supported with the understanding of the role of proper quality control samples; and, (4) evaluate the data and make judgments concerning analytical results.

Student Learning Objective 2: Students will demonstrate effective written and oral communication skills, especially the ability to transmit complex technical information in a clear and concise manner. Specifically, students will: (1) write concluding statements to communicate results and decisions to law enforcement and the legal system; and, (2) defend and justify decisions orally and in writing.

Student Learning Objective 3: Upon the successful completion of the BS Forensic Science degree, students will demonstrate the attitudes, ethics, and values that enable students to reach the highest level of achievement and personal growth. Specifically, students will: (1) demonstrate honesty, reliability, punctuality, motivation, strong work ethic, and good interpersonal skills that are the hallmarks of a professional scientist; and, (2) demonstrate the ethical behavior, learning skills, and initiative needed for life-long learning.

In this presentation, the capstone assessment method will be explained. In the course, the students process, analyze, report, and testify during a mock case. Faculty evaluate the individual students and the grouped data is provided to evaluate at the program level.[2] Meaningful change is accomplished when changes are made in foundational or "downstream" courses when program learning objectives are not met. Specifically, in this assessment cycle, the following three program change needs were identified following capstone assessment: (1) students need more knowledge and practice of evidence collection and processing before final assessment in FOR 499: Forensic Science Capstone; (2) students need additional practice with testimony in the FOR 465W: Expert Witness Testimony course prior to final assessment; and, (3) students need to have decided on an area of specialization in either toxicology and drugs, trace evidence, or DNA prior to registration for the capstone course.

This presentation will further explain the assessment measures and criterion used to measure mastery of each student learning objective, allowing "closing the loop" at the program level.[3]

Capstone, Assessment, Education

E76 Developing an Information Literacy-Intensive Forensic Science Course

Laura Sare, 5000 TAMU, College Station, TX 77843; Sarah Bankston, MS*, Medical Sciences Library, Texas A&M University, 4462 TAMU, College Station, TX 77843; and Jeffery K. Tomberlin, PhD*, TAMU 2475, Dept of Entomology, College Station, TX 77843-2475*

The goal of this presentation is to demonstrate a model in which forensic science educators can utilize resources at university libraries to promote scientific information literacy and lifelong learning strategies for their forensic science students that they can continue to use in their professional forensic careers.

This presentation will impact the forensic science community by highlighting the benefits of forensic science faculty collaborating with subject specialist academic librarians to produce a course that fills a gap in the education of future forensic science practitioners. This course facilitates the development of productive search strategies and explains how different types of scientific research and legal materials are relevant to various forensic science disciplines. This collaboration has demonstrated a need for promoting information literacy, specifically for open-access materials, regarding forensic science information to these students, so once they graduate, they may still acquire the valuable information necessary for their jobs. As a result of this research, it was determined there was a need to expand this information literacy beyond the classroom and National Institute of Justice (NIJ) funding was acquired to allow for the development of these materials as modules to be used by practitioners in crime laboratories to enhance available resources for their use.

Forensic science is a multi-faceted field, including expertise from a variety of disciplines. A challenge for creating a college course to address skills to develop information literacy competencies and encourage lifelong learning for future practitioners is covering those diverse disciplines. This presentation will detail how librarians at Texas A&M University developed a junior-level forensic science seminar in collaboration with a forensic science faculty member to meet the research needs of students in the forensic sciences program. The learning outcomes of this class include: teaching students to describe problem-solving principles; organizing typical operational protocols; recognizing the scientific basis and application of tools and techniques in forensic science; comparing capabilities and limitations; and summarizing and illustrating current scientific, ethical, and legal issues. This presentation will detail the steps taken to create six separate information literacy-intensive classes, including the development of the assignments, and how feedback was provided to the students. These classes include sessions on dissecting scholarly articles and case law, as well as classroom discussions to teach students how to use the structure of research articles and case law to easily evaluate information. By creating this information literacy course, instructors were able to better prepare students for their program's research-intensive courses with the amount of detail required that cannot be covered in a traditional, one-hour library instruction session. Such skills will be of value when working in forensic science fields and when the need arrives for locating similar resources in relation to casework. Additionally, this presentation will address issues raised in class, such as open access, database access, and evaluation of science and legal materials, which helps the students translate current school work to their future careers. To further this concept of information literacy, as previously mentioned, the researchers received NIJ funding to determine how forensic scientists locate and evaluate information, to create educational materials aimed at enhancing these skills, and to increase awareness of other valuable informational resources. Locating and evaluating high-quality forensic science literature will help forensic scientists engage in quality science practices.

Results from this class, which is now in its third year of evaluation, demonstrate that students who take this preparatory course are better prepared for conducting meaningful research for their writing-intensive senior-level classes, both in their abilities to find relevant materials and in how to utilize and cite these materials. Graduating students who go on to graduate or to law school have also reported back that taking this course gave them a foundation to build on in their advanced studies.

Information Literacy, Forensic Science Education, Libraries

E77 Graduate and Undergraduate Education in Forensic Sciences in Turkey

Inanç Pastirmaci, BSc, Üsküdar University, Institute of Addiction and Forensic Science, Üsküdar, Istanbul 34662, TURKEY; Kaan Yilancioglu, PhD, Üsküdar University, Institute of Addiction and Forensic Science, Üsküdar, Istanbul 34662, TURKEY; Tugba Ünsal, PhD, Üsküdar University, Department of Forensic Science, Altunizade Mah. Haluk Türksoy Sok. no:14, Üsküdar, Istanbul, Üsküdar/Istanbul 34662, TURKEY; and Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy Sok. No. 14, Uskudar, Istanbul 34662, TURKEY*

The goal of this presentation is to provide information regarding the undergraduate and graduate educational programs in the fields of forensic science in Turkey.

This presentation will impact the forensic science community by providing information about the undergraduate and graduate forensic science programs available in Turkey.

In Turkey, evaluation of criminal evidence is achieved by government agencies and private corporations, as is the case for the rest of the world. Among these institutions are the Head of Department of Criminal Police Laboratory and District Laboratories, the Head of Gendarmerie Forensic Laboratories and District Laboratories, the Presidency of Legal Medicine and its subsidiaries, the General Directorate of Customs Enforcement's Laboratories, and the Ministry of Health's Presidency of Hifzisihha and District Laboratories. The presence of expert reports can disturb the public conscience, and unsatisfactory court results are a reality in Turkey in that these reports can arrive at different conclusions from the evidence, and a person can interpret evidence differently from when the evidence in question was analyzed. The biggest problem in Turkey is not any form of pressure directed against government agencies, nor are the custom-made reports issued by private corporations; however, the issue is highly related to the presence of inexperienced and unqualified personnel, in short, the absence of quality assurance and lack of external audit. It was deduced in the report of the State Supervisory Council of the Republic of Turkey that "there have been critical defects for training experts in non-medical disciplines" and that "the expert establishments are problematic, and no criminal expert is being trained."

Raising the level of quality in justice services in Turkey to a modern standard, enabling services provided by crime laboratories and crime scene investigation in Turkey to the maintained level, and preventing discrepancies and misinterpretations in reports is only possible by training the personnel who perform the analysis according to a scheme enabling them to become target-oriented. Courses provided to students who graduated from various science disciplines are obviously not suitable and sufficient to enable them to conduct surveys in a crime laboratory and prepare an expert report, nor are any practical courses of evidence analysis taught as a matter of fact. Thus, these people are trained under a mentor system after employment at private corporations or government agencies. Graduates of forensic science graduate programs, on the other hand, struggle to compensate for their lack of knowledge, a problem arising due to the completion of a different undergraduate program. Current graduate programs are far from training future candidates for a broad range of crime laboratories analyzing chemical, physical, and biological evidence in that these people often graduate without having prior knowledge of current trends and practices. It is also a fact that master's or PhD holders of these programs prefer academic life, rather than employment in a relevant field.

In Turkey, as with every developed country, it is necessary to instruct any interested candidate well equipped with knowledge and experience in forensic science at the undergraduate level to prepare them for conducting scientific research, for developing novel methods and instruments, or for future positions, such as private or government crime laboratories. Transforming our expert establishments, whether private or governmental, and our crime laboratories into organizations that are accredited and well-known in Europe and around the world, and also enabling the export of high technology heavily depends on the aforementioned. The Forensic Science program that is proposed to open under Uskudar University's Faculty of Engineering and Natural Sciences will be the first such in Turkey, though many types of this program exist abroad. The learning content was prepared in accordance with the Forensic Science Education Programs Accreditation Commission (FEPAC). FEPAC is a body of the American Academy of Forensic Sciences (AAFS), founded in 1948, which currently has more than 6,500 members and is the only association in the world that accredits undergraduate and graduate education.

Forensic Science in Turkey, Undergraduate Education, Graduate Education

E78 Language Use Among Forensic Professionals

Emily F. Wiegers, MA, LSU FACES Laboratory, 227 Howe Russell Kniffen Geoscience Complex, Louisiana State University, Baton Rouge, LA 70803*

After attending this presentation, attendees will understand patterns of language use that exist among the various forensic professionals.

This presentation will impact the forensic science community by offering insight into various linguistic determinants that influence language use in forensic settings.

Understanding what constitutes proper communication is an important component of interaction for forensic science professionals. Representing a broad range of job titles, work environments, and materials analyzed, forensic professionals engage in various forms of communication among colleagues and the public. The linguistic term "register" refers to the concept that language varies with individuals and their social practices. This study explores register use among the different forensic science disciplines to determine which patterns may exist that are unique to each discipline.

Data on language use were collected using an Institutional Review Board (IRB) -approved anonymous survey that was disseminated online to AAFS membership during the summer of 2016. The survey consisted of 15 questions -— six demographic questions (including age, sex, field, education, and years of experience) and nine questions regarding language use. These latter questions were designed to elicit whether registers exist that are impacted by location or the presence of others, whether or not instruction was given, and considerations of appropriate and inappropriate speech. An open-ended format was used for some of the questions to allow participants to provide examples or further explanation to their responses. Survey responses were used to analyze and compare perceptions of language use among forensic professionals.

Nine hundred seventy-six individuals representing all sections consented to participate in the survey; however, as participants were given the option to skip any question, not all questions received the same number of responses. Participation by the AAFS sections generally reflects membership numbers, with only the Anthropology Section demonstrating a notable increase between survey responses and number of section members.

With regard to language use, 71% of participants indicated their speech was impacted by the presence of other people, with superiors (46%), peers (43%), and students (43%) listed by these participants as most likely to affect language use. The use or avoidance of technical terms was the most common manner in which speech was impacted by others (40% of respondents). Additionally, 65% of respondents indicated that location impacted their speech, with "public space" selected as the most likely location to affect discourse (40%). Alternatively, 14% of participants claimed they felt audience and not location is what influences their speech. With regard to training, 46% of participants indicated that instruction for appropriate language use was not discussed at the start of their career. If language considered inappropriate is used, 49% of participants responded that the consequences would result in a minor reprimand. When asked to provide examples of language considered appropriate for the workplace, 25% of participants responded with terms representing the concept of death and human remains, with the top two reoccurring words being "decedent" (40%) and "deceased" (25%). When asked about inappropriate words, expletive language was cited or alluded to in 37% of responses.

In conclusion, results demonstrate that patterns of how professionals use language in various forensic environments can be observed, regardless of if the speaker is conscious or unconscious of this use. Many participants revealed various levels of awareness that their choice of language was in some way dependent on situation and audience. Survey data can be used to gain insight into a number of professional scenarios of language use as individuals with different backgrounds of education and professional experience define language use in various ways.

This presentation concludes that professionals exhibit metadiscourse awareness in forensic settings.

Forensic Science, Language Use, Registers

E79 Evaluation of the Booz Allen Hamilton Tactical Forensic Device: The VAMPIRE™

Jennifer A. Busk, 6552 Canmoor Drive, Troy, MI 48098; Peter Massey, MS, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; and Timothy M. Palmbach, MS, JD, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand the value of mobile fingerprint capture and identification.

This presentation will impact the forensic science community by providing insight into the capabilities and limitations of the Booz Allen Hamilton VAMPIRE™ as a mobile Automated Fingerprint Identification System (AFIS). These capabilities include photographing developed latent and latent fingerprints, capturing known and live-scan fingerprints, comparing known to known, known to latent/developed latent, and latent/developed latent to latent/developed latent.

Fingerprints have proven to be valuable in the investigation of crimes by placing an individual at a specific location and/or providing insight into whether that individual handled specific items. The VAMPIRE™ is capable of capturing both developed and undeveloped latent prints through a simple "point and shoot" method. Once the image has been captured, the image is compared to both the onboard collection history of other data previously collected and/or a watch list of individuals the operator generates from known persons of interest. The VAMPIRE's™ algorithm provides a list of possible individual identifications leading to possible future verification. No previous research or validation of the VAMPIRE™ has been conducted to date as the device is relatively new and not widely available. By comparing the image quality, image clarity, identified number of minutiae, and image quality map percentages of the VAMPIRE™ captured images with the images more commonly acquired by a Digital Single-Lens Reflex (DSLR) camera, it will be possible to ascertain if the VAMPIRE™ is a valid tool for field and lab-based forensic work.

To evaluate the VAMPIRE™on its captured image quality, image clarity, number of minutiae, and image quality map percentages in similar fashion to Pulsifer et. al., a trio of programs were utilized: the Federal Bureau of Investigation (FBI) Criminal Justice Information Services Division's Universal Latent Workstation (ULW), version 6.6; the GNU Image Manipulation Program, version 2.8 (GIMP); and Wolfram Mathematica, version 11.1.1.[1] Thirty-two friction ridge impressions from the same individual were placed on 15 surfaces of varying textures and porosities. Three magnetic powders (blue, black, and white) and one dye-stain (cyanoacrylate fuming and Ardrox™) were used to develop the latent impressions. Each of the developed impressions was captured by both the VAMPIRE™ and a Canon® EOS Rebel XSi camera and introduced to the ULW where the image quality, image clarity, and number of minutiae identified were recorded. The ULW allowed for application of an image-quality mask. An image-quality mask, also referred to as a clarity map, provided a more standardized analysis of the size and clarity of areas within a given image.[2] Once the image-clarity map was applied, it was "darkened" within the ULW and exported.[1] GIMP was used to brighten the specific darkened colored regions. The image was imported into Mathematica, where a series of commands were written to generate the percentage of the total image that corresponded to the specific colors present. The colors of the quality map range from red (questionable ridge flow present) to the observed royal blue (ridge flow, minutiae and ridge edges are certain). The comparison of the assigned color percentages, as well as the earlier recorded values between the VAMPIRE™-captured images and the DSLR-captured images allowed for any differences between the capture methods to be established.

Preliminary statistical analysis utilizing 3 of the 15 total surfaces (aluminum foil, Styrofoam™, and white painted wood) indicated there was a significant difference between the two capture methods for the number of total minutiae identified in each image. VAMPIRE™-captured images had a significantly larger number of minutiae identified than the DSLR-captured images. No significant differences were found between the two capture methods when comparing the latent quality score of the images and the overall clarity of the images.

Further research is underway to analyze the remaining 12 surfaces. The conclusion will provide further insight into the capabilities and limitations of the VAMPIRE™ as compared to the more commonly used DSLR.

E80 Enhanced Postmortem Fingerprinting Techniques

Selma Delic, MS, DOCJ Regional Medical Examiner Office, 118 Cortland Lane, Bedminster, NJ 07921*

After attending this presentation, attendees will understand the challenges encountered when identifying human remains through postmortem fingerprinting and recognize the utility and importance of enhanced fingerprinting techniques.

This presentation will impact the forensic science community by disseminating a fingerprinting technique which reduces the overall training burden, is quickly mastered by morgue technicians and forensic investigators, is less time consuming to perform, and has proven to be a cost-effective method of obtaining quality fingerprints leading to a positive identification within a fast turnaround time.

In the United States, it is the responsibility of the many decentralized local, county, and state Medical Examiner/Coroner (ME/C) offices to investigate all violent, suspicious, sudden, and unexpected deaths that fall within their jurisdiction.[1] Beyond establishing the cause and manner of death, these offices are also frequently tasked with conclusively establishing the identity of the decedent by scientific and objective means. A majority of cases are identified visually by the legal next of kin or a friend. This common process can present complications when the death occurs suddenly or unexpectedly while unattended at home or the decedent is in a hospital for a brief duration and personal documents are of dubious origin. Due to the resulting emotional stress or visceral responses of the newly bereaved, visual identification is fraught with danger and, at times, is of limited value in cases of advanced decomposition. Despite challenges experienced in this subjective identification method, a significant proportion of the typical ME/C caseload consists of accepting unidentified individuals with little chance of routine visual identification. It is generally expected by the public at large that the offices can establish an identity; however, this expectation is at times unrealized. As of December 2015, there were more than 8,000 unidentified person records reported in the National Crime Information Center's (NCIC) Unidentified Person File database.[2] Additional data suggests ME/C offices reportedly receive approximately more than 4,000 unidentified decedents a year.

In cases involving significant criminal activity, or those likely to involve evidentiary scrutiny during trial, visual identification should be secondarily supported by confirmation alongside a scientific technique: fingerprint comparison, comparisons of dental records, imaging studies, and DNA analysis. Of all these scientific procedures, fingerprint comparison is the first and most commonly used method to positively identify an individual and is used prior to other more costly options.[3] Once fingerprints have been obtained, most ME/Cs have the wherewithal or liaison with law enforcement personnel to establish or confirm the identity of the deceased.[4]

Enhanced fingerprinting techniques are paramount in cases of advanced decomposition or mummification and are frequently used in situations in which the decedent is recovered from scenes involving fire, prolonged submersion in water, other adverse environmental effects, extensive trauma to the face, dismemberment, insect activity, or animal predation. Older techniques for recovering fingerprints in these types of cases involved a combination of injecting fluids subcutaneously or further mutilation by removing the complete finger or hand from the body. These procedures have known limitations to successful deployment and are considered to be expensive, caustic, insensitive, and arguably morally unethical.

The demonstrable fingerprinting techniques of preference have proven effective in the most challenging circumstances. The impressions of the fingerprint are made from these methods and submitted for comparison to the relevant police department. These techniques have been used in a significant sample of cases with exemplary results.

E81 Is Latent Print Viability Affected by Heat (Accumulated Degree Hours) From 60-Watt Incandescent Light Bulbs?

Olivia K. Colella, BA, 13313 Lockgate Place, Herndon, VA; Marilyn T. Miller, EdD, VA Commonwealth University, 1015 Floyd Avenue, Rm 3001A, Box 843079, Richmond, VA 23284-3079; Sylvia Buffington-Lester, Virginia Department of Forensic Science, 700 N 5th Street, Richmond, VA 23219; Francis J. Curran, BS, County of Henrico, Virginia Police Division, 7721 E Parham Road, Richmond, VA 23294; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will understand how time and temperature, as a combined variable, impact the viability of latent fingerprints deposited on 60-watt incandescent glass light bulbs.

This presentation will impact the forensic science community by directly addressing the lack of research regarding the effect of varying environmental factors on pattern and impression evidence, as discussed in the 2009 National Academy of Sciences (NAS) Report.[1] A statistical regression model (using Accumulated Degree Hours (ADH) as the independent variable) will be used to predict latent print viability and provide a time frame for when a print was deposited.

In the fall of 2016, the Henrico County Police Department in Richmond, VA, recovered a print from a light bulb in a burglary case, speculating that it had been removed to prevent suspect identification; however, the defendant asserted that he had touched this light bulb months prior to the crime, and there was no published research from which to assess the validity of this claim.[2] Current research has addressed the detection limits of certain components of fingerprint residue, such as serine, which has been detected by Gas Chromatography/Mass Spectrometry (GC/MS) after exposure to temperatures of up to 150°C.[3] Although this information is valuable, it does not address the practicality of crime scene investigators visualizing and preserving prints, nor does it use time and temperature to estimate the time since a fingerprint is deposited.

This project addresses issues not covered in this study by: (1) recovering latent prints with conventional methods; (2) evaluating fingerprint quality based on a previously established scale; and, (3) relating the combined variables of time and temperature in a regression model that can be used to estimate the elapsed time since a fingerprint was deposited.[4] Through the use of the regression model and popular fingerprint recovery methods, this study will demonstrate the persistence of latent fingerprints and provide law enforcement with additional information that could bring perpetrators of crime to justice.

Ten light sockets were mounted on five strips of shipping wood and wired in parallel to provide equal amounts of electricity to each bulb. Each light bulb was secured into each light socket with gloves. Once secured, nine fingerprints were deposited on each bulb with medium pressure. A 12-hour baseline test was performed to determine the best length of time to leave the bulbs on for subsequent testing. After the baseline test, each unit was turned on for 18 hours, 72 hours, 120 hours, and 168 hours, respectively. A thermal imaging camera monitored the units to record the generation of heat from the bulbs. After each allotted time period, the prints were enhanced with black powder and lifted with tape onto a lifting card to be examined for quality using an 11-point scale.

Latent prints were recovered through the baseline test (1,488 Accumulated Degree Hours (ADH)), so the units were left on longer. Still, latent prints were recovered through 18-hour heat exposure (2,231 ADH). Of the 81 prints recovered, 54 ranked within the top half of the 11-point scale and were identifiable. Results were similar after 48 hours (5,991 ADH) and 72 hours (8,968 ADH). During these tests, 89 and 83 latent prints were recovered, with 58 and 61 being deemed identifiable, respectively. Additionally, latent prints were persistent and proven recoverable after five days (14,875 ADH) and seven days (20,948 ADH). Prints insufficient for identification were often adversely affected by moisture in the print and movement when the print was deposited, which occurred independently of heat.

In conclusion, the analyses of latent prints exposed to heat over time could provide valuable information to law enforcement and is an important addition to the body of work in the field of pattern and impression evidence.

Latent Fingerprints, Accumulated Degree Hours, XX Scale

E82 An Efficient Workflow to Recover Examination-Quality Postmortem Fingerprints From Human Remains

Marzena H. Mulawka, MFS, John Jay College of Criminal Justice, 524 W 59th Street, New York, NY 10019; Bryan Johnson, MSFS*, Federal Bureau of Investigation, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Aaron Uhle, MS, 2501 Investigation Parkway, Quantico, VA 22135; Gary W. Reinecke, MA*, School of Medicine, Medical Campus, 72 E Concord Street, L1006, Boston, MA 02118; David Martinez, BS, 5255 Mount Etna Drive, San Diego, CA 92117; and Leah Hogue, San Diego Sheriff's Department Crime Laboratory, 5255 Mount Etna Drive, San Diego, CA 92117*

After attending this presentation, attendees will recognize and understand the various techniques used during Postmortem (PM) fingerprint recovery for obtaining examination-quality fingerprint records from Unidentified Human Remains (UHR). The incorporation of the highlighted workflow into morgue operations may help identify many of the UHR that are being held within Medical Examiner/Coroner's (ME/C) offices throughout the United States. Not only will identification of UHR yield valuable investigative information, but it also allows for the notification of next of kin regarding the fate of their family member. The use of fingerprints for forensic identification is a rapid, reliable, and cost-effective means to identify UHR.

This presentation will impact the forensic science community by furthering the ability of ME/C offices and other medicolegal professionals to enhance operations by utilizing the PM fingerprint recovery workflow to efficiently and effectively handle UHR identification matters. The specific directions and resources needed to use the updated PM fingerprint recovery techniques will be presented.

The use of friction ridge impressions for identification is well established in forensic science; however, the most efficient workflow for PM fingerprinting is often complex and the need for advanced techniques must be determined on a case-by-case basis. The condition of the friction ridge skin on each decedent will dictate which method must be used to successfully enhance and record any valuable friction ridge information; multiple techniques may be used on each UHR. The wide range of techniques include the reconditioning of skin using tissue injection, soaking/rehydration, boiling, manipulation of degloved epidermal skin, as well as recording techniques such as ink/card, fingerprint powder/adhesive lifter/acetate sheet, fingerprint powder/castings, photography, and digital scanning. While some of these techniques are by no means new or foreign to forensics, their utilization is adapted to serve the cause of identifying UHRs. Moving forward, new potential techniques such as 2D and 3D fingerprint scanning may also be introduced into the proposed workflow. A major difference in printing the deceased versus the living is the manipulation of the fingerprinting medium (i.e., fingerprint card, ink pad, scanning platen, etc.). When printing the deceased, the fingerprint medium is being manipulated against the decedent, as opposed to the living, where the person is being manipulated against the medium. Conditions such as rigor mortis, skin slippage, and mummification can all discourage attempts to obtain PM fingerprints from the decedent. Contrary to the predisposition that a specific decedent may not be printable, ridge detail on the epidermis and the dermis can still allow for acceptable friction ridge fingerprints despite the aforementioned conditions. As a result, reconditioning techniques should be used, followed by attempting fingerprint recovery techniques using the specific workflow that will be proposed by this presentation.

Postmortem Fingerprint, Unidentified Human Remains, Forensic Identification

E83 Fire Debris Analysis

Abdulrhman M. Dhabbah, PhD, King Fahad Security College, Saudi Arabia Riyadh, Riyadh, SAUDI ARABIA*

The goals of this presentation are to demonstrate: (1) the evaporation rate of ignitable liquids poured on cotton at different times; and, (2) the comparison between four types of textiles after impregnating them with ignitable.

This presentation will impact the forensic science community by revealing that: (1) the chemical composition of the volatile fraction collected from three fuels (gasoline, kerosene, and diesel) is notably different; (2) the evaporation rate of gasoline is faster than for kerosene and diesel; (3) a Solid-Phase Microextraction (SPME) sampling technique coupled to Gas Chromatography/Mass Spectrometry (GC/MS) is a very convenient, sensitive, and eco-friendly technique for the determination of volatile fuel residues; and, (4) synthetic textiles retain fire accelerant residues longer than natural fabrics.

Arson is a dangerous crime; even a small amount of an ignitable liquid can cause considerable loss of property and even human life. The identification of the arson source is a significant forensic aspect of the criminal investigation; however, it is not always straightforward, as fire often destroys most evidence of arson. In addition to the complex nature of the accelerants and the fire itself, the various materials that are most commonly used to extinguish fires, such as water, dry chemicals, and foams may also affect or even destroy the evidence. The investigations conducted at a fire crime scene should rapidly collect and analyze the debris materials resulting from the fire, including the detection of any remaining hydrocarbons in order to identify the original ignitable liquid. This is why the extraction, isolation, preconcentration, identification, and determination of these target compounds that could be used to accelerate a fire are highly important.

Among the various methods available for extraction of volatile residues from fire debris, SPME proved to be a fast, simple, and efficient extraction technique. This procedure was used, followed by GC/MS to investigate the residues of gasoline, kerosene, and diesel impregnated on various textile materials: cotton, nylon, polyester, and wool. After impregnation, each textile sample was stored in ambient conditions. The remaining fuel residues were collected by SPME, then separated and detected by GC/MS. The obtained results revealed that the polydimethylsiloxane fiber used for SPME was capable of detecting as low as 200µL of each fuel accelerant at optimum conditions. In addition to the properties of the fire accelerant itself and the ambient conditions, the evaporation rate of the fuel-ignitable liquid also depends on the absorption characteristics of the textile substrate. This study demonstrated that the diesel fuel residues were more persistent on all tissue samples than gasoline and kerosene, even four hours after the impregnation. In the same environment, the three investigated fuels (gasoline, kerosene, and diesel) remained a longer time on nylon, then polyester, wool, and cotton. Therefore, collecting fire debris from synthetic fabric samples such as nylon or polyester should be more interesting for medium periods, to allow identification of the fuel accelerant used in the crime scene.

In conclusion, the results obtained in this work demonstrated that the use of SPME for sampling of accelerant residues in arson debris is a fast and effective method and is more convenient than traditional procedures. It allows detection and determination of the fuel constituents even at very low concentrations.

Fuel Residues, Arson, SPME-GC/MS

E84 Race Differentiation by Raman Spectroscopy of a Bloodstain for Forensic Purposes

Ewelina M. Mistek, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Lenka Halamkova, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222; Kyle C. Doty, BS, 2165 Robinwood Avenue, Schenectady, NY 12306; Claire Muro, PhD, University at Albany, State University of New York, Life Sciences Research, Bldg 01113, 1400 Washington Avenue, Albany, NY 12222; and Igor K. Lednev, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222*

The goals of this presentation are to illustrate: (1) the characteristics of current techniques applied for bloodstain analysis during forensic examination; (2) the importance of human phenotype profiling from body fluids found at a crime scene; (3) the significance of a non-destructive method for examination of trace evidence at a crime scene; (4) the advantages of Raman spectroscopy for crime scene examination; (5) Raman spectroscopy for body fluid analysis; and, (6) the application of advanced data analysis for distinguishing between human races based on bloodstains.

This presentation will impact the forensic science community by demonstrating how a non-destructive and rapid method is ideal for characterizing blood donors for forensic purposes. Gathering information about the donor can narrow the search during an investigation and can exclude irrelevant traces before a stain is subjected to DNA profiling. This study demonstrates the application of Raman spectroscopy, combined with chemometrics, for discriminating between Caucasian and African American blood donors.

Human blood is the most common body fluid found at scenes of violent crimes and it is an extremely valuable form of evidence in forensic investigations. The amount of sample available for an analysis could be extremely small. Therefore, proper handling and examination of an evidence is critical to preserve the trace for further examination. The ideal method for bloodstain analysis at a crime scene would be non-destructive, while providing a substantial amount of information about the sample.

In this study, Raman spectroscopy and advanced statistical analysis were applied to discriminate between Caucasian and African American donors based on dry traces of peripheral blood.[1] Samples from 20 donors varying in sex and age were used for collecting Raman spectra. This study utilized Genetic Algorithm (GA) analysis, which helped to select the spectral regions with the largest diversity between Caucasian and African American peripheral blood. For statistical analysis, Principal Component Analysis (PCA) was used to remove outliers. To discriminate between the two races, Support Vector Machines Discriminant Analysis (SVMDA) models were created. The internal Cross-Validation (CV) revealed 71% correct classification of donors based on all spectra included in a training data set. An outer loop subject-wise CV method was also performed and served to evaluate the performance of the SVM classifier for each individual donor from the training data set. The performance of SVMDA, evaluated by the Area Under the Curve (AUC) metric, revealed 71% probability of correct classification at spectrum level and 83% probability of correct classification at donor level for both races. A specificity and sensitivity of 80% was obtained. This proof-of-concept study demonstrated a great potential of Raman spectroscopy for determining a donor's race based on the bloodstain analysis. This method provides rapid and reliable results without any preparation, destruction, or consumption of the sample. The application of Raman spectroscopy at a crime scene is highly probable due to commercially available portable instruments. Furthermore, not only can a stain be identified as blood using this technology but, by incorporating statistical analysis, more information regarding the donor can be obtained, all in a reliable and statistically confident manner.

This project was supported by awards from the National Institute of Justice, Office of Justice Programs, United States Department of Justice (I.K.L.).

Raman Spectroscopy, Blood, Human Race

E85 Nuclear Magnetic Resonance (NMR) Spectroscopy as a Screening Agent for Designer Opioids

Nicole Homburger, Hofstra University, 2827 Len Drive, Bellmore, NY 11710; Megan Chambers, 112 Fern Court, Colchester, VT 05446; and Ling Huang, PhD, Chemistry Department, 151 Hofstra University, Hempstead, NY 11549*

After attending this presentation, attendees will understand the utility of NMR spectroscopy as a screening agent for designer opioids.

This presentation will impact the forensic science community by revealing a new, non-destructive approach to qualitatively and semi-quantitatively analyze pure opioid standards and mock street sample mixtures after minimal sample preparation.

The formulations of synthetic opioids are constantly changing to maintain their legal statuses. These new drugs, often with equivalent or higher potency compared to traditional opioids, are typically derivatives or analogues of controlled substances such as heroin and fentanyl. The lack of analytical standards and the evolving formulation make it increasingly difficult for forensic scientists to identify these new designer drugs.

In this preliminary proof-of-principle study, 16 designer opioids were analyzed with proton NMR, proton-proton Correlation Spectroscopy (COSY), and Total Correlation Spectroscopy (TOCSY). For each sample, 1mg of the drug in solid powder form was dissolved in 0.75ml of either $CDCl_3$ or D_2O, depending on its solubility prior to NMR scans. Then, 1,024 1H-NMR scans were run, lasting two hours. There were 16 COSY and TOCSY scans run per sample, lasting two hours per sample. After the standards were analyzed, mock street samples were prepared by adding caffeine, acetaminophen, and glucose to one of the standards and running proton and COSY scans. A similar method was used in previous studies to rapidly scan for synthetic cannabinoids.[1]

The preliminary results proved that several signature signals in the proton NMR spectra of designer opioids can be used for rapid screening and identification. The three potential signature signal ranges include 6.52ppm–8.28ppm, 4.59ppm–4.76ppm, and 3.02ppm–3.53ppm. Due to structural differences, some designer opioids did not produce a signature signal, which was expected and can be used to exclude certain compounds. For example, most fentanyl derivatives produced a signal in the range 4.59ppm–4.76ppm; however, opioids that are not fentanyl derivatives do not have this signature signal in their spectra. Of the 16 designer opioids analyzed, 15 produced at least one signal within the range 3.02ppm–3.53ppm. The COSY spectra and TOCSY spectra confirm the interactions between the protons on the benzene rings and alkane regions. In the COSY spectra of fentanyl derivatives, there is an interaction between the protons that produced the signals in the range 3.02ppm–3.20ppm. The opioid signature signals could still be isolated and identified from a mixture profile even in the presence of minimal interference (peaks move <.05ppm) or overlap contributed by the cutting agents. The NMR method also enhances the identification of additional isomers in a mixture.[2] Additionally, the proton NMR peaks were integrated and peak areas were utilized to provide semi-quantitative compositions of the opioids and cutting agents within each mixture.

Non-destructive NMR investigation on designer opioids will allow rapid screening of opioids, while also providing semi-quantitative analysis of the substances in mixed street samples. Subsequent GC/MS analysis can still be performed to confirm the identification. The NMR methods will potentially assist investigators in the prediction of the next designer opioid and help law enforcement keep up with new formulations of designer opioids.

NMR, Designer Opioids, Fentanyl

E86 An 11-Year Review Conducted by the West Tennessee Regional Forensic Center (WTRFC) on Deaths While in an Inpatient Rehabilitation or Counseling Center

Braden E. Taylor, 99 Sawyer Circle, Apt 477, Memphis, TN 38103; and Erica Curry, MD, 298 Schilling Boulevard, Collierville, TN 38017*

After attending this presentation, attendees will be able to recognize some of the most common causes of death seen in the inpatient rehabilitation and counseling center setting, in addition to recognizing a variety of other factors that play a role in drug- and alcohol-related deaths.

This presentation will impact the forensic science community by helping medical examiners recognize the most common causes of death seen in the inpatient rehabilitation and counseling center setting, in addition to providing information that will help rehabilitation centers in implementing programs to better manage the health problems that accompany drug and alcohol addiction.

Drug abuse in the United States continues to be a growing problem. According to the National Institute on Drug Abuse (NIDA), the total number of drug overdose deaths in the United States alone has more than doubled from 2002 to 2015, with deaths caused by heroin exhibiting a 6.2-fold increase.[1] Alcohol abuse also continues to be a widespread issue. The Substance Abuse and Mental Health Services Administration (SAMHSA) reports that an estimated 17.3 million Americans were dependent on alcohol or had problems related to their alcohol use in 2013.[2] With these numbers in mind, rehabilitation centers face the daunting task of managing not only their patients' addictions, but also the sequelae of those addictions. The primary purpose of this study is to present a retrospective review of deaths while in an inpatient rehabilitation or counseling center for the treatment of drug or alcohol addiction reported to the West Tennessee Regional Forensic Center (WTRFC) over a 11-year period, from 2006-2016.

There were 14 deaths of persons undergoing treatment for drug and alcohol addiction in an inpatient rehabilitation and counseling center reported to the WTRFC during this 11-year period. All individuals were either found deceased at the inpatient center where they were being treated (4/14, 28.6%) or were transported to a nearby hospital where they were pronounced deceased shortly after (10/14, 71.4%). The yearly distribution of these 14 deaths ranged from 0 deaths in 2006, 2008, and 2015, and up to 3 deaths in 2012 and 2014 (average of 1.4 deaths per year). Most of the individuals involved were male (10/14, 71.4%) and White (10/14, 71.4%). The average age was 44.5 years (age range 21-66 years). The manner of death in a majority of these cases was natural (11/14, 78.6%), while the remaining cases were classified as either an accident (2/14, 14.3%) or a suicide (1/14, 7.1%). Cardiac-related diseases, including hypertensive/atherosclerotic cardiovascular disease and cardiac arrhythmia associated with cardiomegaly, were responsible for many of these deaths (6/14, 42.9%). Other causes of death included complications of morbid obesity (2/14, 14.3%), chronic obstructive pulmonary disease (1/14, 7.1%), bronchopneumonia (1/14, 7.1%), subarachnoid hemorrhage associated with cocaine (1/14, 7.1%), methadone toxicity (1/14, 7.1%), benzodiazepine withdrawal (1/14, 7.1%), and hanging (1/14, 7.1%). Many of the decedents were being treated at their respective rehabilitation centers for polysubstance abuse (5/14, 35.7%). The remaining individuals sought treatment for either alcohol (4/14, 28.6%), cocaine (3/14, 21.4%), opioid (1/14, 7.1%), or heroin addiction (1/14, 7.1%). Among the 5 individuals being treated for polysubstance abuse, opioids were involved in 4 cases (80%), cocaine and benzodiazepines in 3 cases (60%), and alcohol in 1 case (20%). Many of these individuals also presented with mental illness, including schizophrenia (2/14, 14.3%), schizoaffective disorder (1/14, 7.1%), psychosis not otherwise specified (3/14, 21.4%), and bipolar disorder (2/14, 14.3%). Half of the 14 decedents also reported having feelings of depression upon admission to their rehabilitation center.

This retrospective study provides an initial review of drug- and alcohol-related deaths that occurred during treatment at inpatient rehabilitation or counseling centers in Shelby County, TN. These findings may help rehabilitation centers in implementing programs to better manage the health problems and natural diseases that accompany addiction and prevent similar deaths. These findings will also help medical examiners recognize the most common causes of death seen in the inpatient rehabilitation and counseling center setting.

E87 The Development of a Protein Extraction Protocol in Burnt Bone

Ruben Dario Diaz-Martin, PhD, Universidad Nacional Autonoma de Mexico, Av Universidad 3000, Ciudad Universitaria, Ciudad de Mexico, Distrito Federal 04510, MEXICO; Lorena Valencia Caballero, PhD*, Department of Amphitheater, Facultad de Medicina Edif B, Sótano s/n, Av Universidad 3000, Facultad de Medicina, Ciudad Universitaria, Mexico City 04510, MEXICO; and Javier Rolando Ambrosio, PhD, Universidad Nacional Autonoma de Mexico, Av Universidad 3000, Ciudad Universitaria, Ciudad de Mexico 04510, MEXICO*

The goal of this presentation is to illustrate how burnt bone is a common element at forensic and archaeological scenes. It can provide evidence concerning violent acts such as traumas and, in most cases, represents the unique biological evidence recovery at the scene. The isolation of biological molecules in burnt bone remains is a challenge in forensic and archaeological context because of the damage caused by temperature to the bone. The goal of this work was to design a strategy to perform a protein extraction from burnt bone to obtain biological information about the metabolic status of the subject.

This presentation will impact the forensic science community by presenting a non-demineralized extraction method to obtain proteins from the burnt bone in a single step, which can provide information regarding the premortem condition of the subject from biological material damaged by extreme temperatures.

Bone tissue holds valuable information regarding the physiological status of individuals because the cellular components and mineralized extracellular matrix participate in metabolic events.[1] The burnt bone is a common element of forensic and archaeological scenes; this can provide evidence about violent acts such as traumas and, in most cases, represents the unique biological evidence recovery at the scene. Frequently, the recuperation of biological molecules becomes difficult because of the damage caused by temperature in bone. Although there are several kits available in the market to perform DNA extraction, the isolation of other biological molecules in burnt bone remains a challenge in the forensic and archaeological context.[2,3] The proteins represent valuable biological information about premortem events, such as pathologies, metabolic events, nutritional habits, toxicological information, or even causes of death.[4]

Human remains were obtained from individuals registered in the National Institute of Forensic Sciences (INCIFO) in Mexico City and referred to the Amphitheater Department of Medicine Faculty of National Autonomous University of Mexico (UNAM). The samples were subjected to cremation under controlled conditions at a final temperature of 800°C for two hours. Fragments of rib and skull were recovered after cremation and washed two times with Phosphate Buffer Saline (PBS). The burnt bone was pulverized and all the contained proteins were extracted under reduced conditions, precipitated, quantified by the Bradford method, and evaluated by Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) and Western Blot (WB). After electrophoretic analysis and Coomassie blue staining of the non-demineralized extraction products, it was found that several proteins were revealed; meaning they support the cremation process and the non-demineralized method was feasible for recovering proteins from both bone samples. Additionally, due to the evident different electrophoretic pattern of bone samples (rib and skull), it could mean there is a specific expression of proteins between burnt rib and burnt skull. This suggests it can be possible to determine the expression of proteins in burnt bone tissue as an organ-specific method to provide information about the premortem condition of the subject.

Burnt Bone, Protein Extraction, Proteomics

E88 The Effects of Surface Composition and Time Intervals on the Stability of Explosive Residues

Jessica Shiffert, 1713 Forbes Avenue, Pittsburgh, PA 15219; and Stephanie J. Wetzel, PhD, Department of Chemistry and Biochemistry, 600 Forbes Avenue, Pittsburgh, PA 15282*

After attending this presentation, attendees will understand how delayed collection and various surface compositions affect the stability of explosive residues.

This presentation will impact the forensic science community by allowing attendees to better understand the degradation curve of three explosive residues when deposited on three specific surfaces, which will enable the prioritization of evidence collection and analysis in order to aid in investigations of explosion scenes.

As a result of the increased terrorism occurring around the world, the attacks by Improvised Explosive Devices (IEDs) are rising, which leaves them as a constant threat. These devices are not produced for traditional use and are synthesized with home-made components, which makes them unstable and unpredictable. Therefore, additional investigative and analytical efforts are required to identify the explosive elements in IEDs. Both pre- and post-blast residues can be used to identify the explosive element of the IED. Determining the explosive element can aid in the identification of a suspect, which is vital to investigations. These residues can be found at both clandestine laboratories and explosion sites on and around the IED, and various swabbing techniques can be employed to collect them from these locations. It is known that explosive residues will degrade over time; however, it is unknown how the time before collection and different surface compositions affect this degradation. Understanding the degradation curve of explosive residues can be crucial to an investigation. Additionally, this information can allow analysts to prioritize the analysis of evidence that is more likely to yield an identification.

During this research, an alcohol wipe was used as a universal swabbing method to collect explosive residues from multiple surfaces that could be found on an IED or around a clandestine laboratory. These surfaces included galvanized steel, Poly Vinyl Chloride (PVC), and packing tape. Common explosive residues, Royal Demolition eXplosive (RDX), Trinitrotoluene (TNT), and Pentaerythrite Tetranitrate (PETN) were deposited on these surfaces in the form of a liquid standard. These samples were prepared in triplicate to ensure reproducibility, then stored in air-tight containers for the following time intervals: immediate, three days, one week, two weeks, three weeks, and four weeks. Overall, 84 samples per residue were analyzed, generating a total of 252 samples. An optimized method was developed for Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) in Atmospheric Pressure Chemical Ionization (APCI) negative ion mode to identify the explosive compounds. All samples were compared to the immediate time interval to calculate a percent recovery of the explosive residue, then the data was analyzed to see if a trend was observable in the degradation rates. The results of this experiment show the degradation effects of surface composition and delayed collection.

Explosive Residues, LC/MS/MS, Universal Swab

E89 Cytochrome P450 and Chemical Oxidation of Synthetic Cannabinoids JWH-015 and Bay 59-3074

Oluseyi A. Vanderpuye, PhD, Forensic Science, 504 College Drive, Rm 118, Hartnett Bldg, Albany, GA 31705; Alexis K. Bailey, 1717 Mazor Drive, Columbus, GA 31907; and Christina Dunn, 10 Ironwood Court, Newnan, GA 30265*

After attending this presentation, attendees will learn the applications of Thin-Layer Chromatography (TLC) and Ultraviolet (UV) -Visible spectroscopy to characterizing chemical oxidation of synthetic cannabinoids, and how *in vitro* systems such as human liver microsomes and recombinant cytochrome P450 enzymes can be used to elucidate metabolism of synthetic cannabinoids.

This presentation will impact the forensic science community by identifying metabolites for detection of the abuse of the synthetic cannabinoids Bay 59-3074 and JWH-015.

It is hypothesized that *in vitro* incubation with human liver microsomes will allow production of metabolites of JWH-015 and Bay 59-3074. It is also postulated that oxidation of synthetic cannabinoids with chemical reagents will produce some of the same products produced by cytochrome p450 enzymes in the course of metabolism and eventually allow production of metabolite standards.

Methods used in this research included TLC and UV-Visible spectroscopy of synthetic cannabinoids exposed to human liver microsomes, recombinant human cytochrome p450 2D6, and chemical oxidants (sodium hypochlorite and hydrogen peroxide). These analyses will be supported by Fourier Transform Infrared (FTIR) spectroscopy and High-Performance Liquid Chromatography (HPLC).

The first set of experiments determined that millimolar concentrations of the synthetic cannabinoids JWH-015 and Bay 59-3074 were detectable by TLC on silica gel 25 under UV light. The JWH-015 and Bay 59-3074 were incubated with Human Liver Microsomes (HLM) or with buffer only as controls and, after centrifugation, the products were analyzed by TLC and UV-Visible spectroscopy. As controls for cytochrome P450 enzymatic activity of the HLM, the substrates coumarin, and eosin were incubated under the same conditions. The synthetic cannabinoids were not detectable by TLC after incubation with the HLM. The UV fluorescence of the main component of eosin was unaffected, but the fluorescence of a faster-moving component was decreased in one incubation with HLM. The coumarin incubation contained a new, faster-migrating (higher Retention factor (Rf) value) blue component after incubation with HLM but not after incubation in the control buffer lacking HLM.

UV-Visible spectroscopy detected increases in absorbance at 340nm, 337nm, and 310nm in the JWH-015 after incubation with HLM compared to the control. For the Bay 59-3074, UV-Visible spectroscopy detected a decrease in absorbance at 337nm and 340nm and an increase at 310nm after incubation with HLM. An issue with the incubations of the synthetic cannabinoids with HLM is the necessity to work with relatively high dilutions of these compounds because of the low solubility in aqueous buffers and the need to minimize concentrations of organic solvents in which they are soluble to avoid denaturation of the cytochrome P450s.

The synthetic cannabinoids JWH-015 and Bay 59-3074 were treated with sodium hypochlorite to see if oxidation could be detected by TLC for future comparison of the changes to those produced by cytochrome p450 or HLM. The Rf value (or mobility) of JWH-015 on TLC was decreased after incubation of the compound with sodium hypochlorite compared to control, but that of Bay 59-3074 was unaffected. Incubations with the oxidizing agent were also performed with two control substances: eosin and coumarin. In the case of eosin, two fluorescent components were detected in untreated controls whose intensity diminished with incubation with increasing concentration of oxidant. In the case of coumarin, two components were observed under UV-light on TLC plates, the slower moving of which decreased in intensity with an increasing concentration of oxidant.

It is concluded that *in vitro* incubation with human liver microsomes reveals some promise for producing metabolites for chemical characterization for the synthetic cannabinoids Bay 59-3074 and JWH-015. This may help in detecting metabolites of these compounds in biological samples. Further work can also be conducted by using FTIR and HPLC, but Liquid Chromatography/Mass Spectrometry (LC/MS) and Gas Chromatography/Mass Spectrometry (GC/MS) approaches are likely to be most suited for characterizing these metabolites. Chemical oxidation may be further explored as a means of generating oxidized forms of synthetic cannabinoids that are similar to those produced by metabolism.

Cannabinoids, Cytochrome P450, Metabolism

E90 Optimal Headspace Extraction for the Detection of Volatile Organic Compounds (VOCs) Released From Triacetone Triperoxide (TATP) Using Solid-Phase Microextraction (SPME)

Kelvin J. Frank, Jr., BS, Florida International University, Chemistry Dept, 1712 SW 104th Place, Miami, FL 33174*

The goal of this presentation is to provide attendees with: (1) more insight into the headspace analysis of TATP; and, (2) detailed information into the VOCs associated with this explosive.

This presentation will impact the forensic science community by presenting a precise, safe, non-explosive, volatile compound in the form of a Controlled Odor Mimic Permeation System (COMPS) that will ultimately equip canine teams with the ability to detect TATP. The dominant headspace odors associated with TATP can be used in the creation of effective canine training aids using COMPS.

Due to its high instability and ease of detonation, TATP is often difficult for canine trainers and handlers to access for regular training purposes. As a result, the majority of canine explosive detection teams are unable to reliably detect this explosive.

TATP, first discovered in 1895, has become very prevalent among terrorist and other malicious groups worldwide since the early 2000s. The infamous 2001 "shoe bomber" utilized TATP, as did terrorists involved in the 2005 and 2006 London attacks. Bombs detonated at the University of Oklahoma in 2005 and Texas City in 2006 also contained traces of the chemical. More recently, this explosive was involved in famous attacks in Paris, Brussels, and Manchester in 2015, 2016, and 2017, respectively. One of the main reasons for TATP's increased use is the fact that it can be easily manufactured using inexpensive, commercially available household items, namely acetone and hydrogen peroxide. More importantly, it is very difficult to detect by traditional security scanners since it does not contain nitrogen. Nitrogen is a common component of explosives that security scanners can successful detect; however, these same scanners are unable to detect TATP. It has been proven that explosive detection canines can successfully detect TATP; however, they are unable to train and maintain proficiency with detecting this explosive because of a lack of availability of TATP during routine maintenance training. To combat this, identification of the TATP VOCs, followed by the development of suitable mimic training aids using COMPS will be conducted.

This study will present results of a developed optimal extraction method for VOCs from TATP utilizing a headspace SPME technique on solid, as well as diluted, TATP samples to reveal those headspace components that are most likely responsible for an alert from explosive detection canines. The dominant headspace odors associated with this explosive will, therefore, be used in the creation of effective canine training aids using COMPS. These peroxide-based COMPS will fill the current law enforcement gap of not being able to train explosive detection canines on peroxide-based explosives by providing an alternative and effective training aid. By using COMPS, the signature headspace odor is housed in a permeable polymer that releases the identified odor at a known and controlled rate. This technique will satisfy the thousands of law enforcement detection canines nationwide that are currently unable to detect peroxide-based explosives as a result of a lack of availability of the material for training purposes. A large number of canine handler teams will, therefore, be able to utilize the developed peroxide-based COMPS to train their canines to recognize these signature odors associated with TATP and, ultimately, improve their detection of the actual explosive.

Triacetone Triperoxide (TATP), Solid-Phase Microextraction, COMPS

E91 The Investigation of Ancestral Origins Using Human Cranial Hair

Sirena Lam, 184 Derby Avenue, 2nd Fl, Derby, CT 06418; Robert H. Powers, PhD, University of New Haven, Dept of Forensic Sciences, 300 Boston Post Road, West Haven, CT 06516; and Alyssa L. Marsico, PhD, University of New Haven, 300 Boston Post Road, Dodds 422, West Haven, CT 06516*

After attending this presentation, attendees will gain a different perspective of the amino acids that are present in human cranial hair from individuals of different ancestral origins and will recognize the vital characteristics that could potentially allow for human individualization using hair.

This presentation will impact the forensic science community as it sheds valuable insight on an unbiased method for hair analysis. This research may assist investigators in determining the ancestral origin of individuals using their hair samples on a more objective level compared to conventional forensic hair analyses.

Human hair is often collected at a crime scene, and Microscopic Hair Comparison (MHC) is typically performed, along with DNA analysis, if possible. Unknown samples are microscopically assessed and compared to those of known origin to identify distinct morphological characteristics. Although MHC is a useful screening tool, it relies heavily on the experience and knowledge of the examiner. Hence, it is more subjective and the significance of the results can easily be overstated, leading to flawed testimonies. On the other hand, DNA analysis is a confirmatory test, but results from hair are not always consistent. This is because nuclear DNA degrades rapidly during hair keratinization and is only present in the hair root. Alternatively, mitochondrial DNA (mtDNA) can be used to generate genetic profiles from samples with no root attached as it is found on the hair shaft; however, the amount of mtDNA recovered varies in each case and depends on the individual. Thus, DNA analysis using hair may not be possible in certain cases.

Unfortunately, MHC and DNA analyses are limited options that could serve as roadblocks and potentially reduce the evidentiary value of hair. Therefore, additional studies are necessary to explore other comprehensive techniques. This research utilizes a more objective approach for hair analysis, notably to assist in the differentiation of ethnic origins without the heavy scrutiny and subjective nature of MHC. Hair is mostly composed of proteins and, therefore, contains a large amount of amino acids that can provide information specific to the donor. Considering this, ratios of three amino acids -— serine, phenylalanine, and threonine -— were utilized to investigate differences in hair from donors of different ancestral origins.

With consent, hair fibers from four regions of the head were collected from three individuals of the Mongoloid, Caucasoid, and Negroid anthropological groups. All samples were washed to remove surface contaminants, ground, and digested to break proteins down into amino acids. Finally, samples were derivatized to increase sample volatility and analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). Chromatographic data was obtained using scan mode, the integrated peak areas were measured, and various amino acid ratios were calculated for all individuals. Results indicate that two ratios, serine to phenylalanine and threonine to phenylalanine, are different in all three samples. The greatest difference in both ratios was between individuals of Mongoloid and Negroid descent. These results imply that certain amino acid ratios may vary among people of different ethnic origins and that this method is potentially useful in distinguishing individuals of different ethnic backgrounds in cases in which MHC is insufficient or DNA analysis cannot be performed.

Hair Proteins, Amino Acids, GC/MS

E92 The Classification of Forensic Soil Evidences by Application of Thermally Assisted Hydrolysis and Methylation With Pyrolysis-Gas Chromatography/Mass Spectrometry (THM-Py-GC/MS) and Multivariate Analysis

Choong Sik Lee, MS, Criminal Investigation Command of Korean MND, 22, Itaewon-ro, Yongsan-Gu, Seoul 140-701, SOUTH KOREA*

The goal of this presentation is to discuss the following findings of this study: (1) GC/MS could be applied by *in situ* methylation of low volatile Soil Organic Matters (SOM) contained in a small amount of soil without complicated preparation; (2) the variation in the amount of soil was minimized by data normalization; (3) the chemotaxonomic marker compounds could be determined; and, (4) the data could be statistically interpreted confidently for soil classification. In this study, THM-Py-GC/MS produced many compounds due to the high complexity of SOM.

This presentation will impact the forensic science community by illustrating how SOM profiling can be used as a complement to mineralogical techniques in statistically classifying soil evidences and in finding chemotaxonomic marker compounds in forensic soil classification.

The forensic classification of soil samples was performed by THM of SOM using Py-GC/MS).[1] In this work, 33 THM derivatives were detected as SOM contained in <3mg soil.[2] Soil was *in situ* thermally hydrolyzed and methylated with Tetramethylammonium Hydroxide (TMAH) in pyro-foil. The specific ions of the mass spectra were selected to separate and minimize the interference between SOM peaks. SOM data were normalized with the sum of peak areas to correct the amounts of SOM contained in the soil, and the chemometric approach based on Principal Component Analysis (PCA), Hierarchical Cluster Analysis (HCA), and Linear Discriminant Analysis (LDA) was employed to evaluate and compare the soil classification.[3] The first seven Principal Components (PCs) accounted for 94.8% of the total cumulate variance and these PCs were statistically determined by multiple comparisons (Tamhane's T2 and Dunnett's T3) for the post hoc test (p-value <0.05) and were used to construct the LDA model. It was determined that multiple comparisons (Tamhane's T2 and Dunnett's T3) were a statistically good criterion for deciding on the number of PCs for the LDA model. It was also concluded that the discrimination model correctly classified 40 soil samples into six clusters with high accuracy. Furthermore, the 11 marker compounds were investigated according to the loadings of PCs and the normalized data. It was found that six clusters are differentiated by the presence of lignin, fatty acids, and urea.

This method can provide some advantages: (1) GC/MS could be applied by *in situ* methylation of low volatile SOM contained in a small amount of soil without complicated preparation; (2) the variation in the amount of soil was minimized by data normalization; (3) the chemotaxonomic marker compounds could be determined; and, (4) the data could be statistically interpreted confidently for soil classification.

In this study, THM-Py-GC/MS produced many compounds due to the high complexity of SOM. To differentiate soils, PCA, HCA, MC, and LDA were performed to extract the information necessary to characterize soil groups. These results demonstrated that lignin, fatty acid, and urea can be used as potentially useful compounds to characterize soil samples for forensic purposes. These results represent a preliminary investigation of trace organic matter present in soil. It is believed that SOM profiling can be used as a complement to mineralogical techniques in statistically classifying soil evidence and in finding chemotaxonomic marker compounds in forensic soil classification.

Forensic Soil, Soil Organic Matters, Multivariate Analysis

E93 A Comparison of Bioelectrical Impedance Analysis Techniques for Estimating Postmortem Interval (PMI)

Eriek S. Hansen, PhD, Dept Biological Science, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501; Christiane Baigent, MSc, Forensic Investigation Research Station, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501; and Melissa A. Connor, PhD, Colorado Mesa University, 406 Lowell Heiny Hall, 1100 North Avenue, Grand Junction, CO 81501-3122*

After attending this presentation, attendees will understand the use of Bioelectrical Impedance Analysis (BIA) for estimating the PMI using Accumulated Degree Days (ADD).

This presentation will impact the forensic science community by presenting developments in a new quantitative method for estimating PMI.

Methods for estimating PMI are an integral part of the medicolegal investigation. The probative value of PMI estimation necessitates eliminating subjectivity. Major confounding factors in PMI estimation include: (1) the lack of regionally specific models; and (2) the challenges associated with estimation in late stage decomposition. BIA was a novel approach proposed by Hansen et al. as a quantitative method for PMI estimation.[1] The method was based on the dielectric properties of biological tissue, which function as a resistor-capacitor circuit. Decomposition changes the circuit in ways that can be quantified using BIA. The goal of this research was to further develop BIA techniques for estimating PMI using BIA measurements and ADD.

BIA techniques using human donors were developed at the Forensic Investigation Research Station, Colorado Mesa University, Whitewater, CO. Two BIA measurement approaches, fixed-distance and variable-distance, were tested on different body segments in this study. Both approaches used hypodermic needles inserted subcutaneously. In the fixed-distance approach, the source and detecting electrodes were positioned at left and right midfemur and midhumerus. The circuit formed in tissue between the detecting electrodes and electrode distances did not vary among donors. In the variable-distance approach, larger body segments were isolated by positioning the electrodes at specific anatomical landmarks. Detecting and source electrodes were paired 10cm apart, and the distance between pairs varied among donors according to individual limb length. Three body segments were used: hand-foot, thigh-foot, and hand-shoulder. Resistance (R) and reactance (X_c) were measured using a single-frequency, 400µA, 50kHz BIA unit. An on-site weather station measured ambient temperature hourly. The daily mean temperature was used to calculate ADD. Total Body Scores (TBS) were calculated following Megyesi et al.[2] Measurements of R and X_c were derived to impedance (Z) and standardized by the distance between detector electrodes.

Linear Mixed Effects Models (LMEM) were used to estimate ADD. This statistical model permits repeated measurements on a single donor. The fixed effects were TBS^2 and Z. The random effects for both intercept and slope were Z and the individual Donor. Model estimates were evaluated by comparing observed ADD (x) versus predicted (y) ADD. Analyses were completed in Program R using the lme4 package.[3,4]

Fixed-distance BIA measurements were possible for a maximum ADD of 6,072 for the midfemur and 6,128 for the midhumerus. Variable-distance measurements were possible for a maximum ADD of 874 for the hand-foot, 874 for the thigh-foot, and 778 for the hand-shoulder body segments. Conditional R^2 for the LMEM were 0.91 for the midfemur, 0.89 for the midhumerus, 0.94 for the hand-foot, 0.95 for the thigh-foot, and 0.95 for the hand-shoulder. The observed ADD versus predicted ADD were similar to the 1:1 relationship for each body segment.

The development of BIA as a method for estimating PMI continues to show promise. Hansen et al. demonstrated that the approach can be used on human remains using gel pads.[1] Measurements using gel pads lasted 227 ADD. This study demonstrates that the use of needles with fixed-distance measurements has the potential for significantly longer PMI estimation. Both the fixed and variable measurements accurately estimate ADD, but differ in the period over which measurements were possible.

BIA demonstrates the potential to address two challenging factors in PMI estimation -— the lack of quantifiable methods and the challenge of estimating PMI in late stages of decomposition. As an objective measure of changes to body composition, BIA may be statistically combined with region-specific macromorphoscopic scoring models for more accurate PMI estimation; however, BIA approaches have not yet been subjected to blind validation tests and models are still being refined, necessitating further work.

This project was supported by an award through the National Institute of Justice, Office of Justice, and the United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation were those of the authors and do not necessarily reflect those of the Department of Justice.

Bioelectric Impedance Analysis, Decomposition, Postmortem Interval

E94 Determination of Intent: Accident, Suicide, or Homicide? The Utilization of Social Behavioral Science Within the Medicolegal Death Investigation Process

Barbara C. Wolf, MD, District 5 MEO, 809 Pine Street, Leesburg, FL 34748; Kyle Shaw, MBBS, District 5 MEO, 809 Pine Street, Leesburg, FL 34748; and Brett E. Harding, MBA, District 5 MEO, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will better understand the difficulties in the forensic evaluation of a decedent's state of mind at or near the time of death. Attendees will be more familiar with interviewing and questioning methods for elucidating accurate information that will aid the forensic pathologist in the determination of the cause and manner of death.

This presentation will impact the forensic science community by providing a more scientifically grounded process for assessing the intent of an individual who cannot be interviewed. Medicolegal death investigators, medical examiners, and coroners will be able to apply this process to specific deaths encountered in forensic death investigations.

Many field investigations are conducted each year as part of the process in determining cause and manner of death. In nearly all cases, the manner of death is dependent on the circumstances surrounding the event. Others not only depend on the circumstances but also the intent of the decedent. These situations often present a problem for law enforcement, the medicolegal investigators, and the forensic pathologist because a scientific methodology for ascertaining an individual's state of mind or intent prior to death has not been readily available.

Access, availability, and the cost associated with consulting a forensic psychologist often prohibit obtaining such a consultation. Additionally, the mental assessment conducted by law enforcement, medicolegal death investigators, and even forensic pathologists may be problematic because these professionals may have little to no formal education in the social behavioral sciences.

Medicolegal death investigations vary greatly, as do the backgrounds of the investigative professionals. The goal of obtaining information useful in determining the cause and manner of death can at times be a simple process and at other times complex. These forensic investigations can include various and differing modes that lead to death, falls, motor vehicle collisions, drowning, and aircraft crashes, to name just a few. Recognition of clues distinguishing an accidental, suicidal, or homicidal death can be elusive. Distinguishing the antemortem psychological state of an individual can prove to be even more problematic for investigators.

Inaccurate or incomplete information supplied to forensic pathologists regarding an individual's psychological state may result in a misdiagnosis regarding the manner of death. This could lead to both emotional and financial hardships for families. Also, statistical information used in the allocation of governmental funding can be adversely affected. Finally, and most tragically, is that a homicidal death goes undetected because of inaccurate conclusion.

A survey of forensic literature reveals few basic field methods for accurately gathering this needed information. This study presents a sequential social behavioral field methodology utilized in the course of a medicolegal death investigation. These include scene evaluation and the directed questioning of family, friends, and other individuals. These methods, used as part of a multidisciplinary approach, may yield more fruitful and effective forensic conclusions.

Psychological, Medicolegal, Multidisciplinary

E95 Forensic Archaeology Matters: Methods, Differentiation From and Contributions to, Other Forensic Strategies in Crime Scene Investigation

Sharon K. Moses, PhD, Northern Arizona University, Dept of Anthropology, PO Box 15200, Flagstaff, AZ 86011-5200; and Kimberlee Sue Moran, MSc*, Rutgers University - Camden, N 5th Street, Camden, NJ 08102*

After attending this presentation, attendees will better understand how forensic archaeology and its methodology is differentiated from general archaeology, forensic anthropology, and other forensic methods. This presentation will familiarize attendees with the unique contribution to crime scene investigations that forensic archaeology offers. In general, most crime scene investigation training does not address approaches to and strategies employed with regard to variable environmental factors, human and animal behaviors, and the impact these have on clandestine burials and body dumps. Outdoor settings present a unique set of challenges that call for a unique methodology toward reconstructing the crime scene and collecting evidence that training for indoor crime scene investigation does not typically address.

This presentation will impact the forensic science community by demonstrating the value of forensic archaeology and archaeological techniques to criminal investigations broadly. While archaeological methods have long been employed by forensic anthropologists in body recovery, the same methods utilized by archaeologists have direct applications to all crime scene examination and reconstruction. The recognition of forensic archaeology as a specialty beyond burial excavation will encourage greater incorporation of archaeologists into the forensic community.

This presentation will demonstrate that forensic archaeology is more than simply a learned skill set of technical knowledge for creating grids, excavation, and mapping a crime scene. Forensic archaeologists have an in-depth knowledge of landscapes and seasonal, and environmental changes that affect artifact deposition and distribution (which includes the body) over time in multivariable site formation processes. The value of this in-depth knowledge toward determining the proper approach to each body recovery scene and for contributing to understanding victim and perpetrator interaction in the death event and disposal cannot be overstated. Forensic archaeology emphasizes contextual relationships within an environment and among the evidence of human activity. This fundamental framework of "context" enables a holistic approach to evidence interpretation.

Forensic archaeology in concert with other forensic methodologies offers unique value toward reconstructing the crime scene and/or the deposition of the body, collection methods of artifacts that preserve evidentiary integrity, reconstructing timelines, and working with law enforcement, coroner, and medical examiners' offices *before* the human remains and its associated artifacts are delivered and analyzed in a laboratory setting. Improper handling of the outdoor crime scene can be deleterious to compiling evidence and data for courtroom proceedings and should not be left to those who do not have the academic background and knowledge of a forensic archaeologist.

Forensic Archaeology, Crime Scene Investigation, Methods

E96 Geographic Information Systems (GIS) and Predictive Modeling of Body Disposal Sites

Annemarie C. Gundel, MA, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will understand a new method of locating clandestine body disposal sites in the medicolegal context using GIS and predictive modeling.

This presentation will impact the forensic science community by presenting a new technique to assist in locating clandestine body disposal sites in the medicolegal context. Predictive modeling of body disposal sites will narrow search areas beyond the information provided by witness testimony and blind luck, which will maximize resources for law enforcement when searching for missing victims.

Homicide victims are often discovered by accident or located through witness testimony, both of which are unreliable methods.[1] Moving a victim's body from the scene of the crime to a secondary site for disposal may further complicate the discovery, delaying recovery, identification, and evidence collection. Homicides are exponentially more difficult to investigate, solve, and prosecute without a body. This current study seeks to improve search methods by creating predictive models of body disposal location, which can be used in conjunction with witness testimony and traditional law enforcement search techniques.

Predictive models were created using body disposal data collected from the Office of the Chief Medical Examiner (OCME), Connecticut, to explore the feasibility of predicting body disposal sites. Prior to creating predictive models, spatial statistical tests, including Moran's I, Kernel Density, and Ripley's *K*, were conducted to determine if body disposal sites were homogeneously distributed across Connecticut. Next, two predictive models were created: one inductive model and one deductive model, both using non-sites mimicking Complete Spatial Randomness (CSR). The final inductive model equation was determined using logistic regression and stepwise selection to remove non-significant variables. The final deductive model equation was determined using the weighted map-layer approach using only variables where site values were significantly different from non-site values. Both final equations were entered into arcGIS® 10.3 using the Spatial Analyst extension to generate the final predictive surfaces.[2]

Spatial statistical analyses confirm that body disposal locations are inhomogeneously distributed across Connecticut. Results indicate predictive models of body disposal location are 56%–59% more likely to predict body disposal site location in Connecticut than random chance. At present, the models are most successful at predicting body disposal sites in urban areas. Future modeling efforts should address predicting body disposal site location in rural areas.

Predictive models of body disposal location are not intended to replace the current methods of victim search and recovery; rather, they are intended to be yet another tool in the investigative toolkit. The results of this study indicate that predictive models of body disposal location have a real possibility of narrowing search areas and maximizing resources for law enforcement when searching for missing victims.

E97 Deconstructing Desiccation and Decomposition

Melissa A. Connor, PhD, Colorado Mesa University, 406 Lowell Heiny Hall, 1100 North Avenue, Grand Junction, CO 81501-3122; Christiane Baigent, MSc, Forensic Investigation Research Station, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501; and Eriek S. Hansen, PhD, Dept Biological Science, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501*

After attending this presentation, attendees will understand the importance of testing individual descriptive categories for estimating Postmortem Interval (PMI).

This presentation will impact the forensic science community by presenting the relationship between gross morphological changes in decomposition and their relationship to the environmental variables of temperature, humidity, solar radiation, and wind speed.

Documented attempts to determine the PMI based on gross morphological change date back at least to the 13th century.[1] Micozzi discussed sequential stages of decomposition, but points out that the dynamic nature of several interacting variables make it impossible to assign those stages to an absolute time since death.[2] Despite this caveat, and because of the probative value of the PMI, approximate times are frequently assigned, particularly to the early stages of decomposition (e.g., Clark et al.).[3] Based on the correlation between gross morphological change and temperature, Megyesi et al., as well as others, have proposed predictive models for estimating PMI throughout the trajectory of fresh to skeletonization.[4] Vass and Sorg and Wren added humidity to models (accumulated relative humidity days), and found that shade from a forest canopy played a role in decompositional differences.[5,6] They posit that both regional and microenvironmental differences significantly affect decomposition, supporting the need for regional decomposition sequences. Research conducted using human donors at the Forensic Investigation Research Station (FIRS), Colorado Mesa University, yielded the Total Body Desiccation Score (TBDS) within which Connor et. al. described a region-specific decomposition sequence and discussed its predicative ability in an arid environment, by adding descriptive categories useful for desiccated remains.[7]

This present study takes the general descriptive categories used in the TBDS (color, bloat, moisture, desiccation, and skeletonization) and compares the scores to Accumulated Degree Days (ADD), Accumulated Humidity Days (AHD), Accumulated Solar Radiation (ASR), and Accumulated Wind Speed (AWS). Each variable was calculated in a manner similar to ADD and AHD; a daily minimum/maximum average is successively added across all days within a defined PMI. The lower threshold for ADD is defined as 0°C (following Megyesi et al.); AHD, ASR, and AWS were not assigned a floor or ceiling threshold.[4] TBDS scores were considered both in sum, and by body segment, including: head and neck, torso, arms and legs.

Preliminary results suggest that some TBDS descriptors correlate with ADD more strongly than others (listed in order of efficacy): skeletonization (0.85), moisture (0.82), desiccation (0.70), color (0.69), and bloat (0.57). The head and neck region showed the strongest correlation with ADD (0.91). All environmental factors demonstrated strong correlations to TBDS: ADD r=0.81, AHD r=0.80, ASR r=0.83, and AWS r=0.83.

Further research will be used to strengthen the TBDS method by weighting the factors that were strongly correlated with PMI. Preliminary results at FIRS indicated that placing more weight on specific body regions (i.e., the head and neck region) and considering environmental variables such as solar radiation and wind speed in predictive models, along with temperature, has the potential to increase model robusticity.

Finally, comparative research in other geographical regions needs to be conducted. In the semi-arid west, solar radiation and wind speed were important correlates with decomposition. These additional environmental variables may be more powerful correlates for different decomposition stages and may be useful for developing predictive models. In other environments, these environmental variables may be less important and other environmental variables may be more useful. Exploring these factors will both deepen the understanding of macroscopic variation in decomposition and build stronger, microenvironment-based models for assessing the trajectory of decomposition and building analytical models for estimating PMI on human remains.

This project was supported by an award through the National Institute of Justice, Office of Justice Programs, and the United States Department of Justice. E98 A Comparison of Insect Activity on Different Carrion Types at the Anthropological Research Facility (ARF) in Knoxville, Tennessee

Kristi Bugajski, PhD, 1610 Campus Drive, E, Valparaiso, IN 46383; Angela M. Dautartas, MA*, University of Tennessee, 250 S Stadium Hall, Knoxville, TN 37996; Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Knoxville, TN 37996-1525; and Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 37996*

After attending this presentation, attendees will better understand how entomologists and anthropologists can work together to obtain meaningful research results. Attendees will learn how the insect activity on human cadavers, rabbits, and pigs differ from one another. The hypothesis of this project was that the insect activity would differ in timing and pattern for different carrion types.

This presentation will impact the forensic science community by illustrating how entomologists and anthropologists can have a close working relationship with each other. This research is also important because having suitable substitutes for human cadavers is imperative for research projects.

If one looks into the forensic science literature, there is a wide range of human cadaver substitutes used across the world. Animals in a wide range of sizes and hair content, from rats to pigs and a variety of species in between are used.[1,2] Pigs have been studied at the ARF in Knoxville, TN, previously, but are the only animal to date that has been studied as an acceptable human cadaver substitute.[2] It is not possible for all research to be conducted on human cadavers, so projects such as this one that compare the decomposition of different animals are very important.

Five subjects of each species were placed in the same microenvironment at the ARF during three separate trials. The three trials spanned three seasons: spring, summer, and winter. Decomposition progression was measured using the Total Body Scoring (TBS) system developed by Megyesi and colleagues.[3] Additional data collected included hourly ambient temperature, daily photographs, and the presence of scavenging activity. When insects were active, adult fly and beetle specimens were caught and preserved, and fly larvae were collected and preserved.

From the daily observations and photographs, it was noted that larval activity did not maintain the same location pattern in each carrion species. While some areas of larval activity were similar (e.g., masses in the eyes and nose), the pigs had consistent large masses under the tail and the rabbits had masses internally that were not able to be observed until late stages of larval development. These location pattern differences had distinct impacts on the decomposition progression and corresponding TBS between the different subject species. This aspect of insect activity has previously not been discussed during comparative studies of various carrion species.

Insects that were collected during the experiment are being identified, and the results will be discussed during the presentation. Differences in species composition on different carrion types as well as the timing of the insect activity will also be discussed.

This project was supported by the National Institute of Justice, Office of Investigative and Forensic Sciences, United States Department of Justice. The opinions, findings and conclusions or recommendations expressed in this presentation are those of the researchers and do not necessarily reflect the views of the Department of Justice.

Insect Activity, Forensic Anthropology, Forensic Entomology

E99 Taking the Bite Out of Requesting Antemortem Dental Records

Tracy A. Brookshire, BS, Champaign County Coroner's Office, 202 S Art Bartell Road, Urbana, IL 61802; and David A. Wold, DDS*, 535 S York Road, Ste B, Bensenville, IL 60106*

After attending this presentation, attendees will be able to implement methods of requesting antemortem dental records from a variety of sources and conduct family interviews to assist in the acquisition of antemortem dental information.

This presentation will impact the forensic science community by providing techniques to improve communication between medicolegal death investigators and dental offices for the purpose of requesting comprehensive antemortem dental records in forensic identification, along with methods to assist in family interviews to yield complete antemortem identification information.

Correct identification is one of the primary responsibilities of the coroner or medical examiner. Forensic dental identification is just one of the many tools in that process. Medicolegal death investigators' abilities to quickly and accurately obtain antemortem dental records can expedite this process. Without accurate antemortem dental records, a forensic dental identification is not possible. The first step in acquiring antemortem dental records is conducting a comprehensive family interview. Requesting not only the most recent family dentist contact information, but any additional previous dentists and dental specialists, whether the decedent had military service or had been incarcerated in the department of corrections, in addition to previous employers is also pertinent and can increase the probability of acquiring a multitude of quality dental records.

Basic dental terminology can assist medicolegal death investigators in requesting antemortem dental records. The decedent's previous dentist may only provide a limited amount of previous records unless otherwise specified. When requesting dental records, the most recognized request is for radiographs. Medicolegal death investigators' knowledge of dental radiographs can be very helpful, both to the decedent's previous dentist and to the forensic odontologist. The most widely used types of dental radiographs are panorex, bitewings, and periapical radiographs. A panorex is a radiograph of the entire jaw that extends upward to include the maxillary sinuses and orbital socket and downward to the mandibular jawline and chin. A bitewing radiograph or, as it is sometimes called in layman's terms, cavity detecting radiograph, includes the coronal surface of both maxillary and mandibular arch. A periapical radiograph includes teeth in their entirety including the coronal surface extending to the tip of the root and supporting structures. Along with requesting dental radiographs, it is also extremely important for the forensic odontologist to have access to the written charting, odontograms (a rudimentary depiction of the teeth), ledger, and the medical history. Radiographs only give a one-dimensional picture; having access to written charting and ledgers allows the forensic odontologist to determine restoration surfaces and materials used. The medical history can also yield pertinent decedent information, such as previous medical therapy, surgeries, and implanted devices. Given the digital and electronic age, retrieval of antemortem dental records has become more easily accessible. Entire dental records can be easily emailed to the investigator or forensic odontologist.

Forensic dental identification can be a very quick, accurate, and relatively inexpensive method of identification for the coroner or medical examiner. The accuracy of the medicolegal death investigator in acquiring quality dental records in a timely manner will only expedite this service. It is vital for the medicolegal death investigator to have training in family interviews for the purpose of gaining antemortem dental information in addition to knowledge of the variety of sources of dental records.

Forensic Odontologist, Antemortem Dental Records, Family Interview

E100 A Retrospective Study of Homeless Deaths in the County of Santa Clara, California

Karin E. Wells, BA, 416 Ewell Avenue, Aptos, CA 95003; and Michelle A. Jorden, MD, Santa Clara ME, 850 Thornton Way, San Jose, CA 95128*

The goal of this presentation is to present causes of death and other variables affecting the homeless community upon review of autopsy and investigative reports at the Santa Clara County Medical Examiner-Coroner's Office spanning the years 2011 through 2016.

This presentation will impact the forensic science community by further defining the definition of homelessness used by the Santa Clara County Medical Examiner-Coroner's office and illuminating the trends in homeless deaths over the past six years. For the years 2011 through 2016, there were 476 homeless deaths in Santa Clara County, an increase of 164%. The number of deaths affecting the homeless population continues to rise, with the most deaths observed to date occurring in 2016.

The importance of a definition of homelessness is that it allows for county-wide consistency in classification. Those included in this study's definition of homeless consist of people living on the street in indoor and outdoor makeshift living areas, including homeless encampments, parks, motor vehicles, and recreational vehicles, as well as those individuals living in homeless shelters, motels, or any type of funded or transitional housing. Also included in this study's definition are individuals who did not have a valid living address upon a public records search.

Each year was analyzed separately for the following variables: decedent demographics; cause and manner of death; location of death; medical history; the presence and use of drugs; veteran status; and motor vehicle-related deaths. The yearly data was then compiled and compared to demonstrate trends across the six-year period. These data seek to present the homeless death rate in the United States and report any trends that may help in creating preventative measures to help the homeless at the county, state, and national levels.

All autopsy and investigative reports of homeless deaths in this time period were critically reviewed. The highlights of these data include: the increase in the number of homeless deaths from 2011 through 2016; the consistent use of alcohol and methamphetamine; the increase in heroin-related deaths corresponding with the national opioid epidemic; the location of death; and the rising number of elderly homeless deaths.

There were 50 homeless deaths in Santa Clara County in 2011, followed by 62 in 2012, 78 in 2013, 69 in 2014, 85 in 2015, and 132 in 2016. Between 2011 and 2016, the number of homeless deaths increased by 164%.

Alcohol and drug abuse continues to claim a significant number of homeless deaths each year, with alcohol and methamphetamine being the most commonly abused drugs; however, of interest is the increase in heroin use among the homeless decedents.

Each case was analyzed to determine location of death to illustrate where the greatest number of homeless deaths occurred in Santa Clara County. The most common locations of death comprising all six years were hospitals, emergency rooms, and nursing facilities. The second most common locations were outdoor makeshift living areas. These data demonstrate that the majority of the homeless decedents in Santa Clara County were not dying in shelters or emergency housing.

The average life expectancy for a homeless individual is far younger than the general population (64 years and 78 years, respectively).[1] As the baby boomer generation ages, so does the homeless population, further exacerbating their risk for illnesses. Santa Clara County saw a 320% increase in the number of homeless decedents aged 65 and over between 2011 and 2016.

The increased number of homeless deaths exemplifies some of the risk factors faced by this population. Housing alone will not completely solve the homeless problem; rather, more resources for medical and mental illness, drug addiction, and the elderly population need to be provided. By presenting these data, the goal is to encourage this type of change through policy reform at the county, state, and national levels.

Homeless Deaths, Transient Deaths, Santa Clara County, CA

E101 Chemical Characterization of Tattoo Inks to Aid in the Identification of Highly Decomposed Remains

Trevor E. Curtis, MS, Customs and Border Protection, CA; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the chemical composition of common tattoo inks and the ways in which the ink composition can be used for identification of decomposed remains.

This presentation will impact the forensic science community by describing analytical methods that can be used to determine the elemental and organic composition in common tattoo inks and by demonstrating the identification of ink components in decomposed tissue samples.

The popularity of tattoos is increasing, with recent figures estimating that 24% of the population in the United States currently has at least one tattoo. The depth to which the inks are injected into the skin causes tattoos to remain intact even after extensive tissue damage. Due to the relative permanence of the ink, tattoos are often used to identify victims of mass disasters, based on visual assessment of the tattoo; however, for remains that are in an advanced state of decomposition or that are otherwise severely degraded, visualization of tattoos in this manner is limited.

The purpose of this initial work was to investigate the detection of tattoos based on the elemental and organic composition of the inks. As these inks are not heavily regulated, the first step was to chemically characterize a set of common tattoo inks, then to demonstrate the presence of these components in decomposed tissue samples. A total of 30 tattoo inks were included in this initial study. Inks were blotted onto separate filter papers and dried in a desiccator for 24 hours prior to analysis. Each ink was analyzed by Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy to determine the organic composition and by X-Ray Fluorescence (XRF) spectroscopy to determine the elemental composition.

The IR and XRF spectra were first assessed visually to determine the possible pigments present in the inks. For example, the IR spectra of two blue inks indicated the presence of N-Cu-N absorptions at 1,088 cm^{-1} and C-N-C absorptions at 781cm^{-1} and 756cm^{-1}. The XRF spectra of the same two inks indicated the presence of copper and titanium. The IR absorptions combined with the presence of copper indicated copper phthalocyanine as the major pigment in the inks. Titanium is used as a whitening agent and, hence, further distinction of the inks was possible with the lighter blue ink containing a significantly higher intensity of titanium.

Principal Components Analysis (PCA) and Hierarchical Cluster Analysis (HCA) were then applied to the spectral data to more readily visualize similarities and differences among the inks based on both the elemental and organic composition. The XRF and IR spectral data were combined and PCA was initially applied. Inks of similar color were positioned closely on the scores plot and distinctly from other inks using the first four principal components, which accounted for 80% of the total variance in the data set; however, the lighter-colored inks that essentially differed only in the titanium concentration were not readily differentiated using PCA. Using HCA, similar groups of inks were observed as in PCA, although the lighter-colored inks were more readily distinguished.

Following characterization of the tattoo inks, the detection of ink components in decomposed tissue samples was investigated. In this initial study, only elemental composition was investigated and Scanning Electron Microscopy with Energy Dispersive Spectroscopy (SEM/EDS) was used due to the imaging capabilities offered in addition to the elemental composition analysis. A subset of red, blue, and black inks was analyzed using SEM/EDS and the elemental composition of the inks was compared to that generated previously using XRF spectroscopy. After demonstrating correspondence between the two techniques, SEM/EDS was used to analyze tissue samples that had been tattooed with red ink and allowed to decompose. After 19 days, the carcass was in a state of advanced decomposition, with skin discoloration preventing visualization of the tattooed area. Nonetheless, iron, silicon, and magnesium, previously identified in red ink, were detected at significant levels in the tissue samples. Although preliminary in nature, these results demonstrate potential for the detection of ink components in decomposed tissue samples.

Tattoo Inks, Chemical Characterization, Decomposition

E102 A Five-Year Retrospective Study on Suicide and the Use of Antidepressants in Washington, DC

Breanna M. Cuchara, BS, 31 McDermott Street, Milford, CT 06460; and Francisco J. Diaz, MD, Washington DC Office of the Medical Examiner, 401 E Street SW, Washington, DC 20024*

After attending this presentation, attendees will: (1) understand the need to examine suicidal data; (2) realize the responsibility of death investigators and health agencies to discuss depression and suicide; and, (3) be aware of the trends in drugs taken at the time of death.

This presentation will impact the forensic science community by raising awareness of the impact of prescribing antidepressants and whether this has affected the suicide rate in Washington, DC. This presentation will also open a much-needed discussion regarding depression and other mental illnesses.

Suicide is a major public health concern because it takes the lives of more than 40,000 people nationwide and is the tenth leading cause of death in the United States. According to the National Institute of Mental Health, the suicide rate increased 24% from 1999 to 2014.[1]

Interestingly, while the suicide rate in the United States is increasing, Washington, DC's, rates have decreased 24.6% from 2014 to 2015.[2] In fact, Washington, DC, has one of the lowest suicide rates in the country.[3] The suicide rate in Washington, DC, is significantly less than nearby Virginia and West Virginia. The precise reason for this difference is unknown and warrants investigation. The difference could be due to differences in drugs taken by the decedents, social services available, and/or the recognition of suicidal ideation and public awareness.

Knowledge regarding correlations can give rise to prevention and decreased suicide rates and helps to open discussions about depression and other psychiatric disorders. This work centers on examining the number of deaths by suicide in the past five years and the presence of antidepressants at the time of death.

In 2015, the Office of the Chief Medical Examiner in Washington, DC, investigated 52 suicides, of which 51 decedents were tested for the presence of drugs. The most prevalent drugs found included ethanol, morphine, cocaine, fluoxetine (a Selective Serotonin Reuptake Inhibitor (SSRI)), and bupropion (not an SSRI). The leading cause of death from suicide in Washington, DC, is by firearms, which increased 25% from 2014 to 2015 (versus death by hanging, which decreased from 32% in 2014 to 23% in 2015). Ethanol was found in ~30.8% of suicide deaths in 2015.[2]

In contrast to the popular SSRIs, bupropion is atypical and acts as a Norepinephrine-Dopamine Reuptake Inhibitor (NDRI). There are many antidepressant medications being prescribed today, with SSRIs being the most popular. These SSRIs change the chemicals in the brain that may be unbalanced in people with a major depressive or anxiety disorder. It works by blocking the reabsorption of serotonin, thereby increasing serotonin levels. Fluoxetine and citalopram are examples of SSRIs. SSRIs have been shown to decrease violence toward others, but may also lead to increased suicidal ideation and behavior.[4] The Food and Drug Administration (FDA) requires all antidepressants to include a warning stating that antidepressants may increase the risk of suicide in persons younger than 25 years of age. This warning, put into effect in 2007, is based on two reports of a 2-fold increase of the suicidal ideation and behavior in children and adolescents, and a 1.5-fold increase in the 18- to 24-year age group, a slight decrease for those over age 24, and a much lower risk in the 65+ age group.[5]

Mental health is talked about more openly now than in the past, but talk regarding depression and suicide still too often remains off-limits. Both depressed people and society at large are still uncomfortable with these topics. This fear, along with a lack of support, often prevents people from seeking treatment. Analyzing data and promoting discussions about this difficult subject allows us to get one step closer to decreasing the suicide rate. Death investigators have access to analyzable data that may help reduce the number of suicides.

Suicide, Antidepressants, Death Investigation

E103 Efforts at the Centers for Disease Control and Prevention (CDC) to Improve Fatality Management and Mortality Reporting Practices During Mass Fatality Incidents at the State and Local Levels

Rebecca S. Noe, MPH, MN, CDC, 1600 Clifton Road, Atlanta, GA 30333; DeAndrea Martinez, MPH, CDC, 1600 Clifton Road, Atlanta, GA 30333; Todd Talbert, MA, CDC, 1600 Clifton Road, Atlanta, GA 30333; and Stephanie Dopson, ScD, CDC, 1600 Clifton Road, Atlanta, GA 30333*

After attending this presentation, attendees will understand several activities undertaken by the CDC, in collaboration with the forensic science community, to improve state and local public health preparedness and response to support mass fatality incidents. Attendees will learn how these activities address known gaps in the collecting, recording, and sharing of mortality information after mass fatality incidents.

This presentation will impact the forensic science community by demonstrating how strengthening fatality management, including data sharing with public health, can result in a more effective response to a mass fatality incident at the local, state, and federal levels. This presentation will describe and demonstrate the usefulness of CDC tools to address gaps and to improve the accuracy and timeliness of mortality data at different stages of a public health emergency response. Attendees can use what they learn to examine and update their existing mass fatality plans and exercises in their jurisdictions, if necessary.

Attendees will learn how these activities address known gaps in the collecting, recording, and sharing of mortality information after mass fatality incidents. Attendees will be briefed on the 2017 updates to CDC's *Public Health Preparedness Capabilities: National Standards for State and Local Planning,* specifically to the Fatality Management and Information Sharing Capabilities and any potential considerations for their mass fatality plans.[1] Other developed tools, *Reference Guide for Certification of Deaths Associated with a Disaster (in press) and Disaster-Related Death Scene Data Collection Forms,* will offer attendees up-to-date resources to incorporate into their mass fatality management planning.[2] Finally, attendees will learn about an opportunity to engage with CDC on a new project to develop a fatality management toolkit for state and local jurisdictions.

This presentation will provide a background on the CDC's Public Health Preparedness Capabilities and common gaps in local mortality data management identified by CDC. This presentation will explain the process taken to develop the tools and the purpose and content of each resource. Suggestions on how attendees can use these tools to update their plans will be highlighted using emergency events, for example, events such as tracking heat-related deaths during a heat wave or deaths attributed to a mass fatality incident from a tornadoe across several jurisdictions.

In conclusion, when planning for and responding to incidents with fatalities, it is the responsibility of local and/or state fatality management professionals (e.g., medical examiners, coroners) to ensure the respectful and orderly management of deceased persons, while tracking and sharing mortality data in a timely fashion with public health officials. These data can inform public health practitioners when developing targeted messaging during an event and for refining strategies to prevent deaths from future disaster events.

Mass Fatality Planning, Mass Fatality Incident, Disasters

E104 Disaster-Related Deaths and Data: A New Toolkit and Training to Enhance Death Scene Investigations After Disasters

Sarah Davis Redman, PhD, NORC at the University of Chicago, 3520 Piedmont Road, NE, Ste 225, Atlanta, GA 30305; Catharine Fromknecht, BS, 4350 E W Highway, Ste 800, Bethesda, MD 20814; Sarah Hodge, MPH, NORC at the University of Chicago, 4350 E W Highway, 8th Fl, Bethesda, MD 20814; Stephanie Poland, MA, NORC at the University of Chicago, 55 E Monroe Street, 30th Fl, Chicago, IL 60603; Anindita Issa, MD, Centers for Disease Control and Prevention, Nation, 4770 Buford Highway, NE, Atlanta, GA 30341; Tesfaye Bayleyegn, MD, CDC, 4770 Buford Highway, NE, Atlanda, GA 30341; and Rebecca S. Noe, MPH, MN, CDC/Office of Public Health & Prepardeness & Respo, 1600 Clifton Road, Atlanta, GA 30333*

After attending this presentation, attendees will understand how disaster death scene data can improve public health emergency preparedness, response, and recovery efforts. Attendees will be familiar with the new toolkit, Death Scene Investigation After Natural Disaster or Other Weather-Related Events, designed to help death scene investigators investigate deaths that occurred during natural disasters or other weather-related events. Attendees will learn how information collected at the death scene can enable death certifiers to more accurately and consistently attribute deaths to disasters, and how this in turn helps public health departments identify risk and protective factors associated with disaster-related deaths and refine their strategies to prepare for, respond to, and recover from future disaster events.

This presentation will impact the forensic science community by highlighting the toolkit and new training resources available to assist death scene investigators in collecting data about disaster-related deaths and reporting this information to their Medical Examiner/Coroner (ME/C).

The Centers for Disease Control and Prevention (CDC) contracted with the non-partisan and objective research organization referred to as NORC at the University of Chicago and collaborated with state and local ME/Cs, forensic pathologists, death scene investigators, forensic anthropologists, and epidemiologists to create a new toolkit to assist death scene investigators with disaster-specific data collection. NORC presented an overview of the toolkit at the 2017 AAFS Annual Scientific Meeting; the final toolkit was released in July 2017. This presentation will focus on the forthcoming training resource.

The new toolkit contains supplemental forms and checklists to ensure event-specific data are collected at death scenes of commonly occurring natural disasters or weather-related events (e.g., hurricanes, tornadoes, extreme heat exposures). In addition to their routine data collection form, investigators can use the supplemental forms or checklists to aid in collecting important disaster-specific data. Both the forms and checklists prompt investigators to collect information specific to the disaster or weather-related event that is often available only immediately after the event. Examples of disaster-specific data include information about the decedent (e.g., engagement in activities related to disaster preparation or clean up) and the disaster or event itself (e.g., weather conditions or ongoing alerts).

To supplement the toolkit, NORC and CDC are developing a training resource to assist ME/Cs in preparing their staff to investigate disaster-related deaths. Using a variety of educational approaches and presentation techniques, the training resource provides information about disaster-related mortality data, such as the importance of timely and accurate mortality data in measuring the effect of a disaster as well as the number and type of agencies that benefit from these data after a disaster. The training resource is designed for both new death scene investigators and the continuing education of advanced death scene investigators. NORC is partnering with the American Board of Medicolegal Death Investigation (ABMDI) to pilot and disseminate this new training.

Disaster, Investigation, Training

E105 The Search and Recovery of 43 Victims From the Oso Mudslide in Washington State

Mary E. Cablk, PhD, Desert Research Institute, 2215 Raggio Parkway, Reno, NV 89512*

The goal of this presentation is to educate attendees regarding the devastating landslide that took the lives of 43 people and how recovery efforts were conducted.

This presentation will impact the forensic science community by teaching attendees about: (1) the challenges presented in the recovery of human remains from a natural disaster in mud and water; (2) the use of multiple resource types; and, (3) the requisite support and time needed to recover remains buried under deep, saturated mud.

A small community was devastated without warning in Snohomish County, north of Seattle, WA. On the morning of March 22, 2014, a massive landslide occurred that took the lives of 43 people, destroyed sections of State Highway 530 and a rural neighborhood in a matter of seconds. This was the deadliest mudslide in United States history. The search area was a massive 3.24km^2 (800 acres) with debris estimated to be 7.6 million cubic meters (~270 million cubic feet). Confounding the search and recovery efforts was the fact that the slide crossed and dammed the Stillaguamish River, making it an area of mud estimated to be up to 12m (40 feet) at the time of the emergency response. The last body was reported located exactly four months after the slide occurred. The Snohomish County Medical Examiner's Office reported cause of death for all victims as multiple blunt force injuries and manner of death as Accident.

At the time, the Snohomish County Emergency Management office had ten people on staff, who were suddenly in the position of coordinating and overseeing what became a response that included 240 agencies. The Emergency Operations Center (EOC) was activated for 40 days. The enormity of the devastation quickly overwhelmed local and in-state agencies. On April 3, 2014, President Obama declared the mudslide a major disaster. More than 600 personnel, including more than 160 volunteers, 77 of which were canine handlers, worked on the recovery operations.

A first-hand account of the search and recovery efforts will be presented. It was the use of K9s working alongside heavy equipment that enabled every individual to be located and recovered, even when buried under mud and submerged under water. Volunteer search, rescue, and recovery canine teams located most of the victims in the first 11 days. The challenges of working an area of that size, with resources coming from across the United States, working in cold, wet, and dangerous conditions, without power and limited communication access will be discussed. Physical hazards, such as debris, presented one set of challenges, while chemical and biological hazards presented other challenges. Transportation within the search area required specialized equipment. Coordination between agencies was conducted using a joint command under the Incident Command System (ICS). Not all canine teams were effective, but those with the proper training for the deployment and handlers prepared for such conditions were able to complete search assignments safely and effectively. An on-scene veterinary station was established at the IC as well as the forward base of operations. The United States Army National Guard established an efficient decontamination station including hot and cold running water for canines. A separate decontamination station was established for humans. Lessons learn from this catastrophic natural disaster have and will continue to inform those involved in recovering human remains from mudslides.

Recovery, Cadaver K9, Natural Disaster

E106 Rescue the Living, Find the Missing, and Identify the Found: The Dentify.Me App

Sakher J. AlQahtani, PhD, College of Dentistry, King Saud University, Riyadh 11545, SAUDI ARABIA; Shada Alsalamah, PhD*, King Saud University, College of Computer and Information Sciences, Riyadh 11545, SAUDI ARABIA; Joe Adserias Garriga, DDS, PhD*, c/ Balmes 62 30 la, Barcelona, SPAIN; Kenneth W. Aschheim, DDS*, 44 E 67th Street, New York, NY 10065; Amber D. Riley, MS*, 9855 Erma Road, #103, San Diego, CA 92131; Ricardo H.A. Silva, PhD*, USP-School of Dentistry of Ribeirao Preto, Avenida do Cafe, s/n, Bairro Monte Alegre, Ribeirao Preto, Sao Paulo 14040-904, BRAZIL; and Emilio Nuzzolese, PhD*, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, EU 70124, ITALY*

After attending this presentation, attendees will have acquired a deeper understanding of how a new smart phone application (app) named Dentify.Me can become a valuable tool in mass disaster management. Each day, humans are subjected to catastrophic events. Horrifying mass fatality incidents have been witnessed in every corner of the planet, and the world mourns for victims of natural disasters, war, and violent acts.

This presentation will impact the forensic science community by increasing awareness of how Information Technology (IT) solutions can be used as a resource in mass fatality victims management.

In such incidents, all efforts should be coordinated to rescue living victims, find missing ones, and identify those found. First, all injured victims need to be located or reported so they can be provided with first aid paramedic services. Second, a manifest of missing victims needs to be created so rescue and/or Disaster Victim Identification (DVI) efforts can be utilized efficiently to find the missing; however, the creation of a missing persons' manifest is a time-consuming and often inaccurate process, especially in the early stages of an incident as it is constantly evolving as victims are found and others are reported missing. Deceased victims who have been recovered need to be identified to bring closure to their loved ones as well as receive justice in cases of homicide; however, rescue teams rely on victims and eyewitness reports created manually or on post-active systems for receiving emergency calls. Moreover, all pre- and post-disaster data, also known as Antemortem (AM) and Postmortem (PM) data, respectively, is collected and matched manually by DVI teams for reconciliation. There are no wide-ranging proactive systems today on the IT market to address all three issues at once.

The Dentify.Me app is a proactive application that utilizes a victim-centered solution that automates the process of notifying authorities with an S.O.S., locating victims, generating missing persons' manifests, and collecting and delivering AM data to authorities. Using a semi-structured interview process and document analysis, the software has been optimized to collect essential AM data.

The Dentify.Me app engages with eyewitnesses to automate the incident detection and identification process. It uses hard system's methodology to automatically identify and locate potentially affected victims, alert the rescue team to reach out for the injured, generate a list of the missing, and collect and deliver AM data to the DVI team to assist in the matching process. It is hoped that this proof-of-concept proposed solution, when implemented, will have a great impact on mass fatality victims management by *rescuing the living*, *finding the missing*, and *identifying the found,*to efficiently bring justice to the victims and peace of mind to their loved ones.

DVI, Antemortem Data, IT Solution

E107 Forensic Science Capstone Experience: The Thesis, the Review, and the Practicum

Kimberly Nugent, MSc, UOIT-Faculty of Science, 2000 Simcoe Street, N, Oshawa, ON L1H 7K4, CANADA*

After attending this presentation, attendees will learn how students' personal and professional skills are encouraged through academic capstone experiences.

This presentation will impact the forensic science community by highlighting the three capstone experience options available to University of Ontario Institute of Technology (UOIT) Forensic Science undergraduate students. An overview of the curricula, assessment methods, and learning outcomes will be discussed.

In the UOIT Forensic Science Program, a capstone course is a required curriculum component prior to graduation. The course is delivered using active learning strategies emphasizing experiential learning and independent study. Combining interactive curriculum with traditional lecture material promotes a deeper understanding and a more engaged learner.

A capstone experience may take the form of an honors research thesis, a literature review, or a mock crime scene practicum project. A thesis project provides students an opportunity to conduct novel research by identifying a hypothesis and working through the methods, results, and significance of their work. The literature review course focuses on independent library-based scholarly research. Students synthesize information and provide a critical appraisal of experimental principles where necessary. The mock practicum course provides students with the opportunity to investigate a simulated crime scene and participate in all aspects of the investigation, from crime scene to lab, culminating in expert witness testimony in a mock court setting.

Each capstone project is conducted under the supervision of a forensic professional and allows the student to integrate and synthesize the knowledge gained throughout their program of study. Students' personal and professional skills are encouraged through this academic capstone experience. What's more, career paths and personal goals are fostered by creating a personalized course experience.

Emphasis is placed on developing students' practical and theoretical science skills. These *hard skills* are considered to be the foundational aptitudes that students acquire through lecture and laboratory content. *Soft skills* are also identified and nurtured. Otherwise referred to as interpersonal or social skills, these may include communication, self-motivation, problem-solving, time-management, leadership, and decision-making skills. Both oral and written communications are practiced with a strong focus on scientific report writing. Students are assessed on scientific validity, organization, completeness, and overall style and grammar. Finally, importance is placed on the student's ability to address relevant hypotheses and how the results address the latter.

Both hard and soft skill-sets are assessed in various capacities and all capstone experiences culminate with the submission of a written thesis or report as well as presentation at the year-end Annual Forensic Science Research Day.

Education, Capstone, Experiential Learning

E108 Minimum Education Requirements for Crime Scene Investigators (CSIs): The Missing Link in Forensic Science

Mary Juno, MSc, SJSU Justice Studies Department, Forensic Science Program, One Washington Square, San Jose, CA 95192*

After attending this presentation, attendees will be aware of the low minimum-education hiring requirements for crime scene investigators and the standard on-the-job training a new CSI receives. Further, attendees will understand the potential for error at a crime scene and conceptualize a link between low hiring standards and error.

This presentation will impact the forensic science community by proposing that crime labs and police departments attempt to establish error rates for CSIs and potentially re-evaluate their agencies' minimum education requirements for new CSIs. The community is invited to consider the question: Should crime scene investigation, like other forensic disciplines, be professionalized?

The 2009 NAS Report, *Strengthening Forensic Science : A Path Forward,* rightly criticized many of the subdisciplines of forensic science, causing professionals and researchers to "get hot" on the tasks of tracking and minimizing error and strengthening the scientific underpinnings of their fields; however, the NAS Report hardly mentioned crime scene investigation or any potential problems with it, even though CSIs are at the front end of forensic science where the introduction of error is arguably most critical. Errors committed by the CSI at a crime scene can include failure to: locate and recognize evidence, interpret a screening test correctly, prevent contamination, collect sufficient samples and controls, document evidence adequately, preserve evidence using appropriate packaging and handling, and maintain chain of custody, with limitless variation. No amount of forensic wizardry in the lab can make up for these errors.

Few agencies require new CSIs to possess any formal training in the sciences at the time of hiring. Currently, the most common minimum educational standard for obtaining a position as a civilian CSI in the United States is a high school diploma or General Equivalency Diploma (GED). Once hired, a CSI typically attends a short course on photography and fingerprint lifting and completes a period of supervised field training. At that point, a new CSI may know *what* to do but may not completely understand *why* he/she is doing it.

This presentation examines hiring standards and minimum education requirements for CSIs across the United States as part of a larger study that will explore quality assurance mechanisms in crime scene investigation (or the lack thereof) and the relationship between crime scene investigator error rates and education levels. This study argues that the combination of low education minimums and brief on-the-job training are inadequate. A four-year degree is proposed as the new minimum education requirement for CSIs.

Education, Minimum, CSI

E109 Group Experiential Learning in the Forensic Science Classroom

John A. Williams, PhD, Western Carolina University, Anthropology and Sociology, 101 McKee Hall, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the application of experiential learning in the forensic science classroom.

This presentation will impact the forensic science community by demonstrating the ways in which group experiential learning can be approached within the standard classroom lecture setting.

Collaborative or group experiential learning in higher education is by no means novel. It is (and has been) practiced in various forms and in various disciplines for most of the past century.[1] Group work has been shown to easily excel individual learning in all manners of pedagogy, from problem-solving to verbal skills. The interspersing of small group activities in a standard lecture format is perfectly acceptable and can provide sufficient student value.[2]

The inspiration for this study of small-groups experiential learning is a course on bone trauma. This course serves both forensic anthropology and forensic science majors. It began as a standard, straight-lecture format (Trial 1). In this iteration, static displays of various bone traumas were (and still are) used to illustrate how various events such as fractures occur. Human bone is too precious to experiment with and bones of the white-tailed deer were shown to be a useful alternative.[3] A few excess deer bones were used in class to demonstrate trauma. Student interest in a hands-on application was quite clear. The problem was a lack of sufficient bones for a more in-depth student experimentation. Four years ago, a local source of deer bones acquired from local hunters was established. Beginning that year, students were given a group-based project to simulate a form of bone fracture (Trial 2). Each group was given some degree of latitude in approaching their task. The final projects were, as expected, quite varied in their design and results. The concern was that so much time was spent on the experimental design that the pedagogical goal of the project was lost — understanding how bone responds to trauma. In the next iteration, each student group performed the same experiment and used the same experimental design (Trial 3). It was discovered that, not surprisingly, some groups were better than others at conducting the experiment. Some groups experienced the so-called "Aha!" moments, while others simply performed the experiment as instructed.

All science of teaching and learning, or pedagogical research, is focused on student learning. Within that context, three goals were established for this study of experiential-group learning: (1) connect course content to the real world; (2) reinforce learning through application; and, (3) assist students in making the internal connection of the "how" and "what" with the "why." This project has placed much of its emphasis on this third goal. If they have mastered this ability, when faced with a new circumstance (the "how" and "what"), this skill set should make it possible for them to reach a conclusion (the "why"). As this course continues to evolve, how to apply experiential-group learning to maximize these goals remains an ongoing process.

Education, Experiential Learning, Bone Trauma

E110 A Study of the Forensic Science Education Programs Accreditation Commission (FEPAC) -Accredited Graduate Forensic Science Programs' Curricula

Catherine G. Rushton, EdD, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be able to define how FEPAC-accredited forensic science graduate programs have implemented FEPAC's Graduate Curriculum Standard.

This presentation will impact the forensic science community by identifying the scope of any differences or unique characteristics accredited forensic science graduate programs may exhibit in their curricula, in addition to any inconsistencies. Each graduate program has fulfilled the FEPAC Graduate Curriculum Standard in order to receive accreditation; however, the manner in which they fulfilled these standards may vary among programs. This study sought to understand how each graduate program fulfilled the FEPAC Graduate Curriculum Standard by analyzing the programs' websites and self-study documents.

The National Institute of Justice and the National Academy of Sciences recommended that forensic science training shift from on-the-job training to formal education; however, the reports cited inconsistencies in the curricula of the forensic science degree programs as an impediment to this.[1,2] The FEPAC Standards were created to address this issue; however, no studies have been conducted to determine how the accreditation standards have been implemented by the FEPAC-accredited graduate programs. This study evaluated the self-study responses (n=11) and website information (n=17) specific to FEPAC's Graduate Curriculum Standard to determine how the accredited graduate programs fulfilled the FEPAC Graduate Curriculum Standard. This study also determined to what extent inconsistencies or consistencies exist among the accredited graduate programs' curricula.

This study found that although FEPAC-accredited graduate forensic science programs exhibited differences (unique characteristics) among their curricula, they did not as a whole exhibit significant inconsistencies (lack of agreement). All the accredited graduate programs covered the natural sciences, particularly the areas related to forensic science, such as forensic chemistry and forensic biology; however, the programs' coverage of the comparative sciences, such as firearms and questioned documents, was limited. Evaluation of the 11 FEPAC self-study reports revealed that, on average, these programs exceeded the required minimum instructional hours of core forensic science topics as specified by the FEPAC guidelines. All programs in this study required students to complete an independent research project as their capstone experience, whether thesis or non-thesis. Additionally, all programs included a requirement for students to attend a graduate seminar where students presented their independent research findings.

The study found the FEPAC-accredited graduate forensic science programs' curricula was consistent with unique characteristics among the graduate programs. The curricula were rigorous, scientific-based, and discipline specific. This study evaluated a snapshot of accredited graduate forensic science programs' curricula. Future research should seek to further flesh out the curricula by gathering documents from the graduate programs, such as course syllabi, conducting interviews with the program director or their designee, and administering surveys.

Higher Education, Accreditation Standards, Curriculum

F1 Cross Examination and Direct Examination in Criminal Procedure Discussions in Turkey

Hatice Yilmaz, BSc, Üsküdar University, Altunizade Mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; and Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY*

After attending this presentation, attendees will better understand the cross-examination criminal procedure in Turkey.

This presentation will impact the forensic science community by explaining the lawyer's role in cross examination and criminal law.

An important innovation brought to the criminal court by the Turkish Criminal Procedure Code (TCPC) No. 5271 is the vested right of parties to ask questions. The right to ask questions, which is prevalent in the Anglo-Saxon legal systems, increases the role of participants or defense attorneys, who are tasked with presenting material facts, and imposes vital responsibilities on the attorneys who are perceived as merely inactive participants at trial. Article 201 in the TCPC clearly states that the attorneys and the public prosecutor can be asked questions on the condition that they keep to the trial discipline. In practice, it is observed that witnesses, perpetrators, and attendants are examined by and address their questions to the judge, merely waiting for his queries; however, TCPC Article 201 decisively ensures that the judge cannot interfere except in the case of an objection and the expediency of the objection.

In the TCPC, the same form of the procedure in Article 2016 (to determine who will take the floor) is pursued for asking questions as in Article 201. This study discusses the notions of cross-examination and direct examination, how practicable these are, and the problems faced in practice, along with their solutions. The similarity of posing a direct question to cross examination, which has taken place in Turkish law with Article 201 of the Code of Criminal Procedure, and its place in the accusation system will be taken into consideration. Article 201 of the Code of Criminal Procedure is not a cross-examination method, but only a questioning procedure. It is an application that provides the possibility for participation of the parties to the judge's examination.

If the goal of the criminal procedure is to reach the material fact, it is necessary to investigate the historical development of the concrete case since it is possible to forget events in the period of time between when the concrete fact that took place during the event, which will be deemed as a crime, and the investigation of the material fact. Additionally, evidence not attained or changed by the parties can complicate reaching the fact. In this context, the statements of the parties and parties' witnesses or public witnesses are very important. In Turkey, which adopted the accusation system, the goal is to have the true facts explained by the subjects, which will be put forward through statement examination.

It can be evidenced in the application, that cross-examination, which is one of the necessities of the right to a fair trial, has no real response in Turkish law. In order to reach the real function of direct questioning, the judges have significant responsibilities. Changing the law for justice depends on the realization of all facts of the right to a fair trial. It is evident that Article 201 of the Code of Criminal Procedure does not comply with the cross-examination system. The most appropriate system to the nature of the institution is the accusation system. Although the criminal procedure in Turkey begins with the accusation, there is also a mixed system. This case is an example that there is no cross-examination in the real sense. There are obstacles before the successful application of direct questioning, such as technical infrastructure deficiencies and an insufficiency of the judgment periods.

Courses are provided to law students so they can develop the necessary questioning skills for the legal profession. Through these courses, the contribution of lawyers, who are important participants of the cross-examination system, can be increased. The application of questioning methods cannot be learned by theories as practical trial and doctrinal education are not provided in law faculties. This situation negatively affects the profession of new graduates who want to practice law.

Cross Examination, Forensic Science, Law

F2 Assessment of the Allegations and Evidence in Criminal Proceedings and the Innocence Project in Turkey

Hatice Yilmaz, BSc, Üsküdar University, Altunizade Mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; and Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY*

After attending this presentation, attendees will be familiar with the Innocence Project in Turkey and the assessment of the allegations and evidence in the criminal proceedings.

This presentation will impact the forensic science community by demonstrating that in criminal proceedings, the evidence is important in terms of prevention and impact on the judicial system.

In the legal sense, when a crime is committed, a legal institution subjects the criminal to punishment or security precautions. The history of crime is as old as the history of humanity. Throughout history, states have been subjected to various forms of culpability if they have tried the factions as required by society's dynamics and if the criminal action has been reached by the prosecuted offender. If it is concluded that the person did not commit the crime, he was acquitted.

The crime is not rendered suspect by the issue of proof that comes into play, so the suspect is innocent or must prove himself, which will be hard to prove to the party who claims to have committed a crime. In Roman law and in our legal system, the plaintiff has to prove his claim. In medieval Europe, the plaintiff had to prove that the suspect was innocent. The function of the Law of Criminal Procedure is to show the offender, in return of the actual execution of the application (if it has been exercised) to determine by whom it will be handled. Essentially, the goal is to investigate material facts. The authority that has the authorization to pursue punishment has no right to arbitrarily decide who committed the crime, but must prove it in accordance with the law. Material reality is relative. The parties will naturally go on to influence the court, and the judicial authority will go through the process of finding the truth by examining the evidence.

Article 217/2 of the Criminal Procedure Code in the Turkish Criminal Proceedings, which regulates the judge's discretion, is regulated as follows: "Any crime that has been committed in accordance with law can be proven."

The concept of "evidence," which is the principle of the law of evidence, can be described as each type of trace, effect, document, and record that contributes to revealing whether the acts, having abstract descriptions in the punishment norms, have been realized in the concrete case.

The imputed crime in the Turkish Criminal Procedure can be proven with each type of evidence collected in compliance with the law. As securing justice is achieved by reaching the material fact in the criminal procedure, each type of means can be a proof, which serves to prove the occurring concrete case and the judge has the discretionary power to make a selection between these means.

Although the proof of the material extent of the penal discrepancy in the criminal procedure is limited as to the types of evidences, the principle of evidence freedom does not mean an unlimited freedom.

Evidence, Criminal Procedure, Innocence Project

F3 Evidentiary Neglect: The Failure to Perform an Autopsy

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; and Jeffrey M. Jentzen, MD*, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109*

After attending this presentation, attendees will have a better perspective on when an autopsy should be performed, as well as comprehending the various issues regarding privacy, the public's right to know, and ethical parameters.

The presentation will impact the forensic science community by increasing awareness concerning the various dimensions regarding the role of and need for autopsies.

On February 13, 2016, 79-year-old Supreme Court Justice Antonin Scalia was found dead in bed at a West Texas hunting ranch. His doctor offered that Scalia had suffered from cardiovascular disease and hypertension. Scalia had visited his doctor days before his death complaining of a shoulder injury from tennis. The ranch owner called emergency services and the United States Marshals Service arrived at the ranch. There was no medical examiner in Presido County so the marshals called for the local justices of the peace.[1] When one could not be found, a county judge conducted an investigation "over the phone." The judge declined to order an autopsy after taking into consideration law enforcement's observations of the body and scene, consultation with Scalia's physician, and respecting the wishes of the family. "Our folks never indicated that anything seemed amiss or unusual, but that wasn't our role," declared a spokesman for the Federal Marshals service. "We weren't there to make any determination like that, so I'm not going to be drawn into that."[2]

Almost immediately questions arose from ordinary citizens and conspiracy theorists as to the cause of Scalia's death. The circumstances and rebuttals had a surprising similarity to Teddy Kennedy's Chappaquiddick affair 50 years earlier. Following the tragic death of Secretary Ron Brown in 1996, the federal government had created legislation delegating the responsibilities to invest the deaths of the president, vice president, and members of the cabinet to the Armed Forces Medical Examiner.[3]

A well-performed autopsy is the gold standard for any death investigation. Despite advances in diagnostic technologies, autopsies still detect major findings not identified prior to death in 25%–40% of deaths.[4] Most states have statutes that order mandatory autopsies in deaths in police custody, criminal violence, sudden deaths of infants and children, and others. The National Association of Medical Examiners (NAME) Forensic Autopsy Standards identify 12 types of deaths in which autopsies "shall be performed."[5] On many occasions, medical examiners and coroners have been sued for performing an autopsy against the wishes of the family. There are few, if any, cases in which the medical examiner or coroner was sued for not performing an autopsy.

Performing autopsies protects the public interest and provides necessary information to address legal, public health, and public safety issues in each case. Statutes give medical examiners and coroners wide discretion on the performance of autopsies. In Minnesota, for example, statutes allow for the performance of autopsies when, in the judgment of the coroner or medical examiner, "the public interest would be served by an autopsy."[6] Autopsies should be performed in deaths of prominent persons, recent releases from hospitals, institutional deaths, drug deaths, and, at times, simply at the request of the family in suspicious circumstances.

The failure to perform necessary autopsies creates a gap in medical evidence to explain the cause of a death and can "arouse public interest, raise questions, or engender mistrust of authorities." In the midst of an opioid epidemic and faced with a paucity of trained forensic pathologists, medical examiners and coroners are searching for excuses not to defer autopsies or simply performed external examinations. This practice can have disastrous consequences. In today's media-fueled environment, we cannot be so naïve to believe that "everyone should be treated the same."[7] The deaths of prominent and high-profile government officials need and require careful autopsy examinations. Even a lay person would suggest that the death of Supreme Court Justice would require an in-depth federal investigation. As one family put it, "You are the professional, we are a grieving family, you should have done your job!"[8]

Autopsies, Ethics, Evidence

F4 The Aaron Hernandez Verdict: Hard Work and Critical Analysis Secure Acquittal

Linda Kenney Baden, JD, 15 W 53 Street, Apt 18 B/C, New York, NY 10019; and James Downs, MD*, forensX, LLC, 13015 Abercorn Street, Ste B3 #182, Savannah, GA 31419*

After attending this presentation, attendees will better understand the significance of the collaborative process in case trial preparation and presentation, including expert consultations, site visits, and demonstrative evidence.

This presentation will impact the forensic science community by reinforcing and demonstrating the importance of the process and the significance of the collaborative process in case trial preparation and presentation, including expert consultations, site visits, and demonstrative evidence. In so doing, the process of pursuing justice will be enhanced.

The critical import of understanding the forensic evidence in a case — from the vantage point of what exactly it *does* and *does not* prove — is critical in the pursuit of justice. There are at least two sides to every story, although sometimes a prosecution moves forward insisting that only one version of events is truthful and that the facts revealed by forensic evidence can lead to only a single version — the state's interpretation. The latter seems obvious, simply by the fact that the case is going to trial. Telling the rest of the story requires knowledge, determination, and time.

The fundamental importance of preparation with all the experts in a case is frequently rewarded with a fuller understanding of strengths and weakness of a case. The case preparation phase should also include not only visiting the crime lab and the medical examiner's office, but also the various crime scenes to evaluate possibilities perhaps not considered or dismissed by primary investigators. Such visits may also include scene re-enactment or reconstruction to facilitate a better understanding of what aspects of a case may actually be fact, as opposed to opinion or interpretation. For example, clearly showing relative body positions when injuries were sustained goes beyond the typical "anatomic position" of the autopsy and leads to the conversation about bodies positioning in the real world. Ultimately, counsel should seek first to understand what happened and how it happened in order to place that information into the larger context. Hand-in-hand with the former is comprehending the different elements of the forensic evidence and trying to ensure that the jurors grasp the nuances of the evidence.

Due to limited resources and overwhelming caseloads, the forensic pathologist actually visiting the scene and incorporating that visit with the autopsy findings is a dying exercise. Fewer and fewer offices are able to send the Medical Examiner (ME) to the scene. A regionalized death investigation system, currently being considered by some jurisdictions, would further limit the forensic pathologist visiting the death scene. In many areas, primary death scene functions are performed by lay investigators — either law enforcement, a coroner, or the ME staff. Sometimes, this may result in little more than the police "telling" the pathologist what happened.

In a death case, prosecutors are commonly urged to bring the decedent to life. The defense is usually admonished to minimize or ignore this strategy. In point of fact, the message of the dead may be more important to the defense than to the prosecution. The old adage that the dead speak to the forensic pathologist has its basis in fact. Counsel should work with the medical experts to translate that conversation to the jury in clear, understandable, and *understood* language.

Utilizing the highly scrutinized and widely publicized double murder trial of former professional football player Aaron Hernandez, which resulted in his acquittal, illustrates the importance of preparation and demonstrations. Taking advantage of the varied strengths of the forensic experts can prove remarkably helpful in facilitating conveyance of the message to the jury. To that end, demonstrative evidence, scene representation, and alternate interpretations can be of critical import in communicating with the jury by visually portraying exactly the points that need to be made.

Collaboration, Demonstrative Evidence, Aaron Hernandez

F5 Care Decisions in Desperate Cases in Infancy: *Parens Patriae* or Birth Parents' Responsibility — Lessons From the Case of Charlie Gard

Alexander Robert W. Forrest, LLM, School of Law, Bartolomé House, The University of Sheffield, Winter Street, Sheffield, South Yorkshire S3 7ND, UNITED KINGDOM*

The goal of this presentation is to highlight the differing approaches taken in common law jurisdictions where there are differences of opinions between parents and health care professionals as to the care that should be provided to a desperately ill infant.

This presentation will impact the forensic science community by analyzing how care decisions can best be made when there are significant differences between medical professionals and the natural parents as to the appropriate care that should be given to a desperately ill child.

Charlie Gard was born on August 4, 2016. Initially, he developed normally, but his parents took him to their family physician in early October after he failed to gain weight. He was referred to Great Ormond Street Hospital (GOSH), a tertiary pediatrics referral center. Respiratory failure developed and he required ventilatory support. By the end of October, a clinical diagnosis of Mitochondrial DNA Depletion Syndrome (MDDS) was made. This was confirmed as the RRM2B variant. Functional RRM2B is required for the synthesis of mitochondrial DNA. Non-functional RRM2B results in depletion of mitochondria in body tissues, including brain and muscle. The outcome of the disease is early death from respiratory failure

GOSH consulted, nationally and internationally, on options for Charlie, including possible Nucleoside Bypass Therapy (NBT). His condition deteriorated; he began having fits and became unresponsive. By February 2017, the GOSH staff decided that there were no useful treatment options left and that it was in his best interest that active treatment ceased and palliative care be instituted. His parents did not agree, believing that Charlie was not non-responsive and adhered to the view that NBT might have something to offer him. A Crowd Funding appeal for his treatment in the United States raised £1.3 million (US$1.6 million). The GOSH staff felt this would be futile and, if Charlie had any pain perception left, it would be distressing for him.

His parents and GOSH could not agree on Charlie's best interest. Thus, GOSH asked the High Court to exercise its residual *parens patria* function and decide what was best for Charlie. His parents were represented by counsel *pro bono*. Charlie was represented by counsel appointed by the Children and Family Court Advisory and Support Service (CAFCASS), an independent body that represents children in legal proceedings relating to their welfare.

The Judge, dealt with the question that United States commentators raised as to what business it was of the court's rather than the parents, said, "The duty with which I am now charged is to decide, according to well laid down legal principles, what is in Charlie's best interests. Some people may ask why the court has any function in this process, why can the parents not just make the decision for themselves? The answer is that, although the parents have parental responsibility, overriding control is by law vested in the court exercising its independent and objective judgment in the child's best interests. The Great Ormond Street Hospital has made an application and it is my duty to rule on it, given that the parents and the hospital cannot agree on the best way forward."

The Judge adjourned the hearing in February to allow the parents to obtain additional evidence. This included evidence from a United States expert agreeing that as encephalopathy had developed, treatment with nucleosides was very unlikely to lead to improvement. He also said that if Charlie was in the United States, he would nonetheless treat him at the parents' request.

The Court ordered that Charlie should receive palliative care only and not receive nucleoside therapy. The family appealed, first to the Court of Appeal, which held against them, then to the United Kingdom Supreme Court, which affirmed the judgment, and finally to the European Court of Human Rights, which, in effect, declined to take jurisdiction. Subsequently, GOSH received opinions from experts in the United States and Italy suggesting that NBT might be beneficial to Charlie.

The Judge held another hearing, ordering that there should be a meeting of experts following examination of Charlie and his imaging and laboratory findings. It was then agreed in Court that NBT would not now be beneficial to Charlie. On July 24, the Court ordered that he should be taken to a hospice for palliative care with a timetable allowing time for his parents to agree with GOSH on how it should be accomplished. No agreement was reached. Charlie was taken to the hospice on July 28 and died shortly thereafter.

Nowhere in this sad saga has there been mention of "Death Panels," euthanasia, or Charlie being a prisoner of the State or the NHS. There are two main lessons: (1) as every law student knows, always read the full judgment, not just the headlines, before commenting; and, (2) when dealing with a child's welfare, formal mediation is desirable before initiating litigation.

Parental Responsibility, *Parens Patriae,* Care Withdrawal

F6 Bringing Science Back: Strengthening the Foundation of Fingerprint Examination

Henry J. Swofford, MSFS, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have a greater understanding of what it means to demonstrate scientific validity, the issues surrounding the litigation of fingerprint evidence, and a way forward for the forensic fingerprint community to navigate toward a stronger scientific foundation.

This presentation will impact the forensic science community by discussing the current issues and a path forward for the forensic fingerprint discipline to demonstrate scientific validity in the wake of the highly critical Report by the President's Council of Advisors on Science and Technology (PCAST).

Fingerprint evidence has been admissible in legal proceedings for more than a century and has been practiced by nearly every forensic laboratory throughout the world. Once viewed as the gold standard of forensic evidence, the fingerprint discipline, along with nearly every other forensic discipline, is experiencing a great deal of turbulence as it navigates through the criticisms from the National Research Council (NRC), PCAST, and several other professional working groups and academic commentators. Although the forensic fingerprint discipline was determined to be foundationally valid by the PCAST Report in 2016, questions still remain regarding the validity of the methods when applied to a specific case at hand. The primary concern is the legal field's inability to assess the reliability of fingerprint comparison results for a given case at hand without validated statistical data concerning the strength of the findings, thus bringing into question the scientific validity of fingerprint evidence and threatening its admissibility in criminal courts. These concerns have stimulated a great deal of healthy debate within the forensic fingerprint discipline regarding how forensic science laboratories can move forward in light of these criticisms and demonstrate the applied validity of their methods so they may continue to serve the criminal justice community.

This presentation will provide a candid assessment of the current state of the forensic fingerprint discipline through the lenses of scientific validity, discuss existing gaps between the current state of the practice and the ideal future state, and propose a way forward for the forensic fingerprint community to navigate toward a stronger scientific foundation. As a result, forensic science leadership and criminal and civil litigators will have a much better understanding of the issues related to traditional practices of fingerprint examinations, become familiar with recently developed tools and technologies that can be leveraged by forensic science laboratories to promote more objective, transparent, and standardized practices, and become better positioned to advocate for appropriate improvements within their respective jurisdictions.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Fingerprints, Validity, Science

F7 Mad (Forensic) Scientist and Murder: A Case of Suspected Innocence After 22 Years

Scott Bresler, PhD, University of Cincinnati, Division of Forensic Psychiatry, 260 Stetson Street, Box 670559, Cincinnati, OH 45219; and Donald R. Caster, JD*, University of Cincinnati College of Law, Ohio Innocence Project, PO Box 210040, Cincinnati, OH 45221*

After attending this presentation, attendees will better understand what constitutes a viable *Brady* Claim; that is, what to look for in the files of police officers and forensic scientists, and how to use that information in a legal framework based on personnel files and forensic psychological analysis of the police officers' and/or forensic scientists' fitness for duty at the time of the criminal investigation.

This presentation will impact the forensic science community by shedding light on a problem that is rarely spoken of or investigated — the mental health of forensic scientists and how it may impact their conclusions, in turn affecting the court and undermining its task of seeking just outcomes in criminal matters.

In 1993, James Parsons was convicted of killing his wife, Barbara Parsons, in the bedroom of their home. It appeared that the assailant hit Mrs. Parsons in the head 15 times with a heavy object. Her husband, James, was investigated and claimed to have been away from home working at his auto repair shop during the time in question. This criminal case had remained unsolved for 12 years, when G. Michelle Yezzo, a forensic scientist on staff at the Ohio Bureau of Criminal Identification and Investigation, claimed that she had solved the murder mystery. Using chemical enhancements to find previously undetected bloodstains on a large mechanic's tool and a blood spatter analysis on a sheet reportedly belonging to James and Barbara Parsons, Yezzo gave testimony in court that proved pivotal to the murder conviction. Yet, at the time of this murder conviction, a close review of Yezzo's personnel records revealed that her colleagues and supervisors repeatedly questioned her investigative methods and conclusions. Specifically, some raised the issue that she tended to present evidence with a prosecutorial bias, and she appeared to make mistakes that may have led to "a substantial miscarriage of justice." Moreover, Yezzo's personnel records were replete with many instances in which she exhibited disturbing behavior toward her colleagues. It got to the point that some questioned her mental health, especially during the time she was investigating and came to conclusions leading to the criminal prosecution of James Parsons. It was Yezzo's findings 12 years after the killing that led to Parson's eventual arrest and prosecution. Only circumstantial evidence had been considered until Yezzo's bloodstain analysis on the suspected murder weapon and bed sheet was offered. Interestingly, at the time Yezzo was getting ready to testify in the Parson's murder case, she was investigated and suspended for threatening a coworker.

Twenty-three years later, Ohio Innocence Project attorney, Donald Caster, studied the James Parsons murder conviction. He found that Parsons consistently maintained his innocence and his children never believed their father had killed their mother. Caster was able to obtain the personnel files of Yezzo, and he was shocked by what he found. He hired a forensic psychologist, Dr. Scott Bresler, to review these personnel files, knowing that Dr. Bresler has performed many fitness-for-duty evaluations on persons in positions of trust and power (e.g., doctors, nurses, police officers, firefighters, air traffic controllers). In so doing, Caster established a viable *Brady* Claim and the criminal conviction of James Parsons was vacated after a judicial hearing with new evidence presented in open court. The legal framework for establishing this *Brady* Claim will be described, and the use of Dr. Bresler's analysis of Yezzo's mental state at the time she came to her weighty conclusions will be discussed.

***Brady* Claim, Innocence Project, Fitness for Duty**

F8 An Interpretation of the 2016 President's Council of Advisors on Science and Technology (PCAST) Document in Terms of Forensic Metrology

Veronica Scotti, LLM, Studio Legale Scotti, via Emilia 160, Cadeo, PC 29010, ITALY; and Alessandro M. Ferrero, MSc, Politecnico di Milano, DEIB, Piazza Leonardo da Vinci 32, Milano 20133, ITALY*

After attending this presentation, attendees will better understand how the scientific validity of forensic science methods can be quantitatively assessed by employing the core methods of metrology. In particular, attendees will gain a better understanding of how this may help in evaluating the probability of wrong decisions, when decisions are based on the results of scientific tests.

This presentation will impact the forensic science community by providing an interesting interpretation of the 2016 PCAST document in terms of forensic metrology. This presentation will broaden understanding of how the fundamental concepts of metrology can help with understanding the scientific validity of forensic science methods, and, most importantly, providing a quantitative assessment of their validity.

Recently, a growing discussion regarding the validity of forensic science methods and the way validity can be ensured has been seen. The most recent and interesting document is the PCAST Report, published in September 2016.[1]

On the other hand, ensuring scientific validity of the results obtained from experimental methods is the task of metrology. It is not by chance that forensic metrology has become a popular keyword of both the measurement science and justice.[2,3]

It can be shown that the PCAST Report can be read in a metrological perspective and that the ways scientific validity has been defined have a clear counterpart in the definitions of the contributions to uncertainty given by the International Vocabulary of Metrology (VIM).[4] In particular, the *foundational validity* can be assessed and quantified in terms of definitional uncertainty, while the *validity as applied* can be assessed and quantified in terms of instrumental uncertainty.

Forensic metrology methods enable the experts to evaluate the different contributions to uncertainty and thus provide a quantitative estimate of the validity of the obtained results. This means that a quantitative estimation of the remaining doubt about how well the measurement result represents the measure and can be provided to the trier of facts.

It is also possible to estimate which is the dominant contribution to uncertainty and focus the efforts to discuss and minimize this contribution. This presentation will consider two widely used forensic science methods: DNA profiling and Breath Alcohol Concentration (BAC) tests. This presentation will illustrate that the forensic practice focuses on the definitional uncertainty (in terms of wrong match probability) for DNA analysis, while the dominant contribution to uncertainty is the instrumental one, and focuses on the instrumental uncertainty in BAC tests, while, in this case, the dominant contribution to uncertainty is the definitional one.

Forensic Metrology, Scientific Validity, Measurement Uncertainty

F9 The National Institute of Standards and Technology (NIST) Plans and Approaches to Conducting Scientific Foundation Reviews of Forensic Science Disciplines

John M. Butler, PhD, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899*

The goal of this presentation is to discuss the development of NIST approaches of examining scientific foundations (technical merit reviews) for various forensic science disciplines as requested in the President's Council of Advisors in Science and Technology (PCAST) Report and by the National Commission on Forensic Science.

This presentation will impact the forensic science community by discussing the importance of having documented research and validation studies to support measurement and interpretation claims in forensic science.

Science matters and makes a difference in quality forensic science efforts. Data are necessary to demonstrate that measurement claims are valid and appropriate interpretations can be made. In the past year, the forensic science community has been reminded of the importance of documenting data supporting claims in drawing reliable conclusions on forensic evidence. The PCAST, the National Commission on Forensic Science (NCFS), and the American Association for the Advancement of Science (AAAS) have published recommendations encouraging further research and studies assessing the scientific foundations of forensic disciplines.[1-3]

PCAST and NCFS recommendations request the NIST to examine the scientific literature and conduct technical merit evaluations and validation studies of forensic science methods and practices. For example, the NCFS requested that the results of the technical merit evaluations "be issued by NIST as publicly available resource documents" and that "NIST's evaluation may include but is not limited to: a) research performed by other agencies and laboratories, b) its own intramural research program, or c) research studies documented in already published scientific literature."[2] NCFS also requested that these evaluation documents "should be broadly disseminated in the scientific and criminal justice communities and accompanied by judicial trainings."[2]

The first NIST scientific foundation review underway covers DNA mixture interpretation. In July 2006, the International Society for Forensic Genetics (ISFG) DNA Commission provided a series of recommendations and core principles regarding appropriate interpretation of DNA mixtures.[4] Forensic DNA publications covering the time period of 2007 to 2017 were gathered, analyzed, and summarized as part of understanding how responsive the community has been to the ISFG recommendations. Articles were sorted by topic and relevance to research questions addressed. In addition, interlaboratory study results gathered through NIST studies and other collaborative exercises have been examined as part of this assessment with the hope of designing future interlaboratory studies to explore the capabilities and limitations of probabilistic genotyping systems that aid DNA mixture interpretation.

This presentation will review plans and progress made by NIST and others in these scientific foundation reviews. The important role that interlaboratory studies play in evaluating performance across the forensic science community and the ability to achieve specific levels of measurement accuracy will be emphasized. As part of these scientific foundation reviews, NIST plans to prepare regular reports to help the legal community as well as other scientists understand the capabilities and limitations of specific techniques in forensic science.

Scientific Foundation, PCAST, Validation

F10 The President's Council of Advisors on Science and Technology (PCAST) Report on Forensic Science: Why It Fails Foundational Validity

Kenneth E. Melson, JD, GWU Law School, 2000 H Street, NW, Washington, DC 20052*

After attending this presentation, attendees will have a clearer understanding of why the PCAST Report on forensic science has not negatively impacted the admissibility of comparative forensic science evidence in state and federal courts, and why this "scientific" Report was foundationally flawed from the outset.

This presentation will impact the forensic science community by allowing it to communicate the validity and reliability of its comparative sciences to the courts without being bound by the unnecessarily narrow standards set by PCAST. This presentation will also encourage the forensic science community to understand that additional research is needed to continuously improve the forensic sciences.

The PCAST Report, *Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods*, issued in September 2016, endeavored to elucidate the findings of the National Academy of Sciences (NAS) Report.[2] As courts have pointed out, the PCAST Report added little to the realm of judicial analysis of validity and reliability of comparative-type forensic evidence. The Report fails to identify any general acceptance for the proposition that a black-box study is the *only* way to validate the foundation of a subjective discipline and disregards a plethora of studies demonstrating that examiners can reliably and accurately associate forensic evidence samples with known samples.

The PCAST Report also misstates statistical results of studies, miscalculates error rates, misunderstands the nature of foundational studies, and inaccurately claims the outer bounds of the confidence interval as the rate of error. The PCAST Report further inappropriately asserts that general error rates should be applied to the specific examiner and evidential analysis in the case at bar. Further, the Report arbitrarily sets the upper bounds of acceptable error rate for purposes of validity.

While the PCAST was a policy body, the Report purports to make "scientific findings," a role outside of its charter. The Report professes not to tell the judiciary what to do, for it is the courts that interpret the legal rules, but in a not-so-subtle bout of circular reasoning, PCAST boldly tells the courts what it arbitrarily determined was the single test for validity and reliability under Federal Rule of Evidence 702.

Although the Report fails to follow any scientific methodology in its construct, analysis, or publication, its defenders say the Report has value because of the few recommendations that might be helpful to the scientific community (i.e., those that recommend additional funding and research). Unfortunately, the PCAST timed its Report such that it was released just prior to the end of the Obama administration, with no time for the President, who supposedly asked for the Report, to fund the programs necessary for the continuous improvement of forensic science.

Nevertheless, as with the NAS Report, the forensic science community is taking the recommendations to heart and is continuing to conduct foundational research, including black-box studies. In the end, though, the PCAST Report was not peer reviewed, has an unacceptable error rate, is not generally accepted, failed to use standards and protocols for the review of the literature, and did not have the transparency expected of government reports.

PCAST, NAS, Foundational Validity

F11 Female Murder Victims in Turkey

Güzide Sara Berber, BS, Üsküdar University, Altunizade mah. Haluk Türksoy sok. No:14 Üsküdar, Istanbul 34662, TURKEY; and Sevil Atasoy, PhD, Uskudar University, Institute of Addiction and Forensic Science, Haluk Türksoy sok. 14, Uskudar, Istanbul 34662, TURKEY*

After attending this presentation, attendees will understand the ways in which the murders of women in Turkey are handled.

This presentation will impact the forensic science community by providing statistics regarding female victimization and the murders of women in Turkey.

Violence against women is a common problem that many women face, both around the world and in Turkey, consisting of urban dweller and villager, educated and uneducated, rich and poor, young and old, housewife and working woman.

Violence against women is a human rights violation, with femicide at the peak of the violence. In recent years, there has been an increase in the terrifying dimensions of internal physical violence, which has caused severe injuries and deaths in Turkey. This has become one of the main issues for governments in charge of ensuring the safety of individuals and the peace of society.

Among those who are exposed to physical violence are women and children who cannot defend or protect themselves. The most common types of physical violence against women are sexual assault, kicking, slapping, punching, rough beatings, and torture conducted with hurtful instruments and objects seized at that moment. Additionally, there is verbal and psychological violence, such as severe insults, humiliation, underrating, deprivation of fundamental rights, taking precious savings and money, underestimation, mocking, exclusion, intimidation, and threats, all of which make life unacceptable for women. In severe conflicts, the wife is often seen as an opponent and enemy, the consequence of many mismatches and financial difficulties. Some bursts of anger go beyond beating and lead to killing.

Unless violence against women and the problems of violence within the family are solved, it will not be possible to provide equality between men and women and close the gap in private and public life between women and men. Otherwise, the murder of women will not be prevented. Despite legal regulations, according to results of 2015–17 statistics in Turkey, the number of female murders is increasing every year. Violence against women is a multidimensional problem. The matter has social, cultural, familial, and individual dimensions and the factors leading to the violence have different structures; however, in general, these women remain alone in terms of the violence with which they are confronted and do not have sufficient knowledge, support, and awareness to protect their rights. Because of this, it is important to "Strengthen the Women" to fight against this violence.

Today, violence against women is deemed a violation of human rights, and violence prevention laws are in effect; however, the existence of these laws is insufficient as it takes time for society to adopt legal regulations. Forming bureaucratic mechanisms to facilitate the application of effective laws is necessary. Because of this, without waiting for laws to reflect society, a social awareness against femicide must be developed. In addition to the legal regulations preventing discrimination against women and stopping femicide, regulations have to be effected to strengthen the economic power of women in society. Women are subjected to many types of violence before they are murdered, and the subjects of the violence are not only women — children are also included. Additionally, children who have been witness to violence and murder are left with irreversible psychological damage. For these reasons, it is necessary to take strict measures to prevent both this violence and femicide. These protective measures should not derive from a single source; rather, effective solutions can be determined with state and local administrations and non-governmental organizations.

As a result, although Turkey should be evaluated as a country "forming the assurance of human rights, democracy, superiority of the law, and social justice in the region and paying regard to spread them on a large area," it is obvious that Turkey does not sufficiently prevent violence against women and femicide.

Female Murder, Victims, Violence Against Women

F12 Mandatory Vaccination: The Italian Case Between Clinical and Legal Profiles

Alberto Marchese, Department of Law - University of Messina, via Pietro Castelli, 1, Messina, Sicily 98121, ITALY; Cristina Mondello, MD, Department BIOMORF, University of Messina, via Consolare Valeria, 1, Messina 98123, ITALY; Elvira Ventura Spagnolo, MD*, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; and Aurora Vesto, PhD, Università "Dante Alighieri" Reggio Calabria, Via del Torrione 95, Reggio Calabria , ITALY*

After attending this presentation, attendees will understand the importance of improving knowledge regarding mandatory vaccinations.

This presentation will impact the forensic science community by highlighting the importance of the subject of vaccinations. This subject is widely considered one of the greatest medical achievements of modern civilization. Childhood diseases that were commonplace less than a generation ago are now increasingly rare because of vaccines.

To be effective at eliminating communicable diseases, vaccines must be administered to a sufficient number of people in the community. Thus, public health officials have mandated vaccination for certain diseases as a condition of school attendance.

The Italian government has declared ten vaccines mandatory for children up to age 16 attending school in an effort to combat what it characterizes as misinformation about vaccines. The new measures followed an intense public debate regarding vaccines after a measles outbreak. The government approved making ten vaccines, including measles, rubella, and chickenpox, mandatory beginning September 2017 for children attending Italian pre-schools through the second year of high school. Other required vaccines include tetanus, diphtheria, polio, and hepatitis B. The health minister said children will not be accepted into nursery or pre-schools without proof of vaccinations, while parents of children legally obliged to attend school will face hefty fines for non-compliance. The certification will be required every year.

Because of the success and the mandatory nature of vaccinations, most people would probably not consider vaccination an optional method of medical treatment. For most parents, the "decision" to vaccinate is equivalent to the "decision" to feed one's child. Typically, a doctor informs parents of the school vaccination schedule and the parents' consent to having their child vaccinated; however, for some parents, vaccination is no routine matter. From the time the smallpox vaccine was introduced, vaccination has had its critics. In the two centuries since then, many different types of objections have been raised, with some questioning the scientific qualifications of mass immunization. Others have focused on the personal liberty interests at stake and have objected to the paternalistic nature of government imposition of what is viewed as a personal medical choice. Still others have opposed vaccination for personal or religious reasons.

The overwhelming effectiveness of vaccination programs may lead individuals to ignore the benefits of vaccination and focus more on the risk of side effects. Moreover, some have criticized the coercive nature of these programs. These objections may lead to an unacceptably high number of exemptions, which can compromise vaccination programs and leave the population susceptible to outbreaks.

This presentation explores vaccination programs with an eye toward greater public safety without ignoring the reality of a small but committed group of vaccine critics. This presentation concludes by recommending stricter enforcement of mandatory requirements for most vaccines and greater dissemination of information on the continued importance of vaccinations.

Mandatory Vaccination, Mass Immunization, Health of Children

F13 Distorting DNA Evidence: Methods of Math Distraction

Mark W. Perlin, PhD, MD, Cybergenetics, 160 N Craig Street, Ste 210, Pittsburgh, PA 15213*

After attending this presentation, attendees will understand how misleading statements can confuse DNA evidence. Trial lawyers can apply these methods to sow confusion. Opposing lawyers can block these methods to restore evidentiary clarity.

This presentation will impact the forensic science community by providing insight into how scientific testimony can distort DNA match statistics in criminal justice.

DNA is often key physical evidence in a criminal proceeding. Connecting a defendant to a crime through genetic material left at the scene can be highly persuasive to a jury, and the absence of such a reliable connection may weaken a prosecutor's argument.

The DNA expert's ultimate scientific statement is the match statistic. How much more probable is a match between evidence and the defendant than coincidence? With abundant DNA left by a single person, this match number is one over the Random Match Probability (RMP). The numerator is one because of the perfect match between the evidence and defendant genotypes. The denominator expresses match rarity as the RMP of finding the defendant's genotype by chance.

A biological mixture contains DNA from two or more people. Mixture data can be explained by adding together the genotypes of these contributors. Since the data can be explained in multiple ways, a contributor genotype is a list of possibilities with associated probabilities.

Comparing a "probabilistic" genotype with a reference genotype (relative to a random genotype) yields a match statistic. This Likelihood Ratio (LR) measures identification information — the probability of a match relative to coincidence. When comparing with the reference, the numerator becomes an evidence genotype probability at the defendant's genotype, a number usually less than one. The denominator is again the defendant's RMP.

Court is an adversarial process. While match statistic science is clear, legal rhetoric can cloud the findings. How can a defender confuse people about a simple ratio of probabilities? Answer: by distracting the jury with irrelevant arithmetic unrelated to a meaningful LR.

Methods of math distraction infect courtroom testimony. Three common ploys are: (1) The defendant does not have the highest probability genotype; (2) other genotypes have probabilities that add up to more than half; and, (3) the match probability between the evidence and defendant is small. These math statements are often true, but they are irrelevant to the DNA match statistic. Whereas the LR is a ratio of probabilities, these distractions may feature an arbitrary big number, sum of numbers, or partial ratio. How can a prosecutor demonstrate to a jury that this is just bad math distorting good DNA evidence?

Drawing on transcripts of actual DNA expert testimony, this presentation will teach attendees how criminal defenders and their experts have employed these three methods of math distraction to confuse triers of fact. The transcripts will also highlight how prosecutors and their experts were able to rebut these baseless arguments. While honesty is commendable, sometimes rhetoric is a determining factor in an adversarial proceeding.

DNA evidence is only as persuasive as its presentation. Proponent experts communicate DNA results for jurors to understand. Defenders and opponent experts can confuse jurors about DNA match statistics with methods of math distraction. Prosecutors can expose flaws in these misleading digressions.

Ways of confusing and clarifying DNA match statistics for the finder of fact will be presented. This presentation will provide multiple lawyer and scientist perspectives.

Expert Testimony, DNA Mixtures, Trial Tactics

F14 Is Epigenetics Ready for Prime Time? The Potential of Using DNA Methylation Pattern Evidence to Differentiate Between Monozygotic Twins and to Estimate Age in DNA Donors

Robert F. Hedges, JD, Attorney at Law, PO Box 412, Fruitport, MI 49415*

After attending this presentation, attendees will understand the potential for using epigenetic science in the form of DNA methylation patterns as forensic evidence.

This presentation will impact the forensic science community by assessing the state of the scientific literature on DNA methylation patterns in light of *Daubert* or *Frye* admissibility standards.

Forensic DNA testing was first used in the 1980s and has since revolutionized forensic science. There have been tremendous advances in DNA technology through the decades, including Polymerase Chain Reaction (PCR) amplification and probabilistic genotyping, yet there remain limits to what traditional DNA testing can accomplish. Among those are: (1) differentiating between monozygotic twins; and, (2) estimating the age of a DNA donor.

The discipline of Epigenetics offers potential answers to these questions that may be on the cusp of qualifying for courtroom admissibility.

The Oxford Dictionary defines Epigenetics as "[t]he study of changes in organisms caused by modification of gene expression rather than alteration of the genetic code itself." "Epi-" is a Greek prefix meaning "above," "upon," or "in addition to."

The focus of this presentation will be on one area of epigenetics — DNA methylation. DNA methylation means the addition of methyl groups (CH_3) to the DNA molecule. The methyl groups do not change the DNA code or sequence, but they change the way the DNA is expressed. Stated another way, DNA methylation results in gene silencing. This is necessary for normal growth and development but can also affect disease progression.[1,2]

Of the four DNA bases, traditional dogma holds that only Cytosine (C) can be methylated in mammals, but recent research suggests that Adenine (A) can also be methylated; thus, nearly all of the scientific research has involved cytosine.[3,4] When cytosine is methylated it becomes 5-methylcytosine (5-mC). Most 5-mCs are found adjacent to Guanine (G) bases, which are called "CpG sites." Clusters of CpG sites are called "CpG islands." A test called Bisulfite Sequencing can be used to develop a DNA methylation profile. When DNA is processed using sodium bisulfite, methylated cytosine remains cytosine, while unmethylated cytosine changes to uracil, thus making it relatively easy to map DNA methylation patterns via conventional sequencing methods.[1,2,5]

The scientific literature on DNA methylation is extensive and goes back more than a half century. In 1948, scientist Rollin Hotchkiss described his findings on the methylation of cytosine into 5-methylcytosine, which is still the understanding today. In the 1970s, Sir Adrian Bird described the role DNA methylation plays in gene transcription. The Bisulfite Sequencing test was invented in the 1990s by Marianne Frommer and Susan Clark and is considered the gold standard of DNA methylation analysis.[1,5] Over the decades, numerous studies, many of them involving twins, have reported findings based on DNA methylation. Therefore, there exists a mature, extensive body of scientific research involving DNA methylation, and in recent years, some studies have specifically discussed the potential of DNA methylation science as forensic evidence.[6,7]

Several research papers reporting the ability to differentiate monozygotic twins using DNA methylation patterns will be listed, discussed, and summarized.[8-15] The extent and quality of the research will be examined with an eye toward whether they appear sufficient to meet *Daubert* or *Frye* standards.[16,17]

The case of *Commonwealth v. Dwayne McNair* will also be reviewed.[18] In *McNair*, the prosecution attempted to use a different type of DNA test to distinguish monozygotic twins. Specifically, the prosecution attempted use ultra-deep next generation sequencing to search for somatic mutations.[19] In April 2017, the trial judge ruled such testing does not meet *Daubert* standards for admissibility. The case is on appeal.

Finally, several recent research papers report the ability to estimate DNA donor age to a range of approximately 3.5–6.85 years based on DNA methylation patterns.[7,20-27] Such evidence could be used to settle questions of possible lab contamination in certain DNA cold cases. See, for example, *People v. Leiterman*.[28]

Epigenetics, DNA Methylation, Monozygotic Twins

F15 "Not Suitable for Comparison" Almost Sends the Wrong Man to Prison

Brian J. Walsh, JD, Office of Cook County Public Defender, 69 W Washington, 17th Floor, Chicago, IL 60602*

The goal of this presentation is to review a case in which a strict interpretation decision that a DNA mixture was not suitable for comparison ignored the presence of usable data that corroborated the defendant's innocence.

This presentation will impact the forensic science community by informing attendees of the need for full disclosure of the facts, bases of conclusions, and limitations on those conclusions.

This is a case in which the defendant was charged with murder, based on the statements of an eyewitness naming the defendant as the shooter.[1] Relevant physical evidence included a baseball hat that fell off the shooter's head as he fled. The first round of DNA testing at 15 loci plus a gender marker developed results at 14 loci plus gender. The lab concluded there was a mixture of at least two people, the number of contributors could not be determined, and the mixture was potentially incomplete and not suitable for comparison.

Defense investigation found an alternate suspect who had admitted to others that he had committed the murder.

A second testing of the hat was ordered with comparison to the alternate suspect. Testing was again performed at 15 loci and gender and results were developed at all loci. The same conclusion was reported: a mixture of at least two and that the mixture was potentially incomplete and not suitable for comparison.

Subsequent to a request for disclosure of the case file and supporting data, defense review of the data found good, reliable data that could be examined. Based on the data reported, there was evidence to exclude the defendant as a contributor and to include the alternate suspect as a possible contributor to the baseball hat.

The third-party confessions of the alternate suspect were hearsay statements and not ordinarily admissible at trial. The Unites States Supreme Court has recognized that Due Process rights to a fair trial and the defendant's right to present a defense will override the hearsay prohibition at times when the statements can be shown to be reliable.[2] At a pretrial hearing, those statements were presented along with a DNA report tendered by the defense that the defendant was excluded and the alternate suspect was included as a contributor to the hat. After the court had ruled that some of those statements would be admissible and before trial commenced, the State decided not to prosecute (*nolle prose*), effectively dismissing the case and allowing the defendant to be released.

A straightforward reading of the state's lab reports would have left the defendant with no physical corroboration of the alternate suspect's statements. The report wording that the mixture was not suitable for comparison fails to inform the legal practitioner that there may be good, reliable data that may be used for the defense. The recent National Commission on Forensic Science made various recommendations to the Attorney General, including recommendations on pre-trial discovery and documentation, case record, and report contents.[3] These recommendations are a beginning to address potential pitfalls caused by the failure to adequately consider the defense position. Labs are also urged to consider implementing procedures to reconsider the interpretation decisions or to flag the concerns in the report when presented with other viable interpretations.

Actual Innocence, Due Process, DNA Interpretation

F16 You Be the Judge: An Interactive Session Regarding Admissibility of Scientific Evidence

W. Milton Nuzum III, JD, Supreme Court of Ohio, 65 S Front Street, Columbus, OH 43215; and Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501*

After attending this presentation, attendees will be able to: (1) state the elements of admissibility under the Rules of Evidence required of a trial court judge to admit scientific or technical evidence; (2) evaluate the challenges a judge faces in a variety of situations in his/her role as gatekeeper of admissible scientific or technical evidence; and, (3) apply their knowledge of the elements of admissible evidence in specific case situations.

This presentation will impact the forensic science community by increasing attendees' abilities to apply their knowledge of the elements for admitting scientific evidence in several specific case situations. Attendees will have a better comprehension of the trial court's admissibility standards regarding expert testimony through interactive audience participation of the application of these standards in several case studies.

In the tradition-bound adversarial legal process, judges and jurors in the courtrooms must reach definitive decisions for "a particular moment in time, while this scientific process is going on."[1] Within the dynamic intersection of science and law, justice and science must coexist for the good of society. Historically, courts have viewed science as an indispensable ally in their shared project of pursuing truth. Scientists seek truth by working diligently and gradually on their hypotheses, using relevant scientific methodologies to validate core insights. Scientists also recognize their evolving need to revise and refine their hypotheses and methodologies due to peer review and criticism emanating from various scientific communities.

Understanding the role of judges as gatekeepers will assist attendees in comprehending and appreciating the critical admissibility decisions judges have as gatekeepers of scientific evidence in our courtrooms. *Daubert v. Merrell Dow Pharmaceuticals, Inc*. is the leading case regarding this gatekeeper role of admissibility decision-making.[2] The United States Supreme Court in *Daubert* defined the judge's role as a gatekeeper for admitting scientific knowledge to assist the triers of fact in understanding the evidence. Jurors as judges of the facts must determine the facts in issue in a case by applying valid scientific conclusions to the pertinent facts in the case. Judges should admit conclusions that will qualify as scientific knowledge if the proponents of such evidence can demonstrate that such conclusions are the products of sound scientific methodology derived from the scientific method. Understanding the methodology used by an expert is critical to effective, efficient, and proper judicial gatekeeping.

Moreover, Federal Rule of Evidence 702 requires the following for expert testimony: A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if: (1) the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue; (2) the testimony is based on sufficient facts or data; (3) the testimony is the product of reliable principles and methods; and, (4) the expert has reliably applied the principles and methods to the facts of the case.

This session will focus on teaching attendees to apply these trial court's admissibility standards regarding expert testimony through the vehicle of interactive audience participation.

F17 Post-Conviction Relief: The Many Errors Leading to a Miscarriage of Justice

Charlotte J. Word, PhD, PO Box 35153, North Chesterfield, VA 23235-0153; Robin W. Cotton, PhD*, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118; and Emily C. Paavola, JD*, 900 Elmwood Avenue, Ste 200, Columbia, SC 29201*

After attending this presentation, attendees will better understand why discovery and review of DNA testing data pre-trial are critical and how a litany of errors by the prosecutor and expert witnesses led to the inaccurate presentation of DNA test results, resulting in the conviction of an intellectually disabled man in a capital murder case.

This presentation will impact the forensic science community by providing information regarding the significant efforts needed post-conviction to seek justice for a defendant after a "worst-case scenario" of multiple events occurred at trial, including discovery violations, inaccurate demonstratives depicting the DNA test results, and expert witnesses' testimony that misrepresented the significance of the DNA results.

Kenneth Simmons was convicted and sentenced to death in 1999 for the murder and sexual assault of an elderly woman in Summerville, SC. The trial conviction resulted from grossly misleading DNA testimony, lack of adequate scientific review of the DNA testing for the defense, and encouragement of errors by an overly zealous prosecutor.

Simmons's death sentence was commuted to life imprisonment in 2014, based on a judicial finding that he is intellectually disabled. The Supreme Court of the United States ruled in *Atkins v. Virginia* in 2002, after Simmons's trial, that persons with intellectual disability cannot be executed.[1] On June 23, 2017, Simmons was also awarded a new trial, 18 years after his original conviction, based on a judge's finding that multiple errors in the State's presentation of DNA evidence caused him to be "severely deprived of his due process rights."

The evidence offered by the prosecution to secure Simmons's original conviction included only two items: the now-debunked DNA evidence and a confession obtained after multiple non-recorded interrogations during which Simmons (whose intellectual disability is now established) falsely confessed to other crimes before ultimately confessing to the murder. A judge recently ruled that the State's DNA evidence was false, confusing, misleading, and inaccurate because the State presented a DNA chart that contained fabricated results. Moreover, the State withheld material evidence, including the fact that a second round of DNA testing did not incriminate Simmons and was inconsistent with the original DNA results, and gender-typing test results indicated no male DNA was even present in the evidentiary samples, among other things.

The first serious examination of the DNA evidence presented at trial was conducted at the request of post-conviction counsel in 2005. Although the initial defense expert noted a number of problems with the DNA evidence, the post-conviction judge was uninterested and initially denied any further live hearings on the subject. In recorded depositions, the State's trial DNA experts refused to acknowledge many of their errors and instead maintained that their original testimony was largely accurate and any errors they committed were insignificant.

To address this apparent "battle of the experts," two additional experts examined the DNA case records. The primary findings, submitted in a joint affidavit in March 2011, not only agreed with the first defense appraisal of the DNA testing, but found numerous additional issues such as undisclosed gender-typing test results, additional unreported results, and the laboratory's failure to use a reagent blank control. Subsequently, the post-conviction relief judge agreed to hear their testimony, but persisted in ignoring the serious concerns of the DNA experts. Simmons was finally awarded a new trial after the state supreme court remanded the DNA issues back down to the post-conviction judge.

The reversal of the conviction required 18 years, three defense attorneys, three well-qualified DNA experts, five hearings, and a state supreme court ruling to undo the original damage. This presentation will detail the flawed legal and scientific issues that contributed to the original conviction and ultimately produced the order for a new trial for Kenneth Simmons.

Post-Conviction Relief, Misrepresentation of DNA, Expert Review of Testing

F18 The Need for Scientifically Educated Persons at the Sharp End of Scene Investigations

Peter R. De Forest, DCrim, Forensic Consultants, PO Box 141, Ardsley, NY 10502; and John J. Lentini, BA, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036*

After attending this presentation, attendees will have an increased appreciation of the importance of a scientific education to underpin training in both fire scene investigation and crime scene investigation. This presentation will examine the changes in fire investigation techniques and hopefully propose a model for inducing similar changes in the investigation of crime scenes that do not involve fires.

This presentation will impact the forensic science community by promoting an understanding of the need for scientific expertise and of fire and crime scenes. This presentation will examine how fire investigation has changed and will propose a model for changing crime scene investigators as well.

Errors that occur with respect to determinations of cause and origin in fire investigations are far more likely to be the result of problems with the scene investigation than with the analysis fire debris samples in the laboratory. This has long been the case. It is attributable to a lack of the necessary scientific expertise at the many fire scenes. Historically, where such expertise was unavailable, the vacuum was filled by non-scientist investigators utilizing naïve "rules of thumb" to substitute for scientific understanding. In an ongoing repeating pattern, more experienced investigators taught these rules to less experienced personnel. These rules of thumb, based on a fundamental misunderstanding of fire behavior, were first debunked in the early 1990s, and by 2000, the document that debunked them, the National Fire Protection Association (NFPA) 921, *Guide for Fire and Explosion Investigations,* can be said to have become "generally accepted."

Apprentice-style training, described above, is starting to give way to a demand for more scientific training, but we are not there yet. In 2009, NFPA 1033, *Standard for Professional Qualifications for Fire Investigator,* added a list of specific subjects in which a fire investigator was required to have knowledge beyond the high school level. That list was expanded to 16 subjects in 2014.

There is still no requirement for a fire investigator to possess a bachelor's degree in anything, and that is unlikely to change soon due to cost considerations. It is unlikely that fire investigation agencies can attract talented college graduates for the meager salaries they offer; however, some unqualified investigators have been weeded out through the use of NFPA 1033, where adverse counsel has probed the investigator's basic knowledge. A fire investigator who does not know the basic units of energy, the basic units of power, or the difference between energy and power is per se unqualified. Rather than challenging investigators' methodology, these new challenges are of the investigator's qualifications. If an investigator can be shown in a pre-trial proceeding, either a deposition or a preliminary hearing, to lack the requisite knowledge, the case is likely to be dismissed or to be settled.[1]

There is no such standard to which crime scene investigators are held. While it is fairly obvious that fire, a complex phenomenon involving chemistry and physics, requires at least some scientific knowledge, that is often not the perception in ordinary crime scenes, despite the need to understand basic physics, evidence collection and preservation, and documentation. This presentation will suggest ways to improve the quality of personnel on crime scenes, but there may be the same problems that are experienced in fire investigations (i.e., when a scientist can earn twice as much money in a non-law-enforcement position, that is likely to be the career path he or she chooses).

A person can be taught to perform routine or repetitive tasks, but in order to do those tasks well, it is necessary for the person to understand the scientific principles behind that training. This is difficult to accomplish without a scientific education.

Scientific Investigation, Fire Scenes, Crime Scenes

F19 How Judges and Juries May Perceive Liability Issues Arising From the Operation of Highly Automated Vehicles

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; and Laura L. Liptai, PhD*, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556*

After attending this presentation, attendees will better understand the dynamic relationship between law and technology regarding highly automated vehicles, as well as related ethical and moral dilemmas.

This presentation will impact the forensic science community by increasing competence in understanding legal and scientific issues as to this technology and will allow attendees to recognize possible solutions in developing and understanding appropriate laws in this area.

This presentation begins with an analysis of human errors associated with 85% of motor vehicle accidents. It is hoped that the Highly Autonomous Vehicle (HAV) will address and diminish most of these error types. The full-scale tests of HAVs in difficult control situations will be presented. The side-by-side comparison of HAVs next to human-controlled vehicles will be demonstrated through modeling and full-scale testing. It's impressive, but many unresolved issues exist.

Federal and state laws regulate HAVs being operated on public roads in the United States. When laws from state to state regarding HAVs are reviewed, one can see a myriad of different laws across the United States. The National Highway Traffic Safety Administration (NHTSA) is a federal agency of the Executive Branch and part of the Federal Department of Transportation. NHTSA's mission is to "Save lives, prevent injuries, reduce vehicle-related crashes. Accordingly, NHTSA has proposed Model State Policy to create consistency and unify the national framework of states to regulate all levels of HAVs. This Model State Policy builds on collective knowledge to date and assists in avoiding inconsistent laws and regulations among the 50 states and other United States jurisdictions. Their goal is to avoid the delay of wide acceptance and promote deployment of lifesaving technologies. NHTSA foresees a system wherein states would treat HAVs as the "drivers" of these vehicles. In the interim, Model State Policy suggests states only allow testing and require application and approval before manufacturers are permitted to begin testing. This policy recommends statutes requiring licensed human drivers possessing special training. Overall, this policy urges states to begin addressing issues arising with increased use but recommends states' current usage be limited to testing only.

The legal landscape involving autonomous vehicles will be complex and can include product liability laws such as negligence, strict liability, misrepresentation, and breach of warranty as well as contract law. Jurisdictions adhering to the Second Restatement of Torts would hold manufacturers liable for the sale of their products containing an "unreasonably dangerous" defect even if manufacturers have "exercised all possible care in the preparation and sale" of their products. Other jurisdictions may be utilizing the Third Restatement of Torts, which would specifically deal with manufacturing defects, design defects, and failure to warn to include liability for design defects and failure to warn to "foreseeable risks." The Third Restatement addresses the failure of manufacturers to identify and mitigate dangerous "foreseeable" risks in a similar vein as negligence concepts rather than as strict liability concepts. Liability insurance is another complicating factor as each state has varying laws for impleading the manufacturers versus initiating separate legal actions against manufacturers after the case concludes.

Another dimension involves ethical concerns regarding autonomous vehicles. Will autonomous vehicles fully replace human drivers? What ethical judgments will manufacturers of autonomous vehicles be called upon to make? What socioeconomic impacts flow from the operation of autonomous vehicles? Will these vehicles disrupt the nature of privacy and security? What dialogue needs to take place with government, industry, academia, and the public?

The Uniform Law Commission (The National Conference of Commissioners on Uniform State Laws) recently established a Study Committee on State Regulation of Driverless Cars. Due to this technology rapidly evolving and ripening, four states and the District of Columbia have already enacted their own autonomous vehicle legislation. Moreover, NHTSA has issued guidelines for states to use to regulate these types of vehicles. This Study Committee of the Uniform Law Commission will study the need for and feasibility of drafting uniform state legislation for autonomous vehicles. Their efforts will be discussed.

Autonomous, Liability, Ethics

F20 Quantification of Scientific Opinions and the American Jury System

Robert M. Sanger, JD, Sanger Swysen & Dunkle, 125 E De La Guerra Street, Ste 102, Santa Barbara, CA 93101*

The goal of this presentation is to share concerns with colleagues regarding the conceptual incompatibility of quantification of forensic opinions with the heuristic of the American jury.

This presentation will impact the forensic science community by encouraging thought as to whether quantification is compatible with the current American jury system heuristic. If not, judges, lawyers, and forensic scientists must find ways to adapt the jury system and its present heuristic to a new paradigm that integrates quantification.

Opinions of forensic scientists are generally quantified either in numerical terms or value language that suggest a numerical quantification. Currently, quantification of DNA evidence is typical, but there is an effort to quantify fingerprints, pattern evidence, ballistics, and others. The American jury is not educated in statistics nor in how to integrate quantification into their deliberations. Jurors are generally asked to "weigh" evidence and compare it to a vague "burden of proof" in determining which party wins.

The folk ideal of the American jury is one in which the jurors deliberate impartially, weighing each part of the evidence, considering all the evidence, and then "applying" it to the law; however, the folk ideal of the American jury is seldom, if ever, met in practice. Jurors are human and subject to bias and prejudices, and they are not equipped with the knowledge required to perform statistical analysis. As a result, they employ a folk heuristic.

Lawyers, judges, and forensic scientists must evaluate whether quantification — presenting evidence of Frequentist (F), Random Match Probability (RMP), Likelihood Ratios (LR), Bayesian Analysis (BA), or Bayesian Network analysis (BN) — is compatible with either the folk ideal or the heuristic that characterize the American jury. In other words, if an expert expresses an opinion as to one item of evidence (by F, RMP, or LR) or an opinion about the interrelation of one item of multiple items of evidence (by BA or BN), is this compatible with how the American jury functions ideally or in practice?

It is the position of this presentation that quantification is not compatible with the current American jury system. Juries, in fact, engage in a type of largely non-numerical BN analysis. On a good day (when they do not corrupt the process with, for instance, bigotry), they give some type of folk quantification to the individual pieces of evidence. They then evaluate the evidence as a whole using a heuristic similar to a folk BN analysis, which is then compared to a vague standard of the burden of proof. The jury's enterprise is that of uncertainty, just as is the statistician's. The folk ideal is that the American jury will make an overall network analysis resulting in an LR that favors the unknowable truth within the tolerance stated in the burden of proof.

It is observed anecdotally that expert opinions may carry too much or too little weight with jurors. This intuitive observation is supported conceptually in that quantification by an expert is incompatible with the American jury's heuristic in which one piece of evidence is quantified in a scientific manner and the jury is given no means to integrate that quantification into the heuristic that they are intuitively using to weigh the rest of the evidence. For example, the jury is given the probability of randomly finding a match in a data base (RMP) regarding the DNA profile taken from an object at the scene that corresponds to the defendant's sample. Yet this is only a part of the heuristic by which the jury determines whether the case against the defendant was proven. They weigh this evidence with a network of unquantified evidence before they can weigh whether this quantified evidence even creates a likelihood that the defendant was at the scene (e.g., was the object moved, was there transfer DNA, was the evidence contaminated, was the evidence properly analyzed, was the evidence planted, or was the defendant being framed?). And, if the defendant was at the scene, did the defendant do it? Yet, among these important, unquantified, interrelated, or non-interrelated pieces of evidence, there is a glaring DNA quantification that cannot be statistically multiplied, divided, added, or subtracted with anything else in the jury's analysis.

As we move from quantification of DNA analysis to quantification of fingerprints, pattern evidence, ballistics, and other evidence, thought must be given as to whether quantification is compatible with the current American jury heuristic. If not, judges, lawyers, and forensic scientists need to find ways to adapt the jury system and its present heuristic to a new a paradigm of integrating quantification.

Expert Opinions, Quantification, Jury

F21 What Does "Under the Influence" Mean in Driving Under the Influence (DUI) Drug Cases?

Ronald L. Moore, Esq., JD, Impaired Driving Toxicology, 25422 Trabuco Road, Ste 105-309, Lake Forest, CA 92630*

After attending this presentation, attendees will understand the similarities and differences in the definition of "Under the Influence" in DUI alcohol and DUI drug cases and the additional difficulties in proving "Under the Influence" in DUI drug cases.

This presentation will impact the forensic science community by directing future research in order to overcome present limitations in proving "Under the Influence" in DUI drug cases.

DUI alcohol cases are commonly charged on both per se (over the Blood Alcohol Concentration (BAC) limit) and common law driving while "Under the Influence" theories. Because of the issues involved in establishing science-based equivalent per se limits for drugs, many states only prosecute DUI drug cases under the common law theory. This raises questions regarding to what extent is the alcohol model a basis for understanding what quanta of impairment from drugs is necessary to breach the law, and how the presence or absence of that amount of impairment is proven.

In DUI alcohol cases, there have been several large case-controlled studies that have provided crash-risk-odds ratios for alcohol, which clearly demonstrate the concentration-dependent increase in crash risk from alcohol. This provides an objective basis for setting not only the per se limits based on when the crash-risk-odds ratio increases to a level not tolerated by society, but then setting the quanta of impairment as being equivalent to that which is present at the proscribed BAC. The difficulty with DUI drug cases is that the concentration-dependent crash-risk-odds ratio have not been or cannot be established for the myriad of drugs that may potentially impair driving.

With many drugs or medications, the driver may be less impaired while being treated for his or her medical condition than the person would be without the medication. The mere presence of a medication in the person's blood stream, even when present in therapeutic quantities, is not proof of illegal impairment. Furthermore, there may be some level of effect of the medication which is still consistent with safe driving. The impairing effects of the drug may not occur at the same time or in the same magnitude as the desired effect for which the medication is taken, nor has it been established through research that the presence of physiological side effects of taking medication or drugs (such as pulse rate, blood pressure, pupillary reactions to light, etc.) or performance on field sobriety tests correlate with drug-impaired driving ability. Also, in many DUI drug cases, the traffic stop is predicated on regulatory or equipment violations that do not demonstrate impaired driving. Therefore, with alcohol, crash-risk-odds ratios provide an objective basis for establishing that the requisite amount of driving impairment is present based on an objective measure of BAC and can be extrapolated to the types of behaviors that are present in people intoxicated to that level. Impairment from other substances presents a much more difficult interpretation of how to objectively demonstrate that a driver is too affected by the medication to drive safely.

DUI Drugs, Under the Influence, Driving

F22 Due Process: Unscrambling SCRAM®

Gil Sapir, JD, PO Box 6950, Chicago, IL 60680; and Donald J. Ramsell, JD, 128 S County Farm Road, Wheaton, IL 60187*

After attending this presentation, attendees will appreciate the necessity of unscrambling the Secure Continuous Remote Alcohol Monitor's (SCRAM's®) subjective Transdermal Alcohol Concentration (TAC) test results by the legal community.[1]

This presentation will impact the forensic science community by increasing the realization that the use of convenient biomonitoring devices should not usurp scientific accuracy and reliability in the judicial process.

SCRAM® is designed to measure alcohol content as it diffuses through a person's skin as insensible perspiration.[1] TAC does not directly correlate to Blood Alcohol Concentration (BAC) in a SCRAM®.[2] The Drager fuel cell is contained in an ankle bracelet worn by the offender. The device is manufactured by Alcohol Monitoring Systems (AMS). It is designed for court-ordered alcohol monitoring of TAC readings.[3] The unit's modem transmits continuous periodic measurements every 15, 30, or 60 minutes. Positive TAC readings are sent to a central monitoring location for internal review and confirmation.

The device is commercially available to law enforcement agencies and privately operated correctional institutions. SCRAMs® are not subject to uniform standards and regulations for approval, use, maintenance, and calibration. The units can be purchased without governmental oversight and have lower standards than those promulgated in the Driving Under the Influence (DUI) industry.

SCRAMs® are useful in general population biomonitoring of self-induced alcohol consumption as a passive preliminary testing device; however, SCRAMs® have limitations. This presentation briefly reviews the manufacturer's material and scientific literature for accuracy of results as a basis to suppress the TAC results.

The data is transmitted from the device to a central database for initial screening review by a committee. An analyst subjectively decides if the presumed positive is a confirmed positive, presumed tamper, confirmed tamper, or compliant result. The purported analytical determination is problematic and generates inconsistent reporting. Data from the original SCRAM® device, as compared to the current generation SCRAM® II and SCRAMx® devices, indicate poor performance in identifying alcohol consumption events.[4] SCRAM® results should be considered a presumptive violation followed by a confirmatory test.

Justice Blackmun wrote in *Daubert v. Merrill Dow Pharmaceuticals, Inc.,* "under the Rules the trial judge must ensure that any and all scientific testimony or evidence admitted is not only relevant, but reliable." Accordingly, "evidentiary reliability is based upon scientific validity."[5] Attorneys should question the SCRAM's® results by requiring that the analyst testify in court pursuant to *Melendez-Diaz v. Massachusett*.[6] In *Melendez-Diaz*, the United States Supreme Court held that a laboratory report (evidence affidavit or laboratory certificate) prepared for a criminal prosecution in lieu of court testimony is "testimonial" evidence subject to the Sixth Amendment's Confrontation Clause. It is not a business record.[7] Therefore, the defendant has a right to cross-examine the analyst who conducted the testing — not the probation officer or distributor trained by AMS to validate the results.

Significant issues for a motion to suppress SCRAM® results are: (1) alcohol in the perspiration; (2) alcohol from surficial application of a substance with alcohol or some interfering substance in it; (3) interfering substance in the perspiration; (4) unit being regularly calibrated before and after use; (5) production of separate results for TAC, temperature, and current-times-resistance (IR) voltage; (6) operating procedure not including periodic accuracy checks to validate calibration; (7) calibration log not available to user; (8) valid calibration if within 20% of target value; (9) non-existent independent approved calibration standard to test the transdermal devices; (10) questionable ability to differentiate between methanol, isopropanol, and diethyl ether (huffers); (11) no blank reference prior to sampling; (12) device's inability to make a determination of result; and (13) qualifications and competency of analyst.[8]

The attorney has a constitutional obligation to question scientific evidence. Public policy and convenience should not replace objective, accurate, and reliable monitored TAC results. Flawed evidence should not be admissible. Wrongful convictions must be prevented.

Transdermal Alcohol, SCRAM®, DUI

F23 The Use of Field Sobriety Tests (FST) as Proof of Driving Impairment

Jeremy C. Brehmer, JD, Brehmer Law Corporation, 1200 Truxtun Avenue, Ste 120, Bakersfield, CA 93301; and Ronald L. Moore, Esq., JD*, Impaired Driving Toxicology, 25422 Trabuco Road, Ste 105-309, Lake Forest, CA 92630*

After attending this presentation, attendees will understand the basis for use of Standardized Field Sobriety Tests (SFSTs) as proof of driving impairment in Driving Under the Influence (DUI) alcohol cases and the limitations on extending this rationale to DUI drug cases.

This presentation will impact the forensic science community by educating attendees about the limitations on forensic testimony regarding the use of SFSTs as proof of driving impairment and direct future research to overcome those limitations, if possible.

SFSTs were developed to assist police officers in determining drivers who were likely to be over the legal limit of 0.08% Blood Alcohol Concentration (BAC), as a basis for probable cause to arrest, and in combination with the officer's other observations of driving, post-stop cues, and physical symptoms of alcohol intoxication. Several validation studies (Colorado 1995, Florida 1997, and San Diego 1998) were conducted to illustrate the effectiveness of the SFSTs at predicting whether the officer's arrest decision was correct (subject over 0.08%) based on the number of clues observed.

These tests are then often used by prosecutors as proof that the arrestee's driving was impaired, based on the theory that the SFSTs divided attention skills, which are important in driving, and, therefore, if SFST performance is impaired, then driving would likewise be impaired. This supposition is supported by the relationship between the SFST validation for predicting BACs greater than 0.08% and the demonstrated crash risk increasing at BACs greater than 0.08%.

Crash risk from alcohol is a well-studied objective measure of driving impairment, which increases with increasing blood alcohol level, and forms the basis for laws that make driving at a specific BAC illegal. With drug driving impairment, the association with crash risk at particular drug levels is much less well established. The wide variety of drug effects, and the wide variety of conditions for which drugs are taken, contribute to uncertainty in the meaning of SFST performance when drugs are present.

The mere presence of drugs in the subject's system is not proof of driving impairment. Without a correlation of SFST performance to drug levels, and from drug levels to crash risk, the parallel to alcohol is incomplete. There is no known research which directly links SFST performance to a co-existing crash risk from drugs.

This lack of positive association weakens the assumed association between SFST performance and drugged driving impairment. Due to the immense number of drugs, and their varying type and degree of effects, it would be difficult to establish dose or blood level associations with crash risk for individual drugs. A better approach would be to establish an actual association between the degree of impairment measured, the so-called divided attention skills, and driving crash risk or other objective measures of actual driving impairment, since SFSTs lack face validity for driving impairment.

Field Sobriety Test, DUI, Impaired Driving

F24 WITHDRAWN

F25 The Intersection of Science, Standards, and the Law in Fire Litigation

Terry-Dawn Hewitt, LLM, McKenna Hewitt, 820 S Monaco Parkway, #185, Denver, CO 80224-3703; and Wayne J. McKenna, LLB, McKenna Hewitt, 820 S Monaco Parkway, #185, Denver, CO 80224-3703*

After attending this presentation, attendees will understand: (1) how scientific knowledge and methodologies are being embodied in consensus standards in fire investigations; (2) the legal issues that affect the admissibility of or the weight given to standards in court; and, (3) strategies to help lawyers and experts make optimal use of standards in a court case.

This presentation will impact the forensic science community by explaining the rules from the worlds of standards and the law necessary for lawyers, judges, and experts to make science matter in striving for justice in a litigation setting.

How many injustices result from faulty fire science admitted in court? No one knows; however, from what we know and can reasonably infer, this is a huge problem demanding serious attention. This presentation summarizes the nature of this problem, then explains why science-based documentary standards for fire investigations (such as those produced by the National Fire Protection Association and the American Society for Testing and Materials (ASTM)) are an important part of the solution; however, making effective use of such standards can be complicated by legal rules that limit their admissibility in court. The first step in overcoming this hurdle is appreciating the relationships among: (1) fire science and reliable methodologies; (2) consensus standards within the fire investigation field; and, (3) legal rules relating to the admissibility of standards in court. This presentation examines the intersection of science, standards, and the law so the significance of relevant standards are fully appreciated and can be better utilized by all concerned.

First, injustices in fire cases will be discussed. In recent times, scores of people convicted of serious fire crimes, such as murder or arson, have been exonerated because the conviction was based, at least in part, on discredited methods or disproven scientific assumptions. The *National Registry of Exonerations* details such exonerations, described as "cases in which a person was wrongly convicted of a crime and later cleared of all the charges based on new evidence of innocence."[1] This registry documents dozens of cases of erroneous murder or arson convictions based, at least in part, on "false or misleading forensic evidence" from fire investigations.[2] Another factor in several cases was inadequate assistance of counsel, which was caused by counsel's failure to seek or adequately utilize expert assistance or well-known standards, for example.

As horrendous as it is that faulty fire science has played a role in unjustly convicting so many people, these cases represent the mere tip of the iceberg. They do not account for criminal cases in which defendants are charged or tried based on faulty fire science or whose cases are still in the long, arduous processes of post-conviction relief. Nor do these numbers include those who may have been convicted of (or convinced to plead guilty to) fire crimes based on disproven science or unreliable methodologies — cases which do not rise to the seriousness that merit the attention of innocence projects.

Last, but not least, are the injustices that have occurred in civil cases. The same fire investigation science and methodologies are applied in both civil and criminal cases. There is no way of tracking how many bad decisions in civil cases result from disproven fire science or unreliable methodologies.

This presentation describes the development of industry standards relevant to fire investigations that promote the knowledge and methods of science. Next, the legal rules relating to the use of standards in court are summarized, including legal hurdles to admissibility. Attendees are then introduced to the hierarchy of the standards world and the rules governing standards development processes relevant to the admissibility or weight a court will give standards that are proffered. Finally, attendees are shown how to correlate the information regarding the interplay between science and standards to the legal rules of admissibility, so that science-based standards can be more fully employed in the interests of justice.

Fire Investigation, Consensus Standards, NFPA Standards

F26 The Case of the Missing Millionairess: How Sante and Kenneth Kimes Did Not Get Away With Murder

Kerry J. O'Connell, JD, The NY County District Attorney's Office, One Hogan Place, New York, NY 10013*

The goal of this presentation is to illustrate how a painstaking investigation, involving several forensic science disciplines, helped to prove a case of murder and theft by two grifters.

This presentation will impact the forensic science community by demonstrating how to build a compelling circumstantial case of motive, opportunity, and intent when there is no dead body, DNA, or blood to be found.

Sante Kimes and her son Kenneth "Kenny" Kimes concocted an elaborate scheme to defraud and murder 82-year-old Irene Silverman, a wealthy Manhattan widow who owned and lived in an eight-million-dollar townhouse on Manhattan's ritzy Upper East Side. Silverman rented apartments within the townhouse to business executives and patrons of the arts on short-term visits to the city. In the spring of 1998, Sante and Kenny Kimes resolved to murder Silverman in order to steal the townhouse from her.

Kenny Kimes secured a first-floor apartment in Silverman's home, posing as a well-to-do designer named Manny Guerrin. Unbeknown to Silverman and her house staff, Sante Kimes moved in with him. The defendants set up eavesdropping devices on Silverman's telephone line and learned as much as they could about Silverman and her household routines. They forged Silverman's name on several real estate documents purporting to transfer the ownership of the townhouse to the defendants' off-shore corporate entity. On July 2, 1998, Sante posed as a bedridden Irene Silverman and had the fraudulent signature on the deed of sale notarized.

Finally, on the morning of July 5, 1998, while Silverman's housekeeper was on one of the upper floors of the townhouse, the defendants grabbed Silverman in the first-floor hallway, dragged her into their apartment, and killed her. They wrapped the body in garbage bags, placed it in the trunk of their car, and drove out of town, where they dumped Silverman's remains. Her staff noticed too late that she was missing. With police assistance, the townhouse was searched from top to bottom, but Silverman was nowhere to be found. With the police in tow, two of Silverman's staff entered "Manny's" locked apartment. His belongings were gone, but he had left behind an opened roll of duct tape, a box of 42-gallon trash bags with four bags missing, and a shower curtain. A large pillow and a comforter were missing from the bed.

Meanwhile, federal agents investigating the Kimes mother/son duo arrested them for fraud and found the car. When they learned that Irene Silverman was missing, they notified the New York Police Department (NYPD) and incriminating evidence was found in the car and in the possession of a defense investigator. Documents evidencing forgery were found, and Silverman's signatures on all of the documents in a folder marked "Final Dynasty," including the deed and the transfer tax form, were not genuine. In several instances, the signature appears to have been traced from the rental receipt, which Silverman signed and gave to Kenny. The handwriting in several of the notebooks matched Sante's. The handwriting on a fax requesting an $8,000 check from the Atlantis account matched Kenny's.

The jury heard about all the instrumentalities of death in the Kimeses' car and the bag they had checked at the Plaza Hotel, all of which were recovered in the days after their arrest on the Utah warrant: two loaded guns, an empty stun gun box, a pink liquid sleeping drug under the car's front seat with nearby syringes, and two sinister "Scream" masks. The few items recovered from Apartment 1B — undoubtedly left behind in the Kimeses' hurried frenzy to vacate the building — told the rest of the story. An open roll of duct tape and balled-up duct tape, both bearing Kenny's prints, four heavy-duty garbage bags missing from the box of ten, the shower curtain that had no place in the apartment and seemed to be missing its plastic liner, all indicated quite clearly that Silverman had met her end inside the Kimeses' apartment and at their hands. The absence of any forensic or trace evidence showing either that Silverman was killed in that apartment or that she was transported afterward in the trunk of the Lincoln® is a testament to the defendants' craftiness.

This is a case study of an intense investigation to amass evidence of a homicide without a *corpus delicti*.

Homicide w/o *Corpus Delicti*, Fraud, Circumstantial Evidence

F27 Expert Witnesses: A View From the Bench

Daniel G. Martin, Superior Court of Arizona, East Court Building, 101 W Jefferson, Courtroom 412, Phoenix, AZ 85003*

The goal of this presentation is to provide an overview of the role of expert witnesses in the judicial system from a judge's perspective.

This presentation will impact the forensic science community by providing practical advice to experts who appear in court proceedings.

The testimony of expert witnesses contributes significantly to the United States judicial system. They provide expertise in all types of legal matters, both before, during, and after the proceedings. Experts can be used to enlighten the court or to distill complex information for a jury. They often testify in open court but just as frequently provide expertise behind the scenes in a consultative role. They can be called to impeach an opposing expert or to provide an alternative view of the findings. The training of many experts often excludes any information regarding the judicial system and their role in it. They are not aware of courtroom protocols, the different types of legal proceedings that precede trial, the documents that are prepared in advance of trial, or how to conduct themselves once they are on the stand. This presentation will address those issues from the court's perspective.

The judge has a unique viewpoint on the presentation of expert testimony. There are basic tenets that should be adhered to regardless of the type of legal proceedings at hand. The expert should be impartial and clear about the type of evidence he or she is reporting. The expert should speak in plain language that easily communicates their actions, procedures, thought processes, and conclusions. He or she should be prepared and ready to discuss the pros and the cons of their report. The expert should provide concise answers to questions, should comport himself or herself professionally, and adhere to the rules of the courtroom.

Prior to testimony in court and once the review of evidence is complete and a report of findings has been issued, the expert witness should expect his or her opinion to be made public. There are various stages to the legal process in which the findings will be presented. The expert can expect that those findings will be reviewed by the attorneys and that there will be some form of interview process, which can range from an informal meeting to sworn deposition testimony. Both sides will have the opportunity to question the expert and preparation is critical.

Experts may also be asked to express opinions in the form of a sworn affidavit. Such affidavits often constitute the attorney's interpretation of the expert's findings and may not be fully inclusive or accurate, depending on the level of the attorney's understanding. The expert should carefully review any document of this type to ensure that it accurately reflects his or her findings. If an expert is asked to give a deposition or defense interview, the expert should be aware that the proceeding will be recorded (often by video) and that the transcript can be used to impeach. Experts should maintain their objectivity, speak to the facts, be familiar with the literature that supports their findings, and refrain from expressing conclusions that are not supported by the record. Part of the responsibility of the opposing counsel is to bring out contradictions to the findings when they are helpful to their client(s). This process can be combative, but professional demeanor and honest acceptance of the cons of the findings should be the goal at all times.

Many expert witnesses have not been briefed on courtroom procedure and are unaware of the restrictions on their actions once they are sworn in. They will need to be qualified through preliminary examination as to their education, training, and experience. Providing a résumé or *curriculum vitae* to the attorney ahead of time is a good way to ensure this process goes smoothly. Experts are often the mechanism by which exhibits (reports, photographs, supporting documents, etc.) will be admitted into evidence; however, they cannot discuss them until that process is concluded. Generally speaking, experts may not stand or address the jury directly or review exhibits, photographs, or their report until given approval by the judge. Further, their testimony may be limited by court rulings made in advance of the case or at trial. Preparation for these procedural elements is critical to the effective presentation of evidence.

Experts should be prepared for all encounters they may have with the judicial system. This presentation will provide the practical knowledge necessary to make those encounters successful.

Expert Witnesses, Trial, Testimony

F28 Infrared and Ultraviolet Photography for Individual Identification Using Minor Skin Imperfections

Kendra Rollins, MFS, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037; and Paul Stein, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

After attending this presentation, attendees will better understand the use of "smart chips" incorporated into United States passports for rapid and better biometric identification of individuals at the borders. In addition, attendees will learn whether or not digital Ultraviolet (UV) and Infrared (IR) photography can result in enhancing subtle facial details not yet being utilized for identification.

This presentation will impact the forensic science community by suggesting methods of increasing border security measures, as there are presently important decisions being made regarding immigration into this country.

The United States requires biometric passports for visitors, especially those from politically sensitive areas, which require fingerprints, photographs, and pertinent identification information.

This study hypothesized that detailed facial information can be captured by using UV and IR photography and incorporated into digital photographs. Experiments were conducted with a digital and a modified UV/IR camera.

Photographs were taken of subjects under different lighting conditions with the goal of distinguishing facial characteristics. Sunlight, studio lighting, UV penlight, and black light sources were all utilized. In addition, subject characteristics ranged in age, skin type, and use of makeup. In addition to a Digital Single-Lens Reflex (DSLR) camera to take color photographs, five different filters (one UV and four IR) were utilized with the UV/IR camera. Black light IR and UV images were converted into black-and-white photographs. Sunlight experiments were conducted outside on a cloudless June day, at approximately 2:00 p.m. The camera settings were ISO 100, f/13, and shutter speed of 1/350. A white background was used with the UV penlight at a distance of 4ft from the subject's face and the camera manually set for ISO 2000, f/4, and shutter speed of 1/30. Black light photography was conducted in a dark room with the camera settings of f3.5, ISO 400, and shutter speed of 1/25. The studio lighting was conducted with a Calumet® 950-watt light at 1/8 power with an umbrella and white background. Camera settings were f/11, ISO 160, and 1/80 shutter speed. A female subject used mud and silicone-based makeup to see if the UV and IR lighting would show any differences between texture of natural skin and the use of makeup. Black light images revealed skin damage on the subject's face that could have potential identification value. The post-production images were adjusted in Adobe® Photoshop® and brightness compensated for the density of the filter to create the black-and-white photographs. The results were shown to passport photographers, police, and other individuals to see if they detected any differences in skin tone, skin detail, and any special facial characteristics that can be seen in one image compared to another to aid in facial mapping for identification.

Photographers chose the regular color image as showing the best facial details, images taken with a UV filter were second best, and the use of IR filters did not show any improvements in image detail. Laypeople also chose color images as having the most detail and the use of a UV filter, second best. They were also in agreement with the value of using studio lighting. Therefore, photography in conjunction with facial mapping will play a significant role in maintaining passport security and aid in human identification. Using studio lighting for passport photographs will improve their quality and value for screening at points of entry. Incorporating biometric data (fingerprints, iris scans) in a passport chip would further strengthen passport security measures and enhance methods for human identification.

Forensic Photography, Biometrics, Passport Images

F29 Forensic Archaeology: The Legal Aspect for a Practical Application in the Italian Context

Sara Raponi, JD, Via Mario Fioretti 18, Rome 00152, ITALY; and Matteo Borrini, PhD*, Liverpool John Moores University, School of Natural Science & Psychology, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will understand how archaeology could be applied in the forensic context, not only in the field, but also in court.

This presentation will impact the forensic science community by demonstrating not only the potential of forensic archaeology as a discipline, but also by proposing a review of the legal tools that can allow the application of archaeological techniques to the forensic context.

According to the etymology (ἀρχαῖος and λόγος), archaeology is an evidence-based science that employs methodologies and procedures to reconstruct past events from the physical traces left under and above the ground; however, past events are not limited to those that occurred hundreds or thousands of years ago. The actions related to a recent crime could be considered an "ended event" frozen in the past. For this reason, it is possible to transfer archaeology's *modus operandi* into the forensic world. Forensic archaeology is, in fact, the discipline that applies the stratigraphic techniques to the search, recovery, and interpretation of evidence to reconstruct events with a forensic relevance.

Unfortunately, even if the contribution of forensic archaeology for both the investigation and the trial is recognized worldwide, in some countries, it is still difficult to observe its extensive use. The reasons are related to the complexity of the legal systems, the prerogative of only a few categories of experts on death investigations, and the general lack of knowledge regarding the discipline and its undoubted potential.

Adopting the Italian perspective as a relevant example, the legal instruments for both forensic archaeologists and all other practitioners involved in the investigation could benefit from the use of stratigraphic techniques. With a comparison between the scientific reliability of archaeological methodologies and the Code of Criminal Procedure, it will be possible to delineate how forensic archaeology can fit into the legal system and can be applied for the benefit of a fair trial.

Stratigraphy and evidence-collecting techniques, if performed according to international protocols and guidelines, provide evidence that can be used in court under the rules that control the scientific evidence and its acquisition. In addition, to perfectly integrate the role of the forensic archaeologist in the trial, the possible scientific tasks that the various parties (judge, prosecutor, and defense) could assign to the practitioner will be addressed. This will help practitioners act properly at the scene and in court; at the same time, it will encourage judicial authorities and lawyers to promote the application of archaeological methodologies in cases in which it is necessary to search and recover concealed pieces of evidence.

In conclusion, useful legal references and tools will be provided, not only for the forensic archaeologist, but also for everyone involved in the crime scene investigation and trial. The practitioner and other parties will be able to cooperate and will be aware of the potential provided by the application of stratigraphic techniques to the forensic investigation, particularly when search, recovery, and documentation of buried evidence is required.

An analysis of the practical and legal aspects of forensic archeology, reviewing the legal principles, and the jurisprudence useful to the application of this discipline is necessary.

Forensic Archaeology, Penal Code, Stratigraphy

F30 The Science and Law of Solitary Confinement

Donald E. Shelton, JD, PhD, University of Michigan-Dearborn, Criminal Justice Program, 4901 Evergreen Road, Dearborn, MI 48128-2406*

After attending this presentation, attendees will better understand the scientific studies of the psychological effects of solitary confinement and whether those effects constitute "cruel and unusual punishment" contrary to the 8th Amendment of the United States Constitution.

This presentation will impact the forensic scientific community by providing attendees with a competency regarding the psychological and legal impacts of solitary confinement.

Solitary confinement in the United States typically means isolating a prisoner in a cell for 22 to 24 hours a day without any meaningful human contact or interaction. As of 2013, there were more than 12,000 federal inmates in solitary, and estimates of the national total exceed 80,000.[1] It was first used in the United States in the early 18th century but was abandoned, only to be reborn in the "law and order" era of the 1980s, when rehabilitation ceased to be an active goal of corrections.

Psychiatrists, psychologists, and criminologists have studied the effect of such isolation on mental health. Criminal justice advocates and the courts are now considering whether such treatment amounts to "cruel and unusual" punishment in violation of the 8th Amendment.

Numerous studies have found that isolation and sensory deprivation causes drastic reactions such as hallucinations, confusion, lethargy, anxiety, panic, time distortions, impaired memory, and psychotic behavior.[2] All of the major studies have found that solitary confinement produces a higher rate of psychiatric and psychological health problems than "normal" imprisonment.[3] There is general agreement among many of those who have studied solitary confinement that this mode of imprisonment can produce severe effects.[4]

The United States Supreme Court first discussed the issue of solitary confinement as early as 1890, in a case concerning solitary confinement of a prisoner under sentence of death in the state of Colorado.[5] The court ruled that solitary confinement "was an additional punishment of the most important and painful character" and described how inmates had reacted to solitary confinement in United States 19th-century prisons: "A considerable number of prisoners fell, after even a short confinement, into a semi fatuous condition, from which it was next to impossible to arouse them, and others became violently insane; others still, committed suicide; while those who stood the ordeal better were not generally reformed, and in most cases did not recover sufficient mental activity to be of any subsequent service to the community."

Notwithstanding this early condemnation, virtually every United States court has found that solitary confinement does not constitute "cruel and unusual punishment."[6] The Supreme Court has held that the 8th Amendment may be violated by the conditions of incarceration if they are imposed with "deliberate indifference" or if the conditions violate "the minimal civilized measure of life's necessities."[7,8] Both elements must be present to establish a constitutional violation but "deliberateness" has been somewhat ameliorated.[9]

The legal question is whether the demonstrated psychological harm of solitary confinement represents the denial of a minimal life necessity. The Court has not directly addressed this question but has indicated that deprivation of adequate mental health care violates a duty to provide "basic sustenance" to prisoners.[10] It has not addressed whether the recklessness associated with the imposition of solitary confinement would amount to deliberate indifference.

F31 The Albertani Case: Neuroscience and Criminal Trial in Italy

Michele Vaira, JD, V. le I Maggio 27, Foggia 71122, ITALY; and Laura Muscatello, MD*, Via L Spallanzani 9 Albinea, Reggio Emilia, ITALY*

After attending this presentation, attendees will better understand the scientific and judicial issues that have characterized the criminal trial held in Italy against Stefania Albertani, accused of the attempted murder of her parents and of murdering of her sister, Mariarosa Albertani. This presentation will explain how neuroscience — the set of scientifically conducted studies on the nervous system — can be used in the Italian trial system, with particular focus on the forensic use of the anatomic-genetic-clinical method and the possibility of cross-referencing heterogeneous clinical data.

This presentation will impact the forensic science community by highlighting the need to improve forensic science performance by using knowledge related to the brain, including behavioral genetics. The uniqueness lies in the utilization and enhancement of the anatomic-clinical method and the possible relationship between genetic alterations and legally relevant behavior — the study of the functioning of the normal and pathological mind through the correlation of data of a biological nature and data of a strictly psychological or behavioral nature. This is particularly relevant in the case as the trial judge, the gatekeeper of the judicial system, is faced with controversial conclusions from the defendant and the prosecution, which may affect his decision.

The Case: Stefania Albertani was accused of several crimes, including the murder of her sister, Mariarosa Albertani, (occurring between May13-14, 2009) and the attempted murder of both of her parents.

From information acquired during the investigation, it emerged that Stefania Albertani, after having caused the financial disruption of the family business, killed her older sister, Mariarosa, after isolating her in the home and forcing her to take drugs for psychosis in doses such as to cause her death. She then set fire to the body.

Soon after the sister's disappearance, Stefania was arrested for an attack on her mother, during which she tried to strangle her mother with a belt. A complex criminal pattern emerged, and the accused was interrogated regarding the kidnapping and murder of her sister as well as suppression and destruction of the corpse and the attempted homicide of her parents.

The Capacity to Understand Right From Wrong: In January 2010, the defense argued that Stefania Albertani had acted under the influence of a psychotic pathological condition that had made her totally incapable of understanding right from wrong. In June 2010, the consultant of the Judge of Preliminary Investigations concluded that histrionic disturbances of personality and dissociative disturbances could not, in any way, affect the state of consciousness and the thoughts of the detainee, who at that time had to be considered a person capable of understanding right from wrong.

In September 2010, the defense obtained permission to complete the psychiatric investigations with additional tests. Newer and more thorough psychological assessments were arranged, including psychodiagnostic tests, neuropsychological examinations, cognitive neuroscientific tests, and behavioral genetics investigations. It was claimed that Stefania Albertani was partially capable of understanding right from wrong. The judge agreed with this appraisal and sentenced Stefania to 20 years of imprisonment, recognizing the presence of "alterations" in an "area of the brain that has the function" of regulating "aggressive actions" and, from a genetic point of view, factors "significantly associated with a higher risk of impulsive, aggressive, and violent behavior." In addition to traditional psychiatric examinations, this decision was supported by more in-depth neuroscientific analyzation that revealed the brain morphology and the inherited genetics of the accused.

This is, therefore, the first recognition in Italy, and among the first in the world, of the validity of neuroscience for the assessment of imputability.

Neuroscience, Criminal Trial, Murder

F32 Improving Forensic Competency Evaluations Through Better Participation by Defense Counsel

Paul R. Spyhalski, JD, 211 2nd Street, NW, Austin, MN 55912*

After attending this presentation, attendees will better understand what information should be provided to forensic competency examiners.

This presentation will impact the forensic science community by encouraging all parties to criminal proceedings, but particularly criminal defense counsel, to follow through with a decision to seek an evaluation of the client to properly inform the examiner of the issues resulting in the referral. This presentation will urge criminal defense counsel to provide referring information, as well as other third-party information, to the examiner to assist in the determination of whether the client may constitutionally be tried in criminal court.

"It has long been accepted that a person whose mental condition is such that he lacks the capacity to understand the nature and object of the proceedings against him, to consult with counsel, and to assist in preparing his defense may not be subjected to trial."[1] The United States Supreme Court has "repeatedly and consistently recognized" that "the criminal trial of an incompetent defendant violates *due process.*"[2]

This presentation explores the critical connection between the fields of psychology and the law in determining who may be constitutionally subjected to the criminal processes of the state. Given this link between psychology and the law, forensic examiners expect information from the referring source, and defense attorneys in particular, concerning the nature, extent, and quality of the attorney-client interactions in helping the examiner determine the contours of the evaluation.

Indications from officials at the Minnesota State Operated System (MNSOS) indicate that defense counsel failed to meet the expectations of the examiner in this regard. In particular, defense counsel failed to respond to even the most basic inquiry from MNSOS asking why the client was being referred for examination in roughly 75% of the cases referred to MNSOS for examination.

This failure to provide even the most basic referring information, let alone the failure to provide other additional important collateral information, such as prior treatment records and/or evaluations, contributes to the potential failure of the evaluator to address the issue that resulted in the referral in the first instance. This failure by defense counsel to respond potentially impacts the due process rights of clients to not be tried for a criminal charge if unable to competently make the following decisions required of a defendant during the course of trial: (1) whether to waive the right to remain silent and testify; (2) whether to waive a jury trial; (3) whether to waive confrontation or cross-examination of witnesses; (4) whether and how to put in a defense; and, (5) whether to raise an affirmative defense.

Defense counsel, in expressing a concern about his or her client's competency to stand trial by seeking a referral for examination, should be prepared, at a minimum, to provide information about the quality of the attorney-client relationship in order for the examiner to frame the issues for their own evaluation, report, and eventual testimony, if necessary. Competent defense counsel should also be prepared to assist in gathering records of prior treatment and evaluations to better inform the examiner for this evaluation of the client.

Competency, Capacity, Psychology

F33 Death in the Line of Duty: A New York Police Department (NYPD) Officer Gunned Down During a Botched Robbery

Kerry J. O'Connell, JD, The NY County District Attorney's Office, One Hogan Place, New York, NY 10013*

The goal of this presentation is to illustrate the anatomy of a major case in which NYPD Officer Anthony Sanchez was murdered while responding to a burglary/robbery in progress.

This presentation will impact the forensic science community by discussing forensic techniques used in 1997 and whether those techniques possess the same scientific validity in 2017.

After midnight on May 19, 1997, Scott Schneiderman shot and killed uniformed Police Officer Anthony Sanchez as Schneiderman fled from a botched attempt to rob his own father. He had entered his father's penthouse apartment that night, wearing a mask and armed with a gun, and had terrorized his father and his father's fiancé in an effort to steal the substantial sums of cash that the defendant knew his father kept in his apartment safe. When police officers flooded into the building in response to the 911 call, Schneiderman abandoned his robbery effort and fled into the building's stairwell.

Officer Sanchez was to wait at the front of the building while his partner went upstairs with two other officers. Instead, when another resident answered the numerous buzzers for initial entry, Officer Sanchez entered the building, went to the fourth floor and, alone, started up the fire stairs toward the roof. Schneiderman ambushed Officer Sanchez, who was climbing the stairs in an effort to gain access to the penthouse. Schneiderman heard Sanchez call out, "police," then waited silently above the tenth-floor landing for the officer to come near him. When Sanchez had passed the ninth-floor landing, Schneiderman fired his gun directly down, six or seven times in rapid succession, striking the officer in the back of the neck with one of those shots. Bleeding and coughing up blood, Sanchez retreated down the steps with Schneiderman following after him. Between the seventh- and eighth-floor landings, the officer paused and fired four shots upward toward Schneiderman, hitting the defendant on his side and arm. The officer then continued down the stairs to the second-floor landing, where he collapsed and died.

Meanwhile, multiple 911 callers reported a robbery in progress, and the shots fired by both Schneiderman and Officer Sanchez were captured on some of the recordings. These would prove critical in proving who shot first. Human error in recounting events occurred, yet forensic analysis of the evidence helped to counteract its effect.

Schneiderman was captured hiding in the elevator when the building was searched. He had left a trail of physical evidence along the way, and crime scene detectives documented bullet trajectory, blood spatter, and other evidence in order to reconstruct the scene. Schneiderman claimed self-defense and said that the slain officer fired at him first. He spent more than four hours on the witness stand trying to convince the jury that he was the victim of over-aggressive policing. The evidence disproved that theory by using a combination of forensic science and eyewitness testimony in one of the most gripping trials in New York City history.

Homicide, Crime Scene Investigation, Police Officer Murder

F34 The Dog Alerts But There's No Body: The Science of Human Remains Detection — K-9 Evidence for the Courtroom

Mary E. Cablk, PhD, Desert Research Institute, 2215 Raggio Parkway, Reno, NV 89512*

The goal of this presentation is to educate attendees concerning the current state of cadaver canine detection science and the elements of a sound, defensible K-9 program.

This presentation will impact the forensic science community by informing attendees regarding the current state of science of human remains detection canines that pertains to the reliability and defensibility of their performance.

Cadaver dogs, referred to by a variety of different names, are trained to locate human remains. Lacking a single, unified standard, the reliability of cadaver dog teams varies widely. Properly trained, they are able to detect human remains that may be verified using physical processing (e.g., blood), but analytical tests for all types of human remains do not exist (e.g., human decomposition). Thus, the validity of an alert by a cadaver dog in which no means of corroboration or validation is possible can and has come into question in a court of law.

Cadaver dogs have been used with success for decades, and their use, particularly in high-profile criminal cases, is increasingly reported in popular media. False positives are rarely reported and on deployment, alerts cannot always be resolved. While the scientific literature on cadaver dog capabilities is sparse, their utility remains robust. Peer-reviewed studies point to a discrete set of compounds detectable from human remains, particularly intact decedents; however, those results represent only what the collection and analysis methods can detect, as interpreted by an analyst. No study has linked machine-detected human remains odor to what a canine recognizes as human remains odor.

Knowing the precise chemical composition of human remains odors is not necessary for a detector dog to be reliable, accurate, and precise. Furthermore, what constitutes "reliable" varies in the legal realm and particularly as applied to narcotics K-9s and probable cause. Cadaver dogs are not typically used for probable cause because their trained target odors may be present for non-nefarious reasons (e.g., a bloody nose). In fact, evidence identified by a cadaver dog and corroborated as correct may not have relevance to a case, although the dog's identification of human remains was correct and independently verified.

When a cadaver dog alerts and that alert is unsubstantiated, for any number of reasons, the validity of the alert can be called into question. Published studies have demonstrated the sensitivity and specificity of dogs to detect residual odors, including human remains. Just as with any other technology, not all dogs are trained to the same level, using appropriate procedures to eliminate bias, or to the same range of types of human remains.

This presentation will include discussion of the types of cadaver dogs and their appropriate uses in criminal cases. The current state of science on cadaver dogs will be presented in addition to more broadly relevant science that applies to any detection canine team and program. Key components challenged in court will include residual odor, bias, and training protocols for teams that deploy for criminal cases.

Canine, Detection, Odor

F35 The Need for Transparency in Forensic Report Writing

Sheila Willis, PhD, Forensic Science Ireland, Garda HQ, Phoenix Park, Dublin, IRELAND*

After attending this presentation, attendees will understand the issues that need to be addressed by the forensic scientist and the areas that need to be explicit to ensure transparency in reporting. Attendees will better understand the difference between source and activity propositions.

This presentation will impact the forensic science community by providing a better understanding of the weight of evidence in forensic reports and how the alternative affects this value.

The reporting of forensic science findings is vital to ensure there is some shared understanding of their significance. This is particularly so when the findings need to be shared with a non-scientific audience. Modern forensic science is being redefined as the results from a testing facility. This is done in the erroneous belief that as long as the frequency of occurrence is known with accuracy and tests are capable of being repeated, all is well. There are some instances in which this is the case. There is no reason why the trigger pressure of a gun, the quantity of the active ingredient in a drug, or the level of alcohol in a sample should have any less or different criteria for reporting than many other analytical results from various testing laboratories.

Even so, the situation changes when two propositions need to be addressed, as is often the case in forensic science. Before beginning the testing, additional information is needed in relation to the discriminating power of the tests to be used and the frequency of occurrence of the characteristics to be measured. When probed further, there is a need to establish what questions need to be addressed and following Cook et al., propositions to be addressed can fall at various places in the hierarchy of propositions — subsource, source, activity, or offense.[1] Clearly, the offense level is the realm of the trier of fact, but the forensic scientist can, on occasion, address the probability of findings in activity level propositions; thus, both add value to the court and increase transparency by being explicit in what is being considered.

A forensic scientist may report matching refractive indices and elemental composition for two glass fragments and be influenced in answering questions in court on their significance based on the number of recovered fragments. Thus, two situations with the same apparent forensic findings could get different significance attached following questions in court. This is caused by the scientist reporting the test results but taking transfer and persistence issues into consideration without making these factors explicit.

The European Network of Forensic Science Institutes (ENFSI) produced guidelines to deal with evaluative reporting that advocate the need for a different approach over factual reporting of test results.[2,3] This presentation promotes this approach, which is based on earlier work by Evett et al. and standards produced by the Association of Forensic Science Providers.[4-6]

The approach calls for the scientist to ascertain what the issues are in the case, decide what propositions can be addressed, and conduct a precise assessment on the likely findings, particularly when addressing activity propositions. This approach recognizes that the findings are context-dependent and these factors also need to be made explicit in reports.

The presentation will highlight the critical role played by the alternative proposition on the significance of the findings and on the need for findings to be evaluated in a context.

Transparency, Activity, Propositions

F36 A Tale of Two Futures

Peter R. De Forest, DCrim, Forensic Consultants, PO Box 141, Ardsley, NY 10502; Rebecca E. Bucht, PhD, Pietarinkatu 11 A 13, Helsinki 00140, FINLAND; and Michelle D. Miranda, PhD, Farmingdale State College, SUNY, 11735, NY 11746*

This goal of this presentation is to encourage laboratory-based criminalists, laboratory administrators, attorneys, and other stakeholders to reflect on the direction of the future development and utilization of physical traces from crime scenes.

This presentation will impact the forensic science community by having the potential to enhance the contributions and value of physical evidence in the future.

It will be the best of times, it will be the worst of times …. The fallout from the 2009 National Academy of Sciences (NAS) Report, along with the effects of both accurate and exaggerated media reports of laboratory "failures" and increased awareness of wrongful convictions, have all but cast a shadow on criminalistics. Is there hope for transformation — a chance for criminalistics to emerge renewed and reestablished as an essential and integral part of the criminal justice system? While many attempts have been made to address issues raised by the NAS Report and improve criminalistics, many unresolved questions remain. In addition, there are problems that were not recognized or cited in the NAS study. This presentation considers issues with physical evidence driven investigations. Specifically, this presentation seeks to draw attention to the shortcomings and hazards of certain current trends in criminalistics and contrast them with the untapped potential that exists.

Will the recognition of relevant physical traces at a crime scene still be hampered by being dependent on the limited knowledge and insights of non-scientist crime scene investigators or other non-scientist personnel with relatively short-term assignments? Will laboratory scientists still be relegated to reactive technician roles and become further removed from the formulation of scientific questions to be addressed regarding the physical evidence? Will trace evidence capabilities continue to be eliminated in forensic science laboratories? Will highly "intelligent" computerized instruments serve in place of experienced scientific human minds in developing the structure of the physical evidence investigation to follow at the initial stages of the overall investigation?

OR …

Will the typical, large forensic science service finally be seen as something more than an overburdened testing facility contending with backlogs of poorly selected items taken from poorly investigated and triaged crime scenes? Will the entire physical evidence continuum be recognized as the responsibility of scientists? Will the crime scene be conceptualized as a challenging scientific problem as difficult and as important as any work performed on evidence items in the laboratory? Will experienced senior scientists at long last be able to proactively apply their physical evidence expertise at the outset of investigations? Will laboratory scientists be able to expand beyond their constrained *de facto* roles as reactive technicians to work on defining and solving complex physical evidence problems?

These questions raise additional questions, such as: What role does the criminal justice system envisage for forensic science and forensic scientists? How can the criminal justice system help ensure it gets what it needs out of forensic science? How can the criminal justice system help ensure that forensic science develops in a more useful direction?

Can criminalists choose a future? Which future of these two starkly different futures do criminalists want? How many understand the problem? Which future do lawyers and other non-scientist members of the criminal justice system want? Are scientists and lawyers in agreement? What can be done to bring them into agreement? How badly do all relevant parties want change? What forces have served to maintain the status quo? What can be done to increase the level of scientific contributions across the physical evidence continuum? How can it be done? Who can get it done? What positive role can members of the legal profession play in bringing about needed change?

Physical Evidence Recognition, Crime Scene, Laboratory Analysis

G1 Migratory Flows and Unaccompanied Minors: The Age Assessment Protocol of the University of Turin (Italy)

Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; Emilio Nuzzolese, PhD*, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, EU 70124, ITALY; Davide Santovito, MD, Department of Public Health and Pediatric Sciences, Corso Galileo Galilei 22, Turin 10126, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP – Univesity of Torino, C So Galileo Galilei N 22, Torino 10121, ITALY; and Francesco Lupariello, MD*, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY*

After attending this presentation, attendees will learn the multidisciplinary age assessment protocol proposed by the Medicolegal Department of the University of Turin (Italy) to allow urgent age assessment in circumstances in which law enforcement officers detain individuals of indeterminate age.

This presentation will impact the forensic science community by confirming the importance of dental age methods in the diagnostic procedures targeted at age estimation of unaccompanied minors.

The Italian legislation is paying special attention to the protection of unaccompanied minors. Once their age as a minor is ascertained, unaccompanied minors cannot be subject to expulsion and acquire the right to a residence permit, which can be converted at the age of 18 into a permit for study, employment or self-employment, or health reasons. The growing phenomenon of migratory flows extends beyond anti-terrorism and border control aspects, resulting in the necessity of ascertaining the age of a large number of unaccompanied minors who do not carry valid documents that certify their age. The Forensic Medicine Unit of the University of Turin (Italy) has signed a memorandum of understanding with the public prosecutor's office at the Juvenile Court of Turin to allow urgent age assessment in circumstances in which law enforcement officers detain individuals whose majority or minority is unknown.

The goal of this research is to compare the forensic odontological methods developed by Olze, AlQahtani, and Cameriere against the overall multidisciplinary evaluation of the alleged minor age of unaccompanied foreign minors to determine the forensic significance of dental methods, including aspects such as digital transmission of panoramic radiographs.

Materials and Methods: The protocol applied for age assessment and majority prediction requires the multidisciplinary adoption of several methods according to the following scheme: preliminary medicolegal and radiological assessment of the wrist; possible dental, pediatric-auxologic, and psychological evaluation, following a diagnostic algorithm based on criteria of progressive invasiveness.

A review was performed on the medical records of age assessment visits conducted over a sample of 68 foreigners without a valid birth certificate or ID documentation. The group was also kept under observation for the period of February to June, 2017, and the full technical protocol of dental examination and panoramic radiographs was performed. The results obtained from the entire multidisciplinary diagnostic process were compared with the age assessment methods performed by applying the Olze, AlQahtani, and Cameriere methods individually through Orthopantomograph (OPG) radiographs transmitted remotely for evaluation by the relevant forensic odontologist consultant.

Results: For ten subjects, the match between the alleged and declared age and the ascertained age could be confirmed. Of the 68 subjects, 45 proved to be of age according to the medical records released by the medical examiner following protocol (physical examination, left wrist radiographs using the FELS and Greulich and Pyle methods, oral cavity inspection, and OPG evaluation according to the AlQahtani and Olze methods), whereas 17 proved to be less than 18 years of age and more than 14 years of age.

The dental age estimation against OPG of the lower third molars according to the Olze, AlQahtani, and Cameriere methods exhibited a match with the estimated age through the multidisciplinary procedure with a P-value lower than 0.05.

Conclusions: This sample highlighted the widespread tendency of immigrants to declare an age lower than their actual age, resulting in the legal requirement of attaining majority estimation through a reliable multidisciplinary protocol from an ethical and technical point of view. It is no longer suitable to entrust this majority/minority estimation only to individual assessment methods. It is also essential to integrate the diagnostic process with the evaluation of the dental maturity and eruption of the entire set of teeth and the systematic execution of OPGs submitted to at least two forensic odontological methods for evaluation, including digital transmission of radiographs to the relevant forensic odontologist consultant. Considering the growing number of self-styled foreign unaccompanied minors, this study believes that the protocol employed could represent a valid model that can be deployed across the country, due to its reliability, cost-effectiveness, and timeliness.

Age Assessment, Unaccompanied Minors, Migrants

G2 Measuring Root Transparency for Age-at-Death Estimation: What About the Light?

Joe Adserias Garriga, DDS, PhD, c/ Balmes 62 30 la, Barcelona, SPAIN; Laia Nogue Navarro, UdG, C/ Emili Grahit 77, Girona, SPAIN; Sara C. Zapico, PhD, FL International University, Dept of Chem and Biochem, Modesto A. Maidique Campus, OE116, 11200 SW 8 Street, Miami, FL 33199; and Douglas H. Ubelaker, PhD, Smithsonian Institution, Dept of Anthropology, NMNH, MRC 112, Washington, DC 20560*

After attending this presentation, attendees will acquire a deeper understanding of how to apply root transparency measurements when implementing age-at-death estimation methods.

This presentation will impact the forensic science community by describing the illumination conditions required for measuring root transparency to achieve an accurate age-at-death estimation.

Age-at-death estimation is one of the main goals in forensic identification since age estimation significantly narrows the search possibilities in cases involving missing persons and unidentified bodies. Moreover, age segregation in cases of mass disaster and multiple victims' situations can be of great help in the process of identification. The study of dental tissues has long been considered a proper tool for age estimation; therefore, several age estimation methods involving dental studies have been developed and widely used. Dental age estimation methods can be divided into three criteria: tooth formation and development, post-formation changes, and histological changes. Tooth formation and growth changes are applied for fetal and infant age estimation; however, at the end of dental and skeletal growth, methods addressing post-formation or biochemical changes should be applied. Lamendin et al. developed an adult age estimation method based on root transparency and periodontal recession.[1] The regression formula demonstrated its accuracy for age estimation on individuals between 40 and 70 years of age. Later, Prince and Ubelaker evaluated the effects of ancestry and sex, and incorporated root height into the equation, developing four new regression formulas for males and females of African ancestry and males and females of Caucasian ancestry.[2] Even though root transparency is a key element in the method, the conditions for measuring this element have not yet been established. The goal of the present study is to describe the illumination conditions measured in lumens that result in increased accuracy when applying the Lamendin et al method as modified by Prince and Ubelaker.[2]

Fifty-five single-rooted teeth clinically extracted from known age and sex individuals (19 upper incisors, 11 males and 9 females; 36 upper and lower canines, 19 males and 17 females) were used for this study. Two observers measured root height, periodontosis, and root transparency by caliper from the labial surface, and recorded the measurement in milimeters. Root transparency was measured applying three different lights: 6,500lux, 3,000lux, and 1,600lux. All measurements were repeated on two different days. After taking the measurements, Lamendin and Prince and Ubelaker formulas (modified from Lamendin's method) were employed to estimate the age of the individual. Comparison with actual age was conducted by statistical analysis. There were no significant differences found between age estimation using 1,600lux illumination and the actual age (p=0.872). In contrast, age estimates using the other illumination levels revealed significant differences with respect to the actual age ($p < 0.05$).

Although previous studies analyzed the use of Lamendin parameters involving creation of new formulas for age-at-death estimation based on population differences (Prince & Ubelaker, 2000; Ubelaker and Parra, 2008; González- Colmenares et al. 2007), none of these studies or other studies focused on setting up the correct conditions for the measurement of root transparency.[1-4] As a result, the present work is the first one recorded in the literature to address this issue. This study depicts how illumination conditions may affect root transparency measurement and, therefore, the age estimation methods that rely on this postformation change. These results pointed out that light conditions must be taken into account for correct determination of this parameter. Therefore, this is a pioneer project in this area, which hopefully promotes further studies regarding correct conditions for age-at-death estimation.

Age-at-Death, Root Transparency, Human Identification

G3 Implications of Canine Width, Inter-Canine Distance, and Facial Dimensions in Forensic Identification

Kewal Krishan, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; Vaibhavi Sharma, MSc, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; and Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Bansi Industrial Area, Phase 2, Dept of Forensic Medicine, Jodhpur, Rajasthan 342 005, INDIA*

After attending this presentation, attendees will understand the significance of canine width and inter-canine distance in forensic examinations, especially with reference to sexual dimorphism and two-dimensional facial reconstructions.

This presentation will impact the forensic science community by presenting the utility of important parameters in forensic odontology (i.e., canine width and inter-canine distance) in sexing of the human remains and in assessment of facial dimensions that are likely to assist in two-dimensional facial reconstructions.

Teeth are the most durable and hardest part of the human body. Consequently, dental evidence is recovered most often from mass disaster sites and crime scenes. Dental evidence is considered as valuable substantiation in the process of identification of human remains. In some terrorists' attacks, high-explosion blasts, and high-impact natural disasters, the dental and facial parts are available to Disaster Victim Identification (DVI) teams for identification purposes. In such situations, the dental evidence acts as sole and, thus, important evidence. A few studies are available on canine width, inter-canine distance, and their relationship with some facial measurements. Canine and inter-canine distance may be helpful in the prediction of the remains' sex. Studying the relationship of the inter-canine distance in addition to certain facial dimensions may be helpful in two-dimensional facial reconstructions in forensic identification. Therefore, the main objectives of the present study were to determine the sex differences with respect to canine width and inter-canine distance and to ascertain whether inter-canine distance may be used to estimate certain facial dimensions.

This study was conducted on 240 adult participants (120 males and 120 females) belonging to Himachal Pradesh State of North India. In addition to the canine width and inter-canine distance, the facial dimensions, such as bizygomatic width, physiognomic facial height, morphological facial height, bigonial distance and intercommissural distance, inter canthal distance, outer canthal distance, and tragus-to-wall distance, were measured with standard anthropometric instruments. The descriptive statistics were performed and the Karl Pearson's correlation coefficient was calculated to study the correlation between the measurements. Sex differences in the measurements were statistically analyzed. The mean canine width (mesio-distal crown width) was found to be greater in males than females on both the right and left sides. The sex differences were statistically significant. Similarly, the inter-canine distance was found to significantly larger in males than females in both maxillary and mandibular arches. Significant correlation was observed between maxillary inter-canine distance and intercommissural distance in both sexes; however, the correlation between mandibular inter-canine distance with physiognomic height and intercommissural distance was found to be significant only in females. In males, the correlation between inter-canine distance and facial measurements was not found to be significant. Prediction equations were calculated between inter-canine distance and facial measurements using regression analysis. The regression models were derived to predict facial measurements.

This study confirms the sex-discriminating potential of the dental measurements and concludes that certain facial dimensions can be estimated from the inter-canine distance, thus making it a useful tool in situations in which facial dimensions are not available for facial reconstruction.

Forensic Odontology, Personal Identification, Dental Evidence

G4 Dental Exclusion: What's Next? The Role of the Odontologist As Part of the Identification Team

Taylor L. Gardner, BFSc, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Yolanda Nerkowski, BA*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Robert E. Wood, DDS, PhD*, Ontario Forensic Pathology Service, 610 University Avenue, Toronto, ON M5G 2M9, CANADA*

The goal of this presentation is to emphasize that dental identification is one part of the human identification team — even in single fatalities — and to advise attendees that even in cases of exclusion, the odontologist has a role to play in the identification process.

This presentation will impact the forensic science community by explaining that dental exclusions may occur for any number of reasons, including true exclusions, inaccurate antemortem dental information, wrong antemortem chart information provided to the odontologist, or even purposeful deceit. If an exclusion occurs, the role of the odontologist is not over. The odontologist must coordinate with the identification coordinator to facilitate identification by other means, if this is possible.

A man went missing in December of 2016. He borrowed a friend's vehicle for urgent business and was not seen alive again. The vehicle was found in May of 2017 in a farmer's field. The deceased was in the car in the front passenger seat, positioned facedown in the footwell with his legs extending into the backseat. The deceased was partially decomposed and partly mummified. Homicide was suspected. His hands were slightly mummified. His dentition was intact.

The purpose of autopsy in this case was to determine the means, manner, and cause of death — and identification. In the Province of Ontario, most identifications are performed by visual methods by family members or by circumstantial information. Scientific identification methods are preferred and include: dental comparison, fingerprint comparison, DNA, and medical/surgical devices. In all of the scientific methods, antemortem information is compared to postmortem data. In scientific identifications, a single identification method is most often used. In rare cases, multiple scientific comparison methods are performed for the same case.

What happens, then, when one scientific method contradicts another? Is there a mechanism for dispute resolution and how is this handled? This study presents a case in which comparison of antemortem and postmortem records resulted in an exclusion; however, the body was concurrently identified using fingerprint comparison and released to the family After release, the forensic odontologist reported the possibility of exclusion to the identification coordinator.

At the time of dental exclusion, a Friday before a long holiday weekend and after the body had been released, there was still debate as to whether the body was properly identified or not. With that in mind, the odontologist decided to request that a number of stored blood samples that had been gathered for toxicology be set aside for DNA comparison. This was accomplished through communication with the identification coordinator.

Subsequently, DNA identification confirmed that the fingerprint identification was correct. The possible reasons for a dental exclusion will be discussed.

Identification, Exclusion, Identification Coordinator

G5 Multimodality Multidisciplinary Dental Identification in a High Stakes Case of Prior Misidentification

Taylor L. Gardner, BFSc, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Yolanda Nerkowski, BA*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Robert E. Wood, DDS, PhD*, Ontario Forensic Pathology Service, 610 University Avenue, Toronto, ON M5G 2M9, CANADA*

The goal of this presentation is to illustrate the use of antemortem chart information, conventional radiographic examination, computer-assisted radiographic examination, alternate light photography, and dissecting microscopy used in a single case to finalize identification.

This presentation will impact the forensic science community by demonstrating that most dental identifications are relatively straightforward using comparison of antemortem to postmortem dental records. On some occasions, additional technology needs to be harnessed. This presentation details just such a case.

The identification of all persons is important as part of the autopsy process; however, there are instances in which identification of the deceased is the most important part of the autopsy procedure.

The Syrian conflict began in 2011 and continues to this day. Over one-quarter of a million people have died, and millions have been displaced. The combatants include persons of many nations fighting in numerous factions, including “terrorists” and foreign nationals fighting on various sides.

The body of a young male was traded from ISIS in exchange for an unknown reason. The deceased died at an unknown time, but had gone missing many months before recovery. At the time of recovery, the body was said to have been both autopsied and identified by dental record comparison in Iraq. When the body was returned to Canada, no autopsy had been performed and there was a reasonable concern that the returned body was not the deceased Canadian national.

For that reason, an autopsy was undertaken and a dental identification was requested. The identification was complicated by anatomic issues, continuity of dental evidence issues, and an apparent paucity of congruence between the antemortem information. Considering this, it was decided to return to basic comparison principles and maximize the postmortem information to compare to the records obtained in Canada. This process resulted in postmortem evidence that included Computed Tomography (CT) images, reformatted CT images, conventional dental clinical findings, alternate-light fluorescence photography, and full intraoral radiographs. Additionally, because some of the restorations were so conservative as to be nearly invisible, a dissecting microscope was used and highly refined photographs made to complete the postmortem evidence package. All of the postmortem information was compared to the properly sourced antemortem material, and an identification was finalized. The deceased was returned to his Canadian family properly identified.

Dental Identification, Alternate Light Photography, Computer-Assisted Tomography

G6 The Dental Identification After an Air Disaster 45 Years Ago: The Dubai Accident in 1972 With 112 Victims

Tore T. Solheim, Institute of Oral Biology, Box 1052 Blindern, Oslo 0316, NORWAY*

After attending this presentation, attendees will better understand how forensic odontologists worked after a disaster that occurred 45 years ago. In addition, attendees will be familiar with the problems encountered and understand that not all concepts being employed today are new.

This presentation will impact the forensic science community by demonstrating that there is something to learn from old cases that were solved under rather primitive conditions — conditions that may still be encountered in poorly developed countries today.

On March 14, 1972, a Supercarvelle airplane hit a mountainous area in the Emirate of Fujairah, now part of the United Arab Emirates. The plane was from a Danish charter company, Tjæreborg, and carried Scandinavian tourists from Sri Lanka (at that time Ceylon) to Copenhagen. On board were 106 passengers and a crew of 6 persons. All died. The plane struck the upper part of a rugged mountain and went over the top; wreckage and bodies were dispersed over a 300m by 400m area on the back side of the mountaintop. All bodies suffered severe trauma, some after a fall of several hundred meters, and for some, only small fragments were found.

Ad hoc ID teams were sent from Denmark, Sweden, and Norway. A dentist and a police officer from Norway were included, while the Swedish and Danish teams also included forensic pathologists. Only 14 of the victims were Norwegian citizens.

On March 17, the Norwegian and Swedish teams arrived in Dubai, while the Danish team had arrived the day before. As the Danish team had two dentists, there were four dentists in total.

The teams, including the dentists, went to the accident site, registered, and packed up the bodies. The victims were then transported by helicopter to an old British air base at the Emirate of Sharjah. Here, autopsies could be performed outdoors while the bodies were kept in a refrigerated room. Without computers or the internet, the work in Sharjah was completed on March 28 after ten days. The bodies were returned to Denmark, where a few more bodies were identified. The identification work was terminated on April 24, and a total of 96 victims were identified. The remaining 16 victims were buried in a common grave in Denmark. All Norwegian victims were identified, due in part to antemortem information accompanying the forensic team that went to Dubai. The two other teams did not have that advantage and had to establish a home commission to take care of the antemortem material. All information was set up in systematic way. In addition, an enthusiastic police officer's keen interest contributed to this result. Forty-one victims were identified, including a dental comparison, and 28 by dental comparison alone.

With no Interpol form, a newly designed Danish form was used. With no transportable X-ray machine, an iodine-isotope radiation source, which the Swedish dentist brought with him, was used for exposing the radiographs. Searching through this large amount of data was difficult. It was initially decided to look for characteristic restorations; however, often those registered antemortem were lost postmortem, and those found postmortem were not registered antemortem. One full day was lost without a single identification being made by this approach. Then, the postmortem forms were laid out on a long table and teams compared antemortem forms from postmortem form to postmortem form. Separating the men from the women was attempted, but was often impossible due to the severe destruction of the bodies. Considering all these conditions, the teams succeeded well.

Air Disaster, History, Identifications

G7 OdontoSearch: Modifications, Updates, and Proper Usage

Kenneth W. Aschheim, DDS, 44 E 67th Street, New York, NY 10065; and Bradley J. Adams, PhD, New York OCME, 520 1st Avenue, New York, NY 10016*

After attending this presentation, attendees will better understand using the OdontoSearch program for dental identification.

This presentation will impact the forensic science community by providing an overview of recent modifications of OdontoSearch and will include case examples highlighting proper usage of the program.

It has been two years since the enhanced web version of OdontoSearch was formally introduced to the forensic community at the 68th Annual AAFS Scientific Meeting in Las Vegas, NV. Since that time, there have been significant changes to the program; this presentation will educate attendees about the recent enhancements to the OdontoSearch program. A brief tutorial will also be given regarding the proper use of the program, and informative case examples will be presented.

OdontoSearch is a computerized program which is available online (www.odontosearch.com). It is a tool used by forensic odontologists to statistically determine the frequency that specific dental patterns would be expected to occur in a population. As such, OdontoSearch provides an objective means for users to recognize whether specific dental patterns formed by combinations of missing, filled, and unrestored teeth are common or unusual. The program utilizes a large database of dental records of known individuals for comparison. Empirical comparison of an "unknown" pattern against the reference data in OdontoSearch will reveal the frequency with which this pattern would be expected in the general population. These results can be used to support dental identification in situations in which the observed matching pattern between an unidentified body and a missing person is found to be extremely rare.

The OdontoSearch reference database is constantly growing as more appropriate samples become available for research. Recently, two new sources of dental data have been obtained for incorporation into OdontoSearch. These include the dental data from the 2013-2014 National Health and Nutrition Examination Survey (NHANES), as well as a portion of the "BigMouth" data repository. OdontoSearch 3.0, released in 2015, had a sample size of 57,980 records. With the availability of the NHANES and BigMouth data, the sample size of the next release of OdontoSearch will increase substantially.

The NHANES dental data are periodically collected as part of an initiative by the Centers for Disease Control and Prevention to study dental health. Participants in the newly released 2013-2014 NHANES study represent a cross-section of the United States civilian population. There are more than 9,400 individuals represented in the latest NHANES release, a subset of which is applicable to the OdontoSearch program. Earlier iterations of the NHANES study have formed the foundation of the OdontoSearch reference data.

BigMouth is an oral health data repository available for research.[1] Currently, the BigMouth dental repository is composed of electronic chartings contributed by six United States dental schools as part of the Consortium for Oral Health Research and Informatics. The total BigMouth database holds dental information on more than one million patients. The participating dental schools have generously agreed to contribute their data to OdontoSearch, and a subset of this massive data repository has been converted for use in the next version of OdontoSearch.

Users of OdontoSearch have the ability to customize searches based on specific demographic parameters (age, gender, and ancestry) and/or specific databases, as desired. This can be useful if, for example, the frequency of a dental pattern was needed for only females between 35 and 50 years of age. In addition, language options have been added to OdontoSearch, so all pages can be accessed in Spanish.

When using OdontoSearch, it is important to perform searches only on teeth with exact matches between the antemortem or postmortem records. Explainable discrepancies (e.g., a filled tooth in an antemortem record corresponding to a missing tooth in a postmortem record) should not be included in an OdontoSearch query. Specific "dos and don'ts" of OdontoSearch usage, such as the points listed above, will be discussed, in addition to illustrative case examples.

OdontoSearch, Dental Identification, BigMouth

G8 Atypical Dental Identifications: What to Do When Antemortem Radiographs Are Missing?

Kenneth W. Aschheim, DDS, 44 E 67th Street, New York, NY 10065; and Lawrence A. Dobrin, DMD*, New York City OCME, 471 E Westfield Avenue, Roselle Park, NJ 07204*

After attending this presentation, attendees will have a better understanding of the alternative methods for aiding in dental identifications.

This presentation will impact the forensic science community by presenting cases involving innovative techniques that can be utilized by the forensic odontologist.

When a forensic odontologist is requested to identify a decedent, acceptable antemortem records, especially radiographs, must be available for comparison to the postmortem records. That, of course, is the ideal situation, but quite often circumstances presented to the forensic odontologist require ingenuity to provide the medical examiner's office with help in the identification process. Some interesting examples of cases that required such services are presented in this presentation.

A recent New York City cold case was presented for input in helping with the identification of a military serviceman. The antemortem records, dating back many years, contained only chartings and hand-written treatments; no radiographs were available. OdontoSearch was utilized and provided a statistical likelihood of the records matching, although the software cannot provide a definitive scientific identification; however, the written chart described a unique restorative feature but, unfortunately, it could not be confirmed radiographically. A discussion of why radiographs sometimes failed to image restorative features, as well as the ultimate technique utilized to isolate the hidden features, will be presented.

Following a New York City fire, the forensic odontology team was called in to confirm the identity of several minors. Following standard protocols, the children required postmortem radiographs to verify their identity. Before the process began, the team was informed of religious concerns raised by the community concerning radiographing the decedents. In addition, antemortem radiographs were not immediately accessible, and there was a request by the family for same-day burial. The techniques used to address these concerns, as well as methodology used to confirm the identities, will be discussed.

A fire in New Jersey, the consequence of a homicide/suicide, resulted in the death of a husband, his wife, and their teenage daughter. Reconciliation of the antemortem and postmortem radiographs for the husband and his teenage daughter were straightforward, leading to routine identification for the forensic odontologists. Although the 38-year-old wife had received dental care, no antemortem radiographs existed; however, her dentist could provide high-quality intraoral photographs of the anterior teeth. A technique for modifying the dental autopsy to obtain postmortem photographs of the victim's dentition, the methodology used for the comparison, as well as the pros and cons of the technique, will be discussed.

Forensic odontologists are sometimes asked by the medical examiner offices to confirm an identification despite the fact that antemortem radiographs may not be available to complete the identification process. Routine procedures followed by the forensic odontologist in many instances are not so routine and may require some creativity and innovation, as is described in these cases.

Antemortem, Postmortem, OdontoSearch

G9 The Head in Cement and the Medical Examiner

David S. Lynn, DDS, 1 Millwood Gate, Hicksville, NY 11801*

The goal of this presentation is to illustrate how multiple forensic disciplines can work in conjunction with each other to solve a case of unidentified remains.

This presentation will impact the forensic science community by re-emphasizing the fact that all forensic departments within a single medical examiner's office can, and must, work together to bring about favorable case results.

This case study involves a skull, found partially encased in cement, on the side of a major highway by an unwitting bicyclist. The mound of cement was brought to the Office of the Suffolk County Medical Examiner (OSCME), NY, where a forensic anthropologist carefully extricated the skull from the concrete. The pathologist and the anthropologist observed evidence of blunt force trauma to the head, as well as fractures of the maxilla, mandible, and facial bones.

After removing the skull from the cement mound, a facial impression was visible on the internal surfaces of the cement mound. Another forensic anthropologist described this phenomenon as a form of a Death Mask. This artifact is created when the fatty acids of the skin form a barrier between the concrete and the head, which then leaves a facial impression when the tissues decompose. Hair was also found imbedded in the concrete and was removed for analysis.

A model of the facial impression was made by pouring a silicone material (Dragon Skin™) into the concrete mound, leaving it to set overnight, then carefully removing the cast the next day.

A forensic odontologist performed a dental examination, and radiographs were taken, but no antemortem dental records were available through the police department or the National Missing and Unidentified Persons System (NAMUS). A forensic artist examined the skull, and created a two-dimensional facial reconstruction of the individual in question. The profile created by the forensic anthropologist described a young-to-middle-aged male, with mixed racial characteristics of European (White) and Asian (including Hispanic) traits. The analysis of the hair samples by the forensic scientist revealed light brown, brown, and dark brown fragments exhibiting Caucasian (European) racial characteristics.

A tooth was used to obtain a DNA profile. The DNA profile was consistent with having originated from a male. The profile was entered into the Combined DNA Index System (CODIS). The profile matched another OSCME case from 2009, in which a torso and some fragments of extremities were found in a landfill. Those body parts were previously identified using DNA collected from the missing individual's toothbrush.

The positive ID through DNA and CODIS was of a man of Pakistani descent. His age at the time of his disappearance was 36 years of age. This case is an ongoing homicide investigation.

This case study will illustrate how multiple forensic disciplines, including pathology, anthropology, trace evidence, odontology, artistry, and DNA, all coordinated their efforts to solve a case of unidentified remains.

Identification, Forensic Collaboration, Unidentified Remains

G10 Evaluating a Selfie Identification App in the Forensic Dental Identification Process

Emilio Nuzzolese, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, EU 70124, ITALY; Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; and Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will possess a deeper understanding of how social media and smart phone applications could become a valuable investigative tool in the search for antemortem identifying data.

This presentation will impact the forensic science community by increasing awareness concerning how images of the smile and of anterior teeth could be used in the human identification process.

There are several applications for smart phones that assist in the search for missing persons. Selfie Forensic ID App, developed in 2017 by a forensic odontologist, is the first application developed with the goal of assisting the human identification process using smile photographs archived on the internet, thus increasing the antemortem dental data that can be used in comparison to the postmortem dental data of an unidentified person. Forensic casework portrait photographs are often used in the human identification process using superimposition techniques.

The goal of this presentation is to evaluate the Selfie Forensic ID App by simulating a search of selfie images of potential missing persons taken with the app and that are available on Twitter®, Tumblr®, and Instagram™. The app can be freely downloaded in iOS® and Android™ formats. Selected patients regularly visiting the dentist in Matera and Bari, Italy, were asked to participate voluntarily in this experiment. Fifty patients were selected for their specific and potentially individualizing anterior teeth features that were observable when smiling, such as diastema, rotated or wrongly positioned teeth, fixed prosthetics, or dental crown discolorations. Each of the participants downloaded the app and took a selfie image of the lower third of the face showing the teeth. Registration with name, surname, city, and country is required in order to use the app. Alternatively, users can login via their Facebook® or Google+® profile. Once taken, the selfie images were uploaded to various social networks with the registered names. All patients selected also had a separate portrait photograph taken with a professional camera. After some hours, all selfie pictures taken via the app were available via internet image searches using the names of the persons involved, simulating a missing person search.

The app is able to increase quantity and quality of selfie images of the lower third of the face showing anterior teeth and identifying features combined with the name of the person being searching for. Dental variations and characteristics can become an aid in the comparison process of antemortem and postmortem "matches," thus confirming or excluding the identity of one or more individuals.

It is believed that this new app will promote, to the public, the importance of storing personal identification data in social media in order to avoid bodies remaining unidentified.

Selfie, Identification, Forensic Odontology

G11 Silver-Stain Modification as a Method to Enhance Visualization of Histological Features for Tooth Cementum Analysis (TCA)

Katrin Koel-Abt, PhD, 5328 S 119th Court, Apt 303, Omaha, NE 68137; and Derek E. Peters, MS*, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg D, Offutt Air Force Base, NE 68113-4006*

After attending this presentation, attendees will better understand how to modify the standard histology specimen preparation for tooth cementum analysis. This will significantly increase the visualization of histological features in teeth, aiding in a better accuracy of age- and season-at-death estimation, as well as enabling a better understanding of the microscopic features visible in tooth cross sections.

This presentation will impact the forensic science community by providing a detailed description of specimen preparation and staining, examples of tooth cross sections prepared with the silver-stain compared to unstained specimens, and the respective age- and season-at-death estimates for the two methods. Example pictures will enable visual comparison and identification of structures and therefore illustrate the accuracy of TCA obtained on stained and unstained cementum.

Histomorphological techniques used at the Defense POW/MIA Accounting Agency Laboratory are usually applied to distinguish inconclusive osseous remains from non-human and non-osseous remains. To enhance the traditional aging methods for identification purposes, extensive histological research on teeth of active duty military personal has been conducted to test the accuracy of TCA for age- and season-at-death assessment.[1]

It is generally still a challenge to accurately apply cementochronology, and it is even more challenging to use TCA on degraded and taphonomically altered teeth found during recoveries. Both biotic and abiotic processes can alter dental remains after death and thus affect any identification analysis. The role of TCA and its accuracy of approximately ±1-3 years to the chronological age of an individual is still being underestimated and not routinely applied due to multiple factors, such as equipment set up being complex and expensive, and the learning curve of properly preparing the specimen and analyzing the cross sections for age- and season-at-death assessment being difficult since the analyst must be familiar with cementum biology to accurately read and understand the dental histological features utilized in this method.[1-4] Silver-staining is a somewhat new modification of traditional bone histomorphological methods and is providing several benefits for species differentiation on skeletal remains.[5] Silver-staining used for TCA can enhance contrast of dark and light increments, enabling the analyst to more confidently count the cementum lines and increase the accuracy of results. Additionally, this staining method offers the opportunity to work with much thinner specimens in order to minimize optical errors influencing the accuracy of age estimation on dental cementum, such as the "doubling effect."[6-8]

G12 Macroscopic and Microscopic Changes of Dental Tissues Exposed to Thermal Radiations: Forensic Interest in Fire Disaster Modeling

Aïda Bencheikh, DDS, 35 rue Albert Thuret, Chevilly Larue, Île de france , FRANCE; and Steve Toupenay, DDS*, Institut médico-légal, 2 place, Paris 75012, FRANCE*

After attending this presentation, attendees will better understand how dental tissues could help investigators in fire disaster modeling involving victims.

This presentation will impact the forensic science community by describing the findings from an experimental study conducted in association with the Section of Engineering Fire in the Central Laboratory of Police of Paris (LCPP), France. The benefit of this study lies in its novelty, as dental tissues were the first organic tools used in fire modeling. These findings could be used in fire disasters involving victims.

Human teeth reveal important features that demonstrate their ability to withstand postmortem shock caused by thermal activities. When bodies are seriously damaged by fire, the role of the forensic odontologist becomes even more essential during the identification process. This study was conducted in association with the Section of Engineering Fire in the LCPP using specific tools: the Calorimetric Cone (CC) and the Thermo Gravimetric Analyzer (TGA), which work in fire disaster investigations by using inorganic burned materials found at the fire scene.

The main goal of this study was to analyze the physico-chemical changes of the tooth when exposed to different thermal radiations. Both macroscopic (using CC) and microscopic (using TGA) changes were analyzed to define the mass-loss rate of dental tissues. This work sought to provide a new tool to help the LCPP investigators in fire disaster scenarios involving victims.

Material and Methods: This study used 33 samples of healthy teeth; 66 samples of dental tissues (enamel, dentine, and cementum) were collected from these 33 teeth.

For the microscopic study (TGA), the first study used three teeth and six samples of dental tissues to determine the repeatability and reproducibility of the TGA settings. Then, the healthy samples of dental tissues were burned and weighed from temperatures ranging from 25° to 1,000°C with a heating rate of 10°C/min.

For the macroscopic study (CC), teeth were divided into six groups of four teeth each and placed into six plates in order to reproduce the physiological environment of human teeth surrounded by alveolar bone. These plates were exposed to different thermal radiations from 5kW/m2 to 95kW/m2, corresponding to internal temperatures of 100° to 600° in the dental tissues. The exposure time for each plate was 30min, which represented the mean time of fire in Paris. Macroscopic changes of the teeth when heated were recorded using four photographies taken at T=0 ; T=10 ; T=20 ; and T=30 minutes. Then, samples of dental tissues from these burned teeth were collected, and another microscopic analysis was performed to compare the difference of the mass-loss rates between virgin and burned dental tissues.

Results: The microscopic study found that enamel does not lose mass when heated due to its strongly mineralized histological structure; however, on virgin samples, the cementum and dentin demonstrated three main reactions of mass loss: 280°C-400°C; 360°C-500°C; and 650°C-800°C, with the highest peak of mass loss found at 370°C.

For the macroscopic study, the results revealed a dislocation of the dental crown between the enamel and the underlying dentin at approximately 350°C. The external dislocation of the enamel crown could be linked to the internal mass loss of the cementum/dentin that appears at approximately 370°C.

Given the good repeatability of the experiments conducted with the Scientific Police Laboratory, the findings are promising in the fire investigation field involving victims. From now, dental tissues have a thermograph available in the LCPP with a mass-loss rate recorded according to the temperature of fire exposure. The tooth can be considered as a comparison point for further investigations in fire disaster modeling.

The human tooth is the first organic indicator of fire modeling used in the scientific police investigation and could be used in mass disaster fire cases involving victims. Moreover, the distance between the fire source and a victim would also be possible to estimate using the modelization system in the LCPP.

Fire Disaster Modeling, Forensic Odontology, Dental Tissues

G13 Mass Loss Reaction of Root Canal Materials Exposed to Thermal Radiations: Forensic Interest in Fire Disaster Modeling

Steve Toupenay, DDS, Institut médico-légal, 2 place, Paris 75012, FRANCE; and Aïda Bencheikh, DDS*, 35 rue Albert Thuret, Chevilly Larue, Île de france , FRANCE*

The goal of this presentation is to provide an understanding of how root canal materials could help investigators in fire disaster modeling that involve victims.

This presentation will impact the forensic science community in fire disaster modeling by submitting the outcomes found following an experimental study conducted in association with the Section of Engineering Fire in the Central Laboratory of Police of Paris (LCPP), France. The benefit of this study lies in the continuity of a previous study on dental tissues used in fire modeling. These findings could be used in fire disasters that involve victims.

In the oral cavity, dental roots are protected by alveolar bone. The endodontic material is the most preserved dental material when bodies are severely burned, such as during fire disasters or airplane crashes involving extreme thermal radiations. This study followed a previous study based on dental tissues. This work was conducted in association with the Section of Engineering Fire in the LCPP using specific tools, such as the Calorimetric Cone (CC) and the Thermo Gravimetric Analyzer (TGA).

The main goal of this study was to analyze the degradation of the gutta-percha with and without cement zinc-eugenol oxide when teeth are exposed to different thermal radiations, both macroscopic (using CC) and microscopic (using TGA), when analyzed to define the mass loss changes and thermogram of these root canal materials. This work is intended to provide further organic tools to assist LCPP investigators in fire scenario modeling involving victims.

Material and Methods: Twenty-seven teeth were divided into three groups of nine teeth each and placed into three plates to reproduce the physiological environment of human teeth surrounded by alveolar bone. For each of the plates of nine teeth, three were filled only with gutta-percha, three others with gutta-percha in combination with cement zinc-eugenol oxide, and the last three were filled only with cement zinc-eugenol oxide.

Two preliminary studies using TGA were conducted on root canal material to determine the repeatability and reproducibility of the settings from 25°C to 800°C with a heating rate of 10°C/min. Then, the three plates of nine teeth were placed under the CC with three different thermal radiations: 20 kW/m2, 35 kW/m2, and 50kW/m2. Another TGA microscopic analysis was performed on these burned samples.

Results: The results of this study demonstrate that, when burned, the gutta-percha leaves an important quantity of residues compared with other polymers. Moreover, the gutta-percha and the cement zinc-eugenol oxide revealed a mass-loss reaction between 540°C-765°C, which is the mean fire temperature in Paris.

Following the previous study on human teeth, these findings are still promising in the fire investigation field and further investigations could also be conducted on alveolar bone. During a fire disaster investigation, the LCPP use inorganic burned materials found at a fire scene to modelize the fire scenario. One milligram of dental tissues and root canal material could also be used and considered as a comparison point for the LCPP in a fire scene involving victim(s).

Fire Disaster Modeling, Forensic Odontology, Endodontic Material

G14 Establishing the Necessity for Ethnic Markers in Forensic Odontology: A Literature Review

Eric T. Washington, DDS, Mierboo Dental, 4500 Hugh Howell Road, Ste 710, Tucker, GA 30084*

After attending this presentation, attendees will understand the use of radiographic markers, in addition to skeletal markers that are unique to African Americans, as a benchmark to improve the outcome for the identification and resolution of cases in which forensic odontology is applied, as well as broader forensic applications, if appropriate.

This presentation will impact the forensic science community by determining if the need exists for, or improving the efficacy of, an already-existing protocol for ethnic markers for African Americans in forensic odontology.

The subject to be evaluated is the necessity for ethnic standards and/or protocols for skeletal and radiographic markers or the combination thereof. The specific application for African Americans, as well as other ethnic groups, is an effort to systematize and improve accuracy and focus in forensic odontology.

Radiographs, as well as skeletal and odontogenic markers, in forensics have the objective of identifying subjects via dental records for criminal investigations, missing persons, and antemortem and postmortem comparisons for identification. This challenge has been primarily addressed by using radiographs.[1,2] These systems can be applied to a closed and small population, which would be ideal, for example, in a plane crash with known passengers, but not-so-ideal in a missing persons cold case in which only skeletal remains are available at best. Hence, in the case of one study, small experimental databases are encouraged.[1] In multiple forensic scenarios, dental records may or may not be available.

There are other challenges encountered when depending primarily on radiographs, including, but are not limited to, poor-quality radiographs and the length of time between antemortem and postmortem images. This does not account for developmental and/or restorative changes that may have taken place as well.[3] Some non-radiographic considerations exist, including the analysis of morphology, while others evaluate different aspects of third molars with respect to eruption and mineralization.[4,5]

Following a review of the literature on this subject, we should be able to determine if a comprehensive system exists and, if so, the efficacy of that system. The implications of this existence or non-existence have far-reaching implications in the potential for improvement of the delivery of forensic "service," as forensics is a unique combination of law enforcement, health care, and the legal system, which locally, nationally, and internationally has the potential to improve the quality of life for mankind on a multitiered level when applied with academic vigor, logistical efficiency, and social compassion and ecumenicity in service of "we the people."

G15 Bitemarks in Wrongful Convictions in the United States

Robert B.J. Dorion, DDS, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, PQ H2K 3S7, CANADA*

After attending this presentation, attendees will have acquired information regarding the role that bitemarks have played in wrongful convictions in the United States judicial system in the past 40 years.

This presentation will impact the forensic science community by demonstrating the shortcomings of the judicial system, the necessity for basic education, continuing education, certification, recertification, proficiency testing, and the necessity of funding research.

The need for funding research was emphasized in the 2009 National Academy of Sciences (NAS) Report for improving the forensic science disciplines and thus, hypothetically, reducing wrongful convictions.[1] Only one bitemark research project has been funded in the eight-year interval by the National Institute of Justice (NIJ), a branch of the United States Department of Justice, despite numerous applications for funding.[2]

The Texas Forensic Science Commission report investigated a complaint lodged by the Innocence Project.[3] The latter asked the Commission "to investigate and report on 'the integrity and reliability' of bitemark evidence as used in criminal proceedings."

The President's Council of Advisors on Science and Technology (PCAST) Final Report and Addendum was widely criticized by different organizations and boards dealing with forensics (the American Board of Forensic Odontology, the Society of Crime Laboratory Directors, the International Association for Identification, etc.), law enforcement (the Federal Bureau of Investigation (FBI), the National Association of Attorney Generals, etc.), prosecutors (the National District Attorneys Association, etc.), as well as scientists.[4,5] One such scathing criticism from a scientist states that: "… the PCAST Report (1) is **not** scientifically sound, (2) is **not** based on data, (3) is **not** well-documented, (4) misapplies statistics, (5) is full of inconsistencies, and (6) does **not** provide helpful guidance to obtain valid results in forensic analyses."[6] These comments underline the necessity for balance between pure science and the practical application of a discipline.

The system of justice in North America is based on the premise that the accused is innocent until proven guilty and this burden of proof rests upon the prosecution. The prosecution's failure to demonstrate beyond reasonable doubt plays in favor of the accused. Ultimately, a judge or a jury decides on the guilt or the innocence of the accused. The principal adversarial actors on this stage are the prosecutorial and the defense attorneys. They are the ones that ultimately orchestrate the unfolding play in court. Their success or failure largely contributes to the outcome. All other interveners contribute minor roles to the courtroom stage.

This presentation also outlines the role that inadequate legal defense has played in wrongful conviction in bitemark cases, the failure to have or to use an expert witness at trial, and the use of rogue forensic experts.

In conclusion, wrongful convictions are the scourge of a North American judicial system. There is no single factor responsible for this dilemma.

Bitemark, Expert Witness, Wrongful Conviction

G16 The Defense Expert Witness' Obligation to Silence and Its Consequence of Wrongful Conviction

Robert B.J. Dorion, DDS, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, PQ H2K 3S7, CANADA*

After attending this presentation, attendees will be familiar with the homicide of 16-year-old Brigitte Grenier on June 22, 1990, following a rock music festival near Roseisle, Manitoba. The victim was beaten, mutilated, bitten, received head injuries, and was strangled. Timothy Lawrence Houlahan and Kyle Wayne Unger were charged with first-degree murder, found guilty on February 28, 1992, and imprisoned. On appeal in 1993, Unger's conviction was upheld, while a new trial was ordered for Houlahan. The latter committed suicide before the new trial. On December 2, 1993, the Supreme Court of Canada denied Unger's application for leave to appeal the Court of Appeals decision to uphold his conviction.

This presentation will impact the forensic community by demonstrating the role of the defense expert witness. The defense expert witness has an obligation of silence if not called upon to testify by defense. If the defense expert witness informs the contracting attorney that his client is responsible for the bitemarks, the latter may be unwilling to place the expert on the stand for obvious reasons. Can this, on the other hand, lead to or contribute to the wrongful conviction of a co-accused? What are the ethical implications of silence?

Houlahan, a minor at the time, was the last person seen with the victim heading into a wooded area where her body was found the following day. His clothes and face were covered with mud, he had scratches on his hands and face and blood on his chin when he emerged from the woods the evening Brigitte disappeared. The forensic evidence against him was the victim's blood on his shoe, the suspect's hair on the victim, and unknown to the prosecution until now, bitemarks attributed to him. All of this was prior to the advent of DNA technology.

Unger, on the other hand, was unaccounted for between 3:30 a.m. and 4:00 a.m. the day of Brigitte's disappearance. He emerged with intact clothing and appearance, and the only forensic evidence found was a single hair on the victim's body attributed to him microscopically. Mitochondrial DNA analysis in 2004 demonstrated that the single hair did not belong to him. He was granted bail in 2005, pending a Ministerial decision for a new trial, which was granted. In 2009, Manitoba's Deputy Attorney General withdrew the charges against him without financial compensation; however, the story is more complicated than this brief abstract outline.[1-5]

The prosecution consulted three dentists regarding the bitemarks on the body. Unger voluntarily provided samples of his dentition. The opinions of the dentists were contradictory, and the prosecution decided not to use the evidence at trial. Two of the forensic dentists had no practical experience in bitemark analysis, while the third was a highly experienced bitemark expert and an American Board of Forensic Odontology (ABFO) board-certified forensic dentist. The third dentist's opinion was that the three bitemarks could not have been made by Unger.

In Canada at that time, an accused could legally refuse to provide dental models and impressions. Houlahan refused to provide the latter, and these were not supplied to the prosecution's expert witnesses. This study received three sets of marked, but unidentified as to source, dental models and impressions from the defense, as well as those supplied to the prosecution's expert witnesses.

Much has been written regarding discord in bitemark identification and comparison among bitemark experts. Had the prosecution known that two experienced board certified forensic dentists agreed that Unger could not have created the three bitemarks on the body, would he have spent 14 years in jail and 5 years in limbo? Many European systems of justice would have permitted opposing expert witnesses to consult each other, and the agreement between opposing bitemark experts may have avoided prosecution and incarceration in these jurisdictions. This case demonstrates that bitemark evidence could have contributed to freeing a wrongfully accused and the wrongfully convicted as it has in other cases in the United States, such as the Gregory Ralph Wilhoit case in Oklahoma.[6]

Bitemark, Expert Witness, Wrongful Conviction

G17 Validation of an Algorithm to Mathematically Describe Bitemarks

James McGivney, DMD, 346 Tulip Drive, St Louis, MO 63119*

After attending this presentation, attendees will better understand the basic principles of defining a dentition mathematically.

This presentation will impact the forensic science community by beginning the process of scientifically validating bitemark analysis.

Recently, bitemark analysis has been criticized for lacking a scientific basis. The individuality of a specific bitemark has at times been questioned. This has led to doubt regarding the accuracy of attributing a bitemark wound to a specific biter's teeth. Research has been undertaken to determine how unique a dental pattern is and whether this uniqueness can be measured.

An algorithm for mathematically describing bitemarks has been detailed in the forensic dental literature.[1] The method involves analyzing an image of a dentition to locate the centroids of the biting surfaces of the teeth of interest. Wikipedia defines a "centroid" as "the geometric center of a plane figure." It is the arithmetic mean, or average, position of all the points in the shape. Once the centroids have been established, the centroids are connected with lines (or vectors). A vector is a quantity having direction as well as magnitude, especially as in determining the position of one point in space relative to another. Finally, the angles between consecutive pairs of vectors are calculated and recorded. An angle in planar geometry is defined as the figure formed by two rays (vectors), called the sides of the angle, sharing a common endpoint, called the vertex of the angle. Angles formed by two vectors lie in a plane. When eight teeth are studied, eight centroids will be found. The centroids will be connected by seven vectors, which will describe six angles.

A computer program, Bite2020, was been written in C# (Microsoft C Sharp). The software is based on a centroids-vectors-angles algorithm. The program does the work of finding the centroids of the teeth of interest, then calculates the vectors and angles. The resulting mathematical description is saved in a Microsoft® Excel® file. It is envisioned that the program will be used by forensic odontologists as a routine part of their bitemark case workup. The program has been developed to be intuitive, self-instructive, and easy to use.

Once a dentition has been mathematically described and recorded, the results can be compared to a database of previously recorded dentitions. This will allow the forensic odontologist to assess how unique the dentition of interest is when compared to the realm of heretofore analyzed dentitions.

It is anticipated that a repository of bitemark metrics will be maintained by either the American Board of Forensic Odontology (ABFO), the American Society of Forensic Odontology (ASFO), or another forensic organization.

The purpose of this presentation is to begin the process of validating the ability of the algorithm to accurately identify, analyze, and record mathematical descriptions of bitemarks. The validation process for the purpose of this presentation has been divided into three parts. First, the ability of the algorithm to correctly find, calculate, and record the centroids of a number of standard geometric shapes will be compared to expected values. Second, the ability of one investigator to reproduce the same values when analyzing the same dentitions at different sessions will be evaluated. This measurement is known as repeatability or test-retest reliability. It is used to assess the consistency of a measure from one time to another. The third part will assess the ability of different investigators to reproduce similar values when analyzing the same dentitions. In statistics, this measurement is known as inter-rater reliability or inter-rater agreement, or concordance, and is the metric or degree of agreement among raters and is used to assess the degree to which different raters/observers provide consistent estimates of the same phenomenon.

This algorithm shows promise in formulating a scientific basis for the art of bitemark analysis.

Algorithm, Bitemark, Mathematics

G18 Lessons From 30-Year-Old Louisiana Bitemark Cases: Jackson, Keko, and Others

Robert E. Barsley, DDS, JD, LSU School of Dentistry, Oral Health Resources, Rm 5345, 1100 Florida Avenue, New Orleans, LA 70119*

The goal of this presentation is to assist current odontologists by presenting historical cases in light of today's best practices.

This presentation will impact the forensic science community by highlighting errors that may occur without standards, guidelines, and best practices.

Synopsis: Two 30-year-old bitemark cases that resulted in exoneration will be discussed. The processes and procedures used then will be contrasted to resources that are available today. Additional discussion points will contrast standards, guidelines, and best practices over the decades as well as discuss the ongoing impact from these and other historic cases.

Forensic odontology, specifically bite injury analysis, has progressed and continues to progress since its widespread adoption by practitioners and the United States court system beginning in the mid-1970s. Advances have included educational requirements for certification, increasing educational opportunities in the field, ease and desirability of communication between practitioners, advances in photography to include the use of digital imaging, advances in illumination techniques and equipment, the adoption of and increasing sophistication of digital imaging software, research into the dynamics of bite injuries, and research in computer-aided image analysis, to name just a few.

In Louisiana, several suspects have been convicted of crimes in which bite injury analysis played a role. During a 30-year-period, two convictions have been set aside. In each case, the State of Louisiana, through the office of the local district attorney, declined to retry the suspect. This presentation will discuss those controversial cases, detailing what steps were taken by the odontologist(s), what other steps might have been taken at the time, what additional steps could be taken today, as well as other issues that impacted the cases.

The first case is that of Willie Jackson, convicted of rape — a case that was appealed to the United States Supreme Court, which denied writs. More than a decade after that denial, the Innocence Project was successful in securing a hearing based on DNA evidence not available at the time of the trial. The conviction was set aside and the prosecutor declined to retry the matter. Only a single odontologist was involved in the trial, and a second odontology expert was consulted by the defense during the original appellate process.

In the second case, Anthony Keko, the conviction was reversed on appeal. Six board-certified odontologists were consulted in that case at the trial level, three for the state and three for the defense. Although not all made statements "for the record," there was not complete agreement between a majority of the odontologists on the state side, and likely not for defense, either. In addition to the criminal case, this matter spawned a long-running civil suit that continues to impact the practice of forensic odontology to this day.

This presentation will provide information for the newer odontologist by using these cases to point out errors that may explain, in part, why the field is under such scrutiny today. Hopefully, the experienced odontologists attending this presentation will achieve a greater understanding of the internal conflicts which have contributed to long-standing disagreement over technique and presentation of results in the discipline. In many ways, these two cases are not unlike other cases of that time, as well as other more contemporary cases, some of which have stood the test of time and others that have not. The odontology expert should not ignore the potential of renewed and/or protracted litigation.

Bitemark, Exoneration, Historical Cases

G19 Case Studies of Failure to Diagnose Oral Malignancies: What Is the Standard of Care for Diagnosing an Oral Malignancy?

John D. McDowell, DDS, University of CO, Dental Med, MS-F844, L 26, Rm 130, 13065 E 17th Avenue, Aurora, CO 80045*

After attending this presentation, attendees will be able to: (1) understand what is meant by standard of care for oral health care providers as they encounter suspicious oral lesions; (2) follow a diagnostic algorithm for diagnosing oral malignancies; and, (3) use the concepts of sensitivity and specificity for choosing tests to determine if a lesion is malignant.

This presentation will impact the forensic science community by illustrating the importance of practicing dentists' abilities to competently make decisions in the best interest of their patients when they encounter suspicious hard or soft tissue lesions of the jaws. Additionally, this presentation will assist forensic odontologists when they are called upon to develop opinions regarding standard-of-care issues.

When confronted with potentially confusing diagnostic dilemmas, the competent clinician should, when reasonable, not ignore the diagnostic imperative (the condition that the clinician cannot overlook or dismiss as not possible to the detriment of the patient). If a clinician ignores the diagnostic imperative then that clinician might be considered to have failed to meet the standard of care.

Procedures will be shown that assist in differentiating a possible malignancy from infections and/or inflammatory and reactive lesions. Attendees will also be able to understand the advantages of an early diagnosis over a late diagnosis and recognize benefits associated with the development of a treatment plan that is favorable to patient outcome.

After attending this presentation, attendees will be able to recognize many of the common and less common signs (including those found in radiographs and other imaging studies) and symptoms associated with oral malignancies (carcinomas, sarcomas, and possible combinations of the two). To reduce confusion that may occur when viewing suspicious lesions, different tests are often chosen to diagnose an oral lesion using the principles of sensitivity and specificity. Attendees will be able to understand that a biopsy has high utility and is most often the best way to develop definitive diagnoses leading to effective treatment plans to manage a diagnosed malignancy.

Attendees will further recognize that oral cancer is not common but is certainly not rare. The National Cancer Institute's Surveillance, Epidemiology and End Results Program (SEER) reports that 1.1% of men and women will be diagnosed with an oral cancer at one point during their lifetime. Diagnosis of oral cancers and survival rates following diagnosis have remained stable over the past 20 years in the United States. Increasing immigration from countries where oral/pharyngeal cancers are much more common is expected to increase the number of new cases seen by United States providers.

Several case studies utilizing patient histories, the analysis of physical examinations, and test results leading to a diagnosis of malignancy will be presented. Clinician failures to use a proven diagnostic algorithm resulted in malpractice claims against those clinicians who failed to meet the standard of care.

Attending this presentation will increase the likelihood that health care providers will be able to diagnose oral cancer at the earliest possible time, which will hopefully result in better patient outcomes.

Standard of Care, Diagnosis Utilizing Biopsies, Oral Malignancies

G20 The Good, the Bad, and the Ugly

Peter F. Hampl, DDS, 7898 Greyhawk Avenue, Gig Harbor, WA 98335-4926; and David C. Houpt, DMD, 8745 Pacific Avenue, NW, Ste 101, Silverdale, WA 98383*

The goals of this presentation are to add to the odontologist's awareness of the complexities of this science and to allow the odontologist to observe nature taking its course.

This presentation will impact the forensic science community by illustrating how human bitemark pattern injury analysis is an observational science.

Observational science is a field of science in which controlled observations cannot be conducted in order to study cause and effect. Scientific studies are simply conducted through the observation of nature taking its course and recording the findings over time. An example of an observational science is astronomy, a science in which a person cannot change or control any aspects of the sun, moon, and stars.

The complexities involved with bites inflicted on one human by another involve numerous factors. Just a few of these factors would be position of biter versus the person being bitten, forces involved, bites inflicted antemortem versus postmortem, and the anatomical area being bitten. This is just a short list of the many factors that influence the appearance, evidentiary value, and analysis of human bites. None of these many factors can be controlled or predicted by the observer of the pattern injury. Laboratory studies of human bitemark injuries *in vivo* cannot account for the many variables seen in the real world. Cadaveric studies and *in vivo* animal models lack external validity in that they are not directly relevant to the clinical situation.

In the 1980s and 1990s, the admissibility pendulum swung to a very permissive position relative to bitemark evidence. Recently, the pendulum has swung 180 degrees to a restrictive position, to the point that there are proponents that feel bitemark evidence should never be allowed for prosecution in the judicial system. Bitemark injuries will not go away just because commissions, councils, committees, or panels feel they are not scientific. Indeed, in cases in which bitemark evidence is questioned, the courts still ask for the opinion of the forensic odontologist. There is nothing wrong with pattern injury (i.e., bitemark evidence). It is the decision to go ahead with bitemark analysis with weak evidence and incorrect or even over-interpretation of the pattern injuries that needs to be addressed. The trier of fact has a professional, ethical, and moral obligation to determine the merits of each pattern injury seen in crimes against persons.

It is, therefore, essential for the odontologist to observe as many pattern injuries as possible to be proficient in pattern injury analysis. This study would like to share with attendees three different pattern injury cases. The cases presented will cover a wide range of factors, providing attendees with an opportunity to experience the complexities of pattern injury analysis.

The "Good Case" implies that there are both class and individual characteristics that permitted this study to conclude that the pattern injury was a human bitemark. The reasoning process will be presented to allow attendees to follow the course of events that allowed the determination that the pattern injury was a human bitemark.

The "Bad Case" conveys the idea that although both the victim and the assailant, in a domestic violence situation, admit the pattern injury was a bitemark, this study was unable to arrive at a definitive conclusion.

The "Ugly Case" was a situation in which the authorities investigating the case had determined the pattern injury was a "human bitemark;" but, when an expert was called in for consultation, it was determined from both clinical examination and history that the "human bitemark" was a pattern injury of iatrogenic origin and was not caused by human teeth.

If, in fact, human bitemark pattern injury analysis is an observational science, which this study proposes it is, then the odontologist cannot observe enough pattern injuries. It is hoped that this presentation will add to the odontologist's awareness of the complexities of this science and will allow the odontologist to observe nature taking its course. These cases can then be added to the odontologist's portfolio of pattern injuries.

Observational Science, Pattern Injuries, Bitemarks

G21 Project LifeMeters: A Digital Solution Optimizing Forensic Measurement Tools in Bitemark Analysis

Armin A. Farid, DMD, Podmaniczky Utca 33, III Fl, 8, Budapest 1067, HUNGARY; Hidir Sayli, Alte Allee 78a, Munich, Bavaria 81245, GERMANY; and Nadji Hedjazi, Bary Street 10, München, Bavaria 81245, GERMANY*

The goal of this presentation is to introduce a novel digital tool capable of capturing and creating life-size images of items present or physical injuries inflicted on a human body at a crime scene.

This presentation will impact the forensic science community by demonstrating methods to further digitize the processes involved in evidence conservation. By suggesting a concrete idea for such a tool, this presentation seeks to motivate the forensic science community to digitize more of the processes involved in evidence conservation.

It is a known fact that it can be a great challenge to accurately register bitemarks. Obstacles include poor quality photographs, not having a ruler handy, not knowing the real proportions of items, and using complex image processing software to manually improve image quality. Not having the proper tools available at the crime scene makes it impossible to perform a proper and accurate bitemark analysis, as precision must always be the benchmark of any forensic investigation.

Furthermore, time is of the essence when it comes to conserving the structure of a lesion on a human body before the healing process begins and improves the condition of the original wound. Also, in economically challenged countries around the world, forensic measurement tools such as the American Board of Forensic Odontology (ABFO) No. 2 forensic ruler may be difficult to obtain at a moment's notice, whereas a smart phone is nearly always available on demand.

In conclusion, the idea is to develop a mobile application capable of capturing life-size images of evidence at a crime scene with the scale of a digitally implemented forensic ruler calibrated by the user beforehand. Current devices on the market are unable to accomplish this due to their inability to scan object depth without infrared projectors, making 3D object capturing impossible. If there were hardware add-ons available on the market for mobile devices or if smart phone companies were able to integrate a hardware addition to their products, a mobile app would be able to calculate the exact size of an item. The app could also record the data of the captured image in a file format suitable for further processing. The automatized forensic analysis of an image could make a considerable contribution to the quality of the findings.

Project LifeMeters consists of two technical components. The software component includes an artificial intelligence module that tags specific objects or wound types automatically and provides this information in a report. The smart phone camera hardware component is used for 3D object capturing. The concept is plausible because there are already technologies, such as Google's® Project Tango or Occipital's Structure Sensor, that provide the camera features for smart phones performing instant measurements. There are already two smart phones on the market from Lenovo® and ASUS® with an integrated 3D camera. In addition, the scene recognition demo of the Massachusetts Institute of Technology demonstrates how precise current scene recognition systems are in defining objects within a crime scene.

Bitemark, Digitalization, Crime Scene

G22 An Examination of Bitemark Analysis in the Turkish Judiciary and the High Court

Huseyin Afsin, PhD, Hacikadin Caddesi 18-1, Kocamustafapasa, Istanbul 3400, TURKEY; Yalcin Buyuk, MD, Adli TipKurumu Yenibosna, Istanbul 34260, TURKEY; Abdi Ozaslan, MD, Istanbul University, Cerrahpasa Medical Faculty, Forensic Medicine Department, Fatih, Istanbul 34098, TURKEY; and Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104*

After attending this presentation, attendees will understand how the Turkish judicial system evaluates bitemark analyses in criminal cases.

This presentation will impact the forensic science community by providing information regarding examples of bitemark uses in the Turkish court system.

As societies progress, the justice mechanism needs more reliable and more realistic evidence. This is why forensic dentists should have not only basic dentistry science instruction, but should also be familiar with aspects of medicine and law. The analysis of a human bitemark is one of the most complex and challenging components of forensic dentistry. Courts may use bitemark analysis to increase the certainty with which a perpetrator is convicted or help ensure an innocent suspect is properly exonerated. In this presentation, three cases are demonstrated in which bitemark analyses were used in identifying and convicting suspects. The Supreme Court of Appeals subsequently approved the appeal requests, and the decisions of the Court are examined and evaluated.

Case 1: In Istanbul, in 2002, a 70-year-old man was found dead in the house where he lived alone. The autopsy was conducted by the Forensic Medicine Institute. A bitemark was identified on the right side of the victim. Forensic experts examined this bitemark, which consisted of a seven-tooth impression. At the time, the man's wife was a fugitive and her neighbor was providing the police with contradictory testimonies; thus, the neighbor was taken into custody. As a result of the bitemark comparison, the impressions produced from three teeth in the upper arch and four teeth in the lower arch were found to be consistent with the bitemarks observed on the victim's side.

Case 2: Three separate events within a one-month period left one victim dead and two others injured. The first attack took place in 2002, against a woman who lived alone in Istanbul. There were dozens of deep bitemarks on the victim's face and body and she was admitted to Istanbul University Medical Faculty Hospital Emergency Surgery Service for treatment (evidence of sexual assault was not found). The second attack was in 2003 against an 80-year-old woman found partially dressed in a burning house, also in the district of Istanbul. She had deep bitemarks on her face, arms, legs, and other parts of her body. The killer bit the victim several times, then killed the victim with a piercing tool. Approximately one meter from the body, flesh that was bitten off by the perpetrator was discovered. No signs of sexual assault were found. The third assault also took place in Istanbul in 2003, and involved a United States tourist. The assailant bit the victim over her right eye and on several other places on her face. The killer had two distinct characteristics: the canine teeth were much larger than normal, and the anterior teeth were absent, which created a very specific pattern.

Case 3: In 2010 in Izmir, police discovered a body that had been stabbed in the throat and on various other parts of his body. There was no wallet or cell phone on the body. One of the suspects had bitemarks on his right hand. Examination of three cigarette butts found in the suspect's car revealed that the cigarette butts belonged to the suspect. The suspect was also the owner of the farm where the body was found and was at that particular coffee house on the day of the incident. His son and cousin were with him on that specific day and were also arrested.

In conclusion, in the case of bitemarks, the following protocol is followed: per prosecutor order, the police investigation team collects evidence at the scene from all suspects and victims. The prosecutor's office takes statements from witnesses. Evidence is then sent to the relevant laboratory units to be examined. After obtaining the evidence and laboratory results, a scientific report is prepared by an expert. If there is a contradiction in the reports of the expert panel, the court will send all documents to the relevant specialist department of the Forensic Medicine Institute and request a report. Then, the relevant court will judge the entire contents of the file and issue an independent order. If one of these parties disagrees, the matter is assessed, and a final decision is made by the High Judiciary.

Turkey, Bitemark Analysis, High Court

G23 Recognizing Bitemarks: A Basic Problem

Alexander S. Forrest, MDS, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA*

The goal of this presentation is to raise an alternative to stating in a courtroom or a legal statement that a suspect injury is or is not a bitemark when there is no victim statement to corroborate the diagnosis. Instead, this presentation proposes stating the degree to which an injury matches the class and individual characteristics of a bitemark.

This presentation will impact the forensic science community by illustrating how to reduce the potentially spurious certainty around claims that a particular injury is a bitemark when this is uncorroborated by other evidence. Instead, this presentation takes the conservative option of reporting only on the degree to which the injury meets the class characteristics, enhancing the probity of the evidence, and reducing reliability on "expert experience," which has been shown to correlate poorly with a correct diagnosis.

Several lesions have been reported by Gold et al. simulating bitemark injuries, including fixed drug eruptions, subacute cutaneous lupus erythematosus, pityriasis rosea, tinea corporis, and granuloma annulare.[1] Other injuries may also look suggestively similar to bitemark injuries. Injuries from shoe sole contact, belt buckles, defibrillators, and saws have also been reported as potentially presenting confounding features.[2,3]

A disputed paper purporting to determine the degree to which experienced forensic odontologists could agree on whether or not an injury was caused by teeth raised the issue of whether or not injuries that resemble bitemarks can reliably be differentiated from the real thing.[4] Regrettably, the original project has not been repeated in a rigorous form, but the question is nonetheless an important one. Important elements of a case may turn on the diagnosis.

In the absence of hard research demonstrating that experience in bitemark analysis improves the reliability of the diagnosis, a more conservative approach may be warranted.

Current American Board of Forensic Odontology (ABFO) Bitemark Methodology Standards and Guidelines refer to three categories into which injuries may be classified: (1) Human Bitemark (human teeth created the pattern); (2) Inconclusive (there is insufficient evidence to reach an opinion as to whether or not the pattern is a bitemark); and, (3) Not a Human Bitemark (human teeth did not create the pattern).[5] All of these are subjective judgements.

This presentation discusses the class characteristics of human bitemark injuries and suggests that a more conservative presentation removes the subjective nature of these categorizations. Instead, it is proposed that the class characteristics of a human bitemark be listed and agreed upon (this presentation enumerates a possible list) and that forensic odontologists comment only on the extent to which the injury in question matches these class characteristics. If a threshold is met, then the presence of individual characteristics can be used to determine whether or not the injury is suitable for comparison with a potential suspect dentition.

G24 Dental Age Quicksheets (DAQS): The Use of Rapid Calculation Procedures to Determine "Uncertainty" in Dental Age Estimation (DAE)

Derek M. Draft, DDS, 3100 Wilson Avenue, SW, #3, Grandville, MI 49418; Graham J. Roberts, MDS, King's College London, Dept Orthodontics, Fl 25, Guy's Tower Wing, London Bridge, London SE1 9RT, UNITED KINGDOM; Victoria S. Lucas, PhD, King's College London Dental Institute, Dept of Orthodontics, Fl 22, Guy's Tower, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; and Manoharan Andiappan, MSc, King's College London Dental Institute, Dept of Population and Patient Health, Bessemer Road, London SE1 9RS, UNITED KINGDOM*

After attending this presentation, attendees will be: (1) aware of the differences in the expression and interpretation of the amount of variation associated with DAEs; (2) able to consider the differences in presenting estimate of "uncertainty;" and, (3) in a position to determine the appropriate method of expressing uncertainty.

This presentation will impact the forensic science community by educating attendees on the differences in error calculation and reporting with DAE cases and by improving the accuracy of DAEs by utilizing the correct method of obtaining the pooled standard deviation.

Introduction: DAEs are widely used in forensic human identification, age estimation of asylum seekers, and in forensic anthropology. When calculating the estimated age, the "error of the method" must also be reported. The most common method of reporting the error in DAE is the Standard Deviation (SD). The usual presentation is to indicate the Dental Age (DA) ±1SD, ±2SD, or even ±3SD. These are helpful ranges as they encompass approximately 68%, 95%, and 99%, respectively, of the data.

Historical DAE studies have utilized Tooth Development Stages (TDS), enabling the dental assessor to use the published mean values of the stages to calculate the DA by taking an average of those values. The associated error of the TDS values are also published and the dental assessor therefore averages the SD values of each TDS value used to obtain the overall SD of the DA. The error of the DA is *usually* reported as a multiple of the SD, and, by convention, this is ±2SD.[1] A more appropriate method of calculating the error associated with the DA is utilizing a pooled SD equation, which takes into account a weighted average of the SD by utilizing n-1.

The purpose of this study is to compare the range of values for the SD calculated using the pooled calculation (n-1) with the range of values using the simple average of SD (n).

Materials and Methods: Dental panoramic tomographs from a study of accuracy of age estimation at the 10-year threshold were re-used. The tooth development stages using the Demirjian description were determined and entered into the DAQS. For each subject, the DAQS calculated the age of the subject and the pooled SD n-1 and simple average SD n separately. The range of uncertainty was then expressed as a range of the SD, namely ±1SD, ±2SD, or ±3SD.

Results: It was found that there was a statistically significant difference between ranges of uncertainty calculated respectively from the pooled SD n-1 and SD n.

Discussion: The DA for a single subject is estimated by averaging the mean values for the TDS present on the subject for whom a DA is required. The variation or level of uncertainty is expressed as the SD or multiples thereof.

The data revealed the pooled SD n-1 to be greater than the averaged SD n for 92 of the 100 subjects and the reverse for 8 subjects. The average difference between SDS and SD n-1 is 0.085. This translates into a difference in the estimated DA range of 0.17 years or 2.04 months for ±1SD, 4.04 months for ±2SD, and 6.06 months for ±3SD.

Conclusion: It is clear that the use of the orthodox method of estimating the pooled SD n-1 provides a wider range for the expression of uncertainty, often referred to as the error of the method, compared to the simplistic method of simply averaging the SD.[2] The differences are small, but in the interests of sound logic and improved accuracy, the correct method of obtaining the pooled SD should be used.

Dental Age Estimation, Standard Deviation, Quicksheets

G25 Statistical Tools in Assessing Validity and Reliability of Tools Used in Forensic Odontology

Mithun Rajshekar, MFSc, 2/67 Olinda Grove, Mt Nelson, Hobart, Tasmania 7007, AUSTRALIA*

After attending this presentation, attendees will better understand the importance of using appropriate statistical tools when conducting reliability studies in forensic odontology.

This presentation will impact the forensic science community by explaining in detail the importance of selecting or identifying the best statistical tools available in a broader scientific society that can be applied for forensic purposes.

Background: In 2009, the National Academy of Sciences conducted a review of forensic disciplines and their role as expert evidence in the United States. The review took into consideration cases in which the convicted individual was subsequently exonerated due to DNA testing following judicial reassessment. Together with other latent print identification techniques, the Report was critical of forensic odontology and, in particular, of bitemark analysis and comparison. The National Academy of Sciences reported that the limitations of forensic techniques included inadequate scientific underpinnings, a paucity of research on human observer bias, and lack of technological innovation. The Report indicated that both scientific and systemic changes need to be made to bitemark analyses to ensure their reliability, establish standards, and promote practices that are consistent.

Materials currently used in making dental casts for forensic investigations of bitemarks undergo structural and chemical changes during setting, and the casts may not be completely accurate as a consequence. Intraoral 3D scanning of dentitions has the potential to provide a fast, accurate, and non-invasive method of recording dental information; however, they are yet to be validated for use in forensic investigations.

Goal: The goal of this study was to assess the reliability and validity of a portable intraoral 3D scanner appropriate for recording suspect dentitions in forensic investigations. For the purpose of this presentation, two different approaches of estimating Intraclass Correlation Coefficients (ICC) will be outlined.

Methods: In this study, reliability and validity of the intraoral 3D scanner was quantified by observing the findings of several tests, such as by comparing means of test-retest, rater-rater, and method-method differences, calculation of ICC, and Standard Error of Measurements (SEM) of 110 landmark dental features that were made on 50 sets of human dental casts. To estimate the ICC, along with the conventional method by Fleiss and Shrout, a novel method of concurrent assessment of inter-and intra-rater reliability in a three-factor (subjects, methods, raters) design with replication was conducted by extending the approach of Eliasziw et al. for two factors with replication.[1,2] This presentation will present the findings of ICC analysis using a conventional approach (Fleiss and Shrout) and by using the approach by Eliasziw et al. and the advantages and disadvantages of using the above-mentioned methods in a reliability study with repeated measurements in forensic odontology.

Conclusions: This presentation addresses the paucity of research on using statistical tools to enhance the scientific underpinnings in forensic odontology by understanding their limitations and emphasizing the need for identifying other methodology not previously used in forensic odontology.

Reliability and Validity, Forensic Odontology, Statistical Analysis

G26 Dental Age Estimation Using the Demirjian Method: A Flawed and Obsolescent System

Graham J. Roberts, MDS, King's College London, Dept Orthodontics, Fl 25, Guy's Tower Wing, London Bridge, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; Manoharan Andiappan, MSc, King's College London, Dental Institute, Dept of Population and Patient Health, Bessemer Road, London SE1 9RS; and Victoria S. Lucas, PhD, King's College London, Dental Institute, Dept of Orthodontics, Fl 22, Guy's Tower, London SE1 9RT, UNITED KINGDOM*

After attending this presentation, attendees will be aware of the serious shortcomings of the Demirjian system of Dental Age Estimation (DAE). Attendees will be able to consider the reasons for the difficulty in comprehending and applying this system and will be in a position to use a simpler system of DAE based on the Dental Age Quicksheets (DAQS) approach.

This presentation will impact the forensic science community by providing information that will lead to the adoption of the DAQS system for the accurate estimation of dental age as a surrogate for chronological age.

Introduction: Dental age assessment using the method of Demirjian and colleagues published in 1973 has been widely used over the past 40 years.[1] Despite its widespread use, even a cursory reading of the paper leads to the conclusion that the details of the methodology are elusive. A recent systematic review revealed there were wide discrepancies between the Chronological Age (CA) and the Dental Age (DA) estimated using the Demirjian method.[2] This has led to other criticisms of the reliability of the Demirjian method.[3]

Problems with the Demirjian System: It is convenient to break down the method into two major components: (1) The Demirjian Tooth Development Stages (TDS) — the first of these, the TDS, has made a major contribution to DA studies. The observer agreement when assessing the TDSs has proven to be of the highest level.[4] (2) The System of Mathematical Integration of Ages of Attainment (AoA) — the second issue is the major weakness of the Demirjian system. This is the failure to censor Stage H, which leads to grossly inflated AoA for all the H Stages from LL1 through LL7 (see table below). This results in elevated values for Stage H.

	LL1	LL2	LL3	LL4	LL5	LL6	LL7
Development Stage	H	H	H	H	H	H	H
	Years	Years	Years	Years	Years	Years	Years
AoA UNCENSORED	15.43	15.73	16.69	16.98	14.54	16.29	17.82
AoA CENSORED	12.73	13.05	13.22	13.38	17.59	13.16	15.03
Difference	2.70	2.68	3.47	3.60	3.05	3.13	2.79

The data in this table reveals that the effect of non-censoring is to elevate the AoA by between two and three-fourths and three and one-half years. Although the detailed mathematics are complex, this may explain the underlying cause of the systematic overestimation of DA using the system of constraints.

The original mathematical approach was to use the system of "constraints" to assign to each of the Demirjian TDS a "value" that, when summed, came to 100.[5] This was deemed to be the equivalent of "Full Maturity."

Can It Be Rectified?: The straightforward answer to this is no. Over the past few years, persistent attempts have been made to unravel the mathematical approach to this method, including repeated contacts with the original authors.

Conclusions: The method of constraints used in the original 1973 paper has shortcomings and should no longer be used. The ease of use of modern spread sheets makes elaborate computations straightforward for forensic odontologists. The Demirjian system of TDS remains the choice for DAE. It is the most fully described and most reliable in terms of reproducibility.

Demirjian, Obsolescent, DAQS

G27 Root Pulp Visibility (RPV): Validation of Applicability of RPV in Determining Adult Status

Victoria S. Lucas, PhD, King's College London, Dental Institute, Dept of Orthodontics, Fl 22, Guy's Tower, London SE1 9RT, UNITED KINGDOM; Manoharan Andiappan, MSc, King's College London, Dental Institute, Dept of Population and Patient Health, Bessemer Road, London SE1 9RS; Fraser McDonald, PhD, King's College London, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; and Graham J. Roberts, MDS, King's College London, Dept Orthodontics, Fl 25, Guy's Tower Wing, London Bridge, London SE1 9RT, UNITED KINGDOM*

After attending this presentation, attendees will be aware of the applicability of RPV measurements to predict whether or not a subject of unknown date of birth is above the 18-year threshold, will be able to apply RPV to cases in which the lower third molar has completed growth and mineralization, and estimate with a high level of probability if the individual is above 18 years of age.

This presentation will impact the forensic science community by providing a method with great potential to predict the adult status of subjects without birth records.

Introduction: The gradual loss of RPV with increasing age has been reported in the European literature.[1,2] This enables a reliable prediction of the age above the 18-year threshold. To validate the technique, the first stage is collection and publication of reference data.[1,2] Next, Dental Panoramic Tomographs (DPTs) of subjects of known age are assessed (age and gender masked).

The purpose of this study is to assess the reliability of RPV in predicting whether a subject is below or above the 18-year threshold. In the United Kingdom, 18 years is the age of majority (i.e., adult status).

Materials and Methods: DPTs taken early in 2015 were drawn from the archives of Guy's and St. Thomas' hospitals. The inclusion criteria were DPTs of diagnostic quality of both male and female subjects of known ancestry, aged between 16 and 25.9 years. The DPTs were enlarged to X2 to improve visualization. The lower left third molar (LL8) was assessed to predict maturity using the 8 Stage System of development.[3]

For each LL8 Stage H, RPV was recorded using the original criteria, modified to improve interpretation.[1,2] The assessments were made in random order. The age, gender, and ancestry were not known to the assessor. Intra-rater agreement was determined by randomly selecting 10% of the subjects for reassessment one week later. All data was entered into a Microsoft® Excel® spreadsheet, and a filter process was applied to isolate the data for each of the RPV categories by gender.

Results: A total of 396 DPTs were assessed. The proportion of subjects in each RPV category is shown in the table below.

Root Pulp Visibility: Summary Statistics for Stages A, B, C, D						
			$\bar{x}$	**SD**	**p > 18**	**% > 18**
RPV- •f	59 / 238	24.8%	19.96	2.99	0.74	74.0
RPV- Af	42 / 238	17.6%	22.45	2.22	0.98	98.0
RPV- Bf	103 / 238	43.3%	23.52	1.68	1.00	100
RPV- Cf	31 / 238	13.0%	23.83	1.85	1.00	100
RPV- Df	3 / 238	1.3%	23.49	0.15	1.00	100

• signifies unusable data from DPTs. *f = female, m = male*

Discussion: This validation of RPV using the gold standard of chronological age has demonstrated a high level of reliability for predicting the adult status of a subject. Clearly, it is appropriate to apply these findings to individuals without birth records. It appears that the high level of probability of being aged above the 18-year threshold is greater than shown in the original studies.[1,2]

Conclusions: The use of RPV has great potential for predicting adult status for subjects without birth records.

G28 Dental Age Assessment From Analysis of Canine Pulp/Tooth Volume Ratios Using Cone Beam Computed Tomography (CBCT)

Mohammed A. Barayan, University of Texas HSC San Antonio, 7703 Floyd Curl Drive, San Antonio, TX 78229; David R. Senn, DDS, University of Texas HSC San Antonio, 7703 Floyd Curl Drive, Mail Code 7919, San Antonio, TX 78229-3900; and Husniye Demirturk Kocasarac, DDS, PhD, University of Texas HSC San Antonio, 7703 Floyd Curl Drive, San Antonio, TX 78229*

After attending this presentation, attendees will better understand the correlation between pulp/tooth ratio volume and age assessment and will appreciate the benefits of using Amira™ radiographic software for *in vivo* volumetric analysis of tooth/pulp volume. Additionally, attendees will better understand the effect of gender and arch location of canine teeth in the accuracy of age assessment.

This presentation will impact the forensic science community by providing a non-invasive and dependable modality for age assessment. This presentation also introduces a segmentation tool that provides the ability to segment both the tooth and the pulp structures without including the surrounding bone.

Background: Dental age assessment presents greater challenges for adult cases than for cases involving adolescents or children with mixed dentitions. Some dental methods are invasive and very technique-sensitive compared to others, and some can be applied only to deceased individual cases. Among different potential parameters for age assessment, tooth and pulp space have gained more interest in recent years. It is well known that pulp space decreases in size with aging. Therefore, several studies have evaluated tooth/pulp size ratio using two-dimensional radiographs. Fewer studies have been published using 3D CBCT. The hypothesis developed for this study is that analyses of the ratios of the volumes of canine teeth and their pulps using CBCT can provide an acceptably accurate estimation of age in adults. The purpose of this study was to develop an accurate and non-invasive age assessment method by performing volumetric measurement of tooth and pulp space using CBCT on living subjects.

Material and Methods: The study population consisted of 135 subjects (67 males and 68 females) aged 18 to 75 years old. Maxillary and mandibular canines were used in this study. All scans had been taken earlier for varying diagnostic purposes, such as implant planning and endodontic evaluations. Teeth with caries, fracture, or a history of orthodontic treatment were excluded. Amira™ software was used to quantify the volume of the tooth and pulp space. Pulp/tooth ratio was calculated. All assessments were performed by a single evaluator (a board-certified oral and maxillofacial radiologist), and 60 of the scans were re-evaluated for intraobserver agreement. Data were analyzed using Pearson correlation and regression analyses and significance was set at 0.05.

Result: There was a strong correlation between pulp/tooth volume ratios and age. The age estimates for maxillary canines correlated with chronological age better than the estimates from mandibular canines. There was good intraobserver agreement. The findings indicate that analysis of pulp/tooth volume ratios of both maxillary and mandibular canine teeth are useful for age assessment.

Age Assessment, CBCT, Pulp/Tooth Volume

G29 The Accuracy of Two Dental Age Estimation Methods on Saudi Children: Cameriere's Measurement of Open Apices and The London Atlas of Tooth Development

Dara M. Alsudairi, Alghadeer District, Riyadh, SAUDI ARABIA; and Sakher J. AlQahtani, PhD*, College of Dentistry, King Saud University, Riyadh 11545, SAUDI ARABIA*

The goal of this presentation is to demonstrate how well two methods of Dental Age Estimation (DAE) perform when used on the Saudi population and how they compare with each other. The two methods are: (1) analysis using The London Atlas of Tooth Development and Eruption; and, (2) Cameriere's Measurements of Open Apices of Mandibular Teeth.

This presentation will impact the forensic science community by providing inter-population evidence to demonstrate the accuracy of two new methods of dental age estimation and highlight the differences in conducting these two methods on Saudi children. This presentation will also enhance understanding of the importance of the assessment of dental development in various dental age estimation methods.

Dental development is frequently used to assess maturity and estimate age. The goal of this study was to test and compare the accuracy of two methods of dental age estimation, Cameriere's formula (measurements of mandibular teeth's open apices) and analysis using The London Atlas of Tooth Development, in Saudi children.

Materials and Methods: The sample consisted of 400 Saudi males and females between the ages of 6 and 15 years. Inclusion criteria were good quality, clear panoramic dental radiographs (Orthopantomographs (OPGs)) of healthy patients with no medical history of systemic diseases/disorders. Exclusion criteria were unclear radiographs, hypodontia (one or more missing teeth), hyperdontia (one or more extra teeth), gross pathology (torodontism, microdontia, amelogenisis imperfecta, dentinogensis imperfecta, tumors, abscesses, fractures, etc.), presence of gross caries, or previous orthodontic treatment. Age estimation was performed using Cameriere's formula (measurements of mandibular teeth's open apices) and The London Atlas of Tooth Development on the left side of the jaw.

Chronological age (real age) was blinded from the researchers until all subjects radiographed were assessed and age estimation was completed. Data were managed and analyzed using the SPSS program (v24). Inter- and intra-examiner reliability tests were calculated on a random 10% sample from the radiographs to determine the kappa statistic.

Results: The intra-examiner reliability test was 0.89 and the inter-examiner reliability test was 0.8, which demonstrates excellent agreement.

Mean difference between Estimated Age (EA) and Real Age (RA) was -0.45 years for The London Atlas with a standard deviation of 1.61 years, and was -0.83 years for Cameriere's formula with a standard deviation of 1.34 years; both methods consistently underestimated actual age. The absolute mean difference was 1.19 years and 1.16 years for The London Atlas and Cameriere's formula, respectively. The mean difference between EA and RA using The London Atlas was -0.61 years for males and 0.23 years for females, with no statistical significant difference between genders. Cameriere's formula gave a mean difference between EA and RA for males of -0.89 years and -0.77 years for females, with no statistically significant difference between genders.

Conclusion: The London Atlas of Tooth Development was easier to use because all teeth in both jaws can be used and the availability of an extra dental development stage resulted in better measures of accuracy on Saudi populations.

Age Estimation, Dental Development, Saudi Arabia

G30 Magnetic Resonance Imaging (MRI) of Third Molars in Forensic Age Estimation: Validation of the Gent and Graz Protocols

Jannick De Tobel, MD, Zomerstraat 12/201, Gent, Oost-Vlaanderen 9000, BELGIUM; Griet I.L. Parmentier, MD, Universiteit Gent, De Pintelaan 185, Gent 9000, BELGIUM; Ines Phlypo, DDS, Universiteit Gent, Vakgroep Tandheelkunde, De Pintelaan 185, Gent 9000, BELGIUM; Benedicte Descamps, PhD, Universiteit Gent, IbiTech-Medisip-Infinity Lab, De Pintelaan 185, Gent 9000, BELGIUM; Sara Neyt, PhD, MOLECUBES NV, MeetDistrict - Ghelamco Arena, Ottergemsesteenweg Zuid 808 bus 325, Gent 9000, BELGIUM; Wim Van De Velde, MD, AZ Sint-Lucas, Groenebriel 1, Gent 9000, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Dendermondsesteenweg 483, Kapucynenvoer 7 Leuven, Sint-Amandsberg, Oost-Vlaanderen B-9040, BELGIUM; and Koenraad L. Verstraete, PhD, Universiteit Gent, Vakgroep Radiologie, De Pintelaan 185, Gent 9000, BELGIUM*

After attending this presentation, attendees will be aware of the strengths and weaknesses of two Siemens Magnetic Resonance Imaging (MRI) protocols for third molars that can be applied for age estimation.

This presentation will impact the forensic science community by providing considerations for the interpretation of two main MRI protocols to examine third molars for age estimation. It will be demonstrated that both approaches have their own characteristics and that research using both should continue. These protocols are a next step toward radiation-free dental age assessments.

Background: Panoramic radiographs are used for age estimation in forensic dentistry; however, they imply an exposure to radiation without a medical indication. Moreover, superposition can lead to misinterpretation of the developmental status of the examined structures. To counter these drawbacks, several research groups are studying the use of MRI in forensic age estimation. Per research, dental age estimation by means of third molar MRI has been studied by three research groups.[1-4] Guo et al. described a protocol for 3 Tesla (3T) MRI with a Philips scanner, while Baumann et al. and De Tobel et al. used a 3T Siemens scanner. MRI sequences of the latter two research groups will respectively be referred to as the Graz protocol and the Gent protocol.

Purpose: To validate the Gent and Graz MRI protocols for third molars by evaluating to which extent staging third molars for age estimation is influenced by: (1) in-plane resolution and slice thickness; and, (2) head fixation using a bite bar.

Materials and Methods: Eleven healthy volunteers (5 females, 6 males, 16-30 years of age) scheduled for surgical removal of third molars were included. *In vivo*, two 3T MRI scan protocols were applied: the Gent protocol with T2 Fast Spin Echo (FSE) and thin slice T2 FSE sequences, and the Graz protocol with T1 3D FSE and 3D Constructive Interference in Steady State (CISS) sequences.[1-3] Although bite bar fixation is inherent to the Gent and not to the Graz protocol, for both protocols scans were obtained with and without bite bar. After surgical removal, 39 third molars were scanned *in vitro* with 7 Tesla µMRI, applying T2 FSE and Zero Echo Time (ZTE) sequences, and scanned with µCT. Three observers evaluated the randomized MRI and µCT images in consensus. Assessability was judged and compared in all applied MRI sequences. Third molar staging was conducted according to the technique by De Tobel et al.[5] Staging outcomes between imaging modalities and between MRI sequences (with and without head fixation) were compared.

Results: The Gent T2 FSE sequence (voxel size 0.33 x 0.33 x 2mm³) with and without bite bar was significantly more assessable (97%=38/39 and 81%=26/32, respectively) than the Graz T1 3D FSE sequence (voxel size 0.59 x 0.59 x 1mm³) with bite bar (80%=28/35; P= 0.02) and without bite bar (59%=19/32; P <0.001). The combination of the voxel size and the inherent high-contrast of µCT rendered the optimal reproduction of the hard tissue specimens. Hence, imaging with µCT was considered as comparison standard to visualize and stage third molars. Allocated stages on MRI were most frequently equal to or higher than those on µCT. The difference between staging based on the Gent and the Graz protocol, using the bite bar, was not statistically significant, and neither was the difference in staging based on MRI with bite bar, compared with the same sequence without bite bar.

Conclusion: Compared with µCT, third molars appeared more developed on MRI. Using a bite bar increased the proportion of assessable third molars. By contrast, it did not influence allocated stages to assessable third molars. The differences in in-plane resolution between Gent and Graz protocols also resulted in differences in assessability rather than differences in allocated stages. Images of the Gent protocol allowed interpretation of the highest proportion of third molars available for age estimation.

Funding: Provided by the department of Radiology and Nuclear Medicine at Ghent University and the American Society of Forensic Odontology (ASFO) Research Grant 2017.

Age Estimation, Magnetic Resonance Imaging, Third Molars

G31 The Use of Magnetic Resonance Imaging (MRI) in Forensic Age Estimation of Living Children, Adolescents, and Subadults: Protocol for a Systematic Review and Preliminary Results

Jannick De Tobel, MD, Zomesrtraat 12/201, Gent, Oost-Vlaanderen 9000, BELGIUM; Griet I.L. Parmentier, MD, Universiteit Gent, De Pintelaan 185, Gent 9000, BELGIUM; Nele S. Pauwels, PhD, Universiteit Gent, KCGG, De Pintelaan 185, Gent 9000, BELGIUM; Koenraad L. Verstraete, PhD, Universiteit Gent, Vakgroep Radiologie, De Pintelaan 185, Gent 9000, BELGIUM; and Patrick W. Thevissen, PhD, KULeuven, Dendermondsesteenweg 483, Kapucynenvoer 7 Leuven, Sint-Amandsberg, Oost-Vlaanderen B-9040, BELGIUM*

After attending this presentation, attendees will understand the need for a systematic review of studies on the use of MRI for age estimation. A protocol for an adequate conduct of the review and its preliminary results will be presented.

This presentation will impact the forensic science community by elaborating on the emerging field of radiation-free age estimation by means of MRI. It will be demonstrated that numerous studies have been conducted, but that an overview is necessary to bring age estimation based on MRI of developing anatomical structures into practice.

Background: Established methods for age estimation mainly use radiographs to register and evaluate teeth, carpal bones, and long bones, which are still developing in children and subadults; however, young individuals especially are highly sensitive to radiation exposure. Moreover, radiographs may be misinterpreted because of superposition. MRI overcomes both of these drawbacks. Therefore, several research groups are studying the use of MRI to register the developmental status of the considered body part. In particular, diverse MRI protocols were established depending on the anatomical structures used for age estimation.

Purpose: To review the use of MRI for forensic age estimation in living children, adolescents, and subadults and to provide data on age distribution of the development of different anatomical structures as registered on MRI. The systematic review aims to comply with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement.[1,2] The review protocol was drafted according to the Cochrane Guidelines for review protocols (http://training.cochrane.org/), and registered in Prospero, the international prospective register of systematic reviews (http://www.crd.york.ac.uk/PROSPERO).[3]

Research Questions: How does the development of different anatomical structures, as registered on MRI, relate to chronological age? What is the performance of age estimation based on development of different anatomical structures as registered on MRI?

Search Methods: The following databases were searched: MEDLINE, Embase, and Web of Science. Additionally, reference lists of included articles and study registers were searched. No restrictions were made based on the country of publication, language, or publication date.

Selection Criteria: Two reviewers independently selected articles based on titles and abstracts. Study populations including living subjects up to 30 years were considered. MRI of any field strength studying the development of anatomical structures related to age were included. Cross-sectional observational studies, pilot studies, cohort observational studies, and case reports were considered. Review articles and pilot studies of included main studies were excluded. After resolving conflicts by discussion, the full text papers were evaluated independently for eligibility. Again, in case of conflicts, a consensus decision was made.

Data Extraction and Analysis: Study characteristics tables and data extraction tables for the included articles were independently developed. A tool for the risk of bias and paper quality assessment was developed, based on the Effective Practice and Organization of Care (EPOC) overview and Quality Assessment of Diagnostic Accuracy Studies (QUADAS) -2.[4,5] Authors were contacted for further details and data if these were unclear, not reported, or in a format unsuitable for the review analysis.

Preliminary results: The search through the databases produced 468 results: MEDLINE (*n*=99), Embase (*n*=192), and Web of Science (*n*=177). Additional records, identified through other sources, provided two results. After deduplication, 259 records were screened based on title and abstract, rendering 60 records to be assessed for eligibility by reading the full-text articles. Finally, 34 studies were included for qualitative synthesis and data extraction.

Age Estimation, Magnetic Resonance Imaging, Subadults

G32 A Senegalese Case Study Illustrating a Determination of Age of the Pupils Without Civil Status or With False Declaration of Age by Means of Their Dental Assessment

Khalifa Dieng, DDS, PO Box 6622 Dakar Etoile, Dakar, SENEGAL*

After attending this presentation, attendees will better understand how dental age estimation may allow pupils to gain civil status when they are without civil status or when there is a false declaration of age by their parents.

This presentation will impact the forensic science community by illustrating how the dental age prediction may help pupils obtain a civil status. Certain children in the population of regions who have left and then moved back to Senegal often do not make the proper and necessary arrangements with the registry to attend school. Their parents sometimes make a false declaration of their age to allow access to the school. The government may request the forensic odontologist to assess their dental age. This presentation will add to research being conducted in age estimation for children using a dental formula when it concerns a large number of individuals.

Materials and Methods: Among the many methods for estimating age, this case study was based on two complementary methods, Schour and Massler, and Ubelaker, both of which use dental development tables, a viewer, and panoramic radiographs. A clinical examination is first performed in order to detect any pathology, parafunction, or treatment likely to alter the results. The government's five-day deadline for these tasks allows one to work quickly and in a simple manner. The two methods combined offer age-estimate ranges of more-or-less than 6 months, and assessments were adapted to each stage of dental development in age groups of 4 to 35 years. Age estimation was conducted by direct reading on the tables. This sample consisted of 102 children, 58 boys and 44 girls.

Results: By analyzing the age reported by parents on the census list, and the age that was estimated, 83 of 102 age declarations were false. This corresponds to an 81% false declaration of age.

Discussions: By comparing the reported age according to the dental formula, this study found a significant number of false declarations for those 5 and 6 years (86% and 92%) of age. This is due to the fact that these two age groups are highly targeted for the chance of being recruited.

False statements exceeded correct statements for all age groups. Among the false declarations, each age group had a given percentage: 3 years – 16% false declaration of age; 3½ years – 21% false declaration of age; 4 years – 12% false declaration of age; 5 years – 18% false declaration of age; 6 years – 19% false declaration of age; and 7 years – 14% false declaration of age.

Conclusion: In developing countries, particularly in Africa, these cases of unregistered children are recurrent and the estimate of their dental age is of great help in resolving this problem. In addition, the need to benefit from false declarations of age, such as for immigration, is a pressing motive to promote this discipline in forensic odontology.

Dental Age Determination, Pupils, False Declaration of Age

G33 Cephalometric Analysis of Historic Native American Arikara

Beverly Hedgepeth, DDS, 353 Buck Lake Road, Cookeville, TN 38506; and Murray K. Marks, PhD, University of Tennessee, Dept of General Dentistry, 1930 Alcoa Highway, Bldg A, Ste 340, Knoxville, TN 37920*

The goal of this presentation is to provide attendees with knowledge of a number of dentoskeletal parameters that can help illustrate the relationship of the maxillae, the mandible, and the maxillary and mandibular dentitions to the facial profile.

This presentation will impact the forensic science community by providing the cephalometric analyses on the adult Native American Arikara, which will provide additional information on facial profiles for this historic Great Plains population.

Profile changes over the sample's 232-year time span, if there were any, can be surmised. The proposition being considered is, will a dentoskeletal relationship change enough in approximately 232 years to affect a facial profile change?

This study was conducted on the cephalograms of a historical adult Native American population. The Arikara remains were from five anthropological excavation sites in South Dakota: Rygh (1600-1650), Mobridge (1600-1700), Sully (1650-1700), Larson (1679-1733), and Leavenworth (1802-1832). The time elapsed was approximately 232 years (1600-1832).

Cephalograms of adult Native American Arikara skulls in the sample were made by the University of Tennessee Department of Oral & Maxillofacial Surgery in Knoxville, TN. Fifty-five of the cephalograms were determined to be acceptable for cephalometric analyses. Five cephalograms were from Rygh, 7 from Mobridge, 5 from Sully, 17 from Larson, and 21 from Leavenworth. These cephalograms were digitized and the Dolphin imaging system was used to perform the analyses. Measurements used were taken from the Steiner analysis and the Tweed analysis, both of which are commonly used in orthodontics. From the Steiner analysis, the SNA, SNB, and interincisal angles were used. From the Tweed analysis, the FMA, FMIA, and IMPA were used (Tweed triangle).

SNA measures the angle made by the intersection of lines drawn from the Sella to Nasion and from Nasion to Point A (subspinale). The mean SNA is 82 degrees, so an SNA greater than that suggests a protrusive maxillae while an SNA less than that suggests a retrusive maxillae. SNB measures the angle made by the intersection of lines drawn from the Sella to Nasion and from Nasion to Point B (supramentale). The mean SNB is 80 degrees, so an SNB greater than that suggests a protrusive mandible and an SNB less than that suggests a retrusive mandible. SNA and SNB, therefore, evaluate skeletal protrusion or retrusion relative to the cranial base. The interincisal angle is the angle formed by the intersection of lines drawn along the long axes of the maxillary and mandibular central incisors. The mean interincisal angle is 130 degrees. An interincisal angle less than that reflects protrusive incisors and an angle greater than that reflects retrusive incisors.

The Tweed triangle consists of FMA (the Frankfort-Mandibular plane Angle – the angle formed when the Frankfort horizontal plane intersects with the mandibular plane), FMIA (the Frankfort-Mandibular Incisal Angle – the angle formed when Frankfort horizontal plane intersects the line bisecting the long axis of the mandibular central incisor), and the IMPA (the Incisor-Mandibular Plane Angle – the angle formed by a line that bisects the long axis of the mandibular central incisor and intersects the mandibular plane).

With these measurements, two types of protrusion/retrusion can be determined: skeletal and dental. As noted above, SNA and SNB measure skeletal protrusion/retrusion relative to cranial base. FMA is a skeletal measurement of vertical dimension. Dental protrusion occurs when FMIA is less than normal (60-70 degrees) and/or the interincisal angle is less than 130 degrees. An IMPA greater than normal (85-95 degrees) indicates a protrusion of the mandibular dentition.

Review of the analyses of the 55 cephalograms confirmed that there was no statistically significant change in any of the values during the 232-year period. Therefore, the facial profiles of the sample population quite probably did not change over the time span.

Native American Arikara, Cephalogram, Dentoskeletal Relationship

G34 Correctional Dentistry and Forensic Odontologists: Bridging the Gap

Lisa M. Hofstad, DMD, 424 N 14th Street, Quincy, FL 32351**

After attending this presentation, attendees will better understand the careers and challenges of the correctional dental team. There will be an analysis of the demands, need for service, and barriers faced.

This presentation will impact the forensic science community by demonstrating how the United States correctional facilities could better utilize forensic odontologists in the interest of justice.

The United States incarcerates nearly 2.5 million inmates each year. With a substantial rise in substance abuse and criminality, the demands placed on correctional dentists is also increasing exponentially. As a practicing healing branch of medicine, the correctional dentist is faced with the legal and ethical responsibility of providing services to the inmate patient population while maintaining an appropriate standard of care; however, these dental teams are often working in extreme and substandard conditions. Dentists are frequently working with antiquated equipment and many institutions have yet to upgrade to digital radiography and electronic record keeping. There is a lack of consistency in security and medical management at different facilities. The dentists are attempting to work and provide treatment while simultaneously maintaining a sense of safety for themselves and support staff. There are limited, if any, studies available and minimal documentation of the harsh and warlike conditions in which dental care is being rendered. The shortage of dentists and security staff, as well as the marked increase in the level of violence within certain facilities, is creating such an environment. The potential ramifications for the dental provider in regard to the continuous and routine accessibility of the inmate to dangerous shanks and illegal substances will be examined. Institutions that incarcerate mentally ill offenders are faced with an entirely unique subset of challenges. This is setting the stage for risk, both professionally and personally, for the correctional dental providers. There are many medical health organizations bidding on contracts for the correctional health services; however, there is minimal input and/or advocacy from outside government agencies for the correctional dentist (Occupational Safety and Health Administration (OSHA); Board of Dentistry).[1-4]

Forensic odontologists are called upon to assist law enforcement. They are rarely utilized in the correctional system where bitemarks routinely occur. Teeth become the common weapon, both by aggressors and as a line of defense. Officers, health care professionals, and inmates are all affected by this form of violence and victimization. There remains a culture of silence behind the walls. There are documented cases of corruption and abuse within the system, but no expression of the impact and the medicolegal risk that is placed upon the correctional dentist. Case and situational examples will be presented for review and discussion. In the local jail setting, there is generally a much more controlled environment. Yet again, there is increasing criminality and high recidivism. The requests for dental care exceed the funding that many institutions have allocated for dental services. Additionally, the offenders who are housed and released from these facilities are often the future accused, victims, and the missing/unidentified.

Attendees will recognize the expanding need for and challenges faced by correctional dentists. There is a missing link between the correctional dentist/system and forensic odontologist. By bridging the gap between the correctional system and the forensic odontologist, the correctional system can be educated to become integrated as part of the forensic team. This information will challenge the attendees to examine the role they may have in creating professional harmony.

Corrections, Dentist, Odontologist

G35 An Evaluation of a Multimedia Training Module and Lab for Teaching Radiographic Technique and Safety When Using Hand-Held Portable Dental X-Ray Equipment in Forensic Odontology

Tara L. Newcomb, MS, Old Dominion University, School of Dental Hygiene, 4608 Hampton Boulevard, Norfolk, VA 23529; and Ann M. Bruhn, MS, Old Dominion University, School of Dental Hygiene, 4608 Hampton Boulevard, Norfolk, VA 23529*

After attending this presentation, attendees will: (1) become familiar with safety protocol when using hand-held portable dental X-ray equipment and radiographic techniques for minimizing errors requiring retake images in the categories of placement, angulation, exposure, and other errors; and, (2) be able to develop teaching strategies to train others for the safe and effective use of hand-held portable dental X-ray equipment in forensic odontology.

This presentation will impact the forensic science community by providing information that can be used for understanding and teaching safe and effective use of hand-held portable dental X-ray equipment in forensic odontology.

Hand-held portable X-ray devices are increasingly used in dental and forensic practice. This development introduces new challenges to radiographers for which original safety and technique evaluations must be made and implemented prior to use.[1] Forensic experts were first introduced to hand-held portable X-ray devices in Thailand following the 2004 Asian Tsunami; these devices proved to be essential to dental identification efforts, particularly in mass fatality events.[2] Currently, there is limited research on teaching safe and effective usage of hand-held portable X-ray devices in forensic odontology. Major issues for safe usage and effective radiographic technique have been outlined in the literature as: difficulties in using aiming devices in conjunction with hand-held portable X-ray equipment, radiographic and angulation techniques for minimizing errors requiring retake images, using infection control and Personal Protection Equipment (PPE), and safeguarding of the operator and persons involved in assisting. These problems could result in safety and manufacturer guideline infractions, as well as deviations from the As Low As Reasonably Achievable (ALARA) principles, when compared with other available intraoral X-ray devices, for example, wall-mount units.[3] Teaching and training with multimedia and using computers to present subject matter with sound, graphics, and video have been used in developing forensic training in dental and dental hygiene curricula.[4-5] Multimedia is specifically recommended in forensic training because it is "interactive" and provides an "active learning" experience.[6-7] Multimedia is used across disciplines because it has been found to support the way the human brain learns.[6-7]

For this study, researchers will use a multimedia module with video demonstrations to teach radiographic technique and safety when using hand-held portable X-ray equipment. This module will be made available via a Blackboard University learning system. Forty junior dental hygiene students (participants) enrolled in an Oral Radiology I course will be recruited for the study; researchers will submit applications for Institutional Review Board (IRB) approval. Participants will be required to view the multimedia demonstration video prior to completion of a radiology lab where in-person demonstrations will occur. Participants will take identical sets of X-rays using both a portable hand-held X-ray unit and a wall-mounted X-ray unit. Real human skulls and a standard image receptor holding device will be used to test radiographic technique between the two types of equipment (portable hand-held X-ray device versus a wall-mounted X-ray unit). Participants (N=40) will expose six X-rays per type of equipment for a total of 480 X-rays to be scored in these four radiographic technique subcategories: placement, angulation, exposure, and miscellaneous or other errors. Analysis of Variance (ANOVA) will be used to compare the sum of the errors for each device (portable hand-held device versus a wall-mounted unit). T-test analysis will be used to determine significant differences between the subcategories of each error category. Safety will be measured by a 12-question post-test related to infection control and PPE, ALARA guidelines, and safeguarding of the operator and persons involved in assisting when using portable hand-held X-ray devices. Scores will be presented as grade percentages.

It is hypothesized that a significant difference will be found at the .05 level between the two types of equipment used for radiation exposure (portable hand-held X-ray unit versus a wall-mounted unit), with the portable hand-held X-ray device unit having the least amount of total errors and higher scores on the safety post-test.

This research could impact the forensic science community by providing data on comparing safety and technique exposure from traditional wall-mounted X-ray units to the use of hand-held X-ray devices and as a way to address common radiographic technique errors specific to forensic odontology.

Education, Radiation Safety, Radiation Technique

G36 The Integration of Forensic Dentistry/Catastrophe Preparedness Course Into a Dental Hygiene Bachelor of Science Program Using the American Board of Forensic Odontology (ABFO) Curriculum Guidelines: A 12-Year Study

Winnie Furnari, MS, 82 Onondaga Street, Yonkers, NY 10704*

After attending this presentation, attendees will recognize the value of incorporating forensic classes in pre-licensure dental and dental hygiene curriculum. This presentation will explain the contents for the implementation of the scope of the course, interpret the data as a favorable indication for incorporation in education, and describe the survey results from professionals who have completed the courses.

This presentation will impact the forensic science community by demonstrating the value of the incorporation of the ABFO Guidelines on Forensic Odontology into dental and dental hygiene programs. Attendees will come to value the incorporation of the Catastrophe Preparedness curriculum in course offerings and appreciate the effects these courses have on future interest and participation by dentists and dental hygienists.

A Forensic Odontology/Catastrophe Preparedness course is uncommon in dental and dental hygiene program curricula. The addition of these types of courses has the potential to raise professional awareness and effect future participation in forensic dentistry for new dental professionals and the discipline as a whole. Core Content of Forensic Odontology courses are in place and published by the ABFO. Using these as a guideline, a Forensic Dentistry/Catastrophe Preparedness course is offered at New York University College of Dentistry. This study cumulates 12 years of surveys taken by dental hygiene students upon completion of the Forensic Dentistry/Catastrophe Preparedness from the years 2005 to 2016. Surveys were completed by 85 dental hygiene students who completed the course. It sought to measure students' perceptions of gaining advanced knowledge in core content recommended by the ABFO and courses offered by the National Center for Disaster Preparedness housed at Columbia University in New York for the preparedness modules. The Catastrophe Preparedness Modules are based on the center's competencies and are designed to gain core knowledge for preparedness and response for disasters at work, at home, and in the community.

The survey consisted of 18 questions with multiple-choice answers. A total of 85 students completed the surveys, which represents 100% participation. All of the students willingly participated each year. There were no identifiers nor compensation for participation or consequences for refusal to participate. The survey asked questions concerning gaining knowledge from each of the modules. The survey also sought to relate the reasons for students taking the course and if it affected their future plans to seek further education and participation in forensic dentistry and catastrophe preparedness.

A descriptive analysis was completed and the surveys indicate significant acceptance and satisfaction with the course objectives, content, and experiences. Fifty-nine percent of the students stated they are interested in furthering this type of education. Fifty-two percent stated they planned to join a forensic team and 35 percent stated they plan to join a reserve corps for preparedness and response. Ninety-five percent stated they were prepared in the event of a bioterrorism episode. This study found that students are accepting in expanding their knowledge and experience in this field of study.

From this study, it is clear that the published guidelines for core content for both forensic odontology and catastrophe preparedness in these courses should be a model for the educational experiences and that these educational experiences should be incorporated as essential information for future dental professionals. The results also support the interest and potential for future involvement in the science by students who completed the course. The forensic community will come to value the incorporation of ABFO guidelines on forensic odontology into dental and dental hygiene programs and the effects these courses have on future interest and participation. The incorporation of Forensic Dentistry/Catastrophe Preparedness courses in dental and dental hygiene curricula should become more widespread.

Forensic Dentistry, Dental Hygiene Curriculum, Catastrophe Preparedness

G37 Differential Identification of Three Young House Fire Victims: Methods When Statistics Fail

John B. Nase, DDS, Dental Forensic Services of Indian Valley, 404 Main Street, Harleysville, PA 19438*

After attending this presentation, attendees will be able to recognize how differential analysis of tooth maturity scores in dental age assessment can be used to graphically distinguish between child victims who are statistically the same age. Attendees will also be able to appreciate how radiographic and clinical presentation in childhood identical twins can elicit genetic versus acquired similarities and differences and can be used for exclusion of other victims.

This presentation will impact the forensic science community by discussing how forensic odontology provided a method to aid in the identification of three children, 4.4-year-old identical twins and a third unrelated 4.1-year-old child.

In July 2014, a fire consumed an urban row home in Philadelphia, PA. Four children perished in the fire. One of the victims was an infant and was identified by exclusion.

The medical examiner requested that odontology be employed to compare age estimations and dental uniqueness for the three remaining victims in order to corroborate the correct identity of each. This analysis was aided by the fact that two of the victims were presumed to be female identical twins with a birth date of January 25, 2010 (4 years, 5 months of age at death). For reference, they were designated as "Child A" and "Child B" in this study. The third child was male and had a birth date of May 24, 2010 (4 years, 1 month of age at death) and was designated as "Child C." All three victims presumably had never had professional dental care, so antemortem/postmortem comparisons were not possible.

All three were badly charred, with intact craniofacial structures. Soft tissue resection was accomplished. A full series of radiographs, as well as photographic images, were made on each case.

In comparison of the radiographs obtained to a published graphical standard of dental development, the average maturation of tooth buds, calcification of tooth structure, and eruption pattern indicated an age estimation of 4.5 years (±.58 year) for "Child A" and "Child B".[1] According to the same standard, "Child C" presented with a slightly different estimation of 4.0 years (±.52 year). These estimates via this atlas method were therefore not significantly different from each other.

Staging analysis was then performed on the three sets of radiographs, utilizing 14 permanent teeth, utilizing the unknown sex data set described by Moorees et. al.[2] As expected, the mean average dental ages of the three victims were also not statistically different at 95% confidence; however, a box plot of the 14 individual maturity scores clearly showed the difference between the two identical twins and the third unrelated child. "Child A" and "Child B" shared a strikingly similar growth pattern in their dentition as seen on the radiographs. Both cases exhibit a permanent dentition with the same stage of growth on each tooth, with one exception (tooth #19). Of particular interest is the same delayed calcification of the lower second bicuspids, as compared to the advanced maturation stage of the permanent lower first molars. Based on this analysis, it was determined that "Child C" was, in fact, the non-twin victim and thus positively identified through exclusion.

Mostly due to the lack of antemortem evidence, positive identification between the two twins was not possible; however, it is of academic interest that there existed distinct acquired and developmental differences between them. Both twins exhibited evidence of a finger-sucking or pacifier habit with pre-maxillary protrusion, palatal constriction, and anterior open bite; however, the altered growth was more pronounced in "Child A" with an 8mm anterior open bite versus "Child B" with only a 5mm anterior open bite. Also, "Child A" had an erupted #19 clinically and "Child B" did not. Further, "Child A" presented with slightly advanced eruption of #25 compared to #24, whereas this was reversed in "Child B." Lastly, "Child B" exhibited decay on two primary teeth whereas "Child A' appeared caries-free.

In conclusion, this case demonstrated that individual tooth staging can be useful when the difference in average mean dental age of victims who are close in actual age is not statistically significant. Further, it was shown that even identical twins can have definable differences in dental appearance.

Maturity Score, Dental Staging, Twins

G38 Dental Forensic Identification Information: How to "Get" What We Require

Walter F. Zoller, DMD, 796 Florencia Circle, Titusville, FL 32780; and Jan Westberry, DMD*, 2234 State Road 44, New Smyrna Beach, FL 32168*

After attending this presentation, attendees will have had a thorough review and new information concerning: (1) the challenges and obstacles presented to the forensic odontologist in obtaining requested information from medical examiner investigators, as well as the victim's family dentist; (2) how to recognize and evaluate inaccurate and improper data submissions from the medical examiner investigator and/or the victim's dentist; (3) protocol for improving communications between the victim's dental office and the forensic investigator (this protocol will benefit in circumventing dental office objections and assist those requesting the information to receive the data required, accurate, and in the proper format to achieve the desired identification); and, (4) protocol for improving communications between the medical examiner forensic investigator and the inquiring forensic dentist. A newly designed informational worksheet will assist the medical examiner forensic investigator when interacting with the victim's dental office and handling objections, thus receiving the correct data for presentation to the forensic dental investigator.

This presentation will impact the forensic science community by enabling the forensic dentist, through organized interaction systems with the dental office and medical examiner investigator, to acquire precise and accurate victim data to achieve correct and timely victim identification.

One of the most frustrating things for investigating odontologists is not receiving the requested information that is necessary to perform investigations efficiently and correctly. Information that is received is often inaccurate, incomplete, non-legible, or labeled incorrectly. The many forms of inaccurate submissions making evaluation difficult will be identified and discussed. Revelations with respect to the Health Insurance Portability and Accountability Act (HIPAA) objections will be presented as well.

Victims' dental offices and even many medical examiner investigators are unfamiliar with how to present and format information that the forensic dentist requires. Dental offices and medical investigators do not understand how to digitize radiographs and paper records for presentation. Four to five cases will be presented demonstrating illegible records, mislabeled records, confusion as to what records were submitted vs. what were requested, and HIPAA objections. Specific repeated areas of difficulties will be identified.

This will be followed by: (1) HIPAA objections and solutions; (2) techniques to discuss with the victim's dental office as well as the medical examiner investigator regarding how to digitize records for proper presentation and evaluation; and, (3) a worksheet designed for the medical examiner investigator to standardize what to request and how to request it.

The goal of this presentation is to assist and upgrade communication between the investigating forensic dentist, the medical investigator, and the victim's dentist. Thus, information transfer will be what the forensic dentist requires. This will avoid the difficulty of back-and-forth requests between parties and the waste precious time … time that will delay the goal of the investigating forensic dentist for successful completion of the identification process.

Dental Identification, Medical Examiner, HIPAA

G39 Postmortem Human Identification Challenges Regarding Domestic Disappearance and the Health Insurance Portability and Accountability Act (HIPAA)

Iris L. Shields, DDS, 615 W Mac Phail Road, Ste 208, Bel Air, MD 21014*

The goals of this presentation are to: (1) identify and discuss the importance of the HIPAA Exception Law; (2) summarize the importance of forensic odontology in the postmortem identification process of partnering in an ongoing police investigation; (3) apply a better understanding of HIPAA Exception Law to specific situations involving domestic disappearance and law enforcement investigations; and, (4) examine the challenges of requesting antemortem dental records from health care providers and public/private insurance companies.

This presentation will impact the forensic science community by exploring how the postmortem identification process is delayed and confounded when requests for dental records go unfulfilled or the dental records are reportedly not available due to failure to understand HIPAA Exception Law.

The identification of missing or unknown persons is the most common role of the forensic odontologist.[1] Postmortem dental remains can be compared with antemortem dental records, including written notes, study casts, and radiographs, to confirm identity.[2] Individuals with numerous and complex dental treatments are often easier to identify than those individuals with little or no restorative treatment.

The HIPAA of 1996 established the privacy rule standards that address the use and disclosure of individuals' health information by organizations. The privacy rule applies to health plans, health care clearinghouses, and to any health care provider who transmits health information in electronic form.[3] Within HIPAA is exception law. It permits, but does not require, the covered entity or health care provider to use and disclose protected health information, without an individual's authorization, for the following purposes or situations: (1) to the individual (unless required for access or accounting of disclosures); (2) treatment, payment, and health care operations; (3) opportunity to agree or object; (4) incident to an otherwise permitted use and disclosure; (5) public interest and benefit activities; and, (6) limited data set for the purposes of research, public health, or health care operations.[3]

A major goal of the privacy rule is to assure that individuals' health information is properly protected while allowing the flow of health information needed to provide and promote high-quality health care and to protect the public's health and well-being. The privacy rule permits use and disclosure of protected health information, without an individual's authorization or permission for law enforcement purposes and decedents.[3] Covered entities may disclose protected health information to law enforcement officials for purposes that include, but are not limited to: (1) as required by law (including court orders, court-ordered warrants, subpoenas) and administrative requests; (2) to identify or locate a missing person; and, (3) in response to a law enforcement official's request for information about a victim or suspected victim of a crime.[3] In addition, covered entities may disclose protected health information to coroners or medical examiners to identify a deceased person, determine the cause of death, and perform other functions authorized by law. The dental identification process must be carefully undertaken and relies on the comparison of information from the antemortem record with findings from the postmortem examination, and the efficiency of this process is dependent on the quality and availability of the dental record.[1]

This presentation will explore how the postmortem identification process is delayed and confounded when requests for dental records go unfulfilled or the dental records are reportedly not available due to failure to understand HIPAA Exception Law.

HIPAA, Forensic Odontology, Domestic Disappearance

G40 Use of the Radiographic Positioning Device Holder in the Postmortem Dental Examination

Judy Y. Marshall, DMD, Marshall Family Dentistry, 3443 Tamiami, Ste F, Port Charlotte, FL 33952; and Luke Stanton Marshall, BS, 4080 Lea Marie Island Drive, Port Charlotte, FL 33952*

After attending this presentation, attendees will better understand why it is practical and desirable to implement the use of the radiographic positioning device holder in the postmortem forensic dental examination.

This presentation will impact the forensic science community by introducing the radiographic positioning device holder and demonstrating the advantages of using the holder during the postmortem dental examination.

In the past, traditional dental intraoral radiographic positioning devices have not routinely been used in the postmortem dental examination. Typical postmortem dental X-ray positioning devices have included items such as gauze, wet paper towels, putty, wax, surgical towels, and hemostats. Radiographic positioning devices that are currently manufactured for antemortem dental radiography have not transitioned into widespread use in the postmortem dental setting because these devices are designed to be held in place by the patient, who either bites on the device or holds the device by hand.

With the development of the radiographic positioning device holder, X-ray positioning devices that are currently manufactured for antemortem bite-wing and periapical dental radiography can easily be utilized during postmortem dental radiography. The holder is practical because it accommodates both traditional film and digital sensor positioning devices. The holder can also accommodate radiographic positioning devices that are designed for use with the paralleling technique or the bisecting angle technique.

When antemortem radiographs are available during the postmortem dental radiographic examination, it is desirable to take the postmortem radiographs from an angle that most closely replicates the antemortem radiograph. When utilizing the holder during digital radiography, the holder retains the position of the sensor while the image is viewed. From this fixed point of reference, any necessary angular adjustments can be made so the postmortem radiograph most accurately replicates the antemortem radiograph.

Use of the radiographic positioning device is desirable because it potentiates adherence to the As Low As Reasonably Achievable (ALARA) radiation safety principle. While the ALARA principle ceases to be relevant to the decedent, it remains a radiation safety principle that is applicable to dental radiographers in the postmortem setting.

The radiographic positioning device holder can be useful during the postmortem dental examination for purposes other than radiography. The holder can accommodate a scale or an identification label during postmortem photography. The holder can also function as a backdrop stand.

In conclusion, this presentation demonstrates that use of the radiographic positioning device holder is practical and desirable in the postmortem dental examination. The holder facilitates the adaptation of traditional dental positioning devices for use during postmortem dental radiography while facilitating adherence to the ALARA principle. The holder is also useful during postmortem photography.

Postmortem, Dental, Holder

G41 Identification of a Child Using Comparative Overlays of Primary and Permanent Dentition

Grace Chung, DDS, Clark County Office of Coroner/Medical Examiner, 1704 Pinto Lane, Las Vegas, NV 89106*

The goal of this presentation is to highlight the challenges facing forensic odontologists when making a dental identification of children and young adults. In the events surrounding this case, the Antemortem (AM) radiographs and Postmortem (PM) radiographs displayed very little similarity in that one had mostly primary dentition and the other permanent dentition. This presentation will provide the odontology community with the following objectives: (1) methods of overlaying images to compare developing permanent teeth to erupted teeth radiographically; (2) understanding the importance of collaboration with a team of dentists when a positive identification is not obvious; (3) using age estimation methods as well as comparative analysis to collect several areas of concordance to have a positive identification; and, (4) the protocol for child abuse management within one's community.

This presentation will impact the forensic science community by informing attendees that dental identifications can be made using somewhat non-traditional methods that are quick and effective. This will also bring community awareness regarding the potential shortfalls of an agency such as Child Protective Services and/or school districts to properly report and handle child abuse cases.

Among the various methods used to identify an unknown decedent, identification using dental data is typically quick and definitive; however, in rare instances, traditional methods for dental identification (comparing missing/existing teeth and dental restorations) cannot be utilized easily due to AM radiographs preceding PM radiographs by a long interval of time when a child is undergoing physiological changes of growth.

On April 25, 2017, two men discovered the skeletal remains of an adolescent child in an east valley desert lot in Las Vegas, NV.[1] The body was confirmed by the Clark County Coroner's Office as a young adult, and the coroner called upon the team's forensic odontology section to begin dental charting right away. At the same time, the investigative team acquired the dental records of a boy who went missing from his home in late January 2017. The family and medical examiners were eager to see if this was a match — as always, unknown children's cases are expedited and processed with urgency. The AM radiographs revealed a young child in mixed dentition with only permanent first molars and lower four incisors erupted with all roots still developing. The PM radiographs of the adolescent decedent were all of permanent dentition, and neither set of radiographs nor the clinical evaluation of the remains revealed any evidence of restorations.

This posed a challenge for the odontologists, and initially it was believed that a conclusive finding could not be made; however, upon further investigation and collaboration with one another, they were able to use the Mideo Systems software overlay system to compare several structures of the permanent dentition on the AM radiographs. Also, they overlaid the developing permanent teeth (still in the follicles during development) in the AM radiographs onto the PM radiographs and were able to find consistent anatomical structures in the overlays. By having several areas of concordance, the odontology team was able to make a positive ID quickly. Sadly, the findings of the rest of the investigation were not as celebratory.

It was discovered that this 13-year-old boy's killer was none other than his father. Due to the ability to make a quick ID, law enforcement was able to make the arrest in a timely fashion and bring the suspect to justice. As the story unfolded, it was discovered that this boy was no stranger to Child Protective Services, as he was taken and given back several times in his young life. This case is not only a story of identification using somewhat non-traditional methods, but it is a case of neglect from his family, his school system, and the state agency.

Abuse, Child, Primary

G42 Back to Nice — July 2016: The Dental Identification Team's Role in the Disaster Victim Identification (DVI) Mission of the Terrorist Truck Attack in France

Steve Toupenay, DDS, Institut médico-légal, 2 place, Paris 75012, FRANCE; Aïda Bencheikh, DDS*, 35 rue Albert Thuret, Chevilly Larue, Île de france , FRANCE; and Lise Malfroy Camine, DDS*, 33, av des Sports, Jujurieux 01640, FRANCE*

After attending this presentation, attendees will better understand how the French Forensic Team identified the victims killed by the terrorist truck attack on July 14, 2016, in Nice, France, and what outcomes were found in terms of forensic odontology.

This presentation will impact the forensic science community by demonstrating the method used and the new organizational procedures conducted over three days to identify the 86 victims of 16 different nationalities on a public holiday in Nice, France.

On the evening of July 14, 2016, a 19-ton truck smashed into a packed crowd of people gathered to celebrate Bastille Day on the Promenade des Anglais, the famous seaside walk in the French Riviera city of Nice, France. This attack was claimed by ISIS. In this case, the terrorist killed 83 people and injured more than 400 people before being shot dead by the police. After a few days, three more victims died of their wounds. In this terrorist attack, a total of 86 victims were killed, including 17 children and 24 foreign victims of 16 different nationalities.

Emergency measures were immediately instituted, employing two separate protocols: the first was dedicated to the identification process with a Disaster Victim Identification (DVI) procedure, while the second was focused on the autopsy. A well-staffed forensic odontology team was immediately set up, including ten French odontologists from all over the country. For three days, the odontologists worked non-stop, with two teams working in parallel.

The dental Antemortem (AM) team worked within the global AM cell, in close collaboration with the French Forensic Police, the National Gendarmerie within the Unité Nationale d'Identification des Victimes de Catastrophe (UNIVC), the International Criminal Police Organization (INTERPOL), and other independent forensic experts. These teams collected antemortem data of missing people in a facility located in the city center of Nice, accommodating an exceptional venue to investigate, interview, and support the victims' families.

The dental postmortem team worked non-stop in the Forensic Institute of Nice in pairs examining decedents to improve the accuracy of the records and reduce the risk of error due to operator fatigue. This team also examined the unconscious and unknown victims' dentition in the intensive care department of Nice hospital.

Both antemortem and postmortem teams used INTERPOL forms to record data. The two teams worked together to compare and establish the identification of victims based on the dental records of missing people and unknown deceased victims.

Every day, one to two identification commissions, including forensic experts, were organized as new matches were found. Among these experts, one dentist was present in each commission to submit the dental findings. A total of six commissions took place, allowing the identification of all dead and unconscious victims.

The excellent outcomes found during the identification of the victims in Nice reflected the efficient collaboration between the different sections of the DVI unit and the forensic odontology team. The dental identification process played an important role in this organization.

The method and outcomes of this identification process will be explained in this presentation. The difficulties and means implemented to counteract these problems will also be highlighted.

Disaster Victim Identification, Terrorist Attack, Forensic Odontology

G43 The Accuracy of Dental Identification of Adults With Unrestored Teeth by Visual Comparison With Radiographs of Mixed Dentition

Ludovica Gorza, via Jacopo Sannazzaro 2 bis, Padova 35125, ITALY; and Scheila Manica, University of Dundee, Dundee, UNITED KINGDOM*

After attending this presentation, attendees will better understand the forensic identification process by dental means. Attendees will learn that in a case of unrestored dentition with a long time lapse between Antemortem (AM) and Postmortem (PM) data, visual comparison of dental radiographs is an adequate method.

This presentation will impact the forensic science community by confirming the value of dental radiographs in identification, which should not be restricted to the analysis of the dentition only. On the contrary, all visible cranio-facial structures and bone characteristics surrounding the teeth should be attentively compared.

Nineteen examiners from the United Kingdom, Canada, the United States, Australia, Brazil, Italy, Iceland, Mauritius, and Mexico (15 forensic dentists and 4 forensic anthropologists) participated in a web-based questionnaire to assess identification in 12 cases; each case required the radiographic comparison of one dental PM panoramic radiograph to three dental AM panoramic radiographs belonging to three different individuals, of which only one was the correct match. The examiners were given four options following the American Board of Forensic Odontology (ABFO) guidelines: established identification, possible identification, insufficient data, or exclusion; the observers also explained the reason for each of their conclusions. The radiographic samples were provided by Italian private clinics; the time lapse between the correct AM and PM radiographs varied from 3 to 18 years.

The total of 684 answers were analyzed. The sensitivity of the methodology was 53.5%, the specificity was 86.4%, and the accuracy was 75.4%. This suggested that excluding the incorrect individuals was easier than matching the correct radiographs; however, achieving a positive identification more than 50% of the time should be considered a satisfactory result, considering that only half the panoramic was compared and no background of the subjects was provided. Examiners with sensitivity higher than 80% primarily compared dental anatomy, particularly root and crown morphology, and primarily analyzed incisors and first molars; approximately 41% of the answers also quoted the maxillary sinus morphology or other bone characteristics, such as trabeculation and mental foramen. Anatomy and development of third molars represented an important misleading feature for identification, which was chosen by most examiners with sensitivity lower than 80%; additionally, the comparison of non-dental features dropped significantly.

Dental identification is not an easy task and hasty conclusions may have catastrophic consequences, such as the exclusion of the correct individual and the misidentification of the wrong person. Even in cases with a long interval between AM and PM radiographs and unrestored dentitions, the meticulous attention to anatomical features helped reaching a conclusion. A constant examination of non-dental features would have probably reduced the error rate. This process requires time, knowledge of anatomy, embryology, and development and aging modifications, not only of the dentition, but of all cranio-facial structures; the accuracy of assessment could be improved by specific training.

Radiographs, Identification, Unrestored Dentition

G44 Active Participation of the United Arab Emirates' Disaster Victim Identification Team Using Dental Identification

Salem Altalie, Abu Dhabi Police GHQ, Forensic Evidence Dept, Medical Examiner Office, Abu Dhabi, UNITED ARAB EMIRATES; Sakher J. AlQahtani, PhD, College of Dentistry, King Saud University, Riyadh 11545, SAUDI ARABIA; and Patrick W. Thevissen, PhD, KULeuven, Dendermondsesteenweg 483, Kapucynenvoer 7 Leuven, Sint-Amandsberg, Oost-Vlaanderen B-9040, BELGIUM*

After attending this presentation, attendees will be informed regarding the active participation of United Arab Emirates' (UAE) Disaster Victim Identification (DVI) Team in dental identification of the Air Asia QZ8501 airplane crash victims in Indonesia.

This presentation will impact the forensic science community by demonstrating the international contribution of the UAE DVI Team in general, and forensic dentists in particular, under the International Criminal Police Organization (INTERPOL) umbrella.

Human dental identification plays a key role in DVI because it is considered a prime identifier. It is used as a single identification procedure (using WinID™ version 3) or integrated in multidisciplinary procedures (DVI System International version 5); however, Deoxyribonucleic Acid (DNA) and fingerprint analyses are also identifying techniques well practiced in the UAE.

Although a global increase of unexpected large-scale accidents such as transport crashes, war explosions, and terrorist attacks cause an increasing number of unidentified or/and missing persons, only a few situations mandated a forensic odontologist involvement in the UAE.

A major disaster occurred in 1983 in the desert of Abu Dhabi. A Boeing® 737-2P6 from Gulf Air crashed and 112 victims were found. The 26 children among the victims were investigated by dental experts from the United Kingdom. One of the main obstacles that prevented confirmation of the identity of all victims was the lack of antemortem dental data from passengers with an Indian and Pakistani nationality.

In 2004, a Kish Fokker 50 airplane crashed in Sharjah, resulting in 45 victims. Dentists from the Dubai Health Authority were assigned to conduct the dental identification without previous related knowledge, training, or preparedness. It resulted in confusion and delayed identification.

Both of these aforementioned disaster identification interventions highlighted the need to establish a well-prepared UAE human identification team. In 2010, the UAE DVI team was established. The official certificate accession of the UAE as a member of the Steering Group of INTERPOL for DVI was obtained in 2011. The UAE became the first Arabic country member of the International Organization for Forensic Odonto-Stomatology (IOFOS) in 2011. Since 2014, the UAE has had a forensic odontological participant in the Scientific Working Group on Quality Assurance in the INTERPOL Forensic Odontology Section, contributing to updating the INTERPOL dental forms.

In 2015, the first active participation of the UAE DVI with the specific involvement of forensic odontologists was required for the Air Asia QZ8501 airplane crash in Indonesia. Eight forensic odontologists from six countries participated in the identification of 162 victims. Forty-two percent of the victims were identified based on dental methods and 37% with combined techniques. UAE had no countrymen victims in the air crash, but UAE forensic dentists had the ethical obligation to share their scientific approach for identification after the request of the Indonesian DVI team.

Forensic Odontology, Disaster Victim Identification, Human Dental Identification

G45 A Study of Morphological Patterns of Lip Prints in Relation to Gender and Blood Groups Among the Egyptian Population

Dina A. Shokry, MD, Kasr Alaini, Cairo 00202, EGYPT*

After attending this presentation, attendees will understand the study of the distribution of different lip print patterns among large Egyptian samples in Greater Cairo to ascertain whether there was a correlation between lip print characteristics, blood groups, and gender of the studied population.

This presentation will impact the forensic science community by explaining how lip print patterns assisted in the identification of Egyptians.

Background: Dental, fingerprint, and DNA comparisons are considered the most common techniques to obtain fast and secure personal identification. The public awareness of fingerprints is very high so there are usually deliberate attempts to not leave fingerprints at a crime scene. For this reason, among others, there is still an increasing need for reliable alternative methods of establishing identity. The lip-print study (cheiloscopy) is considered a new tool for human identification in both civil and criminal issues.

Objective: The present work was conducted to study the distribution of different lip print patterns among a large Egyptian sample in Greater Cairo and to ascertain whether there was a correlation between lip print characteristics, blood groups, and gender of the studied population.

Methodology: This study included a total of 1,000 subjects, including 640 females and 360 males ranging in age from 12 to 75 years, with 15 sets of identical twins, and 34 families of Egyptian residents in the Greater Cairo area.

Method of Lip Print Recording: Red or brown, non-glossy, non-persistent, non-metallic lipstick was used to obtain clear lip prints. White paper (white A4 ROCO Premium 80g copy paper) and tissue paper (Kleenex®) were used to obtain the impressions as per Aggrawal.[1] Blood groups were recorded from subjects who were aware of their blood groups.

Analysis of the Lip Print: The lip prints were analyzed based on Renaud's classification.[2]

Results: Throughout the entire study, no identically similar lip print pattern appeared in two subjects; however, many subjects displayed the same groove types in the same areas of the lip, but specificity of the groove pattern was evident in either the site or the direction of branching or reticulation of the groove. The groove type A (complete vertical) was the highest recorded pattern in both males and females (47.9% and 49.7%, respectively), followed by groove type C (complete bifurcation), which represented 43.8% of the Upper Left (UL) area in males and 45.4% of the Lower Right (LR) area in females, while groove type G (reticular type) represented 27.0% and 24.4% of the Upper Middle (UM) area in both males and females, respectively. This was followed by groove type E (complete branched), which constituted 25.0% of the Lower Left (LL) area in males and 16.9% of the Lower Middle (LM) area in females. Groove type D (incomplete bifurcated) represented 15.3% of the Upper Right (UR) area in males and 19.5% of the UL area in females, followed by groove type B (incomplete vertical), which constituted 13.0% and 13.6% in the UR areas in males and females, respectively.

As for the distribution of lip print types in relation to blood groups, the current results revealed that the frequency of lip print type F (incomplete branched), B, and E were the highest detected patterns among individuals with blood group A positive. Distribution of types I (horizontal), H (x-shaped), and G (reticular) were the most frequently recorded patterns among individuals with blood group B positive. Moreover, lip print types I and G were the most frequently detected patterns among individuals with blood group AB positive. Lip prints type J (other forms), H, and G revealed increased expression among individuals with blood group O positive.

Conclusion: This study confirms the uniqueness of lip print patterns for every participant, even twins and family relatives, supporting a role for cheiloscopy in the identification process, both in civil and criminal issues, but also disproves any significant statistical correlation of lip print pattern with gender and ABO blood groups. It is recommended that more studies be conducted on different population groups to analyze these variations and to establish a database to be used as a reference in criminal investigations in addition to the provision of technical and financial support to analyze in-depth the correlation between lip prints and ABO blood groups. Also, a newer computer software technique needs to be developed to assess and accurately detect lip print characteristics.

G46 Collecting Antemortem Dental Data

Gwenola Drogou, DDS, 18 Rue Saint Bieuzy, Ploemeur 56270, FRANCE; Aime Conigliaro, MSc, IRCGN, Caserne Lange, 5 Boulevard de l'Hautil, Pontoise 95300, FRANCE; and Charles E. Georget, PhD, 45 Quai Charles Guinot, Amboise 37400, FRANCE*

After attending this presentation, attendees will better understand the importance of and polymorphism in antemortem dental data.

This presentation will impact the forensic science community by illustrating the different forms antemortem dental data can take, how to collect and transmit this data, what problems may arise in this process, and possible improvements.

Whether in individual or mass casualty cases, the quality of antemortem dental data is crucial for success in the identification process.

The first problem encountered with an unidentified body is learning the deceased's supposed identity; in the case of a mass disaster, making a list of all the presumed deceased persons is crucial. A missing persons' dental records database may exist in certain states, but there is no real uniformity. The problem of identifying migrants, whose purported identity may be falsified and whose actual dental records may be very difficult to obtain, also arises. Over these past few years, and especially in the case of terrorist attacks, social networks have been used to announce calls for help, and missing persons apps for smart phones have been created. In the case of Disaster Victim Identification (DVI), the International Criminal Police Organization's (INTERPOL's) protocol for collecting antemortem dental data is followed. Several questions about this data collection must be detailed: Where? When? By whom? For whom? How? What? The process of collecting these data must be exhaustive and must try to focus on one sole investigator to contact the family of the deceased. Despite our computerized culture, neither national nor international dental databases exist. Collection must be conducted for each victim, in each country, and attempts must be made to contact the dentist(s) involved.

During data collections, forensic dentists have often had to be very resourceful and imaginative in seeking out dental records. It is sometimes difficult to find the victim's dentist, and these tasks often take on the feel of a true investigation with a race against the clock. This may be the case for those victims who have not been to a dentist, those who have moved residences, and those involved in disasters involving entire families — in this case, DNA problems may also arise — or in disaster scenarios, such as Hurricane Katrina in the United States, where many medical records were destroyed. In case the forensic team is unable to find the victim's dentist, then insurance company, health, mutual, or military records may be consulted.

As opposed to postmortem data, which are systematized (e.g., systematic numbering, photographs, radiographs, odontograms), antemortem data take wide and varying forms. Antemortem data may include family testimony, practitioner's testimony, dental records, odontograms, and radiographs of varying forms, as well as personal or professional photographs, casts, quotes, prostheses, implants, surgical material, letters (professional correspondence), and, more rarely, facial reconstruction.

Once these data have been transmitted, a pair of forensic dentists analyze and transcribe the data into an odontogram that is then completed and verified by analyzing radiographs, which are an essential identification element. Practical cases will help to illustrate this data collection process.

Even if the victim's dentist is identified, other problems may arise. Although rare, physicians may refuse to share data; more often, computer system changes or a lack of data backups may impede access to past data. Files may also have been damaged in a fire, flood, or another natural disaster. Computer problems may also make data transmission challenging.

In addition to the technical elements, the psychological aspect of these investigations must not be overlooked. The investigating forensic dentist contacting the victim's dentist may be the first harbinger of bad news. This work is conducted in a group of two within the odontological team, which is itself incorporated into the antemortem team, where sometimes victims' families are received. Communication and support among team members is fundamental, and third-party psychological support may be provided.

In order to improve the quality of future antemortem data, dentists and future dentists must be informed regarding how important it is to safeguard proper records and radiographs. The creation of a national database of missing persons could facilitate comparisons with the data recovered from non-identified bodies. A standardized procedure and an exhaustive investigation must be conducted to allow exchange of information among different countries, transparency, traceability, and quality control. The quality of our work in collecting antemortem dental data is essential to achieve a positive dental identification.

Antemortem Data, Identification, Dental

H1 A Rare Presentation of Alexander Disease

Edana D. Stroberg, DO, Office of the Chief Medical Examiner, 901 N Stonewall Avenue, Oklahoma City, OK 73117; Kenneth D. Hutchins, MD, Miami-Dade County, Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136; and E.O. Lew, MD, Miami-Dade County, Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136-1133*

After attending this presentation, attendees will better understand Alexander disease, a rare leukodystrophy, and its presentation.

This presentation will impact the forensic science community by increasing attendees' understanding of Alexander disease and the importance of a thorough neuropathologic evaluation in cases of anoxic encephalopathy.

Introduction: Alexander disease is an extremely rare, usually progressive and fatal, neurological disorder.[1] Initially, it was detected most often during infancy or early childhood, but as better diagnostic tools have become available, it has been found to occur with similar frequency at all stages of life.[1] Approximately 95% of Alexander disease cases are caused by mutations in a gene named *GFAP* for a structural protein called glial fibrillary acidic protein that is found exclusively in astrocytes in the central nervous system.[1] Alexander disease has been estimated to occur at a frequency of approximately one in one million births.[1] There are three forms of Alexander disease: infantile, juvenile, and adult. Juvenile Alexander disease is characterized by difficulty in talking and swallowing and the inability to cough.[2] There can also be weakness and spasticity of the extremities, particularly the legs.[2] Unlike the infantile form of the disease, mental ability and head size may be normal.[2] Survival can extend several years following the onset of symptoms, with occasional longer survival into middle age.[2] The course of the disease may involve signs of swallowing or speech difficulty, vomiting, ataxia, and/or spasticity and kyphoscoliosis can occur.[2] The most striking neuropathological feature is the diffuse presence of eosinophilic fibrinoid bodies in the cytoplasm of fibrillary astrocytes.

Material and Methods: The decedent was a 14-year-old girl with a history of narcolepsy, sleep apnea, and scoliosis. Eighteen months prior to her death, the decedent and several others were playing in a backyard pool. When the decedent did not resurface, one of the children notified the supervising adult, who pulled her out of the pool. She was transported to a local hospital and recovered; however, she began to display signs of global developmental delay with onset of impulse control issues, anxiety, depression, self-mutilating behaviors, dysphagia with bouts of aspiration pneumonia, and ataxia. Two weeks prior to her death, she was hospitalized for self-mutilation and her condition progressed to her refusing to eat, talk, or get out of bed. She was also found to be bradycardic and hypothermic. She became unresponsive and was found to have worsening cerebral edema with cerebellar tonsillar herniation.

Results: At autopsy, she was found to have cerebral edema and scoliosis of the thoracic spine. Neuropathologic consultation revealed a non-perfused, respirator-type, macerated brain and spinal cord with diffuse collections of eosinophilic fibrinoid bodies (Rosenthal fibers) in all sections.

Conclusion: The decedent experienced a near-drowning episode and was diagnosed with anoxic encephalopathy when she was 12 years old. Afterward, she experienced a myriad of psychiatric and neurologic issues that were determined to be sequelae of anoxic encephalopathy. A Magnetic Resonance Imaging (MRI) of her brain revealed atrophy of the cervical spinal cord and periventricular white matter changes, which can be seen in both Alexander disease and anoxic encephalopathy. She became unresponsive in the hospital and care was withdrawn after the girl had been on a respirator for multiple days. At autopsy, she had a non-perfused, macerated brain and spinal cord, which is a known complication of being on a respirator. Her brain and spinal cord were submitted for neuropathologic evaluation, which revealed Alexander disease. The decedent experienced onset of the disease at approximately 12 years of age, which unfortunately coincided with a near-drowning event with resultant anoxic encephalopathy, thus confounding her clinical course. This case highlights the importance of performing a thorough neuropathologic evaluation when necessary, even when it is presumed to be of little informative value because of autolytic changes in the brain.

H2 Adrenal Gland Changes in Relation to the Cause of Death

Cristina Mondello, MD, Department BIOMORF, University of Messina, via Consolare Valeria, 1, Messina 98123, ITALY; Elvira Ventura Spagnolo, MD*, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Letteria Minutoli, MD, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY; Domenico Puzzolo, MD, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY; Vincenzo Macaione, MD, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY; Consuelo Malta, BS, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY; Mariagrazia Rinaldi, BS, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY; and Antonio Micali, MD, University of Messina, Via Consolare Valeria, 1, Messina 98125, ITALY*

After attending this presentation, attendees will understand the importance of improving knowledge regarding adrenal gland involvement in response to stress related to the death process and their changes in relation to cause of death.

This presentation will impact the forensic science community by highlighting: (1) whether the adrenal gland is undergoing structural and/or molecular changes in relation to different causes of death; (2) if these changes have significant differences; and, (3) if it is possible to create a timeline of the death process resulting in more or less prolonged pain.

The adrenal response to stress occurs in a syndrome that reflects activation of the sympathoadrenal system and the Hypothalamic-Pituitary-Adrenocortical (HPA) axis, and a "stress syndrome" maintains homeostasis in emergencies, such as "fight or flight" situations. One of the principal tissues involved in the stress response is the adrenal gland; in fact, there is clear evidence of fasciculata activation with the release of cortisol and the release of adrenaline from the medulla.

The literature suggests that the biochemical analyses of catecholamines may be useful markers for investigating various stress responses in the process of death involving bleeding, burns, cold exposure, physical hyperactivity, or drug abuse; this is possible when these markers can be used in combination with other chemical and immunohistochemical markers; however, in postmortem investigation, catecholamines have been considered rather unstable markers for investigating the cause or process of death due to pain, terminal medical care, and postmortem interference.[1]

This study sought an adrenal tissue marker that was involved in the stress response process with special reference to activated/stimulated receptors by the activation of the sympatho-adrenal system and HPA. The β2-AR (adrenergic receptor) was chosen because stress promotes the release of epinephrine, a catecholamine stress hormone that binds to β(2)-adrenergic receptors (β(2)ARs) with high affinity.

Cases with several causes of death were selected in order to conduct an immunohistochemical analysis by the β2-AR antibody. Several causes of death were drowning, sudden cardiac death, sepsis, hanging, strangulation, traffic accident, and fire. This study revealed a different expression of β2-AR immunopositivity in relation to the cause of death; highlighted was the fact that the positive staining varied both for localization (fasciculate and/or glomerulosa and/or reticularis zone and/or medulla) and quantity. The results were then analyzed in relation to factors such as sex, age, and timing of the death process.

H3 A Forensic Case of a "Missing Brain" in a Preterm Newborn: A Postmortem Imaging Study Based on Computed Tomagraphy (CT) and Magnetic Resonance Imaging (MRI) With and Without A Contrast Agent

Fabrice Dedouit, MD, PhD, Centre Universitaire Romand De Médecine Légale, Service De Medecine Legale, Chemin De La Vulliette 4, Lausanne 1000, SWITZERLAND; Sylviane Hanquinet, MD, PhD, Department of Pediatric Radiology, Children's University Hospital of Geneva, Rue Willy Donzé, 6, Geneva, SWITZERLAND; Mehrak Anooshiravani, MD, Department of Pediatric Radiology, Children's University Hospital of Geneva, Rue Willy Donzé, 6, Geneva 1011, SWITZERLAND; Bruguier Christine, Ch. du Bugnon 21, Lausanne, SWITZERLAND; Kewin Ducrot, University Center of Legal Medicine Lausanne-Genev, Chemin de la Vulliette 4, Lausanne, SWITZERLAND; Bettina Schrag, MD, Hopital Du Valais, Institut Central, Medecine Legale, Av Du Grand - Champsec 86, Sion 1951, SWITZERLAND; Marc D. Bollmann, MD, Centre Universitaire Romand, De Medecine Legale, Ch. de la Vulliette 4, Lausanne 25 1000, SWITZERLAND; and Silke Grabherr, PhD, Centre Universitaire Romand de Médecine Légale, Chemin de la Vulliette 4, Lausanne 25, Vaud 1000, SWITZERLAND*

After attending this presentation, attendees will better understand the advantages and limitations of enhanced and non-enhanced imaging techniques that can be seen in a forensic case of a preterm newborn.

This presentation will impact the forensic science community by revealing the results of a forensic case of hydranencephaly in a male preterm newborn who successively underwent Postmortem Computed Tomography (PMCT), Postmortem Magnetic Resonance imaging (PMMR), Postmortem Computed Tomography Angiography (PMCTA), and Postmortem Magnetic Resonance Imaging Angiography (PMMRA).

In addition to the classic non-enhanced PMCT, a postmortem vascular opacification consists of a PMCTA. Other radiological techniques are the PMMR and the PMMRA. A case is presented of a preterm newborn, forensically managed, who underwent imaging techniques prior to a medicolegal autopsy.

Material and Methods: This case involved a young woman with a denial pregnancy who delivered a premature male newborn with a believed gestational age between the 22nd and 24th week of pregnancy at the hospital. The newborn died four hours after birth. The general attorney requested a medicolegal autopsy. The body first underwent external examination, then radiological explorations. The external examination revealed neither traumatic nor malformative lesions. The umbilical vessels consisted of two arteries and one vein.

The forensic imaging management: PMCT — conducted on a 64-row CT unit using soft and bone tissue kernels. PMMR — the body underwent a total body MRI exploration using a 1.5 Tesla® scanner. Next, 3D T1W (weighted) and T2W axial acquisitions were performed on the brain; the rest of the body (except the members) was explored through 3D T1 coronal and a 2D T2 coronal mDIXON. PMCTA — the umbilical vein was catheterized with a radiological sheath (5 French). The vein was manually filled with a 6% dilution of the oily contrast agent with paraffin oil. A first-enhanced CT acquisition was performed. The umbilical artery was filled in the same manner as the vein. A second, enhanced-CT acquisition was performed. PMMRA — a 3D T1 coronal acquisition was performed on the body. The corpse underwent a medicolegal autopsy. Histological examinations were performed after formalin fixation.

Results: The forensic imaging results: The PMCT revealed the absence of cerebral hemispheres, which were replaced by fluid. A hyperdense central mass was visible in the supra-chiasmatic region. Instead of the posterior part of the left brain parenchyma, an ovoid dense mass was visible, surrounded by a visible hyperdense fluid-fluid level. The brainstem was visible and appeared normal. The cerebellar hemispheres presented cystic lesions. The PMCT revealed no skeletal malformation.

The cerebral PMMR confirmed the absence of the cerebral hemispheres replaced by fluid. The central mass was hyperintense on T1-weighted images and corresponded to a thalamic mass. The posterior fluid-fluid level was hyperintense on T1-weighted images, as was the left posterior mass. Both cerebellar hemispheres revealed cystic changes. MR imaging was typical of hydraencephaly.

The PMCTA revealed the absence of opacification of the intra-cerebral veins. The vertebral arteries and basilar trunk (with both posterior inferior cerebellar arteries) were fully opacified. The posterior cerebral arteries were visible until P3 segments. The internal carotids, in their cavernous portions were visible, opacified through the posterior communicating arteries. The anterior or middle cerebral arteries were not visible. The cervical terminal part of both internal carotids was not opacified.

The PMMRA revealed a correct filling of the venous transverse sinuses and internal jugular veins. The cervical terminal part of both internal carotids was not opacified.

The autopsical and histological results: The autopsy and the neuropathology analysis confirmed the findings in the brain, with parenchymal destruction due to hypoxo-ischemic changes, all corresponding to the diagnosis of a massive necrotico-hemorrhagic hydranencephaly.

Discussion/Conclusion: Hydranencephaly, a pathological change seen in the fetus, is a destruction of the cerebral hemispheres with occasional persistence of occipital and temporal tissue. The destroyed brain is replaced by cerebrospinal fluid and delimited by leptomeninges. Gray nuclei, trunk, and cerebellum may present abnormalities. This massive ischemia of the brain is secondary to a vascular unclear cause that affects the two internal carotids during the second trimester of pregnancy.

Per research, this is the first case describing the forensic management of a preterm newborn with hydranencephaly, including PMCT, PMMR, PMCTA, and PMMRA, which allowed a complete neuro-vascular analysis.

Forensic Imaging, Postmortem Angio CT, Postmortem Angio MR

H4 When the Walls Close In: Chronic Allograft Vasculopathy on Autopsy of an Orthotopic Heart Transplant Patient

Farshaad Bilimoria, MD, 10 Allegheny Center, Apt 224, Pittsburgh, PA 15212; Stacey L. Reed, DO, 9500 Babcock Boulevard, Apt 54, Allison Park, PA 15101; Mark L. Bunker, MD, Allegheny General Hospital, 320 E North Avenue, Pittsburgh, PA 15212; and Jan F. Silverman, MD, Allegheny General Hospital, 320 E North Avenue, Pittsburgh, PA 15212*

The goal of this presentation is to illustrate a rare form of vascular occlusive changes that can be seen on autopsy and can lead to misdiagnosis.

This presentation will impact the forensic science community by demonstrating the chronic changes of vascular structures in transplant patients and how these changes can lead to ischemic damage of the transplanted organ.

Introduction: Heart transplantation procedures have been steadily increasing in the United States. The Organ Procurement and Transplantation Network reported 3,191 transplants in 2016 in America and 67,301 in total since 1988. Advancements in post-surgical therapies have decreased acute rejections and increased the one-year survival rates. Unfortunately, the long-term survival rates have not followed, as chronic, progressive arteriopathies compromise the blood flow to the transplanted heart and lead to ischemic injuries.

Materials and Methods: This case involved a 46-year-old Caucasian male who had undergone orthotopic heart transplant in 2005 and had multiple episodes of rejection due to medication non-compliance. The patient arrived at the hospital for his scheduled plasmapheresis session for presumed antibody mediated rejection, where he complained of numbness, lightheadedness, and dyspnea. A right heart catheterization revealed hemodynamic signs suggestive of ongoing rejection despite recent aggressive treatment. The patient was admitted and was initially responding favorably, but was found unresponsive on day eight. Despite multiple lifesaving efforts, the patient unfortunately expired.

Results: Postmortem examination revealed acute myocardial infarction involving the septum and the posterior and lateral left ventricular walls. The coronary arteries exhibited varying degrees of chronic allograft vasculopathy with intimal arteritis.[1] The vessel walls revealed concentric tunica intimal thickening, resulting in luminal narrowing of 25%-50%. The epicardial and intramural arterioles showed lymphocytes in an infiltrative and perivascular pattern. Obliterative transplant arteriopathy could be appreciated in the intramural arterioles, with up to 90% luminal narrowing.

Discussion: Chronic allograft vasculopathy is diagnosed in one-third of heart transplant patients five years after the procedure and in half of these patients by ten years.[2] The most widely accepted etiology is immune-based, wherein the recipient's immune system recognizes the foreign tissue, releases a cytokine cascade, resulting in growth factor expression and eventually smooth muscle proliferation in the artery walls.[3] The incidence has remained stable despite advancements in immunosuppressive treatments.[2] With an increase in heart transplant patients surviving beyond five years, recognition of chronic allograft vasculopathy will be needed to avoid misdiagnosis from similar diseases to such as: atherosclerotic coronary artery disease, acute transplant rejection, and autoimmune and/or infectious myocarditis.

Chronic Allograft Vasculopathy, Intimal Arteritis, Obliterative Arteriopathy

H5 Fatality Following Percutaneous Endoscopic Gastrostomy Tube Insertion

Hannah C. Jarvis, MRCS, Office of Chief Medical Examiner, City of New York, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will better understand vascular injury and a fatal hemorrhage as a rare complication of Percutaneous Endoscopic Gastrostomy (PEG) tube insertion. The associated autopsy findings, risk factors for vascular injury and hemorrhage, and the use of therapeutic complication as a manner of death will also be discussed.

This presentation will impact the forensic science community by alerting the forensic pathologist of this complication of percutaneous endoscopic gastrostomy tube insertion, which can be demonstrated at the time of autopsy by careful dissection. This presentation will also impact clinicians by recognizing the potential for vascular injury at the time of tube insertion and patients at increased risk of hemorrhage.

PEG tube placement is a minimally invasive method of providing long-term enteral nutritional support.[1] The procedure was first conceptualized and performed in 1979 in Cleveland, OH, by Drs. Ponsky and Gauderer for use in the pediatric population. Their goal was to avoid a traditional laparotomy and instead provide a minimally invasive technique for gastrostomy tube insertion.[2] Following the initial success of the procedure, an estimated 100,000 to 125,000 PEG tube insertions are now performed every year in the United States.[3] Absolute contraindications to PEG tube insertion include pharyngeal or esophageal obstruction, active coagulopathy, and any general contraindication to endoscopy.[4]

A 54-year-old man with metastatic gastric adenocarcinoma was admitted to the hospital for management of dysphagia and a 30lb weight loss. He was initially receiving total parenteral nutrition via a central line. During his admission, he developed an upper extremity deep vein thrombosis for which he was started on heparin treatment. The heparin was stopped the following day after he developed hematemesis. Subsequently, he underwent a PEG tube placement in the interventional radiology department.

Following his transfer back to the intensive care unit, he was noted to be hypotensive and tachycardic. A massive transfusion protocol was initiated and an attempted coil embolization of the presumed vascular injury was initiated; however, the patient died during the procedure.

At autopsy, the torso was remarkable for diffuse petechiae and ecchymoses. A gastrostomy tube was extending from the epigastrium. There were seven liters of blood in the peritoneal cavity. The gastrostomy tube had perforated the greater omentum immediately adjacent to the transverse colon, with hemorrhage along the serosal surface, but no defect in the colonic wall was identified. The tube then perforated the pylorus of the stomach, but also inadvertently transected the right gastroepiploic artery. The gastric wall was diffusely thickened, up to 1cm. Also of note was advanced hepatic cirrhosis.

Serious or fatal complications following PEG tube insertion are rare. Approximately half of all patients will experience a minor complication, most frequently a wound infection.[5] Mortality rates are reported to be approximately 2% and have resulted from esophageal perforation, peritonitis, and severe respiratory distress.[6] Fatal hemorrhage is very rare with only two prior reported cases.[6,7] In both of these cases, the patient had undergone a prior cholecystectomy resulting in intra-abdominal adhesions, resulting in distorted anatomy. In this particular case, the recent use of heparin as well as the underlying advanced hepatic cirrhosis may have contributed to the profuse hemorrhage. The cause of death was hemorrhagic complications of PEG tube for the treatment of metastatic gastric adenocarcinoma. The manner of death was therapeutic complication. The therapeutic complication manner is used in a few jurisdictions in the United States and is defined as fatalities due to predictable complications of appropriate medical therapy.[8]

Although a rare complication, clinicians should be aware of the possibility of a vascular injury during PEG tube insertion and underlying natural diseases (such as hepatic cirrhosis) or concurrent medical therapy that may confer an additional risk of bleeding. Careful dissection at the time of autopsy with the gastrostomy tube *in situ* will help identify the underlying fatal injury.

H6 Examining the Distribution of Manner and Cause of Deaths at Hotels and Motels

Heather I. Chen, BA, Western Michigan University, SOM, 911 S Park Street, Kalamazoo, MI 49001; and Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008*

The goals of this presentation are to compare deaths occurring in hotels/motels to deaths occurring in the decedent's residence with specific attention to: (1) the manner of death; (2) the cause of death; and, (3) the variation in the method of suicides.

This presentation will impact the forensic science community by illustrating the significantly higher incidence of unnatural deaths of people who die in a hotel/motel by comparison to a decedent's residence.

This retrospective analysis is important in order to raise awareness of: (1) the proportion of deaths that occur in a hotel/motel due to unnatural causes; and, (2) the need for a high index of suspicion of unnatural deaths.

Within our counties, 82 deaths occurred at a hotel/motel from January 1, 2011 to June 30, 2017. Twenty-five of the decedents were females from 23 to 85 years old and 57 were male from 21 to 80 years old. Of these 82 deaths, 35 (42%) were classified as natural, 31 (38%) accidents, 12 (15%) suicides, and 4 (5%) undetermined. When compared to deaths that occurred at the decedent's residence in the same period, a far greater percentage of those are due to natural causes. Of 4,970 deaths reported that occurred at the decedent's residence, the manner of death was 3,919 naturals (79%), 567 accidents (11%), 341 suicides (7%), 47 homicides (1%), and 96 undetermined (2%).

Of the 47 unnatural deaths (accident, suicide, indeterminate), 38 (81%) were drug-related. An opioid was present in 27 of the 38 drug-related deaths and the most common opioid present was heroin.

Of the 12 hotel/motel suicides, five drug related fatalities (42%), four hangings (33%), two gunshot wounds (17%), and one plastic bag suffocation (8%) were observed. The modality used in suicides within the hotel/motel deaths differed from suicides at the decedent's residence where a majority of the suicides were due to gunshot wounds. By comparison, at the decedent's residence, suicide modalities were 168 firearms (49%), 93 (27%) hangings, 53 drug-related (16%), 8 (2%) sharp force injuries, 8 (2%) carbon monoxide poisonings, 8 (2%) asphyxiations/suffocations by plastic bag, and 3 (<1%) drownings.

Wasserman and Stack also found a higher number of suicides due to hanging in motels.[1] A study that looked at place compared to method of suicide found hotel or motel suicides were 4.9 times more likely to use drugs in comparison to suicides committed outdoors or on railways.[2] A study from Germany confirmed the increased number of unnatural deaths in hotels: 12 of 22 hotel deaths were natural, 9 unnatural, and 1 undetermined.[3] In Canada, researchers followed 15,100 homeless and marginally housed people from 1991 through 2001 and found mortality rates for those living in shelters, rooming houses, and hotel/motels were higher for drug-related deaths, alcohol-related deaths, and suicides.[4]

A recent study analyzed guest perceptions of hotel/motel rooms where a death had occurred.[5] The researchers found if a participant knew a previous guest had died in a room, they were more likely to see the room as less valuable, opt to stay in a different room, and feel uneasy when imagining an overnight stay. Perception of that room eventually returns to baseline, but many years after the death event.

In conclusion, the number of unnatural deaths exceed natural deaths, and drug-related fatalities were the most common. Investigators should have a high index of suspicion for unnatural deaths, especially drug-related deaths, when investigating deaths occurring in hotels and motels.

Forensic Pathology, Hotel and Motel Deaths, Suicide

H7 An Unusual Case of Repeat Exertional Rhabdomyolysis With Associated Lymphocytic Thyroiditis and Sickle Cell Trait

Heather I. Chen, BA, Western Michigan University, SOM, 911 S Park Street, Kalamazoo, MI 49001; and Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008*

The goals of this presentation are to: (1) highlight clinical findings of a death following a second episode of exertional-rhabdomyolysis in a Sickle Cell Trait (SCT) patient also found to have lymphocytic thyroiditis at autopsy; and, (2) review return to play/duty recommendations for rhabdomyolysis in SCT individuals.

This presentation will impact the forensic science community by detailing a case in which SCT, exertional-rhabdomyolysis, and lymphocytic thyroiditis contributed to the death of an otherwise healthy person.

A 33-year-old male soldier in the National Guard began complaining of difficulty breathing and pain and requested medical assistance during a fitness test. Following emergent transfer to the hospital, he became combative and showed altered mental status. He was diagnosed with rhabdomyolysis. Three days after admission, the patient went into full cardiac arrest and died.

According to the decedent's relatives, he was hospitalized a year earlier for exertional rhabdomyolysis following the same annual fitness test. He was known to be positive for SCT, but was otherwise physically fit and without ongoing medical problems. The patient did not take any prescription medications and did not smoke or drink alcohol. He was not placed on any restrictions following this episode of rhabdomyolysis, other than recommendations to adequately hydrate.

His death resulted from complications of exertional rhabdomyolysis, including acute renal failure, intestinal ischemia, disseminated intravascular coagulation, and multiple organ failure. An unexpected finding at autopsy occurred on microscopic examination of the thyroid gland: significant lymphocytic infiltrates with germinal centers and destruction of thyroid follicles. He had a significantly elevated Thyroid Stimulating Hormone (TSH) and anti-thyroid peroxidase hormone on antemortem and postmortem samples. His toxicology screen of admission blood was negative for all screened substances.

For single-episode cases of rhabdomyolysis, the most common causes are cocaine use, exercise, and immobilization.[1] However, if an individual has recurrent episodes of exertional rhabdomyolysis, that person should undergo investigation for an underlying cause. Repeat episodes may be a result of SCT, hypothyroidism, or acquired myopathies, such as polymyositis, congenital muscle disorders such as muscular dystrophy, or metabolic myopathies impair fat metabolism.[1] Recommendations suggest athletes and military personnel should not return to play or duty if they have SCT since many activities can cause repeat episodes of exertional rhabdomyolysis.[2,3]

SCT and hypothyroidism are both risk factors for developing rhabdomyolysis. A study of 47,944 United States Army Black soldiers on active duty who had undergone testing for SCT had a significantly higher risk of exertional rhabdomyolysis.[4] A few case reports revealed hypothyroidism predisposes individuals to rhabdomyolysis and Acute Kidney Injury (AKI). The pathogenesis is unclear, but the hypothesis is hypothyroidism impairs glycogenolysis and mitochondrial oxidative metabolism, which can lead to rhabdomyolysis under physical stress.[5,6] Hypothyroidism as a cause of rhabdomyolysis and AKI should be considered in patients with decreasing renal function, high creatinine kinase, and no obvious cause.[7]

Though not the most common causes of rhabdomyolysis, underlying etiologies, including SCT and hypothyroidism, should be considered by the pathologist performing the autopsy in deaths due to exertional rhabdomyolysis. Microscopic examination of the thyroid is recommended.

Rhabdomyolysis, Sickle Cell Trait, Forensic Pathology

H8 Pediatric Death by Macrophage-Activation Syndrome (MAS) Related to Epstein Barr Virus: The Role of Microbiological and Histological Postmortem Investigations

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Francesca Pepe, MD, Viale Europa, località Germaneto, Catanzaro 88100, ITALY; Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; and Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will be able to describe the impact of forensic science in cases of sudden pediatric death.

This presentation will impact the forensic science community by demonstrating the importance of immediate treatment in MAS to minimize the risks of sudden pediatric death.

In the context of immune-mediated diseases, MAS is a severe and potentially life-threatening complication of systemic inflammatory disorders. It may occur in response to an infection (often viral), malignancy, or a rheumatic disease. MAS typically appears in patients with Systemic-onset Juvenile Idiopathic Arthritis (SoJIA) and its adult equivalent, adult-onset Still's disease; it also is reported in other pediatric inflammatory disorders, including juvenile Systemic Lupus Erythematosus (SLE) and Kawasaki disease. It is a rare disorder. MAS expresses a close clinical resemblance to a group of histiocytic cell disorders collectively known as Hemophagocytic Lymphohistiocytosis (HLH). MAS is classified among the secondary, or acquired, forms of HLH. Primary HLH is a genetic disorder of immune regulation caused by mutations in genes encoding proteins required for the cytolytic activity exerted by NK cells and cytotoxic T cells. The clinical presentation of MAS is usually acute, may be dramatic, and is often difficult to distinguish from a severe sepsis. Typically, patients present fever, hepatosplenomegaly, lymphoadenopathy, profound depletion of all cellular blood elements, liver dysfunction, disseminated intravascular coagulation, and central nervous system dysfunction. Blood tests reveal: leukopenia, anemia, and thrombocytopenia; hyperbilirubinemia; high levels of Lactate Dehydrogenase (LDH), ferritin, and triglycerides; an increase in liver enzymes and cholestasis; normal or suddenly decreased Erythrocyte Sedimentation Rate (ESR); and sharply increased SCD25 and CD163. Coagulation is often altered, with elongation of the PT and PTT, hypofibrinogenemia, and the presence of fibrin degradation products (sharply increased D-dimer). In the field of forensic pathology, this postmortem diagnosis it is often difficult to detect; for this reason, cases sometimes remain unsolved. The treatment of MAS is not completely standardized. Steroids are considered the first-line therapy. Cyclosporine has demonstrated efficacy in non-responsive patients. The delay in diagnosis and multiorgan involvement are associated with a worse prognosis, so it is important that treatment is immediately instituted to prevent irreversible damage to the tissues and sudden pediatric death.

Case Report: A 2-year-old child was hospitalized for fever and vomiting. The child was pale and had dry skin. Nothing else was reported from the examination of the remaining systems. The hospital staff gave her antibiotics, antipyretics, and antiemetics. The results of chest and abdominal X-rays during the period of hospitalization were negative. A few hours after her admission, the child began to manifest mottled skin and bilious vomiting. She had kidney failure, absence of peripheral pulses, and loss of consciousness with convulsions and defecation. The child was treated with intubation, diazepam, and cortisone. Laboratory tests revealed lymph monocytosis, hyperglycemia, increased C-Reactive Protein (CRP) and ESR, and marked metabolic acidosis. Approximately six hours later, the first cardiac arrest occurred, but resuscitation was successful. Subsequently, two additional cardiac arrests ocurred, with a fatal outcome. After her death, an autopsy was performed. The microbiological data on postmortem samples from the lungs, pleural fluid, pericardial fluid, and cerebrospinal and ascitic fluid were negative for the detection of bacteria and yeasts. Microbiological investigation of the blood exhibited positivity for Epstein-Barr Virus (EBV) (Cytomegalovirus (CMV) and Mycoplasma pneumonia were negative). The postmortem histological examination revealed: labeled macrophage activation thymic cortical parenchyma; cardio-pulmonary thrombosis; pulmonary atelectasis; foci of interstitial pneumonia; follicular hyperplasia of lymphoid tissue associated with the intestinal and colon mucosa (Mucosa-Associated Lymphoid Tissue (MALT)); chronic hepatitis; and cerebral edema. The comparison of the clinical data with the autopsy data accompanied by microbiological investigations established that the MAS and Disseminated Intravascular Coagulation (DIC) in a child infected with EBV was the cause of death.

Conclusions: Cases of pediatric death with the absence of an antemortem diagnosis require a detailed analysis of antemortem clinical data with multidisciplinary collaboration with a pediatrician; it is necessary to conduct microbiological postmortem surveys on biological fluids in order to detect viruses and bacteria and to conduct histological investigations to explore in detail the thymus and lymphoid organs.

Forensic Science, MAS, Pediatric Death

H9 A Doubtful Case of Suicide by Firearm: The Comparison Between the Forensic Analysis of the Crime Scene and the Computed Tomography (CT) -3D Postmortem Investigation in Reconstructing the Manner of Death

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; Santo Gratteri, MD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Forensic Pathology Dept, Ospedale Colonnello D'Avanzo, Foggia I-71100, ITALY; Paola Frati, PhD, Dept of Anat Histol Forensic and Orthop Sciences, University of Roma "La Sapienza," Viale Regina Elena 336, Roma 00161, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the impact of CT-3D postmortem investigation and forensic analysis of the crime scene in cases in which there were doubts concerning the manner of death.

This presentation will impact the forensic science community by demonstrating the importance of radiological investigations to clarify doubtful cases of suicide by gunshot wounds.

Suicide is a public health problem; generally, it is underestimated. Many different factors may influence personal decisions about the choice of suicide modality. In forensic pathology, some cases of suicide are not clear, particularly when the body is moved, when the dynamics of the crime scene are uncertain, or the method of suicide is unusual. In gunshot suicides, the primary problem is understanding the dynamics of the shot; specifically, after the gunshot, the body may be subjected to passive movements or the shot is not immediately fatal and thus the individual can move away from the exact point where the shot or shots were fired.

The case of a man found dead in the countryside just a few meters from his home is presented. The victim was in a supine position above steep ground near a tree. Next to his right foot was a dark green hat on the ground. A dirty rifle with handcrafted changes was located approximately two meters to the left side of the corpse. There was a gunshot injury to the victim's left chest. Blood spatters were detected between the thumb and the index finger of the left hand. The analysis of the clothes revealed the presence of lacerations on the left thoracic area. A knife was found in his left trouser pocket. Near the corpse, a 96.5cm wooden stick with a V-shaped smooth tip was found, recently honed by a sharp blade. The wife stated the man did not show any psychological problems and that he had gone hunting in the morning. An autopsy was performed that revealed a gunshot wound that had jagged and irregular edges and an oval 3cm x 2.5cm shape with blackish shades as a contact hit. Under the gunshot wound, an ecchymotic-bruised complex of 3cm x 2.5cm was detected on the left intercostal region, at the level of the fifth intercostal space. A CT-3D 64-slice postmortem imaging allowed the reconstruction of the corporeal pathway and the detection of multiple bullets inside the pleural cavity and in the left under-scapula region. At autopsy, 30 bullets were detected, along with a cylindrical plastic element compatible with an explosive cartridge fragment. The directionality of the corporeal pathway determined that the shot was fired from left to right and from bottom to top in an oblique direction; the rifle (leaning on the ground) was activated with the aid of the stick that was used by the victim as a lever. The stick with the V shape was previously honed by the victim himself with the knife found in his trouser pocket.

Conclusions concerning the manner of death were deduced after several simulations that considered as most likely the hypothesis of the barrel being supported under the left armpit and the weapon's being fired by the right-handed and previously prepared stick. This case demonstrates how the analysis of circumstantial data emerging from the inspection, with the support of postmortem radiology, in cases of gunshot wounds is a valuable aid in reconstructing the dynamics of the event. In this case, the question was raised that perhaps the man had fallen and the shot from the rifle was accidental. The accidental theory was excluded due to the circumstantial and radiological elements that made it possible to discover the truth. Therefore, it is suggested that in all cases of firearm injury, a careful inspection is performed of all measurements as well as a pre-autopsy CT-multislice to detect the bullets and perform vector analysis of the shot or shots fired.

Forensic Science, Suicide, CT-3D Postmortem

H10 The Analysis of Pattern Injuries From Blunt Trauma and Sharp Force in a Forensic Case of Homicide: An Experimental Study Using a Pig Head Model

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Alfredo Manca, Public Prosecutor, Corso Mazzini, Crotone 88900, ITALY; Giuseppe Capoccia, Public Prosecutor, corso mazzini, Crotone 88900, ITALY; Manolo Vozza, Arms of the Carabinieri, Investigative Unit of Crotone, Crotone 88900, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the impact of an experimental study using pig head models in order to identify the compatibility of injuries produced compared to those found on the victim.

This presentation will impact the forensic science community by demonstrating the importance of the correlation between the analysis of pattern injuries and weapon identification.

Blunt trauma can have various patterns. Each injury is different depending on the nature and mass of the weapon and on the force and manner employed. Difficulties arise in the identification of the weapon, in checking the compatibility with the injury, in the determination of the acting force, and in the discrimination of each injury. Investigations are complicated by the use of different weapons at the same time. Therefore, it is necessary to analyze injury patterns by replicating each wound on an experimental model, similar to a human one. In the literature, several studies have used pig bones in order to evaluate various injuries or to reproduce particular conditions, such as for burn injuries.

Often, it is difficult to determine the nature of the injuries, especially when they are multiple, overlapping, and made by blunt objects with an unidentifiable shape. The forensic pathologist must answer questions about the weapon used and is not always able to do so. Detecting the weapon is crucial and investigators search for it at the crime scene or where the attacker may have thrown it away. The pathologist's tools are experimental, especially when the weapon is not found or many weapons have been used. The autopsy is fundamental, as is the analysis of the margins, shape, and morphology of each injury.

A woman was found dead in her apartment with multiple wounds on her chest, head, face, and hands. An inspection was conducted during which all rooms were evaluated to find the crime weapon(s). In a wardrobe, knives were found wrapped in cloths and a cloth of the same color was found on the bed. All of the knives found did not show blood spots or latent traces. At the autopsy, the victim exhibited 11 injuries with clear and infiltrated margins attributable to 11 stab wounds from a cutting weapon. Only three of them were penetrating: one on the chest that lacerated the left lung and two on the right side and abdomen with hepatic lacerations.

Head injuries were present as a result of multiple stab wounds on the same point. There were 20 such injuries; each had indented margins, infiltrated with rounded and convex features, totally different from cutting injuries. These injuries exhibited multiple underlying cranial fractures attributable to the use of a blunt object repeatedly coming into contact with the head of the victim (ascertained by analyzing the victim's position at the inspection), first on the occipital region, then on the right temporo-parietal region. An experimental study was conducted on pig heads obtained from a slaughterhouse in compliance with animal experimentation regulations. Each head was placed on a cloth. Metallic and wood cutting and blunt weapons were chosen. Among the blunt objects classified and measured were: various hammers, metal pipes, screwdrivers, pipe wrenches, sticks, bats, picks, shovels, and hoes. Among the cutting weapons chosen were: single- and double-edge cutting knives, clasp knives, cleavers, and various kitchen knives. All the weapons were tested on pig skin. Head blows were made by a subject of the same weight and height as the suspect, with his right and left hand. Each injury was photographed and measured. From the comparison of the data emerged a compatibility of cutting wounds due to a single-edge cutting knife, with similar morphological characteristics compared to the victim's injuries. The analysis of blunt weapons exhibited a compatibility with metallic pipe injuries with the same rounded and convex morphology of multiple and overlapping wounds found on the head and face of the victim. This study has proven that the injuries were attributable to the use of two distinct weapons with different traumatic mechanical actions and that the aggressor used stronger force on the head with the metal tube, causing multiple cranial fractures. These data allowed for the detection of the inconsistencies declared by the aggressor and the discovery of the weapons that had been discarded in the countryside.

Forensic Science, Blunt Trauma, Pig Head Model

H11 The Role of Crime Scene Investigation and Judicial Inspection in Bath-Related Deaths: A Case Report With Forensic Implications

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Forensic Pathology Dept, Ospedale Colonnello D'Avanzo, Foggia I-71100, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; and Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will understand the role of the forensic pathologist in determining the dynamics of bath-related deaths.

This presentation will impact the forensic science community by describing the procedure performed and the issues encountered in solving a case of bath-related death.

In Italy, more than four million domestic accidents happen every year, of which 8,000 are fatal. Such accidents can occur in the bathtub. In the literature, cases of drowning, sudden deaths, frequently associated with hyperthermia, and electrocution are described. The judicial inspection plays a decisive role in bath-related deaths, providing forensic evidence that could be lost if not immediately collected, especially in cases in which autopsy may not provide sufficient data to clarify the dynamics.

The case of a girl found dead in her home is presented. During the inspection, the girl was found on the couch. From the testimonies of the family, it emerged that the victim was found dead in the bathtub, then the body was moved by her father. An analysis of the rooms of the house, especially the bathroom, was conducted. Every object in the bathroom was cataloged and photographed. The bathtub was placed next to a sink on which an extension cord connected to a charging cell phone was found. An assessment of the electrical installation of the home was then performed. Subsequently, an external examination of the victim was conducted. The corpse had cutis anserine with pilo-erection on the dorsal area and the presence of a large area of skin burns (II and III degree) extended from the right shoulder to the left and caudally to the right gluteus. An impression of a rectangular shape (12cm x 3cm) from contact with an energy source on the dorsal region was found. Two burns on the right arm and a likely electrical mark with the exit point on the third finger of the right foot were collected. Samples of the skin, subcutaneous tissue, and muscle of all injuries were taken. The histological investigation was performed according to a protocol of paraffin-embedded formalin-fixed samples and preparation of slides. The microscopic examination exhibited: (1) the presence of small cavities or air bubbles (alveolus by high temperature) in the stratum corneum of the epidermis, which also presented carbonate residues on the surface; (2) polarization and elongation in clumps of cells of the stratum basale and stratum spinosum; and, (3) coagulative necrosis of the dermal connective.

In bath-related deaths, the judicial inspection and careful evaluation of the circumstantial data are crucial. The forensic pathologist must investigate whether the body has been moved from the bathtub, if it contains water, and measure its temperature. External examination of the victim allows an evaluation of the injuries and determines their nature, shape, dimensions, and microscopy to determine the histopathological features. It is also essential to conduct a toxicological investigation to exclude other causes of death. In this case report, there were difficulties because the victim was found far from the bathtub; however, the correlation of circumstantial data with autopsy data clarified that the burns present were generated by direct contact with an electrical power source, compatible with the extension cord found during the inspection. Plausibly, the girl, during her bath, used a charging cell phone connected to an extension cord near the bathtub. After the accidental fall of the extension cord, the latter was in contact with the water and the skin, causing death by electrocution. Therefore, there was also an increase in temperature on the contact surface of the skin, causing burns by Joule effect. In these cases, the pathologist must examine the electrical system, the current type, and the presence of automatic locking mechanisms. In this case, the electric current had a voltage of 220V and there wasn't any safety device. The comparison of the collected data allowed for the identification of the cause of death and, above all, the clarification of the dynamics of the event as well as the responsibility of other people in the accident. This case also emphasizes the importance of home security systems and using life-saving devices to prevent deaths associated with such accidents.

Forensic Science, Bath-Related Death, Crime Scene

H12 Sudden Death: The Role of Histopathological Investigations in a Case of Eosinophilic Myocarditis (EM)

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY; Ciro Di Nunzio, MFS, PhD*, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; and Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will be able to describe the impact of histopathological investigation in a postmortem diagnosis of EM.

This presentation will impact the forensic science community by demonstrating the role of timely diagnosis to avoid sudden deaths in the absence of cardiac-specific symptoms.

The heart is a prime target of Polynuclear Eosinophil (PE) toxicity that is due to the release of basic proteins by eosinophils, including major basic proteins, cationic protein, and peroxidase. The most common manifestation of PE toxicity is Chronic Parietal Endocarditis (CPE). The heart damage appears to be a direct result of tissue injury produced by toxic eosinophil granule proteins; however, it is not known what causes eosinophilia in these patients and why the endocardium is especially susceptible to this type of injury. A number of parasitic infections may give rise to EM. Occasionally, drug reactions and rejection of a transplanted heart may produce EM. The incidence of EM is low but probably underestimated. The most common cause of death is the short-term occurrence of cardiogenic shock or dilated hypokinetic cardiomyopathy. Some patients have been successfully treated by early, intensive corticosteroid therapy and/or heart transplantation; however, diffuse myocardial involvement may lead to heart failure, and some of these patients may later develop dilated cardiomyopathy. The causes of sudden deaths are manifold, but, in the forensic field, very few cases of eosinophilic myocarditis are described in the literature. The difficulties of the postmortem diagnosis derive from the need to conduct in-depth histological exams and because the macroscopic data are unspecific.

Case Report: A 32-year-old Black man, a native of Liberia and an immigrant to southern Italy, was found dead in the immigration center. The external inspection of the corpse revealed an athletic constitution. The autopsy showed subarachnoid hemorrhage and fibrotic pleural adhesions of the ribs, and the heart exhibited an increase in volume, with grayish areas on the front surface. The cause of death remained unresolved; thus, the forensic pathologist conducted histological examinations. In particular, the heart was analyzed after fixation in 10% formaldehyde. The slides of the organs were prepared in paraffin and stained with hematoxylin-eosin. Histopathological examination provided the diagnosis of acute necrotizing EM of undetermined origin. Toxicological tests were performed and were negative. From the man's clinical history, it emerged that the day before death, the supervisors of the immigration center had called an ambulance as the man appeared to be in a confused state with pain in the posterior region of the right leg. Despite his recovery at that time, the man then died in the hospital within a few minutes without any possibility of intervention. Histological examination revealed an acute myocarditis associated with cerebral ischemic necrosis and subarachnoid hemorrhage. Therefore, in this case, it is shown that the eosinophilic action carried both cardiac and brain toxicity, generating a detrimental acute necrosis of tissue.

Conclusions: In cases of EM, it is important to make an early clinical diagnosis, and it is especially essential not to underestimate the neurological symptoms manifesting as early symptoms of heart disease, which may more quickly direct a diagnosis. In the forensic field, only histopathological investigation can identify the specific diagnosis.

Forensic Science, Eosinophilic Myocarditis, Sudden Death

H13 The Role of Proteomics for the Forensic Estimation of Postmortem Interval (PMI): A Preliminary Experimental Study

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the application of proteomics for the estimation of time of death.

This presentation will impact the forensic science community by describing an operative experimental model used in order to analyze the PMI from the exact moment of death.

Proteomics is a branch of molecular biology that allows the systematic identification of the proteome from a quantitative and qualitative point of view. There are several studies in the literature that have analyzed animal or human biological samples using proteomic methods at different times since death. Regarding humans, no study has analyzed human samples from the exact time of death (time zero). Therefore, not knowing the exact time of death, studies were conducted in which the PMI analyzed was roughly calculated and was not known with certainty. In addition, before discovery, the corpse was exposed to various extrinsic factors, such as temperature or humidity. Therefore, proteomic analysis could be strongly influenced or altered by exposure to thermal variations of the sample.

This presentation introduces the operating model of an experimental study currently underway at the Department of Legal Medicine of the University of Catanzaro. The model is based on taking peripheral blood samples from patients who died at the intensive care unit, following an operation. The study was approved by the Ethics Committee of the University. The informed consent was signed by family members before the death of the patient. Samples were taken according to predefined time intervals, starting from the exact time of death (time zero) and up to two hours after the death. Samples were immediately centrifuged to extract plasma and stored at -80°C and were subjected to proteomic analysis by western blot and mass spectrometry at the Proteomic Laboratories of the University of Catanzaro. Although the experimental study is still ongoing, consistent results both with the time interval examined and the data already known in the literature are expected. In fact, a review of literature on this topic has already revealed that several proteins can undergo not only quantitative changes in terms of increase or reduction directly proportional to the PMI investigated, but also qualitative changes. According to the scientific evidence available in the literature, the expected results of the study are related to the search for quantitative and/or qualitative alterations from the exact moment of death of some markers, already showing time-dependent variations such as: (1) ubiquitous cellular proteins, like High Mobility Group Box 1 (HMGB1), and (2) specific organ proteins (muscle proteins due to progressive degradation, such as Cardiac Troponin I and T (cTn I and cTnT) and proteins related to brain damage, such as Glial Fibrillary Acidic Protein (GFAP) or talin).[1-4]

The proposed model is the first to conduct proteomic investigations on human biological samples from the exact moment of death without exposing the corpse to temperature variations or other extrinsic factors.

Finally, this operating model is intended to: (1) identify the possible role in the estimation of PMIs of new potential protein biomarkers expressed in peripheral blood from the exact moment of death; (2) verify and evaluate in detail the variation of the proteomic profile of markers already known in the literature; and, (3) focus on the analysis of the so-called "early PMI" for forensic purposes.

H14 A Case of Sudden Death From Takayasu Arteritis (TA): The Role of the "Histopathological Autopsy" in the Diagnosis of a Rare Disease

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Andrea Galassi, MD, S Bortolo Hospital, Viale Rodolfi 37, Vicenza, IL 36100, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Roberto Raffaele*, Via Thailandia N 1, Croton, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will better understand the role of TA.

This presentation will impact the forensic science community by demonstrating the role of histopathological investigations in cases of sudden death.

The autopsy represents the gold standard to determine cause of death. Sometimes autopsy cannot determine the pathologies that led to death, especially when only microscopic data determines such mechanisms. The pathologist uses histopathological examination even when the cause of death is already known at autopsy, but it becomes crucial when autopsy data are doubtful. In cases of sudden death, a macroscopically visible anatomical anomaly is not always present. Therefore, histopathological autopsy becomes crucial in diagnosis.

Reported here is the case of a 50-year-old woman who suddenly died in the emergency room; she was being seen for dizziness and nausea. An autopsy was performed as the woman enjoyed good health and was a sportswoman. The analysis of the anamnestic data revealed only the presence of a history of dizziness in the absence of other signs or symptoms. The autopsy revealed the presence of sclerosis of the thoracic and abdominal aorta with widespread coronary sclerosis. The lungs and brain appeared to be edematous and congested. There were no other pathological alterations. A histopathological investigation was performed revealing the presence of an ascending left coronary embolization and aortic wall thrombosis. The analyzed emboli, as well as the atheroma on the aorta, detected the presence of an eosinophilic infiltrate compatible with various forms of eosinophilic vasculitis. Histopathologic analysis further demonstrated the presence of non-infectious vasculitis associated with Anti-Neutrophil Cytoplasmic Antibody (ANCA) -associated autoimmune mechanisms. The vessels of all organs without eosinophilic infiltrates were analyzed. The limitation of the vasculitic phenomena to the aorta indicated a diagnosis of TA. Heart sections exhibited disruption areas of intercalated disks, coherent with ventricular fibrillation associated with small areas of necrosis, homogenization of diffuse eosinophilic sarcoplasmas, and wavy fibers. Such aspects were most present at the tip of the heart. These data revealed a terminal cause of myocardial ischemia with left ventricular fibrillation in the genesis of sudden death. This forensic case represents a rare case of autoptsy findings of Takayasu syndrome. This finding, in this case, indicates the cause of death.

TA is a chronic inflammatory large-vessel vasculitis that affects the aorta and its major branches. It can affect the vessel, mainly by stenosis, occlusion, and aneurysm, due to the thickening of the vascular wall. The prognosis of patients with TA is good, and the silent asymptomatic phase of this vasculitis can be long [1-6]. Sometimes the onset of this pathology can be fatal, with complications such as aneurysm rupture and congestive heart failure that may develop as a consequence of hypertension, granulomatous myocarditis, coronary heart disease, and/or aortic regurgitation. Sudden death can also be a rare complication of the disease. In the reported case, a correlation between TA and sudden death caused by aortic involvement with coronary embolization is shown. Such association is not a common finding. The correlation between systemic vasculitis and sudden death even in healthy subjects who do not exhibit comorbidity is emphasizedas is the importance of preventing fatal events, especially through cardiological follow-up of patients presenting with these pathologies. In these cases, from a forensic point of view, especially when the cause of death does not macroscopically emerge at the autopsy, it is fundamental that the histopathological investigation is conducted, which may sometimes be crucial in the diagnosis.

H15 Methods for Optimizing Postmortem Fingerprint Recovery From Mummified Fingers

Lee Morgan, Western Michigan University School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; Marty Johnson, PhD, Kalamazoo Public Safety Crime Laboratory, 150 E Crosstown Parkway, Kalamazoo, MI 49001; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; Carolyn V. Isaac, PhD, 1000 Oakland Drive, Kalamazoo, MI 49008-8074; Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007*

After attending this presentation, attendees will: (1) understand that traditional methods used to obtain postmortem fingerprints from mummified fingers are not always easy or successful; and, (2) learn two additional methods that can be used to optimize postmortem fingerprint recovery from mummified fingers.

This presentation will impact the forensic science community by introducing two additional techniques for obtaining postmortem fingerprints from mummified fingers.

In many medicolegal death investigation offices, a routine part of the postmortem examination of bodies involves the collection of fingerprints. A variety of challenges exist when attempting to take fingerprints from certain decedents. Decomposition, water immersion with subsequent wrinkling of finger pad skin, and trauma may cause great difficulty in obtaining suitable fingerprints at autopsy. Some of the most challenging cases involve mummified fingers, where shrunken, wrinkled, and hardened finger pads can make it nearly impossible to obtain suitable prints. The forensic literature includes recommendations regarding how to overcome these challenges.[1-4] Commonly employed methods involve attempts at rehydration, followed by various techniques for print acquisition, such as powder and adhesive lifts and Micro-Sil™ Silicone Impression Compound.[4] Despite these recommendations, obtaining useable prints is not always possible. Those responsible for obtaining postmortem fingerprints should use all available means to acquire suitable fingerprints.

This report presents two relatively simple methods using baby powder and transillumination, which may be useful in obtaining suitable fingerprints from mummified fingers. Both can be performed on fingers *in situ* or following finger removal from the body.

The baby powder method is most useful for situations in which the fingers are extremely darkened by mummification. Following attempts at rehydration, as previously reported in the literature, the finger pads are dried. Next, white powder, such as baby powder, is lightly brushed onto the finger pad surfaces, using a fingerprint brush. The powder adheres to the fingerprint ridges and enhances the dark grooves of the fingerprint resulting in what appears to be a "negative image" of how one normally visualizes an inked finger pad. A photograph or 10X to 20X microphotograph of the white-powdered finger pad can then be produced, with subsequent digital inversion for comparison purposes.

The transillumination method is more complex but still relatively simple to perform. Using forceps and a thin, sharp scalpel, the subcutaneous tissues underlying the finger pad are accessed via the skin proximal to the finger pad. The subcutaneous tissues immediately underlying the finger pad are then carefully removed by planed excisioning with the scalpel. The hardened subcutaneous tissues can literally be carved away in thin layers, working outward, toward the skin surface of the finger pad. Once enough tissue is removed, a relatively thin band of epidermis and underlying dermis will remain. Using a fiber-optic light source, the planed surface underlying the finger pad is illuminated. The overlying finger pad will be transilluminated, allowing for photography of the fingerprint ridge detail and subsequent digital inversion of the photograph for comparison purposes.

Fingerprints, Autopsy, Mummification

H16 Forensic Radiology in Medicolegal Autopsy Practice

Thomas B. Duong, BS, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Ray-Young Tsao, BS, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Sheila Spotswood, MD, 6230 La Cosa Drive, Dallas, TX 75248; Carolyn V. Isaac, PhD, 1000 Oakland Drive, Kalamazoo, MI 49008-8074; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007*

After attending this presentation, attendees will have gained an appreciation of the wide array of case types in which traditional radiography (X-ray (XR)) plays a valuable ancillary role in medicolegal autopsy performance.

This presentation will impact the forensic science community by providing an overview of case types in which traditional XR provides valuable information as a part of a complete medicolegal autopsy examination. This presentation will also provide important examples and reminders of various "pearls" as well as "pitfalls" concerning postmortem forensic XR.

Forensic radiology encompasses the acquisition, interpretation, and reporting of radiologic images for the purpose of medicolegal investigations, including, but not limited to, cases presented in a court of law.[1] In the context of death investigation, forensic radiology is an extremely important component in the evaluation of certain case types. While XR is the oldest and most widely used modality in forensic radiology, Postmortem Computed Tomography (PMCT) and Postmortem Magnetic Resonance Imaging (PMMRI) have been gaining interest in the forensic community.[1] This review will focus on XR, as it is the modality most readily available and widely used by forensic pathologists.

The American Society of Radiologic Technologists (ASRT) formed a task force in 2010 to investigate training discrepancies among personnel performing forensic XR. Focusing on improving image quality and safety of radiologic personnel, the study found large gaps in existing training paradigms.[2] For example, there are still no set training standards for forensic imagers in the United States, and there is wide variability in the forensic XR services available at different forensic autopsy centers.[2] The National Association of Medical Examiners (NAME) Inspection and Accreditation program requires that accredited medical examiners' offices "have access to radiographic equipment or services," but does not specify that such services actually be located within the medical examiner facility.[3] To better address these deficiencies, those who perform and interpret forensic radiologic imaging studies should have a broad understanding of the case types in which postmortem XR is useful.

Not every forensic autopsy requires postmortem radiologic imaging; however, in some case types, forensic XR is essential. The NAME Autopsy Standards state that X-rays must be taken in the following case types: infants, explosion victims, gunshot victims, charred remains, and cases in which decomposition obscures or causes loss of identifying features and/or evidence of trauma.[4] In addition, several other case types may benefit from postmortem XR, including cases of suspected air embolism, sharp force injury, and certain other trauma, including suspected child abuse cases, unidentified remains, elderly or disabled decedents with suspected abuse or neglect, certain cases with implanted medical devices, and others.

This review presents an overview of medicolegal autopsy case types in which postmortem forensic radiology provides valuable, sometimes essential, information. For each general category of case type, specific examples are provided, along with a discussion of important aspects of the radiologic exam, including potential pitfalls. Providing an overview of forensic radiology in medicolegal autopsy practice better enables the forensic pathology community to develop appropriate standards and to address the deficiencies that currently exist within the medical examiner community.

H17 Age Determination of Traumatic Subcutaneous Hematomas Using 3.0T Magnetic Resonance Imaging (MRI): A Feasible Approach

Kathrin Ogris, MD, Medical University of Graz, Institute of Forensic Medicine, Universitaetsplatz 4/II, Graz, Styria 8010, AUSTRIA; Thomas Widek, MSc, Ludwig Boltzmann Institute, Clinical Forensic Imaging, Universitaetsplatz 4/2, Graz, Styria 8010, AUSTRIA; Martin Söllradl, MSc, Medical University of Graz, Department of Neurology, Auenbruggerplatz 22, Graz, Styria 8036, AUSTRIA; Patrick P. Torreiter, MD, Medical University of Graz, Institute of Forensic Medicine, Universitaetsplatz 4/II, Graz, Styria 8010, AUSTRIA; Peter Grabuschnigg, MD, Medical University of Graz, Institute of Forensic Medicine, Universitaetsplatz 4/II, Graz, Styria 8010, AUSTRIA; Thorsten Schwark, PhD, Medical University of Graz, Institute of Forensic Medicine, Universitaetsplatz 4/II, Graz, Styria 8010, AUSTRIA; and Eva Scheurer, MD, Institut für Rechtsmedizin, Pestalozzistr.22, Basel 4056, SWITZERLAND*

After attending this presentation, attendees will recognize that the dating of soft tissue hematomas is particularly important for the reconstruction of criminal acts, such as child abuse cases, and thus may have significant medicolegal consequences. Accurate timing of injuries can define or at least set limits on a period of time during which a crime took place and can lead to an inclusion or exclusion of potential suspects.

This presentation will impact the forensic science community by underlining the importance of radiological methods in forensic medicine.

In clinical forensic medicine, it is often important to determine the time of origin of soft tissue injuries. As subcutaneous hematomas are usually not relevant for clinicians, only limited knowledge exists regarding the detection and dating of traumatic lesions in the subcutaneous fatty tissue using Magnetic Resonance Imaging (MRI); however, visual assessment of external hematoma color, the currently used method for estimating hematoma age, is unreliable due to inter-individual differences and its great inter-observer variability.[1] Consequently, dating of hematomas is difficult, due to the lack of an objective and reliable method. The first MRI studies revealed that the contrast behavior between blood and soft tissue could be used to obtain objective information on blood characteristics and temporal changes.[2] Based on initial results regarding artificially created hematomas, the goal of this study was to create an age estimation model and to validate this approach with real hematomas of known age.

In 30 healthy volunteers, without coagulation disorders or medication influencing blood clotting, artificial hematomas were created by injecting 4ml of autologous blood into the subcutaneous fatty tissue of the thigh after a basis MR scan. The artificial hematomas were scanned repetitively at different points in time (directly after the injection and 3h, 24h, 3d, 7d, and 14d after the injection). All measurements (n=180) were performed on a 3T scanner using a multifunctional coil. The MR sequence protocol consisted of a Proton Density-weighted Turbo Spin Echo (PDwTSE) sequence with fat saturation (Spectral Adiabatic Inversion Recovery (SPAIR)) in oblique and axial orientation. Data were analyzed by measuring signal intensities in the hematoma and fatty tissue. Afterward, contrast coefficients were calculated and averaged at single points in time and approximated by a mono-exponential fit.[3] Based on the fitting curve, three contrast cut-off values ($\geq$0.75, <0.75 – $\geq$0.60 and <0.60) for three age categories ($\leq$24h, >24h – $\leq$7d and >7d) were defined, and the suitability of these thresholds was validated with real traumatic hematomas. Therefore, in ten healthy volunteers (exclusion criteria as stated above), hematomas were created using blunt force (paintball shot to the thigh) following a basis MR scan. For all consecutive MR measurements (n=60), the same setup as for the artificial hematomas was used. Subsequently, blinded data evaluation and age categorization according to the predefined thresholds were performed.

Overall, nearly 70% of all investigated hematomas were categorized correctly. For the first age category (hematoma age $\leq$24h), a sensitivity of 73% and a specificity of 93% were found. The Positive Predictive Value (PPV) was 92% and the Negative Predictive Value (NPV) was 78%. In the second age category (hematoma age <24h – $\leq$7d), the sensitivity was 70%, the specificity 68%; PPV was 52%, and NPV was 82%. For the third age category (>7d), a sensitivity of 50%, a specificity of 92%, a PPV of 56%, and a NPV of 90% were calculated.

All real hematomas were detectable at each point of time using MRI. The majority of the tested hematomas was correctly classified, but most notable was the quite accurate age estimation of hematomas within 24h of origin. In forensically relevant cases of living victims, the detection of recent bruises is especially important because it is a well-known fact that not every hematoma is immediately visible. The results of this feasibility study reveal that the presented approach for hematoma dating is a suitable, objective, and examiner-independent method to detect and estimate the age of bruises. The implementation of an objective MR-based age estimation approach may consequently improve the forensic expert's report in court, and thus ensure a higher degree of legal certainty. The applicability of the proposed model will be further validated with a higher number of hematomas of different ages and additional MR sequences.

Hematoma, Age Determination, MRI

H18 A Comparison of Peak Sound Levels of Non-Contact and Contact Gunshots Into a Gelatin Block

Katrina Van Pelt, DO, West Tennessee Regional Forensic Center, 637 Poplar Avenue, Memphis, TN 38105; Paul V. Benson, MD, UTHSC/Shelby County Medical Examiner, 637 Poplar Avenue, Memphis, TN 38105; and Kevin Jenkins, MD, West Tennessee Regional Forensic Center, 637 Poplar Avenue, Memphis, TN 38105*

The goal of this study is to ascertain any difference between peak sound levels of contact and non-contact gunshots.

This presentation will impact the forensic science community by providing insight into whether or not a contact gunshot may reduce the auditory report of the gunfire.

Nearly all firearms create noise that is more than the 140 decibel level.[1] One author reported handgun and rifle sound levels at or near the muzzle ranging from 157 to 165 decibels.[2] A one-year retrospective review of suicidal contact gunshot wounds at the West Tennessee Regional Forensic Center, Memphis, TN, revealed 50 cases examined for either autopsy or external examination. Of those 50 cases, 5 cases included reported circumstances of an on-scene individual, other than the decedent, who reported that they did not hear the lethal gunshot auditory report.

This study will compare the sound levels of contact and non-contact handgun discharges for the calibers .22 long rifle, .38 special, and 9mm North Atlantic Treaty Organization (NATO) firearms fired into ballistic gelatin blocks. Many sound meters have a peak sound level limit of 130 decibels or less, thus testing of gunfire peak sound level at or near the muzzle requires high-quality, laboratory-grade sound meters with much higher decibel limits. The cost and availability of such sound meters could limit future duplication or expansion upon this study. Additionally, this study examines any difference in peak sound level versus highest possible peak levels; therefore, sound levels are obtained at a predetermined distance from the muzzle that does not overload an easily affordable, commercially available meter.

Peak sound level measurements were obtained utilizing a Dayton Audio® iMM-6 calibrated measurement microphone in combination with a sound level meter application from the National Institute for Occupational Safety and Health (NIOSH) installed on an Apple® iPhone® 6. The sound level meter application was programmed for NOISH standard, 80-decibel threshold level, C frequency weighting, fast-time weighting, and 3 decibel exchange rate. The 16" x 6" x 6", 10% clear ballistic gelatin block used meets the Federal Bureau of Investigation (FBI) protocol for testing terminal ballistics of human tissue. The hypothesis is that contact gunshots into a gelatin block will have lower peak decibel levels than non-contact gunshots into a gelatin block. The hypothesis is founded on the proposition that expanding gases will expand inside the gelatin block instead of outside the gelatin block, resulting in a lower peak decibel level. If the hypothesis is supported, it may explain why one-tenth of the suicidal gunshot cases in which an auditory observer was present did not hear the lethal gunshot.

This information may be useful in future death investigations and may be useful for medical examiners, medicolegal death investigators, law enforcement investigators, attorneys, and forensic scientists. The information from this project will better enable death investigators, medical examiners, and law enforcement officials to evaluate the validity of reports of circumstances surrounding and leading up to a death involving a contact gunshot wound.

Contact, Gunshot, Decibel

H19 The Accuracy of 3D-Printed Models Using Measurements Obtained From Volume-Rendered Computed Tomography (CT) Images

Kelly Weintraub, MD, OCME Maryland, 900 W Baltimore Street, Baltimore, MD 21223; Zabiullah Ali, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will appreciate the accuracy and usefulness of 3D-printed models created using measurements obtained from volume-rendered CT images.

This presentation will impact the forensic science community by elucidating the precision of volume-rendered models from CT images and raising awareness regarding their potential validity, reproducibility, reliability, and utility in providing visual aids for legal proceedings.

Forensic pathologists are frequently called upon to be expert witnesses in a wide variety of cases. Courtroom testimony often requires pathologists to explain scientific concepts and complicated injuries that can be confusing and difficult to describe to a jury. With the increasing availability of 3D printers, there has been a rising interest in using 3D models to enhance such testimony. A 3D reproduction of a skull with multiple blunt force injuries, for example, can help jurors better understand how, where, and with what force the decedent was struck. In addition to providing a nearly first-hand experience for an audience, 3D models create an opportunity to illuminate physically small but important autopsy findings that can be difficult to appreciate with a 2D photograph or autopsy report.

For a 3D model to be truly impactful in courtroom testimony, it should be a nearly exact representation of the deceased. An effort should thus be made to determine how accurately 3D-printed models reproduce objects that can actually be measured, such as bone. If there is a very small or negligible difference between the measurements from the 3D model and bone itself, a valid argument can be made to use 3D models whenever appropriate.

In practice, though, generating 3D models by means of physical measurements may be difficult. To render a 3D model of a cranium with blunt force trauma, for example, remains must be completely skeletonized to obtain accurate dimensions. A previous study at the Office of the Chief Medical Examiner for the State of Maryland investigated the accuracy of CT-derived dimensions from specific skeletal elements and determined there was a very minimal difference between physical measurements and those obtained from CT imaging. As such, a reasonable step is to create 3D models using data points from CT images of skeletonized remains. To validate the accuracy of these 3D reproductions, their measurements can then be compared to those of the original skeleton.

Seven skeletonized crania from the previous study were analyzed using multiple cranial measurements, such as orbital breadth, orbital height, nasal breadth, and nasal height. They were then scanned with a General Electric® (GE®) Light Speed RT-16 multi-detector scanner at the Office of the Chief Medical Examiner for the State of Maryland with a slice thickness of 1.23mm. The acquired images were then volume rendered using the GE® Advanced CT Workstation (AW-2 version aws-2.0-5.5).

The data from these CT scans will be converted to Stereolithography (STL) format using free software. The STL format will then be converted by free slicing software to generate a G-code file for 3D printing. 3D models will be created via a filament-based 3D printer with a 0.4mm nozzle printing. Models will be printed using Polylactic Acid (PLA) 1.75mm filaments and 0.1mm thick layers.

3D-printed models of a portion of the skulls from the prior study will be made and measurements from these models will be compared to those taken previously. Percent differences between these measurements will determine if there is an acceptable difference between the two values and validate the use of 3D models in legal proceedings as a demonstrative aid. An accurate representation of what was seen at autopsy could be an invaluable resource for all forensic pathologists.

3D Printing, Postmortem CT, Legal Proceedings

H20 Detection of Human Male DNA From Whole *Lucilia sericata* (Meigen) (Diptera: Calliphoridae) Larvae Using the Quantifiler® Trio DNA Quantification Kit

Laura Ann Nutton, PathWest, 221B Forrest Street, Palmyra, Perth, Western Australia 6157, AUSTRALIA; Brendan Chapman, BSc, Murdoch University, School of Vet & Life Sciences, 90 South Street, Murdoch, Perth 6150, AUSTRALIA; and Paola A. Magni, PhD, Murdoch University, School of Vet & Life Sciences, 90 South Street, Murdoch, Western Australia 6150, AUSTRALIA*

After attending this presentation, attendees will better understand how the Quantifiler® Trio DNA human quantification kit was used in a novel pilot study to demonstrate that it may be possible to detect human male DNA from multiple whole *Lucilia sericata* (Meigen) (Diptera: Calliphoridae) larvae up to 12 days post-colonization at 24°C under laboratory conditions.

This presentation will impact the forensic science community by revealing that the results from this pilot study indicate that these samples have the potential to extend the window for identification of offenders in cases of rape homicides in which the postmortem interval may exceed the efficiency of swab sampling.

Lucilia sericata (Meigen) (Diptera: Calliphoridae) is a forensically relevant blow fly species and is considered a primary colonizer of remains, both in Australia and around the world. In rape homicide cases, there can be a reduction in the integrity of the anatomical architecture of the cadaver as a consequence of larval feeding. Offender DNA deposited in the cadaver in rape homicides is important evidence that the sexual offense has occurred and the identity of the offender(s). In these cases, it may be that larvae, typically used for the estimation of time since death, now serve as an important reservoir for DNA storage and preservation. The Quantifiler® Trio kit is highly sensitive, capable of quantifying as little as 1pg/µL of human male DNA while also providing a measure of the template degradation.

In this pilot study, *L. sericata* larvae were reared under laboratory conditions at 24°C. The larvae were provided homogenized chicken liver mixed with human semen to mimic a vaginal environment post-coitus, and both larvae and swabs were collected for 12 days. The extracted DNA samples were concentrated with a vacuum desiccator and quantified with the Quantifiler® Trio DNA quantification kit in half-volume reactions using a QuantStudio™ 6 Flex. In this pilot study, it was shown that at 24°C under laboratory conditions, human male DNA could be quantified from multiple whole *L. sericata* larvae up to 12 days post-colonization. Furthermore, the human DNA from larvae typically exhibited lower levels of degradation compared to the swab samples.

Quantifiler® Trio, *Lucilia sericata,* Forensic DNA Analysis

H21 Infant Death Following Home Birth: A Case Report of Fatal Hypoglycemia in a Neonate

Leah M. Schuppener, DO, University of WI Hospital, Dept of Pathology, 600 Highland Avenue, Madison, WI 53792; and Robert F. Corliss, MD, University of WI Hospital, Dept of Pathology, 600 Highland Avenue, Madison, WI 53792*

After attending this presentation, attendees will better understand the importance of maternal clinical history, the histologic autopsy findings, and the role of Immunohistochemistry (IHC) in diagnosing islet cell hyperplasia in infant deaths due to hypoglycemia.

This presentation will impact the forensic science community by reviewing a case of fatal neonatal hypoglycemia in an infant born to a diabetic mother and by discussing the autopsy findings that can be used to support that cause of death.

Background: Pancreatic Islet Cell Hyperplasia/Hypertrophy (ICHH) refers to a proliferation and increase in size of the insulin-producing beta cells of the Islets of Langerhans in response to elevated serum glucose levels. ICHH is a common finding in Infants of Diabetic Mothers (IDMs) and a known risk factor for neonatal hypoglycemia. Although most cases are transient, neonatal hypoglycemia can be severe, resulting in infant death. Because hypoglycemia cannot be reliably diagnosed postmortem, ICHH may be the only diagnostic finding in infant deaths related to hypoglycemia, warranting histologic evaluation of the pancreas in all autopsies of IDMs.

Case Report: An infant girl at 37 weeks and 3 days gestation was delivered at home with midwife attendance to a 36-year-old *Gravida* 4 *Para* 3 (G4P3) mother with a history of insulin-dependent gestational diabetes and newly diagnosed, poorly controlled type 2 diabetes mellitus. The mother's previous pregnancy was reportedly complicated by gestational diabetes and transient neonatal hypoglycemia. At delivery, APGAR scores were seven and ten at one and five minutes, respectively; however, several hours after birth, the infant was reportedly not feeding well and was found to be severely hypoglycemic (28mg/dL). Formula and sugar water were administered, bringing the blood sugar to 48. Despite this, the heart rate decreased to 74 and the pulse oximetry went to 68. Emergency Medical Services (EMS) were called and the midwife immediately started Cardiopulmonary Resuscitation (CPR). The infant was transferred to an outside hospital and resuscitated for 70 minutes before being pronounced dead.

Methods: An autopsy was performed in addition to a review of the literature.

Results: External examination revealed the infant to be macrosomic (10 pounds at 11 hours of age) but otherwise without developmental abnormalities. The umbilical stump was desiccated but without purulence or drainage. Autopsy did not reveal evidence of trauma or significant natural disease. The placenta was not submitted for examination. Histologic examination of the pancreas revealed marked hyperplasia/ hypertrophy of the islet of Langerhans and insulin-producing beta cells. The cause of death was determined to be complications of neonatal hypoglycemia.

Discussion: A diagnosis of neonatal hypoglycemia should be considered as a potential cause of death or contributing factor in IDMs who have severe pancreatic islet cell hyperplasia and hypertrophy at autopsy. The finding of ICHH, although not specific, is strongly suggestive of maternal glucose dysregulation and may aid a pathologist in determining the cause of death in infants, particularly in the setting of absent maternal clinical history, prenatal care, and birthing history.

Islet Cell Hyperplasia, Neonatal Hypoglycemia, Infants of Diabetic Mothers

H22 Patterns and Trends of Teenage Homicides in the State of Maryland: A Forensic Autopsy Study (2006-2015)

Ling Li, MD, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223; Xiang Zhang, MD*, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223; Juan Ning, MD*, East China University of Political Science and Law, 112 Huayang Road, Shanghai 200046, CHINA; Daming Sun, MD, 1575 Wan Hang DU Road, Shanghai 200042, CHINA; Donghua Zou, MD, Forensic Science Institute, Shanghai, CHINA; Mary G. Ripple, MD, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will better understand the trends and patterns of teenage homicides in Maryland.

This presentation will impact the forensic science community by improving attendees' knowledge regarding the demographic distribution among teenage homicides and the circumstances as well as risk factors of teenage homicides. This presentation will also highlight the role of the forensic pathologist in the surveillance of deadly firearm injuries to teenagers and to our community.

Teenager mortality is an important public health issue because the majority of deaths among teenagers are caused by preventable external causes of injury, such as accidents, homicides, and suicides. Homicide is an extreme outcome of the broader public health problem of interpersonal violence. Homicide in children and youths has received a great deal of deserved publicity in recent years.

This study is a retrospective analysis of teenagers who were the victims of homicide in the State of Maryland from 2006 to 2015. Data analysis included: (1) the trends in teenage homicides from 2006 to 2015; (2) the demographic distribution among teenage homicides; (3) the circumstances of death and risk factors, including ethnicity, gang affiliations, known criminal history, drug and alcohol abuse; and, (4) the autopsy and toxicology findings and cause of death. Over the 10-year period, there were 4,945 homicides in Maryland. Of the 4,945 homicides, 554 (11.2%) were teenagers aged 12-19. The teenage homicide rate ranged from 0.49 to 1.41 per 100,000 population, with highest rate in 2008 and the lowest rate in 2014. The rate of male teenage homicide was more than seven times higher than the rate of females. Race distribution was also significant. African Americans comprised 87% of teenager homicides with a rate of 29.7 per 100,000 population, followed by Hispanic teenagers (5.64 per 100,000 population) and White teenagers (1.24 per 100, 000). The most common known motive/scenario was physical altercation/argument (11.7%, *N*=65), followed by robbery (2.5%, *N*=14), and drug-related (1.8%, *N*=10). The other known motives/scenarios included relationship issues, sexual assaults, and gang-related. There was a positive criminal history for 131 of the decedents. These included traffic violations, such as driving without a license, assault and battery with and without a deadly object, robbery, possession of drugs and narcotics, possession of firearms, attempted murder, and murder. Firearm injuries were the most common cause of teenage homicide (80.1%, *N*=447), followed by sharp force injuries (14.1%, *N*=790) and asphyxia (2.7%, *N*=15). Toxicology analysis revealed that 14.4% (*N*=80) of teenage homicide victims tested positive for alcohol and 18.6% (*N*=103) were positive for illicit drugs, such as cocaine, narcotics, phencyclidine, and methamphetamine.

Homicide is one of the leading causes of death in teenagers in the forensic autopsy population. As presented in this study, firearms and drugs significantly contribute to teenage homicides, primarily due to accessibility and availability. Thus, it is important to educate teenagers regarding the deadly consequences of firearms and drugs in school.

Teenager, Homicide, Forensic Autopsy

H23 An Evaluation of Elderly Deaths: A Retrospective Forensic Autopsy Study in Maryland (2005-2015)

Kendra Oghomwen Ireigbe, 6 Witherwood Court, Apt 3A, Towson, MD 21204; Allison Hausen*, 41 Dartmouth Road, Bridgewater, MA 02324; Feng Shi, MS*, Dian Diagnostics, Forensic Science Institute, Hangzhou, CHINA; Juan Ning, MD*, East China University of Political Science and Law, 112 Huayang Road, Shanghai 200046, CHINA; Donghua Zou, MD, Forensic Science Institute, Shanghai, CHINA; Xiang Zhang, MD*, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223; Ling Li, MD, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, State of Maryland, 900 W Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will better understand the epidemiological characteristics of elderly homicides in Maryland.

This presentation will impact the forensic science community by providing insight into the risk factors of elderly homicide, vulnerabilities of the elderly, and characteristics of the suspects. This presentation will also assist the community in developing effective prevention efforts.

Since 1900, life expectancy in the United States has dramatically increased, and the principal causes of death have changed. At the beginning of the 20th century, many Americans died young. Most did not live past the age of 65, their lives often abruptly ended by one of a variety of deadly infectious diseases. But, over time, death rates dropped for all ages, most dramatically for the young. By the dawn of the 21st century, the vast majority of children born in any given year could expect to live through childhood and into their eighth decade or beyond. Elderly care and mortality have become an important public health issue.

According to the definition set by the Center for Disease Control and Prevention (CDC), an elder person is generally regarded as someone aged 60 years or older. The objective of this study was to evaluate the patterns of the causes of death among the elderly whose deaths were investigated by the Maryland Office of the Chief Medical Examiner (OCME). Maryland consists of 23 counties and Baltimore city with a population of 5,773,552, of whom 1,058,253 (18.6%) are aged 60 or older. A total of 4,528 elderly deaths were investigated by the OCME during 2005 to 2015. Of the 4,528 cases, 1,899 (41.9%) individuals died of natural causes, 1,908 (42.1%) were due to accident, 283 (6.3%) committed suicide, and 234 (5.2%) were homicide victims. There were 205 (4.5%) individuals whose manners of death could not be determined after thorough death scene investigations and complete postmortem examinations.

This study focused on the epidemiological profile of elderly homicides in Maryland. The number of elderly homicide deaths ranged from 13 in 2013 to 30 in 2015, with the average homicide rate of 1.63 per 100,000 population per year. More males than females were homicide victims with the ratio *(M: F)*=1.85:1. Of the 234 cases, 48% were White, 48% were African American, 2% were Asian, and 2% were Others, which included Hispanic, Native American, and Unknown. The motive behind the elder homicide was known in 73% (*n*=170) cases. The study revealed that robbery (*n*=45) is the most common motive, followed by altercation (*n*=41) and financial issues (*n*=15). Investigation revealed that of the 234 cases, the perpetrators were family members in 31.2% (*n*=73) cases and roommates, neighbors, or other acquaintance in 18.8% (*n*=44) cases. Therefore, 50% (*n*=117) of the perpetrators were known by the victims. Forty-two (17.9%) victims were killed by strangers, 13 (5.5%) by police, and the suspect was unknown in 62 cases (26.6%). There were 18 deaths involving homicide/suicide. Of the 18 deaths, six victims were killed by their husbands who then committed suicide, one was killed by the wife, one killed by a son, and one by a brother. The main causes of the homicides/suicides were either financial or health issues. The leading cause of death in elderly homicide was firearm injuries, followed by sharp force injuries and blunt force injuries. There were seven victims whose deaths were the result of neglect and/or abuse by their family members.

In conclusion, this study indicates that the elderly have a higher risk of being victims of domestic homicides. Understanding the vulnerabilities of the elderly and the characteristics of suspects and victims is the key to developing effective preventive measures.

Elderly Homicide, Abuse, Forensic Autopsy

H24 WITHDRAWN

H25 The Microbiome of Human Cadavers Can Provide an Estimate of the Postmortem Interval (PMI)

Aaron M. Lynne, PhD, 1900 Avenue I, Box 2116, LDB #300, Huntsville, TX 77341; and Sibyl R. Bucheli, PhD*, Sam Houston State University, Dept of Biological Sciences, Box 2116, Huntsville, TX 77340*

After attending this presentation, attendees will better understand the human microbiome, how it changes during decomposition, and how it can be used to estimate the PMI.

This presentation will impact the forensic science community by serving as a novel tool for PMI estimation to be used in conjunction with current methods.

Estimating the time since death, or PMI, is critical to criminal investigations for identifying the deceased, validating alibis, and excluding possible witnesses. Estimating the PMI in unintended death scenes can be challenging, particularly when physical evidence is limited. Recently, researchers have developed models using the succession of microorganisms associated with cadavers to estimate the PMI.[1-5] These preliminary models indicate that microbial communities of decomposition can serve as temporal (succession-based) and spatial (origin-based) physical evidence.[2,5] This study proposes that the microbiome on human cadavers is successive and predictable and can be used to calculate the PMI.

Twenty-four human cadavers were placed outdoors to decompose under natural conditions at the Southeast Texas Applied Forensic Science (STAFS) facility. Two bodies were used for each experiment for four experiments per year (corresponding with the four seasons) and repeated each year for a total of three years. Microbial samples were taken from four body locations over the course of decomposition, processed for 16s ribosomal RNA (rRNA) sequencing using the MiSeq® platform and analyzed with QIIME™ 1.9.1.

Results revealed that microbial community structure did change through the course of decomposition of all body sets. While the bacterial community structure of initial samples varied (likely due to the variation of microbiome between individuals), all samples became more similar as decomposition progressed. Bacterial decomposer taxa (bacteria that differentially increased during decomposition) are shared across sample sites within experiments and across environments as well as the skin of host species. Therefore, the community assembly of cadaver microbial decomposers appears to be a generalizable process. A random forest regression model was used to model the PMI as a function of the changes in community structure and found the model to be able to provide accurate estimates of the PMI.

A potential impact of these results is the value of microbial data as physical evidence in medicolegal death investigations. The ability of PM microbes to estimate PMI is therefore a huge opportunity for forensic science to complement and improve upon current methods.

Microbiome, Decomposition, Postmortem Interval

H26 A Quantitative Assay for Accurate 16S DNA Quantification for High-Throughput Sequencing (HTS) Library Preparation of Microbial Samples

Raquel Green, 2723 Waterford Way, Apt 2D, Midlothian, VA 23112; Elena Martinez Planes, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; Denise Wohlfahrt, BS*, Virginia Commonwealth University, 2808 Bywater Drive, Apt 132, Richmond, VA 23233; Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; J. Brooks, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; and Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will better understand how to quantify microbial DNA from human samples for improved performance of microbial HTS applications.

This presentation will impact the forensic science community by presenting a new method that will improve performance of microbial sequencing in their laboratories.

Sequencing and classification of microbial taxa within forensically relevant biological fluids has varied applications from individualization to body fluid identification. A distinct advantage as a method for body fluid identification is that it can be easily implemented into a comprehensive HTS panel for human identity. The quantity of bacterial DNA from human samples is currently estimated based on the quantity of total DNA isolated from the sample. This method overestimates the quantity of bacterial DNA due to the mixed nature of the sample and consequently makes library preparation unreliable and variable. The purpose of this project was to develop a reliable assay that can accurately and specifically quantify microbial DNA within a mixed sample for reliable 16S library preparation in advance of high-throughput metagenomics sequencing.

Venous blood, saliva, semen, vaginal and menstrual secretions, urine, and fecal matter were extracted using standard DNA isolation protocols. A quantitative Polymerase Chain Reaction (qPCR) method was developed using universal 16s rDNA primers, and cycling conditions were adapted for qPCR. A commercially available microbial community DNA standard consisting of pooled genomic DNA from eight bacterial and two fungal species was used to develop an accurate, precise standard curve. Five samples of each of the previously mentioned body fluid samples were quantified to determine the dynamic range necessary to detect bacterial communities within all body fluids. Following qPCR optimization, 16S libraries were amplified and evaluated from several samples at various DNA concentrations in order to determine the precise amount of microbial DNA needed for successful HTS library prep. DNA extracts were quantified using a standard human DNA assay to calculate the average ratios of human DNA to bacterial DNA in each biological fluid. Last, the body fluids were subjected to HTS to evaluate the success of the chosen microbial DNA quantity optimal for library preparation.

Bacterial concentrations between body fluids ranged from 5.12ng/µl to 0.001ng/µl. Saliva, vaginal secretions, and menstrual secretions proved to have a higher abundance of bacteria compared to blood and urine, which are considered to be “sterile” in healthy individuals, and beyond dormant bacteria or bacteria collected from skin surfaces upon exit of the respective fluids. A sample was considered negative if quantified below 10pg/µL. Results from gel electrophoresis reveal that successful HTS sequencing can be expected with 20pg of microbial DNA as quantified using this novel method.

This research has shown that quantification of microbial DNA from DNA extracts of forensically relevant body fluids is successful and increases library preparation reliability and success.

Body Fluid Identification, 16S rDNA, Microbiome

H27 Insects Attached to Vehicles Traveling on Roads in Mexico

Carolina Núñez-Vázquez, PhD, Consejo Nacional de Ciencia y Tecnología, Mexico City, MEXICO*

The goal of this presentation is to provide information regarding insect data that may be attached to vehicles traveling on different roads in Mexico during various climatic seasons of the year; this information can be used when necessary to establish probable routes taken by a vehicle involved in an investigation.

This presentation will impact the forensic science community by explaining how the information generated will be highly supportive for research that requires establishing probable routes taken by a vehicle involved in an investigation.

Forensic entomology is a discipline that greatly supports the field of legal medicine due to the different manners in which it contributes, such as: the establishment of the postmortem interval or period of insect activity, possible circumstances of death, determination of toxic agents in the body, determination of a possible postmortem move of the body, and assisting in the establishment of possible roads on which a vehicle could have traveled (the latter being the focus of this research).

In Mexico, efforts are being made by researchers to make forensic entomology known and applied in the legal system; thus, it is necessary to generate scientific information that can be available for use when required by experts or researchers, since most of the information available comes from abroad and cannot always be applied to Mexico.

This research was conducted in the south/southeast area of Mexico and covered a large region that stretches from the Gulf of Mexico to the Pacific Ocean. Currently, different insects have been collected from vehicles that travel a 1.130km section of road that begins at the border city of Tapachula, Chiapas, and continues to Mérida, Yucatán. This route consists of different ecosystems, such as wet forest, cloud forest, rivers and lakes, and grasslands, and there is a great diversity of insects that are associated with these ecosystems.

This study will continue on the main roads of the country during different climatic seasons. The information obtained will be shared on the web through a georeferencing database of forensically important insects that researchers have been working on and can be consulted by experts who require this information.

Forensic Entomology, Ecosystems in Mexico, Insect Biodiversity in Mexico

H28 A Checklist of Forensically Important Blow Flies (Diptera: Calliphoridae) Collected From Human Remains in Central Indiana

Lauren Weidner, PhD, 901 W State Street, West Lafayette, IN 47907; and Caroline Garvin Hanau, BS, 44 Knoll Crest Court, West Lafayette, IN 47906*

After attending this presentation, attendees will better understand the importance of forensic entomology in criminal investigations. Attendees will also be informed about the species of Calliphoridae that colonize human remains in central Indiana.

This presentation will impact the forensic science community by providing case-by-case information pertaining to blow fly colonization of human remains. This will provide insight into blow fly biology and, furthermore, will increase knowledge of how seasonality, temperature, and other variables can play a role in the behavior of these forensically important insects. This presentation will also reveal the most common primary blow fly colonizers of human remains in the study area, which may be applicable to surrounding regions. To date, relatively little information has been published on blow fly species diversity and abundance on actual human remains; consequently, this study will help to fill this deficiency in the literature.

The field of forensic entomology has seen immense growth over the past several decades. Insects can be used to help answer questions pertaining to time since death or movement of remains in homicide investigations as well as providing insight in abuse and neglect cases; however, to improve our use of insects in these types of investigations, we must first know their distribution and biodiversity in a given range.[1] Several areas of the United States have records of surveying forensically important blow flies, using traps baited with beef liver or other decaying remains.[2-4] Many of these studies have shown that these types of traps can provide a sufficient sample of species that would be expected to colonize human remains in that area; however, given the logistical difficulty in sampling insects from human remains, very few studies conducted in the United States have been able to compare blow fly diversity in traps with those found on humans. This study presents the results from a survey of the forensically important blow flies found colonizing human remains in Central Indiana in 2016 and 2017. The findings from this work will provide baseline data that can be compared with future collections of forensically important blow flies on non-humans in Indiana.

Forensic Entomology, Blow Flies, Human Remains

H29 The Characterization of Louisiana Winter Carrion Decomposition and Its Effects on Accumulated Degree Day (ADD) Estimations

DeAnn L. Lemus, BA, Southeastern Louisiana University, Dept of Biological Sciences, Box 10736, Hammond, LA 70402; and Erin J. Watson-Horzelski, PhD, Southeastern Louisiana University, Dept of Biological Sciences, Box 10736, Hammond, LA 70402*

After attending this presentation, attendees will better understand the potential errors related to postmortem estimations based on ADDs of blow fly development during cooler months of the year. The goal of this presentation is to illustrate differences between observed thermal heat units versus those hypothetically available for growth.

This presentation will impact the forensic science community by demonstrating the importance of understanding the external (ambient) and internal cadaver sources of thermal heat at a crime scene.

Insects are poikilotherms (i.e., cold-blooded animals), thus, their growth and development rates are temperature-dependent. As a result, the summation of degree hours or days (thermal units) at a crime scene can be used to predict the overall energy budgets required to complete specific life stages of necrophilous insects present on human remains.[1] For entomologists to estimate postmortem intervals based on ADDs, three basic requirements must be met: (1) access to species-specific published development data; (2) scientifically based and general acceptance of species-specific development thresholds for growth (i.e., biological minimum and maximum); and, (3) accurate climatological information (ambient temperature, relative humidity, precipitation, etc.) associated with the crime scene or Cadaver Decomposition Island (CDI). Development data are available for various forensically important fly species (i.e., Calliphoridae, Muscidae, Sarcophagidae). In recent years, there has been an increase in forensic entomology studies focusing on improvements for both laboratory-reared blow fly development and thermal summation models (ADDs calculations), particularly associated with the curvilinear portion of insect; however, limited seasonal field experiments have been conducted to document the external and internal sources and fluctuations of thermal heat units associated with blow fly larval masses during cooler seasonal temperatures (i.e., biological minimums for growth).[2,3]

This study analyzed the effects of ambient and carcass temperatures throughout decomposition of adult swine carrion during the winter 2017 season in Hammond, LA. Winter decomposition of large vertebrate carcasses in Louisiana is characterized by prolonged carcass decomposition and periods of reduced insect activity due to fluctuating ambient temperatures.[4] Southeast Louisiana has a humid subtropical climate with long, hot, humid summers and short, mildly warm winters. This region rarely experiences freezing temperatures and regularly records dramatic ambient temperature swings within a 24-hour period (i.e., temperatures dropped from 27.2°C to 1.1°C overnight from January 25 to January 26, 2017). Wide-ranging temperature fluctuations occur sporadically through the cooler months in Louisiana and can cause considerable problems when postmortem estimations are based on traditional ADD formulas. The "typical winter forensically important species" of Calliphoridae in Louisiana varies greatly depending on how warm the winter is. Winter indicator species typically include *Calliphora vicina* (Robineau-Desvoidy), *Phormia regina* (Meigen), and *Lucilia coeruleiviridis* (Macquart), whereas spring and summer species include: *L. coeruleiviridis*, *Cochyliomyia macellaria* (F.), *Chrysomya rufifacies* (Macquart), and *Chrysomya megacephala* (F.). As a result of mild winters and occasional summer-like temperatures, it is not uncommon to recover crime scene evidence in December or January that includes all of the above species at a single site.[5]

This research includes two phases: (1) winter 2017 field study using three adult swine carcasses (36kg-50kg) placed in a hard-bottom flatwoods forest at Southeastern Louisiana University's Outdoor Classroom from January 26, 2017 to May 17, 2017; and, (2) laboratory study using Caron Products® Insect Growth Chamber to simulate observed winter ambient field conditions (thermal units minus carcass affect). Carcasses were sampled daily, every other day, biweekly, and weekly until day 112. Each sampling event included manual sampling of insects, digital photography, and multiple temperature measurements within the CDI, including: (1) FLIR® C2™ compact thermal imaging system (infrared camera) to document carcass surface temperatures and maggot mass activities within the carcass; and, (2) dual-digit temperature probe for internal carcass temperatures (mouth, anus), maggot mass, and ambient temperature. ADD estimations were calculated for *C. vicina* and *P. regina* using observed thermal heat units at the carcasses and climatology data from Hammond Regional Airport.

H30 The Necessity of Glycolic Acid Testing in Suspected Antifreeze Ingestion Deaths

Abigail J. Grande, MPH, WMU Homer Stryker MD School of Medicine, 1000 Oakland Drive, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Paul Moorman, South Bend Medical Foundation, 530 N Lafayette Boulevard, South Bend, IN 46601; and Prentiss Jones, Jr., PhD, WMU Homer Stryker MD School of Medicine, 300 Portage Street, Kalamazoo, MI 49007*

After attending this presentation, attendees will be more familiar with: (1) Ethylene Glycol (EG) and its toxic metabolites; and, (2) the necessity of EG and glycolic acid testing in forensic toxicology laboratories.

This presentation will impact the forensic science community by discussing a specific case that illustrates the need for glycolic acid testing to be made readily available at all forensic toxicology laboratories.

EG, a colorless, odorless, yet sweet-tasting poisonous diol is found in antifreeze and other industrial products, including hydraulic brake fluids and de-icing solutions.[1,2] The intoxicating effects related to EG ingestion are similar to those of ethanol; however, an ingestion of approximately 100mL is reportedly fatal in most adults.[1] EG poisoning is often intentional and is responsible for approximately 5,000 poisonings each year in the United States.[3] Symptoms of EG poisoning include central nervous system depression, seizures, cardiopulmonary complications, acute renal failure, and delayed neurological sequelae.[1]

EG is metabolized into glycoaldehyde and then into Glycolic Acid (GA), which is metabolized further into oxalic acid and formic acid.[1] Much of the EG is excreted through the kidneys, while its acidic metabolites, especially GA and oxalic acid, account for much of the toxicity of EG.[1] The oxalic acid precipitates as calcium oxalate in the kidneys and into the vascular endothelium of the brain and other organs.[2] Clinical diagnosis of EG intoxication is challenging due to the lack of testing capabilities for EG in anything but large clinical laboratories.[1] Although forensic toxicology laboratories are able to perform testing for EG, most toxicology screening methodologies do not detect the substance; requests for specific EG testing is required. Testing for the acidic metabolites of EG is even more scarcely available, even though the severity of EG intoxication has been directly correlated to the concentration of GA.[1]

This presentation reports a case of a 25-year-old male, found deceased on the floor of a hotel room. A departure note was located in the room, in addition to an empty package of over-the-counter sleeping pills, antifreeze/coolant, toilet bowl cleaner, dietary supplements, an empty bottle of a sleep aid, and an empty bottle of vodka. It was unclear how long the individual had been deceased, as he had not been seen for approximately nine days. Mummification of the distal extremities was present, consistent with early decomposition.

A complete postmortem examination yielded no immediate cause of death. Toxicological testing of postmortem blood was positive for diphenhydramine (87.7ng/mL), nicotine, and cotinine. Toxicological testing of postmortem blood and urine samples for all other substances was negative. Additional specified testing for EG was negative, as well. Histological examination identified crystalline precipitates consistent with calcium oxalate crystals within renal tubules. Additional investigation uncovered screenshots from the decedent's cell phone that involved questions entered into an online search engine such as "how long does it take to die from antifreeze?". In an effort to correlate histological and investigative findings, repeat EG testing was requested, which was again negative. Subsequent GA testing on a postmortem blood sample was obtained at an outside laboratory, with positive qualitative results.

While EG testing was negative, confirmation was made, via histologic identification of renal calcium oxalate crystals and subsequent positive GA toxicology testing, that the death resulted from an intentional antifreeze/ethylene glycol ingestion. The decedent most likely survived for some time, while fully metabolizing the EG into its acidic metabolites, causing organ system malfunction and death. The case serves to emphasize the importance of histologic examination of the kidneys in order to identify EG-related deaths. Additionally, this case illustrates that, in some scenarios, EG testing may be negative, but the identification of GA can be used to confirm that the death resulted from EG intoxication.

Ethylene Glycol, Glycolic Acid, Antifreeze

H31 When Thromboembolism is Inevitable — A Case Report of a Lung Cancer Patient's Unexpected Death

Alberto Alongi, University of Palermo Section of Legal Medicine, Via del Vespro, 129, Palermo 90127, ITALY; Emiliano G. Maresi, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY; and Antonina Argo, Via Del Vespro 127, Palermo 90100, ITALY*

The goal of this presentation is to share an uncommon thromboembolism case in a patient suffering from a Large-Cell Lung Carcinoma (LCC).

This presentation will impact the forensic science community by highlighting how pulmonary thromboembolism, a well-known complication of lung cancer, could give access to a medical legal litigation for "unexpected death."

Case: A 49-year-old Caucasian female was taken by ambulance to the hospital after complaining of uneasiness. On this occasion, pulmonary embolism was diagnosed using an angio Computed Tomography (CT) that also detected the presence of solid lesions and parenchymal thickenings, suggestive of an etheroplastic process. The biopsy, performed by bronchoscopy, diagnosed an anaplastic LCC. Moreover, during her hospital stay, venous thrombosis was detected in the lower limbs. Anticoagulant treatment with EBPM followed by warfarin therapy was initiated. After obtaining a good clinical response, the patient was released. Over the next four days, due to leg pain in the lower left side, new tests were conducted and an International Normalized Ratio (INR) of 1.99 was found (range 1.5–2.5). The patient was taken to the emergency room and exhibited blood pressure of 120/60mmHg, a heart rate of 119bpm, and oxygen saturation of 95%; after new hematochemical examinations, an incalculable INR and a positive result of D-dimer (75.2µg/mL) were found. The cardiological and the vascular surgery examinations highlighted the thrombosis of the left poplitial vein. The patient then chose to leave the hospital the same day. After again feeling ill, she arrived at the emergency room and died a few minutes later.

The autopsy findings were a fibrinous saddle thromboembolus present inside the pulmonary trunk; this is a known complication of severe, advanced lung cancer, from which the patient suffered. Cancer thrombosis pathogenesis is complex and involves multiple factors, including general factors, factors related to the inflammatory response of the tumor, and specific properties of cancer cells; the latter, in fact, release substances that induce inappropriate activation of blood coagulation, favoring thrombosis. A patient with an incalculable INR means that the blood was hyperthinned. In cases of deep venous thrombosis/embolism, the therapy is based on anticoagulation and, in this particular case, the drug therapy was over-effective. The presence of very effective anticoagulation (INR incalculable), as in this case, would not have allowed the use of other pharmacological/mechanical therapies.

This clinical scenario, framed as an unexpected death, has given rise to legal litigation. The case presented is not unusual, clinically speaking; in fact, in the absence of a clinical history, the case was treated as an expected death by the public prosecutor.

Unexpected Death, Lung Cancer, Thromboembolism

H32 Fatal Intrahepatic Hemorrhage After Nadroparin Use for Total Hip Arthroplasty

Alessandro Bonsignore, MD, PhD, University of Genova, Dept of Legal & Forensic Medicine, Via de Toni 12, Genova, Liguria 16132, ITALY; Cristian Palmiere, MD, Curml Centre Universitaire, Romand Medicine Legale, 4 chemin de la Vulliette, Lausanne 25 1000, SWITZERLAND; Francesca Buffelli, MD, Istituto Giannina Gaslini, Fetal and Perinatal Pathology Center, Largo G Gaslini 5, Genova 16147, ITALY; Francesco De Stefano, MD, University of Genova, Dept of Legal & Forensic Medicine, Via de Toni, 12, Genova 16132, ITALY; and Francesco Ventura, MD, University of Genova, Dept of Legal & Forensic Medicine, Via de Toni, 12, Genova 16132, ITALY*

After attending this presentation, attendees will better understand the physiopathology of spontaneous intra-hepatic hematoma, an exceptional but potentially lethal condition that may occur in patients who receive pre-operative and/or post-operative therapeutic doses of anticoagulants.

This presentation will impact the forensic science community by informing attendees of the possibility of intra-abdominal bleeding from the liver in patients who have received Low-Molecular-Weight Heparins (LMWHs), undergone major surgery, and present post-operative hemodynamic instability, especially in those with a pre-operative diagnosis of hepatic cyst.

LMWHs have become the predominant choice for deep venous thrombosis prophylaxis and treatment; however, their use may cause bleeding complications. Intrahepatic bleeding is exceptional and few cases have been described in the literature thus far.

A unique case of fatal intrahepatic hematoma complicated by nadroparin use in a 65-year-old woman with a hepatic cyst of the anterior part of the right lobe (diameter 2.8cm) admitted to the hospital for a unilateral total hip arthroplasty is presented. The woman did not have a history of any bleeding disorders, coagulopathies, thrombocytopenia, or diabetes and had never received anticoagulant or anti-platelet medication.

Pre-operatively and post-operatively, the patient received nadroparin calcium by subcutaneous injection beginning 12 hours before surgery at 0.4ml (3,800 IU) per day. On post-operative day nine, the patient complained of severe abdominal pain and developed abdominal distention, hypotension, and tachycardia. She was admitted to the intensive care unit and immediately transfused. There was no apparent source of bleeding at the surgical site; however, in view of the abdominal distension, a bedside ultrasound was performed that demonstrated free fluid in the abdomen, primarily around the perihepatic area. Her medical status continued to deteriorate despite supportive care and she went into shock. Attempted manual cardiopulmonary resuscitation was unsuccessful and the patient died before laparotomy could be performed.

A forensic postmortem examination was requested by the inquiring authorities due to suspicion of medical malpractice.

At autopsy, hemoperitoneum (2,000ml of blood and clots) was evident. A ruptured subcapsular hematoma involving the right lobe of the liver was observed, while no other pathological findings were found. The hemorrhage within the simple hepatic cyst (a biliary malformation, which does not have communication with the intrahepatic biliary tree, microscopically lined by a single layer of cuboid or columnar epithelial cells, resembling biliary epithelial cells) induced by the nadroparin use was likely responsible for the subsequent hepatic hematoma, liver rupture, and death.

Visceral injury following cardiopulmonary resuscitation (external cardiac massage), which has frequently been described in the literature (including cardiac, hepatic, splenic, and mesenteric lacerations), was also taken into consideration; however, no fractures of the ribs or sternum were observed at autopsy. Moreover, the epicardium, myocardium, mediastinum, lungs, aorta, and spleen were unremarkable and did not reveal contusions or lacerations. All of these findings tend to exclude the possibility that the hemorrhage within the cyst and the ruptured hematoma of the liver might have been complications of the cardiopulmonary resuscitation and support the hypothesis of a spontaneous intrahepatic hemorrhage.

In conclusion, the need for pathologists to be informed about rare clinical life-threatening conditions is illustrated in order to avoid erroneous evaluation of hypothetic professional liability profiles.

Low-Molecular-Weight Heparin, Intrahepatic Hemorrhage, Sudden Death

H33 A Case Series: A Massive Hepatic Subcapsular Hematoma as an Unexpected Hypoxic Complication — A Preventable Neonatal Death, Not a Latrogenic Rupture of the Liver!

Francesca Buffelli, MD, Istituto Giannina Gaslini, Fetal and Perinatal Pathology Center, Largo G Gaslini 5, Genova 16147, ITALY; Alessandro Bonsignore, MD, PhD, University of Genova, Dept of Legal & Forensic Medicine, Via de Toni 12, Genova, Liguria 16132, ITALY; Luca A. Ramenghi, MD, Istituto Giannina Gaslini, Neonatal Intensive Care Unit, Largo G Gaslini 5, Genova 16147, ITALY; and Ezio Fulcheri, MD, Istituto Giannina Gaslini, Largo G Gaslini 5, Genova 16147, ITALY*

After attending this presentation, attendees will understand the physiopathology of a massive Subcapsular Hematoma of the Liver (SHL) and its implications for the evaluation of potential medical liability profiles.

This presentation will impact the forensic science community by bringing attention to the possible complication of perinatal hypoxia, awareness of which may help avoid erroneous judgments of the performances of gynecologists and obstetricians. This presentation will also impact society and the clinical community by highlighting the fact that neonatal death due to this complication may be avoided through timely diagnosis and appropriate therapy.

SHL, consisting of a confined collection of a variable amount of blood that raises the hepatic capsule, rarely occurs in neonates and is often undiagnosed or misdiagnosed, even in postmortem examinations. SHL is an unstable condition caused by maternal, placental, or fetal factors that, in cases of pressure surges, can suddenly increase its volume, causing the rupture of the capsule. SHL has a non-specific presentation (characterized by unexplained hypovolemia or anemia) and should be considered, especially in infants with very low birth weight, preterm delivery, and/or suffering from intrauterine hypoxia. The diagnosis is frequently made at autopsy, with the main finding being hemoperitoneum.

As cardio-circulatory collapse is sudden and unexpected, such cases often arouse suspicion of professional negligence or malpractice. The collection of blood under Glisson's capsule sometimes leads forensic pathologists to misinterpret the SHL pattern as iatrogenic rupture of the liver.

The presented cases, which were studied at the Istituto Giannina Gaslini, a highly specialized Italian pediatric hospital, were as follows:

Case	Gestation (weeks)	Birth weight (grams)	Sex	Delivery	APGAR Score (1min and 5min)	Clinical presentation	Diagnosis of hemoperitoneum due to rupture of SHL	Outcome/Age at death (hours)
1	24+2	782	F	Vaginal, breech presentation	5 and 5	IUGR, suspected perinatal asphyxia, leucopenia and low platelet count	Postmortem	72
2	35+4	3065	F	Vaginal	0 and 0	Intrauterine fetal death	Postmortem	0
3	39+4	3410	M	Vaginal, two Kristeller's procedures	9 and 9	Severe respiratory distress with metabolic acidosis	Postmortem	16
4	29+2	960	F	Cesarean section	8 and 9	IUGR, respiratory distress, anemia, pathologic Eco Doppler	Early postnatal	Surviving

The first two cases underwent clinical autopsy and the third case involved a complete forensic approach. In all three cases, after clinical data collection, macro- and microscopic examination led to the conclusion that death had been caused by acute anemia due to hemoperitoneum, following the rupture of the hepatic capsule caused by the presence of a huge amount of sub-capsular blood.

The experience of the three fatal cases led neonatologists to suspect SHL in the fourth case; their early sonographic diagnosis of SHL was promptly followed by the infusion of blood and fresh frozen plasma, by continuous inotropic support with dopamine, and by hematoma drainage.

Hodge was probably the first to report a case of SHL.[1] The recent literature reports a varying incidence of SHL from 1.2% to 9.6% in autopsy series, and the severity of the bleeding is described as potentially life-threatening within minutes, before treatment can be initiated.

In conclusion, it should be stressed that cooperation and the exchange of information among clinical and forensic pathologists, neonatologists, obstetricians, and gynecologists is the only effective method of avoiding long and complex medical malpractice litigation. Achieving this goal requires widespread knowledge of the physiopathology of neonatal conditions predisposing to sudden and unexpected death, which are unrelated to malpractice. Among these, SHL should be considered in newborns affected by very low birth weight, preterm delivery, and intrauterine hypoxia. Additionally, from a clinical point of view, early diagnosis and treatment are essential in order to avoid fatal hemorrhagic shock.

Subcapsular Hematoma, Unexpected Complication, Neonatal Sudden Death

H34 Video Game-Associated Deaths in the Tidewater District of Virginia (2015-2017)

Alison Bybee, BS, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510; and Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510-1046*

The goals of this presentation are to examine the types of fatalities, in a medical examiner's system (forensic deaths), in which video games may have played a role and to consider the significance of video games, including distracted attention, in situations resulting in death.

This presentation will impact the forensic science community by examining and classifying deaths, via a medical examiner's system, that reveal a relationship to playing video games. Video game play may be an unrecognized contributor to forensic deaths; this presentation will provide an analysis of the types of cases encountered in one medical examiner's system and supports tracking whether video game play was present when monitoring forensic deaths.

Video games have been anecdotally reported in association with deaths from exhaustion or natural causes.[1,2] This presentation investigates the types and occurrences of forensic deaths associated with video games in a medical examiner's system in southeastern Virginia.

Nine deaths were identified on initial review. The ages of decedents playing video games when they died ranged from 14 to 48 years, with a mean age of 33.875 years; three of the decedents were teenagers. Two decedents were female; seven were male. Five of the decedents were White, four were Black, and none were Asian or Hispanic. Black race is overrepresented in these video game deaths in comparison to the current population of Virginia, which is 70.0% White, and 19.80% Black. Five of the deaths were witnessed, and four were unwitnessed. Six deaths occurred either while a decedent was playing a video game or the decedent was last seen alive playing a video game and was found dead next to the game. Five of these deaths were eventually determined to have a natural manner; one death was attributed as accidental, having combined natural disease with a methadone and olanzapine overdose. Cardiac factors were significant in five of the six natural deaths, including all of the teenagers (causes of death included dilated cardiomyopathy, anomalous right coronary artery origin, and cardiomegaly). One of the remaining deaths was a witnessed suicide by gunshot that occurred while the decedent was playing a video game; one death was an unwitnessed accidental drowning of a toddler in a backyard swimming pool that occurred while the caretaker was playing a video game.

Representative cases include: a 35-year-old man who developed a myocardial infarction while playing video games; a 14-year-old boy with an unknown history who underwent a witnessed collapse while playing video games and was found at autopsy to have a pituitary stalk/hypothalamic lipoma, as well as cardiomegaly; and a 44-year-old woman with no known history, aside from obesity, who underwent a witnessed collapse while playing video games and was found at autopsy to have unsuspected hypertrophic cardiomyopathy.

Discussion: Video games in relationship to death have not previously been studied in the Virginia medical examiner's system. These cases demonstrate that video games may be associated with sudden collapse from cardiac causes in teenagers and young adults as well as middle-aged people; it is unknown whether the game itself plays a role. Suicide associated with video games has been reported previously in teens; in this study, it occurred only in a 35-year-old man.[3] Questions raised by this case series include whether violent video games show any association with suicide, and whether video game addictive behavior is related to caretaker negligence.[2] These findings suggest that the association with and/or contribution of video games to sudden and unexplained death, particularly in childhood deaths, may need to be tracked for death review.

Video Games, Forensic Deaths, Death Review

H35 Sudden Cardiac Death and Epilepsy-Related Gene Mutations in Sudden Unexpected Death in Epilepsy (SUDEP)

Andrew S. Williams, MD, Ontario Forensic Pathology Service, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Anne E. Keller, MPH, The Hospital for Sick Children, Division of Neurology, 555 University Avenue, Toronto, ON M5G 1X8, CANADA; Robyn Whitney, MD, The Hospital for Sick Children, Division of Neurology, 555 University Avenue, Toronto, ON M5G 1X8, CANADA; Kris Cunningham, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Drive, Toronto, ON M3M0B1, CANADA; Michael S. Pollanen, MD, PhD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Elizabeth J. Donner, MD, MSc, The Hospital for Sick Children, Division of Neurology, 555 University Avenue, Toronto, ON M5G 1X8, CANADA*

After attending this presentation, attendees will be able to define SUDEP, understand the application of the definition to individual cases, describe contemporary theories on the mechanism of death in SUDEP, and list several "neurocardiac" genes currently under investigation as biomarkers of SUDEP risk.

This presentation will impact the forensic science community by updating attendees on the theoretical mechanisms of death in SUDEP and how these relate to potential individual genetic differences in "neurocardiac" genes and by reinforcing the definition of SUDEP for uniform cause-of-death certification in these cases.

Background: SUDEP is a sudden, unexpected, witnessed or unwitnessed, non-traumatic and non-drowning death in an individual with epilepsy, with or without evidence of a seizure and excluding documented status epilepticus, in which postmortem examination does not reveal a cause of death.[1] This definition does not predicate that the epilepsy be primary or idiopathic epilepsy. SUDEP is a leading cause of epilepsy-related premature mortality, with an estimated incidence of 1.22/1,000 persons with epilepsy, accounting for more deaths on an annual basis than Sudden Infant Death Syndrome (SIDS).[2] The precise mechanism by which epilepsy results in death remains unknown. Several theories have been proposed, including cardiac arrhythmia, respiratory failure, and "electrocerebral shutdown".[3]

A major difficulty in the clinical treatment of epilepsy is that it is not understood why some individuals die of SUDEP while other patients with epilepsy of a similar "severity" survive.[3,4] One possibility is that those who die of SUDEP have an underlying genetic mutation in a gene related to ion transportation or cardiac function that predisposes them to sudden death.[5] The current work was undertaken to assess the proportion of cases of SUDEP that demonstrate genetic changes in genes associated with sudden cardiac death and/or epilepsy.

Methods: Cases were selected from autopsies performed between January 1, 2014, and December 31, 2016, through the Ontario Forensic Pathology Service. Genetic testing was performed on 36 cases that had been signed out by the pathologist with the cause of death given as SUDEP and that had a sample suitable for genetic testing. Analysis was performed by GeneDx®. Each case was assessed by the Sudden Cardiac Arrest Panel ((SCAP) 120 genes) and Comprehensive Epilepsy Panel ((CEP) 87 genes).

Results: The 36 cases were comprised of 21 males and 15 females, with ages ranging from 3 years to 60 years. Variants of Uncertain Significance (VUS) in SCAP panel genes were detected in 20 cases (proportion with SCAP VUS: 55%) and involved 20 genes. VUS in the following genes was detected in multiple individuals (*n*): *SCN10A* (5), *RYR2* (4), *SCN5A* (2), *LMNA* (2), *TTN* (2). VUS in CEP panel genes were detected in 20 cases (proportion with CEP VUS: 55%) and involved 26 genes. VUS in the following genes was detected in multiple individuals (*n*): *PIGO* (2), *PNKP* (2). Ten cases were called negative on both the SCAP panel and CEP panel (proportion with SCAP or CEP VUS: 72%). No known pathogenic variants were detected. Further in-depth analyses of the VUS are ongoing.

Conclusions: This preliminary interrogation of genes associated with sudden cardiac death and/or epilepsy in a cohort of patients dying of SUDEP reveals a high prevalence of variants currently classified as VUS. Several genes displayed multiple variants across several individuals, which is an intriguing result, and further analyses of the specific variants are ongoing. Forensic pathologists should be aware that the leading mechanistic theories of death in SUDEP involve cardiac arrhythmia, respiratory failure, and electrocerebral shutdown. Genetic variations may account for why some patients with epilepsy die of SUDEP while others survive.

Epilepsy, SUDEP, Sudden Death

H36 A Novel Approach to Radiographic Identification of Skeletal Remains by the Z-Projection of Cranial Computerized Tomography (CT) Scans

Carlos J. Zambrano, PhD, OCME-Oklahoma, 901 N Stonewall, Oklahoma City, OK 73117; Angela Berg, MA, RN, OCME-Oklahoma, 1115 W 17th Street, Tulsa, OK 74107; Marc Allen Harrison, MD, OCME-Oklahoma, 901 N Stonewall Avenue, Oklahoma City, OK 73117; and Eric Duvall, DO, OCME-Oklahoma, 901 N Stonewall Avenue, Oklahoma City, OK 73117*

After attending this presentation, attendees will have a general understanding of how to process a CT image series into a z-axis projected image that can be used in conjunction with or in lieu of conventional antemortem radiographs to establish positive identification.

This presentation will impact the forensic science community by providing a methodology that simplifies a CT image series along the z-axis into one image that can be easily compared to a postmortem radiograph. Additionally, this methodology can be used to provide an antemortem radiograph of a missing person that could be used to compare to unidentified skeletal remains.

A primary objective of the medicolegal death investigation is to establish positive identification of unidentified remains via scientific means. In many instances, identity can be quickly determined via fingerprint comparison when the decedent has prints on record. Unfortunately, establishing positive identification becomes more challenging when the decedent is in advanced stages of decomposition or completely skeletonized, thus requiring the use of other methods, such as DNA or radiographic comparisons. Although DNA provides strong statistical support for identity, it is constrained by the availability of reference samples for comparison and has time and financial drawbacks regarding the processing and analysis of samples. Alternatively, radiographic comparisons are a likely means for positive identification because they obviate the practical and logistic limitations of other methods and are often readily available in many instances.

The use of CT imaging has steadily increased since its introduction into clinical medicine, resulting in the possibility of using antemortem CT data for identification purposes; however, most facilities that are tasked with conducting a medicolegal death investigation do not have access to CT equipment and cannot do slice-by-slice comparisons. Although CT scout films may be taken during a clinical exam, the image quality and/or view may not provide sufficient points of concordance to conclude a positive identification when comparing these antemortem films to postmortem radiographs. One solution to this dilemma is to utilize software that can project the CT image series along the z-axis (a z-projection) to create a 2D image. The resulting z-projection is essentially an inferior-to-superior radiograph, created by "flattening" the CT images, which can then be easily compared to postmortem radiographs taken using conventional equipment. This methodology is particularly useful when dealing with skeletal remains and could provide an additional approach for identification via radiological comparisons from antemortem CT images of missing persons to unidentified skeletal remains within the National Missing and Unidentified Persons (NamUs) database.

Creating a z-projection for identification purposes is, per research, a novel approach that can be easily accomplished using free and readily available software such as ImageJ. This presentation will discuss the following: (1) the steps to import and/or create an image series to generate a z-projection; (2) considerations regarding anatomical planes from a CT series in order to generate appropriate postmortem radiographs for comparison; (3) two examples of z-projection used to identify a decedent; (4) the value of generating z-projections for missing persons in NamUs to possibly aid in the identification of unidentified individuals; and, (5) future research using the projection of antemortem CT series for identification purposes. Implementation of software to create projected images from an antemortem CT series will provide forensic anthropologists, radiologists, and pathologists another avenue for the positive identification of remains.

Forensic Radiology, Positive Identification, CT Scan Project

H37 A Case of Congenital Laryngeal Stenosis Diagnosed at Autopsy

Angelina I. Phillips, MD, MUSC, 165 Ashley Avenue, Ste 309, MUSC908, Charleston, SC 29425*

After attending this presentation, attendees will understand the usual pathophysiology and presentation of congenital laryngeal stenosis and its diagnosis at autopsy.

This presentation will impact the forensic science community by demonstrating the methods necessary for recognizing and diagnosing cases of congenital laryngeal stenosis at autopsy.

Congenital laryngeal stenosis is a rare condition in which the diameter of the upper airway at any point from the epiglottis to the thyroid cartilages is markedly narrowed.[1-7] This condition is usually diagnosed early in pregnancy as a part of Congenital High Airway Obstruction Syndrome (CHAOS) with ultrasound-detected pulmonary abnormalities, abnormalities of the heart and diaphragm, and increases in amniotic fluid levels.[1-7] While most cases are sporadic occurrences, a few cases reported in the literature suggest an autosomal dominant inheritance.[1,4] CHAOS has reportedly occurred in association with other syndromes such as Fraser syndrome, short rib polydactyl syndrome, Vertebral Defects, Anal Atresia, Cardiac Defects, Tracheo-Esophageal Fistula, Renal Anomalies, and Limb Abnormalities (VACTERL) syndrome, or chromosomal abnormalities such as deletion of chromosome 5p and partial trisomy 5.[1-5] Laryngeal stenosis with prenatal care is usually manageable and survival rates are good when emergent treatment is provided; however, if the stenosis goes unrecognized prior to delivery, the mortality rate can range between 80% to 100%.[2,6,7]

This presentation describes a case of congenital laryngeal stenosis diagnosed at forensic autopsy of a 39-week term gestation infant delivered to a 36-year-old *gravida* 5 *para* 3 mother. The maternal gestational history was largely unknown except for reports of a prior pregnancy ending with preterm delivery of a still-birth fetus who had numerous physical deformities. The prenatal history of the current pregnancy was unremarkable except for gestational diabetes; the mother received regular ultrasounds that exhibited appropriate fetal growth and movement. The mother declined an amniocentesis for genetic testing.

After presenting for induction of labor, the infant was delivered in the hospital and was noted to have APGARs of 1, 1, 1, and the following physical abnormalities: "webbed fingers, small ears, abnormal genitalia, and left eye deformity." The infant survived for approximately one hour, during which time she experienced marked respiratory distress and eventually died. The case was referred to the forensic pathologist by the coroner's office for autopsy.

At autopsy, the body measured 49cm long and weighed 3,200 grams. Significant external findings included minor facial abnormalities, including a small left eye with a partially fused lid, a small left nasal opening, syndactyly, and ambiguous genitalia. Internally, there was stenosis of the larynx at the level of the glottis/subglottis and lumen diameter of ~0.2cm; airways distal to the stenosis were dilated with mucus congestion. Additionally, the right and left lungs weighed 38.3 grams and 27.2 grams, respectively, and were congested but otherwise normal in appearance. Ascites was noted with approximately 20ml of serous fluid in the peritoneal cavity. Microscopically, there was vascular congestion of the alveolar capillaries and numerous intra alveolar foamy macrophages. The remaining organs examined were all histologically appropriate for gestational age.

In this case, the clinical presentation and finding of markedly narrowed larynx are consistent with a death due to the obstruction/constriction of the airway; thus, the primary cause of death was determined to be due to congenital laryngeal stenosis. The reported case is an unusual presentation of a very uncommon anomaly.[8] The presentation of congenital laryngeal stenosis at a full-term delivery is rare, especially when the presentation is unexpected.[8]

Congenital Laryngeal Stenosis, CHAOS, Forensic Pathology

H38 Congenital Hypertrophic Cardiomyopathy in a Neonate: A Rare Etiology for Unexpected Death

Nathan S Shaller, MD, Wake Forest Baptist Medical Center, 1 Medical Center Boulevard, Winston Salem, NC 27157; Anna G. McDonald, MD, Wake Forest Baptist Medical Center, 1 Medical Center Boulevard, Winston Salem, NC 27157; and Patrick E. Lantz, MD, Wake Forest Baptist Medical Center, 1 Medical Center Boulevard, Winston-Salem, NC 27157*

The goal of this presentation is to highlight the necessity for a thorough cardiac examination, prenatal and pediatric medical record review, and discussions with family members when faced with the unusual finding of an enlarged heart in an infant.

This presentation will impact the forensic science community by highlighting the need to consider a broad differential when approaching a hypertrophic heart in the infant population and recognize the presence of posterior rib fractures due to resuscitative efforts.

Full postmortem examinations are critical in sudden unexpected infant deaths. This study presents a rare case of congenital hypertrophic cardiomyopathy with asymmetric hypertrophy, regional myofibrosis with calcifications, and myofiber disarray causing sudden death in a neonate.

A 2-week-old male neonate with no significant past medical history made an unusual crying sound prior to becoming unresponsive while being fed a formula bottle by his biological father. Paramedics responded and found him apneic and asystolic. Resuscitative efforts were continued in route to a local children's hospital with no change in clinical status. His mother had an unremarkable prenatal course with no evidence of diabetes and a normal 19-week anatomy ultrasound. The infant was born at 38 weeks and 0 days gestation via emergent Cesarean section due to fetal decelerations. Birth weight was 3.35kg (25 to 50 percentile) with a head circumference of 35cm (25 to 50 percentile). Initial APGAR scores were 8 and 8 at one and five minutes, respectively. He received supplemental oxygen at birth due to a dusky appearance and responded appropriately. A soft, grade II systolic murmur was heard but resolved prior to hospital discharge. He appeared healthy with no medical issues. Notably, the newborn screen sent at approximately 36 hours of life was within normal limits and he passed the congenital heart disease screen.

Autopsy findings included an enlarged heart with right ventricular enlargement and asymmetric hypertrophy of the interventricular septum (thickness=1.5cm) as compared to the left ventricle (thickness=0.6cm) and an accompanying dilated ductus arteriosus. Multiple regions of white, firm fibrosis were present throughout the myocardium, with the largest measuring up to 1.0cm in the interventricular septum. Microscopically, multifocal hypocellular myofibrosis was present with adjacent calcification and myocyte disarray, seen most prominently in the interventricular septum with extension into adjacent papillary muscles. No additional cardiac anomalies were identified. Other findings included a tetra-lobated right lung. No dysmorphic features were present. Rib fractures were present anterolaterally (right #3-4, left #3-4) and posteriorly (right #3-6, left #2-7) with minimal soft tissue hemorrhage due to cardiopulmonary resuscitation.

This neonate was diagnosed with congenital (infantile) hypertrophic cardiomyopathy. The diagnosis of hypertrophic cardiomyopathy requires left ventricular hypertrophy with a notable absence of other abnormalities to explain the degree of hypertrophy. Infantile hypertrophic cardiomyopathy is extremely rare, with an annual incidence of 3.6 per one million children. Clinical signs are variable and range from presenting with a heart murmur, evidence of heart failure, or sudden death, such as in this case with discovery at the time of autopsy. The etiology for hypertrophic cardiomyopathy is equally heterogenous in the pediatric population and includes glycogen storage diseases, mitochondrial disorders, neuromuscular disorders, certain genetic syndromes (most commonly Noonan syndrome or Beckwith-Wiedemann syndrome), infants born to obese or diabetic mothers, and inherited or *de novo* mutations in the sarcomeric protein genes. No evidence of a storage disorder, syndromic findings with dysmorphic features, or maternal diabetes was ascertained in the clinical history or postmortem examination. Both parents of the infant subsequently have had normal cardiac anatomy on echocardiograms and normal electrocardiograms. Genetic testing has not been performed at this time. This case highlights the need to consider a broad differential when approaching a hypertrophic heart in the infant population and recognize the presence of posterior rib fractures due to resuscitative efforts.

Hypertrophic Cardiomyopathy, Sudden Unexpected Infant Death, Posterior Rib Fractures

H39 Acute Neonatal Appendicitis — An Autopsy Diagnosis

Asha Sigei, East Tennessee State University, 1185 W Mountain View Road, Apt 2210, Johnson City, TN 37604*

The goal of this presentation is to present a case of ruptured acute appendicitis in a 19-day-old neonate.

This presentation will impact the forensic science community by illustrating how acute neonatal appendicitis remains a diagnostic challenge. The majority of cases are discovered only during postmortem examination. A high index of clinical suspicion and meticulous analysis of clinical features can lead to an early diagnosis and a more timely surgical intervention to reduce its associated high mortality rate.

Acute neonatal appendicitis is a very rare condition with high mortality. It remains a diagnostic challenge despite the availability of advanced diagnostic imaging. Reported here is a 19-day-old male baby who presented with a clinical picture of a possible small bowel obstruction, and was found at autopsy to have a perforated appendicitis.

Case Report: This case involves a 19-day-old male infant born at full term via spontaneous vaginal delivery following an unremarkable pregnancy. He received a Hepatitis-B vaccine shortly after the delivery and stayed in the newborn nursery for two days prior to discharge. He was diagnosed with thrush at ten days old and was managed with nystatin.

He presented at an emergency department with one-day complaints of increased fussiness and difficulty feeding and was noted to have a slightly distended and tender abdomen. A septic workup was performed and included a Complete Blood count (CBC) (revealed leukocytosis of 28.5k/UL), a negative blood culture, a lumbar puncture (clear fluid with a negative Gram stain), urinalysis (25mg/dL protein with negative nitrite and leukocyte esterase), and elevated C-Reactive Protein (CRP) (194.6mg/L). The patient was subsequently started on antibiotics for neonatal fever. During his three days of hospitalization, the clinical team requested a transfer to the pediatric Intensive Care Unit (ICU) due to worsening of abdominal distension, increasing white count to 43.81k/UL, and suspicions of small bowel obstruction.

The patient further deteriorated during transfer and was significantly obtunded on arrival to the pediatric ICU. He was grossly edematous, with abdominal distension, anisocoria, bruising along the right flank, absence of reflexes, and minimal spontaneous movement. Radiographic studies performed included a Kidneys, Ureter, and Bladder (KUB) (showed absence of air in the rectum, edema of the bowel walls, but no free air on cross-table film), an abdominal X-ray (showed a mild-to-moderate degree of gaseous distention of the bowel), and a chest X-ray (showed bilateral pulmonary opacities). The patient was acutely managed for hypoxia associated with severe metabolic acidosis, hypokalemia, hypotension, and hypoglycemia. He subsequently had several episodes of recurrent wide complex tachycardia and pulseless electrical activity. After multiple resuscitations, he was pronounced dead several hours after the transfer.

An autopsy was performed and the most significant findings were gangrenous appendicitis with evidence of rupture and marked acute serositis identified in the rectal serosa and focally in the mesenteric peritoneum. There was dilation of the transverse colon and proximal descending colon but no obstruction of the bowel was identified.

Discussion: Acute neonatal appendicitis is a very rare clinical entity with 0.04%-0.2% reported incidence.[1] It is more common in males, with up to a half of all reported cases involving premature infants.[2] The different factors attributing to the low incidence include funnel-shaped appendix with a wide opening into the cecum, soft liquid diet, lack of fecalith, recumbent posture, and the presumed infrequent occurrence of viral-induced lymphatic hyperplasia in the periappendiceal region.[3]

The rarity of this disease coupled with the associated diagnostic challenge largely contributes to the reported high mortality rate of up to 28%.[2] Abdominal distension, a non-specific clinical feature, is the most common clinical feature present in up to 89% of the patients and was one of the presenting features of this patient. Other clinical features are non-specific and include vomiting, refusal to feed, irritability, temperature instability, and leukocytosis.[4] Radiological findings also include non-specific findings such as abnormal gas pattern, free peritoneal fluid, obliteration of psoas shadow, right iliac fossa abscess, and a thickened abdominal wall.[5] Other useful diagnostic tools include abdominal ultrasonography and spiral computed tomography.

Perforation plays a significant role in determining the prognosis. Due to the delayed diagnosis and management, the incidence of perforation and subsequent peritonitis is high in neonatal appendicitis. Other factors contributing to the increased susceptibility to perforation in this population include the thin appendiceal wall, a non-distensible cecum, a relatively small omentum insufficient to wall off infection, and a small capacity of the abdominal cavity, resulting in easy dissemination of infection.[6]

In conclusion, similar to this case, acute appendicitis remains a diagnostic challenge and, in the majority of cases, is discovered only on postmortem examination. A high index of clinical suspicion and meticulous analysis of clinical features can lead to early diagnosis and more timely surgical intervention to reduce the associated high mortality rate.

Neonatal Appendicitis, Rare Clinical Entity, High Mortality

H40 The Sixth Biggest Earthquake in the World: The Working Strategy of a Forensic Identification Team Among Chaos

Carlos A. Gutierrez, MS, Chaminade University of Honolulu, 3140 Waialae Avenue, 115 Wesselkamper Science Center, Honolulu, HI 96816*

After attending this presentation, attendees will understand the organization of the identification team and their importance during the 8.8 earthquake and tsunami that affected the coast of Constitucion City, Chile, on February 27, 2010.

This presentation will impact the forensic science community by indicating that identification processes were successful in this huge mass disaster event.

On February 27, 2010, Chile was affected by the sixth biggest earthquake in human history. The 8.8mww (per the United States Geological Survey (USGS)) had a duration of 3 minutes and 45 seconds and was felt by nearly the whole country. After the earthquake, three tsunamis hit the Chilean coast and created more damage in Constitucion City, Concepcion, and Talcahuano.

The city with the most deceased as a result of this natural disaster was Constitucion. Constitucion is a city in the central south coast of Chile, 359 kilometers south of Santiago (Capital City); they have an urban population of 37,000. At the moment of the mass disaster, Constitucion had a local medical examiner's office (the SML) and a local office of national registration ID office (the RCI). The nearest police forensic laboratory was Laboratorio Carmelo Garcia (LABOCAR) located 111 kilometers away in Talca City.

Immediately after the disaster, all utilities (water, electricity, and gas) and communications were lost with some damage to freeways and highways. The chiefs of the SML, RCI, and LABOCAR created an ad hoc protocol to work collaboratively and create a temporary morgue in the Municipal gymnasium where the SML and LABOCAR received, analyzed, and identified all the victims' bodies.

The main goal for SML and LABOCAR was to examine the bodies and verify if they had injuries related to the event, complete the antemortem International Criminal Police Organization (INTERPOL) form, fingerprint all victims, and attempt preliminary identification with the relatives of the victims. The goal for RCI was to confirm the identity using the preliminary identification and the fingerprints of the victims.

The identification process was divided into three steps: (1) Step 1 — Although a large victim pool, identification was achieved with relative ease using fingerprints and visual identification by next of kin; this step was completed three days after the earthquake; (2) Step 2 — Identification was more difficult due to decomposition, which was observed in nearly all bodies; this step was complete six days after the earthquake; and, (3) Step 3 — Identification using visual appearance or fingerprints was not possible due to decomposition. The only techniques useful for identification were DNA and forensic odontology; this stage was completed 33 days after the earthquake.

During the work on this mass disaster in Constitucion City, the identification team received 94 decedents between February 27 and March 31, 2010. Of the total victims, 51 were female and 43 were male; the ages of the victims were between 0 and 89 years. The cause of death in the victims was crushing, suffocation, drowning, heart attack, polytrauma, and cranial polytrauma.

This collaborative effort resulted in the positive identification of 100% of the victims. The visual and fingerprint identification process was successful in 89 cases. In the other five cases, the identification was confirmed by forensic odontology and reconfirmed with DNA.

This study is significant for several reasons. Understanding the importance of teamwork in the successful victim mass fatality identification process, in difficult/challenging working conditions, along with strategies to work with other agencies is essential. This event is an example of effective interagency collaboration in an emergency situation (without a pre-existing protocol).

Earthquake, Tsunami, Disaster Victim Identification

H41 Differentiating Impact and Heat-Related Skeletal Fractures From a Small Plane Crash

Cassie E. Skipper, MA, University of Nevada, Reno, 1664 N Virginia St, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia St, Reno, NV 89557; and Laura D. Knight, MD, Washoe County Regional Medical Examiner's Office, 990 E 9th Street, Reno, NV 89512*

After attending this presentation, attendees will have a better understanding of skeletal trauma resulting from thermal damage and/or a rapid deceleration event.

This presentation will impact the forensic science community by outlining the differences between skeletal fractures induced by heat and those related to rapid deceleration events. In a medicolegal context, it is important to distinguish the cause of fractures encountered during autopsy. Because heat-related and peri-mortem fractures can be difficult to distinguish, this information will serve to better inform the medicolegal community and increase the accuracy and speed of trauma identification in similar scenarios.

To illustrate differences in skeletal trauma sustained from fire or impact events, this presentation will present a case study of remains recovered from a plane crash. In November 2016, a fixed-wing air ambulance carrying four passengers crashed in Elko, NV. The plane subsequently caught fire, leading to both impact fracturing of the skeletal remains as well as burning and heat-related fractures. The main goal of this investigation was to identify the respective trauma patterns on each decedent and attribute them to the impact or to thermal causes.

Fracture type, location, and cause were documented on each individual and digital photographs were taken in the medical examiner setting, without extensive anthropological preparation. The majority of the fractures were found to result from the impact as evinced by unburned tissue surrounding the trauma sites. Further, these fractures were in the mid-shaft of many long bones, which is also commonly seen in high-velocity impact trauma. Heat-related fractures were seen in areas of charring and burning of the skeletal and soft tissues. The standard pugilistic posture, so-named due to its similarity to a boxer's stance, was observed in two individuals, with associated heat fractures of the bones of the hand and wrist. Pugilistic posture results from protein coagulation and shortening of the muscle fibers in the extremities and torso due to thermal effect; thermal fractures are also commonly present in the extremities, and these fractures are due to heat rather than occurring as a result of any mechanical force of the thermal contracture of the muscles. Several fractures exhibit limited charring (i.e., evidence of thermal damage does not extend across the entirety of the fractured surface) and are likely related to the impact event.

Overall, fractures that exhibit no or incomplete heat damage (i.e., lack charring and/or calcination) can be related to other forces (in this case, a rapid deceleration event). Because heat fractures lack the kinetic energy required to extend into unburned areas, any fracture located in an area unaffected by thermal change can be attributed to the impact event. Fractures related to fire exposure will exhibit fire damage; heat fractures result when heat breaks down the connective tissue, thereby exposing more of the bone to thermal destruction.[1] When fractures exhibit full or incomplete charring/calcination, careful examination is required to determine whether they are due to heat exposure or were sustained from other forces before exposure to the fire. The location and suspected cause of trauma can aid in making this determination, as this case study highlights. Furthermore, such examinations can be made in the typical medical examiner's office setting with some forethought to consider the differential diagnosis for these types of trauma.

This report presents a case study of four individuals from a plane crash and outlines the impact and heat-related skeletal trauma. The means to differentiate the two is also discussed, which includes a careful consideration of the morphology of the fractures and the unique events of the case.

H42 Central Italy Earthquake: A Disaster Victim Identification (DVI) Experience

Chantal Milani, DMD, MS, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Andrea Berti, PhD, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Filippo Barni, PhD, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Luca Gasparollo, BS, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Cesare Rapone, BS, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Carlo Belardo, Lyceum, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Veronica De Pisapia, JD, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY; Fabio Crescenzi, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 10191, ITALY; Enrico A. Risso, MD, MFM, MFFLM, Piazza Colombo 3/16 A 5, Genova 16121, ITALY; and Luigi Ripani, PhD, Carabinieri R.I.S. - Scientific Investigation Dept, viale Tor di Quinto 119, Rome 00191, ITALY*

After attending this presentation, attendees will better understand the different approaches of DVI, taking into account the challenges and pitfalls that may occur using the same standard protocols in different and complicated cases.

This presentation will impact the forensic science community by sharing the multidisciplinary experiences regarding the earthquake that hit Italy during the night of August 24, 2016. The 6.0-magnitude earthquake caused the death of 297 people, hitting the central part of Italy in the regions of Lazio, Umbria, and Marche. The cities and villages which experienced the worst damage were Amatrice, Arquata del Tronto, Peschiera del Tronto, and Accumuli. Those cities and villages were close to the epicenter of the earthquake.

The DVI forensic team included a biologist, a fingerprint expert, a forensic anthropologist/odontologist, a forensic photographer, and general assistants. The situation was complicated by the fact that, between the ruins, there was not enough space for a mortuary camp, and the examinations had to be performed on the ground, in an extremely hot environment, and during continuous tremors due to the aftershock. The logistic DVI center was set up in Amatrice, one of the most badly hit areas, with very limited road and bridge access, the majority of which collapsed during the earthquake or just after. Because of the limited amount of space available (approximately 3,000 square meters), the family liaison officers had to work very close to the postmortem examination area, rendering their job extremely difficult.

The bodies recovered from the ruins were placed in body bags and sent to the camp with an identification number, precise address of the recovery, and a "possible ID" (i.e., the name or the names of missing people from that address). All the data were collected in a database. The relatives and the next of kin in the immediate area were interviewed in order to collect relevant data for identification, such as photographs, information about clothing, personal belongings, prosthetic implants, scars, tattoos, and distinguishing marks. The names of the family doctor and dentist were also collected to obtain further medical information and, if possible, a dental chart.

During the initial examination, forensic photography of the body, clothing, and personal belongings was performed; fingerprints, DNA samples, and a dental chart were obtained; and a preliminary examination was conducted of the trauma on the bodies. A quick networking system between the forensic anthropologist/odontologist and the victims' doctors and dentists was set up to obtain medical information as quickly and efficiently as possible. This system could not be applied to those medical practitioners whose offices were affected by the earthquake or located in areas that could not be reached.

Since the earthquake occurred at 3:36 a.m., the location that victims were recovered was crucial for identification; in fact, the majority of victims died in their sleep, as a quick escape was nearly impossible.

Despite the many problems encountered, the hot climate, and the limited space, all identification processes were completed within two days by means of anthropological profiles, dental charts, and the examinations of personal belongings. The identification of the remaining bodies (3% of the victims) was conducted by DNA analyses and the further acquisition of dental charts, requiring a few more days. Fingerprint analyses were only performed on immigrants.

DVI, Identification, Mass Disasters

H43 A Fatal Sex and Drug Party: Understanding the Real Cause of Death

Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Isabella Aquila, MD*, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Aldo Di Nunzio*, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Luca Lepore, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Michele Di Nunzio, BS, Biogem scarl, Via Camporeale, area PIP, Ariano Irpino (AV) 83310, ITALY; Matteo Antonio Sacco, MD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Antonio Perna, MD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will better understand the death differential diagnosis of the mechanical obstruction of external airways, the depressing effects of heroin on the respiratory centers of the brain, and the anaphylactic disorder caused by the interaction of heroin with mast cell receptors.

This presentation will impact the forensic science community by providing results of a multidisciplinary collaboration, which is fundamental to understanding the cause of death associated with the use of heroin in drug addicts. Moreover, it is hoped that tryptase levels in the blood and in the pericardial fluid will be routinely analyzed in heroin death cases.

In early February 2015, two drug dealers organized a sex and drug party in a flat located in the vicinity of Naples, Italy. The police were wiretapping them. During a telephone conversation, the police heard one of the drug dealers say, "She died by suffocating on by my big penis during the fellatio … we left her on the street." The next morning, a resident found a body on the street near the flat where the party took place. The forensic expert who arrived at the scene said the victim was allegedly 30 years of age, 174cm tall, and had presumably died the previous day. There was a reddish fluid discharge around her mouth and nose. Her leggings were lowered and the gluteal region exhibited signs of dragging via an inflammatory infiltrate. The corpse was identified as the transsexual BC.

The autopsy did not reveal any signs of venipuncture or violence. The victim hadn't been raped prior to death. The medical examiner found pulmonary congestion and general congestion of the parenchymal organs resulting from blood stasis. Petechial hemorrhages and brain swelling were also found. The examiner took oral, vaginal, and anal swabs for genetic analysis, and blood, urine, and bile for toxicological tests. Only the vaginal swabs were positive for the presence of sperm, and the DNA profile obtained was a mixture comprised of BC's epithelial cells and sperm cells of unknown people. The blood tests were positive for morphine (251ng/ml), 6-monoacetylmorphine (15ng/ml), codeine (32ng/ml), cocaine (167ng/ml), and benzoylecgonine (350ng/ml). The urine analysis was positive for morphine (224ng/ml), codeine (11ng/ml), cocaine (39ng/ml), and benzoylecgonine (1,172ng/ml). The bile was also positive for morphine (720ng/ml), 6-monoacetylmorphine (27ng/ml), codeine (28ng/ml), cocaine (1,768ng/ml), and benzoylecgonine (320ng/ml). The ethanol level was 0.91g/l in the blood and 1.90g/l in the urine.

Additionally, the histopathological analysis conducted on fragments of the central lung parenchymal area revealed activated mast cells, lymphocytes, and monocytes. A tryptase quantification analysis was performed on the serum and on the pericardial fluid. The values were, respectively, 15.8µg/l and 11.1µg/l, both higher than normal.[1,2]

In conclusion, the absence of signs of venipuncture on BC's body, the presence in the victim's blood and urine of alcohol, morphine, 6-monoacetylmorphine, codeine, and cocaine was proof that she had inhaled drugs. This scenario would suggest she died of a fatal cocktail of drugs and alcohol. Instead, the presence of active mast cells, together with lymphocytes and monocytes in the lungs, associated with tryptase levels in the serum and in the pericardium, revealed that her death had been caused by an anaphylactic disorder.[3-7] When left by the roadside, she was still alive and, with proper resuscitation efforts, she could have been saved.

H44 Considerations on Death Caused by Heroin Inhalation: A Literature Review

Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Aldo Di Nunzio*, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Isabella Aquila, MD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Michele Di Nunzio, BS, Biogem scarl, Via Camporeale, area PIP, Ariano Irpino (AV) 83310, ITALY; Emilio D'Oro, MD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will better understand how death is caused by the depressing effects of heroin on the respiratory center of the brain after inhalation.

This presentation will impact the forensic science community by illustrating the results of a multidisciplinary collaboration, which is fundamental to understanding the cause of death of individuals who use heroin occasionally and only by inhalation.

The police report containing MP's statements reads that at 8:00 p.m. on a mid-July day in 2010, five men whose average age was 28 went to a secluded park area by the Sabato bridge in Benevento (southern Italy). They first drank two liters of wine and four liters of beer. After approximately one hour, KN took a half-liter plastic bottle, placed a pierced piece of aluminum foil on the mouth of the bottle, made a hole sideways into which he inserted a straw, and lit the dark-colored substance lying on the piece of foil. This phenomenon is known as *chasing the dragon.*[1,2] All the men inhaled the fumes produced by the combustion through the straw. At midnight, the friends went away, leaving KN alone near the bridge. At 9:00 a.m. the next morning, at his mother's request, the police began looking for KN. They found him lifeless just where his friends had left him. The medical examiner arrived at the scene and, based on the thanato-chronological data he had collected, said that the victim had died approximately between 10:00 p.m. and midnight the previous day. He did not have any external skin and/or skeletal lesions except for some reddish fluid leaking from his right ear canal.

During the autopsy, the medical examiner found no signs of venipuncture nor any self- or other-inflicted injuries. The oral cavity was intact and free of contaminations. Instead, the medical examiner found minor signs of cerebral edema, severe pulmonary congestion with a serum-and-blood secretion discharging when pressed, and a general congestion of the internal organs caused by the inhibition of the breathing center. The medical examiner collected samples of blood, urine, and bile for toxicological testing. The blood tests were positive for morphine (252ng/ml) and traces of codeine. The urine was positive for morphine (2,392ng/ml), codeine (9ng/ml), cannabinoids (53ng/ml), and ethyl alcohol (1.09g/l). The bile was positive for morphine (120ng/ml), 6-monoacetylmorphine (17ng/ml), and codeine (11ng/ml).

In conclusion, the absence of signs of venipuncture on KN's body, the presence of morphine, codeine, and alcohol in his blood, and morphine and codeine in the urine were proof that KN had taken drugs by inhalation. This scenario suggests that he died due to an overdose of morphine resulting from heroin inhalation. Through the literature review, the study can affirm that death caused by heroin inhalation, associated with apparent low levels of morphine in the blood, is due to a low drug tolerance and to interactions with other Central Nervous System (CNS) depressants or other systemic factors that have not yet been identified.[3-5]

H45 The Lethal Attack of Cane Corso Dogs: A Multidisciplinary Approach to Solve the Puzzle

Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Isabella Aquila, MD*, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Michele Di Nunzio, BS*, Biogem scarl, Via Camporeale, area PIP, Ariano Irpino (AV) 83310, ITALY; Antonio Della Valle, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Aldo Di Nunzio, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; Angela Serino, Magna Graecia University, Viale Europa, Germaneto, Institute of Legal Medicine, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will be aware of the importance of a multidisciplinary approach to resolve court cases in which it is difficult to understand the unfolding of events.

This presentation will affect the forensic science community by demonstrating how a multidisciplinary approach was fundamental in establishing the cause of death of a man attacked by Cane Corso dogs. Moreover, this presentation will emphasize the importance of interaction between different forensic professionals, such as pathologists, veterinarians, geneticists, toxicologists, and odontologists.

The Cane Corso is a large and muscular Molosser breed of dog. Males stand 25.0 to 27.5 inches and females 23.5 to 26.0 inches at the withers. Weight is in keeping with the stature, ranging from 90 to 120 pounds. It is believed to be the descendant of a breed of warfare dogs used by the Romans as auxiliaries in the Legions. This ancient Italian breed of dog is usually trained as a guard and hunting dog.

In October 2015 at 8:00 p.m., a 61-year-old man was found dead in a farm orchard located near Sant'Angelo in Formis (Caserta, southern Italy). The corpse was face up (supine position) in a pool of partially dried blood, near an olive tree. He had died 4-6 hours earlier. His face, arms, legs, and abdomen exhibited signs of severe contusions and lacerations from dog bite wounds. He wore socks and shoes, as well as shreds of a sweater, shirt, and undershirt. His trousers were buttoned but pulled down to the ankles. Other shredded clothing was scattered for a range of two meters. All of his clothes exhibited dog bite marks. An overturned basket of olives was found near the tree. A police officer told the forensic expert he had seen a black dog moving away from the corpse and disappearing through a hole in the wire fence. The forensic expert took a sample of blood from the dog's lower lip. Initially, it was assumed that the dog (labeled as dog 1) had attacked the victim while he was picking olives from his trees. Subsequently, during the on-the-spot investigation, five more Cane Corso dogs were located in the area surrounding the crime scene. They were labeled with numbers 2 through 6 and placed in a kennel for further investigation.

The autopsy revealed traumatic wounds caused by several dog bites. The victim's death was due to a hemorrhagic and traumatic shock caused by Molosser dog bite wounds. The lethal bites were discriminated from non-lethal bites and from postmortem lacerations. The dental arches undoubtedly matched those of a dog. With the help of an odontologist, the medical examiner sampled three of the lethal cutaneous arches and fixed them in a formaldehyde/acetic-acid/ethanol solution. A multiple comparison was conducted between the victim's cutaneous arches, the bitemarks on the clothes, and the six dogs' dental impressions[1-4]. Comparisons revealed matches for dog 1 and dog 2.

Several spots on the corpse around the bites were swabbed while cloth samples were taken to perform a genetic analysis.[5,6] The sample taken from the dog 1's lip was the victim's blood. The genetic profiles of dog 2 and of another dog that was not in the kennel were found on the victim's trousers.

The medical examiner sampled only blood specimens for toxicological analysis because the bladder was empty. Gas Chromatography/Mass Spectrometry (GC/MS) analysis was negative.

The histopathologist analyzed fragments of the victim's heart and found that he suffered from coronary artery disease, congestive heart failure, and minor bleeding events of the epicardium. The histological analysis confirmed the vitality of several lesions, suggesting that the man was still alive before the attack.

A multidisciplinary approach was necessary to solve the case. It was determined that the victim's death was due to a hemorrhagic and traumatic shock caused by Molosser dog bite wounds. Moreover, in cases of traumatic death in which animals are directly involved, the collaboration of different forensic professionals is very important. Finally, forensic veterinary medicine has now become an indispensable branch of forensic science in such cases.

Forensic Science, Dog Bites, Canine DNA Profiling

H46 Patterns of Bruising in Cases With and Without Alcohol Abuse

Daniel Krona, MD, Rattsmedicinalverket, Solvegatan 25, Lund 22362, SWEDEN; and Carl Johan Wingren, PhD, National Board of Forensic Medicine, Sölvegatan 25, Lund, Scania 22362, SWEDEN*

The goal of this presentation is to increase the scientific support for conclusions about injury patterns and to better interpret blunt force trauma in cases of alcohol abuse.

This presentation will impact the forensic science community by reviewing the basis for interpreting bruising in cases with and without alcohol abuse.

This presentation will be an example of how the dead teach the living by examining the distribution and extent of bruising in cases of medicolegal autopsies with and without alcoholism and testing the hypothesis that in alcoholism bruising is more extensive. Such information is important when reaching conclusions concerning the distribution of blunt force trauma in both the medicolegal autopsy setting and in the setting of clinical forensic medicine (e.g., examining live victims or suspects of crimes).

In Scandinavian countries, forensic pathologists are concerned with both medicolegal death investigations and clinical forensic medicine. Of importance in both branches is separating injuries inflicted during everyday life and those inflicted by violent assaults, for example.

Since the forensic pathologist gains experience of the normal distribution of injuries in the medicolegal autopsy population, this knowledge can be used to interpret injuries in the living. Generally, it is assumed that chronic alcohol abusers have a heavier burden of blunt force trauma compared to a population without such abuse.

To objectively classify the level of alcohol consumption, blood levels of Phosphatidylethanol (PEth) in whole blood were used to classify the studied population into three groups: low, intermediate, and high consumers of alcohol. PEth is a marker of alcohol consumption registering alcohol intake during approximately two weeks preceding the death and is routinely used at the forensic medicine unit in Lund, Sweden. Cases in which PEth had been analyzed were identified and the autopsy reports were then studied for information regarding bruises. Bruises were counted, their location noted, and, from the original data collected, information about their size and if they were recent was also noted.

In this study, 118 consecutive forensic autopsy cases were identified in which a PEth blood sample analysis had been ordered, beginning in February 2017 and working backward to October 2015. After excluding traffic accidents, homicides, decomposed cases, and cases not finalized, this resulted in a total of 101 cases that were included in the study.

The association between the three categories of PEth (low, moderate, and high alcohol consumption) and having more than three bruises on the body was analyzed using logistic regression. No conclusive associations between the PEth concentration and the numbers of bruises were observed; however, observing only the point estimates indicated a tendency of a U-formed association between the number of bruises and the PEth categories, in which the most number of bruises were observed in the high consumption category and the least number of bruises were observed in the medium consumption category. It appeared as if female sex was associated with an increased number of bruises. No conclusive association between age and number of bruises was observed.

In conclusion, no statistical support for the hypothesis that alcoholics in a medicolegal autopsy setting are subjected to more accidental blunt force trauma reflected in the number of bruises compared to non-alcoholics could be identified in this study. The results may be produced by low statistical power and selection bias, and the study should be extended to include a consecutive and larger population. Nonetheless, this study provides an example of how to increase scientific support for arriving at conclusions regarding patterns of injuries in both the medicolegal autopsy setting and in clinical forensic medicine.

Medicolegal Autopsy, Clinical Forensic Medicine, Bruises

H47 Fatalities Due to the Failure of Continuous Subcutaneous Insulin Infusion Devices: A Report of Six Cases

Timothy L. Williams, MD, King County MEO, 325 9th Avenue, Box 359792, Seattle, WA 98104-2499; Andrew Ziegler, BS, Ohio Northern University, Ada, OH 45810; Nicole A. Yarid, King County MEO, 325 9th Avenue, Seattle, WA 98104; Daniel L. Schultz, MD, Lifelink Tissue Bank, 9661 Delaney Creek Boulevard, Tampa, FL 33619; and Elizabeth A. Bundock, MD, PhD, Office of the Chief Medical Examiner, 111 Colchester Avenue, Burlington, VT 05401*

The goals of this presentation are to provide: (1) an understanding of how insulin pumps work; and, (2) recognition of potentially fatal malfunctions of insulin pumps.

This presentation will impact the forensic science community by providing the results of a series of cases that have not previously been presented in the literature.

Treatment of diabetes mellitus often requires injection of exogenous insulin to manage the disease. Some patients elect to use Continuous Subcutaneous Insulin Infusion (CSII) devices rather than repeated needle sticks for the administration of insulin. Malfunctions of any component of the CSII device can result in insufficient insulin delivery and, if not recognized in a timely manner, can lead to fatal ketoacidosis.[1] While there are studies describing complications of CSII devices in living patients, the literature is extremely limited in describing CSII failure-associated mortality.

This study presents a series of six cases of fatal diabetic ketoacidosis resulting from insulin infusion set malfunctions in patients undergoing continuous subcutaneous insulin infusion. The six cases were compiled from four different medical examiner offices in the United States. The patients varied in age, ranging from 37 to 79 years old. Both genders are represented as are both types of diabetes mellitus. Autopsy examination, including toxicologic analysis, was performed on all cases. In four of the six autopsies, no anatomical abnormalities were observed. The findings in the other two autopsies were either not significant to cause the patient's death or could be considered secondary to the patient's history of diabetes.

Infusion set malfunctions are among the most common and significant complications of CSII devices.[2,3] In all six cases, the malfunction was identified to be failure of the cannula to puncture or remain in the skin (in five of the six cases, the insulin infusion set failed to puncture the skin, and in one case it appeared that the Insulin Infusion Set (IIS) had initially punctured the skin to some extent, but it was unclear if the cannula had failed to fully insert or had inserted and subsequently dislodged). Also, in five of the six cases, the cannulas were bent or kinked; in one case, the cannula appeared straight but was not inserted through the skin. Four of the six cases involved perpendicularly inserted cannulas, all of which were bent or kinked. Of the two angled cannulas, one was bent and another had failed to insert. In all cases, infusion set malfunction resulted in the failure of insulin infusion, which then resulted in fatal ketoacidosis.

The cause of death in all cases was certified as either diabetic ketoacidosis or complications of diabetes mellitus; however, since it is possible to consider the unexpected natural death of diabetic ketoacidosis which occurred as a result of improper application of their therapeutic device as either natural or accident, there is variation in classification of the manner of death. In the six cases presented in this study, manner of death was classified as accident in three cases and natural in three cases.

Recognition of these potentially fatal CSII-device malfunctions is important in order to prevent future deaths. Though only six cases are presented, given the widespread use of this treatment modality, it is likely there are unrecognized instances in which failure to properly place the IIS cannula during CSII therapy allowed the patient's diabetic condition to progress to a fatal state of ketoacidosis. Examining and understanding these six deaths can lead to future prevention through advancing technological applications and educational practices as well as contribute to proper classification of deaths related to CSII failure.

Insulin Pump, Insulin Infusion, Mortality

H48 Bathtub-Related Deaths

Anders Rietz, National Board of Forensic Medicine, Fogdevägen 1, Umeå, Västerbotten 90355, SWEDEN; Anders Eriksson, MD, PhD, Umea University, Dept Forensic Medicine, PO Box 7616, Umea SE-907 12, SWEDEN; and Jeffrey M. Jentzen, MD, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109*

After attending this presentation, attendees will better understand the epidemiology and circumstances of bathtub-related deaths. Attendees will also learn about the evaluation of scalp lacerations and how these wounds correlated with deaths due to falls in bathtubs.

This presentation will impact the forensic science community by adding new knowledge regarding injuries sustained in bathtub-related deaths, with emphasis on the correlation with lacerations of the scalp.

This presentation seeks to answer the questions that were of importance in a recent high-profile case in which court testimony centered around the presence and orientation of scalp lacerations as an indication of a fall in a bathtub: Do lacerations of the scalp occur at all in bathtub-related drownings and, if so, is a certain shape of the wounds more frequent?

Determining the cause and manner of death in a bathtub death can be difficult. This study grew out of questions in a high-profile death in which a woman was found dead in a bathtub. This study describes the epidemiology and circumstances of bathtub-related deaths in Sweden. In reference to this case, traumatic head injuries, including the orientation of the scalp laceration, were highlighted. Searches in the database of the National Board of Forensic Medicine in Sweden were conducted for the time period 2007 through 2013. Cases in which the decedent was found in a bathtub, jacuzzi, or hot tub were included. Deaths in showers were also included but were analyzed separately.

A total of 381 cases were identified — 365 bathtub-related deaths and 16 shower deaths. The most common cause of death was, as expected, drowning, followed by intoxication. Suicide was the most common manner of death, but all manners of death were encountered, including two homicides. The prevalence of severe traumatic injuries (AIS>3) was low and was most prevalent among suicides from a violent method, such as gunshot or massive lacerations. A total of six cases had a laceration in the scalp similar to that described in the present case, and four of these cases were bathtub drownings. In three of the four cases, it is plausible that head trauma may have reduced the person's state of consciousness and thus contributed to the drowning and the fatal outcome; however, in neither case was the laceration stated as a (contributing) cause of death by the forensic pathologist. Three of the injuries were located around the bony structures of the right eye (the wounds were transversal, oblique, and vertical), one was on the medial surface of the left ear (vertical), and two were on the back of the head, just right of the inion (oblique and transversal).

In conclusion, all manners of death are possible in a bathtub-related death; however, as expected, suicide was the most common manner of death and drowning the most common cause of death. The prevalence of severe traumatic injuries is low and, when present, it is usually in a suicide from a violent method, such as gunshot or massive lacerations. Lacerations of the scalp in a bathtub drowning *do* occur in various orientations, but the impact of these upon the fatal outcome needs to be explored further.

Bathtub-Related Deaths, Drowning, Scalp Lacerations

H49 Suitcase Concealment: An Interdisciplinary Analysis of the Taphonomic Processes and Their Effect on Postmortem Interval (PMI) Estimation

A. Skylar Joseph, MS, PO Box 307, Elbow Lake, MN 56531; Gary W. Reinecke, MA, School of Medicine, Medical Campus, 72 E Concord Street, L1006, Boston, MA 02118; and Ian Dadour, PhD, Boston University School of Medicine, Program in Forensic Anthropology, Dept of Anatomy & Neurobiology, Boston, MA 02118*

After attending this presentation, attendees will better understand the entomological and decompositional changes that are likely to occur when a body is concealed within a suitcase after death.

This presentation will impact the forensic science community by providing results from an experiment that analyzed the taphonomic effects of body concealment within suitcases, a topic that has had only minimal previous research conducted.

In cases of homicide, suitcases provide concealment and may ease the transport of a body with minimal likelihood for detection. In order to create a minimum Postmortem Interval (mPMI) estimate, it is first necessary to understand the unique taphonomic processes that occur when a body is concealed within a suitcase. In this study, the experimental carcasses consisted of pig (*Sus scrofa*) heads, which were concealed within either hard-shell plastic suitcases or fabric suitcases; the control pig heads were left on the surface of the ground to decompose naturally. Starting on day 3 of each study period, and continuing every other day until day 15, three suitcases of each type were removed from the field for analysis of the entomological activity inside the suitcases and the decompositional stage of the pig heads. Additionally, the ambient temperature and the temperature inside each type of suitcase was recorded by temperature data loggers throughout the duration of each study period. The study was conducted at Boston University's Outdoor Research Facility in Holliston, MA. This study was repeated twice, once in May and once in August 2016.

Temperature comparisons revealed that the hard-shell plastic suitcases reached significantly (<0.001) hotter temperatures than both the ambient temperature and the temperature inside the fabric suitcases. Insect activity began immediately on the control samples during both study periods; however, during study one, insect activity was not present inside the fabric suitcases until days 3-5, and did not occur inside the hard-shell suitcases until days 5-7. During study two, insect activity inside both types of suitcases was present by day 3, but not guaranteed to occur until day 4 or later. Some differences in insect species were noted between the controls and the suitcases, as well as between both types of suitcases. Most notable was the presence of a number of fly (Diptera) species inside the suitcases that are generally associated with late decomposition. Additionally, while beetles were present on the control samples, none were found inside the suitcases. All control samples mummified within days, while all of the experimental samples experienced wet decomposition, often resulting in skeletonization by day 15.

In conclusion, this study has shown that not only does concealment within a suitcase change the taphonomic history of the body enclosed, but that the type of suitcase also influences the taphonomic factors that the body will experience. Ultimately, this study will aid in the ability to better predict the mPMI for cases in which a body is concealed within a suitcase.

Suitcase Concealment, Taphonomy, Postmortem Interval

H50 Insects and Bacteria as Forensic Decomposition Markers of Buried Rat Carcasses

Lavinia Iancu, PhD, Institute of Biology – Bucharest, Romanian Academy, Splaiul Independentei, Nr. 296, Bucharest 060031, ROMANIA; Georgiana Necula-Petrareanu, PhD, Institute of Biology – Bucharest, Romanian Academy, Splaiul Independentei, Nr. 296, Bucharest 060031, ROMANIA; Emily Junkins, MS, University of Oklahoma, 770 Van Vleet Oval, Norman, OK 73019; and Cristina Purcarea, PhD, Institute of Biology Bucharest, 296 Splaiul Independentei, Bucharest 060031, ROMANIA*

After attending this presentation, attendees will have a detailed understanding of carcasses decomposing in soil and of the necrophagous entomofauna identified during the stages of decomposition. Moreover, attendees will be provided with information regarding the bacterial dynamics of buried carcasses and with the proposal of two bacteria taxa as putative markers for the postmortem interval estimation.

This presentation will impact the forensic science community by adding important data regarding the decomposition process in soil as well as the insects and bacteria associated with carcass decomposition. This type of research, rarely studied to date and the experimental research conducted on exposed remains, will provide much-needed qualitative and quantitative information on necrophagous insects and bacteria associated with buried carcasses.

The decomposition process of surface remains and their associated necrophagous entomofauna has been well studied compared with buried carcasses. The insect diversity and succession pattern for buried and exposed carcasses are different due to the variations of edaphic and environmental conditions. In the case of buried remains, the occurrence of necrophagous insects can be delayed or inhibited by the climatic conditions, soil type, and depth of burial. At the same time, the carcass bacterial community structure is expected to differ between buried and exposed conditions. This becomes an important distinction in cases such as violent criminal actions, when the perpetrator tends to dispose of the cadaver by frequently burying it in a shallow grave.

In this context, the current study focused on monitoring the decomposition process of buried rat carcasses from shallow graves, the diversity and dynamic of insects and bacteria throughout the decomposition stages, and the environmental parameters' influence on these variations at a depth of 40cm. The survey took place in the spring (March) and summer (June) months of 2016 in a green urban area of Bucharest, Romania. For each case, 30 rat (*Rattus norvegicus*) adults were used as study models, and a specimen was destructively sampled every 24 hours, starting immediately after death. Both the necrophagous insect specimens (adults and larvae) and the tissue from the rat small intestine were sampled and taxonomically and genetically identified. Furthermore, the air and soil temperature, relative humidity, precipitation rate, and soil pH were recorded daily.

Necrophagous insect species were absent in March, given the low temperatures that did not exceed 10°C in soil, and thus were observed and sampled solely in July. Two Diptera (Muscidae, Phoridae) and two Coleoptera (Leiodidae, Staphylinidae) families were identified, encompassing five and two species, respectively. All Diptera developmental stages were observed and sampled from the remains, beginning with the active decomposition stage, while Coleptera were present only in the last stage.

From the small intestine and insect tissues, the total genomic DNA was extracted and the bacteria diversity was investigated by Illumina® MiSeq® analysis and taxonomy was assigned via QIIME™ platform and Greengenes database. A preliminary screening of the bacterial community structure of the small intestine during decomposition stages, determined by 16S recombinant DNA (rDNA) Denaturant Gradient Gel Electrophoresis (DGGE), led to the identification of two bacterial taxa belonging to Firmicutes of permanent and sporadic occurrence. The analysis of their relative content during decomposition, quantitated by quantitative Polymerase Chain Reaction (qPCR), led to the identification and proposal of putative bacterial markers for postmortem interval estimation.

The results exhibit correlations between the insect species presence and environmental parameters variation, stages of decomposition and bacterial communities' diversity and dynamics, and modification of soil pH throughout the evolution of the decomposition process. This data represents the first study of bacterial diversity determined by 16S rRNA Illumina® sequencing for buried carcasses in a natural environment, proposing microbial markers for forensic investigations based on quantitative evolution of certain bacterial taxa.

Buried Carcasses, Insects, Bacteria

H51 The Influence of Depth and Mixtures on the Bacterial Profiling of Soil Using Next Generation Sequencing

Emily R. Heinz, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand how different soil depths and mixtures alter the bacterial profiles produced from soil samples and that these factors must be considered when collecting known soil samples in order to produce strong associations between evidentiary soils and the site of a burial.

This presentation will impact the forensic science community by examining how various depths of soil and mixed samples, as may be encountered in burials, affect the bacterial composition of soil, thus expanding the knowledge necessary to successfully individualize forensic soil samples.

Soil is a commonly recovered form of trace evidence found on items such as shovels, tires, or clothing that has the potential to be traced back to its place of origin. Successful identification of soil can be valuable for forensic applications, as it can link a suspect or victim to the scene of a crime. In the past, soil has been analyzed primarily using physical class characteristics. More recently, researchers have sought to individualize soil evidence by analyzing the huge number of bacteria that inhabit it.[1,2] Many factors affecting the bacterial profiling of soil have been studied, including temporal and spatial changes; however, potential vertical changes have yet to be rigorously examined. The bacterial composition of soil may change as depth increases, as was found over horizontal space.[3,4] This could be particularly important in burials, where soil from various depths would be mixed. Understanding how depth and mixtures affect the bacterial profiles of soil is imperative in understanding how to collect and analyze known soil samples.

In the research presented, soil samples were collected from the surface and 5, 10, 20, 40, and 60 inches deep at a central coring location and four nearby corings. Five habitats were examined: two separate agricultural fields, a coniferous forest, an untreated yard, and a deciduous woodlot. Using these depth samples, mixtures were created to simulate a burial by homogenizing equal masses of soil from all six depths for each of the 25 corings. Different combinations of depths were used as training sets for supervised classification to examine the best way to collect depth samples in the case of a mixture or burial.

Bacterial DNA was extracted from soil samples using a DNeasy PowerSoil® kit, and variable regions 3 and 4 of the bacterial 16S recombinant DNA (rRNA) gene were amplified using universal barcoded primers. Bacterial sequences were produced on an Illumina® MiSeq® and visualized via abundance charts and non-metric multidimensional scaling. A bagged trees algorithm was used to objectively associate depth and mixture samples to a habitat and to provide likelihood scores that each of the classifications was correct.

In four of the habitats, there were increases in the bacterial classes Betaproteobacteria and Nitrospira and decreases in Sphingobacteria and Spartobacteria with depth. In contrast, the coniferous forest displayed increases in Deltaproteobacteria and Nitrospira, and decreases in Sphingobacteria and Alphaproteobacteria. The mixture samples for all habitats exhibited a bacterial profile resembling the shallowest soils. Graphically, as depth increased, the soil samples drifted away from the surface samples in multidimensional space, with the 40" and 60" samples being furthest away from the shallow samples while the mixtures grouped closest to the surface, 5", and 10" samples.

The central coring mixtures were then compared to different depths from the four surrounding corings using supervised classification. When compared to surface, 5", or surrounding mixtures, 100% classification accuracy was achieved. This accuracy decreased as depth increased, with the 60" samples producing 20% classification accuracy when used as the training set. This mimics the bacterial composition differences seen between the mixtures and the deep samples, as well as the deep samples being far away from the others in multidimensional space. The results indicate that the deep soil samples contribute very little to the mixture's bacterial profile and, thus, may not need to be collected, even when soils are from a burial.

These results elucidate the effects of vertical spatial changes, along with mixtures, on the bacterial composition of soil via next generation sequencing. Our understanding of these changes aids in the determination of how to best collect and analyze known soil samples when a burial has occurred.

Soil Bacterial Profiling, Next Generation Sequencing, Bacterial 16S Sequencing

H52 A Survey of Bacterial Diversity Associated With Various Life Stages of *Lucilia sericata* and *Phormia regina* Collected From Central Virginia

Denise Wohlfahrt, BS, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Room 2015, Richmond, VA 23284; Michael Shane Woolf, MS, 1023 Tupelo Court, Charlottesville, VA 22903; Rina Lidder, BS, 12047 Heather Down Drive, Herndon, VA 20170; and Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Room 2015, Richmond, VA 23284*

After attending this presentation, attendees will better understand bacteria associated with blow flies that colonize human remains. This information will help forensic scientists in improving accuracy associated with the estimation of the Postmortem Interval (PMI) based on entomological and microbial evidence.

This presentation will impact the forensic science community by helping provide a better understanding of carrion resource utilization, blow fly colonization pattern determination, and in improving precision in PMI estimation using entomological and bacterial evidence.

Reliable and valid methods for the PMI determination are frequently sought. Information obtained from the colonization of insects and the related bacterial succession on carrions may be utilized for PMI estimation, but this can lead to erroneous results due to known variations between individuals and species.[1] Apart from the bacterial communities found with human remains, it is important to note what bacteria may be specifically associated with blow flies colonizing these remains immediately after death. Blow flies often associated with carrions in Virginia are *Lucilia sericata* and *Phormia regina.*

This comparative analysis of the various life stages of *Lucilia sericata* and *Phormia regina* was performed as the initial setup of an ongoing study, including various species of blow flies associated with human remains in central Virginia. Although extensive data exists on the biology of blow flies, a well-replicated study on bacteria associated with different life stages of many blow flies is missing. This study characterized bacteria associated with different life stages of *Lucilia sericata* and *Phormia regina* by using 16S recombinant DNA (rDNA) MiSeq® sequencing. Five *Lucilia sericata* colonies and four *Phormia regina* colonies were established from female flies collected from Richmond, VA, and nearby areas on beef liver bait. First-generation eggs, third-instar larvae, pupae, adults, and second-generation eggs were collected from each colony for DNA extraction using the organic Cetyl Trimethyl Ammonium Bromide (CTAB) extraction method and dual-index 16S rDNA MiSeq® sequencing using the protocol as described by Kozich et al.[2] Sequences were then analyzed using Mothur version 1.39.4, and statistical analysis was performed using R version 3.4.0.[3,4]

The majority of bacteria associated with both *Lucilia sericata* and *Phormia regina* belonged to the phyla Firmicutes, Proteobacteria, Bacteroidetes, and Actinobacteria and are intragenerationally inherited, varying only in their relative abundance. In *Lucilia sericata,* the class Flavobacteria was present at high relative abundance (12.1 %) in pupal samples, whereas its relative abundance was very low (<1%) in all other samples. In *Phormia regina,* the class Actinobacteria was present at high relative abundance (>7%) in the adult samples, where the relative abundance in the remaining samples was very low (<1%). In *Lucilia sericata*, the genus *Vagococcos* was present at high relative abundance in larva, adult, and second-generation egg samples (>12%). In *Phormia regina*, the genus *Lactococcus* was present at high relative abundance in larva and pupa samples (>20%). In both species, egg samples had high relative abundance of the genus *Yersinia*, whereas its relative abundance was very low (<1%) in all other samples.

In conclusion, this ongoing study provides information on the bacterial communities associated with the various life stages of blow flies and their importance in forensics.

Blow Fly, Postmortem Interval, Necrobiome

H53 The Utility of Barnacles in Forensic Investigations

Ian Dadour, PhD, Boston University School of Medicine, Program in Forensic Anthropology, Dept of Anatomy & Neurobiology, Boston, MA 02118; Danea Pirtle, BA, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02118; Gary W. Reinecke, MA, Boston University School of Medicine, Medical Campus, 72 E Concord Street, L1006, Boston, MA 02118; and Paola A. Magni, PhD, Murdoch University, School of Vet & Life Sciences, 90 South Street, Murdoch, Western Australia 6150, AUSTRALIA*

After attending this presentation, attendees will understand the usefulness of barnacles in determining a postmortem submergence time and/or floating time of remains in a marine environment. This, when coupled with sea current knowledge, can impact the provenance of those remains.

This presentation will impact the forensic science community by providing awareness regarding submerged remains as to what to observe and collect and how barnacle growth rate can aid in the total minimum Postmortem Interval (minPMI).

Estimating the minPMI is a necessary part of a forensic investigation. Besides the pathologist's assessment of the typical signs of death, minPMI can be estimated using forensic entomology, the scientific discipline that considers insects and other arthropods that colonize the remains. In an aquatic environment, insects as well as crustaceans have the potential to provide data regarding the time the remains have spent in the water (i.e., Floating Time (FT) and Post Mortem Submersion Interval (PMSI)), and this can also assist in determining the minPMI.

Barnacles (Crustacea: Cirripedia) are common crustaceans that colonize solid and durable substrates in marine environments and can often be found in association with human and animal remains floating in the sea. Scientific literature reports that barnacles are typically found colonizing shoes. Barnacles can colonize both floating remains and submerged remains and their growth rate is dependent on the water temperature. Despite their potential to be indicative of the FT and/or PMSI, at present, research is depleted and only a few case studies have considered it for this purpose.

The present research is focused on the barnacle colonization of different types of shoes (sporty vs. elegant) placed in the sea (Boston Harbor, Boston, MA). The objectives of this study were: (1) the identification of the species of barnacles that colonize shoes; (2) the identification of the settlement preferences of the barnacles associated with the shoes; and, (3) to determine the growth rate of the barnacles associated with the shoes.

For the purpose of this research, in early March 2016, 64 sport shoes and 64 patent leather shoes were placed in the Boston harbor at 8m–10m below the sea level. Four of each shoe type were collected every two weeks from April 2016 to November 2016, inclusive. Each shoe was photographed and the barnacles and other sea life colonization was documented. Individual barnacles from each shoe were sampled and measured to determine species and age as well as the overall colonization density and settlement preference. Data loggers were placed with the shoes to record temperature throughout the course of the study.

Results show that *Amphibalanus improvisus* (Darwin) (Crustacea: Cirripedia: Sessilia) colonized the vast majority of shoes. Colonization occurred quickly and continued throughout the study period. A significant difference in colonization densities was found between the sport and patent leather shoes, with the patent leather seeing higher densities. Barnacles also showed preferential colonization of specific sections on both shoe types. Overall, higher quantities of barnacles were found on the exteriors and bottoms of shoes and low quantities of colonization on the insides, tongues, and laces. Barnacle growth was found to be significantly affected by water temperature. Statistical analysis of the effect of water temperature, time, and shoe type on the size of the largest barnacle revealed a highly significant effect from temperature and shoe type and no significant effect from time. Time and shoe type had a highly significant effect on the total number of barnacles per shoe, whereas water temperature had no significant effect.

Barnacle, PMSI, Growth Rate

H54 The Beaver Dam, Flies, and the Ax: You Can't Hide From Mother Nature

Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; John A. Lewis, Jr., DDS, 407 Heritage Place, Flowood, MS 39232; L.R. Funte, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Brent Davis, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Anastasia Holobinko, PhD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Heidie Newby, BS, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; and Anna C. Follett, BA, 2945 Layfair Drive, Apt 526, Flowood, MS 39232*

After attending this presentation, attendees will understand the importance of a cooperative, multidisciplinary approach to investigating and solving a complex homicide.

This presentation will impact the forensic science community by demonstrating the value of incorporating forensic disciplines into complex investigations. Experts in forensic pathology, forensic anthropology, and forensic odontology contributed to law enforcement investigation efforts in the interpretation of homicide injuries and complex postmortem influences occurring within diverse environments (i.e., dismemberment with an edged instrument, mutilation, gunshot wounds from multiple weapons, and evidence of peri-mortem and postmortem influences).

The decedent was taken by two acquaintances to a remote wooded area to inspect a clandestine "below-ground" methamphetamine cooking laboratory. The decedent, who was suspected of being a police informant, was killed and subsequently buried in the same hole as the alleged underground laboratory. Approximately two weeks later, the killers became nervous about the body being discovered and returned to the grave. The decedent was exhumed, dismembered to facilitate removal, packaged in plastic bags, wrapped in tarps, and subsequently submerged in a nearby lake.

The victim remained missing for 22 months and was discovered due to a natural event that changed the landscape. A beaver dam supporting the lake failed, revealing tarps containing the remains. Within the rolled-up tarp were five plastic garbage bags. Initial examination revealed numerous pupal cases associated with the bags. To insure accuracy of trauma interpretation, the contents of each bag were scrutinized and documented.

Radiographs of each bag revealed what appeared to be the fragmented remains of a single decedent, multiple bullets associated with the torso, a severely deformed skull with a "lead snowstorm" appearance, large bone separation that appeared to be straight-edged and occasionally angled, resembling blunt trauma. A cinder block was also observed in the radiographs.

An autopsy on the decomposed remains confirmed a single, incomplete individual. Identification was confirmed through antemortem and postmortem dental radiograph comparisons and DNA analysis. The degree of skeletal representation was highly variable due to the sustained traumatic injuries. The cause of death was diagnosed as multiple gunshot wounds as evidenced by a shotgun wound to the posterior skull and multiple gunshot wounds to the chest and abdomen; gunshot wounds were also observed in the sacrum and lumbar vertebrae.

The sharp trauma was indicative of a heavy edge-beveled blade that cuts soft tissue and bone, but lacks penetration due to a thick blade. The chopping action initially cuts, but does not penetrate far before breaking the bone. Sharp chops associated with blunt trauma occurred on the mandible, posterior C2, and extremities.

The antemortem, peri-mortem, and postmortem analysis of a violent death involved a thorough investigation and the cooperation of personnel representing pathology, anthropology, odontology, forensic autopsy, and local law enforcement. The collective efforts of the above individuals resulted in a positive identification of the decedent, in the determination of the cause and manner of death, and in the conviction of the assailant.

And then there was the ax ….

Dismemberment, Taphonomy, Multidisciplinary Approach

H55 Exogenous Factors Affecting Bacterial Profiling of Soil on Clothing Via Next Generation Sequencing

Sierra Kaszubinski, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; Emily R. Heinz, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand that bacterial profiles derived from soil and recovered from clothing are a viable source of trace evidence despite exogenous variables affecting the profiles.

This presentation will impact the forensic science community by illustrating that factors affecting soil bacterial profiles do not entirely disrupt the profile, which gives soil identification improved utility in forensic analysis.

Soil is potentially a valuable form of trace evidence, helping associate an object on which it is found with a crime scene. Historically, soil has been analyzed via visual and chemical class characteristics. Today, molecular tools have expanded the scope of forensic soil analysis to include microorganisms (e.g., bacteria, fungi). Most recently, Next Generation Sequencing (NGS) allows the millions of DNA sequence reads to be used to identify soil microbes and determine a microbial profile that distinguishes soil samples.[1] To be useful in forensic applications, stability of these profiles is key, as factors that change an evidential profile could nullify an association with the soil's place of origin.

Soil on clothing has been shown to be a viable source of evidence through bacterial profiling of the 16S ribosomal RNA (rRNA) gene; however, such studies did not involve a person wearing the item.[2] It is possible that the human skin microbiome or body fluids (e.g., blood) might alter a soil bacterial profile on clothing, either by augmenting the bacteria present or through selection for or against certain bacteria when exposed to a new growth environment. Understanding the effect of such variables is key for the use of soil bacterial profiling as a forensic resource.

In this study, 12 participants wore new T-shirts for 24 hours (in accordance with Institutional Review Board (IRB) approval), and cuttings were taken from the back of each worn T-shirt. The T-shirts were then exposed to soil from four different habitats and stored in paper bags. At the same time, pure soil samples from the habitats were aged in weigh boats. Cuttings/samples were taken from each at day 0 and monthly for six months. In a separate experiment, soil from a habitat was mixed with fresh pig blood in three different ratios (1:10, 1:1, and 10:1 soil:blood) and placed on clean T-shirts. Three T-shirt replicates were either stored in plastic bags (wet) or allowed to air dry and stored in paper bags. Soil/blood cuttings were taken from each T-shirt at day 0, week 1, month 1, and month 2.

DNA was isolated from all soil samples using a MO BIO PowerSoil® kit. A 500bp stretch of the 16S rRNA gene containing variable regions 3 and 4 was amplified using universal, barcoded primers. Amplicons were purified and sequenced on an Illumina® MiSeq®. Bacterial profiles from the T-shirts were visualized using abundance charts and associated via non-metric multidimensional scaling. A random forest algorithm was used to objectively assign the soil evidence to habitats, and scores were generated that reflect the confidence of that classification.

Bacterial profiles were obtained from each worn T-shirt and all soiled cuttings. In all instances, the T-shirt soil profiles correctly classified with the habitat of origin, and there was no detectable influence from human microbiomes. For T-shirts exposed to soil and blood mixtures, the effect of blood on the soil bacterial profiles differed depending on storage type, time since exposure, and the soil/blood ratio. All treatments resulted in very similar bacterial profiles on day 0, which was maintained in the dry T-shirts and those with little blood (10:1); however, the wet T-shirts at 1:1 and 1:10 ratios differed markedly from the other samples after week 1 and through month 2. Notably, *Bacilli* and *Gammaproteobacteria* increased substantially in bloody wet T-shirts, bacterial classes that include species that are known blood pathogens.

The results demonstrate that soil on clothing can accurately and reliably associate with soil from a crime scene. The soil dominates the bacterial profile of samples exposed to the human skin microbiome or to small amounts of blood. Even when blood-saturated, dry storage or immediate sampling allows the soil on T-shirts to accurately associate with its place of origin. Despite purposefully introducing potentially confounding variables, bacterial profiling-based soil identification from clothing maintains its viability for forensic analysis.

Soil Identification, Bacterial Profiling, Next Generation Sequencing

H56 A Comparison of the Geographical Variability of the Thanatomicrobiome of Finnish and American Corpses

Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Sheree J. Finley, MS, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Sari Tuomisto, PhD, University of Tampere, Lääkärinkatu 1, Tampere 33520, FINLAND; and Pekka J. Karhunen, PhD, University of Tampere, Faculty of Medicine and Life Sciences, FI-33014 Tampere University, Tampere, Pirkanmaa 33014, FINLAND*

After attending this presentation, attendees will better understand the comparison of the 30S small subunit of the prokaryotic ribosome-based sequencing to characterize the thanatomicrobiome of postmortem liver from corpses derived from different geographical locations, namely the United States and Finland.

This presentation will impact the forensic science community by providing results to support the Human Postmortem Microbiome Project (HPMP) catalog. This presentation will also add to research in regard to distinct geographical locations in which corpses originate.

Human thanatomicrobiome studies have shown that microorganisms inhabit and proliferate externally and internally throughout the body and are the primary mediators of putrefaction after death. Yet little is known about the source and diversity of the thanatomicrobiome in regard to geographical factors in which corpses are found. Prokaryotic 16S ribosomal RNA (rRNA) gene sequences are extensively used in forensic microbiology as reliable biomarkers for the taxonomic classification and phylogenetic analysis of the thanatomicrobiome. Upon death, all immune mechanisms in the human body that were operational during life cease, and commensal bacteria start to degrade the body as a part of the natural calendar of death. Presumably, the postmortem microbial composition dynamics of internal organs (e.g., liver) are distinct due to geographical variabilities. The richness of postmortem bacterial abundances in the liver is due, in part, to several factors: its location juxtaposed to the microbe-rich intestinal tract; its location near pancreatic enzymes, stomach acids, and gallbladder fluids that initiate putrefaction through autolysis that spreads quickly to the liver; and its reservation of nutrient-rich blood from the portal vein and hepatic artery that are excellent growth media for bacteria.

This study investigated the microorganisms obtained from the liver of corpses from Finland and the United States. The thanatos model assessed liver samples from 65 human remains from the two countries (n=130) with postmortem intervals ranging from 3 hours to 264 hours. To distinguish the composition and diversity of thanatomicrobiomic signatures, Polymerase Chain Reaction (PCR) and high-throughput sequencing targeting the V4 region (Class I) of the 16S rRNA gene using bacterial primers 515F-806R was performed. The bioinformatic results revealed that there were significant differences ($p<0.001$) among location (Finland versus the United States) and postmortem interval in unweighted and weighted UniFrac Adonis tests. Also, recent thanatomicrobiome findings for United States cadavers discovered that a majority of the microorganisms in the human body after death were the obligate anaerobes, *Clostridium* spp. On the contrary, in the current study, there was a paucity of *Clostridium* spp. in the Finland corpses.

In conclusion, the influence of different geographic locations in determining the distinct microbial community profiles to provide empirical data that will potentially build predictive thanatos models that can further designate the recovery of bodies from discrete locations was demonstrated.

Thanatomicrobiome, Corpse, 16S rRNA

H57 The Ecology of the Human Postmortem Microbiome: Insights From a Large-Scale Study

Jennifer L. Pechal, PhD, Michigan State University, 243 Natural Science Bldg, Dept of Entomology, East Lansing, MI 48824; Carl J. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; Heather R. Jordan, PhD, Mississippi State University, PO Box GY, Mississippi State, MS 39762; and M. Eric Benbow, PhD, Michigan State University, Depts of Entomology & Osteopathic Med Specialties, 288 Farm Lane, East Lansing, MI 48824*

After attending this presentation, attendees will better understand the human postmortem microbiome. The majority of research related to the postmortem microbiome involves the use of surrogate animal models (e.g., swine or rodent) or donated bodies placed in anthropological research facilities.

This presentation will impact the forensic science community and practitioners by providing data from a large-scale (185+ cases) characterization of the human postmortem microbiome.

Studies using these methodological approaches, while scientifically valid, result from financial, legal, and/or resource availability limitations. Few published studies have used real-world cases to investigate microbial community changes during the postmortem interval. This presentation will describe the human microbiome characteristics from samples collected during routine death investigation in Detroit, MI.

Since samples were collected on a daily basis, and not limited to the number of donors to a facility, this presentation will offer a unique perspective to the microbial community constituents, composition, and function across a variety of death circumstances. Further, there is a lack of established, long-term collaborations between basic researchers and forensic pathologists to reliably and consistently collect data during death investigation to study the ecology of microbial communities after death. Therefore, this presentation will provide unique insight into the largest known repository of postmortem microbiome samples and the considerations needed for collecting during death investigations.

Microbial samples were collected from 188 cases seen in the Wayne County Medical Examiner's Office in Detroit, MI. Sterile, DNA-free cotton-tipped swabs were used to collect microbial communities from five individual, external anatomic locations: the eyes, external auditory canal, nose, mouth, and rectum. For this study, a variety of cases were desirable to characterize postmortem microbial community stability and variation; thus, no demographic or manner of death was selected *a priori* to collections to ensure samples were obtained from a diverse set of death circumstances. DNA was extracted under aseptic conditions using a commercially available kit with a modified protocol; DNA was quantified using commercially available kits for a fluorometer and a microchannel-based automated electrophoresis system to ensure adequate sample quality and yield for next generation sequencing. The 16S ribosomal RNA (rRNA) V4 gene amplicon region was sequenced for each sample using a 2 x 250 base pair, paired-end approach using a high-throughput sequencing platform. Samples were processed using bioinformatic pipelines to analyze 16S rRNA gene sequences and to predict metagenome functional content from marker (amplicon) genes.

The dataset consisted of samples collected in 2014–2016. There were a balanced proportion of cases between male (56%) and female (44%), and Black (48%) and White (52%). The average (±Standard Deviation (SD)) age was 44±15 years with a range from 18-88 years. Deaths from homicide had a lower average age (35±13 years), while natural deaths had a higher average age (53±11 years). Accidents and suicides were in between (40±14 years and 49±17 years, respectively). Microbial analysis results revealed distinct postmortem microbiome signatures based on anatomic location and time since death. Microbial taxa characterized in the postmortem communities were consistent with communities previously detected in antemortem studies (e.g., *Alloiococcus otitis* in the external auditory canal samples). There were clear microbiome differences among sampling areas as decomposition time increased. Proteobacteria had a statistically significant increase ($p<0.05$) in abundance two days after death. A statistically significant increase in predicted cellular motility was detected after two days postmortem across sampling locations.

In conclusion, this dataset reveals the spatial and temporal variability of the human postmortem microbiome across the largest-scale survey of death investigation in a major, metropolitan city known to date. While traditional techniques for estimating the postmortem interval are important during death investigations, there is potential for using microbial communities as additional biomarkers to corroborate time-since-death estimates. As a community, we need to build the foundational datasets derived from real-world cases to test the validity of microbial communities as postmortem interval indicators. The collaboration between researchers and practitioners to improve non-traditional datasets, such as this one, will ultimately enhance science with practical application to the broader forensic community.

Forensic Science, Forensic Pathology, Postmortem Microbiome

H58 A Global Partnership to Study Geographic Variation in the Human Postmortem Microbiome (HPMM)

M. Eric Benbow, PhD, Michigan State University, Depts of Entomology & Osteopathic Med Specialties, 288 Farm Lane, East Lansing, MI 48824; Jennifer L. Pechal, PhD, Michigan State University, 243 Natural Science Bldg, Dept of Entomology, East Lansing, MI 48824; Heather R. Jordan, PhD, Mississippi State University, PO Box GY, Mississippi State, MS 39762; Vadim Mesli, MD, Institut Medico Legal, Rue Andre Verhaeghe, CHRU Lille, Lille Cedex, Nord 59037, FRANCE; Erwan Le Garff, MD, Institut Médico-Légal/Forensic Institute, Rue André Verhaeghe, Lille Cedex, Nord 59037, FRANCE; Valéry C Hedouin, MD, PhD, CHRU CS 70001, Lille, Hauts de France 59037, FRANCE; Carlo P. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207*

In recent years, there has been interest in using microbiomes in the forensic sciences. There are also several publications documenting the excellent potential for this new line of evidence collection; however, many of these studies have either used non-human models (e.g., swine) or donated human remains that are evaluated in controlled environments, limiting our understanding of the variability in the HPMM collected during routine death investigation, especially in widely separated geographic areas. After attending this presentation, attendees will have a better appreciation for the variability of the HPMM at two scales: (1) within a large metropolitan city; and, (2) across three European cities. Further, attendees will be introduced to a developing global partnership to study the HPMM. The mission of the global HPMM partnership is to expand studies of postmortem microbial ecology so scientists can better understand the potential broad application of the HPMM in practice, and the challenges and limitations that will be addressed as this new science emerges into forensic use.

This presentation will impact the forensic science community by providing new data from an ongoing, large-scale (>180 cases) study of the HPMM from samples taken during routine death investigation received at the Wayne County Medical Examiner's Office in Detroit, MI, and compared to new collections from France, Italy, and Austria. Additional impact will be to bring awareness of this global effort and perspective to evaluate the HPMM and discuss some of the challenges and limitations with bringing this new technique into practice.

Microbial samples were collected from 188 cases at the Wayne County Medical Examiner's Office from 2014 to 2016 during routine death investigation, and 25-30 cases received as autopsies or during investigation in Lille, France, Napoli, Italy, and Salzburg, Austria. All samples were collected using standardized kits constructed and packaged in the same location at Michigan State University under aseptic conditions. Each kit contained individually packaged, sterile, DNA-free cotton-tipped swabs and 1.7ml microcentrifuge tubes with 200µl molecular-grade 96% ethanol for each case. Kits were shipped to each international location for standardized collections. For each case, individual swabs were used to collect microbial communities from five anatomic locations: the eyes, external auditory canal, nose, mouth, and rectum. After standardized swabbing, each swab head was placed into an individual tube, then the entire kit was placed at -20°C until DNA extraction and sequencing. DNA was extracted and quantified under aseptic conditions using commercially available kits. The 16S ribosomal RNA (rRNA) V4 gene amplicon region was sequenced for each sample using a 2 x 250 base pair, paired-end approach using a high-throughput sequencing platform. Samples were processed using bioinformatic pipelines to analyze 16S rRNA gene sequences.

In the Detroit dataset, cases were a balanced proportion of cases between male (56%) and female (44%), and Black (48%) and White (52%). The average (± Standard Deviation (SD)) age was 44 (±15) years with a range from 18 to 88 years. The cases from France represented 28% male and 72% female with an average age of 82 that ranged from 58 to 95 years; cases from Italy and Austria are being processed. Taken together, the HPMM was most highly influenced by anatomic location and then by the Postmortem Interval (PMI), suggesting that anatomic site should be considered before attempting to estimate PMI. Many of the taxa reflected antemortem communities, but this changed with increasing PMI. There was high variation even within body areas from the large sample size from Detroit; however, Proteobacteria was consistently more abundant at longer PMIs. Not surprisingly, much of the variation in the HPMM, even within body area, is likely attributable to antemortem health and lifestyle that is often associated with geographic area and the sociocultural environment.

The enthusiasm for using the HPMM in the forensic sciences is increasing globally; however, there is an urgent need to obtain a more quantified assessment of the local, regional, and global variability in postmortem microbiome communities. Part of this assessment will also require identifying key microbial taxa that are clear forensic indicators and are consistent among different lifestyles, geographic areas, and sociocultural environments. The new global partnership is intended to provide the collaborative network for achieving such inquiry to move this emerging science into future practice.

Forensic Microbiology, International Partnerships, Proteobacteria

H59 Fluorescent Bacteria in the Gut of Mice Carcasses Provides Insight on Postmortem Microbial Translocation

Zachary M. Burcham, BS, Mississippi State University, 75 B S Hood Road, Mississippi State, MS 39762; Jennifer L. Pechal, PhD, Michigan State University, 243 Natural Science Bldg, Dept of Entomology, East Lansing, MI 48824; Jeffrey L. Bose, PhD, University of Kansas Medical Center, 4003 Wahl Hall, W, Kansas City, KS 66160; M. Eric Benbow, PhD, Michigan State University, Depts of Entomology & Osteopathic Med Specialties, 288 Farm Lane, East Lansing, MI 48824; Carl J. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; and Heather R. Jordan, PhD, Mississippi State University, PO Box GY, Mississippi State, MS 39762*

After attending this presentation, attendees will better understand how host commensal microorganisms transmigrate and thrive immediately following the death and decomposition of the host. In addition, these microbial communities possess investigative potential during the discovery of remains in determining the postmortem interval.

This presentation will impact the forensic science community by providing original data that investigates how commensal bacterial populations transmigrate, colonize, and proliferate following death and the successional decomposition of the associated host. Data obtained will significantly further knowledge of how genetically marked commensal bacteria in the gut transmigrate through their host as decomposition progresses.

Microorganisms play a vital role in the decomposition of remains. Bacteria, archaea, and eukaryotes begin competing against each other to break down and utilize highly nutritious tissues. Organisms able to withstand the changing environment and equipped with proteins that allow more efficient tissue destruction and cell motility have a competitive advantage. Recent work has shown that these bacterial communities are dynamic during decomposition, leading to questions of their utility for either taxonomic or metabolic markers to the postmortem interval. This presentation describes how two genetically labelled communities of *Staphylococcus aureus*-RFP and *Clostridium perfringens*-pZMB2 were orally introduced to a mouse model for colonization of the gut in a living host and subsequently tracked as they migrated through the carcass during decomposition. Aerobic and anaerobic bacteria were monitored in each organ by plate counts, and genetically labelled organisms were tracked using Real-Time quantitative Polymerase Chain Reaction (RT-qPCR). *S. aureus*-RFP was able to be detected by fluorescent imaging *in vivo* to determine colonization routes associated with different physiological events of host decomposition. Mice were dissected and organs harvested at timepoints starting at 1 hour and up 30 days after death. The organs were swabbed for plating, then preserved for total RNA extraction. The total RNA was used for RT-qPCR to identify the inoculated *C. perfringens* and *S. aureus* loads in each organ at each timepoint. These methods provide original data to uncover how commensal bacterial populations transmigrate, colonize, and proliferate across multiple organs following death and the successional decomposition of the associated host. Data obtained significantly furthers investigations identifying microbial behavior during decomposition that may be unique to the postmortem interval to allow for measurements of the time of death used in forensic investigations.

Microbial Transmigration, Decomposition, Postmortem Interval

H60 Autopsy Sampling to Uncover Human Resistome Diversity

Heather R. Jordan, PhD, Mississippi State University, PO Box GY, Mississippi State, MS 39762; Zachary M. Burcham, BS, Mississippi State University, 75 B S Hood Road, Mississippi State, MS 39762; Jennifer L. Pechal, PhD, Michigan State University, 243 Natural Science Bldg, Dept of Entomology, East Lansing, MI 48824; Hannah Campbell, BS, Mississippi State University, PO Box GY, Mississippi State, MS 39762; Jason Rosch, PhD, 262 Danny Thomas Place, Memphis, TN 38105; Carl J. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; and M. Eric Benbow, PhD, Michigan State University, Depts of Entomology & Osteopathic Med Specialties, 288 Farm Lane, East Lansing, MI 48824*

After attending this presentation, attendees will be informed regarding a novel method for uncovering the human resistome within a given population and will be familiar with an Antibiotic Resistance (AbxR) gene dataset from samples collected during routine death investigation in Detroit, MI.

This presentation will impact the forensic science community by providing novel data characterizing antibiotic-resistance genes identified through samples collected at autopsy of bodies within 24 hours of death. This presentation offers unique methodology demonstrating the utility of autopsy sampling in order to surveil antibiotic resistance within a population to predict potential outbreaks of antibiotic-resistant threatening bacteria. Per research, this is a first-of-its-kind study.

Bacteria have expressed AbxR genes long before the antibiotic era, but the use of antibiotics in agriculture and human medicine has dramatically increased their prevalence and intra- and interspecies transfer (e.g., human-to-livestock and microbe-to-microbe). Most studies have focused on the gut, using fecal samples or other minimally invasive sampling methods in healthy individuals to characterize the human resistome; however, the body contains many unique microbial communities not easily accessible in a living individual that likely also contribute to AbxR. Also, surveillance efforts focus on the clinical cases themselves and seldom focus on the potential cases that can arise in the general population.

This study investigated the ability to use postmortem microbiome sampling during autopsy as a method to detect the AbxR genes present in a human population located in Wayne County, MI. Cases were sampled (as previously described) within 24h after death to assess AbxR gene prevalence, identity, and transfer potential in a human population. Thirty-nine bodies were systematically swabbed during autopsy at eight anatomic sites to collect microbial DNA. The DNA from multiple body locations was combined from 20 individual cases to represent the "overall" body postmortem resistome. The samples were analyzed for the presence of 84 known AbxR genes using quantitative Polymerase Chain Reaction (qPCR) arrays. Samples from the calvarial trabecular space/interhemispheric fissure from the remaining 19 bodies were sequenced using Whole Genome Shotgun (WGS) sequencing and assembled into metagenomes that were aligned to known and putative AbxR genes.

Results from qPCR assays revealed that each of the 20 cases had an average of 7.1 AbxR genes. The most commonly positive AbxR genes detected were *ermB* and *mefA,* which were present in 90% of bodies. Genes resistant to the macrolide antibiotic class predominated, with 46% of all the positive AbxR genes. WGS revealed an average of 13.25 AbxR genes per body with *tetQ* as the most commonly found AbxR gene (42% of all the positive) out of the unique 42 AbxR genes detected. Results of this work expand human resistome research to include samples from locations not easily accessible by using samples taken during autopsy.

These novel surveillance methods will allow investigators to sample multiple anatomic sites in a wide range of individuals in the population to obtain information on the incidence and prevalence of antibiotic resistance genes and their presence in the community. Since death is, to some extent, a process with fewer selection biases and wide geographic distribution, sampling at autopsy can help reduce sampling bias and provide a more robust approach to detect the presence of AbxR genes associated with clinically important drugs, such as vancomycin, methicillin, and polymyxins, in the general population. Continuous sampling will also allow for uninterrupted surveillance of these genes once a baseline for their presence is established and serve as a sentinel when new ones are introduced, potentially even before they become clinically significant.

Antibiotic Resistance, Autopsy, Microbiome

H61 An Affordable Immersion Pump for Postmortem Computerized Tomography Angiography (PMCTA) in Forensic Pathology: The First Ten Cases

Wolf Schweitzer, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND; Patricia M. Flach, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; Dominic Gascho*, Universitat Zurich, IRM/Forensic Institute, Wintherthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; Lars Ebert, PhD*, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; Jakob Heimer, MD*, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zuerich CH-8057, SWITZERLAND; and Michael Thali, MD*, Universitat Zurich, IRM / Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND*

The goal of this presentation is to demonstrate how using an affordable immersion pump (a $16 to $20 device) compares with a roller pump (as part of a Heart-Lung Machine (HLM)) in terms of postmortem vascular filling. Results, particularly for intracranial vessels, are better for the immersion pump.

This presentation will impact the forensic science community by explaining how the replacement of an expensive technology, available since 2005 when PMCTA's were introduced and roller pumps were regarded as de-facto state-of-the-art, with more suitable and massively more affordable technology has the capacity to improve results and expand the user base.

Purpose: Approximately ten years after roller pumps were introduced for forensic postmortem Computed Tomography (CT) angiography, it remains an open question as to why a relatively expensive pump mechanism (costing around $1,000 for a used, old HLM to $80 000 for dedicated top-of-the-line postmortem equipment) is actually necessary for PMCTA. Roller pumps make sense for non-Newtonian fluids like blood, where mechanical hemolysis is also a factor; however, in PMCTA, watery or oily liquid is pumped into the vascular system of a body. After it was established in a feasibility study that a simple immersion pump (priced around $15 to $20) can be calibrated to obtain a linear voltage-flowrate relationship for the contrast agent solution used, and that ideal vascular filling at least as good as a roller pump is achieved, this study presents the results of the first ten cases.

Method and Material: Immersion Pump (IP): a Barwig model 0444 pump (max. 10L/min) was used (required PMCTA flow rate 0.2L/min–0,8L/min) (cost around $16-$20 EUR, power supply from $20 EUR and up). Roller pump/HLM: Stoeckert Shiley HLM (max. 10L/min) was employed. Cases: ten cases from forensic pathology caseload were selected in which PMCTA was seen as relevant and examined with the IP. Ten controls examined with the HLM were used for comparison. Both arterial and venous sides were filled from a femoral access. PMCT/PMCTA: Dual source/energy CT scanner was used (100kVp tube voltage, automatic dose modulation). Reconstructions were obtained on Siemens syngo.via software.

Results: Vascular filling was compared related to cerebral vessels, large vessels, coronary arteries, neck and head arteries, extremity arteries, and, on the same level, veins. Figures show the results. Results were the better with IP. Tube handling was problematic at first but was greatly supported by adding custom 3D-printed support structures.

Discussion: The results may be explained by the fact that the fluid contrast agent admixture is very efficiently pumped by immersion or centrifugal pumps. So, in fact, a physical benefit a roller pump may have for pumping non-Newtonian fluids does not seem to work for this application.

Conclusion: To be able to perform a postmortem CT angiography with very affordable equipment of the same quality as high-priced equipment means that a parametrized method can be validated and employed in far more institutes than when using expensive parts.

PMCTA, Virtopsy, Forensic Imaging

H62 Exsanguination on Postmortem Computed Tomography (CT) — What Remains When Blood Leaves the Body

Jakob Heimer, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zuerich CH-8057, SWITZERLAND; and Vasiliki Chatzaraki, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zuerich CH-8057, SWITZERLAND*

After attending this presentation, attendees will understand the typical findings that can be seen or expected on postmortem CT in cases of fatal bleeding.

This presentation will impact the forensic science community by providing a review of the literature on exsanguination on postmortem CT as well as results of a case-control study in order to support the scarce literature on the subject.

Introduction: Exsanguination is a common cause of death and may be differentiated in internal and external hemorrhage. Internal blood loss may occur naturally in gastrointestinal bleedings, but it is also frequent in deceleration trauma and consecutive vascular ruptures. The cause of lethal external exsanguination is nearly always non-natural and most common in cases of sharp force injury, traffic accidents, and any form of dismemberment. In classic forensic pathology, loss of a large volume of blood can be assumed when a body presents with only minor lividity. The spleen, kidneys, and liver usually present with discoloration and pallor at autopsy. For postmortem CT, the low density of the lungs as well as decreased cross-sectional areas of great vessels has been reported.[1,2] This study attempted to compare organ radiodensities organs and measure vascular cross-sectional areas in order to characterize exsanguination on postmortem CT.

Methodology: (Results for the control group are printed in **bold**.) In this case-control study, 60 cases that died from internal or external exsanguination were retrospectively matched with cases of identical age and sex. All controls presented no history or evidence of antemortem or peri-mortem loss of blood at external examination and autopsy. The case group was 66% **(66%)** male with a mean age at time of death of 55.1 (**55**) years. The interval between death and CT examination was 29 (**34**) hours. Causes of death were "blood loss" in all cases, with internal (31), external (27), and both internal and external (3) bleeding. In the control group, causes of death were cardiac (36), central nervous (14), metabolic (4), respiratory (4), due to infection (2), and hypothermic (1). Density of the lungs, spleen, kidneys, and liver and were measured by manually applied regions of interest using syngo.via. Cross-sectional areas of the ascending aorta, the descending aorta, and the superior vena cava were measured in a transversal slide at the height of the tracheal bifurcation.

Results: (Results for the control group are printed in **bold**.) Average cross-sectional areas differed significantly (P<0.001) for the ascending aorta (3.5cm^2; **5cm^2**), the descending aorta (2.36cm^2; **3.36cm^2**), and for the superior vena cava (2.21cm^2; **4.02cm^2**). Radiodensities of kidneys (40.5HU; **39.9HU**) and the spleen (50.9HU; **49.9HU**) did not differ between cases and controls. Radiodensity of the liver was significantly (P<0.001) higher in cases (56.8HU) than in controls (**46.3HU**). Pulmonary density was significantly (P<0.001) lower in cases (-661HU) than in controls (**-529HU**).

Discussion: While kidney and spleen radiodensity exhibited no difference between cases and controls, liver density was higher in cases of lethal exsanguination. This may be explained with the higher-than-blood parenchymal density of the liver antemortem (47.5HU) in comparison to the spleen and kidneys, resulting in an average increase of radiodensity with less blood content.[3] For the lungs, a lesser blood content reliably leads to a reduction in radiodensity. The reduction in cross-sectional areas of vascular structures close to the heart represents a collapse of the vessels in cases of exsanguination. This collapse is more pronounced in the vena cava in comparison to the aorta, most probably due to thinner vascular walls. In conclusion, decreased vascular cross-sectional areas as well as decreased pulmonary density and increased liver density are indicators for fatal exsanguination and may support and grade this diagnosis.

H63 Global Illumination in Postmortem Computed Tomography (CT): A Presentation of Its Use in Forensic Medicine

Martin Kolopp, Rue du Morvan, Vandoeuvres-lès-Nancy 57500, FRANCE; Alain Blum, PhD, CHRU de Nancy - Imagerie Guilloz, 29 Avenue du Maréchal de Lattre de Tassigny, Nancy 54000, FRANCE; and Laurent Martrille, MD, Service de Medecine Legale, Faculté de Médecine, BP 184, Vandoeuvres-les-Nancy Cedex 54505, FRANCE*

The goals of this presentation are to: (1) introduce the global illumination technique; (2) explain the application of 3D reconstruction in forensic medicine; and, (3) explain the advantages and disadvantages of 3D reconstruction vs. visual examination.

This presentation will impact the forensic science community by improving the quality and accuracy of 3D reconstruction of postmortem CT. Forensic diagnosis prior to the autopsy will be easier and exposure to a non-medical audience more comprehensible.

Postmortem CT (PMCT) and 3D reconstructions are commonly used in forensic medicine and enable highlighting lesions before any forensic examination, especially the autopsy. They are also a good way to present medicolegal findings to a non-medical audience, such as state attorneys, judges, and juries. For a number of years, the technique frequently used for the modeling of 3D reconstructions was the Volume-Rendering Technique (VRT).

More recently, a novel technique has appeared in medical imaging: Global Illumination (GI) (also referred to as cinematic rendering technique in the literature). This technique simulates the complex illumination of an object and is commonly used in virtual cinematography. Its application in medical imaging enables the production of a more realistic and, therefore, a more accurate and comprehensible 3D reconstruction of the CT images.

The cases presented are from the Institute of Legal Medicine of Nancy, France. In some medicolegal cases (i.e., degraded cadavers, ballistic cases), a PMCT is systematically performed prior to the autopsy. This study treated these images with GI in order to explore the possibilities and interest of this new technique in forensic medicine.

In the case of bone study, three types of approaches were compared: the VRT reconstruction, the GI reconstruction, and the visual examination (during autopsy and/or after anthropologic preparation). Compared to the VRT, GI offers more realistic views of the skeleton: simulation of the shadows helps the observer better understand the reconstruction in 3D (depths and reliefs) and the illumination enables modification of the position of the light source and, therefore, the appearance of the bone lesions.

Compared to visual examination, GI has advantages and disadvantages: it enables the exploration of lesions before any dissection of the cadaver; the application of textures and colors according to the density level permit a reconstruction very similar to visual examination; the segmentation of each anatomical structure or bone fragment enables precise study of bone lesions and the reconstruction of complex fractures. However, the quality and accuracy of the 3D reconstruction depends on the resolution of the PMCT. Thus, in some cases, the finest fracture lines were not visible on VRT and GI but were observed by visual examination. A case is presented in which fine impacts of a blunt or spiky weapon were present on the left temporal bone around a major penetrating wound. All of these impacts were only seen during the autopsy.

In medical imaging, the algorithms of 3D reconstructions are more complex and accurate, permitting the realization of more realistic images. Among them, GI and the software it uses are not routinely employed in France, but the results are promising, both in forensic medicine and for clinical application. In the literature, some papers present clinical applications of GI, with only one in forensic medicine.[1] The examples presented here illustrate that they cannot replace the visual examination at autopsy.

Postmortem CT, 3D Reconstruction, Global Illumination

H64 Detection of Pulmonary Thrombembolism and Postmortem Clotting on Postmortem Magnetic Resonance Imaging (MRI)

Lars Ebert, PhD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; Dominic Gascho, Universitat Zurich, IRM/Forensic Institute, Wintherthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; Michael Thali, MD, Universitat Zurich, IRM / Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND; Patricia M. Flach, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND; and Barbara Fliss, MD, MSc, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich CH-8057, SWITZERLAND*

The goal of this presentation is to learn how to detect and distinguish between postmortem clotting and Pulmonary Thromboembolism (PE) in postmortem MRI.

This presentation will impact the forensic science community by providing another tool to detect natural causes of death by using MRI without performing an autopsy.

The purpose of this study was to develop a feasible imaging protocol superior to Postmortem Computed Tomography (PMCT) and to establish diagnostic parameters for diagnosing PE on Postmortem Magnetic Resonance (PMMR) imaging. The PMCT and PMMR protocol developed here should enable further users to distinguish between postmortem clotting and pulmonary embolism by using postmortem imaging.

The study of 113 subjects consisted of 67 males and 46 females ranging from 17 to 89 years of age (mean 55.8 years in males and 53 years in females). This collective was taken from cases which were brought to the Institute of Forensic Medicine in Zurich. The autopsy of each case was ordered by a district attorney. If the case history provided information which led to the suspected diagnosis of a pulmonary embolism, it was included in the study group and was prospectively investigated by PMCT and PMMR for the presence of PE and/or postmortem clotting (cruor). After the postmortem imaging process, an autopsy was performed to verify the radiological findings.

Pulmonary embolism was detected in 20 cases; the remaining 93 cases were investigated for the morphology of cruor (clotted blood). Age graduation of the pulmonary embolism was performed by PMMR, autopsy, and histology using hematoxylin and eosin and elastic van Gieson staining. The postmortem sedimentation effect in which the cellular components of blood split from the plasma and deposit according to gravity was used for the applied imaging protocol on PMMR (supine and prone position).

Visual distension of the pulmonary arteries in PE was observed in all cases, but not in the cases with postmortem clotting. Repositioning of the corpse from a supine to a prone position proved to be beneficial in 90% of cases; pulmonary embolism did not exhibit any relocation after repositioning of the corpse, except in two cases of hyperacute PE. All cases with cruor showed movement of the clot within the blood vessel. Postmortem motion artifacts are first described in 20.4% of cases.

Hyperacute PE (grade 1) presented with a homogenous and hypointense signal on T2w images; acute PE (grade 2) presented with slightly heterogeneous, but still homogenous hypointense signal; subacute PE (grade 3) presented with heterogeneous and slightly hyperintense signal; and chronic PE (grade 4) presented with predominately homogenous with scarce portions of heterogeneous but hyperintense signal. In contrast, the cruor pattern was homogenous hypointense when the cruor was of a “red currant jelly clot” type and heterogeneous hyperintense in the “chicken fat clot” type.

In conclusion, this study shows that reliable detection of pulmonary embolism is feasible by PMMR and that this method allows for determination of the age and composition of an embolus based on morphology and signal intensity in the PPMR without performing an autopsy.

Postmortem Imaging, MRI, Pulmonary Thromboembolism

H65 A Comparison of Postmortem and Antemortem Computed Tomography (CT) for the Identification of Adults With Unique Anatomical Variations

Casey P. Bitting, DO, Office of the Chief Medical Examiner, 900 W Baltimore Street, Baltimore, MD 21223; Zabiullah Ali, MD, Office of the Chief Medical Examiner, 900 W Baltimore Street, Baltimore, MD 21223; Nikki Mourtzinos, DO, Office of the Chief Medical Examiner, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, Office of the Chief Medical Examiner, 900 W Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will recognize the utility of CT comparison in the identification of human remains using antemortem-postmortem CT comparison of unique anatomical variations. Furthermore, attendees will recognize the ability of the forensic pathologist to make these comparison-based identifications.

This presentation will impact the forensic science community by exploring additional skeletal features that would facilitate the identification of human remains using CT, especially fragmented or incomplete human remains from cases of mass fatalities.

Identification of human remains, whether complete or partial, is a critical and challenging task for a forensic pathologist.[1] Although DNA analysis remains a steadfast tool in the identification of fragmented, commingled, or partial human remains, time and cost constraints make it particularly prohibitive. Historically, radiological examination for identification has proven useful in comparing various anatomic structures including, but not limited to, cranial features, osseous structures, soft tissues, and teeth.[2-5] Compared to other modalities, radiological examination, more specifically analog imaging, is more cost-effective and has been widely used in the medical examiner setting as a means of identification.

At the Office of the Chief Medical Examiner (OCME) for the State of Maryland, postmortem CT is routinely used as an adjunct tool for diagnostic or identification purposes. Postmortem CT has been extensively used for its utility in identification based on comparison of anatomical variations, including nasal turbinates and sinuses, cranial sutures, degenerative and idiopathic changes of the spine, and anomalous or unusual development of skeletal structures.

To broaden the spectrum of potential identifying characteristics, a study was conducted by retrospectively and prospectively collecting cases with postmortem CT images obtained in the OCME office from 2015 through 2017. The final cases were then selected based on the availability of antemortem CT images to specifically assist for additional morphological features that could be useful in confirming the identities of incomplete remains. Once all images were obtained, a unique identifier was assigned to each postmortem CT image for the purpose of blinding the designated forensic pathologist, with experience in forensic radiology, who would perform the comparison. The results were qualitatively assessed for accuracy and reliability for identification purposes. CT scanning has proven to be a useful and scientific method of identification, especially in cases of limited radiographic studies or partial anatomic remains available for identification.

This study demonstrates that identification of human remains, even in a fragmented state, could be performed by a forensic pathologist with limited CT experience, in a medical examiner setting.

Postmortem CT, Identification, Human Remains

H66 Photogrammetry Applied to Forensic Pathology: Low-Cost Support to "Freeze the Body in Time"

Laura Donato, Via Tripolitania 195, Rome 00199, ITALY; Alessandro Di Luca, MD, Via Domenico Chelini 7, Roma 00197, ITALY; and Rossana Cecchi, PhD, Department of Medicine and Surgery, Via A. Gramsci 14, Parma, Emilia Romagna 43126, ITALY*

After attending this presentation, attendees will understand the usefulness of the photogrammetry technique during an autopsy.

This presentation will impact the forensic science community by providing a recording 3D technique that would also be user-friendly and a valuable support during an autopsy.

The major challenge in every type of forensic investigation, both during the crime scene and in the autopsy phases, is gathering a sufficient amount of information to reconstruct the conditions of a crime scene or a dead body. This can be achieved by the long and difficult work of gathering data that will, objectively, be insufficient to "fix in time" every aspect of the examined situation. Moreover, traditional acquisition methods risk providing information that is too related to the investigator's point of view. The solution lies in freezing, by virtual means, the scene and/or the body in order to obtain a representation that is free of the investigator's influence.

The technologies that are currently available allow this, but they impose a high monetary cost. The method described in this presentation suggests the possibility of achieving such an objective at a very low cost. The only requirements are a digital camera and appropriate computer software. This technique derives from a full photographic report based on photogrammetry.

Photogrammetry is a highly sensitive technique that allows the gathering of the metrical data of an object (shape and position) by acquiring and analyzing stereometric pictures. Several different types of software are capable of this technique. On average, the different programs allow the acquisition of up to 500 pictures of the object (acquired from several points of view) in order to provide a 3D reconstruction of it. Once the pictures are uploaded in the software, they are processed with a method known as Structure From Motion (SFM), which consists of recognizing a point in common between various images using the Scale Invariant Feature Transform (SIFT) algorithm. This allows the creation of a cluster of points characterized by their special positioning in a system of coordinates and intensity scale values (color, depth, etc.), allowing the re-creation of a 3D version of the object.

The original photogrammetry technique was used in architecture and geology to obtain accurate reproductions of the plans of buildings or natural cavities. In time, it was expanded to include the bio-medical field and became indispensable in the creation of anatomical models and the creation of 3D prosthetic devices.

This study introduces the use of the photogrammetry technique to the field of forensics.

Forensic Science, Photogrammetry, Virtual 3D Rendering

H67 Forensic Photography: Focus on Small Findings Using Digital Consumer Cameras

Valeria Hofer, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zuerich CH-8057, SWITZERLAND; Rosa M. Martinez, MD*, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND; Michael Thali, MD*, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND; and Wolf Schweitzer*, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND*

After attending this presentation, attendees will understand how a clear, specific instruction for sharp, focused images with consumer cameras can assist trainee doctors in taking better pictures, particularly of small findings.

This presentation will impact the forensic science community by explaining how the importance of having medical personnel able to take sharp, focused pictures of very small findings is not restricted only to doctors; it equally affects forensic nurses, mortuary technicians, and others.

Background: While forensic literature abounds with the mention of petechial hemorrhages or congestive hemorrhages, reliably photographing them using digital consumer cameras has neither been officially attempted nor documented comprehensively in an actual setting. The challenge consists in capturing hemorrhages as small as 0.3mm in diameter. An easy-to-understand instruction set was developed and the success in applying it to five test users was recorded. The impact on the quality of a series of test target photos was scored.

Methods and Materials: Given "feature" size for pinpoint hemorrhages of approximately 0.3mm and given image dimensions of 3,000 pixels with any "feature" requiring a minimum of 40 pixels for adequate digital representation, total metric image size should not exceed approximately 22mm. A step-by-step guide on how to reliably produce focused pictures of small targets with such dimensions was devised. Using a typical compact digital consumer camera (Canon® Powershot® G16, Backside Illuminated-Complementary Metal-Oxide Semiconductor (BSI-CMOS) sensor 1/1.7" with 4,000 x 3,000 pixels equating to 12 megapixels), compared the resulting digital image focus of four targets was compared. These targets contain submillimeter-sized features. Images were taken by five test users (trainee doctors in the same institute, with a self-reported basic to intermediate proficiency level, not advanced or professional). Image quality was compared before and after exposing the test users to a step-by-step guide on how to reliably produce focused images. General recommendations were made available from the outset. In a step-by-step instruction, suggest four criteria were suggested: (1) the use of an aperture priority above 5.6; (2) sensitivity (ISO) of not above 800; (3) an exposure of no longer than 1/60 second; and, (4) an optimal angle perpendicular to the feature being photographed. A score was devised that rated the photos on the basis of these criteria. Thus, an optimal image would yield 40 points.

Targets: This study used a printed array of small dots, a bank note featuring tiny anti-forgery perforations, a textile band featuring fabric structure, and a plastic model of a heart valve that contained small ink spots.

Results: Instructing this visual and easy-to-follow, step-by-step guide for correct setup and image-taking approach resulted in better images. The image series before the instruction across all five participants yielded an average of 25+/-1.8 score points per image; afterward, a mean score of 29.5+/-3.3 score points was achieved (statistically significant, Wilcoxon $p<0.04$); however, these efforts did not achieve perfect 40 score points in all instances.

Discussion: Quality improvement usually requires precise instructions and easy-to-follow approaches. Introducing high-tech to a medical frontline workflow does not succeed without these. General recommendations for forensic photography, typically citing the rule of thirds (usually not even applicable in macro photography) or vague explanations regarding image noise, seemed not overly helpful. The results of this study and where efforts need to be further improved to maximize outcome will be presented and discussed.

Forensic Photography, Consumer Cameras, Forensic Nursing

H68 The Redevelopment of the Mississippi State Medical Examiner's Office

Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; L.R. Funte, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Brent Davis, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Anastasia Holobinko, PhD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; and Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, MCL, 215 Allen Stuart Drive, Pearl, MS 39208*

The goal of this presentation is to reveal how the development of a structured state medical examiner system has improved medicolegal death investigations throughout the state of Mississippi.

This presentation will impact the forensic science community by demonstrating how a structured medical examiner system has improved the quality of the forensic pathology services throughout the state of Mississippi.

For more than 30 years, Mississippi contracted with non-board-certified pathologists to provide autopsy services to coroners, law enforcement, and district attorneys to assist them with medicolegal death investigations. This arrangement resulted in numerous false convictions leading to appeals. Many cases were reopened and overturned due to the efforts of the Mississippi Innocence Project.

The core of the problem was untrained and unsupervised pathologists tailoring their reports and testimony to support the expectations of law enforcement and district attorneys in order to obtain convictions. The majority of the examinations were performed in local funeral homes with substandard facilities. This deficiency compromised documentation of findings, collection of evidence, and chain of custody. Further, two independent pathologists reportedly performed a total of approximately 1,800 autopsies per year under these conditions. This total is unfeasible given the complexity involved in cause- and manner-of-death determinations.

The state of Mississippi finally recognized the need for a structured state medical examiner's system. In an attempt to rectify the issue with non-board-certified forensic pathologists, the state contracted with an adjacent state's medical examiner's office; this situation was terminated following unsatisfactory fulfillment of the contractual agreement.

Since 2011, Mississippi has hired only physicians who are board-certified in forensic pathology by the American Board of Pathology. A new facility was constructed in 2015 to jointly house the Mississippi crime laboratory and the medical examiner's office. The state-of-the-art facility contains four autopsy stations, each with its own 55" monitor for viewing digital radiographs and entering case information into an evidence-tracking database program. The physical continuity between the medical examiner's office and the state crime lab allows immediate access to multidisciplinary services, such as toxicology, firearms and ballistics, trace evidence, fingerprinting, and DNA analysis. Although a satellite office on the Gulf Coast remains unstaffed, the facility is sufficiently equipped to accommodate regional demands.

The medical examiner's office consults with a board-certified forensic odontologist, an arrangement which has facilitated numerous dental identifications. The office also recently hired two forensic anthropologists who are developing a statewide skeletal recovery and identification program.

While the quality and continuity of autopsy services has dramatically improved, there is a continual battle regarding funding and staffing issues.

Mississippi, State Medical Examiner, FP Board Certification

H69 Investigation of the Forensic Pathology Services of the National Institute of Legal Medicine and Forensic Sciences of Colombia

Miguel Arturo Velasquez Acevedo, MSc, Instituto Nacional de Medicina Legal y Ciencias Fo, Calle 7A 12A51, Bogota, DC, COLOMBIA*

The goal of this presentation is to show the degree of fulfillment of the facilities requirements for which the forensic pathology services of the National Institute of Legal Medicine and Forensic Sciences (INMLCF) of Colombia conduct medical-legal necropsies, using as a reference the requirements established by the National Association of Medical Examiners.

This presentation will impact the forensic science community by demonstrating the importance of the quality and execution of medicolegal autopsies and how they impact the final judicial investigation.

The INMLCF is the Colombian agency in charge of providing technical and scientific support to the administration of justice. In addition to other forensic services, the INMLCF performs medicolegal necropsies consisting of 114 points of attention to establish the cause and the manner of death.

This report presents the results of a study of the INMLCF forensic pathology services where such necropsies are performed. The goal of this study was to identify certain situations at these facilities, using as the main reference point the requirements established by the National Association of Medical Examiners. From the epistemological point of view, this research is qualitative and essentially corresponds to a descriptive study.

For this purpose, a self-administered survey was designed and applied using the LimeSurvey® platform. The results of this survey reveal that none of the services meet all the requirements; that the degree of fulfillment in the requirements varies widely between the different areas of care; that there are important limitations in the access of resources required to perform certain necropsies, such as access to X-rays. The results of this study will allow the senior management of the institute to determine the scope related to the purpose of accrediting such services. This study will establish actions to intervene at the facilities that require intervention, to make decisions regarding the provision of forensic services, and to suspend services rendered as a result of conditions that are considered to be unworthy (either for their own personnel or for their clients and/or users) or conditions that put the quality of necropsies or the safety of personnel and visitors in jeopardy. This may result in: (1) the relocation of necropsy services, among others; and, (2) submitting the need to incorporate resources to meet the requirements of both the administration of justice and society in general, based on objective facts, to the pertinent authorities.

Accreditation, Forensic Facilities, NAME Requirements

H70 Autopsy By Videoconferencing

Benjamin Mokdad, IML CHU Rouen 1 Rue de Germont, Rouen, Normandie 76000, FRANCE; Anne-Claire Lhoumeau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76031, FRANCE; Sophie Thureau, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; Cyril Gricourt, 1 rue de Germont, Médecine Légale, Rouen, FRANCE; Isabelle leblanc, MD, CHU Charles Nicolle - Institut Médico-Légal, 1 rue de Germont, Rouen 76000, FRANCE; and Gilles Tournel, PhD, CHU Charles Nicolle - Institut Médico-Légal, 1 Rue De Germont, Rouen 76000, FRANCE*

The goal of this presentation is to demonstrate how thanatology by videoconferencing constitutes an easier way to perform investigations, providing many advantages over the current practices.

This presentation will impact the forensic science community by explaining how this innovative project presents many logistical, pedagogical, and economic advantages and is part of a global media-judicial project.

Videoconferencing has existed in nearly all types of large and small business fields since the early 1960s; however, its use for forensic medicine has not been fully utilized to reach experts around the world. The initial objective of this study was to quantify the cost of transporting investigators to the Medico-Legal Institute in France during an investigation versus applying new methods to reduce expenses by finding ways to modernize and innovate forensic medicine.

This study covers a three-year period of evaluating the total expenses for the activities required to investigate crime scenes in the city of Rouen, France. The expenses include distances travelled by investigators, such as the local police and gendarmes (French police force) to be present at the forensic institute of Rouen to participate in an active investigation. Distances were estimated using the mapping features from the website Mappy.fr. The stipends, travel expenses, and material equipment used for the investigators were acquired using the audits from the French courts and tax offices.

Over three years, the investigators traveled more than 75,396km (46,849 miles) for a total of 2,720 hours of travel. This represents a minimum material cost of $33,000, a minimum human expense of $150,000, and vehicle downtime of 1,303 hours. These figures are minimal because they do not take into account the frequent presence of more than two investigators, multiple vehicles, or inherent traffic problems, which would increase the overall cost.

Thanatology by videoconferencing, while recording and encrypting data over secure networks channels, constitutes an easier way to perform investigations, which has many advantages over current practices. In addition to the indisputable cost restraints, the use of videoconferencing allows experts of different specialties to work together on the same case, even when separated by great distances. Delays due to travel are significantly reduced, allowing faster analysis. Judges can to take part from their offices during a live or recorded investigation. The investigator can solicit a forensic pathologist during a corpse discovery from his or her smart phone by an encrypted application dedicated to professional videoconferencing before he or she decides to solicit him or her for the crime scene investigation. Videoconferencing can also be an educational tool for the training and development of new investigators, judges, doctors, and students.

This innovative project presents many logistical, pedagogical, and economic advantages and is part of a global media-judicial project. Videoconferencing will quickly demonstrate its efficiency in view of the current high level of equipment required of police stations, the gendarmerie, and public prosecutor's offices. This system will greatly optimize the collaboration between justice and forensic medicine, and it will constitute a new teaching tool for our services while realizing savings for the Ministries of Justice and the Interior.

Videoconferencing, Thanatology, Forensic Medicine

H71 A Review of In-Custody Deaths in Mississippi

Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Brent Davis, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; L.R. Funte, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Anastasia Holobinko, PhD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; and Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, MCL, 215 Allen Stuart Drive, Pearl, MS 39208*

The goal of this presentation is to review the history and structure of the prison system in Mississippi and to present various cases in which inmates have died while in custody.

This presentation will impact the forensic science community by demonstrating the challenges in determining the cause and manner of deaths occurring while a person is in custody.

The first reported prison to be developed in Mississippi was in 1789 in the city of Natchez. The first centralized prison was not established until April 1840 and was designed to house 200 inmates. Overcrowding soon became an issue. Subsequently, the Governor released 40 inmates in order to increase the manpower of the Confederate Army. The prison was eventually overrun by Sherman's army on his march to Atlanta, GA. The current State Penitentiary in Parchman, MS, was built in 1901.

A federal mandate in 1972 ordered the state to develop a plan to address issues that included racial segregation, possession of weapons, drugs and alcohol, and the punishment of inmates. The Mississippi Department of Corrections (MDOC) was established in July 1976. Under their jurisdiction, there are 3 state-run prisons, 11 regional prisons, 6 private prisons, and 4 restitution centers. In addition, each of the 82 counties has at least one county jail. The MDOC houses approximately 21,000 inmates, 47 of whom are currently on death row. The MDOC inmate population figure is the second-highest in the nation.

The investigation of in-custody deaths is a multidisciplinary team effort and presents challenges at all levels. The most recent data available at the time of this submission shows a total of 65 in-custody deaths reported in 2016. This presentation will provide photographic and video documentation of scene and autopsy evidence that illustrates the variability exhibited by in-custody deaths falling under the jurisdiction of the Mississippi State Medical Examiner's Office.

Establishing the correct cause of death and manner of death is the crux of the issue. Media coverage and reporting of the deaths in conjunction with social media is essentially instantaneous and may cause misrepresentation of the facts and result in premature public bias against law enforcement personnel. As an impartial entity able to perform medicolegal postmortem examinations that elucidate the presence or absence of non-accidental traumatic injury, the State Medical Examiner's Office is uniquely equipped to contribute its expertise in the interpretation of these findings to assist in the education of law enforcement individuals. Identification of in-custody drug deaths is another benefit for the Department of Corrections and the Mississippi Bureau of Narcotics in tracking in-custody drug use.

In-Custody Deaths, Cause of Death, Mississippi

H72 The National Institute of Justice's (NIJ's) National Missing and Unidentified Persons System (NamUs) and the Federal Bureau of Investigation (FBI) Laboratory Collaboration: Using Next Generation Identification (NGI) to Solve Unidentified Persons Cases

Gerald M. LaPorte, MSFS, National Institute of Justice, Office of Inv & Forensic Science, 810 Seventh Street, NW, Washington, DC 20531; Bryan Johnson*, FBI Laboratory, Latent Print Support Unit, Quantico, VA 22135; and Luther S. Schaeffer, MSFS, MS, National Institute of Justice, Office of Investigative and Forensic Sciences, Office of Justice Programs, 810 Seventh Street, NW, Rm 6271, Washington, DC 20531*

After attending this presentation, attendees will understand new efforts that resulted in the identification of more than 190 Unidentified Persons (UP) cases over the course of six months.

This presentation will impact the forensic science community by explaining how new technology and enhanced methods for fingerprint identification can be used to solve UP cases.

In 2007, NIJ reported on the "Nation's Silent Mass Disaster," describing the more than 100,000 active missing persons cases and more than 40,000 sets of unidentified human remains in the United States.[1] At the time, resources to assist with unidentified remains and missing persons were minimal and disjointed and something needed to be done. Two principal needs were identified. The first was a centralized repository for the nation's unidentified and a way to capture essential information, including biometrics that would allow for comparisons with open missing persons cases. The second was a way to close the communication gap among agencies, jurisdictions, and the public so they could share information, collaborate on cases when needed, and help relatives searching for family members. To help meet these needs, the NIJ created the NamUs. By the end of 2007, NamUs' unidentified decedent database was online, followed by the missing persons' database. NIJ continued to expand the system and added another complimentary database for unclaimed persons that includes deceased people who have been identified, but for whom no next of kin has been located to claim them. As of July 2017, 14,389 UP cases have been entered into NamUs, but 11,483 of these cases remain open. Many of the unidentified human remains residing in NamUs are not readily identifiable. Of the active UP cases in NamUs, only 24% were noted to have recognizable faces. Factors that prevent visual recognition of the decedent include, but are not limited to, burning/charring, insect predation, traumatic injury, decomposition, or skeletonization of the body due to environmental factors.

In February of 2017, the FBI Laboratory and NIJ's NamUs initiated a partnership to begin searching all UP fingerprints through the FBI's NGI system. NGI provides the criminal justice community with the world's largest and most efficient electronic repository of biometric and criminal history information.[2] Using a different type of capability that allowed a more pointed search of each individual finger, a total of 2,184 individual fingerprint images (both 10-print cards and individual recordings) representing 1,465 individual UP cases were submitted to the FBI Laboratory Latent Print Support Unit and, within four months, a total of 193 identifications were effected. Of the 193 UP cases, 12% of the cases were ruled homicides and 31% were undetermined.

Many criminal justice agencies, including medical examiners and coroner's offices, are not aware of this program or have not considered re-examining fingerprints from unidentified decedent cases, especially since the implementation of NGI which came online in 2013. The new searching capabilities and enhanced methodology now available can more effectively identify fingerprints and should be considered by all medical examiners' and coroners' offices, even if previous searches resulted in unsuccessful outcomes.

H73 Jay Dix Memorial Bonus Day Lecture Series

Michael A. Graham, MD, Saint Louis University School of Medicine, Division of Forensic Pathology, 3556 Caroline, Rm C305, St. Louis, MO 63104; Joseph A. Prahlow, MD*, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Andrew M. Baker, MD*, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415; Rudy J. Castellani, MD*, Center for Neuropathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and James R. Gill, MD*, OCME, 11 Shuttle Road, Farmington, CT 06032*

After attending these presentations, attendees will understand how medicolegal deaths are evaluated and certified and how and why deaths related to the specified topics occur. Attendees will be aware of a systematic approach to the evaluation of such deaths that can be readily implemented in their daily practices.

These presentations will impact the forensic science community by providing a comprehensive review of what causes and contributes to deaths related to the specified topics. Attendees will better be able to systematically evaluate deaths in their daily practices in which the specified topics may have played a role.

A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual series of lectures is intended to provide the non-forensic pathologist forensic scientist a comprehensive basic review of selected topics in forensic pathology in order to increase familiarity and understanding and enhance inter-discipline communication.

This year's lecturers will discuss the medicolegal investigation of death and its certification -- the investigation of deaths due to firearm injuries, deaths that are temporally related to law enforcement apprehension and custody, deaths involving blunt trauma, and adult deaths involving acute and chronic head trauma.

Blunt force injury is one of the major categories of mechanical injury. Blunt force injuries are among the most common injuries sustained by people. These injuries include abrasions (scrapes), contusions (bruises), and lacerations (tears). Blunt force is also a substantial component of chop wounds, injuries caused by relatively heavy-edged objects, such as a machete or ax. Multiple factors and mechanisms are involved in injuries and deaths involving blunt forces. Understanding and evaluating injuries and deaths in which blunt force injuries may have played a role requires: basic knowledge of injuries caused by blunt forces and how to distinguish them from other types of trauma; recognition of patterned injuries; and recognition of injury patterns (e.g., pattern of falling versus pattern of being struck by an object). This lecture will provide a comprehensive review of these issues.

Firearm injuries constitute a major category of physical injury. Firearm fatalities are a major cause of non-accidental morbidity and mortality in the United States. The appearance of these injuries is affected by the firearm, ammunition, range of fire, victim anatomy, and, in some cases, intervening targets. Multiple factors and mechanisms are involved in injuries and deaths involving firearm injuries. Understanding and evaluating injuries and deaths in which firearm injuries may have played a role requires basic knowledge of injuries caused by firearms, how these injuries are produced, and how to distinguish them from other types of trauma. This lecture will provide a comprehensive review of these issues.

Head injury is a common cause of trauma-related morbidity and mortality among adults. Findings in serious head injury depend on the mechanisms of injury, duration of survival, and, in some cases, co-morbid conditions. Proper evaluation of head injury is important in recognizing how an injury was sustained, excluding various potential or alleged mechanisms, evaluating accuracy and reliability of witness accounts, and aid in identifying the perpetrator in those cases involving inflicted injury. This lecture reviews the features of acute and chronic adult head injury, mechanisms of injury, manifestations of head injury, and the interpretation of anatomic and clinical findings in the context of a medicolegal death investigation and quality of evidence in the literature.

The certified cause and manner of death have far-reaching ramifications, impacting areas such as grief, estate settling, insurance claims, civil litigation, criminal investigation and adjudication, investigations by regulatory agencies, public health policy, and research funding allocation, among others. The medicolegal death investigation is a multidisciplinary process designed to collect information pertaining to the deaths of individuals who die of conditions or under circumstances that place them under the jurisdiction of the medical examiner or coroner so that the medicolegal official is able to accurately and reliably determine cause and manner of death of these decedents. The determination of the cause of death is the practice of medicine and, like other medical practices, is based on integrating and interpreting information about the circumstances (history), physical examination (decedent and scene of incident/death), and ancillary studies (e.g., laboratory analyses, radiographic imaging). Accurate and comprehensive information obtained during a medicolegal death investigation contributes to the ability of the forensic pathologist to reliably and accurately determine the cause of death, identify other factors that contributed to death, and properly classify the manner of death. This lecture explores components of a modern medicolegal death investigation and discusses the fundamentals of the certification of deaths.

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to custody. The custody process can be divided into several stages — pre-custody, pre-incarceration, and incarceration. Particular diseases and injuries tend to occur and/or become manifest during each of these stages. This lecture will systematically review what diseases and injuries cause/contribute to death in the phases of custody related to apprehension and arrest, how they affect physiology and anatomy, when they are typically operative, and how they are manifest. Recognizing what occurs during the various stages of custody allows a systematic approach to assessing deaths that occur during the custody process. This lecture will review the conceptual and practical aspects of understanding and investigating deaths that are temporally related to the apprehension/arrest phases of custody.

Death Investigation, Forensic Pathology, Trauma

H74 Mind Over Matter: A Death Potentially Related to Non-Epileptic Seizures

William T. Harrison, MD, Duke University Medical Center, 524 Libson Street, Durham, NC 27703; and Tiffany O'Neill, DO, 1 Medical Center Boulevard, Winston-Salem, NC 27157*

The goals of this presentation are to: (1) review the clinical definitions of pseudoseizures, seizures, and epilepsy; (2) discuss a clinical case in which a young individual with a history of pseudoseizures died suddenly with no other identifiable anatomic or toxicologic cause of death; (3) emphasize the necessity of a thorough neuropathologic examination in cases in which a decedent may have had a history of epilepsy or pseudoseizures; and, (4) review the recommended sections that should be examined histologically at autopsy.

Psychogenic non-epileptic seizures, otherwise known as pseudoseizures, are well known to neurologists and psychiatrists, but are rarely encountered by forensic pathologists. This presentation will impact the forensic science community by reviewing the clinical and psychological aspects of pseudoseizures in comparison to true seizure disorders and discussing how the forensic pathologist should approach an autopsy of a decedent with a history of pseudoseizures. Non-epileptic seizures have not been thought to be a cause of death, but this case will raise the discussion of whether this is entirely true.

Non-epileptic seizures have an incidence of 2 to 22 people per 100,000 people. Many of the people who are diagnosed are worked up for epileptic seizures and have negative results. The seizures are thought to occur from psychological distress, as opposed to epilepsy, in which the seizures are brought on by electrical problems in the brain.

Presented here is the case of a 17-year-old female who was found unresponsive by her mother who then called Emergency Medical Services (EMS). EMS pronounced her dead at the scene. Reportedly, her feet were on the bed and her head was down in an adjoining closet with her face against a plastic bag.

Per medical records, the decedent was being followed for seizure-like events, approximately three to four events per week. An electroencephalogram was performed and reported to be normal and lab work was significant only for a low vitamin D level. The neurologist seeing the decedent diagnosed her with pseudoseizures, otherwise known as Psychogenic Non-Epileptic Seizures (PNES). These seizure-like events began after she had moved to a new place and only occurred when she was awake. There was no family history of epilepsy or neurological problems. Several days prior to her death, she was noted to have had a seizure-like event and knocked out a window with her foot. No major anatomic cause of death was found at autopsy. Postmortem toxicology was positive for therapeutic levels of sertraline and its metabolite.

A literature search was conducted in respect to non-epileptic seizures and death, of which there were no results. There is a link between Sudden Unexpected Death and Epilepsy, commonly known as SUDEP, but there was no known association with non-epileptic seizures. A discussion was had with the decedent's neurologist, who did not believe that non-epileptic seizures could result in death but may result in an inability to control the body. The mother of the decedent reported a plastic bag near the decedent's face, so it is possible there may have been an asphyxial component involved if the decedent had been having a non-epileptic seizure and her head fell near the bag.

Pseudoseizure, Epilepsy, Asphyxia

H75 Subdural Hematoma, Retinal Hemorrhages, and Cerebral Venous Sinus Thrombosis (CVST): Homicidal or Natural Death

Joshua Vandeburgh, 213 E South Street, Kalamazoo, MA 49007; Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and Rudy J. Castellani, MD, Center for Neuropathology, 1000 Oakland Drive, Kalamazoo, MI 49008*

The goals of this presentation are to: (1) identify the spectrum of cerebral changes secondary to CVST; (2) discuss the relationship between subdural hematoma and CVST; (3) discuss the relationship between retinal hemorrhage and CVST; and, (4) better interpret the manner of death in patients presenting with subdural hematoma and CVST.

This presentation will impact the forensic science community by advising attendees that the relationship between sinus thrombosis and subdural hematoma is of critical importance in assessing the manner of death in young children. This case, in addition to the literature review, provides valuable insight into this controversial issue.

Background: In the setting of witnessed, severe traumatic brain injury with subdural hematoma, CVST is not a meaningful differential diagnostic consideration; however, in the pediatric setting, severe traumatic brain injury within the home may be unwitnessed, especially among infants and toddlers. In such cases, the caretaker may not provide an accurate account of the extent, severity, or mechanism of trauma. Moreover, victims of inflicted head trauma often suffer neurological collapse with increased intracranial pressure, resulting in non-perfusion and organizing coagula within venous sinuses, mimicking CVST. The question may then be raised as to whether CVST was a primary process or an event secondary to abusive head trauma.

Methods: This study presents the autopsy findings in a 2-month, 21-day-old male infant who initially presented to hospital with seizures. The infant's father indicated that the infant fell during a diaper change but did not cry or respond. Subsequently, the father placed the child on the living room couch for a nap and within minutes he noted that the infant changed positions with his face toward the back of the couch. The father and paternal grandmother then noticed a diminished level of responsiveness. The father "shook" the infant briefly in an attempt to arouse him. Neither the father nor paternal grandmother report the infant hitting anything while being shaken. A Computed Tomography (CT) scan on presentation demonstrated acute subdural hemorrhage along the high right frontoparietal convexity near the vertex and along the interhemispheric fissure posteriorly with a maximum 3mm thickness. Magnetic Resonance Imaging (MRI) with and without contrast demonstrated restricted diffusion consistent with ischemia, within the right cerebrum and most of the left cerebrum. No venous sinus thrombosis was noted in the initial MRI. Ophthalmological evaluation revealed extensive intraretinal hemorrhages. The infant's neurological status failed to improve and he was eventually placed in hospice care. He expired approximated five weeks after presentation.

Results: Autopsy examination demonstrated bilateral extracerebral fluid collections with neomembranes. The underlying parenchymal tissue showed extensive ischemic brain injury. Ophthalmic pathology examination was remarkable for intraretinal, multilayered hemosiderin deposits and hemosiderin deposits involving the optic nerve sheaths. Noteworthy was organizing CVST with neovascularization and calcification, involving the superior sagittal sinus, transverse sinuses, and torcula.

Conclusion: This case raises the issue of CVST as a potential mimic for abusive head trauma. Literature review reveals that CVST as a cause of subdural hematoma is rare, but not non-existent. Although the MRI findings did not reveal evidence of CVST at presentation, the presence of unequivocal organizing CVST, the paucity of such lesions in longer term survival of abusive head trauma, and the lack of evidence for brain swelling and increased intracranial pressure clinically, suggested that CVST as the primary process could not be excluded. Abusive head trauma with subsequent cerebral venous stasis was also not excluded.

Cerebral Venous Sinus Thrombos, Subdural Hematoma, Retinal Hemorrhage

H76 Postmortem Evaluation of Mild Traumatic Brain Injury (Concussion): Importance and Relevance

Melissa M. Blessing, DO, Mayo Clinic, 200 First Street, SW, Rochester, MN 55905; and Ross Reichard, MD, Mayo Clinic, Div-Anatomic Path, Hilton 11, 200 First Street, SW, Rochester, MN 55905*

After attending this presentation, attendees will: (1) understand the pathophysiology of mild Traumatic Brain Injury (mTBI); (2) understand the medicolegal implications of mTBI, (3) understand appropriate case selection for postmortem mTBI evaluation; and, (4) understand techniques used to evaluate for mTBI.

This presentation will impact the forensic science community by explaining the importance and relevance of mTBI evaluation in the medicolegal setting, expanding upon the predominantly animal-based research, and increasing the ability of forensic pathologists to appropriately evaluate for mTBI.

MTBI, also referred to as concussion, is caused by mechanical trauma. The clinical features of mTBI include possible transient loss of consciousness and/or amnesia surrounding the event, a Glasgow Coma Scale between 13-15, and only rare imaging abnormalities.[1] The pathophysiology of concussion involves a predominantly excitatory neurotransmitter cascade with variable long-term sequelae.[2,3] Although animal studies have suggested structural changes following mTBI, trauma in humans resulting only in concussion rarely leads to death. Two recent cases elucidate the existence and extent of structural Central Nervous System (CNS) changes in humans following concussion and suggest the importance of postmortem evaluation for diffuse Traumatic Axonal Injury (dTAI) in select cases.

In the first case, a helmeted 72-year-old female bicyclist was struck by a motor vehicle traveling at approximately 30mph. Clinical evaluation revealed anterograde amnesia, a likely transient loss of consciousness, and Glasgow Coma Scale of 14 (of 15) which was 15 (of 15) upon arrival to the emergency department, consistent with mTBI. She sustained clavicle, rib, transverse process, and pelvis fractures and required respiratory support for a "flail chest." Head Computed Tomography (CT) was negative for acute pathology. She refused surgical intervention for her traumatic injuries and died two days later. At autopsy, petechial hemorrhages were extensive within white matter. Histological examination revealed organizing fat emboli. Immunohistochemical evaluation with Amyloid Precursor Protein (APP) unexpectedly revealed distinct axonal swellings in regions characteristic of dTAI.

In the second case, a 77-year-old female pedestrian was struck by a motor vehicle traveling between 20mph and 30mph. She was amnestic toward the event and had a brief loss of consciousness. She suffered head trauma and a scalp laceration, but maintained a Glasgow Coma Scale of 15 (of 15) and was diagnosed with a concussion. She sustained rib, clavicle, and pelvic fractures. Head CT revealed a temporal bone fracture, focal subarachnoid and small subdural hematoma without midline shift. She was anti-coagulated at the time of her injury, so thus was followed with serial head CT scans which unfortunately showed subdural hematoma expansion and midline shift. In spite of medical management, she became globally encephalopathic and died five days after her injury. At autopsy, neuropathological examination confirmed the clinical findings and demonstrated dTAI in addition to changes associated with increased intracranial pressure.

Academic and public interest in concussions is growing. While the sequelae of repetitive mTBI are becoming better understood, research demonstrating structural changes following a single episode of mTBI is predominantly animal-based.[3-8] These two cases show similar findings in humans, supporting the co-existence of both metabolic and structural post-concussive pathology. This is relevant to the medicolegal community for numerous reasons. The finding of structural damage upon neuropathological evaluation may be key to an investigation by elucidating incongruent details. For example, it allows postmortem evaluation for brain injury that may be unexpected given limited gross and/or intracranial pathology but prohibited the decedent from escape or self-defense. Alternatively, it may be relevant when considering if the injury could have impacted decision making. Finally, this microscopic finding enables postmortem correlation with imaging techniques designed to evaluate for mTBI during life.[9]

Appropriate sampling for histology and/or stock tissue is straightforward but must be thorough.[10] Although gross findings are unlikely in mTBI, postmortem evaluation for dTAI following known or suspected concussion samples the same white matter regions as in severe TBI. The posterior corpus callosum just anterior to the splenium is particularly high-yield.[9] Cerebral hemispheric white matter, posterior limb of the internal capsule, and the dorsal brain stem including pons and superior cerebellar peduncle(s) should also be sampled. Both Hematoxylin-Eosin (H&E) and the APP immunostains should be requested on these sections. In addition to highlighting TAI, APP demonstrates Vascular Axonal Injury (VAI) and other trauma sequelae. Experience is needed to differentiate these processes histologically; neuropathology textbooks and colleagues are helpful resources.

Postmortem evaluation for dTAI following concussion can yield information that is highly relevant to the cause and manner of death. Although the demonstration of structural changes of concussion is relatively new, a lower threshold for dTAI sampling is likely warranted. Forensic pathologists and neuropathologists should consider evaluating for dTAI when antemortem mTBI is reported or suspected as part of a complete medicolegal examination.

Forensic Neuropathology, Traumatic Brain Injury, Concussion

H77 Forensic Neuropathology of Cerebral Palsy (CP): The Implications for Cause-of-Death Determination

Zhanna Georgievskaya, City of New York OCME, 520 1st Avenue, New York, NY 10016; Yue Meng, BA*, Hofstra Northwell School of Medicine, 500 Hofstra Boulevard, Hempstead, NY 11549; Jacqueline Nunez, MD, City of New York OCME, 520 First Avenue, New York, NY 10016; Declan Mcguone, MBBS, City of New York OCME, 520 First Avenue, New York, NY 10016; and Rebecca Folkerth, MD, PhD, City of New York OCME, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will better understand the spectrum of neuropathologic substrates underlying CP.

This presentation will impact the forensic science community by informing attendees of: (1) the differential diagnosis of CP, including perinatal hypoxia-ischemia, developmental anomalies, post-infectious sequelae, and storage/metabolic/genetic disorders; (2) the gross and microscopic presentations of these conditions; and, (3) the approaches for forensic neuropathologic workup at autopsy.

Introduction: CP is the most prevalent physical disability in childhood and includes a heterogeneous constellation of non-progressive movement and posture disorders due to insults to the developing fetal or infant brain. Symptoms are spasticity (hemiplegia, diplegia, quadriplegia), dyskinesia, ataxia, and/or hypotonia, as well as variable cognitive impairment. Colloquially, "cerebral palsy" is applied to many ill-defined neurologic conditions arising in childhood and leading to long-term institutionalization. Thus, medical examiners often investigate their deaths and are responsible for determining the underlying cause and manner of death. This study sought to more accurately categorize the underlying neurolopathologic substrate in cases of "CP" referred to the City of New York Office of Chief Medical Examiner (OCME) over a two-year period.

Methods and Results: During this interval, 20 cases were referred to the OCME with the clinical diagnosis of CP. The investigation report, medical documentation, and clinical history were reviewed, as were gross and microscopic data. Fifteen decedents were male and five female; age range was 2-59 years (median, 28 years). Neuropathology fell into five specific categories: (1) hypoxic-ischemic injury (n=9); (2) genetic/syndromic/metabolic disorders (n= 5); (3) post-infectious sequelae (n=3); (4) traumatic brain injury (n=1); and, (5) other (n=2). For Category 1, examples include perinatal hypoxic-ischemic injuries with periventricular leukomalacia, germinal matrix hemorrhage and periventricular hemorrhagic infarct, status marmoratus, and aqueduct stenosis with hydrocephalus. Category 2 included Coffin-Lowry, Cornelia de Lange, and Klippel-Feil syndromes, and neocerebellar aplasia/hypoplasia.

Neuropathology was directly relevant to cause and manner of death in 15 cases owing to severe disability with general deconditioning, septic and respiratory complications, and malfunctioning of life-support equipment. In occasional cases, the neuropathologic diagnosis had direct impact on an affected family member for whom a specific diagnosis had not been made (e.g., neuronal ceroid lipofuscinosis in a twin).

Conclusion: In virtually all cases labeled as "CP," a specific neuropathologic diagnosis is possible, allowing more accurate categorization of cases and of corresponding cause and manner of death. Such specificity may have important clinical consequences for families and caretakers.

Cerebral Palsy, Hypoxic-Ischemic Injury, Developmental Neuropathology

H78 Preliminary Results of Synaptic Neuroplasticity of Memory Areas: A Comparison Between Violent Deaths and Sudden Deaths

Antonietta Lanzarone, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Antonina Argo, Via Del Vespro 127, Palermo 90100, ITALY; Elvira Ventura Spagnolo, MD, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Stefania Zerbo, MD, Via Del Vespro, 127, Palermo 90100, ITALY; Daniele Daricello, MD, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Rosario Barone, MD, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Maria Laura Uzzo, MD, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; and Giovanni Francesco Spatola, MD, BIONEC University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY*

The goal of this presentation is to understand the differences between cases of violent and sudden deaths in retrieving memories during the antemortem phase by activating dendritic spines. The hypothesis is to demonstrate that in the antemortem phase of violent death, the subject had a dendritic spines modification in areas of memory due to a difficult emotional experience, unlike sudden death.

This presentation will impact the forensic science community by providing valuable assistance to forensic pathologists to determine (for doubtful cases): death by violence; if, during the antemortem period, the subject was a victim of violence by their own killer (psychological violence, physical violence, etc.); and if, during the antemortem period, the subject had a strong emotional experience (suicide, instigation to suicide, etc.). All of these situations produce retrieving memories.

Recent experimental evidence has clarified the important role of some brain areas in the creation and retrieval of memories. In particular, memory mechanisms are linked to the modification of dendritic spines and their plasticity. The scientific literature offers many studies that clarify the framework of synaptic neuroplasticity in chronic mental diseases such as depression or post-traumatic stress disorder, but there are no works that attempt to clarify the neuroplasticity mechanisms that can be realized in a short time, as in violent death cases.

Toward this end, this study compared two groups of subjects. The first group consisted of violent deaths (suicide, homicide) compared to the second group consisting of sudden deaths. All subjects had been autopsied within 24 hours of death. This study includes subjects of a broad range of ages, between 20 and 60 years. During the autopsy, brains were removed and fixed with formalin, then sectioned to separate prefrontal, hippocampus, and amygdala areas in order to obtain samples to analyze.

Samples were treated with the immunofluorescence technique with antibodies against PSD95 and studied with confocal microscopy. PSD95 is one of the proteins involved in the development of dendritic spines from the first week of postnatal life and is part of the protrusions that are contained in the post-synaptic density. Some studies show that this protein is responsible for maintaining the size and binding force of the synapses. During this first step, prefrontal cortexes of six subjects were compared.

The prefrontal cortex is dedicated to the elaboration of current sensory experience in relation to data derived from previous personal experiences. In cases of violent death, a synaptic activation has been demonstrated by the presence of numerous dendritic spines responsive to PSD95 immunofluorescent. This positive response to PSD95 is more represented in violent death, especially when compared with sudden death cases in which the prefrontal cortex is nearly completely negative to the chosen marker.

In conclusion, these preliminary results encourage the continuation of these tests to assess whether there is a change in the synaptic pattern due to the recovery of memories during the antemortem phase and whether memory data retrieval is related to the manner of death (differences were found between a suicide by jumping from a height and a murder by stabbing).

Neuroplasticity, Violent Death, Forensic Science

H79 Cardiac Manifestations of Churg-Strauss Syndrome: A Case Report and Literature Review

Melissa Wils-Owens, BS, Eastern Virginia Medical School, 700 W Olney Road, Lewis Hall, Ste 1100, Norfolk, VA 23507; and Wendy M. Gunther, MD, OCME, Tidewater District, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510-1046*

After attending this presentation, attendees will be familiar with the characteristics of the rare disease eosinophilic granulomatosis with polyangiitis, formerly known as Churg-Strauss Syndrome, and the life-threatening cardiomyopathy associated with the syndrome.

This presentation will impact the forensic science community by emphasizing the differential diagnosis of eosinophilic syndromes and their life-threatening sequelae in young populations suspected of substance abuse.

A 22-year-old man with a history of long-standing asthma called 911 with complaints of chest pain and shortness of breath. He had presented to the emergency room on multiple occasions for the past two years, had been admitted eight times, and had undergone nerve biopsies for foot drop without diagnostic findings; he was believed to have mononeuritis multiplex. Earlier in the year, after an episode of eosinophilic pneumonia with leukocytosis, he was newly diagnosed with Crohn's disease. During his longest hospital admission in the last six months, Computed Tomography (CT) scan had diagnosed multiple hepatic abscesses, believed to be due to high-intensity steroid therapy. He was never out of hospital for more than a few days before returning with vague complaints of abdominal or chest pain that did not result in clear diagnoses. Medical records documented growing concern with his narcotics dependence and demands for stronger pain medications.

On the day of his death, the man appeared acutely ill at home. Police identified white powder at the scene. The man displayed combative behavior in the ambulance; with oxygen, he improved enough to transfer himself from the ambulance gurney to the emergency room bed. Within 15 minutes, he suddenly lost pulse and blood pressure and could not be resuscitated. Drug overdose was suspected, versus acute asthma exacerbation.

Autopsy showed "bread and butter" pericarditis and diffuse myocardial lesions without clear etiology that did not correspond to the coronary artery distribution. There were multiple recent wedge-shaped renal infarcts in the absence of any thromboembolic disease. Modest pulmonary hyperinflation was not suggestive of a fatal asthma attack; the lungs showed palpable granularity. The gastrointestinal tract was abnormal, but showed no gross evidence of Crohn's disease; there were no hepatic abscesses.

Histology identified Eosinophilic Granulomatosis with Polyangiitis (EGPA), formerly known as Churg-Strauss disease, in the heart, lungs, kidneys, gastrointestinal tract at multiple levels, and retroperitoneal vessels. There was extensive myocardial scarring, with both acute and resolving lesions. Histology confirmed no Crohn's disease. Toxicology was deemed non-contributory.

Cardiac involvement in EGPA includes carditis (myo-, endo-, and pericarditis), pericardial effusion, rhythm abnormalities, cardiac tamponade, and dilated cardiomyopathy, overall causing half of deaths attributable to EGPA. While only 25% have clinical cardiac symptoms, cardiac evaluations of patients with EGPA yield abnormal results in up to 62% of cases, highlighting the importance of early cardiac evaluation in patients with chronic asthma, gastrointestinal inflammation, and neuropathy.[1] The French Vasculitis Study Group has engendered a five-point system for assessing mortality risk, which includes reduced renal function, proteinuria, gastrointestinal hemorrhage, involvement of the central nervous system, and cardiomyopathy.[2,3] This patient fulfilled five of six diagnostic criteria, and three of five high-mortality criteria, with cardiomyopathy carrying the most significant prognostic weight.

Due to his narcotics dependence and steroid therapy masking his peripheral eosinophilia, his life-threatening EGPA cardiac involvement was not identified prior to autopsy. If cardiac imaging is initiated early in the disease process, and myocardial EGPA is treated aggressively, outcomes improve.[1] Autopsy findings such as those in this case can help guide future diagnoses.

Churg-Strauss Syndrome, Refractory Asthma, Allergic Eosinophilia

H80 Decomposition Odor Analysis Techniques and Prospective Applications in Postmortem Examinations

Katelynn A. Perrault, PhD, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816; Pierre-Hugues Stefanuto, PhD, University of Liège, Allée du 6 Août, 11, B6c, Liège 4000, BELGIUM; Lena M. Dubois, MSc, University of Liège, Allée du 6 Août, 11, B6c, Liège 4000, BELGIUM; Vincent Varlet, PhD, University Centre of Legal Medicine, Chemin de la Vulliette 4, Lausanne 1000, SWITZERLAND; Silke Grabherr, PhD, Centre Universitaire Romand de Médecine Légale, Chemin de la Vulliette 4, Lausanne 25, Vaud 1000, SWITZERLAND;and Jean-François M. Focant, PhD, University of Liège, Allée du 6 Août, 11, B6c, Liège 4000, BELGIUM*

After attending this presentation, attendees will understand the most recent chemical analysis techniques used to profile odor from decomposing mammals, as well as how these techniques are currently being applied to postmortem examination of human remains.

This presentation will impact the forensic science community by demonstrating a new method for obtaining information regarding the postmortem status of the remains by using a minimally invasive postmortem technique.

After death, decomposition processes release numerous Volatile Organic Compounds (VOCs) due to the breakdown of tissues by enzymatic and microbial degradation. These contribute to decomposition odor, which can be a tool used to locate human remains using biological detectors and/or chemical sensors. Since the first study of decomposition odor in 2004, methods for the collection and characterization of decomposition odor have evolved substantially, elucidating numerous new trends in the mechanism of cadaveric VOC production under different circumstances. Simultaneously, whole body Postmortem Computed Tomography (PMCT) has become a more common technique used in medicolegal centers worldwide, providing a means of detecting pockets of gases containing cadaveric VOCs through virtual autopsy. The long-term goal of this research is to use PMCT scanning in combination with new gold standard techniques in decomposition odor analysis to provide quantitative taphonomic information in forensic postmortem investigations.

This presentation will provide an overview of the evolution of odor sampling techniques as well as comprehensive Two-Dimensional Gas Chromatography/Mass Spectrometry (GCxGC/MS) for cadaveric VOC analysis. In addition, new applications of gas analysis for cadaveric VOCs have recently been demonstrated for minimally invasive postmortem examination procedures. It is hypothesized that the combination of whole body PMCT, in combination with Headspace/Solid-Phase Microextraction (HS/SPME) and GCxGC/MS analysis, could provide a valuable tool for postmortem examination procedures in the future.

A first proof-of-concept study was performed using PMCT gas reservoir sampling in combination with HS/SPME of VOCs from gas samples and analysis by GCxGC/MS for gas samples from three bodies associated with forensic casework. This study demonstrated that chemical differences existed between samples collected from different areas of a body, as well as between the same sample collection regions for different bodies. This provided a foundation for a secondary study that focused on full optimization of HS/SPME parameters, introduction of a deuterated internal standard mix for quality control, and stability testing, as well as an expanded study on 20 samples from five bodies associated with forensic casework. This optimized method can now be applied in future work to larger cohort studies as part of an established medicolegal network of laboratories that will contribute samples to a combined database. This will allow temporal trends to be better understood and provide robust data for statistical correlation of VOCs with postmortem interval considering factors such as age, weight, gender, etc.

This research is significant because it provides foundational data for further studies aimed at establishing decomposition odor analysis as a valuable postmortem investigation tool, especially as an alternative to more invasive procedures targeted at taphonomic characterization of bodies.

Taphonomy, Pathology, Volatile Organic Compounds

H81 Time and Temperature Effects on Volatile Organic Compound Generation During Early Decomposition

Brittany N. Reed, BSc, 38 Poplar Street, Cedar Run, NJ 08092; Robert H. Powers, PhD, University of New Haven, Dept of Forensic Sciences, 300 Boston Post Road, West Haven, CT 06516; and R. Christopher O'Brien, PhD, University of New Haven, Center for Wildlife Forensic Research, 300 Boston Post Road, West Haven, CT 06516*

The goal of this presentation is to inform attendees of recent advancements in the pattern of volatile organic compound evolution during the decomposition process.

This presentation will impact the forensic science community by providing insight into the relationship of time and temperature in the form of accumulated degree hours with the pattern of evolution of Low Molecular Weight (LMW) alcohols and related compounds in relation to Postmortem Interval (PMI).

Currently, there are few scientific methods based on chemical measurements used to estimate the PMI, highlighting the need for more information regarding this important parameter.

PMI can be an important parameter in many homicide or potential homicide investigations. During the immediate postmortem period, breakdown of organic materials takes place, resulting in the formation of LMW volatile compounds from both autolytic processes and, eventually, microbial activity. It was hypothesized that there is a differential pattern in which LMW alcohols and related compounds are generated from tissue during the process of autolysis and decomposition. Further, it was also hypothesized that the pattern of volatile compounds present in a tissue sample may be used, with consideration of time and temperature in the development of a potentially useful analytical technique of measuring PMI.

This study evaluated the pattern of evolution of VOCs from porcine liver at different time/temperature intervals throughout the decomposition process via Headspace/Gas Chromatography (HS/GC). Identification of specific compounds was accomplished by HS/GC/mass spectrometry. Ethanol was determined to evolve from decomposing pig liver in a time/temperature dependent fashion and to serve as a useful marker against which to evaluate the generation of other low molecular-weight alcohols and amines in both a temporal and quantitative manner. This study, therefore, utilized the ratio of several compounds to ethanol in an effort to relate accumulated degree hours of decomposition to the ratio of the marker compound-to-ethanol ratio.

This research has highlighted the potential for the use of specific chemical measurements and their role in estimating the PMI. The time/temperature-dependent compound ratios have been shown to have potential regarding evaluation of the PMI in death cases, which may augment observational information such as stage of decay and insect activity.

LMW Alcohols, Accumulated Degree Hours, Postmortem Interval

H82 The Big Sleep: Elucidating the Early Sequence of Molecular Events in the First Hours of Death to Determine the Postmortem Interval

Sara C. Zapico, PhD, FL International Univ, Dept of Chem and Biochem, Modesto A. Maidique Campus, OE116, 11200 SW 8 Street, Miami, FL 33199; Paula Núñez, PhD, Departamento de Biología Funcional. García-Pedrero, PhD, Hospital Universitario Central de Asturias, Edificio FINBA Lab ORL - IUOPA, Avda Roma s/n, Oviedo, Asturias 33011, SPAIN*

After attending this presentation, attendees will better understand the early sequence of molecular changes triggered immediately after death at the cellular level, ultimately providing a quantitative tool for determination of early postmortem interval.

This presentation will impact the forensic science community by demonstrating the added value of understanding cell death regulatory pathways and the crosstalk between autophagy and apoptosis for the estimation of postmortem interval.

Determination of postmortem interval is analyzed using multidisciplinary approaches. Among them, thanatochemistry methodologies seem to be useful and accurate in respect to classical methods. In this line, some works studied the stability of RNA expression using housekeeping genes, although only a few reports have to date investigated the thanatotranscriptome, thereby analyzing gene expression levels in internal organs of cadavers.

Decomposition begins approximately four minutes after death with a process called autolysis, inducing destructive changes in tissues and cells involving cell death; however, the nucleus remains without alterations until four days after death, thus making feasible the application of molecular and cellular methodologies for time-since-death estimation. In fact, recent trends point to the analysis of the expression of autophagy proteins (thanatophagy) toward this purpose.

Autophagy is often observed in dying cells, trying to mitigate a given stress. If the stress persists, cells can respond by activating processes of apoptosis. Even though autophagy and apoptosis represent distinct cellular processes, the protein networks that control their regulation and execution can be highly interconnected.

Based on these premises, the goal of this research was to study early postmortem interval (between two and eight hours) by analyzing: (1) messenger RNA (mRNA) and protein expression levels of both autophagy and apoptotic genes; and, (2) oxidative stress production and the expression of melatonin receptor, as a regulatory gene implicated in this process.

Four adult male Wistar rats were euthanized at the same time with intra-peritoneal injections of xylazine. The rat bodies were placed in the laboratory at room temperature and 20mg of gastrocnemius muscle were biopsied from each rat at different time points (zero, two, four, six, and eight hours) after death. Each sample was divided in two halves: one for oxidative stress and protein expression analysis and the second half for RNA extraction.

After processing on a standard lysis buffer, supernatants from the first half were divided in two for oxidative stress and protein expression analyses. Proteins were quantified by fluorometric assay, with concentrations ranging between 0.41 mg/ml and 23.18mg/ml. Standard Western blot protocol was used to study protein expression, followed by densitometric quantification.

Oxidative stress production was measured by fluorometric assay and the results expressed as Relative Fluorescent Units (RFUs).

RNA was extracted using Trizol protocol, and quantified by spectrometry, ranging concentrations between 483.5ng/µl and 1,622.1ng/µl. The next step was complementary DNA (cDNA) synthesis by reverse transcription, followed by quantitative Polymerase Chain Reaction (qPCR) to analyze the mRNA expression levels of autophagy (LC3, Beclin-1, ATG7 and ATG12) and apoptotic regulatory genes (FasL and PTEN) as well as the melatonin receptor (MT2). The relative gene expression was calculated using the $2^{-\Delta\Delta CT}$ method, and mRNA levels were normalized to Glyceraldehyde 3-Phosphate Dehydrogenase (GAPDH) levels.

The mRNA expression data for autophagy genes were in good agreement with the sequence of cellular events leading to autophagy. Thus, LC3 expression, implicated in the first phase of autophagy, was found to rapidly increase with a maximum peak at two hours. The other autophagy-related genes, implicated at later stages, showed a time-dependent increase until four hours after death. At this point, it seems that apoptotic signaling was triggered since FasL and PTEN mRNA levels as well as Cytochrome C protein expression consistently increased until six hours after death. In contrast, oxidative stress similar to autophagy expression pattern was induced until four hours, then it decreased at six hours, and finally it further increased at eight hours, which can be correlated with the summit of autolysis process. Furthermore, as expected, induced MT2 expression parallels free radicals production at four and eight hours. Applying a multivariate regression analysis, a strong positive correlation was found between the expression levels of autophagy and apoptotic genes and the time since death.

These findings provide a proof-of-principle for a novel quantitative method to estimate early postmortem interval based on the crosstalk between autophagy and apoptosis. Future research may be directed to search for additional markers extending time-since-death estimates.

Postmortem Interval, Autophagy, Apoptosis

H83 Utilizing Radio Frequency Identification Technology (RFID) to Automate Data Acquisition Between the Baltimore Office of the Chief Medical Examiner (OCME) and the Living Legacy Foundation Organ Procurement Organization (OPO)

Pamela A. Ferreira, MD, 7802 Arbor Grove Drive, Apt 234, Hanover, MD 21076; Rick Kolovich, The Living Legacy Foundation, 1730 Twin Springs Road, #200, Halethorpe, MD 21227; Kendra Harris, MBA, The Living Legacy Foundation, 1730 Twin Springs Road, #200, Halethorpe, MD 21227; Michael Eagle, OCME, 900 W Baltimore Street, Baltimore, MD 21223; William Spencer-Strong, MBA, OCME, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223*

The goals of this presentation are to: (1) accurately and efficiently monitor individual cooling times of decedents at the OCME; (2) assist in the determination of transplantable tissue prior to recovery; and, (3) understand the critical time components that are needed to determine tissue donor suitability.

This presentation will impact the forensic science community by showing a way to automate cooling time data acquisition so that efficiency between OPO and OCME agencies increases and ultimately leads to an increase in tissue donors.

Time of death and cooling times are critical data needed to determine tissue donor suitability. According to the American Association of Tissue Banking (AATB), warm ischemic time shall not exceed 24 hours as long as the decedent was cooled within 12 hours of death. The time limit shall not exceed 15 hours if the decedent was not cooled within 12 hours of death.[1] The current system utilized between the Living Legacy Foundation (LLF) OPO and the OCME in Maryland requires OPO staff to call the OCME to obtain cooling times. Obtaining the crucial and time-sensitive information so as to assist the OPO in determining donor suitability is an additional time-consuming task levied on the forensic investigators and autopsy services personnel.

In 2011, the OCME opened their new facility in Baltimore, MD. In this new construction, the OCME incorporated Radio Frequency Identification Technology (RFID) to track medical case files with a potential expansion to track the location of decedents. In discussions with the OCME to improve current practices, the LLF inquired about the use of existing technologies to obtain accurate and timely access to cooling times. It was determined that the RFID readers located above the autopsy coolers might provide a way to automate this data capture.

In late 2015, the LLF met with the OCME leadership to propose a feasibility study to examine the use of RFID to track the movement of decedents in and out of the autopsy coolers. It was determined at that time that existing chart tracking software could be used to potentially import cooling time data into the OCME electronic intake screen. Over the next several months, the LLF trialed individually barcoded ID tags and performed a preliminary validation to determine the range and accuracy of the RFID antennae.

The next step included the actual tagging of decedents into the existing OCME database upon intake. Cooling time data was captured in "comma separated values" (csv) format, which is not a user-friendly format, and was difficult to interpret by LLF call center staff. With OCME information technology support, an additional table was added to the electronic intake screen that would import in and out cooling times on tagged decedents. A recent revision included a unique barcode field that automatically populates during the intake process to eliminate the possibility of entry error. The LLF created an Installation Qualification and Operation Qualification (IQ/OQ) document co-signed between the OCME and LLF that will be utilized in final validation and for auditing purposes.[2]

Final validation of this project began in August 2017 and will determine accuracy of data reading and import to the intake screen. A secondary goal is to test the system for failure and the ability to recognize and default to the previous process in the event of software outage. It is estimated that this new RFID data capture will have gone "live" by the 4th quarter of 2017. It is anticipated that by automating cooling time data acquisition, it will increase efficiency between both agencies and ultimately lead to an increase in tissue donors. By utilizing RFID, it is predicted that processes will be streamlined, donation will be optimized, and, more importantly, allow OCME staff to continue their daily duties uninterrupted.

H84 Nailfold Capillaroscopy Efficacy in Assessing Postmortem Interval (PMI) Compared to Vitreous Potassium Concentration: A Preliminary Study

Marianna Meroni, Center for the Excellence in Biotech Research CEBR, University of Genoa, viale Benedetto XV, 9, Genoa, GE 16132, ITALY; Valerio Ferretti, MD, Center for the Excellence in Biotech Research CEBR, University of Genoa, viale Benedetto XV, 9, Genoa 16132, ITALY; and David Bauer, MD, PhD, Pathology Dept, Univeristy of Genoa, Genoa 16132, ITALY*

The goal of this presentation is to introduce a new method in assessing PMI that seems to be more effective and reliable than vitreous potassium concentration.

This presentation will impact the forensic science community by demonstrating the originality of methods that have never been used in the forensic sciences to assess PMI.

Background: Postmortem vessel changes have been widely investigated to understand the pathophysiology mechanisms entailing capillary leaks. The multiphase Postmortem Computed Tomography Angiography (PMCTA) method allows one to analyze and restore the anatomy of circulation and is of particular interest in investigating the vascular damage-related causes of death.[1] External aspects of the postmortem modifications, such as hypostasis and color changes, are explained by the microvascular rearrangement in which blood clots precipitate within the vessel and the non-corpuscular part of the blood progressively expands throughout circulation.

An unequivocal and reproducible tool to determine the progressive onset of these changes has not yet been identified; even the efforts of forensic science requires several methods to attempt to establish and quantify the PMI.[2] At present, the most reliable seems to be the analysis of the potassium concentration in the vitreous fluid of the eye. By a mathematic model connecting the rise of this ion to the PMI, some authors have proposed a reasonable accuracy of the time-of-death estimation.[3]

Nailfold Videocapillaroscopy (NVC) is a highly reliable, reproducible, logistically practical, and cost-effective favorable technique, in which the nailfold bed capillaries of the fingers of the hand (excluding the first finger) are directly observed by the operator via a magnification lens (usually 200x). It is extensively used in cardiology, dermatology, and rheumatology settings to assess the capillary shapes, often predictive of clinical outcomes. It has recently been integrated by a software that allows it to perform automatic, instead of ocular, measurements of the number and intensity of capillary abnormalities, thus limiting the inter-observer variability and providing a semiquantitative, validated score.[4] Among the assessable alterations, perivascular edema due to capillary leakage can be easily scored.

Methods: After the approval of the local ethics committee, this study considered one-day consecutive subjects on whom autopsies were performed in the University Hospital. The exact time of death was available for all subjects. The bodies were kept at 20°C and the autopsies were performed in an interval randomly ranging from 12 to 36 hours after death; potassium (mmol/l) vitreous samples were collected, and NVC performed, bilaterally. NVC edema was scored by a dedicated software (VideoCap®) and expressed in a continuous quantitative score, set as *0*=perfectly defined shapes, no flu effect, to 35 (according to the potassium vitreous value range considered in most studies), consisting of completely undistinguishable vessels due to the perivascular "fog."[5-7] Obtained values were plotted versus known PMI by Pearson correlation and multivariate non-linear regression (Analysis of Covariance (ANCOVA)). The PMI was expressed in hours in the decimal system, and the statistical analysis was conducted by SAS/STAT® software Version 9.3. A statistical significance of $p<0.05$ with 95% confidence interval was retained.

Results: A total of 15 non-traumatic and 5 violent deaths were included (13 males and 7 females, average age 60±14 years). Among the 40 collected samples (potassium concentration from both eyes and the average edema score for the eight fingers examined, for both hands), the concentrations of potassium ranged from 8.4mmol/L (PMI of 12 hours) to 35.1mmol/L (PMI of 30 hours), while NVC edema scored, respectively, from 8.8 to 34.9. Both values were positively and significantly correlated with PMI ($p<0.001$) but with a different accuracy: vitreous potassium, R^2=0.83 vs. NVC, R^2=0.99 ($p<0.05$, 95% confidence interval, 34 degrees of freedom). (See Figure 1, below).

Discussion/Conclusion: The PMI assessment has always represented a cardinal objective of forensic science, supported by increasing accuracy due to technology. The obtained data reflects the pathophysiology of the capillary leaks process that begins immediately after death, being conceptually in line with the potassium increasing concentration in the vitreous after metabolic processes stops. Despite the limited number of observations, this work represents a totally original approach in PMI definition, thanks to the contribution of a very simple, reproducible, and standardized technique. Extended data are needed for the validation of the NVC method in capillary assessment to confirm its reliability in determining PMI.

H85 Partially Skeletonized Remains Demonstrating Dragging Injuries, Internal Beveling of the Skull, and Tracheal Obstruction: A Team Approach

Brandy Shattuck, MD, Western Michigan Homer Stryker MD, School of Medicine, 1000 Oakland Drive, Kalamazoo, MI 49008; Carolyn V. Isaac, PhD, Western Michigan Homer Stryker MD, School of Medicine 1000 Oakland Drive, Kalamazoo, MI 49008; and S. Adam Shahid, PhD, Western Michigan Homer Stryker MD, School of Medicine, 1000 Oakland Drive, Kalamazoo, MI 49007*

After attending this presentation, attendees will recognize how a multidisciplinary team approach to partially skeletonized remains can help assist in determining timing of death and mechanism of trauma.

This presentation will impact the forensic science community by highlighting entomologic and anthropologic findings in partially skeletonized remains that may be found in medical-legal death investigations.

Skeletonized or partially skeletonized remains present challenges in forensic pathology. While identification of the remains has become easier with advances in fingerprinting, DNA, and comparative medical radiography, determining cause of death, manner of death, and approximate time of death can be difficult in this population. This study presents a case of partially skeletonized remains with distinctive bone damage on posterior surfaces and a cigar-like collection of leaves in the trachea.

Adjacent to a field, a partially skeletonized set of remains was discovered with multiple electric cords around the ankles and the neck. At the postmortem examination the next morning, the remains were found to have dry desiccation and mummification of the skin with skeletonization of the posterior aspect of the body, and a noticeable portion of the posterior cranial vault was missing. A forensic anthropologist was consulted to assess the skeleton. In addition to the skull, there were smooth, flat areas of bone disruption on multiple vertebrae, ribs, scapula, humerus, ulna, metacarpals, ilia, sacrum, femur, calcanei, and hand and foot phalanges. Such injury patterns are consistent with vehicular dragging as reported in the literature.[1-3] Furthermore, gross examination of the disrupted bones revealed evidence of gravel embedded in the bone margins. The margins of the residual skull were smooth and flat, with the exception of a single semi-circular defect that appeared to have inward beveling consistent with projectile trauma; however, the sharp, semi-circular defect did not have any associated skull fractures. The forensic anthropology team returned to the recovery site and subsequently recovered a section of skull that matched the area of inward beveling.

Further examination of the remains revealed a tightly rolled collection of green leaves in the trachea. A white larva was identified within the center of the leaf collection. An entomologist was consulted to identify the larva and to collect additional insects on the remains. The larva was determined to be a leafcutter bee (*Megachilidae*). The decedent was subsequently identified by fingerprint analysis. Law enforcement reported that the decedent was last known alive approximately three weeks prior to the discovery of his remains.

This unique case demonstrates the importance of having access to a multidisciplinary team when dealing with skeletonized remains in the forensic setting. The forensic pathologist was not familiar with leafcutter bees and their preference for nesting in open tubular structures, such as a trachea. One should carefully consider the circumstances and the possible mechanism of injury when assessing beveling in skeletonized remains that may have been dragged. While the pattern of inward beveling is closely associated with projectile trauma, it should be considered in cases of dragging. This team approach provided insight into the approximate timing of death and to the mechanism of skeletal injury, even if a discrete cause of death could not be determined.

H86 Does Black Tar Heroin "Protect" King County, Washington, From Fentanyl-Related Mortality?

Nicole A. Yarid, King County MEO, 325 Ninth Avenue, Seattle, WA 98104; Richard C. Harruff, MD, PhD, King County MEO, 325 Ninth Avenue, Box 359792, Seattle, WA 98104; Andrea Orvik, 2246 Forest Acres Drive, Johnson City, TN 37604; Janinne Blank, 501 Kensington Avenue, Buffalo, NY 14086; and Sini Panicker, 22624 Dulles Summit Court, Dulles, VA 20166*

The goals of this presentation are to: (1) describe regional differences in the so-called opioid epidemic; and, (2) explain possible reasons why King County, WA, has experienced a smaller proportion of fentanyl-related deaths.

This presentation will impact the forensic science community by attributing at least part of the high regional variability of drug overdose rates to the supply and demand of various opioids, specifically in the supply of black tar heroin, which appears to reduce the demand for the more potent fentanyl-type drugs.

In contrast to other regions around the country that have experienced rapidly rising opioid overdose death rates, King County, WA, has seen a relatively modest rise in overdose deaths. The present study was conducted to provide possible explanations for the differences.

Methods and Materials: Data on fatal overdoses in King County were obtained from the King County Medical Examiner's Office in Seattle, WA. Similar data were obtained from West Virginia and Erie County, NY. Data on overdose deaths in British Colombia, Canada, were obtained from the British Colombia Coroners Service report of June 30, 2017.

Results: From 1999 to 2016, drug overdose rates in King County increased from 11.9 to 16.9 per 100,000 population. Over the same period, the rates in Erie County increased from 2.6 to 35.5 per 100,000. In West Virginia, the total number of drug overdose deaths for the whole state increased from 212 in 2001 to 879 in 2016. In British Columbia, drug overdose deaths for the province climbed from 269 in 2012 to 967 in 2016. While drug overdoses deaths increased nearly exponentially in Erie County, West Virginia, and British Columbia, the rate of increase in King County was close to linear. The spectrum of drugs responsible for the increasing death toll was also different. In King County in 2016, the most common opioid responsible for fatal overdoses was heroin; only 22 deaths were due to fentanyl and related fentanyl-type drugs. In British Columbia, fentanyl-type opioids accounted for most of the three-fold increase in overdose deaths from 2012 to 2016. In West Virginia in 2001, only 9 deaths were caused by fentanyl type drugs; in 2016, the number was 360. In Erie County, fentanyl-type drugs were present in 229 of the 327 overdose deaths in 2016. Although heroin accounted for a sizeable proportion of opioid-related deaths in all locales, the physical characteristics of the drug varies from place to place. In King County, black tar heroin is the predominant form, while in British Columbia; Erie County, and West Virginia, heroin is predominantly a white or other color powder.

Discussion and Conclusions: Although opioid-related deaths have soared throughout the country in the last several years, the crisis in King County differs from the three places used for comparison in two ways: in King County, the rate of increase of drug overdose deaths is fairly modest rather than explosive; also in King County, fentanyl-type drugs are fairly uncommon in overdose deaths. The most likely explanation for the difference is the physical characteristics of the drug. Black tar heroin, by far the predominant form in King County, is a black gooey substance rather than a powder. This physical characteristic would make it difficult to simply mix black tar heroin with another powdery drug, such as fentanyl, while it would be easy to mix fentanyl into a powdery form of heroin. But this explanation may not be the only one. While it would be relatively simple to adulterate black tar heroin with fentanyl during the "cooking" phase of drug preparation, for unknown reasons, this appears not to happen very often. Very few seizures of black tar heroin have been found to contain fentanyl, and toxicology reports in King County infrequently find heroin and fentanyl together. It is also possible that mixing fentanyl into black tar heroin has no marketing advantage. King County has a strong history of black tar heroin consumption, and it is possible that the current supply of black tar heroin merely suits the local demand. While efforts continue to control both the supply of and the demand for abused drugs, it does appear that, ironically, black tar heroin "protects" King County against more potent fentanyl-type opioids.

Black Tar Heroin, Opioid Epidemic, Toxicology

H87 "Graze Laceration and Graze Fracture": Injuries Which Are Unnamed in Literature

Nilesh K. Tumram, MD, Department of Forensic Medicine and Toxicology, 85 Adarsh Grih Nirman Sanstha, Anantnagar, Nagpur, Maharashtra 440013, INDIA*

After attending this presentation, attendees will have a better understanding of the types of injuries found in various traffic accidents not mentioned in the literature. This presentation will also discuss the importance of recognizing such injuries, their mechanism of causation, and their importance in forensic cases.

This presentation will impact the forensic science community by introducing new terminologies for trauma caused by accidents in relation to the mechanism and manner of causation.

Humans have progressed from an early primitive state to the advanced state of the modern era. During this time, humans have been subjected to different types of trauma. Many of the injuries occurring are well classified in the literature. Still, a medical doctor faces different types of injuries that have little-to-no mention in the scientific literature. Naming the injury is very important as the nomenclature of such injuries is very helpful for future identification of the injuries as well as correlating them with the manner or object by which they occurred.

This study highlights some injuries that were found in trauma caused by vehicle mishaps. These injuries occurred due to dragging of a body for some considerable distance by high-speed vehicles. When such injuries occur to a victim and he is brought to the hospital, it becomes imperative for the doctor to name the injury correctly. This will be useful not only for treatment but also for future medicolegal purpose.

Graze laceration: These are injuries that occur when the surface of the body gets dragged over rough surfaces for a considerable period, causing grazing/friction of the body surface by that of the rough surface, resulting in a graze laceration.

Graze/grinding fracture: This fracture is caused by forceful dragging of the body involving bony parts over a rough surface for a considerable period, causing grazing/friction/grinding of the bone coming into contact with the rough surface, resulting in a graze/grinding fracture.

This study presents a case series depicting injuries featuring graze lacerations and graze/grinding fractures from road traffic accidents. This presentation will also discuss the importance of having knowledge of such injuries when dealing with medicolegal cases.

Trauma, Graze Laceration, Graze Grinding Fracture

H88 Fatalities to Children Falling Into Abandoned Borewells: A 10-Year Study

Nilesh K. Tumram, MD, Department of Forensic Medicine and Toxicology, 85 Adarsh Grih Nirman Sanstha, Anantnagar, Nagpur, Maharashtra 440013, INDIA*

After attending this presentation, attendees will understand the fatalities caused to children who accidentally fall into abandoned borewells.

This presentation will impact the forensic science community by informing attendees of the danger to children of playing in the vicinity of abandoned borewells regarding manner of causation of death, probability of survival, and the correlation of borewell depth with survival, if any.

There is a growing scarcity of fresh water reservoirs used for drinking, irrigation, and day-to-day washing and other personal usage. India has a varied geography, from snow in the mountains in the north to deserts in the west. The east has large broad rivers like the Ganges and Brahmaputras, while the south faces heavy rainfall. All these regions face the scarcity of potable water. To overcome this difficulty, ground water accessed by constructing open wells and borewells. In drought areas, open wells don't satisfy the need of water for various irrigation and drinking purposes. For this, borewells are a good alternative. The diameter of such borewells should be no more than seven to eight inches. Sometimes these borewells are dug up to 1,000 feet deep. Most often, the borewells are successfully dug to obtain water; however, sometimes the borewell doesn't produce enough water. Such borewells are then abandoned without taking proper measures to seal them.

Such abandoned borewells pose a danger to the public. Due to the small diameter of these borewells, they are not a real threat to a normal adult, but small children are particularly at risk of accidently falling into them. The children can become accidentally stuck and trapped in the tubing or the hole of the borewell and are unable to extricate themselves. If immediate rescue does not occur, chances of survival are diminished. Such a scenario may also happen in other regions of world where such borewells are also dug.

Recently, news of people, particularly children, dying due to a fall in a borewell has received attention from the authorities, the media, and the public at large.[1,2] Such incidents are preventable and valuable lives could be saved.[3,4] A total of 43 incidents of victims falling in borewells was noted during the period from 2006 to 2015. Most of these cases were of children less than 6 years old, with a male preponderance. Most of these victims were not able to survive in the hostile environment inside the borewell.

This presentation will describe the age and sex distribution of fatalities from falls into borewells. The reason for the victims being involved in falls into borewells will be described. The medicolegal death investigator should become more familiar with incidents of victims being trapped in borewells and the manners of death caused by these events.

Human Fatality, Borewell, Children

H89 A Fatality Caused by Molten Metal Splash During A Field Visit Near A Furnace: A Case Report

Nilesh K. Tumram, MD, Department of Forensic Medicine and Toxicology, 85 Adarsh Grih Nirman Sanstha, Anantnagar, Nagpur, Maharashtra 440013, INDIA*

After attending this presentation, attendees will understand the current case of a fatality caused by a molten metal splash during a field visit that occurred near a furnace of a smelter factory.

This presentation will impact the forensic science community by creating an awareness of the possibility that people working on or visiting furnaces containing molten metal should be aware of the possibility that exploding, splashing molten metal could cause a fatality or serious injuries to the operator or bystanders. This presentation highlights the fact that such molten metal explosions do occur and can cause fatal injuries.

Molten metal splash is the most common cause of melt deck injuries and is caused by the addition of wet materials to the molten bath. Wet charge materials are a serious safety hazard in all foundries. Water, moisture, or any liquid-bearing material instantaneously turns to steam when coming into contact with molten metal — expanding to 1,600 times its original volume and producing a violent explosion. This occurs without warning and throws molten metal and possibly high-temperature solids out of the furnace, putting workers, the furnace itself, and nearby plant equipment at risk.

A water/molten metal explosion can occur in any type of furnace; however, for an induction furnace, the aftereffects may be more serious, including the possibility of additional explosions caused by liquid in a ruptured cooling system coming into contact with molten metal in the bath. Molten metal need not be present in the furnace for a water/molten metal explosion to occur. Explosions can also occur if sealed drums or containers containing water are charged into an empty but hot furnace. In this case, the force of the explosion will eject the newly charged material and quite likely damage the refractory lining as well.

This presentation highlights a case in which the victim, while on a field visit to a factory, was fatally injured by molten metal splash. This presentation will also discuss the importance of having knowledge of such injuries when dealing with these medicolegal cases.

Molten Metal, Splash, Explosion

H90 Animal Tusk Injuries: Are They Unique With Specific Animals?

Nilesh K. Tumram, MD, Department of Forensic Medicine and Toxicology, 85 Adarsh Grih Nirman Sanstha, Anantnagar, Nagpur, Maharashtra 440013, INDIA*

The goals of this presentation are to discuss: (1) injuries caused by animals that use their tusks when attacking; (2) specific animal tusk patterns; and, (3) the importance of recognizing tusk injuries, their mechanism of causation, and their importance in forensic cases.

This presentation will impact the forensic science community by introducing a better understanding of the manner and pattern of injuries caused by tusks of different animals, particularly wild boars.

Humans have historically always been subject to different types of trauma. There can be increased conflict with humans and animals due to shrinking animal habitat. Some of the animals have various patterns of injury causation. Some attack by using fangs, paws, horns, etc. Other animals have tusks, which they use primarily to search for food. Tusks have a variety of uses, depending on the animal. Social displays of dominance, particularly among males, are common, as is their use in defense against attackers. Elephants use their tusks as digging and boring tools. Walruses use their tusks to grip on ice and to haul out on ice. The presence of a tusk in only the male narwhal suggests that, for these whales, the tusk is a secondary sex characteristic. Though primarily a tool for obtaining food or as a sign of a secondary sexual characteristic, when the animal is in combat, these tusks can become a tool for attacking the encroacher and can cause fatalities.

Many of the injuries occurring to humans have been well reported in the literature; however, a medical doctor encounters different types of injuries that have little or no mention in the available literature. Identifying the injury is important as the method of causation of such injuries is very helpful for future identification as well as correlating the injury with the manner or object of causation. Additionally, the site at which such injuries occur on the human body can, to some extent, determine the possible animal and its method of causing the injuries.

This presentation highlights tusk injuries found in traumas caused by animal tusks. These injuries occurred due to striking, biting, or dragging of the body for some considerable distance. When such injuries occur to a victim and that person is brought to the hospital, it can necessarily be important for the doctor to identify the injuries. This will be useful not only for treatment but also for future medicolegal purposes.

Trauma, Tusk Injury, Animals

H91 The Recovery of Vertebrate DNA From the Gastrointestinal (GI) Tract of Flesh-Eating Insects: A Mass Disaster Simulation Study

Pardon T. Masarirambi, BSc, 22 W 13th Avenue, Apt 5, Emporia, KS 66801*

After attending this presentation, attendees will: (1) understand that genetic analyses of flesh-eating insect gut contents found on and near the scene may reveal the identity of missing humans or endangered wildlife species in cases in which the body remains are not visible or available; and, (2) recognize that the value of insects on crime is not limited to Postmortem Interval (PMI).

Mass disasters and terrorist attacks may leave bodies in pieces, burned beyond recognition, or unable to be immediately located. At times, bodies/body parts are moved or scavenged by wild animals in events such as brutal killings, natural deaths, and airplane crashes in remote areas. This presentation will impact the forensic science community by informing attendees that flesh-eating insects are known to colonize decomposing bodies and, when used in forensic cases, may provide crucial evidence that could bring closure to mysterious deaths, determine removal of remains from a suspected crime scene, and establish the credibility of witness statements.

In this investigation, adult *Dermestes maculatus* beetles and larvae were reared in three separate colonies. Each colony fed on fresh flesh meat (*Bos taurus* (beef), *Sus scrofa* (pork), and *Meleagris meleagris* (poultry)). The Quick-DNA™ Tissue/Insect Miniprep Kit was used to extract total DNA. The Polymerase Chain Reaction (PCR) assay utilized species-specific primers that successfully amplified fragments (poultry: 183bp; pork: 212bp; and beef: 271bp) of 12S ribosomal RNA (rRNA), 12S rRNA, and ATPase subunit 6 genes and 8 genes, respectively. The results imply that DNA recovered from the GI-tract reveal what flesh-eating insects fed on.

In a further study, human blood was mixed with beef meat to simulate a mass disaster. The beetles were exposed at room temperature at intervals of 2, 4, 8, 12, and 24 hours. Following extraction of the entire beetle/larvae a Quantifiler® Trio kit was used on a Real-Time PCR 7500 Sequence Detection System and the total amount of amplifiable human DNA and male DNA found ranged from 0.0002ng/µL to 0.184ng/µL. The thermal cycler protocol consisted of holding Stage (1 rep): Step 1, 95° for 2 minutes, cycling Stage (40 cycles): Step 1: 95° for 9 seconds, and Step 2: 60° for 30 seconds.

The GlobalFiler™ amplification kit that contained primers necessary to amplify 21 autosomal loci, Y indel, Y-chromosomal Short Tandem Repeat (Y-STR) locus, and sex determining marker (amelogenin) were used on the genetic analyzer GlobalFiler™ 3500. The protocol was: initial incubation step of 95°C for 1 minute, 29 cycles of denature 94°C 10 seconds, anneal/extend 59°C 90 seconds, final extension 60°C 10 minutes, and final hold was 4°C. A full female DNA profile and partial male DNA profile were developed and matched to the reference profiles made from buccal cheek swabs. The results show that human DNA can be recovered and individualized from flesh-eating insects that could be potential secondary sources of DNA.

Flesh-Eating Insects, Vertebrate DNA, Mass Disaster

H92 Medicolegal Issues in a Death Due to Duchenne's Muscular Dystrophy

Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; and Philip Vasin Bystrom, BA, Western Michigan University School of Medicine, 145 E Exchange Place, Apt 2A, Kalamazoo, MI 49007*

After attending this presentation, attendees will: (1) recognize the importance and appropriateness of performing medicolegal autopsies in certain cases involving chronically disabled persons; (2) recognize the importance of medicolegal death investigation involvement in certain cases involving medical therapy-related complications; and, (3) understand the challenges involved with manner-of-death certification in deaths due to therapy-related complications.

This presentation will impact the forensic science community by focusing on several important issues that can present challenges for those within the death investigation community. These challenges include the investigations of deaths involving chronically debilitated individuals, deaths related to medical intervention/therapy, and the controversies related to certifying the manner of death in such cases.

An important public health function of medicolegal death investigation involves the identification of deaths that are considered preventable. By implementing preventive strategies based on the identification and reporting of such incidents, it is hoped that similar deaths may be avoided. In order to identify such preventable deaths, it is frequently necessary to perform a medicolegal autopsy; however, there are several groups of decedents in which a medicolegal autopsy is rarely performed. Two such groups include persons who have chronic debilitating conditions and those who die in the hospital with severe underlying disease. Although most of the deaths occurring in these two patient populations do not require medicolegal death investigation or autopsy, it is important to note that, in certain circumstances, the investigation of such cases is entirely appropriate. This report presents a case of death in a chronically debilitated, terminal patient, who died as a result of a complication of medical therapy.

Presented is the case of a 28-year-old male with Duchenne's Muscular Dystrophy who died of complications related to gastric tube dislodgment and subsequent sepsis. The patient was hospitalized for an acute-on-chronic episode of respiratory distress and was put on a ventilator and fitted with a gastric tube. The patient later complained of abdominal discomfort and an exploratory surgery revealed peritonitis. The patient died shortly thereafter under general anesthesia during emergency surgery. Autopsy revealed purulent exudate over the serosal surfaces of the intestines that extended into the mesentery and peritoneal lining. There was focal hemorrhagic exudate that was limited to the area immediately surrounding the gastric tube entrance site. Culture of the peritoneal cavity was positive for *Pseudomonas sp.*

Medicolegal autopsies are often not performed on patients with an underlying chronic debilitating condition if they die in a hospital setting. These deaths are common and expected and it is often assumed that, in most cases, the cause of death is either directly or indirectly related to the underlying condition. There is some merit to this assumption. For instance, a recent two-year-long study of the cause of death in an inpatient hospice program found that all 48 patients autopsied died of causes related to their underlying condition.[1] However, assuming that *all* deaths in this subset of patients can ultimately be traced back to the underlying medical condition leads us to overlook preventable causes of mortality such as complications arising from medical interventions.[2] It is thus unfortunate that medicolegal autopsies are not performed when warranted since they can help to identify sources of treatment-related deaths. This would ultimately aid in quality improvement resulting in better outcomes for future patients.

In addition to providing an impetus for discussing deaths in chronically debilitated persons and deaths related to medical intervention, the presented case highlights a classic dilemma faced by those who complete death certificates. Manner-Of-Death (MOD) certification is not an exact science and such determinations can vary. Although general guidelines for MOD determination have been promulgated by the National Association of Medical Examiners, variation remains.[3] The current case raises questions concerning the most appropriate MOD ruling in such cases.

In conclusion, medicolegal autopsies could help improve hospital outcomes in patients with underlying chronic debilitating diseases. The cause of death in these patients is often thought to arise as a natural sequelae of the chronic underlying disease. Performing a medicolegal autopsy on these patients has the possibility of identifying treatment-related deaths that would hopefully improve hospital outcomes.

H93 Electrocution Due to Multiple Entry and Exit Wounds — A One-of-a-Kind Case Report

Puneet Setia, MD, All India Institute of Medical Science, Jodhpur, Bansi Industrial Area, Phase 2, Dept of Forensic Medicine, Jodhpur, Rajasthan, INDIA; Navneet Ateriya, MD, All India Institute of Medical Sciences, Jodhpur, Bansi Industrial Area, Phase 2, Dept of Forensic Medicine, Jodhpur, Rajasthan, INDIA; Ashish Saraf, MD, All India Institute of Medical Sciences, Jodhpur, Basni Industrial Area, Phase 2, Dept of Forensic Medicine, Jodhpur, Rajasthan 342005, INDIA; and Tanuj Kanchan, MD, All India Institute of Medical Sciences, Jodhpur, Bansi Industrial Area, Phase 2, Dept of Forensic Medicine, Jodhpur, Rajasthan 342 005, INDIA*

The goal of this presentation is to introduce a unique case in which the deceased suffered multiple entry and exit wounds at several places on the body, making it difficult to identify the primary site of contact, as well to explain how these could have occurred in the absence of any object that could justify such wounds.

This presentation will impact the forensic science community by describing a situation in which multiple entry wounds may be present without evidence of how the wounds were caused, thereby cautioning attendees that in all cases of multiple entry wounds, the presence of multiple contact points is not a necessity or that there can be multiple contacts occurring in quick succession.

Electrocution injuries are a less-frequently encountered occurence in forensic practice, but they may lead to great morbidity and mortality. Electrical injuries are usually unintentional and occur in household settings. Electrocution is likely to cause injury to the tissues through which it passes. Death is very rapid in cases of electrocution and, in most cases, no gross abnormalities are observed in the internal organs. The only evidence usually found is the presence of an external electrical contact wound.

Passage of current through the human body is usually associated with a single entry and single exit wound. This presentation reports on a rare case of electrocution in which at least 16 electrical contact wounds were found on the body of the deceased male. These were entry wounds distributed over both upper limbs and the left side of the chest and axilla. Histopathology confirmed these were electrical wounds. The exit wounds were present in the form of multiple pinhead-sized lesions, showered over both soles of the feet. According to the eyewitness account, the left side of the body was in contact with an iron gate, thereby suggesting that injury marks on the left side of the body were all entry wounds. The eyewitness account ruled out multiple contacts in short duration. Thus, the only option for the entry wound on the right side of the body was due to the deceased coming in contact with the iron gate in such a way that the gate was in contact with him at multiple places on the body; however, the construction of the gate as well as the position of the deceased was such that this was not possible. One possibility was that the wound on the opposite side was caused when the deceased was being removed from the gate, in which case it would be an exit wound; however, the gross condition suggested it was an entry wound. Thus, it was possible that the right upper limb came into contact with the iron gate because of body movement during the electrical contact. A visit to the scene revealed an iron ceiling that was in contact with the iron gate, and a live wire was in contact with both; due to the rainy season, the surrounding area was wet.

This case highlights the presence of multiple entry wounds in electrocution and emphasizes the importance of the scene visit to correlate the autopsy findings.

Electrocution, Entry Wound, Exit Wound

H94 Is Methamphetamine Use Associated With an Increased Suicide Risk in Adolescents and Young Adults?

Ransom A. Ellis IV, Jackson County Medical Examiner Office, 950 E 21st Street, Kansas City, MO 64108; and Diane C. Peterson, MD, Jackson County Medical Examiner Office, 950 E 21st Street, Kansas City, MO 64108*

After attending this presentation, attendees will better understand the role methamphetamine abuse plays in leading to mental instability and suicide.

This presentation will impact the forensic science community by drawing attention to the recent increase in suicides associated with methamphetamine abuse occurring in the adolescent and young adult population.

Methamphetamine is a potent central nervous system stimulator elevating mood and leading to a heightened sense of euphoria. Chronic use is known to manifest as mood/anxiety disorders, psychosis, violent behavior, and suicidal ideation. This is achieved by methamphetamine's interaction with the dopaminergic system ultimately damaging nerve terminals leading to psychiatric pathology.

According to the National Institute on Drug Abuse, in 2012, 1.2 million people (0.4% of the United States population) reported having tried methamphetamine. This report has made an observation concerning the association of methamphetamine use with suicide among young adults within the Kansas City, MO, metropolitan area. This study undertook a retrospective record review of cases at the Jackson County Medical Examiner's Office (JCMEO) between the years of 2012 and 2016, reviewing suicide data of individual closed cases. This study defined the age range for "young adult" as less than the age of 40 years. All cases contained associated toxicology and investigative reports.

For the years 2012-2016, the JCMEO had 976 cases of suicide. Of the 976 cases, 416 were cases of individuals ranging in age from 11 to 39 years. In 2016, 12% of reviewed suicide cases involved intoxication with methamphetamine, 75% of which demonstrated recent suicidal ideation and depression per investigative history. Data from 2015 revealed 15% of suicide cases were positive for methamphetamine. Suicidal ideation and depression were noted in 77% of case histories; arguments and pending incarceration were thought to be contributory factors in the remaining cases. In 2014, methamphetamine positivity in suicide cases sharply decreased to 6.6%. Of these cases, 60% of histories reported suicidal ideation, and the remaining 40% were thought to be the result of arguments. Data from 2013 revealed 11% of cases demonstrated methamphetamine positivity, 86% of which revealed suicidal ideation and depression. In 2012, 15% of suicide cases revealed methamphetamine positivity and 62.5% had reported suicidal ideation. The overall average percentage of methamphetamine-positive cases for this total time period was 14.4%.

The suicide data was compared to closed cases ruled as accidents in which methamphetamine was considered the direct cause of death or as a contributing factor. Between the years of 2012 and 2016, 1,983 cases were deemed accidents, 162 of those listed methamphetamine as the cause of death or as a contributing factor, with 54 of these cases within the study's age range. In the adolescent and young adult ages with accidental manners, the overall average of methamphetamine-positive cases for this time period was 3%.

In conclusion, the results of this study reveal that methamphetamine abuse is much higher in younger adults committing suicide than in accidental overdose cases within the Kansas City metropolitan area.

Methamphetamine, Suicide, Young Adult

H95 Acetyl Fentanyl: Trends and Concentrations in Metro Detroit

Sarah E. Avedschmidt, MD, University of Michigan, 1301 Catherine Street, Ann Arbor, MI 48109; Carl J. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 E Warren, Detroit, MI 48207; David Moons, MD, PhD, Wayne County MEO/University of Michigan, 1300 E Warren Avenue, Detroit, MI 48207; Daniel S. Isenschmid, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Kilak Kesha, MD, National Forensic Pathology Services - Auckland, Forensic Pathology, LabPlus, Private Bag 110031, Auckland City Hospital, Auckland 1148, NEW ZEALAND; and Avneesh Gupta, MD, University of Michigan, 1301 Catherine Street, Rm 5226 Med Sci I, Ann Arbor, MI 48109*

After attending this presentation, attendees will be able to recognize acetyl fentanyl on postmortem toxicology as a marker of illicit fentanyl.

This presentation will impact the forensic science community by making forensic pathologists and toxicologists more knowledgeable regarding the possible etiologies of the presence of acetyl fentanyl in postmortem toxicology.

Acetyl fentanyl (N-[1-phenethylpiperidin-4yl]-N-phenylacetamide), a derivative of fentanyl, is a non-prescription synthetic opioid that is 4 to 5 times more potent than heroin and 15 times more potent than morphine, but much less potent than fentanyl and other fentanyl analogs.[1] Acetyl fentanyl is used in the adulteration of fentanyl, heroin, and cocaine and the first outbreak of acetyl fentanyl-related deaths was reported in Rhode Island in 2013.[1]

The trends and concentrations of acetyl fentanyl-related deaths have been followed at the Wayne County Medical Examiner's Office (MEO) in Detroit, MI, from 2015 to the present. Between April 2016 and January 2017, 21 deaths were reported at the Wayne County MEO, where acetyl fentanyl was found in the decedent's peripheral blood; these were compared to the previously published 75 acetyl fentanyl-related deaths between February 2015 and March 2016 from the same MEO.

Of the recent deaths, 62% (13) were male, 38% (8) female, 52% (11) were White, 38% (8) Black, and 1% (2) Hispanic. The mean age was 44.5 years. The mean concentration in the peripheral blood was 0.9ng/mL (range 0.1ng/mL to 2.7ng/mL). All 21 deaths had fentanyl, 52% (11) heroin, 71% (15) other opiates, 24% (5) cocaine, 0.5% (1) both heroin and cocaine, 29% (6) benzodiazepines, and 20% (4) ethanol present in the peripheral blood. Compared to the 75 previously reported acetyl fentanyl-related deaths, in the period between February 2015 and March 2016, the current data exhibits markedly decreased acetyl fentanyl concentrations. The average acetyl fentanyl concentration from the previous data set was 9.25ng/mL with a range of 0.28ng/mL to 37ng/mL; the current data revealed an average acetyl fentanyl concentration of 0.9ng/mL with a range of 0.1ng/mL to 2.7ng/mL. Also in the recent data was a higher percentage of cases with multiple drugs, with other opiates present in 71% of the deaths compared to the 21% reported previously. The other drugs present were found in similar frequencies and with a similar demographic distribution.

All 21 of the recent cases had acetyl fentanyl concentrations below 2.7ng/mL with an associated toxic concentration of fentanyl (>3ng/mL) in the peripheral blood. This means that the primary drug toxicity was due to fentanyl. Since acetyl fentanyl has not been reported in association with the clinical use of fentanyl, the former's consistently observed lower peripheral blood concentrations are most likely an artifact in the manufacture of the consumed illicit fentanyl.

Acetyl Fentanyl, Concentration, Toxicity

H96 A Lesson Learned From a Case of Unexpected Death of a 73-Year-Old Woman Due to a Congenital Diaphragmatic Hernia

Silvia D. Visona, MD, University of Pavia, Via Forlanini 12, Pavia 21100, ITALY; Fiorella Lanzillotta, MD, University Center of Legal Medicine, Via Forlanini 12, Pavia 27100, ITALY; Luisa Andrello, MD, Henri Guisan Street, 3, Bellinzona, Canton Ticino 6500, SWITZERLAND; Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Antonio M.M. Osculati, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY; and Matteo Moretti, MD*, Department of Forensic Medicine, Via Forlanini 12, Pavia 27100, ITALY*

After attending this presentation, attendees will understand that a diaphragmatic hernia can be a life-threatening condition even in adult patients, as it may remain silent until the onset of serious consequences. These cases might come to the pathologist's attention as unexplained and unexpected deaths.

This presentation will impact the forensic science community by highlighting the need for surgeons to be vigilant regarding congenital internal hernias, as they may become symptomatic later in life. This condition usually presents in the newborn. A few cases may present in older patients, often with non-specific symptoms that make the diagnosis difficult. This study reports a rare presentation of congenital diaphragmatic hernia in a 73-year-old woman.

On a Saturday, a 73-year-old woman was admitted to the emergency department presenting nausea with dark vomiting that had been on-going for several hours. The patient also reported an episode of transient loss of consciousness. The clinical evaluation did not point out anything remarkable, except abdominal tenderness. Laboratory investigations did not reveal any pathological results; no chest radiograph or abdominal echography was performed. Considering the symptoms reported by the woman, a peptic ulcer disease with hematemesis was suspected and the patient was informed about the need to undergo an Esophagogastroduodenoscopy (EGDS); however, the procedure was planned for the following Monday, two days after the symptoms began. In the following hours, the woman, who had been moved to a surgery department, complained of severe abdominal pain, associated with repeated "coffee ground" vomiting. Details concerning the patient's condition were not reported on her medical chart and no medical measures were taken, except for antisecretory drug therapy and parenteral nutrition. Suddenly, on Monday morning, the woman had several episodes of projectile vomiting and became hemodynamically unstable, with a subsequent cardio respiratory arrest. The patient could not be revived despite all resuscitative measures.

A forensic autopsy was performed to determine the cause of death. The gross examination revealed a wide-neck defect of the left diaphragm with herniation of the fundus of the stomach into the left thoracic cavity, covered by a membranous sheet of tissue (hernia sac). Only mild intrathoracic adhesions were present, and the herniated contents could be easily reduced to the abdomen. The size of the defect was 8cm x 6cm. An atelectasis of the left lung's lower lobe was also observed. The stomach presented an altered shape, with no other pathological findings, neither macroscopic nor microscopic. The gastric content consisted of partially digested food.

Therefore, the cause of death could be identified as a cardio-respiratory arrest due to the compression of the left lung and heart by the large diaphragmatic hernia, which was classified as a posterolateral (Bochdalek) congenital hernia. Considering the cause of the death, provided by the evidence from the forensic autopsy, a medical mistake was identified regarding the diagnosis and treatment of this patient. Although it is documented that the clinicians first addressed their suspicions toward a peptic ulcer, by focusing their choices entirely on this hypothesis, they failed to follow the recommended protocol in cases of hematemesis (which specifically suggests an EGDS within 24 hours). Therefore, the doctors' behavior has to be considered negligent, as a large diaphragmatic hernia was missed.

The death of the patient was preventable with an accurate physical examination and further diagnostic exams, which would have allowed an early diagnosis and adequate treatment; however, because of the rarity of the onset of symptoms due to this condition in older patients, and the non-specificity of the symptoms presented, this condition was not considered by clinicians.

Diaphragmatic Hernia, Unexpected Death, Medical Responsibility

H97 Sudden Death of a 3-Year-Old Girl Due to a Rare Thymic Neoplasm

Silvia D. Visona, MD, University of Pavia, Via Forlanini 12, Pavia 21100, ITALY; Luca Tajana, University of Pavia, Dept of Legal Medicine, Via Forlanini 12, Pavia 27100, ITALY; Matteo Moretti, MD, Department of Forensic Medicine, Via Forlanini 12, Pavia 27100, ITALY; Luisa Andrello, MD, Henri Guisan Street, 3, Bellinzona, Canton Ticino 6500, SWITZERLAND; and Antonio M.M. Osculati, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY*

After attending this presentation, attendees will be familiar with a rare cause of sudden death in children that can be avoided if diagnosed and treated early.

This presentation will impact the forensic science community by highlighting the need for clinicians to consider a mediastinal mass in cases of breathing difficulty in children. The present case outlines one of the many contributions that forensic pathology can make to medical knowledge, providing warnings that can prevent similar deaths in the future.

At home, a previously healthy 3-year-old girl suddenly presented with difficulty breathing associated with cough and stridor. The parents called the emergency services. Doctors gave the baby a corticosteroid and an aerosoltherapy with adrenalin. When the child was taken to the emergency department, the symptoms ceased and she was thus discharged. Five days later, another similar episode occurred. Again, by the time the patient was admitted to the hospital, the symptoms had already stopped. A diagnosis of laryngospasm was rendered and the parents were advised to take the baby to an allergist for a detailed examination. The baby was allowed to go home with a prescription for a corticosteroid and a bronchodilator. No instrumental examinations were performed.

After three days, during which nothing remarkable was noticed by the parents, the little girl had another episode of difficulty breathing, followed by a loss of consciousness. When first aid arrived, the baby was in cardiac arrest. Resuscitation efforts were initiated but were unsuccessful, and death was declared.

A forensic autopsy was ordered by the prosecutor to consider the possibility of a medical mistake.

The external examination revealed a well-nourished, 98cm-long girl. The autopsy disclosed a large mediastinal mass that measured 11cm x 11cm x 6.5cm and weighed 540g. The neoplasm was within the thymus and had already invaded the pericardium and pleura, reaching the diaphragm. The lungs were partially collapsed, due to the large mass occupying the plural space, and showed edema and congestion. Histologically, the neoplastic nature of the tissue of the thymic mass was confirmed, as well as its invasive tendency. Therefore, death was attributed to the mechanical compression by the mass on the airways, the lungs, and the heart. The mass was identified as a malignant thymus neoplasm, classified as a carcinoma.

This type of tumor is extremely rare, especially in childhood, and its prognosis is poor if not diagnosed early, due to its invasiveness and rapid growth. Early diagnosis and complete resection are essential in order to achieve a good outcome.

The evaluation of the medical conduct excluded any medical responsibility in the mismanagement of the patient during the two admissions to the emergency department. This conclusion was reached by considering the lack of specific indications of the instrumental examinations (chest radiography, Computed Tomography (CT) scan), as the hypothesis of a laryngospasm due to an allergic reaction seemed to be the most probable. In fact, the clinical pattern was consistent with this diagnosis and nothing remarkable was observed during the objective examination (especially concerning the thorax). Only by performing the autopsy was it possible to arrive at the diagnosis.

The present forensic case represents a contribution to the improvement of clinical science, as it brings out a very rare cause of sudden death in childhood that, if recognized early, can be successfully treated. This case is worth highlighting as the knowledge it imparts can be helpful in avoiding similar deaths in children.

Sudden Death, Thymic Neoplasm, Medical Responsibility

H98 Sudden Death During Sexual Intercourse: A Fatal Aortic Dissection and Sildenafil Abuse

Diana Bonuccelli, MD, Department of Legal Medicine, Cittadella della Salute, Lucca, ITALY; Massimo Martelloni, MD, Department of Legal Medicine, Azienda USL Toscana Nordovest, Cittadella della Salute, Lucca, ITALY; Alberto Mandoli, MD, Department of Legal Medicine, ASL Nordovest Toscana, Cittadella della Salute, Lucca, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Dept of Forensic Pathology, Via Fossato di Mortara 70, Ferrara 44100, ITALY; and Stefano D'Errico, MD, Department of Legal Medicine, Azienda USL Nordovest, Cittadella della Salute, Lucca 55100, ITALY*

The goal of this presentation is to introduce a case of sudden death of a 66-year-old man during sexual intercourse. A complete postmortem examination and toxicological analysis revealed the cause of death.

As there is a rarity of fatal cases in sildenafil users, this presentation will impact the forensic science community by informing attendees of the pathological effects of sildenafil and will emphasize the necessity for an echocardiographic examination before prescribing sildenafil.

Aortic dissection is one of the most dramatic cardiovascular diseases since the first detailed description suggested by Morgagni in 1761. It is defined as blood present between the layers of the aortic wall (false lumen), outside the true lumen, as a result of the decomposition of the media. The separation in the media is in 95% of cases caused by the blood flowing through a tear in the intima (intimal tear or flap), while in 5% of the cases, the cause is bleeding within the media (intramural hematoma). The most frequent etiologic factors reported are chronic hypertension, hereditary connective tissue diseases, and congenital aortic valve diseases (bicuspid and unicuspid aorta). Few fatal cases of acute aortic dissection during sexual intercourse in sildenafil abuse have been reported in literature; it has been supposed that sildenafil use, independent of changes in the aorta pressure, could trigger an aortic dissection. *In vitro* studies reveal that sildenafil has vasorelaxant properties in rat aorta; thus, with a decreasing aortic stiffness, sildenafil can trigger intimal tearing. Other studies performed on pulmonary arteries stated that without changing pulmonary artery or systemic blood pressure, sildenafil increases the pulmonary flow and proliferates pulmonary smooth muscle cells. Based on all of these, sildenafil use can make the aorta wall more sensitive and can trigger the dissection.

Case Report: This study presents the case of a 66-year-old man with no history of cardiac problems who suddenly collapsed during sexual intercourse. His partner stated he used to take sildenafil a few hours before sex. During sexual intercourse, he suddenly complained of the onset of chest pain and fatigue before collapsing. He was not using any other medications regularly. A complete postmortem examination was performed the day after death and type A (DeBakey type I) aortic dissection was detected and recorded as the cause of death. Toxicological examination was performed and confirmed the use of sildenafil. Because dissection occurred in the critical time interval between the peak plasma concentration time and half-life of sildenafil and because the patient had no history of any triggering factor (mechanical stress, trauma, etc.), sildenafil is thought to have triggered the dissection.

Sudden Death, Sildenafil, Aortic Dissection

H99 Aortic Dissection in Cocaine Abuse: A Fatal Case

Stefano D'Errico, MD, Department of Legal Medicine, Azienda USL Nordovest, Cittadella della Salute, Lucca 55100, ITALY; Sara Niballi, MD, Department of Legal Medicine, Azienda USL Toscana Nordovest, Cittadella della Salute, Lucca, ITALY; Benedetta Guidi, MD, Via Santa Dorotea 1, Pescia, Pistoia 51017, ITALY; Marco Conti, MD, Department of Legal Medicine, AUSL2, Lucca, AB, ITALY; Diana Bonuccelli, MD, Department of Legal Medicine, Cittadella della Salute, Lucca, ITALY; and Anna Talarico, University of Ferrara, Via fossato di mortara 70, FERRARA 44121, ITALY*

The goal of this presentation is to introduce a fatal case of aortic dissection after cocaine abuse. A complete postmortem examination and toxicological analysis revealed the cause of death.

This presentation will impact the forensic community by examining the rarity of fatal cases of aortic dissection in cocaine abusers and by emphasizing the importance for complete postmortem examinations in these cases.

Aortic dissection is generally thought to require a pathogenic co-factor, usually severe arterial hypertension or a connective tissue disorder and a predisposition to weakness in the aortic media and sudden changes in hemodynamic shear stress. The association between cocaine abuse and aortic dissection is well documented in the literature, but few fatal cases are reported. Presumably, the mechanisms relate first to an underlying process that has weakened the elastic media of the aorta and, second, to the severe sheer forces that result from the sudden and profound hypertension and tachycardia that accompany cocaine (particularly crack) use. Cocaine, by inhibiting the reuptake of both epinephrine and norepinephrine at the neural synapses, leads to profound sympathetic stimulation that presumably causes such sheer stress on the aorta's intima that a small "nick" or tear occurs. This physiology is particularly acute with the use of crack cocaine, after which the onset of systemic effects is almost immediate. With the use of cocaine, such tears may occur most often at the ligamentum arteriosum because this region of the aorta is relatively fixed anatomically and is less able to withstand the accelerating aortic pressure wave that speeds down the aorta after ventricular contraction. Once such an intimal tear has occurred, the weakened aortic wall allows entry of luminal blood, followed by propagation of the dissecting hematoma down (and/or up) the aorta. A second possible mechanism is that chronic cocaine use itself may lead to premature atherosclerosis. It has been postulated that recurrent cocaine exposure makes the endothelium more permeable to atherogenic low-density lipoprotein and may accelerate the migration of leukocytes to the aortic wall. Thus, predisposition to aortic dissection could include not only the impact of hypertension, but chronic cocaine's effects on the aorta as well.

Case Report: This study presents the case of a 50-year-old man found lifeless in his car that was parked in front of a disco. Medical history was unremarkable for acute cardiac problems, but he was known as a cocaine abuser. A complete postmortem examination was performed the day after death; type A (DeBakey type II) aortic dissection was detected and cardiac tamponade recorded as the cause of death. Samples of organs were collected for a complete histopathological study. Toxicological examination was performed and confirmed the suspicion of cocaine abuse.

Aortic Dissection, Cocaine, Death

H100 Bilateral Adrenal Hemorrhage Following Arthroplasty: A Case Study

Sina Kipry, BA, 8800 Pine Forest Road, Apt 4102, Pensacola, FL 32534; Drake Thrasher, 1300 3rd Avenue, S, Apt 237B, Birmingham, AL 35294; and Predrag Bulic, MD, Medical Examiner, District 23, 4501 Avenue A, Saint Augustine, FL 32095*

After attending this presentation, attendees will understand the significant signs, symptoms, and sequelae of bilateral adrenal hemorrhage (BAH) and its correlation with arthroplasty.

This presentation will impact the forensic science community by providing information on the importance of recognizing that BAH can be a fatal consequence to total hip or knee arthroplasty.

Acute BAH, although rare, is a potentially life-threatening condition presenting with non-specific symptoms, such as minor to severe abdominal pain, nausea, vomiting, fever, tachycardia, hypotension, hyponatremia, and hypokalemia. BAH is a common occurrence in post-operative periods, septicemia, and trauma. Total hip and knee arthroplasties are common surgical procedures that are accompanied with anticoagulants to prevent the occurrence of deep venous thrombosis and pulmonary embolism. A rare correlation has potentially been identified between the use of rivaroxaban and other common anticoagulants as possibly causing thrombocytopenia, which may lead to BAH.

The goal of the present work was to present a case of BAH brought on by anticoagulation therapy following total knee arthroplasty and to make physicians aware of this condition in order to prevent unnecessary deaths. Additionally, the information presented could prove vital to forensic pathologists in determining cause of death in these circumstances.

A fatal case of BAH resulting from knee arthroplasty in a 64-year-old male is reported. Arthroplasty was successfully completed with no early post-operative complications. The patient was discharged home on Postoperative Day (POD) one and placed on rivaroxaban to prevent thromboembolic events. On POD seven, he presented in the emergency room complaining of severe abdominal pain, coughing, burping with bright red blood, and labored breathing. He was admitted on POD eight; biochemical exams indicated normal sodium levels (139mmol/L), normal potassium levels (3.7mmol/L), elevated glucose levels (173Hmg/dL), high creatinine (1.25Hmg/dL), normal white blood cell count (7.7 x 10’3/microL), and normal platelets (246 x 10’3/microL). On POD ten, while the decedent was being discharged, he died. Autopsy would ultimately find the cause of death, which was bilateral adrenal hemorrhage due to right knee arthroplasty.

BAH is a rare disease that can follow major joint surgeries and should be suspected in patients presenting with severe abdominal pain, nausea, and coughing who do not respond to standard medical treatment. Computed Tomography (CT) scans and hormone assays should be acquired at earliest suspicion of BAH. Physicians should be aware of admitted patients presenting with the signs and symptoms of BAH, especially following arthroplasty.

Bilateral Adrenal Hemorrhage, Arthroplasty, Anticoagulation

H101 Trends of Cannabis- and Alcohol-Related Single-Vehicle Accident Fatalities at the Jackson County Medical Examiner's Office From 2012 to 2016

Tiffany A. Hollenbeck, DO, Office of the Jackson City ME, 950 E 21st Street, Kansas City, MO 64108; Adrian Baron, MD, Boulder County Coroner's Office, 5610 Flatiron Parkway, Boulder, CO 80301; and Diane C. Peterson, MD, Office of the Jackson City ME, 950 E 21st Street, Kansas City, MO 64108*

The goal of this presentation is to examine the demographics as well as the toxicology in cannabis- and alcohol-related single-vehicle accident fatalities at the Jackson County Medical Examiner's Office.

This presentation will impact the forensic science community by demonstrating the increasing prevalence of cannabis-related single-vehicle accident fatalities and the increased blood tetrahydrocannabinol levels of the subjects involved at the Jackson County Medical Examiner's Office.

Cannabis use has increased in popularity in recent years; various studies reveal cannabis to be the number one illegal drug used among those reported driving under the influence in several different countries.[1-4] Some of these same studies as well as others demonstrate there is a dose-related association between the increased blood Tetrahydrocannabinol (THC) concentration and the heightened risk of a traffic accident and death.[4,5] Many studies have also shown that when cannabis and alcohol are used in combination, there is a higher incidence of traffic accidents compared to when each drug is used alone.[3,5]

The goal of this study was to examine all of the cannabis- and alcohol-related single-vehicle accident fatalities at the Jackson County Medical Examiner's Office in Kansas City, MO, in the past five years and to discuss the trends of alcohol-only related fatalities versus cannabis-only related fatalities versus combined cannabis- and alcohol-related fatalities. This study also examined the postmortem blood THC concentration trends of the drivers. In addition to toxicology, the race, gender, and age of the subjects were studied. Finally, the time of day the accident occurred was also recorded. All traffic fatalities processed at the Jackson County Medical Examiner's Office from January 1, 2012, to December 31, 2016, were reviewed. Only the drivers of single-vehicle accident fatalities were selected for this study. The postmortem toxicology of the drivers was examined with an emphasis on reviewing alcohol and cannabis levels specifically. During the years studied, the number of traffic fatalities ranged from 93 to 135 per year, with an average of 115. Of those fatalities, 29 to 55 (average 44) individuals were drivers in single-vehicle crashes.

The results of this review revealed that there was an increase in the number of cannabis-only and cannabis-plus-alcohol-related single-vehicle accident fatalities by 57% and 125%, respectively. A 204% increase in the average blood THC concentrations was noted over the five-year period, with the average THC blood concentration being 254.31ng/ml in 2016 compared to 83.6ng/mL in 2012. The demographics of the drivers did not change over the five-year period, with males being more prevalent over females and Caucasians more prevalent than African Americans. Generally, the majority of the drivers were under the age of 40 years. No particular trend was identified in the time of day the single-vehicle fatalities occurred.

Public health concern has grown recently due to the increased numbers of individuals driving under the influence of cannabis as well as the level of intoxication of these drivers. This study provides supporting evidence that there is increasing incidence of cannabis-related traffic fatalities as well as upward-trending blood THC concentrations; this may coincide with increased social acceptance and popularity of cannabis usage as a recreational and possibly medicinal drug.

Cannabis, Motor Vehicle, Blood Tetrahydrocannabinol

H102 Cranial Abnormalities Seen at Autopsy

Timothy Wysozan, BS, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Carolyn V. Isaac, PhD, Western Michigan University School of Medicine, Dept of Pathology 1000 Oakland Drive, Kalamazoo, MI 49008; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007*

After attending this presentation, attendees will be more familiar with incidental cranial abnormalities that may be present at autopsy. This presentation will explore the etiology, appearance, and what, if any, significance the abnormalities may represent.

This presentation will impact the forensic science community by providing a reference series of select cranial abnormalities that may be encountered at autopsy, with a discussion regarding their significance.

Autopsies are an integral part of the medicolegal paradigm. During an autopsy, a pathologist is typically focused on identifying abnormalities related to the death of the individual. Examination of the brain is an important component of a complete medicolegal autopsy, requiring reflection of the scalp with removal of the upper cranial vault. This is typically followed by dura mater removal. Following brain and dura mater removal, a careful examination of the skull is part of the standard autopsy practice. This includes examination of not only the external aspect of the skull, but also the interior surface adjacent to the brain. A variety of cranial findings may be evident during complete internal and external skull examination at autopsy. Some of these may have significant relation to the cause of death, for example, gunshot wounds and other similar traumatic events; however, many others may be considered incidental findings and likely play no direct role in the death of the patient.

The aforementioned cranial abnormalities can be broadly classified into several categories. One classification scheme includes the following categories: acute and remote trauma, defects related to medical intervention, disease-related entities, genetic anomalies, and developmental or other natural processes. Each category will be discussed, providing specific examples of each, including etiology, appearance, and significance. Examples include: acute and remoted trauma, including cranial defects and healing fractures related to past trauma; defects related to medical intervention, including bone discoloration, healing surgical interventions, and birth-related injuries; disease processes, including Paget's disease and malignancies; and developmental or other natural processes, including arachnoid granulations, prominent parietal foramina, hyperostosis frontalis interna, and intra-sutural bones.

Cranial abnormalities may suggest recent (or remote) trauma, medical therapy and/or intervention, disease processes, or various developmental, genetic, and other natural processes. These abnormalities may represent incidental findings, and it is important for the forensic practitioner to understand the etiology and significance of the findings to determine whether they may be related, either directly or indirectly, to the cause of death. Forensic pathologists should be cognizant of the wide variety of cranial abnormalities they may encounter in order to appreciate their etiology and understand their significance, or lack thereof, in the individual's death.

Cranial Abnormalities, Autopsy, Postmortem Examination

H103 Tied to His Own Apron Strings: A Case of Accidental Strangulation by Power Tool

Christine James, DO, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; Karl E. Williams, MD, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; and Todd M. Luckasevic, DO, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222*

The goal of this presentation is to illustrate a rare case of accidental strangulation by a bib apron while using a power tool.

This presentation will impact the forensic science community and the general population by illustrating the unexpected dangers of using power tools while wearing presumed "protective" clothing/attire.

Introduction: Deaths associated with power tool use are rare. Most involve accidental electrocution or, less commonly, penetrating/cutting injuries. Accidental strangulation due to power tools has not been previously reported in the literature. Aprons are considered a type of protective layer, but as with any loose article of clothing, can prove to be a hazard.

Materials and Methods: This case involves a 73-year-old Caucasian man with an interest in restoring and repairing African fertility statues. He was wearing a protective cloth bib apron while using an electric power grinder with a rotating buffer attachment to polish a piece of art. The apron became entangled around the rotating buffer head. Twisting of the apron was transmitted to the neck strap, which then wound quickly and tightly around the decedent's neck, leading to strangulation. The decedent fell backward. During the event, the buffer became unplugged. The victim was found by his wife when she returned home later in the day. Emergency personnel responded to the scene; however, death was obvious and no resuscitation efforts were attempted.

Results: External examination revealed a fully dressed Caucasian male wearing shorts, a T-shirt, clear vinyl gloves, and a blue canvas bib apron. The grinder/buffer was found to be on the "max" setting with the bulk of the apron twisted around the buffer head and approximately 15 turns of the neck strap of the apron wound tightly around the neck. The 1.5-inch-wide apron strap was removed to reveal a circumferential parchment-like ligature abrasion above the level of the thyroid cartilage. Dissection of the strap muscles of the neck was unremarkable and the hyoid bone was intact. Florid petechial hemorrhages were present in the conjunctivae and palpebral fissures. Scleral hemorrhages were also present bilaterally. The upper lip had a midline laceration and contusion.

Conclusion: While personal protective equipment is highly recommended when working with power tools, any loose clothing may prove hazardous. Aprons, neckties, and necklaces may become caught in mechanisms. Power tool users should be especially cautious of tools with rotating heads. Quick disconnects, avoiding distractions, and supervised use are recommended to minimize bodily injury.

Accidental Strangulation, Apron, Power Tools

H104 Troubling Trocars: The Time-Consuming Recovery and Wound Documentation of Fragmenting Bullets

Christine James, DO, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; Courtney E. Healy, BS, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; and Todd M. Luckasevic, DO, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222*

The goal of this presentation is to illustrate the time-consuming process of wound documentation and recovery of high-performance fragmentation bullets.

This presentation will impact the forensic science community and the general population by illustrating the destructive nature of the copper fragmenting bullets, which have recently entered the public marketplace for self defense. This presentation will also address the complications pathologists face while determining the pathway of the bullet due to its separation into multiple projectiles and the additional time required for projectile recovery.

Introduction: Copper fragmenting bullets entered the public marketplace in 2014, marketed toward self defense. The Liberty Ammunition Civil Defense bullet and G2 Research's Radically Invasive Projectile (R.I.P.®) are designed to inflict maximum trauma by expelling metal trocars that track away from the base of the bullet. These bullets are advertised as able to "defeat all barriers, such as sheet metal, sheet rock, windshields, plywood, and heavy winter clothing." The separation of the trocars cause damage to multiple organs and prove to be problematic when trying to describe the path of the bullet, as they create up to nine separate wound channels. When multiple gunshot wounds are present, the trocars may not be reliably reassimilated with their corresponding base, causing further documentation complications. The process of documenting the wound path and recovering all fragments is tedious and time-consuming, greatly reducing efficiency in the autopsy suite.

Materials and Methods: Two cases involving copper-fragmenting bullets were evaluated. The first involves a 25-year-old African American male who was shot while drinking inside a bar. The decedent was shot in the left chest and forearm. He ran after the assailant before collapsing on a sidewalk outside the establishment. Emergency personnel arrived on scene and found the decedent unresponsive. He expired at a nearby hospital.

The second case involves a 16-year-old White male who was shot while sitting in the back of a friend's car during a marijuana drug deal. He was shot multiple times in the head and neck and was declared dead on arrival of emergency personnel.

Results: Autopsy of the first homicide victim revealed penetrating gunshot wounds to the chest and a perforating gunshot wound to the left forearm. One bullet lacerated the upper left lung, the pericardium, the left atrium, and the root of the aorta. A second bullet lacerated the diaphragm, spleen, liver, left lower lung lobe, pericardium, right ventricle and atrium, and right upper lung lobe. Trocars lacerated the stomach, small intestines, colon, mesentery, the left lung, and the left chest wall. Each were located and retrieved with great effort.

Examination of the second victim revealed multiple perforating gunshot wounds to the head and neck. One bullet lacerated the right neck and fractured the C3 vertebrae, while two others fractured the maxilla. A fourth bullet entered the neck, lacerating the left jugular vein. The fifth bullet lacerated the right parietal lobe. Trocar fragments were recovered from the oral cavity and could not be ascribed to a specific shot.

Conclusion: R.I.P.® and Liberty Civil Defense fragmentation bullets, while marketed for self defense, cause extensive organ damage and significantly increase autopsy time for the forensic pathologist. The extra trocars from the projectile ravage the tissue and can be difficult to locate. Reimaging the body and organs may be necessary for retrieval. The bullets also pose serious complications for the forensic pathologist when describing the wound path. The trocars of these bullets splay outward, causing additional wound paths that may intersect with each other or intersect with the paths from additional bullets. Associating the trocars with their respective bullet base can also be challenging when multiple shots are fired. In addition to the damage done to the body, these bullets do damage to the efficiency of the autopsy suite.

R.I.P.®, Trocars, Fragmentation Rounds

H105 Mixed-Mode Assessment of Reference Lung Weights in a Medicolegal Autopsy Setting — A Bayesian Approach

Torfinn Gustafsson, MD, Section of Forensic Medicine, Umeå University, PO Box 7616, Umeå SE-907 12, SWEDEN; Anders Eriksson, MD, PhD, Section of Forensic Medicine, Umeå University, PO Box 7616, Umea SE-907 12, SWEDEN; and Carl Johan Wingren, PhD, National Board of Forensic Medicine, Sölvegatan 25, Lund, Scania 22362, SWEDEN*

After attending this presentation, attendees will understand the relationship between postmortem lung weight and cause of death in a medicolegal autopsy setting.

This presentation will impact the forensic science community by providing new reference lung weights and the association between these reference weights and the cause of death.

Organs are routinely weighed at autopsy and, as such, present immediately accessible objective information that may be of importance for determining disease states and the cause of death.

Lungs are of particular interest as "heavy" lungs have been suggested as an autopsy finding associated with causes of death frequently encountered in a medicolegal autopsy setting, such as drowning and intoxication.[1-9] Problematic is the fact that "heavy lungs" have eluded a definition due to the high variability in lung weight.

Different reference weights have been suggested.[10-16] There have also been attempts at creating linear regression models using individual characteristics to estimate postmortem lung weight.[16] With the exception of one study, neither height, weight, age, nor Body Mass Index (BMI) have yielded R2 values of practical importance.[10] Previous studies were also generally limited by using selected and small populations.

A possible solution to this problem would be to model the lung weight as dependent on the cause of death. It is believed by some that this would be better suited for practical use, as it would appear that lung weight "as is" is far too variable to be of any use. Toward this end, this study attempted to create a varying intercepts regression model using groups based on underlying cause of death as intercepts and individual parameters as case-level predictors.

In Sweden, all medicolegal autopsies are performed at one of six departments of the Swedish National Board of Forensic Medicine. Organ weights and individual characteristics as well as the underlying cause of death are included in the medicolegal autopsy registry.

Using Stan®, interfaced through RStan, this study created multiple mixed-mode Bayesian general linear models using groups based on cause of death as varying intercepts and individual characteristics as case-level predictors.[17] Models were then compared for over- and underfitting, using the Widely Applicable Information Criterion (WAIC), after which a final "meta-model" based on individual model predictions weighted by their relative WAIC weight was created.[18,19]

Data from 2007 through 2013 was analyzed, including decedents 18 years or older but excluding cases with a postmortem interval longer than five days as well as cases with lacking, incorrectly registered, or extreme values. As the International Statistical Classification of Diseases and Related Health Problems (commonly known as the ICD) is ill-suited for a medicolegal autopsy population, groups were created based on the most common case types in our population. As this dataset is also very large, highly granular groupings could be created, allowing for instant subgrouping of different intoxicants in fatal intoxication cases. Results are presented using Highest Probability Density Intervals (HPDI).

This study found that group mean values exhibited a clear difference where expected, for instance between intoxication (mean 1303g (1,053–1,545g 95% HPDI)) and asphyxia (mean 1,029g (788–1,272g 95% HPDI)]; however, when accounting for individual case error rate, predictions were quite wide with significant overlap between case groups (e.g., intoxication (mean 1,303g (684–1,921 95% HPDI)) almost entirely overlaps asphyxia (mean 1,030g (411–1,647g 95% HDPI)).

It is believed this model still yields better, more realistic estimates for what constitutes normal lung weight in the estimated case groups, as these values represent probability distributions and values are less likely closer to the HPDI boundaries.

This reverse approach of assessing lung weight as a function of the cause of death also facilitates differential diagnostics as it provides the forensic pathologist with a better grasp of the context of a given lung weight in relation to one or more possible causes of death. In conclusion, this study submits these estimates are more realistic in forensic practice than previously published raw population means.

Forensic Pathology, Lung Weight, Bayesian Analysis

H106 Predicting Fatal Intoxications in a Medicolegal Autopsy Population Using the Weight of the Lungs

Carl Johan Wingren, PhD, National Board of Forensic Medicine, Sölvegatan 25, Lund, Scania 22362, SWEDEN; Anders Eriksson, MD, PhD, Section of Forensic Medicine, Umeå University, PO Box 7616, Umeå SE-907 12, SWEDEN; and Torfinn Gustafsson, MD, Section of Forensic Medicine, Umeå University, PO Box 7616, Umeå SE-907 12, SWEDEN*

After attending this presentation, attendees will understand the issues with defining "heavy lungs" as well as the sensitivity of heavy lungs to identify fatal intoxication cases in a medicolegal autopsy setting.

This presentation will impact the forensic science community by providing clear information on the predictive power of heavy lungs as well as new, easily applicable methods to reduce pre-toxicology uncertainty.

Fatal intoxications are common in a medicolegal autopsy setting, constituting approximately 10% of medicolegal autopsies in Sweden (internal data); however, these cases are associated with sparse findings during autopsy.

Increased lung weight at autopsy has been suggested as a finding suggestive of such deaths.[1-7] Previous literature is generally limited by a descriptive approach, including only opioid deaths and lacking a definition of "heavy lungs". Different reference lung weights have been suggested.[8-14] There have also been attempts to create linear regression models using individual characteristics to estimate postmortem lung weight.[14] With the exception of one study, neither height, weight, age, nor BMI have yielded R2 values of practical importance.[8]

The goal was to: (1) create a model to identify cases with heavy lungs; and, (2) assess the predictive power of heavy lungs in identifying cases of fatal intoxications during autopsy.

This study identified all medicolegal autopsy cases in Sweden from 2000 through 2013 of persons older than 18 years, and the estimated lung weight was calculated in each case using a previously published linear regression model.

Additionally, the mean ratio between lung and heart weight was calculated overall as well as in groups stratified for age and sex. Raw lung weight and regression estimates as well as the ratios were used to identify cases with heavy lungs and evaluated the associations with fatal intoxications.

On average, cases of fatal intoxications had heavier lungs compared to other cases. This difference of 158g (145g–172g 95% Confidence Interval (CI)) was significant ($p<0.001$).

In predicting fatal intoxications, it was observed that raw lung weight had low performance and models based on the lung/heart weight ratio had better predictive power than models based on lung weight point estimates. The ratio may serve as an indication of a fatal intoxication with a sensitivity of 70% to 80% and specificity of approximately 60%.

These findings suggest that using only raw lung weight to estimate the probability of fatal intoxication is of little value in medicolegal autopsy cases. The ratio of lung-to-heart weight may, lacking better methods, be useful as an estimate of the degree to which the forensic pathologist should suspect fatal intoxication.

H107 How Should Live Entomological Samples Be Stored?

Valentina Bugelli, MD, Dept. of Medicine and Health Sciences, via Francesco De Sanctis, Campobasso 86100, ITALY; Valeria Schmidt, Kennedyalle 104, Frankfurt Am Main, GERMANY; Carlo P. Campobasso, MD, PhD*, University of Campania, Dept Experimental Medicine, via Santa Maria di Costantinopoli, 16, Napoli 80138, ITALY; and Jens Amendt, PhD, Institute of Forensic Medicine, Dept of Biology, Kennedyallee 104, 60596 Frankfurt am Main, Frankfurt, GERMANY*

After attending this presentation, attendees will better understand the current state of the art in collecting and storing entomological samples from a body during autopsy or at the death scene.

This presentation will impact the forensic science community by providing guidelines for sampling and storing living samples of the forensically important blow flies, *Lucilia sericata* and *Calliphora vicina*.

Sampling and storing insect evidence alive is an important task in forensic entomology as different methods can influence survival and growth rates of the living samples. The best practices recommend that living fly larvae should kept under controlled and known conditions (2°C-6°C, preferably) and stored in vials with an air-permeable lid equipped with sawdust or a paper for absorbing excretion liquids. Samples should then be transferred to an expert within 24h. Although this time interval seems to be a realistic approach, cooling the samples appropriately or catering them during storage seems to be a serious logistical problem. Unfortunately, many of the above recommendations are mainly based on expert opinions rather than scientific evidence.

In order to look at the effect of the lack of cooling and/or inappropriate storing of entomological samples before their arrival in the laboratory, the following experiment has been performed. Samples of all larval stages (*L1*=24 hours after hatching at 25°C, *L2*=48h after hatching, and *L3*=72h after hatching) of the forensically relevant blow fly species *Lucilia sericata* and *Calliphora vicina* were divided in two main groups with 33 larvae for each group. The first group was stored at room temperature (~20°C) and the second group in a refrigerator (5°C) for 16h without air, a food supply, or sawdust. Next, they were kept at 2°C-6°C in a Styrofoam™ box for 8h, simulating a transport situation. After 16+8=24h, the storage Mortality Rate (MR) was calculated and 25% of the surviving larvae were killed in hot but not boiling water. Their length was measured and the remaining living specimens were reared (25 C) on their food substrate until adult eclosion. The results were then compared with a control group in which larvae were not sampled but left to feed in the rearing boxes with air-permeable lids on their food substrate at 25°C. All containers were checked for MR every 24h for the effect of 24h of hypoxia on adults; later, hatched flies were frozen and separated according to sex. The length of the left mesothoracic tibia and dc-um vein of the left wing were measured using a dissecting microscope and computer software.

Results revealed a high MR for L3 larvae stored both at Room Temperature (RT) and in a cool environment (100% for both species at RT; for chilled larvae 100% of *L. sericata* and 54.03% of *C. vicina* with an MR in the control 2.53% for *L. sericata* and 8,08% for *C. vicina*). For *L. sericata* L1, the MR was respectively 16.16% at RT, 4.55% for chilled samples, and 2.25% in the control group. For *L. sericata* L2, the MR was 24.73% at RT, 10.61% for chilled samples, and 7.24% in the control group. For *C. vicina* L1, the MR was 35.86% at RT, 10.6% for chilled samples, and 2.94% in the control group. For *C. vicina* L2, the MR was 12.65% at RT, 10.61% for chilled samples, and 9.05% in the control group. Results highlight that the 24h interval time of storage can stop the larval growth in comparison with the control group. The lack of growth was extremely significant in *L. sericata* samples: 0.39cm for L1 at RT and 0.38cm in chilled samples; 0.72cm and 0.71cm for L2 at RT and in chilled samples; 0.17cm and 0.14cm for L3 at RT and in chilled samples. The lack of growth was in *C. vicina* samples of 0.47cm for L1 at RT and 0.45cm in chilled samples, 0.68 cm for L2 at RT, and in chilled samples, 0.25 cm and 0.24 for L3 at RT and in chilled larvae.

The duration of storage needs to be considered when performing the age calculation of larvae to estimate the minimum Postmortem Interval (PMI_{min}). The living larval samples should be stored at least at cool temperatures (e.g., in a refrigerator) instead of room temperature. This is strongly recommended for larvae with a size <1cm (L1-L2 stages) based on the high MR for L3 samples. For larvae >1cm, such as L3 samples, the recommendation is to add paper to the storage vials with air-permeable lids for absorbing the liquids (excrements, enzymes) and to reduce the interval of storage and transport considerably, keeping the temperatures low at a refrigerator level.

Forensic Entomology, Sampling Methods, Storing Methods

H108 Death by Hanging: The High Prevalence of Intervertebral Disc Vacuum Phenomenon in Thoracic and Lumbar Spine in Postmortem Computed Tomography (PMCT)

Vasiliki Chatzaraki, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zuerich CH-8057, SWITZERLAND; Jakob Heimer, MD, Universitat Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zuerich CH-8057, SWITZERLAND; Michael Thali, MD, Universitat Zurich, IRM / Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND; and Wolf Schweitzer, Universitat Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, Zurich CH-8057, SWITZERLAND*

The goal of this presentation is to suggest that death by hanging, under various mechanisms, may be associated with the origin of gas collection in the intervertebral discs that is revealed in postmortem imaging, especially by cadavers of a young age.

This presentation will impact the forensic science community by indicating that intervertebral vacuum phenomenon may be an additional finding in hanging cases that have undergone postmortem imaging.

Introduction: Postmortem imaging, in addition to PACT, has become the most frequently applied method in routine investigations.[1] CT provides high sensitivity in gas detection and the assessment of the condition of intervertebral discs.[2,3] Vacuum Phenomenon (VP) describes the gas collection in the intervertebral joint spaces and is associated with various pathologies, including Degenerative (DG) skeletal changes and trauma. Increased volume space of a joint through traction causes intra-articular gas collection.[4] In hanging, gravity pulling the body weight downward will affect the spine.[5] It was hypothesized that the expansion of the spine during hanging may cause gas accumulations in the discs. Also investigated was if Simon's bleedings could be predicted from the presence of VP in PMCT due to a similar origin (i.e., traction of the body and the spine).[6]

Materials and Methods: A group of 36 hanged bodies with PMCT was studied retrospectively. For each hanged case, a control case with another manner of death was chosen of the same sex and age (maximum of differences +/-2 years) and a matching degree of DG conditions. Each group was split into two equal age groups (n=18), one group of ≤43 years of age and one group >43 years of age. Cases with signs of putrefaction, those having undergone resuscitation, and those with trauma were excluded. Gas accumulations of the intervertebral discs and DG skeletal changes were evaluated in PMCT. Then, autopsy reports of the hanging cases were reviewed for the assessment of the presence of Simon's bleedings.

Results: The preliminary results revealed a significant association between hanging and VP in PMCT in the group ≤43 years old in the sample of the hanged group. The proportion of the hanged cases ≤43 years old that exhibited VP in PMCT is statistically different from the proportion of the control cases with other manners of death and VP in PMCT in the same age group. In the sample of the >43 age group, there was no significant association between manner of death and VP. There was no significant association between Simon's bleedings and VP. Simon's bleedings were significantly associated with complete rather than incomplete hanging.

Discussion: In people who died by hanging in the age group under 43 years, VP is to be expected more frequently than in people in the same age group with a different manner of death. This association does not occur in the age group below 43 years. The small number of cases is a limitation. DG skeletal changes and low bone mineral density are already associated with VP.[4,7] Intervertebral VP is also associated with increasing age and the elderly.[7] By hanging, the traction of the intervertebral joint spaces, especially in complete hangings, can play an additional role, among others, for the pathogenesis of vertebral VP. Simon's bleedings cannot be predicted in PMCT, as they are not associated with increasing age and DG skeletal changes because of decreased spinal mobilization.[6]

H109 An Autopsy Case of Pulmonary Embolism and Underlying Multiple Myeloma

Raman Baldzizhar, MD, Strong Memorial Hospital, 539 French Road, Rochester, NY 14618*

After attending this presentation, attendees will better understand how previously undiagnosed plasma cell neoplasm can contribute to fatal pulmonary embolism.

This presentation will impact the forensic science community by providing results from a case report in an area with very little previous research. This presentation will also add to research being conducted in forensic pathology by broadening the understanding of how undiagnosed plasma cell neoplasm can contribute to sudden death, enabling a better appreciation of these processes in death investigations.

Multiple Myeloma (MM) is characterized by the neoplastic proliferation of plasma cells producing a monoclonal immunoglobulin.[1] The diagnosis of MM requires clonal bone marrow plasma cells ≥10% or biopsy-proven bony or soft tissue plasmacytoma plus either the presence of related organ or tissue impairment or the presence of a biomarker associated with near-inevitable progression to end-organ damage.[2] Pulmonary embolus refers to obstruction of the pulmonary artery or one of its branches by thrombus.

A 62-year-old Black male with a past medical history of back pain, obesity, hypertension, and diabetes had a witnessed "falling out" in which he fell backward and became unresponsive. After Emergency Medical Services (EMS) arrival, he was found in pulseless electrical activity. The patient was pronounced dead soon after his arrival at the hospital. The most remarkable gross autopsy findings were bilateral thromboemboli in main, segmental, and subsegmental pulmonary arteries. Microscopically, the histology of vertebral bone showed hypercellular (90%) for the age bone marrow with the majority of the cells being atypical plasma cells. Immunohistochemical stains revealed cells of interest being positive for CD138, light chain lambda, and immunoglobulin G. Protein electrophoresis of postmortem blood showed the presence of M-spike and 1g/dl paraprotein and serum immunofixation exhibited IgG Lambda paraprotein in the gamma region.

In conclusion, this report provides evidence that even when the cause for sudden death is obvious grossly, some routine histology may provide valuable information about the underlying disease. In this case, myeloma significantly contributed to the fatal embolic event by the production of a hypercoagulable state. It was observed that in patients with newly diagnosed and untreated myeloma, increases in Von Willebrand factor and factor VIII and a decrease in protein S levels result in a hypercoagulable state which may promote the development of thrombo-embolic complications.[3]

H110 An Analysis of Skeletal Trauma in Suspected Child Abuse Fatalities: A Procedure Involving Radiology, Pathology, Histology, and Anthropology

Bradley J. Adams, PhD, New York OCME, 520 1st Avenue, New York, NY 10016; and Sean C. Kelly, MD, New York OCME, 520 1st Avenue, New York, NY 10016*

After attending this presentation, attendees will have a better understanding of the procedures for the analysis of skeletal fractures associated with child abuse cases.

This presentation will impact the forensic science community by describing a multidisciplinary approach to the interpretation of skeletal trauma in child abuse cases.

Thorough documentation and analysis of fractures is critical for the investigation of suspected child abuse fatalities. This presentation details a multidisciplinary procedure involving radiology, pathology, histology, and anthropology for the documentation, analysis, and interpretation of skeletal fractures.

The forensic pathologist has the ultimate responsibility for evaluating all the different pieces of evidence when making his/her eventual determination of cause and manner of death. In addition to the findings at autopsy, the forensic pathologist will also benefit from findings provided through radiology, histology, and anthropology. These modalities can play critical roles in the final certification of pediatric deaths and will also be useful in criminal proceedings if the case is deemed a homicide.

Radiography is a critical first step in the assessment of skeletal fractures. Antemortem radiographic studies may be available from a hospital and will be of obvious importance to the forensic pathologist. A postmortem series should also be completed prior to autopsy. At a minimum, standard two-dimensional X-ray images should be completed, but high-resolution Computed Tomography (CT) scans can also be extremely useful. Any skeletal specimens removed at autopsy should be re-radiographed as visualization of fractures and associated healing (if present) will be improved. In some instances, it may be helpful to have a radiologist interpret the images, especially regarding fractures in various stages of healing.

During autopsy, the forensic pathologist will document and photograph fractures, sites of hemorrhage, and vital reaction. Areas of fracture (or suspected fracture) are removed during autopsy for additional studies, including histology and anthropology. As noted above, it is advantageous to also take radiographs of the harvested specimens prior to initiating any additional examinations.

In order to allow both histological and anthropological analyses to be completed, a sampling procedure has been developed in which "windows" are cut through the fracture locations. It has been found that a hand-held rotary tool with a diamond blade allows for precise sections to be removed through fracture locations. Cutting a window through the fracture allows for the small section to be decalcified and slide mounted for histological evaluation while the larger section can be submitted for maceration and gross anthropological analysis. Through these studies, it is possible to document whether the fractures are acute, subacute, or show remote stages of healing.

The procedure outlined above is similar to recommendations made by Andrew Baker in the 2013 version of his excellent handout titled *Gross and Microscopic Evaluation of Pediatric Fractures at Autopsy* with only slight modifications.[1] One main difference is the role of anthropology in the process. Maceration of specimens (only to be completed after histology sampling) can provide an additional line of documentation and interpretation of fractures that can be useful to the forensic pathologist and which can be very illustrative in court proceedings. In some instances, additional subtle fractures have been observed after maceration that would have been missed on X-ray and during autopsy. The sampling procedure presented in this report allows both histological and anthropological analyses to be completed.

These recommended procedures for the documentation, analysis, and interpretation of skeletal fractures in suspected cases of child abuse have been applied on numerous cases at the New York City Office of Chief Medical Examiner. This presentation will describe the recommended multidisciplinary procedures in detail. In addition, several case examples will be presented, demonstrating how this approach was applied and how the findings proved to be critical in these challenging cases.

H111 Reducing Misdiagnosis in Child Abuse

Brooke H. Blake, MD, University of Texas Medical Branch Galveston, 301 University Boulevard, Route 0443, Galveston, TX 77555; and Michael Laposata, PhD, University of Texas Medical Branch Galveston, 301 University Boulevard, Route 0443, Galveston, TX 77555*

After attending this presentation, attendees will better understand the actions and goals of a Diagnostic Management Team (DMT) and its use in investigating suspected child abuse cases.

This presentation will impact the forensic science community by providing a description of the work of an expert group of coagulation specialists, medical examiners, and pathology residents reviewing suspected child abuse cases to reduce the possibility of misdiagnoses.

A DMT is a group of medical experts, specializing in specific areas, that meet regularly to review cases in real-time to advise on the selection of appropriate diagnostic tests and to interpret complex laboratory test results.

This expert team approach has been successfully implemented in several academic medical centers to provide clinical consultation in coagulation, transfusion medicine, hematopathology, microbiology, and several other areas. At the University of Texas Medical Branch in Galveston, TX, a DMT has been established to specifically evaluate cases of potential child abuse and determine if there is an underlying coagulation or vascular disorder to account for bleeding and bruising.

A 2015 report from the National Academy of Medicine revealed that every adult and many children in the United States have experienced at least one diagnostic error, often with very serious consequences.[1] The report indicates that there are many contributing factors to this problem, some of which are related to cognitive bias toward a specific diagnosis. With published information that 19 out of 20 potential cases of abuse are correctly diagnosed and one is a misdiagnosis, the misdiagnosis frequently occurs because of a significant bias toward a diagnosis of child abuse. There are few true experts in the United States dealing with coagulation disorders, and with 1 out of 20 cases misdiagnosed, approximately 30 percent of which involve a missed coagulation disorder, hundreds of cases are incorrectly diagnosed and treated in the United States annually.[2] Biases involving anchoring, premature closure, context errors, availability bias, and affective bias all influence a diagnosis of child abuse.

This misdiagnosis of child abuse often leads to removal of the child from a loving family and often punishes an innocent and loving parent or caregiver. To avoid a misdiagnosis of child abuse in a bruised or bleeding child, living or deceased, a DMT composed of experts in coagulation, in partnership with a group of pathology residents planning a career in forensic pathology, meets monthly to discuss presumed child abuse cases from all over the United States that have been submitted to a coagulation expert at the University of Texas Medical Branch for review and expert opinion. Each case is reviewed thoroughly by one resident, then presented at the DMT meeting. A set of diagnostic questions, which are relevant to the specific findings in the case, is formulated for further analysis, and each question is researched in the literature to provide published evidence for the conclusions offered in the final report. This expert-driven DMT review of cases has resulted in arguments that support diagnoses for and against child abuse.

In this presentation, three cases analyzed by an expert DMT are shown with the following results: (1) diagnosed as abuse; (2) underlying disease present, which make abuse unlikely; and, (3) no definitive answer because of the high diagnostic complexity.

The concept of introducing true experts in coagulation, bone disease, and dermatology, who review all child abuse questions related to bleeding/bruising, bone fractures, and skin changes, respectively, greatly reduces the risk of diagnostic error presumed in child abuse cases.

Diagnostic Management Teams, Child Abuse, Misdiagnosis

H112 Antemortem Versus Postmortem Bone Fractures: The Usefulness of Morphological Observation Using Scanning Electron Microscope

Silvia D. Visona, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY; Chiara Rossetti, MD, Forensic Medicine, University of Brescia, Piazzale Spedali Civili, 1, 25123 Brescia (BS), ITALY; Yao Chen, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY; Matteo Moretti, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY; Luisa Andrello, MD, Henri Guisan Street, 3, Bellinzona, Canton Ticino 6500, SWITZERLAND; Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Andrea Verzeletti, MD, University of Brescia, Piazzale Spedali Civili, 1, Brescia 25123, ITALY; and Antonio M.M. Osculati, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY*

The goal of this presentation is to observe the morphology of bone fractures using a scanning electron microscope to ascertain a number of specific characteristics that can be used for distinguishing between peri-mortem and postmortem fractures.

This presentation will impact the forensic science community by providing new tools to distinguish vital fractures from postmortem fractures.

One of the most important evaluations in the forensic assessment of a trauma is the timing of the injuries in respect to the time of death, which is more difficult in bone fractures than skin lesions; however, in many cases, it is crucially important to determine if the person was alive when the fracture occurred.

The evidence of bone remodeling is crucial for determining that a skeletal injury was produced antemortem. When the cortical surface of bone is disrupted by a fracture, a well-known series of events normally ensues. Initially, vascular damage causes a hematoma that forms in the area of injury. Within hours, the clot is invaded by inflammatory cells; after several days, fibrous matrix begins to replace the clot. Later, the callus is remodeled and converted to lamellar bone.

The length of time required for the production of new bone or other signs of healing is very variable and depends on the location of the injury, the health status of the individual, genetic variations, and other factors. The evidence of remodeling associated with the fracture indicates that the injury occurred at least a week before death.

For forensic purposes, it is often necessary to establish the vitality of fractures supposedly produced very shortly before death, when the healing process has no time to progress enough to be observable using the common methods (macroscopic evaluation and light microscopy). Therefore, it was hypothesized that the new morphologic markers, using a scanning electron microscope, are able to distinguish vital fractures from postmortem fractures.

The fracture lines and their relation to bone microstructure were studied on 15 fragments of fractures collected from the skulls of individuals who died from head trauma (i.e., traffic accidents, falls from heights, gunshot injuries). For each case, a forensic autopsy was performed. Each sample was compared to another bone fragment collected from the same subject during the autopsy and then experimentally fractured using a hammer. All samples were fixed in glutaraldehyde solution for 48 hours, then dehydrated and dried. These were coated with gold using a metal ion spattering instrument. The samples were examined with a Zeiss EVO® 40 scanning electron microscope.

The results demonstrated that a relevant, different pattern can be observed in vital fractures compared to postmortem fractures. High-power views indicate that the vital fracture is characterized by a pull-out of elastic and collagen fibers, as well as "bridges" formed by fibers, not seen in postmortem fractures, that have flatter surfaces with characteristic "micro-cracks."

The present study, therefore, suggests the usefulness of the scanning electron microscope in the evaluation of bone fractures, especially in regard to the timing of the injury.

Scanning Electron Microscope, Bone Fractures, Vitality Evaluation

H113 Posterior Rib Fractures in Non-Traumatic Pediatric Deaths

Jennifer C. Love, PhD, Office of the Chief Medical Examiner, 401 E Street, SW, Washington, DC 20024; and Kristinza W. Giese, MD, Office of the Chief Medical Examiner, 401 E Street, SW, Washington, DC 20024*

The goal of this presentation is to present a case series of non-traumatic pediatric deaths in which posterior rib fractures were observed. The learning objective is to understand possible mechanisms causing posterior rib fractures in infants.

This presentation will impact the forensic science community by raising awareness of posterior rib fractures observed in non-traumatic pediatric deaths. Posterior rib fractures are considered suspicious for non-accidental injury, but mechanisms other than non-accidental trauma must be considered.

Rib fractures observed in infants and young children are considered suspicious for Non-Accidental Injury (NAI), especially fractures located in the posterior region of the rib. In fact, Barsness and colleagues found that in children under the age of 3 years, the positive predictive value of rib fractures for NAI was 95%.[1] Dolinak reports that in 11% of consecutive infant autopsies (*n*=70), subtle Cardiopulmonary Resuscitation (CPR) - associated rib fractures were found in the anterolateral region of the ribs.[2] In several of the cases, multiple ribs were fractured bilaterally. No fractures were found in the posterior region of the ribs.

Researchers theorize that the mechanism causing CPR-related rib fractures is different from the mechanism causing posterior rib fractures. CPR rib fractures result from the anterior chest being forced posteriorly while the back is supported, causing the rib to fail in the mid-clavicular region. Posterior rib fractures are caused when the thorax is squeezed in an anterior/posterior direction while the back is unsupported forcing the posterior rib against the transverse process of the vertebra. This action creates a Type I lever at the costrotransverse articulation site.

In 2000, the American Heart Association, in collaboration with the International Liaison Committee on Resuscitation, recommended a new "two-thumb" technique to administer CPR to infants. The method involves placing both thumbs on the sternum of the patient, encircling the chest with the hands, placing the finger tips lateral to the spine, and compressing the sternum. This technique is similar to the mechanism commonly proposed for inflicting NAI rib fractures. Clouse and Lantz reported on four cases of premature infant decedents who each received "two-thumb" CPR.[3] Posterior rib fractures were observed in all decedents and NAI was excluded in each case.

Three infant deaths investigated by the District of Columbia (DC) Office of the Chief Medical Examiner were found to have posterior rib fractures and no other signs of trauma. Each decedent was transported from a private home to the hospital by the DC Fire and Emergency Medical Services (FEMS) with CPR in progress. FEMS standard operating procedure is to perform "two-thumb" CPR on infants. In each case, the posterior rib fractures were observed after the periosteum and intercostal muscles were removed from the pleural surface of the ribs. At each fracture site, little to no hemorrhage was observed. The fractures were both complete and incomplete and were positioned at the rib head or angle. In each case, several ribs were serially fractured, with up to six ribs fractured in one case. In all cases, the fractures were unilateral. Anterior rib fractures were also observed in two of the cases.

The autopsy findings in the presented cases suggest CPR-related posterior rib fractures. In each case, the fractures were subtle and difficult to recognize on radiographs as well as during the autopsy. These three cases should raise caution regarding the diagnostic value of posterior rib fractures for NAI.

Posterior Rib Fractures, Pediatric, Non-Accidental Injury

H114 A Frozen Newborn: A Multidisciplinary Approach in a Case of Infanticide

Enrica Calabrese, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Raffaella Marino, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Omar Bonato, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Matteo Fabbri, MSc, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Dept of Forensic Pathology, Via Fossato di Mortara 70, Ferrara 44100, ITALY; and Rosa Maria Gaudio, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY*

The goal of this presentation is to introduce a multidisciplinary approach to a complex case of a newborn infant found deceased in a house freezer. In order to assist the judicial authorities and police inquiries in classifying a crime, radiologists, gynecologists, and forensic pathologists need to be involved. In these cases, the role of the medicolegal team was pivotal in clarifying the newborn's cause and time of death, separate existence, and viability. According to Italian law, infanticide is a crime committed by a mother against her own infant child "immediately after or during delivery," who has suffered "conditions of abandonment connected to childbirth."[1]

Little is written in the literature regarding how to handle this type of forensic case; therefore, this presentation will impact the forensic science community by providing a methodical approach to this medicolegal issue.

A 40-year-old woman, *gravida* 5, *para* 5, was admitted to the emergency department with headache, asthenia, and metrorrhagia. On admission, the patient was conscious and alert, but soon after became confused and disoriented, complaining of loss of sensation in both legs. At the evaluation, she was hemodynamically unstable, with a significant drop in her hemoglobin level (Hb 3.7g/dl); an abdominopelvic Computed Tomography (CT) scan with angiography detected an enlarged uterus (25cm) with thick myometrium and the presence of mixed-density fluid and gas within the endometrial cavity. She was immediately taken to the operating room for an instrumental revision of the uterine cavity. The placenta was spontaneously delivered and macroscopic features revealed that it was full-term. According to hospital records, the previous delivery, which occurred at home in the bathroom, was unexpected, resulting from an unknown pregnancy. Nothing else was reported from her recent gynecological and obstetrical history.

Subsequently, the police, assisted by the medicolegal team, searched the woman's house for the missing newborn. The crime scene investigation revealed the home was full of clutter and garbage, with many household pets and mice. After two days of intensive searching, a newborn infant was found in a hidden freezer. The infant was stacked in the freezer with several frozen foods, wrapped in a wool sweater, and enclosed in two plastic bags. The body was naked and in the fetal position, and sex could not be determined in the frozen state as the genitalia were hidden by the legs.

A multidisciplinary forensic approach included a CT scan and genetic and toxicological analyses; an autopsy was then performed. The histological and immunohistochemical examination of specimens from the newborn, the placenta, and the umbilical cord were helpful for the postmortem investigation.

The CT scan demonstrated the anthropometric parameters were appropriate for the gestational age of a full-term infant. Furthermore, it revealed air in subsegmental regions of the lungs, as well as in the stomach. No fractures were detected.

The body was thawed at the time of the autopsy, seven days after being found. The external examination verified a newborn female infant, full-term at the time of death. The umbilical cord was still anchored to the abdominal wall and lacerated at its distal part. There were no injuries on the skin or signs of suspected asphyxia. The autopsy also revealed a subgaleal hematoma over the right temporal-parietal scalp, and no apparent subdural or subarachnoid hemorrhages. No cardiac malformations were found. When the lungs and the clipped stomach were placed on water, they floated. All findings demonstrate that the newborn infant was born alive. Further investigation revealed characteristics of a dysfunctional family and led to the intervention of protective services.

Infanticide, Frozen Newborn, Histopathology

H115 A Review of Multiple Dog-Mauling Fatalities of Infants Less Than Six Months of Age and Neonates in Travis County, Texas, and Cook County, Chicago, Illinois

Kendall V. Crowns, MD, Travis County Medical Examiner's Office, 1213 Sabine Street, Austin, TX 78767; Michelle S. Montonera, MS, Travis County Medical Examiner's Office, 1213 Sabine Street, Austin, TX 78701; and Adrienne Segovia, MD, Cook County Medical Examiner's Office, 2121 W Harrison Street, Chicago, IL 60612*

After attending this presentation, attendees will have a greater understanding of the injuries found in neonates and infants mauled by dogs.

This presentation will impact the forensic science community by presenting unique findings regarding neonates mauled by dogs.

There are numerous dog bite fatalities in the United States every year. Most of these fatalities occur in children between 1 and 12 years of age. In contrast, deaths among neonates (less than four weeks of age) and infants less than six months old comprise a small percentage of pediatric deaths. In the 1-to-12-year-old age group, injuries typically involve the head and extremities. The injuries consist of multiple abrasions and lacerations. The lacerations involve the underlying blood vessels and result in death from hemorrhage; however, deaths in infants less than six months of age can also be the result of extensive crushing injuries.

This study reviewed seven dog-mauling fatalities of infants from Travis County, TX, and Cook County, IL. The ages ranged from six days to six months old.

Family members discovered two of the neonates suspended by their heads from the dogs' mouths. The injuries predominately involved the head and neck region and consisted of puncture wounds, lacerations, skull fractures, and brain hemorrhage. In one case, examination of the spinal cord demonstrated hemorrhages along the cord and nerve roots. The third neonate was found on the ground with extensive injuries to the torso, head, and neck. While similar injuries also occurred in the older infant age group, additional injuries to the torso with rib fractures and lacerations of the lungs and liver were identified in this age group as well. The neonates averaged 8 pounds in weight, 20 inches in length, and had an average head circumference of 32.5cm. The older infants averaged 12.4 pounds in weight, 24.5 inches in length, and had an average head circumference of 39.4cm.

Fatal injuries in neonates and infants are related to the physical characteristics of this age group: immobility, low weight, and short stature. Neonates can present with a unique subset of injuries to the neck region. Because they have relatively smaller head circumferences when compared to older infants, larger dog breeds can pick up and shake the neonate by the head, causing cervical spine injuries.

In conclusion, when a neonate is the victim of a dog mauling, the cervical spinal column should be removed and examined for injuries to evaluate shaking as a possible mechanism of death.

Dog Mauling, Neonates, Cervical Spine Injuries

H116 Distinguishing an Accidental Drowning From a Homicide: The Death of a 72-Year-Old Woman in Mississippi

Charles E. Middleton IV, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; L.R. Funte, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; and Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208*

The goal of this presentation is to stress the significance of a thorough forensic investigation. Attendees will appreciate the nuances of distinguishing accidental from non-accidental trauma, as it relates to forensic pathology.

This presentation will impact the forensic science community by demonstrating how a forensic pathologist can uncover evidence that will prompt an inquiry or change the course of an ongoing investigation. The presence or absence of certain signs can guide the forensic investigation in various directions. This presentation will illustrate the importance of forensic evidence when determining the manner and cause of death.

On June 12, 2017, the Madison County, MS, Sheriff's Office responded to a call concerning a motor vehicle accident. The accident was reported by the driver of a log truck. He stated that he was driving by a lake when he noticed a black car, which was partially submerged. He informed the authorities that he was driving on a two-lane road, so he did not stop until he came across an individual who was working in his front yard. Once he told the homeowner about the vehicle in the lake, he got back into his truck and continued down the road without leaving his name or contact information. Upon arriving at the scene, law enforcement observed a body floating face down in the center of a lake. A purse retrieved close to shore revealed a credit card; the name on the card was recognized by one of the first responders. Authorities contacted the decedent's boyfriend, who explained that the couple had just returned to Mississippi following a brief vacation in Atlanta, GA. He stated that the victim dropped him off at his residence shortly after noon and proceeded to drive in the direction of her own residence. The boyfriend had no further information to provide.

The victim's body and her car, a 2009 black Toyota® Camry®, were retrieved from the lake. The vehicle was submerged in approximately eight feet of water and had sustained damage to the front grill, bumper, and windshield. The passenger window was in a rolled-down position; the glass was intact. The key was in the ignition, but the plastic Frequency Operated Button (FOB) end of the key was missing. The gearshift was in the reverse position, and the hazard lights were turned on and functioning, as the car was removed from the water. The car was towed to a body shop, and the decedent was transported to the State Medical Examiner's Office.

The external examination of the victim was unremarkable except for a laceration noted to the medial aspect of the right first toe and a contusion inferiomedial to the right kneecap. The decedent was cool to the touch, in full rigor, displaying purple fixed lividity posteriorly. On examination of the eyes, bilateral scleral hemorrhage was noted. The autopsy revealed bilateral hyperinflated lungs, hemorrhage of the tongue, bilateral hemorrhage of anterior strap muscles of the neck, petechiae of the scalp, focal hemorrhages of the right scalp, including the right temporalis muscle, and bilateral hemorrhage of the deltoids.

It is important to distinguish the victim's manner of death. The narrative provided by the witness and boyfriend suggest the death was an accidental drowning; however, the damage sustained to the victim's car was inconsistent with the injuries found on the victim's body, as there was an absence of blunt force trauma that should be present in a motor vehicle accident. In addition, the autopsy revealed multiple findings consistent with a struggle. Specifically, the bilateral scleral hemorrhage and scalp petechiae are consistent with hypoxia as a cause of death. Even more significant are the hemorrhages of the anterior strap muscles of the neck, suggesting strangulation as the manner of death.

The investigation is ongoing.

Strangulation, Drowning, Blunt Force Trauma

H117 Diatom Test: Still an Irreplaceable Analysis

Paolo Frisoni, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Stefano Tomasi, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Chiara Marini, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Erica Bacchio, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Raffaella Inglese, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Dept of Forensic Pathology, Via Fossato di Mortara 70, Ferrara 44100, ITALY; and Letizia Alfieri, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY*

The goals of this presentation are to verify how: (1) the standardization of a diatom test on femoral bone marrow allows for more scientifically correct data to increase the accuracy of the diagnosis of death by drowning and to discriminate it from other causes of death; and, (2) this work seeks to confirm the high specificity of the diatom test.

This presentation will impact the forensic science community by showing how exceptional knowledge of the method, and the ability to apply it rigorously, could be a useful means of confirming a diagnosis of drowning.

Since the early 1900s, the diatom test has been included among tests that allow the diagnosis of drowning. There are many studies on this subject that confirm the diagnostic reliability of this test, while acknowledging its obvious limits (no rigorous implementation by the operator and false positives).

Diatoms are aquatic unicellular algae, widespread in both fresh and salt waters worldwide. They contain a cell wall made of silica (frustule) of various shapes, which reveal gaps for external exchanges (pores). Frustule is highly resistant to chemical and physical treatments that can dissolve human tissues, and for this reason it can be pointed up.

The theory behind the diatom test is that when fluid enters the lung, diatoms enter within the fluid and pass the alveolar-capillary barrier. If the circulatory system is functioning, diatoms are disseminated to peripheral organs; this is an indication of breathing activity at the entrance of the drowning medium in airways. After their diffusion, diatoms can be found in several tissues. The femoral bone marrow is preferred both because of its resistance to external contamination and in cases of a highly decomposed body.

It is important to consider that diatoms decrease their concentration during the transit from outside to the bone marrow, decreasing by 100 to 1,000 times (finding an excess of diatoms means there was a contamination). Moreover, high-dimension diatoms are most likely contaminants (not rigorous implementation by the operator and false positives). It is also important to match the diatoms found in bone marrow and those found in the drowning medium. This comparison could lead to a clear identification of the drowning area.

This study is based on the analysis of 53 corpses recovered from water, of which 36 drowned and 17 died from other causes. In all cases, a complete autopsy, histological investigations, and the diatom test were performed.

In the diatom test, a sample of femoral bone marrow was collected during the autopsy using sterile surgical devices further cleansed with diatom-free alcohol. From this sample, 10ml of bone marrow was processed with nitric acid and successively examined with an optic microscope, using bright field and phase contrast.

Among the drowned subjects examined, 28 tested positive (77.77%) and 8 negative (22.22 %); among the decedents found dead in water, none showed diatoms in the bone marrow. The Fisher test was performed, demonstrating that these two groups were significantly different ($p<0.0001$).

Therefore, a diatom test, executed in a meticulous and standardized manner, could be considered essential support for a drowning diagnosis, in addition to more common practices (analysis of the circumstances, postmortem examination, and histological findings). This method, inexpensive and easy to reproduce, could be an important aid for the pathologist to differentiate drowning cases from other cases of death occurring in water.

Drowning, Diatoms, Forensic Pathology

H118 Armanni-Ebstein Lesions and Hypothermia: A Five-Year Retrospective Study From the Cook County Medical Examiner's Office

Lorenzo Gitto, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome 00169, ITALY; Serenella Serinelli, MD, Sapienza University, Department of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome 00185, ITALY; and Ponni Arunkumar, MD, Cook County MEO, 2121 W Harrison Street, Chicago, IL 60612*

After attending this presentation, attendees will understand the significance of Armanni-Ebstein lesions in the diagnosis of fatal hypothermia.

This presentation will impact the forensic science community by studying the association of these lesions in deaths due to hypothermia in one of the coldest counties of the United States.

Hypothermia is defined as a body core temperature below 95°F (35°C). The final cause of death is due to ventricular fibrillation, asystole, internal asphyxiation or hypoxia due to a left shifting of the oxygen-hemoglobin dissociation curve, or failure of enzymes and electrolyte dysregulation. Usually, the diagnosis of hypothermia is based on circumstantial evidence, but there are some morphological findings that can help the forensic pathologist reach the correct diagnosis: bright red postmortem lividity; hemorrhagic spots of the gastric mucosa (Wischnewsky's spots); several pancreatic changes, such as focal or diffuse pancreatitis, hemorrhagic pancreatitis, patches of fat necrosis; hemorrhages into the core muscles; and fatty changes in the heart, liver, and kidneys. Scene findings of paradoxical undressing or terminal burrowing may assist the pathologist in the diagnosis of hypothermia.

Researchers have found a possible association between the Armanni-Ebstein phenomenon and hypothermia deaths. Armanni-Ebstein changes are subnuclear vacuolization of renal tubular epithelial cells due to glycogen or lipid deposits. These lesions are typically observed in poorly controlled diabetic states.

According to the literature, Armanni-Ebstein changes are constantly observed in subjects with a history of diabetes mellitus. An association between diabetes mellitus and hypothermia has been described. Metabolic complications of diabetes mellitus can cause secondary hypothermia. Conversely, primary hypothermia can worsen a decompensated diabetic state. Hence, Armanni- Ebstein lesions can be found in cases of hypothermia and diabetic ketoacidosis.

Case files from the electronic database of the Cook County Medical Examiner's Office in Chicago, IL, were retrospectively reviewed over a five-year period from July 2011 to July 2016 for cases in which deaths were due to hypothermia. The search was performed using the keyword "cold" in the "Cause," "Due to," and "Injury description" fields. All cases had investigative reports. Cases in which a complete autopsy was performed were selected for this study. Autopsy reports were reviewed, and the age, gender, and pathological findings were summarized. Specific details about diabetic status, if available, were noted. In cases in which histological sections of the kidneys were available, the slides were examined for the presence of Armanni-Ebstein lesions. Periodic Acid-Schiff (PAS) and Oil-red staining were used to demonstrate the material in the lesions.

There were a total of 133 cases of fatal hypothermia, with autopsies performed in 111 cases. Histology slides were available in 44 of the 111 cases. The ages ranged from 0 to 99 years (average 55 years) with a male-to-female ratio of 2.7:1.

This research provides an interesting study targeted at demonstrating the significance of Armanni-Ebstein lesions in cases of fatal hypothermia. The results of this study will be discussed with attendees.

Armanni-Ebstein, Hypothermia, Forensic Pathology

H119 Hypothermia Deaths Due to Environmental Exposure in King County, Washington

Tara Dixon, MD, King County MEO, 325 Ninth Avenue, HMC Box 359792, Seattle, WA 98104; Brian Mazrim, MD, King County MEO, 325 Ninth Avenue, HMC Box 359792, Seattle, WA 98104; and Richard C. Harruff, MD, PhD, King County MEO, 325 Ninth Avenue, Box 359792, Seattle, WA 98104*

After attending this presentation, attendees will be able to explain the contributing variables in hypothermia deaths in vulnerable populations and describe the paramount importance of scene and circumstances in determining cause of death in the absence of specific anatomic markers.

This presentation will impact the forensic science community by emphasizing the importance of scene and circumstances in determining cause of death in cases of environmental exposure in the absence of specific anatomic findings related to hypothermia. This study has important implications for public health and public policies related to homelessness and protecting vulnerable populations.

The Pacific Northwest has a temperate climate without extremes of temperature, yet hypothermia deaths due to environmental exposure are not uncommon. Data from the King County Medical Examiner's Office (KCMEO) in Seattle, WA, were examined to better understand the contributing factors in hypothermia and the criteria used to determine cause of death.

Methods and Materials: KCMEO records from 2005 through 2016 were selected for all deaths due to hypothermia from environmental exposure. Cases were reviewed in addition to toxicology reports for cause and manner of death, demographics, detailed circumstances, and potential contributing factors. Historical weather data were obtained for each date of death or date of discovery for cases dying in the hospital. Population data were obtained from the 2010 United States Census, and estimates of the homeless population were obtained from local statistics. To assess the specificity of gastric Wischnewski lesions in hypothermia deaths, all autopsy reports for the same time interval containing the term "Wischnewski" were reviewed.

Results: There were a total of 101 cases identified. The annual rate ranged from 5 to 16 per year with a maximum of 16 in 2015. Deaths occurred during all months of the year, with a peak of 32 deaths in December. Daily minimum temperatures associated with each death ranged from 16°F to 56°F with a median of 39°F. The male:female ratio was 69:32. Ages ranged from 24 to 95 years with a median of 57 years. The racial distribution was as follows: 85 White, 6 Black, 4 Asian/Pacific Islander, 5 Native American, and 1 Other. Of all cases, 87 were dead at the scene and 14 were found alive but subsequently died in the hospital. Decedents were found indoors in 15 cases and outdoors in 86 cases. Of those found indoors, all were living alone, and 5 were aged 75 years or older. Altogether, 32 were considered homeless. Based on homeless estimates in King County, this represents an incidence of hypothermia death among the homeless of up to 56 per 100,000 in 2015, compared with 0.76 per 100,000 in the general population. Evidence of intoxication was present in 46 cases. Non-toxic causes of potential incapacitation, ranging from trauma to dementia, were documented in 28 cases. Wischnewski lesions were documented in 25 cases of hypothermia death and in 25 autopsies unrelated to hypothermia. Additional analysis of circumstances found one or more factors that may have contributed to death as follows: 32 were homeless; at least 8 were living indoors in an unheated residence; 65 were incapacitated by intoxicants, injury, and/or natural disease; 7 had underlying dementia or psychiatric illness; and 2 were involved in a motor vehicle collision with a prolonged interval of discovery. Only two cases were engaged in outdoor recreational activities. Paradoxical undressing and/or burrowing were not appreciable features in this study.

Discussion and Conclusions: In this study, the certification of death due to environmental exposure was made by consideration of scene and circumstances. Wischnewski lesions were not found to be a reliable indicator of hypothermia death. Moreover, hypothermia deaths in King County were not necessarily associated with freezing temperatures, indicating that winter in maritime temperate climates may present an unexpected hazard for vulnerable populations, including the homeless and the indigent elderly living alone. Intoxication increases vulnerability as do non-toxic causes of incapacitation, such as underlying dementia or natural disease. Overall, the findings of this study have important implications for public health and welfare services designed for protecting vulnerable populations. As the homeless population in King County continues to rise, it becomes increasingly important to monitor hypothermia deaths as a measure of public policy.

Systemic Hypothermia, Environmental Cold Exposure, Homelessness

H120 Common Cutaneous Injuries Found in Drowning Deaths

Abigail J. Grande, MPH, WMU Homer Stryker MD School of Medicine, 1000 Oakland Drive, Kalamazoo, MI 49008; Timothy Wysozan, BS, 300 Portage Street, Kalamazoo, MI 49007; and Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008*

After attending this presentation, attendees will be more familiar with cutaneous injuries that may be seen in drowning deaths. This presentation will explore possible mechanisms underlying these injuries, particularly focusing on cutaneous injuries that occur while the decedent is submerged in water.

This presentation will impact the forensic science community by identifying the frequency of cutaneous injuries in drowning deaths and will provide a reference of cutaneous injuries that may occur to aid forensic pathologists in determining the possible causes of commonly recognized injuries in drowning victims.

Cutaneous injuries are often found in suspected drowning deaths. These injuries are thought to occur as the body drags across the bottom of the body of water or as the body comes into contact with rocks, marine life, underwater objects, and even boats.[1] For example, bodies that have traveled a significant distance in a river may demonstrate grinding down of tarsal and carpal bones due to dragging of the hands and feet along the bottom of the body of water.[2] Classically, these cutaneous injuries are distributed over the face, hands, forearms, knees, and feet as submerged bodies have a tendency to be in a "head down" position.[1] It can become difficult for a forensic pathologist to determine whether these injuries were caused ante- or postmortem, as various types of injuries can occur while submerged in a body of water.[3,4] This also includes cutaneous injuries due to postmortem animal predation.[4]

To date, this study is not aware of previous studies that quantified the frequency and types of cutaneous injuries seen in drowning deaths. In order to accumulate data, this study drew from a web-based database of deaths investigated by medical examiners/coroners from multiple counties in Michigan and Indiana from 2008 to 2017. Cases were identified by use of the term "drown" in the cause-of-death field and further narrowed down by location of death being a lake, pond, or river. A review of the autopsy photographs and the evidence of injury section of the autopsy reports identified cases with cutaneous injuries. All 65 identified cases occurred in freshwater. Approximately 71% of the deceased individuals presented with evidence of cutaneous injuries, including, but not limited to, abrasions, lacerations, and contusions. Injuries on the body were found most frequently on the head (49%) and extremities (43%), but were also found on the trunk (19%) and neck (3%). Some of these injuries appeared to be from postmortem animal activity.

Determining the timeline and cause of cutaneous injuries is an integral part of the medicolegal postmortem examination. This becomes especially difficult in the setting of a drowning, when the body can acquire postmortem injuries from a variety of sources, some of which may mimic antemortem trauma. Members of the forensic community should always remain cognizant of the fact that cutaneous injuries are frequently associated with drowning deaths and, in many cases, may be caused postmortem, with no correlation to the immediate cause of death.

Drowning, Cutaneous, Injuries

H121 A Probabilistic Analysis of the Cause of a Traffic Death Following Two Crashes Using National Crash Data

Michael Freeman, MD, PhD, Forensic Research & Analysis, 425 NW 10th Avenue, Ste 306, Portland, OR 97209; and Ellen M. Freeman, 4118 SE Cesar E Chavez Boulevard, Portland, OR 97202*

The goal of this presentation is to present the analysis of the most probable cause of a fatal head injury following two traffic crashes occurring in close temporal sequence.

This presentation will impact the forensic science community by illustrating a multidisciplinary, evidence-based assessment of cause of death in a fatal traffic crash investigation.

Medicolegal investigation of the mechanism and cause of death in most fatal traffic crashes is relatively straightforward; there is typically evidence of direct or indirect blunt force trauma to the head, neck, or chest that can be matched with a reconstructed crash injury mechanism; however, in some unique circumstances, there are plausible alternative explanations for observed injuries that require further investigation.

This presentation describes the death of a 19-year-old female driver of a Sports Utility Vehicle (SUV) that was involved in two crashes occurring in close temporal sequence. The collision series began when the decedent's Ford® Explorer® SUV carrying five restrained occupants swerved to avoid a semi-tractor/trailer that had entered its lane. The vehicle began to yaw clockwise, then tipped and rolled 2.5 times, coming to rest on its roof in the same lane in which it had been traveling. The Ford® sustained extensive roof crush. Two of the passengers were able to exit the vehicle, and none of the occupants recalled the driver verbally responding.

Approximately one minute after the vehicle had stopped moving, a southbound semi-tractor/trailer struck the SUV on the driver's side at 33.5mph. The driver, who was found inverted and hanging from her seatbelt with her head and left arm partially ejected, was pronounced dead at the scene. Autopsy revealed a comminuted transverse fracture through the temporal and occipital bones and a pontomedullary transection, as well as extensive abrasions, lacerations, and pressure marks noted about the head, face, neck, torso, and both upper and lower extremities.

There was no reliable evidence from either the autopsy or from an engineering/biomechanical perspective as to which of the crashes caused the fatal head injuries. From a common-sense perspective, it was reasonable to view the second collision as having a very high probability of causing serious head injury, as the decedent's inverted head and neck were at the level of the bumper of the approaching semi. At the same time, the high degree of roof crush sustained by the SUV in the rollover also suggested a high risk of head and neck injury.

An analysis of national crash data was undertaken to quantify the risk of death for each of the two crashes so that a determination of comparative risk could be made. To this end, data were abstracted from the United States National Automotive Sampling System-Crashworthiness Data System (NASS-CDS). The parameters for the analysis included all SUVs that underwent a rollover, and the outcome was risk of death for a belted, non-ejected driver with more than one foot of roof crush at their seating position. The risk of death in such rollover crashes was 1.8% for drivers, or 1 in 56.

The same type of analysis was performed for the second crash, using nearside impacts of a "T-bone" configuration, and adjusted for the severity of the collision, which, at 33.5mph impact speed placed it in the upper 1.5% of all side impacts for severity. The associated risk of death was 16%, or 1 in 6.3. The risk ratio between the two crashes was 16.0/1.8=9.0; thus, a comparison based purely on risk indicated that the second crash was nine times more likely to have caused the fatal injuries.

Further review of the evidence indicated that the inverted driver was likely struck in the head by the bumper of the approaching semi, as there was a small amount of blood found on the bumper. This fact likely increased the risk of death from the second impact substantially, relative to the 16.0% estimated risk for upright occupants. Thus, it was more accurate to consider that the absolute risk of death from the first crash (1.8%) indicated that there was a >98% probability that the decedent survived this initial crash; thus, as the risk of death from the second crash approached 100%, the risk ratio would likewise increase.

Traffic Death, National Crash Data, Forensic Epidemiology

H122 Immune Responses in Opioid Use

Henry J. Carson, MD, Cedar Rapids, IA*

After attending this presentation, attendees will be able to: (1) identify situations in which opioid use is present but not definitely diagnostic of cause or manner of death; (2) collect and store specimens for opioid and immune analysis; (3) apply laboratory and anatomic findings to establish immune response in cases of opioid use; and, (4) apply immune responses in death certificates.

This presentation will impact the forensic science community by demonstrating how these findings can be used to perform forensic, toxicological, and immunological examinations of decedents and to certify the cause and manner of death.

Death from the abuse of prescription or illicit opioids is acutely on the rise in the United States.[1] Death from drug abuse is usually determined by toxicological examination of the blood or other body fluids in conjunction with an autopsy, scene investigation, and detailed decedent history; however, in some cases, the levels of opioids detected do not reach toxic levels, let alone fatal levels.[2,3] It was hypothesized that there is a subset of opioid users in whom immune activiation is a substrate of the mechanism of death, and they can be identified by demonstrating evidence of allergic or anaphylactic reactions.

In this experiment, cases from a ten-year period were reviewed. All cases with toxicological evidence of opioid use were recorded. The cases were further grouped by evidence of immune response in the presence of opioid use. Evidence of immune activation was based on external findings such as rash or scratches from recent pruritis; internal evidence such as overlapping lung apices from asthma; microscopic evidence such as lung changes of asthma; or elevated mast cell tryptase levels. Groups were compared with *t*-tests and chi-square 2x2 contingency tables.

In all, 49 cases of opioid use were identified. Of these, five had evidence of immune response in the presence of opioids: two with scratches, three with evidence of asthma, and one with elevated mast cell tryptase. There was no significant difference between the two groups based on age, race, or sex. There was no significant difference in the types of drugs or opioids identified in the two groups. There was no significant difference in the manner of death. Of a number of clinical histories and causes of death identified, asthma was the major condition that was significantly associated with immune response in the presence of opioid use.

In conclusion, men and women were equally likely to have used opioids in this study group, typically in their fourth and fifth decades. No specific type of opioid was favored. Other prescription drugs were frequently present. The most common cause of death was overdose or drug interaction. The manner of death was typically accident. Immune response was evident in 10% of the cases. A history and evidence of asthma was significantly associated with immune response and as a cause of death.

H123 Preliminary Findings From the Drug Enforcement Administration's (DEA's) National Forensic Laboratory Information System (NFLIS) Medical Examiner/Coroner Office Survey

DeMia P. Pressley, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Artisha R. Polk, MPH, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Liqun Wong, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Terrence Boos, PhD, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Hope Smiley-McDonald, PhD, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; Katherine N. Moore, MS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; Edrina Burnette, MS, RTI International, 3040 Cornwallis Road, Research Triangle Park, NC 27709; Jeffrey M. Ancheta, BS, RTI International 3040 Cornwallis Road, Research Triangle Park, NC 27709; Neelima Kunta, BS, RTI International, 3040 Cornwallis Road, Research Triangle Park, NC 27709; David Heller, BS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; and Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will understand the DEA's NFLIS expansion and results from their 2017 medical examiner/coroner office survey.

This presentation will impact the forensic science community by providing specific knowledge of medical examiner and coroner office operations, policies, practices, and resource needs of the United States' medicolegal death investigation system.

The NFLIS represents an important DEA resource in monitoring illicit drug abuse and trafficking. Available NFLIS data reflect the results from drug chemistry analyses conducted by federal, state, and local forensic laboratories across the country (NFLIS-Drug). NFLIS-Drug currently includes more than 95% of the nation's crime laboratories that regularly report data from solid-dosage drug analyses from law enforcement seizures. NFLIS-Drug data are used to support drug scheduling decisions and to inform drug policy and drug-enforcement initiatives nationally and in local communities around the country.

Over the next few years, DEA will expand NFLIS to include drug-related mortality data from the nation's Medical Examiner and Coroner offices (NFLIS-MEC) and drug testing results from public and private toxicology laboratories (NFLIS-TOX) across the United States. The new NFLIS-MEC and NFLIS-TOX data collections will extend DEA's radar in identifying new and emerging drugs and to inform drug use patterns. In preparation for this expansion, DEA conducted a 2017 NFLIS-MEC office survey and a Toxicology Laboratory (TL) Survey. Preliminary results from the MEC survey will be discussed in this presentation.

The MEC survey was designed by NFLIS staff with the help of external MEC and toxicology consultants. Mailed surveys were sent to all identified MECs (*N*=2,156) in the United States. NFLIS staff performed several actions to increase survey responses, including verification calls to confirm MEC office contact information and point of contact, prompting call reminders about the mailed survey, and non-response calling to collect two critical questions. In addition, NFLIS staff reached out to all state coroners associations, the National Association of Medical Examiners, and the International Association of Coroners & Medicals Examiners, among others, to encourage participation. Survey responses were collected via a mixed mode data collection (web, mail, and telephone). Data collection began in June 2017 and concluded in October 2017. Survey results highlighting findings related to operation, caseloads, turnaround times, toxicology testing practices, accreditation, and information management systems of MEC offices will be discussed. Where possible, the data will be presented by type of office and size of jurisdiction. The results will provide attendees a broad understanding of the operations, policies, practices, and resource needs of the nation's medicolegal death investigation system. Moreover, DEA will outline its plans for the NFLIS expansion.

NFLIS, DEA, Medical Examiner/Coroner

H124 Developing "Real-Time" Surveillance for Drug Overdose Deaths in King County, Washington

Nicole A. Yarid, King County MEO, 325 Ninth Avenue, Seattle, WA 98104; Julia Hood, PhD, King County MEO, 325 Ninth Avenue, Seattle, WA 98104; and Richard C. Harruff, MD, PhD, King County MEO, 325 Ninth Avenue, Box 359792, Seattle, WA 98104*

After attending this presentation, attendees will be able to explain why data from death certificates are not effective for "real-time" surveillance of drug overdose deaths and describe methods by which death investigations can be used more effectively in the face of ever-increasing drug overdose deaths.

This presentation will impact the forensic science community by describing methods by which death investigations can be part of "real-time" surveillance of drug overdose deaths.

Across the country, the opioid epidemic is rapidly evolving. In some regions, there has been a major shift in the type of opioids seen due to fentanyl-type drugs. Unfortunately, overdose data are generally available only after many months and represent a historical analysis rather than a useful surveillance tool. The present study was conducted to increase understanding of the delays in collecting and using overdose data and to develop a method by which information from drug overdose death investigations can be used as part of "real-time" surveillance.

Methods and Materials: Death investigation records and death certificates for drug overdose deaths reported by the King County Medical Examiner's Office (KCMEO) in Seattle, WA, from 2007 through 2016 were examined to evaluate for each case the time delays between when death occurred, when toxicology reports became available, when pathologists cleared the death certificate, and when the death certificates were referred to the Office of Vital Statistics. As a means of developing a "real-time" surveillance model, KCMEO pathologists maintained a daily tally of the overdose deaths, making predictions for each case of the drug(s) that were likely to be detected in the toxicology analyses, based on the scene and circumstances documented by the death investigators. Dialogue has been initiated with local law enforcement agencies to share investigative details regarding all potential overdoses, including predicted drugs. After the toxicology results were reported from the laboratory, the predicted drug(s) were compared with the detected drug(s), and the accuracy of the predictions was evaluated.

Results: Estimates from each of the time periods from death to certification were determined for 2,388 drug overdose cases. The number of days from death to final certification averaged 54 days, with a median of 50 days, ranging 3 to 217 days. Toxicology reports accounted for the greatest delay from death to certification, averaging 40 days, with a median of 44 days, ranging 5 to 519 days. In some cases, the pathologist called the laboratory for results and certified deaths before the reports were available, and in other cases, analyses continued long after the deaths were certified. Administrative functions comprised a minor proportion of the delay — usually less than one week. Comparing the accuracy of predicting what drug(s) might be identified in each drug overdose case, made when the case was initially examined, with the drug(s) subsequently reported by the toxicology laboratory found predictions to be at least partially correct in approximately 93% of cases. Cases in which predications were incorrect often involved deaths associated with white powders.

Discussion and Conclusions: Death certificates are useless for "real-time" surveillance of drug overdose deaths. In the present study, half of the death certificates were not completed until more than 50 days after the death. Not surprisingly, the major portion of the delay was the time required for toxicology results to be reported. This delay is not unique to one office; it is a universal barrier to using drug overdose data as a timely surveillance tool. In the extended period between death and final determination of cause of death, the investigation is essentially stalled. Information regarding drug source is frequently difficult to discover, and witnesses, often protected by Good Samaritan laws, are unlikely to provide valuable information; however, as the results of this study show, experienced death investigators and forensic pathologists, when presented with information gathered from the scene, are fairly accurate in their ability to predict the drugs responsible for death. Hopefully, in the future, rapid reporting of details regarding suspected overdose deaths to local law enforcement agencies will make "real-time" surveillance worthwhile for many different agencies.

Drug Overdose Investigation, Real-Time Surveillance, Toxicology

H125 New Psychoactive Substances (NPS) -Related Deaths in Sweden — An Alarming Development

Gisela Pettersson, MD, National Board of Forensic Medicine, PO Box 7616, Analysvägen, Umeå S-90742, SWEDEN; and Gunilla Thelander, BSc, National Board of Forensic Medicine, Dept of Forensic Genetics and Forensic Tox, SE-58758, Linköping, SWEDEN*

After attending this presentation, attendees will better understand the prevalence and other data of NPS in Swedish medicolegal autopsy cases.

This presentation will impact the forensic science community by informing attendees of abuse trends in general for NPS in Sweden and of the increased toxicity of new synthetic opioids in particular.

Introduction: This study was conducted to follow up on a previous investigation of NPS in medicolegal autopsy cases in Sweden with analyses of, for example, time trends, demography of the decedents, and the formation of clusters of cases caused by the same NPS.

Method: Data from medicolegal autopsies positive for NPS in blood and/or urine were reviewed regarding age, sex, cause of death, place of death, and type of drug. It was also noted whether the decedent had a documented substance abuse at the time of death. The cases were divided into three groups: true lethal intoxications (A), possible intoxications (B) in which NPS was a possible contributing factor, and cause of death not directly related to drug intoxication (C). The study period was 2016 and the results were compared to earlier findings from the time period between 2007 and 2015. A cluster was defined as more than five true lethal intoxication (A) cases in Sweden in the same year due to the intake of one specific NPS.

Results: In 2016, 129 NPS-positive cases were found. Of the decedents, 112 were male (87%), the average age was 34 years, and the median age was 32 years. Seventy-nine of the cases (61%) were determined as true lethal intoxications (A), and in 42 cases (33%), NPS was determined as a possible contributing factor (B). Thus, NPS was the sole or contributing cause of death in 94% of all NPS-positive cases. A majority of the decedents (72%) were found in their own home, the fatalities were scattered across Sweden, and 63% of the decedents had a substance and/or alcohol abuse mentioned on the death certificate. Three clusters due to intoxication of one specific NPS were identified within the time period studied, namely by the synthetic opioids acrylfentanyl, tetrahydrofuranfentanyl, and 4-fluoro-isobutyrfentanyl. Variants of "spice" caused a fourth cluster. In all, 48 different NPS were detected in 2016.

Discussion: Unlike previous years, the number of NPS-positive cases did not increase in 2016, but the true lethal intoxications (A) nearly doubled and remarkably few of the NPS-positive cases were entirely caused by something other than NPS. This study found seven different fentanyl analogues, and these caused nearly all of the true lethal intoxications (A). The emergence of new potent opioid analogues is challenging for forensic pathologists as well as toxicologists, and awareness of these particular NPS is important to all professionals working in connection to substance abuse.

Conclusion: As previously shown, there is a high risk of death due to NPS intoxication if the user is male, approximately 30 years of age with a known substance abuse, and uses the NPS in the own home environment. The emergence of new fentanyl analogues in 2015 and 2016 has further elevated the risk of lethal intoxication compared to previous years.

NPS, Postmortem, Increased Toxicity

H126 Deaths in Denver With the Detection of Cannabinoid Metabolites: 2010-2016

Derek Bumgarner, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204; Meredith A. Frank, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204; Krista L. Timm, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204; and James Louis Caruso, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204*

After attending this presentation, attendees will understand the timeline of legalization of marijuana in Colorado and the impact this has had on deaths in Denver, CO.

This presentation will impact the forensic science community by reporting on the incidence of detection of cannabinoid metabolites in forensic cases and discussing trends for deaths in Denver, CO, in relation to the legalization of marijuana in the state of Colorado, a previously unreported topic.

Federal law prohibits cannabis for medicinal and recreational purposes by its classification as a Schedule I Controlled Substance. Amendment 64 to the Colorado State Constitution legalized the personal possession of cannabis for medicinal and recreational consumption in November 2012; state-regulated commercial sales of cannabis products to the general public commenced on January 1, 2014.[1] This study explores the effects that cannabis legalization has had on mortality statistics in Denver, with examination of pre/post legalization trends regarding manner of death.

The Denver Office of the Medical Examiner (DOME) is responsible for medicolegal death investigation in the City and County of Denver, where three Board-certified forensic pathologists and one forensic pathology fellow oversee investigation of sudden or unexplained deaths. In this jurisdiction, deaths are categorized by manner, which consist of natural, accident, suicide, homicide, and undetermined. Samples of postmortem peripheral blood or antemortem specimens (if available) are retained and submitted for testing of commonly abused drugs, including cannabinoids (Tetrahydrocannabinol (THC), and metabolites of 11-hydroxy delta-9 THC, delta-9-THC, and delta-9 carboxy THC).[2] Toxicological testing was performed according to internal laboratory protocols with appropriate controls at National Medical Services, Inc, Willow Grove, PA, by means of High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS).

DOME employs a searchable database regarding cases within its jurisdiction, which includes a coding system that allows documentation of substances detected by toxicological testing. Query of the DOME database revealed a total of 3,075 postmortem examinations in which toxicology studies were ordered during 2010–2016. Of these postmortem examinations with toxicology, 688 (22%) were positive for cannabinoids. Given that the state legalization for commercial sales of marijuana commenced on January 1, 2014, it is determined that 1,682 cases occurred "pre-legalization" and 1,393 cases were "post-legalization." Those cases that resulted positive for the detection of cannabinoids during these time periods, as well as the trends within various manners of death, will be discussed.

Of the total cases with toxicology, 1,185 were ruled with a manner of non-traffic accident (39%), natural 989 (32%), suicide 344 (11%), homicide 252 (8%), traffic-related accident 163 (5%), and undetermined (5%). Pre-legalization, there were 653 non-traffic accidental deaths, and of these, 82 (13%) resulted positive for cannabinoids. Post-legalization, there were 543 non-traffic accidental deaths, and of these, 88 (16%) resulted positive for cannabinoids. Pre-legalization, there were 615 natural deaths, and of these, 127 (21%) resulted positive for cannabinoids. Post-legalization, there were 374 natural deaths, and of these, 98 (26%) resulted positive for cannabinoids. Pre-legalization, there were 126 suicides, and of these, 16 (13%) resulted positive for cannabinoids. Post-legalization, there were 218 suicides, and of these, 75 (34%) resulted positive for cannabinoids. Pre-legalization, there were 128 homicides, and of these, 67 (52%) resulted positive for cannabinoids. Post-legalization, there were 124 homicides, and of these, 56 (45%) resulted positive for cannabinoids. Pre-legalization, there were 73 traffic-related accidental deaths, and of these, 23 (32%) resulted positive for cannabinoids. Post-legalization, there were 90 traffic-related accidental deaths, and of these, 40 (44%) resulted positive for cannabinoids. Pre-legalization, there were 98 deaths with an undetermined manner, and of these, 11 (11%) resulted positive for cannabinoids. Post-legalization, there were 44 deaths with an undetermined manner, and of these, 5 (11%) resulted positive for cannabinoids.

Frequent detection of cannabis metabolites was identified in all manners of death in Denver for the years 2010–2016, and the results of this study reveal an overall increase in the presence of cannabinoid metabolites in fatalities during the three years following the legalization of marijuana sales in Colorado. Furthermore, cannabis metabolite detection was increased post-legalization in manners of non-traffic accidents by 3%, suicide by 17%, traffic-related accidents by 12%, and natural by 5%. Homicides demonstrated a decrease in detection of cannabinoids by 7%. Deaths which remained undetermined in manner revealed no significant change.

Marijuana, THC, Legalization

H127 Levamisole: A High-Performance Cutting Agent

Nadia Solomon, MSc, St. George's University School of Medicine, PO Box 7, St. George, GRENADA; and Jonathan Hayes, MD, District 20 Medical Examiner's Office, 3838 Domestic Avenue, Naples, FL 34108*

After attending this presentation, attendees will better understand the mechanisms of action of cocaine and amphetamines and will learn about the physical, chemical, and pharmacologic properties that have made the anthelminthic agent levamisole one of the most unlikely and widely encountered cocaine adulterants. Attendees will also be acquainted with the possible role of levamisole in cocaine-related fatalities.

This presentation will impact the forensic science community by reviewing the rise of levamisole as a cocaine adulterant and explain the properties of the chemical that almost make it the perfect cocaine cutting agent. An argument will be made for screening of the compound in cocaine-related fatalities to more accurately determine cause of death in these cases. Cocaine cut with levamisole has been associated with a number of deaths; the role levamisole plays in these deaths should be considered.

Drugs like cocaine and amphetamines are abused because of their stimulatory effects. Illicit drugs are frequently diluted (cut) with a variety of materials prior to sale/resale to bulk up the product and increase profit.[1,2] Adulterants are generally selected due to their physical resemblance to cocaine, low cost, or added physiological effects.[2,3] One such adulterant is the imidazothiazole derivative levamisole, an amphetamine and anthelminthic agent acting as a ganglion stimulant in mammals and a depolarizing muscular blocker in nematodes (roundworms).[4,5] Although marketed for numerous uses in humans, including an appetite suppressant, immunomodulatory agent, and antineoplastic agent, it was withdrawn from the United States market in 2000 due to side effects; it is currently marketed only for veterinary purposes as an anthelminthic.[1,4,6-8] Recent estimates suggest that the proportion of cocaine laced with levamisole may now be higher than 80%.[9,10]

In vivo, levamisole is metabolized to aminorex, which is bioactive.[1] The potency of aminorex has been found to be comparable to cocaine, and aminorex's amphetamine-like properties may be responsible for levamisole's psychostimulant effects.[1] Levamisole also readily crosses the Blood Brain Barrier (BBB) and has a longer half-life than cocaine.[1] Through various biochemical mechanisms, levamisole prolongs the action and potentiates the effects of cocaine and may continue to provide amphetamine-like stimulation after the direct effects of cocaine have worn off.[1,4,7,11] Additionally, levamisole is inexpensive relative to other potential adulterants, increasing cocaine profits.[4,9,12] These features make levamisole (and aminorex) an attractive choice as a cocaine additive.[1]

Levamisole use can present with a number of adverse effects, include nausea and vomiting, headache, fatigue, fever, diarrhea, myalgia, dizziness, confusion, and rash.[13] Serious complications include agranulocytosis, leukopenia, thrombocytopenia, vasculopathy and vasculitis, dermal necrosis, leukoencephalopathy, psychosis, pulmonary hypertension and hemorrhage, glomerulonephritis, emboli, arthritis, Coronary Artery Disease (CAD), and circulatory collapse.[1,4,13,14] Some of these complications appear to be associated with levamisole's propensity to provoke hypersensitivity reactions in people with certain genetic predispositions.[7,11] Such reactions have been reported previously, with reoccurrence of symptoms after re-exposure.[11] Reviews on immunologic associations note the presence of Anti-Neutrophil Cytoplasmic Antibodies (ANCA), including perinuclear ANCA (pANCA), cytoplasmic ANCA (cANCA), and type III cryoglobulinemia.[11,14] Given its association with so many potentially deadly side effects, it is not surprising that numerous fatalities, typically attributed to pathology of the heart, brain, or lungs, have been linked to levamisole exposure through tainted cocaine.[7,8,15-18]

Easy to obtain, inexpensive, physically similar in presentation, and with the inherent ability to potentiate and perpetuate the effects of the primary agent, levamisole seems the perfect choice for maximizing profit while leaving consumers none the wiser, except in those cases with deadly consequences. Cause of death in patients with cocaine and levamisole intoxication may be due to any number of mechanisms, ultimately severely impacting the heart, lungs, and brain. Given its prominence as a cocaine additive, its presence in a majority of cocaine specimens evaluated in numerous centers around the world, its known side-effect profile and its role in autoimmune reactions, and its potential role in facilitating or exacerbating pathological processes leading to sudden death, toxicological screening for levamisole is an important element in the analysis of suspected cocaine-related fatalities.

Cocaine, Levamisole, Cutting Agent

H128 Fire Marshal and Medical Examiner Collaboration in the Investigation of a Complex Homicide

Christine James, DO, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; Donald Brucker, PhD, Allegheny County Fire Department, 400 N Lexington Street, #200, Pittsburgh, PA 15208; and Karl E. Williams, MD, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222*

After attending this presentation, attendees will better appreciate the advantages of collaboration between law enforcement and other agencies in the investigation of complex death scenes, especially those in which the presence of trained fire scene investigators are involved.

This presentation will impact the forensic science community by exploring the ability of trained investigators from disparate disciplines to interact synergistically to enhance the scientific analysis of death scenes.

When fire department Emergency Medical Services (EMS) personnel were called to the scene of a fire, they discovered an unconscious but living 15-year-old Black female. The victim exhibited evidence of a gunshot wound to the head and superficial thermal damage to the face, trunk, and extremities.

She was transported to a local hospital where she was found to have a carbon monoxide level of 40%. A tangential gunshot wound to the right side of the neck and face was also present.[1] This wound fractured the right mandible but exited the head in the right temporal scalp without damage to deeper vital structures in the head or neck. Attempted resuscitation efforts, which began at the scene and continued in the emergency department, were unsuccessful.

Investigation by the fire marshal revealed that two separate fires had been started in separate rooms in the house using material found at the scene, but resulted in only minimal damage to the structure. Unsuccessful attempts to burn the victim could be identified by burn patterns on the body, and the patterns of the thermal trauma could be positively correlated with objects used to start the fire.

Scene investigation utilized blood-spatter patterns and ballistic trajectory analysis to reconstruct the scene of the shooting. Autopsy findings were of a superficial gunshot wound of the head and dense, soot-laden blood in the upper airways.

Death was certified as being a combination of acute fume inhalation and gunshot wound of the head.[2]

A suspect was quickly identified and confessed to the shooting, but related a scenario that was at variance with the scene and autopsy evidence. He was subsequently found guilty of first-degree murder, arson, recklessly endangering, illegal possession of a firearm, and theft.

Fire Death, Gunshot Trauma, Homicide

H129 An Atypical Suicide by Submachine Gun: A Case Report

Martin Kolopp, Rue du Morvan, Vandoeuvres-lès-Nancy 57500, FRANCE; Alain Blum, PhD, CHRU de Nancy - Imagerie Guilloz, 29 Avenue du Maréchal de Lattre de Tassigny, Nancy 54000, FRANCE; Marc-Antoine Leupold, MD, CHRU de Nancy, Rue du Morvan, Vandoeuvre-lès-Nancy 54511, FRANCE; and Laurent Martrille, MD, Service de Medecine Legale, Faculté de Médecine, BP 184, Vandoeuvres-les-Nancy Cedex 54505, FRANCE*

The goal of this presentation is to disclose the forensic and imaging evidence that led to the hypothesis of suicide by submachine gun, namely, the characteristics of entrance and exit wounds and the trajectories and specifications of the weapon used.

This presentation will impact the forensic science community by exposing an atypical suicide method rarely described in the literature.

After a shooting in the neighborhood, Mr. K entrenched himself in his house, waiting for the police. The Groupe d'Intervention de la Gendarmerie Nationale (GIGN), an elite unit of the French police, laid siege to the house for 24 hours before hearing gunshots from inside. During their intervention, they found Mr. K dead, cross-legged on the floor, backing onto a bed frame, collapsed on his right side, with several gunshots wounds on his body. Next to the cadaver, they found a submachine gun whose safety lever, located on the back of the pistol grip, was neutralized with tape.

The weapon, a 1949 French submachine gun from the weapons manufacturer of Chatellerault, was loaded with 9×19mm Parabellum bullets, full metal jacket. Four cartridges seem to have been loaded into the weapon, three of which seemed to have entered the victim. The cadaver was then transported to the forensic institute of Nancy, France, for further examination.

Postmortem Computed Tomography (CT) revealed a wound on the left section of the occipital bone, a fracture of the seventh cervical vertebra, a fracture of the back of the left sixth rib, a wound in the manubrium, and a defect in the third costovertebral junction. The 3D reconstruction was rendered using the global illumination technique and revealed the presence of a metallic object in the neck and of metallic fragments near the two sternal lesions.

The autopsy revealed three ballistic wounds. All entrance wounds were located on the front of the thorax and neck and the trajectories were nearly in the sagittal plane, oblique from bottom to top. The first projectile penetrated on the left side of the sternum and crossed the proximal aorta and the back part of the left sixth rib. The entrance wound presented a zone of soot easily swiped away and revealing blackened seared margins, typical of a loose-contact wound. The exit wound was unusual due to a probable fragmentation of the projectile and the presence of the bed against the skin. It consisted of two shored exits, with elongated orifices and abrasion edges. The second projectile penetrated next to the jugular notch of the sternum and transfixed the trachea and the sixth cervical vertebra. The entrance wound was very unusual; it consisted of a large round opening (4x3cm) with irregular abraded edges. The wound was only penetrating, and the projectile was found in the subcutaneous tissue of the back of the neck. The third projectile penetrated under the chin, on the median line, fractured the hyoid bone, penetrated the base of the skull, and exited through the occipital bone. The entrance wound presented a blackened, seared margin on the upper side, suggesting a near-contact angled wound. The exit wound was typical with a beveled-out hole in the skull and a stellate skin lesion.

The first and third projectiles were the cause of lethal lesions (perforation of the aorta and the brain). The characteristics of the entrance wounds suggested short-range shots. Finally, the first trajectory was nearly horizontal and the two others were more obliquely directed upward. One can therefore imagine a first loose-contact shot in the sternum and the next two shots were due to the neutralization of the safety lever, keeping the weapon in automatic mode. With a firing rate of 600 rounds per minute, five milliseconds were sufficient to fire the four loaded bullets, and recoil can explain the changes in trajectories. In conclusion, the forensic evidence was consistent with the hypothesis of suicide, given the conditions of cadaver discovery and the observations reported by the investigators.

Atypical Suicide, Submachine Gun, Global Illumination

H130 Ballistic Analysis of an Attempted Murder Using a Porcine Model

Michael Freeman, MD, PhD, Forensic Research & Analysis, 425 NW 10th Avenue, Ste 306, Portland, OR 97209; Karl E. Williams, MD, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; and Anders Eriksson, MD, PhD, Umea University, Dept Forensic Medicine, PO Box 7616, Umea SE-907 12, SWEDEN*

The goal of this presentation is to describe an experimental analysis of two competing theories for the circumstances of a gunshot wound, in which a porcine model was used as a proxy for a human thigh.

This presentation will impact the forensic science community by describing a porcine model experiment for the purpose of assessing the plausibility of two competing scenarios in the investigation of an attempted murder.

This presentation will provide the description of the investigation of competing explanations for the circumstances of a close-range gunshot wound from a hunting rifle and the associated prosecution of an attempted murder charge, including an ad hoc experiment to test the victim's explanation for the circumstances of a gunshot wound to the proximal thigh.

The case involves a gunshot wound to the proximal thigh from a jacketed .243 Winchester® round. The victim, a 21-year-old male, had described the injury as resulting from a point-blank (<2 feet) shot into the thigh from a hunting rifle. He claimed to have been held at gunpoint, with the rifle leveled at his chest while standing, and to have slapped the muzzle of the rifle downward, at which point the weapon was fired. The bullet entered at the upper thigh, resulting in a comminuted fracture of the proximal femoral metaphysis, with the bullet fragment remaining largely intact and retained in the soft tissues near the fracture. The injuries included a transected femoral artery and lacerated femoral vein. The round that was fired was a 100-grain (6.5gm), copper-jacketed, tapered, solid lead-core bullet, with a 2,960fps (902m/s) muzzle velocity, and 1,945 ft-lbs (2,637Nm) of energy. The defendant claimed that the rifle discharged while pointed at a concrete floor, and that the injury resulted from a ricochet from the floor. The defendant was charged based on the victim's account of how the events transpired.

An initial review indicated there was no physical evidence supporting either scenario. In the plain radiograph of the femur fracture, the bullet and fragments were in a superior position to the fracture. The entry wound was described as 2cm in diameter. An initial review of the evidence cast doubt on the victim's account, as (1) the size of the entry wound was inconsistently large for a direct shot; and, (2) the fragments from the bullet were above the fracture, indicating an inferior-to-superior travel path rather than the opposite. As there were no reference materials to consult regarding the specific circumstances of the case, it was determined that an experiment would be conducted to test the plausibility of the victim's account of the shooting.

Pig models have been previously described as a relatively close proxy for a human anatomical/pathological response to gunshot; thus, a fresh pig hind leg was selected as the closest proxy for a human thigh.[1] A jig was constructed to hold the pig leg, which was first radiographed, then marked to identify the location of the femoral metaphysis. Damp newspaper was used as a backstop to retain and retrieve any bullet fragments that might penetrate the specimen. High-speed video was used to capture the bullet entering and exiting the specimen. Once the pig leg was secured, a sharp probe was used to further ascertain the underlying bony anatomy of the femur. Using ammunition from the same box used in the shooting, a shot was fired from a distance of 17 inches (43cm) from muzzle to specimen and recorded at 10,000 frames per second. The shot resulted in an entry wound that was approximately 0.6cm in diameter, which struck the femur and exited the rear aspect of the specimen, and subsequently penetrated ~2cm of the damp newspapers. The exit wound was approximately 8cm in diameter, and palpation and radiograph of the femur indicated it was shattered, and fragments of bone were missing (projected into the backstop).

Based on the results of the experiment, it was determined that the scenario of the shooting claimed by the victim was implausible. The explanation for the shooting provided by the defendant was deemed much more probable (i.e., that the bullet struck the defendant as the result of a ricochet).

Gunshot Wound, Porcine Model, Ballistic

H131 The Effect of Public Awareness and Legislation Against Strangulation on the Occurrence of Gender-Based Violence in King County, Washington

Micheline Lubin, MD, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104; Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 9th Avenue, Box 359792, Seattle, WA 98104; Jillian Jetter, MPH, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104; David Martin, JD, King County Prosecutor, W554, 516 Third Avenue, Seattle, WA 908104; Nicole Siver, Washington State Attorney General's Office, 800 Fifth Avenue, Ste 2000, Seattle, WA 98104; and Cloyd Steigerr, Washington State Attorney General's Office, 800 Fifth Avenue, Ste 2000, Seattle, WA 98104*

After attending this presentation, attendees will be able to: (1) list various national and local efforts directed against intimate partner and domestic violence; (2) explain the legal definition of strangulation; (3) trace the rates of all female homicides and those due to strangulation from 1980 to 2016; and, (4) evaluate the evidence that national and local policies and efforts are important in controlling gender-based violence.

This presentation will impact the forensic science community by tracing the declining occurrence of female homicides in King County, WA, from 1980 to 2016 and by illustrating that female homicides due to strangulation constitute a substantial proportion of deaths due to intimate partner and domestic violence. The results of this study provide evidence that local and national efforts directed against gender-based violence are important for controlling these crimes.

Since the Violence Against Women Act (VAWA) was passed in 1994, a number of national and local initiatives have increased public awareness, criminal investigations, and prosecutions directed against Intimate Partner Violence and Domestic Violence (IPV/DV). More recently, in 2007, Washington State enacted legislation promoted by the King County Prosecuting Attorney's Office making strangulation an aggravated assault (Assault 2 felony offense) if prosecution proves that the defendant interfered with the victim's ability to breathe or restricted blood flow to the brain. Because IPV/DV continues to be a major concern in gender-based violence, the present study was conducted to analyze the occurrence of female homicides over the past four decades with special attention to the proportion of female homicides by strangulation.

Methods and Materials: Records of the King County Medical Examiner's office from 1978 to present were reviewed to identify all female homicides occurring in King County according to demographics and mechanism of injury. Data from the Washington Attorney General's Office Homicide Investigation Tracking System were used to identify motives for assault. Data from the King County Prosecuting Attorney's Office and Washington State Administrative Office of the Courts were used to estimate the number of non-fatal domestic violence assaults charged with strangulation.

Results: There were a total of 848 homicides resulting in the death of females in King County over the nearly four-decade period of this study. Despite considerable year-to-year variation, there was a progressive decrease in the number of female homicides. From 1980 to 1989, there were an average of 28.6 female homicides per year; from 1990 to 1999, 25.2 per year; from 2000 to 2009, 15.7 per year; and from 2010 to 2016, 14.4 per year. From 1980 to 2016, strangulation was involved in 20% of cases in which there was a known cause of death and in 14% of female homicides perpetrated by a current or former intimate partner. The proportion of female homicides by strangulation declined as follows: from 1980 to 1989, 23%; from 1990 to 1999, 17%; from 2000 to 2009, 15%; and from 2010 to 2016, 12%. After the King County Prosecuting Attorney's Office Domestic Violence Unit was established in 2000, the number of domestic violence felony filings averaged approximately 1,200 per year, and after the strangulation law went into effect in 2007, strangulation became one of the most frequently filed charges. Correspondingly, from 2007 through 2016, 13% of female homicides were by strangulation, compared to 19% of female homicides by strangulation from 1980 to 2006.

Discussion and Conclusions: The results of this study reveal that strangulation accounts for a considerable proportion of female homicides, especially in IPV/DV. Over the past four decades, the annual number of female homicides has declined by 50%. The proportion of deaths due to strangulation has declined by nearly the same extent. While it is difficult to attribute any single policy or initiative to the declining rates, it is reasonable to conclude that public campaigns to enhance awareness, as well as criminal investigation and prosecution of gender-based violence, are important deterrents of intimate partner and domestic violence.

Female Homicides, Domestic Violence, Strangulation

H132 Two Dead Bodies in a Cemetery: An Unexpected Lightning Strike

Alexandra M. Hart, MD, Erie County Medical Examiner's Office, 501 Kensington Avenue, Buffalo, NY 14214; Katherine F. Maloney, MD, Erie County Medical Examiner's Office, 501 Kensington Avenue, Buffalo, NY 14214; Nicole A. Yarid, King County Medical Examiner's Office, 325 9th Avenue, Seattle, WA 98104; and Tara J. Mahar, MD, Erie County Medical Examiner's Office, 501 Kensington Avenue, Buffalo, NY 14214*

The goal of this presentation is to educate police, scene investigators, medical examiners, and coroners on classic scene and autopsy findings in a lightning strike.

This presentation will impact the forensic science community in regard to the scene and autopsy findings of a death due to a lightning strike, as well as the performance of a scene investigation and examination of these deaths.

In early August 2016, the bodies of a man and a woman were found in a cemetery. They were 34 and 32 years old, respectively, and had a history of intravenous as well as other illicit drug abuse. Drug paraphernalia was identified at the scene, which included syringes and small bags of white powder. Both decedents were also noted to have recent injection sites of their anterior forearms; however, examination of the scene revealed damage to a tree adjacent to where the decedents were discovered that appeared recent and possibly electrical in nature. Additionally, there were thunderstorms in the region overnight, with multiple lightning strikes to the ground reported. The bodies were transported to the medical examiner's office for an examination.

The following day, an examination of both decedents was performed at the medical examiner's office. Examination of the woman revealed a thermal injury of the upper right side of her back associated with a burn of her overlying shirt and bra. She also had "blow-out" damage to the toes of both of her sneakers and socks. Examination of the man revealed classic Lichtenberg figures (ferning) of the anterior torso. Toxicology testing was performed and revealed the presence of fentanyl, as well as other illicit drugs including methamphetamine and heroin at concentrations which could be consistent with a drug overdose in the blood of both decedents. The cause of death for both decedents was certified as: (1) electrocution due to lightning strike; and, (2) acute mixed drug intoxication.

Lightning strikes are an uncommon cause of death with 39 fatalities reported in the United States in 2016 and 312 deaths reported since 2007 according to data collected by the National Oceanic and Atmospheric Administration. The vast majority of fatal lightning strikes occur in the summer (July and August) with men outnumbering women nearly 9 to 1. Classic findings at autopsy include Lichtenberg figures, thermal burns, and associated damage to clothing where present. Examination of the scene and knowledge of the weather at the time of death is crucial to making the diagnosis of an electrocution due to a lightning strike. Additionally, a full internal examination and toxicology testing are a necessary components of a thorough investigation of a possible lightning strike. Electrocution due to a lightning strike will have classic scene and physical findings that should be documented to make the appropriate diagnosis. Other potential causes of death should be considered and excluded where necessary.

Lightning Strike, Electrocution, Fentanyl

H133 An Unusual Case of Suicide in a Young Skydiver

Pierre-Antoine Peyron, MD, Département de Médecine Légale, CHU Lapeyronie, 371, Avenue Doyen Gaston Giraud, Montpellier 34295, FRANCE; Eric Baccino, MD, Hopital Lapeyronie, 371, Av du Doyen Gaston GIRAUD, Montpellier, Cedex 5 34295, FRANCE; and Emmanuel Margueritte, MD, Chu Montpellier-Dept Médecine Légale, Av Doyen Gaston Giraud, Montpellier 34295, FRANCE*

The goal of this presentation is to report a well-documented case of suicide in a young, experienced civilian parachutist.

This presentation will impact the forensic science community by raising awareness that, as in all medicolegal investigations, every skydiving fatality should require a thorough forensic investigation involving a multidisciplinary approach to allow the forensic pathologist to ascertain the exact cause and manner of death in light of all available relevant information.

Deaths associated with parachuting are very uncommon and the vast majority of these are accidental.[1] Very few suicides have been reported in survey reports on skydiving fatalities worldwide, and the scientific literature contains very limited data about suicidal deaths of skydivers.[2]

This study reports an unusual case of suicide in a 26-year-old civilian skydiver with no significant past medical history, whose body was found dead on an airfield after a 4,000-meter freefall jump. According to witnesses, the victim's main and reserve parachutes did not open and his body remained in a stable freefall arched position until ground impact, then bouncing once on the ground and falling back a few meters away. The backpack the victim was still carrying contained the main and reserve parachutes still packed and properly attached to the harness. The victim's altimeter, helmet, and shoes were found nearby the weed-free area adjacent to the impact site.

A postmortem examination performed two days later revealed a severe multiple blunt trauma with a significant antero-posterior flattening of the body, consistent with a high-energy impact with the ground. Extensive abrasions were arranged symmetrically on the front of the body, whereas no injury was observed on the back, consistent with a ground impact in a stable "belly-down" position. Upon internal examination, there were multiple skull fractures, as well as spinal, rib, pelvic, and limb fractures, with open and symmetrical shoulder and knee fractures. These skeletal injuries were associated with widespread soft tissue hemorrhages and severe injuries to the internal organs, including the brain, heart, and lungs, that exhibited extensive lacerations. No additional injuries that could have been inflicted to the victim prior to the jump nor any evidence of previous natural disease that could have precipitated or contributed to the death were noted. Toxicological analyses performed on the organs, the gastric content, and the vitreous were negative.

Police investigation revealed that the victim, who had considerable skydiving experience and had performed more than 130 jumps, had died during his third consecutive jump of the day, as weather conditions were good. The investigation also discovered that he had recently experienced marital problems and had expressed suicidal thoughts in text messages sent to his wife just before jumping out of the plane.

An expert examination of the parachuting equipment ruled out any evidence of gear malfunction, such as incorrect packing or failure of the chute. In addition, the examination found the Automatic Activation Device (ADD) that allows the reserve parachute to be automatically deployed at low altitude if the skydiver has not released his main chute had been disabled prior to the third jump, with no evidence of criminal intent found.

On the basis of the autopsy findings, testimony of witnesses, and police investigation data, manner of death was considered to be suicide.

Per research, this is the first well-documented case of suicide in a parachutist that has been reported in the scientific literature to date. This case stresses the need to conduct a thorough forensic investigation to determine the cause and manner of death in skydiving fatalities.

H134 An Exceptional Case of Acute Respiratory Failure Caused by Intra-Thoracic Gastric Perforation Secondary to Overeating

Alessandro Di Luca, MD, Via Domenico Chelini 7, Roma 00197, ITALY; Vincenzo M. Grassi, MD, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome 00168, ITALY; Gerardo Di Masi, MD, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome 00100, ITALY; Eleonora Ricci, MD, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome 00100, ITALY; and Antonio Oliva, MD, PhD, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome, ITALY*

After attending this presentation, attendees will better understand a very rare and devastating mechanism of death, including autopsy findings and related patient history, allowing them to completely and efficiently assess similar cases.

This presentation will impact the forensic science community by reporting a very well-documented case of gastric perforation due to overeating in a psychiatric patient that resulted in death. This study provides information regarding a rare occurrence reported through the clinical history and the results of the forensic investigation, providing an in-depth and complete point of view.

An 18-year-old female patient arrived at the emergency department complaining of feeling abdominal pain and fullness after a heavy meal. She reported a history of *anorexia nervosa* without previous abdominal surgery. At the physical examination, she was reported to be filthy with feces and had a severe abdominal distension with dull percussion and mild abdominal tenderness in the epigastric region. Intestinal sounds were absent. She also reported intermittent nausea without vomiting. A total body computed tomography revealed massive stomach dilatation. The stomach occupied the abdominal cavity and the left hemi-thorax. Physicians began an intravenous fluid replacement and attempted to place a nasogastric tube; however, during the maneuver, a generalized seizure occurred, followed by cardio-respiratory arrest. A diagnostic autopsy was requested by the hospital. During the autopsy, the pathologist observed a significant dilation of the anal sphincter; suspecting a sexual assault, the judicial authorities were alerted, as required by Italian law. The case was assigned to the Legal Medical Department for a forensic autopsy. During the second autopsy, an anal orifice expansion (3.5cm x 25cm), with no signs of violence, was observed; food was found in the epiploon retrocavity. The stomach was hyper-distended and perforated at three different points; the diaphragm was also perforated. The left lung was completely collapsed and was covered with traces of food.

The history of *anorexia nervosa*, clinical objectivity, and autopsy evidence led to the suspicion of an intra-thoracic gastric perforation secondary to acute massive dilation of the stomach due to overeating. Diaphragmatic perforation caused by the stomach is a less-common complication than gastric perforation in patients with eating disorders. Physicians must have knowledge of this complication in order to reach a quicker diagnosis, perform a timely intervention, and provide patients with all necessary information regarding possible risks. Medical-legal aspects of this event though a comparison with scientific literary evidence will be discussed.

Respiratory Failure, Gastric Perforation, Overeating

H135 Determining the Difference Between Blunt and Sharp Force Traumas in Human Head Hair

Amy Evans, BS, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Carol J. Ritter, MS, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will understand how hair can be utilized as a reconstructive tool at crime scenes to assist in narrowing the cause of death when the victim's body cannot be found.

This presentation will impact the forensic science community by creating standards for microscopic hair analysis, thus allowing cases to be solved more efficiently with the use of hair as evidence.

Hair has been proven to be a useful specimen for evaluating past drug use and in distinguishing between animals and humans via the measurement of the medulla.[1] In addition, numerous studies have been published on traumatic deaths of the sharp and blunt force varieties. In sharp force trauma, homicides and suicides are the most common cause of death from stabbing or cutting inflictions.[2] On the other hand, blunt force trauma involves direct and indirect stress propagations that are typical of car accidents or beatings.[3] Recently, research was completed to show that patterns are exhibited in the hair post- trauma; however, this study was unable to define specific characteristics and was unable to link statistics to this pattern-based analysis.[4]

During this research, trauma recreation was completed for both sharp and blunt force trauma with the use of varying weapons on hair in attempt to define traits that are unique to each type of trauma. Statistics can then be applied to provide measures of consistency and repeatability of this experiment. Each hair was photographed and evaluated under crossed polars before and after recreation with a photomicrograph. One strand of hair was then taped onto a wooden circular post meant to mimic a human skull. [5] Cuts were inflicted for sharp force with the following weapons: a box cutter, glass, serrated and non-serrated knives, scissors, and flathead and Phillips-head screwdrivers. Blows were administered for blunt force trauma with a metal baseball bat, a crowbar, a hammer, a hollow copper pipe, a metal pipe, jagged and smooth rocks, and a piece of wood. Based on the makeup of these weapons, it was expected that sharp force implements would leave behind a smooth straight pattern, while blunt force weapons would exhibit a jagged pattern due to a more forceful blow needed to break the hair. This was completed for the three common race categories of hair studied in forensic science (Caucasoid, Mongoloid, and Negroid) to evaluate the similarities and differences in the trauma patterns both across and within races.

Based on the 90 hairs evaluated to date, a majority of sharp force cuts exhibited smooth characteristics with the exception of the serrated knife, which appeared as jagged due to the uneven cutting edge of the knife. The blunt force weapons exhibited much more variability, with most being smooth or a combination of smooth and jagged. The screwdrivers displayed the most combination of traits, which is not surprising as they have both a sharp edge for cutting and a blunt force component due to compression. Additionally, damage was only evident away from the break in blunt force trauma, which provides an important method to differentiate between the two traumas. Further, when damage was present, color changes under the polarized light microscope were sparse. Comparison across trials of the same race showed much more consistency within the same weapon for Negroid and Mongoloid compared to Caucasoid.

Future research will attempt to study the influences hair dyes, shampoos, and age may have on breakage characteristics. Furthermore, hair samples will be acquired from actual traumatic fatalities to compare to the above recreations, then blind samples will be given to volunteers to determine if they can differentiate sharp and blunt force trauma via the established pattern types.

H136 Violence Against Vulnerable Persons: The Death of a Transgendered Individual in Mississippi

L.R. Funte, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Brent Davis, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; Anastasia Holobinko, PhD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208; and Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, MCL, 215 Allen Stuart Drive, Pearl, MS 39208*

After attending this presentation, attendees will understand the variation observed in homicide cases as it pertains to violent acts committed against vulnerable individuals (e.g., transgendered) in the state of Mississippi.

This presentation will impact the forensic science community by discussing a case of homicide in which the violence was perpetrated by a 20-year-old male against a transgendered individual.

In 2016, the body of a 28-year-old pre-operative male-to-female transgendered individual was found dead in a hotel room located on the Mississippi Gulf Coast. It was learned that the decedent had traveled to the area with friends and planned to attend a sporting event.

External examination observation revealed female undergarments and accoutrements and the presence of male genitalia; the testicles were descended into the scrotum and appeared atrophic. Upon postmortem examination, multiple sharp force injuries were identified. Approximately 190 individual stab and incised wounds were noted in the head, face, neck, axillary region, torso, chest and shoulders, back, and an extremity. Injury of the left lung, the right external jugular vein, the right subclavian vein, the larynx, and the left axillary vein were identified. There was also multifocal subarachnoid hemorrhage. Abrasions were noted on the face, neck, and chest. Defense-type injuries were present on the left hand and left upper extremity.

The skull was retained and fixed in formalin for subsequent anthropological analysis.

Images released from the decedent's hotel surveillance cameras led to the arrest of a suspect who was charged with capital murder and robbery. It was established that the decedent had prior contact with the killer before her death and had arranged to meet with him instead of attending the rodeo event with her friends. The suspect, stationed at a local military base, eventually entered into a plea agreement with prosecutors after investigators learned he had borrowed a knife from someone on base the day of the murder. He claimed that he and the victim had been chatting online for several months, but decided to meet when she and her friends traveled to Biloxi, MS, for the rodeo. The suspect said that immediately upon returning to the victim's hotel room, they engaged in anal sex. When he subsequently learned of the victim's transgender status, the suspect said he "lost it" and that he did not remember much after that.

After capital murder charges were reduced, the former Navy seaman pleaded guilty to second-degree murder and robbery. He is currently serving a total sentence of 48 years in prison.

Transgender, Homicide, Sharp Force Injury

H137 Establishing Organ Weight Norms for Caucasian and Minority Populations Using Autopsy Data From Two Institutions and the Evaluation of Autopsy Reports Using a Novel Free-Text Analysis Tool

Emily Wolak, DO, 4777 Tramway Boulevard, NE, Apt 115, Albuquerque, NM 87111; Daniel W. Dye, MD, Jefferson County Coroner/Medical Examiner Office, 1515 6th Avenue, S, Rm 220, Birmingham, AL 35233; Sarah Lathrop, DVM, PhD, 4920 Edwards Drive, NE, Albuquerque, NM 87111; Garon Bodor, MS, University of New Mexico Office of the Medical Inv, PO Box 23, Sandia Park, NM 87047; and Matthew D. Cain, MD, Office of the Medical Investigator, 1101 Camino de Salud, Albuquerque, NM 87102*

The goal of this presentation is to review organ weight data from adult autopsies performed across multiple demographics at two different institutions. A reference range of the expected weight for each organ examined, taking into account Body Mass Index (BMI), age, race, and sex will be presented. In addition, this presentation will illustrate the utility of macros to automate the review of autopsy reports for natural disease diagnoses.

This presentation will impact the forensic science community by providing a reference range of normal expected organ weights for unique demographic populations. This presentation will also underline the utility of developing custom programs to analyze reports.

Methods: Demographic and organ weight data was collected from 13,283 autopsies performed between 2013 and 2016 in the state of New Mexico, Office of the Medical Investigator (OMI) and from 2011 to 2016 from Birmingham, AL, Jefferson County Coroner/Medical Examiner Office, University of Alabama at Birmingham (UAB). Organs examined included brain, heart, lungs, kidneys, spleen, and liver. To evaluate adult organ weight norms, cases were excluded if they fell into any of the following categories: age less than 18 years, natural, pending or undetermined manner of death, documented postmortem changes, or greater than 48 hours between death and autopsy. In total, 2,552 cases were included in this study. Specific organs were excluded if there was evidence of trauma or natural disease that could influence organ weight (i.e., myocyte hypertrophy and heart weight). Lung weights from overdose cases were removed because of the frequency of pulmonary edema. Additionally, to better accomplish the task of removing natural disease, 400 OMI autopsy reports from 2013 were reviewed manually to flag diagnoses that would impact organ weight. After a list of diagnoses was established, a script (macro) in Visual Basic for Applications (VBA) was developed in Excel® to evaluate the same group of autopsies for natural disease. This macro was evaluated for accuracy against the manually flagged cases. Once the list of cases with normal organs (no disease, no trauma) was identified, Statistical Analysis System (SAS) was used to perform statistical analyses on the demographics and organ weights, with p-values of 0.05 or less considered statistically significant.

Results: Preliminary data indicate that OMI and UAB serve different populations and that all races, except Asian/Pacific Islander, were represented: OMI had 44.4% White non-Hispanic, 38.5% White Hispanic, 14.6% American Indian, and 2% African American, while UAB had 58.7% White non-Hispanic, 39.3% African American, and 2% White Hispanic. The OMI decedents were older than those at UAB ($p<0.0001$) and were significantly more obese ($p<0.0001$). Manner of death was statistically significant with a higher percentage of homicides at UAB (24.1%) than OMI (11.6%). BMI significantly affected organ weights, especially the liver and heart, which tended to be markedly heavier. Male organ weights were significantly heavier than females, regardless of race. African Americans had the largest mean heart weight (364 grams) while White non-Hispanics had the heaviest livers (1,709 grams).

The VBA script evaluated OMI autopsy reports and was in strong agreement (94.9% across flagged organs) with the method of manually flagging cases for natural disease. A sampling of 20 UAB autopsy reports correlated similarly. Kidney conditions were missed most often (92% agreement). Missed diagnoses were typically the result of a missing phrase in the program's vocabulary describing a diagnosis; for example, fatty liver was initially missed since the program scanned for steatosis. The script also struggled with misspelled words in reports. Of note, manually flagging cases missed several diagnoses (21 on heart alone) that the macro identified.

Conclusion: This study is the first to analyze how healthy organ weights are affected by multiple demographics, including race, BMI, age, and sex. Organ weights were most significantly increased with higher BMI and male sex. Additionally, this study developed a macro that was effective at flagging natural disease within organs. With this information, equations can be developed to predict normal weights on the majority of organs within these demographics and can establish average weights on a plethora of natural disease flagged by the macro. Additionally, there are histologic correlations for each organ; for example, correlations between histologic evidence of hypertrophic myocytes and interstitial fibrosis can be made to heart weight. Finally, future studies are planned to incorporate this organ weight data with Computed Tomography (CT) imaging data.

Organ Weight, Reference Calculator, BMI

H138 The Thanatotranscriptome: An Assessment of Messenger RNA (mRNA) Abundances in Cadaver Prostate Tissues

Sheree J. Finley, MS, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Mariah Tolbert, BSc, 611 Marlyn Drive, Prattville, AL 36067; Silvia D. Visona, MD, University of Pavia, Via Forlanini 12, Pavia 21100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Via Forlanini 12, Pavia 27100, ITALY; and Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104*

After attending this presentation, attendees understand how to use the thanatotranscriptome of prostate tissues to gain further insight into apoptotic pathways after death. Precisely, attendees will understand that RNA is stable in cadavers' prostate tissues and is sufficient for profiling gene expression for up to 60 hours.

This presentation will impact the forensic science community by providing information on transcriptional mRNA abundance profiles of postmortem prostate tissues in which there is a paucity of previous studies.

Molecular autopsy has the potential to provide valuable information to establish the cause and manner of death in medicolegal investigations. Gene expression studies are well-established components of antemortem research with broad applications ranging from elucidating basic mechanisms responsible for physiological processes to ascertaining therapeutic targets in pathophysiological conditions; however, gene expression studies and their applications in the medicolegal field are still in their infancy. The thanatotranscriptome, or "transcriptome of death," involves the study of mRNA transcripts occurring in human tissues after death (*thanatos*, Greek for death). The identification of transcript abundances in human body tissues through mRNA-based profiling is potentially useful for forensic investigations.

It was hypothesized that there are detectable and significant disparities in transcript abundances in cadaver tissues from homicide and suicide victims compared to individuals who succumbed to natural causes. The intent of this study was to determine molecular markers (i.e., mRNAs) that provide accurate information regarding the cause and/or manner of death. This study investigated genetic studies involving organ- and manner-of-death-specific profiling of apoptosis gene expression panels through the application of Polymerase Chain Reaction (PCR). This procedure was performed using postmortem prostate tissues from actual criminal cases from the University of Pavia, Italy. Complementary DNA (cDNA) was synthesized and RNA concentrations were measured. The goal of this study was to provide detailed insight into expression of 84 key genes involved in complex apoptotic pathways from prostate tissues.

The results demonstrate that at 38hrs Postmortem Interval (PMI), most of the genes related to induction and positive regulation of apoptosis, Caspases, are upregulated more at 60hrs PMI. This finding suggests that apoptosis is upregulated compared to the control group. Several antiapoptotic genes, such as BCL2 and BCL2 A genes, are more expressed in 38hrs, but at 60hrs, they are drastically reduced in expression and, in some cases, to the insignificant fold-change level. These outcomes propose that initially, in the control group, cells fight with their antiapoptotic machinery; however, later, proapoptotic machinery takes over.

In conclusion, this study demonstrates that RNA molecules are stable in postmortem prostate samples, which makes RNA a sufficient molecule for gene expression studies. This study design validates a technique that will meet the demand for rapid and reproducible thanatotranscriptomic methods. These novel techniques will correlate apoptotic gene expression patterns as possible biomarkers compared to classic methods by expanding the capacity of molecular autopsy techniques.

Thanatotranscriptome, Prostate, RNA

I1 Elder Abuse: Perception and Knowledge of the Phenomenon by Healthcare Workers From Two Italian Hospitals

Ignazio Grattagliano, PsyD, University of Bari, Via Mauro Amoruso 68, , Bari 70124, ITALY; Graziamaria Corbi, PhD, via Giovanni Paolo II-Loc Tappino, Campobasso 86100, ITALY; Carlo P. Campobasso, MD, PhD, University of Campania, Dept Experimental Medicine, via Santa Maria di Costantinopoli, 16, Napoli 80138, ITALY; Lidia Scarabaggio, RN, University of Campobasso, Via F. De Sanctis 1, Campobasso 86100, ITALY; Roberto Catanesi, MD, P.za Giulio Cesare, Bari 70124, ITALY; Nicola Ferrara, MD, via Giovanni Paolo II-Loc Tappino, Campobasso 86100, ITALY; Carlo Sabbà, MD, University of Bari, P.za Giulio Cesare, Bari 70124, ITALY; and Giorgio Fiore, MD, University of Bari, Piazza Giulio Cesare, Bari 70124, ITALY*

After attending this presentation, attendees will better understand the importance for forensic and healthcare practitioners to recognize early signs of physical, psychological, and emotional abuse on elderly people.

This presentation will impact the forensic science community by demonstrating that the absence of early recognition of elder abuse can be a major disadvantage for the community.

Background: With a rapidly aging population in countries worldwide, the number of elderly adults vulnerable to abuse, neglect, and exploitation is expected to grow. Hospital personnel usually play a crucial role in identifying mistreatment and making appropriate referrals as they are usually the first people with a medical background to see these victims. Physicians and nurses are also mandatory reporters of elder abuse in accordance with state requirements.

Goals: To establish a level of awareness and perception of elder abuse by healthcare workers, to understand if these workers are able to recognize and report elder abuse properly, and to identify the physical elements of abuse and neglect.

Methods: The research tool was a survey of 35 questions. Selected questions were chosen from previously validated questionnaires used in other similar published survey studies. Participants were represented by physicians, nurses, and care assistants working in the internal medicine and geriatric services of two different University Hospitals, representative of the Italian public health system in Southern Italy (Cardarelli Hospital of the University of Molise and Policlinico of the University of Bari "Aldo Moro").

Results: The results included 98 of 142 administered questionnaires (69.0% response rate). All data were further analyzed, taking into account age, gender, work experience, and qualifications. For the majority of all personnel, neglect represents a type of abuse; however, approximately 40% of the physicians and 37% of the nurses considered the concept of abuse to be false. The surveyed population was aware that many seniors are victims of abuse and that elder abuse is a form of violation of personal rights, but 46.94% were unsure about the existence of standard procedures for reporting abuse and/or treatment, suggesting low attention paid to the problem and little information provided by institutions on abuse reporting procedures. Regarding whether participants suspected abuse, most nurses (45.7%) and care assistants (68.8%) declared they had never had suspicions of abuse, while 48.7% of physicians stated suspecting abuse on one to three occasions in their lifetime. Only 23.9% of the nurses, 22.4% of the physicians, and 18.8% of the care assistants stated they had witnessed abuse between one and three times in their lives. Surprisingly, in both suspected or witnessed cases, the health care personnel did not take any action and did not report the abuse to public authorities or to adult protective service agencies.

Conclusions: The results of the present survey on health care professionals demonstrate that there is still a strong need for education and specific training programs on elder abuse.

I2 Financial-Psychological Crime: The Madoff Case

Ignazio Grattagliano, PsyD, University of Bari, Via Mauro Amoruso 68, , Bari 70124, ITALY; Alessio Ostuni, MD, Sections of Legal Medicine and Criminology, Policlinico of Bari Italy, Piazza Giulio Cesare 11, Bari 70124, ITALY; Maricla Marrone, MD, P.za Giulio Cesare, 1, Bari 70124, ITALY; Anna Cassano, PsyD, P.za Giulio Cesare, 11, Department of Forensic Psychiatry, Bari 70124, ITALY; Fulvia Carucci, PsyD, Department of Education, Psychology and Communication, Via Crisanzio 42, Bari 70124, ITALY; Michele Di Marcantonio, PsyD, Department of Education, Psychology and Communication, Via Crisanzio 42, Bari 70124, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; Lucia Tattoli, PhD, Sezione di Medicina Legale, University of Turin - Corso Galileo Galilei, 22, Torino 10126, ITALY; Carlo P. After attending this presentation, attendees will better understand the link between financial fraud and psychopathy.

This presentation will impact the forensic science community by exploring the psychological and forensic profiles of victims and perpetrators, with the goal of demonstrating how some individual attributes and characteristics, such as a respectable front, charisma, or strategic presentation of a self-image, are positively correlated with the fraudster profile.

In 1920, Charles Ponzi was the first to conduct a large-scale tax fraud scheme. The basis of a Ponzi scheme relies on individuals entrusting a portion of their capital to a subject mediating between the individual and the market, in a process known as financial mediation. The trigger of the scheme is the faith the client has in the intermediary and his superior knowledge in this field. In the fraud mechanism, the perpetrator needs to convince future victims to allow him/her to handle their savings in order to make investments that do not actually exist, promising relatively large returns in a limited period of time. The client/victim, who first obtains financial gains that satisfy his/her expectations, continues to invest and convinces other people to do the same.

At the end of 2008, a famous New York broker and ex-president of the National Association of Securities Dealers Automated Quotation (NASDAQ) named Bernard L. Madoff was accused of fraud and was arrested. Madoff succeeded in perpetrating the fraud thanks to his ability to handle first impressions. In other words, he possessed the specific communication trait that can manage the fundamental human tendency to imagine, plan, and regulate social behavior in such a way as to leave a strong impression on others, convincing them of the truth of the self-image presented. In psychological terms, what convinces people to invest in such plans is the fraudster's ability to exploit people's weak points, such as greed, trust, and fear. According to Schiller's theory of the positive feedback investment cycle of large-scale bubbles, when many people believe they will receive good profits, they communicate their belief to other potential investors, making it seem like a mistake to miss out on the investment.[1] This triggers phenomena such as familial bias and imitation: the stories and perceptions of the profit to be gained from a given investment make it appear to be affected by a minimum or negligible risk. As persuasion tools, these are even more effective than the fraudster's own persuasive strategies. In fact, according to Greenspan, the success of the Ponzi scheme was attributable to the human tendency to model actions on those of others, especially when dealing with matters that the client knows little about.[2]

Typical traits of the victims of these schemes are a limited knowledge of financial matters, little available money, older age, or a low level of education (excluding those affected by mental disease).[3] Characteristics of the "fraudster" are being male, between the ages of 35 and 65, an advanced education, "a respectable front" (strictly connected to the self-image presentation strategy), charisma, and a marked ability to handle social relationships.[4] One of the most devastating consequences of such schemes is the fraud trauma syndrome that engenders emotions such as rage, pain, anxiety and fear, mistrust of the future, isolation and devastation, as well as symptoms such as insomnia, panic, anxiety attacks, or depression.[5] The line between fraud trauma syndrome and post-traumatic stress disorder is becoming less and less clearcut.[6] The sense of betrayal of the trust placed in the fraudster provokes a feeling of abuse and violence in the victim. Many victims report that they have even considered committing suicide, or have suffered a worsening of preexisting medical conditions. Similar to victims of rape, victims of fraud tend not to denounce the crime they have suffered due to feelings of guilt induced by the social and legal systems.

I3 Sudden Death of a Child: What Could Have Happened in a Family With a Different Socioeconomic Status?

Erica Bacchio, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Omar Bonato, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Letizia Alfieri, MD, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; Natascha Pascale, MD, Viale Degli Aviatori, Foggia 71100, ITALY; Simone Onti, MD, Unit of Legal Medicine, University of Ferrara, Via Fossato di Mortara 70, Ferrara 44121, ITALY; Stefano Malaguti, MD, via Fossato di Mortara, n70, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Dept of Legal Medicine, Via Fossato di Mortara, 70, Ferrara 44121, ITALY; and Margherita Neri, MD, PhD, University of Ferrara, Dept of Forensic Pathology, Via Fossato di Mortara 70, Ferrara 44100, ITALY*

After attending this presentation, attendees will better understand the importance of the diagnosis of malnutrition and failure to thrive in a child death investigation.

This presentation will impact the forensic science community by providing elements to diagnose the exact cause of death in a child neglect or abuse case as well as the legal outcomes which may result.

Fatal child starvation is uncommon in Italy, and, according to the National Statistical Data, malnutrition is related to being overweight and morbid obesity.

Child abuse and maltreatment are defined as a series of deliberate actions and/or omissions that are conducted by adults (parents, relatives, caretakers), or other children or adolescents, that result in physical or emotional damages or the imminent risk of serious damage or death. Maltreatment/abuse can be expressed as: a failure to provide age-appropriate care, spousal abuse in the child's presence, psychological maltreatment, physical maltreatment, and sexual abuse. Classifying various forms of child maltreatment is useful for exemplifying goals, but children are usually victims of different types of maltreatments simultaneously. The neglect of a child without appropriate care is an ongoing pattern of inadequate care by parents and caregivers. It includes child neglect, lack of care, inappropriate care at the time, and excessive care.

Child neglect is defined as a type of maltreatment related to the failure of parents to provide for the child, which could cause serious damage. The signs of child neglect are a sense of abandonment, refusal, failure to thrive, or other forms of abuse (which may be life threatening). Neglect has received less attention than physical and sexual abuse, probably because it is difficult to identify and often includes other forms of maltreatment.

This case study describes a 2-year-old girl who was found dead on the sofa by her mother's partner. The child was known to social services for suspected abuse after being admitted to the hospital for a fracture of an upper limb and bruises, which the mother reported as an accidental fall. Furthermore, the child was suffering from psychomotor retardation associated with serious self-inflicted injuries with bites, hitting her head against the wall, and pulling out her own hair. Consequently, she was transferred to neuropsychiatry, but the drug therapy (periciazine) administrated by her mother was ineffective. A week before her death, the child was admitted to a pediatric hospital with severe anemia, failure to thrive below the third percentile of growth, and electrolyte imbalance; however, the mother decided to take the child back home, against the advice of doctors.

The case had multiple risk factors leading to neglect: the mother's young age, low socioeconomic status and education, dysfunctional family characteristics (child's parents were half-siblings, adopted by two different families), the presence of an adult unrelated to the child (mother's new partner), and parental stress.

The case study included the scene investigation, autopsy, toxicology, and police investigation. The external examination was remarkable for multiple limb bruises, bitemarks on her hands and upper limbs, and scratches on the face. The autopsy was negative. There was no chest or head trauma, only the results of the known upper limb fracture. The gross examination of the heart revealed left ventricular hypertrophy and histology exhibited the usual finding of restrictive cardiomyopathy, such as interstitial fibrosis. The toxicological test was positive for a therapeutic range of periciazine.

Finally, the cause of death established was cardiac arrest due to restrictive cardiomyopathy, which is known for having a poor prognosis in children. This case met legal challenges due to disagreements regarding the cause of the child's failure to thrive. In other words, the legal question was whether malnutrition was due to neglect or to cardiomyopathy. In the end, although neglect was not the cause of death, it certainly was related to it. In any case, studies reveal there is poor knowledge of child neglect among medical resources, which leads to a higher rate of sickness and death among these children. This case report illustrates that even in highly suggestive cases of abuse or neglect, it is necessary to refer to the report of the child's death investigation and pay attention to risk factors in the family context; beginning from the crime scene investigation and medical records to the autopsy and histological findings.

Establishing the cause and the manner of death may lead to different legal outcomes in cases that clearly involve child abuse or child neglect.

Child Neglect, Cardiomyopathy, Maltreatment

I4 Self-Cutting and Suicide Risk Among Adolescents: The Case of the "Blue-Whales"

Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. "Città della Salute e della Scienza," Turin, ITALY; Sara Simona Racalbuto, PsyD, Department of Pediatric Emergency, Turin, Piazza Polonia 94, Torino 10100, ITALY; Ignazio Grattagliano, PsyD, University of Bari, Via Mauro Amoruso 68, Bari 70124, ITALY; and Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will understand the importance of training healthcare staff to promptly recognize suicidal risk behaviors among adolescents.

This presentation will impact the forensic science community by providing information regarding the media phenomenon known as the "Blue-Whale-Challenge," which includes self-cutting; this carries a high potential risk of suicide.

The Blue-Whale-Challenge is a dangerous internet phenomenon that consists of a series of duties, imposed by an administrator to players who must complete a list of actions involving self-mutilation. The game lasts 50 days, with players usually completing one duty per day, and ends with the suicide of the player.[1] The term "Blue-Whale" results from the similarity of suicidal behavior among beached whales. The phenomenon began in 2013, in Russia, on the "VKontakte" social network, with the first case of suicide in 2015. The inventor was a psychology student, expelled from his university. The student said that his purpose was to clean society of people of no value.[2] The phenomenon spread among teenagers in Russia, then in other areas, due to the media resonance caused by television broadcasts and newspaper articles that featured information regarding the game. After a wave of panic caused by an article concerning the many suicides related to the Blue-Whale phenomenon in Russia, the inventor was arrested in 2016.

Around the world, the phenomenon accounts for many cases, some of which have often turned out to be hoaxes or emulators. In Italy, the first news about the Blue-Whale appeared in June 2016 in a national newspaper, but only in May 2017 did a well-known television program deal with the subject, using reports that did not quote official sources. From that moment on, the police began receiving calls and newspapers published alarming news concerning Blue-Whale incidents, which were often quickly denied. Between May and June 2017, five suspected cases of Blue-Whale have been managed by the officers of the unit. The officers were dedicated to the evaluation of suspected abused children ("Bambi") of the "Ospedale Infantile Regina Margherita" (Turin).

The data collected during the multidisciplinary evaluation of these cases was reported: all patients were female; one case involved a 17-year-old girl, while the other four cases involved 14-year-old girls; all families experienced critical economic, social, or psychological issues; in two cases, the girls' parents were separated; in one case the father had been sent away from home as he beat his wife and daughter; and the last girl described her father as extremely aggressive and oppressive. During the psychological evaluation, all girls recounted difficulties in integration at school and anxiety. One girl confessed to having purposely taken an excessive dose of alprazolam. In three cases, the medical examiners identified scars related to previous self-cutting. In one case, this activity was recent and the lesions on the forearm were thought to resemble a whale. There was no evidence to sustain an involvement in the Blue-Whale-Challenge or the influences of an administrator in any of these cases, but rather emulative behavior caused by psychological issues. Only one of these girls was hospitalized, while psychological help programs were prescribed for the other girls.

Self-harm is the strongest predictor of suicide among young people. Between 40% and 80% of suicide victims had self-harmed in the past.[3,4] In particular, longitudinal data indicated that self-cutting is a significant risk factor for complete suicide in children and adolescents.[5] Young people who self-harm report that it is difficult to talk about their suicidal feelings and they do not really feel "listened to" when they do.[6] Indeed, clinical staff often has a negative attitude toward self-harm and may not possess the ability to deal with it effectively. In this series of cases, there was a strong demand for attention, illustrated through self-cutting and simulation of participation in a life-threatening game. In accordance with the literature, all of these young people experienced negative life events and had difficulties in relationships with families and friends.[7] Given these premises, it is crucial that frontline medical staff receive training about self-harm and suicidal behaviors to reduce suicide rates. It has been demonstrated that even short-term training can significantly improve staff attitudes.[8] This presentation provides attendees with a better knowledge of behavioral and psychological factors that highly increase the risk of suicide among adolescents.

I5 Acute Stress Disorder (ASD) Symptomatology and Crime in a Nationally Representative Sample of Youth

Joseph Chien, DO, VA Portland Health Care System, 3710 SW US Veterans Hospital Road, Portland, OR 97239; Bronte T. Pagan, BS, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; Kayla E. Wyant, BA, University of New Haven, 300 Boston Post Road, New Haven, CT 06516; and Kendell L. Coker, PhD, University of New Haven, 300 Boston Post Road, New Haven, CT 06516*

After attending this presentation, attendees will appreciate the correlation between ASD symptomatology and criminal behavior in youth and will use this knowledge to implement early interventions for traumatized youth.

This presentation will impact the forensic science community by presenting data that will encourage clinicians and policy-makers to pay close attention to symptoms of ASD in youth, as early intervention may help prevent the development of Post-Traumatic Stress Disorder (PTSD) and potentially may deter youth from committing crimes.

No previous studies have examined the relationship between ASD and criminal behavior among youth. This study looked at data from the National Comorbidity Survey-Adolescent Supplement (NCS-A). Participants in this survey, which took place between February of 2001 and January of 2003, consisted of 10,148 youths between the ages of 13 and 18 years. Interviews were conducted using computer-assisted personal interviews, computer-assisted telephone interviews, and telephone interviews.[1] This study hypothesized that analysis of a nationally representative sample of youths would reveal a relationship between symptoms of ASD and criminal behavior. Since the NCS-A was conducted prior to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*), symptoms of PTSD from the *DSM-IV* were mapped to *DSM-5* criteria for ASD. Due to changes in the *DSM-5* criteria for ASD, the youths in this study were described as having "ASD symptomatology." Data were analyzed using the Statistical Package for the Social Sciences (SPSS) to estimate prevalence rates of ASD symptomatology and examine the relationship between ASD and criminal involvement.

Youths with ASD symptomology were significantly more likely to report arrest-related crimes than youths without any lifetime diagnosis. Youths with ASD symptomology had 25.4 greater odds of a report arrest for a violent crime when compared to youths who did not meet criteria for any lifetime diagnosis. Additionally, youths with ASD symptomology had 8.3 greater odds to have reported arrest for property crimes and 17.9 greater odds to have reported arrest for "other" crimes compared to youths without any lifetime diagnosis. Youths with ASD symptomology had 11.6 times greater odds of reporting, but not being arrested for, a property crime, 24.2 times greater odds for a violent crime, and 10.9 greater odds for any other crime when compared to youths who did not meet the diagnostic criteria for any *DSM-IV* lifetime diagnosis.

The data presented here provide a more accurate picture of the relationship between ASD and related crime, allowing for prevention and intervention strategies to be potentially developed. Focusing on at-risk youths to provide support and education is crucial. Due to the inevitable nature of certain trauma, intervention strategies must be catered to those youths who are experiencing ASD symptoms. Without addressing youths who are experiencing symptoms of ASD, their conditions may progressively worsen into more severe trauma-related disorders.[2,3] The quality of life for these untreated youths decreases severely and serves as an increased risk factor for criminal involvement, suicide, and other comorbid psychiatric disorders.

Acute Stress Disorder, Crime, Adolescents

I6 Female-Perpetrated Sexual Abuse on Children: A Five-Year Long Italian Experience

Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Caterina Petetta, MD, Sezione di Medicina Legale DSSPP, C So Galileo Galilei N 22, Torino 10121, ITALY; Anna M. Baldelli, JD, Prosecution Office of the Juvenile Court, Turin, Corso Unione Sovietica, 325, Turin 10135, ITALY; Sara Simona Racalbuto, PsyD, Department of Pediatric Emergency, Turin, Piazza Polonia 94, Torino 10100, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. "Città della Salute e della Scienza," Turin, ITALY; Ignazio Grattagliano, PsyD, University of Bari, Via Mauro Amoruso 68, Bari 70124, ITALY; and Giancarlo Di Vella, MD, PhD*, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will better understand the gender-specific features of child sexual abuse perpetrated by women compared with male-perpetrated abuse.

This presentation will impact the forensic science community by providing tools to recognize a form of sexual abuse often difficult to identify because of its intrinsic characteristics.

In the literature, little attention has been paid to females who sexually abuse as most of the studies focused on male perpetrators.[1] The phenomenon has typically been reported as relatively rare with a male-to-female sexual offenders ratio equal to 20:1. Available data indicate that women constitute approximately 5% of all sexual offenders.[2]

Despite this, female-perpetrated abuse is responsible for a non-negligible number of victims and offenders who need clinical attention. In addition, the phenomenon is certainly underestimated because it is difficult to diagnose females for several reasons: sexual abuse is often perpetrated by women who care for the child during routine daily activities, such as bathing or dressing, so sexual offending is often hidden behind the woman's caretaking behavior.[3] Moreover, in most cases, a strong affective bond between the victim and the offender is created, so that the child does not reveal the abuse. The emerging cases that are reported for investigation appear to be the "tip of the iceberg" with respect to cases that are not reported. Finally, there are usually no clinically detectable lesions because sexual abuse is typically not conducted via violent acts.

In order to contribute to the knowledge of this topic, this study reports the data collected from January 2012 to June 2017 in the multidisciplinary unit called "Bambi," dedicated to the evaluation of suspected abused children, of the "Ospedale Infantile Regina Margherita" (Turin). Among 474 cases of suspected child sexual abuse, in nine cases (1.9%), the potential perpetrator was a woman: one child was male and the others were female. The children were between 3 and 9 years of age (four 4-year-olds, two 5-year-olds, two 9-year-olds, and one 3-year-old). In five cases, the parents of the children were divorced. The perpetrators in two cases were the mothers of the children, in four cases the paternal grandmother, in two cases a female neighbor, and in one case the babysitter. In only one case was the sexual abuse conducted in association with other perpetrators. One of the perpetrators already had a diagnosis of psychiatric disorders (borderline disorder and depression). In all cases, the perpetrators committed the abuse by touching and licking the ano-genital area, and in four cases, by also penetrating the vagina or anus. In one case, the culprit forced the child to watch porn videos. All children, except one, spontaneously described to the medical staff members the abusive actions perpetrated by the offender. More detailed information on the clinical and judicial path of each case will be provided during this presentation.

Although it is a common belief that if a female is involved in a sexual abuse, she must have been forcefully coerced by a male partner, the reported cases, in accordance with previous studies, suggest this is often not true.[4,5]

Considering the unusualness of the phenomenon, although many treatment requirements appear to be similar to those of male sexual offenders, it is crucial that the gender-specific features of the phenomenon be taken into account, rather than attempting to fit female sexual offenders' treatments to existing male models.[1]

This presentation provides attendees with additional knowledge regarding female-perpetrated sexual abuse on children in order to understand gender-specific criminal offending patterns and provide an important tool in the development of prevention and rehabilitative strategies.

Child Abuse, Female Perpetrators, Sexual Abuse

I7 Sexual Offending and IQ: What Is the Relationship?

R. Gregg Dwyer, MD, EdD, Medical University of South Carolina, Community & Public Safety Psychiatry Division, 29-C Leinbach Drive, Charleston, SC 29407; and Emily D. Gottfried, PhD*, MUSC, Charleston, SC 29407*

The goals of this presentation are to: (1) inform those involved in assessments of persons who have sexually offended of considerations of intellectual functioning as it relates to etiology and, in turn, risk of reoffending; and, (2) provide treatment providers with data on the potential impact of intellectual functioning for treatment planning use.

This presentation will impact the forensic science community by improving the ability of evaluators of sexual offending behavior to determine etiology. This presentation will also impact attendees by helping risk and treatment providers to develop treatment plans with likelihoods of successful outcomes.

The current proposed presentation will focus on the range of intelligence estimates in a sample of adult men convicted of sexual offenses. Specifically, this presentation will include the data of approximately 1,040 individuals who were serving time for a sexual offense conviction and being assessed for potential civil commitment under the South Carolina Sexually Violent Predator (SVP) Act. A previous meta-analysis of 25,146 adult male sex offenders reported that sexual offenders obtain lower Intelligence Quotient (IQ) scores than non-sexual offenders, but that this difference is likely accounted for by the large proportion of individuals with sex offenses against children in those studies.[1] Additionally, a relationship between IQ score and the presence of pedophilic disorder was noted.[1] Based on previous research, it was hypothesized that as the offenders' intellectual functioning (i.e., IQ score) decreased, so did the age of the victims. [2,3] This study hypothesized that offenders with below-average IQ would have younger (i.e., at least pre-adolescent age range) victims than those with average or above-average IQ scores. It was also hypothesized that as IQ score decreased, the report of childhood sexual abuse victimization of the offender would increase. This study hypothesized that the offenders with above-average IQs would be more likely to have no other criminal history beyond the sexual offense(s). Finally, it was predicted that the presence of a pedophilic disorder would be associated with lower IQ scores than of those offenders not meeting diagnostic criteria for pedophilic disorder. Preliminary analyses indicate that IQ scores in this sample ranged from 43 to 164, with a mean IQ score of 91.88 (*Standard Deviation (SD)*=16.00). Approximately 35% of the sample (*n*=364) had been diagnosed with at least one mental illness, to include paraphilic disorders (*n*=25). The sample had an average of 2.17 (*SD*=2.57) victims and the number of victims ranged in age from 1 to 45 years. This presentation will also address the challenges of providing effective sex offender treatment to offenders with intellectual impairments.

Sexual Offenders, Intellectual Functioning, Sexually Violent Predators

I8 Do Sex Offenders Secretly Reoffend During Treatment?

Thanh Ly, BSc, 59 Willwood Crescent, Ottawa, ON K2J 2Z5, CANADA; and J. Paul Fedoroff, MD*, Royal Ottawa Hospital, 1145 Carling Avenue, Ottawa, ON K1Z 7K4, CANADA*

The goals of this presentation are to provide insight on: (1) the likelihood of unreported sexual reoffenses occurring during treatment; (2) which sexual reoffenses are more likely to occur; (3) the likelihood of sex offenders disclosing their reoffenses to health care professionals; and, (4) the period sex offenders are more likely to reoffend.

This presentation will impact the forensic science community by debunking misconceptions of persons who have committed sexual offenses. Attendees will become more aware of the types of reoffenses that are most likely to be secretly committed by sex offenders. Persons undergoing treatment for problematic sexual behaviors will be given hope that the treatment outcome is usually positive.

It was hypothesized that if reoffenses were reported, hands-off reoffenses were more likely to occur than hands-on (contact) reoffenses. The other hypothesis was that the majority of relapses and/or reoffenses would have occurred between six months and one year of treatment, if any were reported.

The methodology of this study is unique in the sense that it is virtually untraceable and provides complete anonymity and confidentiality to its participants. An anonymous poll booth was set up in a room where group therapy normally takes place and was located away from cameras and possible prying eyes. Participants were instructed to complete the survey during the break or discreetly during group therapy. They were to go behind the cardboard trifold and had the option of wearing cotton gloves in case of concerns regarding tracing their responses through fingerprint analyses. Participants were also instructed to use the felt-tipped pen provided so all answer sheets would look identically filled and their responses would be untraceable through any form of handwriting analyses. After completing the survey, they were to drop their responses through the slit of a sealed cardboard box. Before starting the survey, a deck of cards was passed out to all participants and they were to choose one card from the deck. The research assistant had a second deck of cards, which was identical to the first deck given to participants. The second deck was shuffled in front of the participants and a card was randomly selected from the deck. The group was told that the participant with the matching card was told not to reveal himself/herself and was also told to complete the survey with false responses and claim that he/she had reoffended. This would provide assurance to participants that if they had disclosed reoffenses, it would be virtually impossible to distinguish their disclosure from the assigned liar's disclosure. Participants then completed the survey discreetly during group or during the break.

Results of the study revealed that the majority of sex offenders did not reoffend while in treatment. When reoffenses did occur and were not reported, the majority of those reoffenses were breaches of conditions. The least likely re-offense to occur, even in secret, were contact offenses that involved sexual touching of a child and/or sexual touching of an adult. Re-offenses were also most likely to occur between the first six months and one year of treatment. Those who had secretly reoffended were also unlikely to disclose their relapses to their doctors.

Given that most reoffenses reported were non-sexual breaches, professionals in charge of supervising and/or re-integrating offenders back into the community can improve on preventing breaches. Since pornography-related offenses were the second-most likely to occur, prevention methods may need to be installed to reduce accessibility of illegal pornography. Furthermore, these results inform professionals that treatment can prevent reoffenses, but when reoffenses occur, it is unlikely their patients will disclose those incidents. It also cautions professionals to be vigilant of potential reoffenses during the first six months to one year of treatment. Future research should investigate factors that increase the likelihood of disclosure to health professionals or disclosure of a pending relapse.

Sex Offender, Paraphilia, Sexual Reoffenses

I9 The Unfolding Development of Forensic Behavioral Science

John L. Young, MD, Yale University, 203 Maple Street, New Haven, CT 06511-4048*

After attending this presentation, attendees will apply a deeper understanding of the underpinnings of their fields to their work and, as a result, will enjoy more satisfying conversations with colleagues of other disciplines.

This presentation will impact the forensic science community by increasing appreciation for gathering and applying sound information — both new and old.

The founding of the American Academy of Forensic Sciences (AAFS) marked the commitment of serious professionals in each of the forensic sciences to contribute to the unending progress in the quality of their work. Their intention applied to both the reliability and validity of the methods and procedures to use in each field. In doing so, our founders expected to promote justice and thereby serve not only parties in litigation, but all humanity as well.

Regarding the behavioral forensic sciences, it is useful to understand their history as developing over a four-stage course, beginning with a time of genuine, although poorly acknowledged, ignorance. In time, it became difficult to demonstrate that behavioral experts' opinions offered anything better than random chance; the equivalent of a coin toss.

Experiencing the painful impact of even moderately good scientific methodology on their theory-based testimony sufficed for most experts to usher in the second developmental stage. By roughly the early 1970s, working groups from several universities began the publication of statistical scales, based on subjects' behavioral histories, medical and social histories, and varied additional data yielding estimates of probabilities of future behaviors.

Meanwhile, the age of scans, the third developmental stage, was getting underway. In the United Kingdom during the mid-1970s, engineers working for Electronic Music Incorporated (EMI) developed crude planar images of living human subjects' brains. To do this, they took advantage of technical refinements in the generation and detection of X-rays. Soon enough, these "EMI scans" became valued for their clinical utility. In the forensic arena, their use has demonstrated both the value and the danger of the saying that a picture is worth a thousand words. Having a basic understanding of the workings of the more recent scanning technologies, especially Magnetic Resonance Imaging (MRI), only strengthens this recognition.

The final phase, for the present at least, is that of genetics. Here, the behavioral forensic specialist needs to comprehend at least the elementary jargon of the DNA expert and related forensic specialists. Any efforts to do so are soon handsomely repaid. As progress in this fourth stage continues, we may look forward to important conversations among forensic experts as they recognize the many diverse likenesses in their professional DNA.

Development, Interdisciplinary, Progress

I10 Application of the Equivocal Death Psychological Autopsy for Investigation: A Case Study

Cinzia Gimelli, PsyD, PhD, Science & Method, Via Regina Margherita 9/d, Reggio Emilia 42124, ITALY*

After attending this presentation, attendees will better understand the role of the Equivocal death Psychological Autopsy (EPA) for investigation.

This presentation will impact the forensic science community by discussing the specific technique of EPA as applied during the investigation process in cases registered as a suicide and reinvestigated from the point of view of homicide.

Forensic psychological evaluation has contributed significantly as an aid to investigation in many sensitive cases. There are various subfields of forensic psychology and one such technique is that of the psychological autopsy. A psychological autopsy is an extremely important tool to ascertain the mental status of any individual before his or her death; it throws light on various facts that may have been missed during the investigation. An EPA is useful in aiding the investigation process, especially in controversial deaths. The technique of EPA is relatively new in Italy. This particular technique was applied during an investigation for a referred case in which there was a controversy in terms of the investigating agency and the family in deciding between suicide and homicide.

Introduction: Forensic psychology deals with the application of principles of human behavior and cognition to the legal, civil, and criminal delivery system. It is also the scientific discipline dealing with the understanding of factors that culminate in the expression of violent and legally unacceptable behavior; this brings the perpetrator of the actions under the focus of law and the need for specialized rehabilitation. A forensic psychologist tries to understand the causes of criminal behavior and tries to establish a link between the crime, crime location, the victim, and the offender; however, forensic psychologists also try to work in areas related to victimology or the victim's psychology. Forensic psychologists also attempt to understand why a particular victim was chosen, as this aspect throws light on the offenders modus operandi. Similarly, forensic psychologists also perform psychological autopsies in equivocal deaths. Equivocal death analysis is by far the most demanding work. An equivocal death analyst requires extensive information about the victim and circumstances surrounding his or her demise before rendering a knowledgeable opinion of the victim's personality and behavior. The goal of equivocal death analysis is not to prove the manner of death, but to arrive at an informed opinion as to whether a homicide, a suicide, or an accident most likely occurred. Psychological autopsy is a retrospective psycho-social examination of a descendent to the time of his or her death. It is an extension of victimology that reconstructs the deceased's psychological state before his or her death. This presentation attempts to portray the importance of the EPA technique in an equivocal death case of a young man whose death was initially registered as a suicide and was reinvestigated as a homicide due to various controversial aspects in the overall case.

Case Report: This case has been tested through the method of psychological autopsy. The case involves a 48-year-old male who was found dead (by hanging) by his best friend. The case was initially declared to be a suicide; however, his family insisted that it was a homicide and not a suicide. The case was thus referred for an EPA to better understand the entire case and to check for investigative leads. The EPA was conducted using a detailed study of his personal diary, his postmortem report, and the court petition filed by the family. Information gathered from interviews with key informants by means of direct interviews and past photographs were also utilized as sources of information for this report. The psychological autopsy method entailed reconstructing the biography of the deceased through psychological information gathered from personal documents; police, medical, coroner records, and first-person accounts, either through depositions or interviews with family, friends, coworkers, school associates, and physicians.

Results: The results revealed that, with deep psychological investigations, the possibility of homicide cannot be ruled out completely.

Conclusions: Psychological autopsy is an important and valuable tool for aiding an investigation. This presentation provides detailed information regarding an individual's death using various sources and reveals new points that could have been missed during the initial investigation process. This technique is an investigative approach that provides direction in equivocal deaths and attempts to bring justice to the victim.

Equivocal Death, Psychological Autopsy, Forensic Psychology

I11 A Review of More Than 20 Parricides and Crime Scene Behaviors: Does It Differentiate Mental Illness, Psychopathy, or Abuse as the Reason for Killing Parents?

Eleanor B. Vo, MD, OmaDesala Psychiatric Services, 1901 N Olden Avenue Ext, Ste 3A, Ewing, NJ 08618-2111; Kaveh Cyrus Ghaedi, DO*, Rutgers University—Newark, Department Psychiatry, 671 Hoes Lane, D325, Piscataway, NJ 08854; and Wade C. Myers, MD*, Brown University, Dept of Psych & Human Behavior, Forensic Psychiatry Program, 1 Hoppin Street, Ste 204, Providence, RI 02903*

The goal of this presentation is to further attendees' understanding of parricide and crime scene analysis to better understand the motive of the crime.

Parricide, while a rare event, has devastating impact on families and others. The crime scene could show details as to the motive of the crime. This presentation will impact the forensic science community by demonstrating how, with further analysis of the crime scene, the motivation could be better extrapolated to improve treatment of cases with mental illness or abuse as compared to psychopathic intentions.

Children killing their parents is a rare event that falls into three areas or profiles: (1) children that have mental illness; (2) children that are abused; and, (3) children that are psychopaths. Parricides, while rare, are one of the most sensational crimes that attract the attention of the media, clinicians, and researchers worldwide. Much research has been conducted on the topic of parricide despite only being approximately 1.5% to 2.4% of all homicides yearly. Often research focuses on the offender and the victim's characteristics to be able to evaluate the crime and motive; however, there is very limited research into the crime scene behaviors. When looking at more than 20 cases of parricide and reviewing the crime scene information from case information in addition to researching data from public records, data has shown that one-third of the children who kill their parents are abused, one-third are mentally ill, and one-third are psychopathic killers. When looking at crime scenes, there is information that can be helpful to both police and mental health providers about the motive of the crime.

This study, after observing the patterns of the crime scene, anticipates demonstrating that children who are abused or mentally ill are more likely to cover the body or even stay in the home with their deceased parents' bodies. Psychopathic offenders will demonstrate less care at the crime scene and not have the empathy to cover or disguise the bodies due to their lack of connection to the parents. Most research has focused on the demographics, motives, social, legal and psychological factors, such as mental health and abuse history. Minimal research of crime scene behaviors in parricide cases have been explored. Crime scene profiles or analyses have been examined when investigating other cases, but not specifically for parricides. When the research has been examined at parricide cases, the focus has been on age and weapons were used, not the basic crime scene information. Often, the basic crime scene details are dismissed, but they can be an invaluable tool for investigators and police in helping to understand the offender of violent crimes. By scrutinizing data from crime reports, publications, and cases, the data on the crime scene can be used to better evaluate the connection of the crime scene data to the reason for the parricide. This concept has not been examined in parricide cases, which could help better understand the events and circumstances that lead an individual to taking their parents' lives.

To examine the components of crime scene behaviors and their implications within parricide, data from adolescent parricides will be presented. This study will present preliminary data concerning parricide offenders and crime scene behaviors, such as the condition of the body when found (covered, face covered, moved, or hidden); the type of attack (blitz, surprise, conned/deceived); the presence of defensive wounds; signs of overkill; and the weapon used.

Parricide, Psychopathy, Crime Scene

I12 Narcissism and Violence: Criminological Understanding in a Homicide Case of Complete Decapitation

Ignazio Grattagliano, PsyD, University of Bari, Via Mauro Amoruso 68, Bari 70124, ITALY; Gabriele Rocca, Via De Toni 12, Genoa, ITALY; Alessandro Bonsignore, MD, PhD, University of Genova, Dept of Legal & Forensic Medicine, Via de Toni 12, Genova, Liguria 16132, ITALY; and Alfredo Verde, PhD, Via De Toni 12, Genoa, ITALY*

After attending this presentation, attendees will be able to recognize some of the characteristics of the relationship between narcissism and violence as well as the role of self-conscious emotions, including problems of self-esteem, in the etiology of a homicide case involving complete decapitation.

This presentation will impact the forensic science community by demonstrating: (1) how narcissistic behaviors have an important influence on forensic psychiatric evaluation results; and, (2) the need for reliable and more careful attention to both the subject's history as well as investigation and evaluation results.

According to the literature, narcissists tend to become violent when they are confronted with a threat to the self. Nevertheless, the role that provocation plays regarding the personality of the aggressor has not been studied very much from a clinical criminological perspective. In order to better assess the importance of understanding the findings of forensic psychiatric evaluations in such circumstances, this study provides a case of intra-familial homicide in which a nephew shot his uncle with a firearm due to an apparent territorial dispute, after which he completely decapitated the victim and disposed of the head.[1]

The information acquired during psychiatric investigation revealed a man who was deeply troubled by family conflicts that began in childhood; his relationship with his parents was characterized by deep ambivalence, as well as a lack of stable and well-defined object relations. These elements conditioned the development of thought processes and behavior, which are characterized by intense feelings of inadequacy toward one's fellow man. The offender coped with these emotions by avoiding social relationships and having the tendency to be highly controlling of the world around him. The subject also exhibited a deeply fragile identity that was brought about by the ambiguity he experienced during his childhood. It was for this reason that he felt empty and "out of place" and sought out idealized figures who would provide him with an apparent sense of stability that would allow him to construct an acceptable ego. Among these figures, one uncle stood out who was a role model for the subject from when he was very young. Later, the uncle became very strict in addition to being an obstacle to the offender's ability to develop a healthy self-esteem. This uncle also threatened to expropriate a piece of land that was allegedly owned by the nephew.

This homicide presents an important paradox: the gap between the obvious horror and high level of destructiveness of the act committed and the apparent banality of the motives and the reason he killed in such a manner. In fact, expert testimony has demonstrated that violent acts directed toward the uncle were neither premeditated nor the result of psychotic elements. On the criminological level, understanding the motive can be found in both the combination of the killer's personality (depression and narcissism) and the triggers for his violent behavior (the grudge he held against the victim, who was guilty of closing the door on their relationship). This was a source of great humiliation and embarrassment for the perpetrator as he believed this abandonment to be both unjust and unfounded. The ensuing suffering he endured triggered a desire for revenge related to the offenses he endured (the uncle's unacceptable behavior) and for the latest narcissistic wound that was inflicted. In other words, the key to reading the crime lies in comprehending how the perpetrator's personality not only developed but was also grafted onto the victim's.[2,3]

This homicide has its origins in the distorted relationship between the two subjects, one of whom was convinced to have incurred irreparable damage. The other is merely the projection of the perpetrator's true enemy, who, in reality, does not exist and is imaginary in nature. In cases such as this one, unlike in serial murders, there is a scapegoat onto which the accumulated anger and aggression may be directed. The victim becomes the unsuspecting symbolic intermediary and symbolic message of the murderer.

One wonders about the nature of the relationship between the perpetrator and the victim. What could have motivated such violence in which the nephew (the offender) first shoots a pistol at his uncle and subsequently decapitates him using a machete? Following psychiatric evaluation, the perpetrator was found to have a narcissistic personality.

After attending this presentation, attendees will better understand the psychopathic mechanisms underlying a phenomenon that spread in some realms of the Catholic church, namely the sexual abuse of minors.

This presentation will impact the forensic science community by serving as an example on which to base a scientific explanation of the phenomenon not only in terms of the victims, but also of the offenders.

The John Jay Report of 2004 revealed that in most cases of sexual abuse of minors that came to light concerning the Catholic church in the United States between 1950 and 2002, the episodes involved puberal, preadolescent, and adolescent minors, and so should really be referred to as ephebophilia (offence against minors aged 10 to 17 years). In total, 4,329 priests (accounting for 4.3% of parish priests and 2.5% of priests belonging to religious communities) were accused, on plausible evidence, of the sexual abuse of minors.[1]

Sexual abuse by priests seems to be a reactive behavior likely generated by insufficient emotional, affective, sexual, and relational maturity; in other words, a compensation mechanism that attempts to fill a void of affection, erotism, and sexuality. The abuse is seen and rationalized as similar to masturbation or pornography so that it does not tarnish the public function of a church minister. The choice of a minor is also due to the fact that satisfaction is thus sought outside the commitment of a relationship.

The John Jay College of Criminal Justice reported (referring to 2004) that 64% of the accused priests had abused males only, 22.4% females only, and 3.6% had abused both sexes. This has very often led to attributing the plague of sexual abuse to an increase in the number of homosexual priests.[1]

In fact, it is sexual immaturity, due to entering a seminary at an early age, and the lack of any sexual education, together with a strong vulnerability to narcissism (in relational terms), that leads the subject to turn his attentions to young people of both sexes. The youths are perceived as psychosexual peers. The sexual choice (mostly male) largely reflects opportunity rather than sexual leanings. It is easier to approach boys and there can be no fear of unwanted pregnancy, as is risked in relations with puberal or postpuberal girls. Finally, some priests conceive of celibacy as the abstention from sexual relations with women. Therefore, they convince themselves that sexual relations with boys do not contravene their vow of celibacy. The boy is seen simply as a means for obtaining pleasure in all safety.

Those most likely to suffer abuse by ministers, the victims, are generally young people with some social or physical lack, who are therefore vulnerable. At first, they feel "special" because they have been chosen by the charismatic figure of the priest, but later they develop conflicting, confused feelings during the episodes of abuse, and, finally, they feel betrayed and alienated from the church.

Sexual abuse by a priest is a sexual and relational betrayal perpetrated by a Father Confessor of the community — a man the child has learned to trust more than any other since birth. Therefore, it is a psychological shock for the victim, provoked by a violent overstimulation and personal betrayal that triggers the activation of various defense mechanisms. As a result of the sexual abuse, the child loses faith in the world as a relatively safe, foreseeable place, is unable to build a positive, confident self-image, and can no longer trust in relationships with others.[2]

In order to contain the phenomenon, it is not sufficient for physicians and psychologists to study only the victims; they need to analyze the perpetrators as well and conduct a scientific study of their traits, personalities, and internal operative models. This is not easy, because the institutions and public opinion are ill-equipped to deal with crimes that arouse such strong, aggressive reactions. The expert approaching the study of such phenomena could run into difficulty when faced with feelings and behaviors that test his/her empathic powers and so run the risk of collusion. The adoption of a scientific approach in the attempt to help the perpetrator, too, may interrupt the cycle of violence and thus offer real help for victims, past, present, and future.[3]

I14 Are There Similarities Between Forensic Technician and Sworn Peace Officer Stress?

Selena M. McKay-Davis, MFS, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Paul Stein, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

After attending this presentation, attendees will better understand the physical, psycho-social stress and traumatic experiences endured by forensic technicians and sworn peace officers. Moreover, this survey examined the levels of perceived job-related stress and mental health concerns in forensic technicians and sworn peace officers, both on duty and off duty.

This presentation will impact the forensic science community by promoting stress and mental health awareness for forensic technicians who investigate crime scenes and encouraging research into this relatively unexplored area.

The results of occupational stress, especially in forensic technicians, has not yet been fully appreciated by law enforcement agencies or human resources departments involved in recruiting and training these professionals. Understanding the lasting impact of occupational stress on forensic technicians will enable law enforcement agencies and their families to proactively train, recognize, and help forensic technicians cope with many job-related stressors.

This study hypothesized that sworn peace officers and forensic technicians would report similar levels of overall job stress while on duty and that both occupations would report significant physical and psychological impacts as a result of their crime scene-related occupations. Forensic technicians provide field services at every possible type of crime scene with varying levels of direction and support from sworn peace officers. The primary field services assigned to forensic technicians includes identifying, documenting, collecting, preserving, and conducting preliminary analysis of physical evidence in relation to criminal investigations. They are constantly exposed to the stressful world of violent crime. As a result, forensic technicians can also experience physical and psychological stress, violence, and security vulnerability similar to other law enforcement first responders; however, unlike the latter, there is a lack of research regarding the impact of the stress and danger experienced by forensic technicians on their mental and physical health.

This has now been addressed in this study through the development and administration of an anonymous survey that gathered scaled, yes/no, and fill-in-the-blank type choices to 25 basic questions regarding perceived stress, physical danger on and off duty, physical and psychological life impact of job-related duties, preferred stress management networks, and coping strategies. Participants included forensic technicians and sworn peace officers employed at California law enforcement agencies with one or more years of experience processing major crime scenes.

Forensic technicians (N=37) and sworn peace officers (N=36) submitted qualifying surveys. The results indicated that perceived on-duty stress was significantly higher ($P \leq 0.05$) for the forensic technicians (M=3.50, S*tandard Deviation (SD)*=.99) compared to the sworn peace officers (M=2.99, SD=.97) based on the scaled (1-5) responses. The off-duty stress rating was higher for forensic technicians than sworn peace officers, but was not statistically significant. It was noted that of the 54 pre-selected stressors common to law enforcement, forensic technicians and sworn peace officers shared 10 of the top 20 ranked stressors. Two-thirds of all stressors were ranked statistically similar between the two occupations. Forensic technicians reported negative job-related impact responses in 14 out of 17 physical and psychological impact categories, whereas sworn peace officers reported negative job-related impacts in only 8 of the categories. Furthermore, forensic technicians and sworn peace officers exhibited statistically similar career-related impacts in 10 of the 17 physical and psychological categories. Perceived danger was experienced less frequently by forensic technicians compared to sworn peace officers, but was not statistically different. Last, both forensic technicians and sworn peace officers reported using friends and family for stress management more frequently, followed by peer support, and ,last, mental health resources. When compared to sworn peace officers, forensic technicians reported lower availability, awareness, and utilization of agency mental health support services, something this study suggests needs to be addressed.

The survey responses from this study suggested a similarity of work-related stressors that are shared by both forensic technicians and sworn peace officers; however, it appears that the perceived effects of stress for forensic technicians exceeded that of sworn peace officers. These findings indicate that the initial hypothesis, in part, can be rejected.

Forensics, Crime Scene Investigator, Stress

I15 Variation in Genes Affecting Dopamine Turnover, Oxytocin, and Serotonin in Inmate and Student Populations

Elizabeth Chesna, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Ana I. Blanco, MS, 805 Hackberry Road, #2, San Juan, TX 78589; Charity M. Beherec, MS, Texas DPS, 1404 Lubbock Business Park Boulevard, Ste 200, Lubbock, TX 79403; Gabriella Cansino-Jones, MS, 11350 Four Points Drive, Apt 1121, Austin, TX 78726; Peyton Gandy, MSFS, 2052 Myrtle, Unit 3, Dover, DE 19901; Jessica Wells, PhD, Department of Criminal Justice, 1910 University Drive, Albertsons Library, Boise, ID 83725-1955; Danielle Boisvert, PhD, Department of Criminal Justice and Criminology, 816 17th Street, Huntsville, TX 77340; Todd Armstrong, PhD, Sam Houston State University, College of Criminal Justice, 816 17th Street, Huntsville, TX 77320; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340; and David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will gain knowledge concerning the relationship between Single Nucleotide Polymorphisms (SNPs) associated with genes of oxytocin, serotonin, and dopamine as well as specific behavioral traits. Furthermore, attendees will learn about these genetic differences in an inmate population compared to a student control population.

This presentation will impact the forensic science community by demonstrating the genetic influence on aggressive and antisocial behavior. These behaviors have become a major problem as the United States currently has the highest incarceration rate in the world. Moreover, antisocial and aggressive behavior are two of the leading causes of mental health referrals. The strong heritability and environmental issues surrounding criminal activity indicates that a genetic underlying can help explain at least some features related to these behaviors.

Behavior is a complex process influenced by both genetics and the environment. Some neurotransmitters have been associated with social behavioral traits, including: Oxytocin (OXT), Serotonin (5-HT), and Dopamine (DA). Certain genes (such as genes of receptors, transporters, and enzymes involved in metabolic pathways of these neurotransmitters) are associated with these neurotransmitters. These genes contain polymorphic sites that can be studied to relate or link them to certain behavioral traits. SNPs are single-base variations found at a specific location on the genome and are considered to be the most abundant type of polymorphism in humans. While some associations between SNPs and behavior have been made, this study analyzes multiple SNPs within the three most common ethnic groups in the United States (Caucasian, Hispanic, and African American) in both inmate and student populations.

This study analyzed a total of 17 SNPs: 12 SNPs associated with DA turnover (rs2283739, rs1799836, rs3788862, rs909525, rs979605, rs740603, rs737865, rs739388, rs1611115, rs165599, rs4680, and rs129882), two SNPs associated with the OXT gene (rs877172 and rs4813625), two SNPs related to the serotonin receptor (5HTR2A) (rs6314, and rs6311), and one SNP located within the serotonin transporter gene (5-HTT) (rs25531) using Single-Base Extension (SBE). A student sample set (N=200) and inmate sample set (N=100) were genotyped, and individuals participated in a survey designed to assess 31 behavioral traits.

Significant associations were found within the control population for two SNPs associated with OXT and 5-HT: rs6314 and antisocial behavior in Hispanics (p=0.008), and rs877172 and antisocial behavior in Caucasians (p=0.001). Furthermore, statistically significant differences in haplotype frequencies were observed in inmate vs control populations in SNPs associated with dopamine turnover (monoamine oxidase; MAOA). These results indicate that these SNPs play an important role in social behavior, including antisocial behavior.

The results of this study provide some evidence that OXT, 5-HT, and enzymes related to DA turnover can influence behavior. It was found that SNPs associated with these neurotransmitters influence antisocial behavior. These behavioral SNPs may be used in early prevention or treatment of psychiatric disorders, which have a large impact the medical field and criminal justice system. Furthermore, understanding the influence of OXT, 5-HT, and DA on behavior may help explain the etiology of aggressive and antisocial behavior.

Single Nucleotide Polymorphism, Oxytocin, Dopamine

I16 Phenotypic Characteristicts in Different Groups of Psychopathic Individuals

Donatella La Tegola, PhD, University of Bari, P.za Giulio Cesare, 11, Bari 70124, ITALY; Alan R. Felthous, MD, Saint Louis University School of Medicine, Forensic Psychiatry Division, 1438 S Grand, St. Louis, MO 63104-1027; Roberto Catanesi, MD, P.za Giulio Cesare, Bari 70124, ITALY; Domenico Montalbò, MD*, p.za G. Cesare, 11, Bari 70124, ITALY; and Felice F. Carabellese, MD, University of Bari, Section of Forensic Psychiatry, p.za G. Cesare, 11, Bari 70124, ITALY*

After attending this presentation, attendees will be able to recognize phenotypic characteristics in different groups of psychopathic individuals.

This presentation will impact the forensic science community by helping identify any phenotypic gender-specific factors related to psychopathy.

Psychopathy in a personality disorder entailing traits and behaviors that have a negative impact on individuals and society. The diagnostic criteria for psychopathy has a long history in psychiatry and overlaps with criteria of other personality disorders, especially antisocial personality disorder and narcissistic personality disorder. These include egocentricity, superficial charm, a grandiose sense of self-worth, the need for stimulation, pathological lying, a manipulative approach to relationships, a lack of remorse and guilt, callousness, a lack of empathy, impulsivity, irresponsibility, and an inclination toward criminal behaviors. The confusion in the use of the term "psychopathic" could be explained by different phenotypic characteristics in different groups of psychopathic individuals and by gender differences.

The Psychopathy Checklist-Revised (PCL-R) is one of the most commonly used measures of psychopathy.[1] The total score of PCL-R is composed by interpersonal and affective (factor 1) scores and lifestyle scores (factor 2). The current study investigated discrepancies in scoring of PCL-R between a male psychiatric forensic sample, a female psychiatric forensic sample, a female prisoner sample, and female prisoners who had been convicted for Mafia-related crimes. Prior research on psychopathy has primarily focused on the problem in men. Only a few studies have examined whether psychopathy even exists in women, and, if so, how the disorder manifests itself within them. Research on differences between the sexes has suggested that psychopathy is less frequent in women than in men; however, it is debated whether the observed differences in the occurrence of male and female psychopaths reflect actual physical differences in the frequency of psychopathy, or whether those differences reflect factors related to aspects of the diagnostic tools and the terminology used, which surface when these criteria for evaluating psychopathy are applied to women. This study has shown how the psychopathic individuals in the different female samples demonstrated similar phenotypic characteristics. On the contrary, differences between the sample of women and that of men were observed: female sufferers more often seem to demonstrate emotional instability, verbal violence, manipulation of social networks, and, to a lesser degree than male psychopaths, criminal behavior and instrumental violence.

The importance of a correct diagnosis of "psychopathy" relates to its potential usefulness with regard to issues such as the choice of treatment strategies, treatment evaluation, risk assessment, and the prediction of future violence. If one assumes that the same research results achieved in studying men are automatically transferable to women, one does risk misjudgments of enormous consequence. For instance, within the field of forensic psychiatry, the diagnosis of psychopathy is often used to justify the length of prison terms. In some countries, indefinite prison terms can be given to criminals with this diagnosis. The diagnosis of psychopathy may also be used to justify patients' exclusion from treatment programs as well as other punitive measures.

Psychopathy, Gender-Specific Factors, Phenotypic Characteristics

I17 The Psychopathic Semantics of Serial Killer Theodore Robert Bundy

Kaveh Cyrus Ghaedi, DO, 32 Bartle Court, Apt B, Highland Park, NJ 08904; and Ross Crosby, PhD, Neuropsychiatric Research Institute, 120 Eighth Street, S, PO Box 1415, Fargo, ND 58107-1415*

The primary objective of this study is to perform an exploratory analysis using quantitative linguistic analysis software, Linguistic Inquiry and Word Count (LIWC), to study how one prototypical psychopathic serial killer used language within various contexts over time.

This presentation will impact the forensic science community by providing exposure to a novel and relatively affordable way of gleaning insights into psychopathology by looking at individual differences in language use.

Theodore Robert Bundy (1946-1989), or "Ted," was the quintessential psychopathic serial killer, prototypical of how the clinical construct was extensively detailed *qualitatively* by psychiatrist Dr. Hervey Cleckley[1] and later further refined and *quantified* by psychologist Dr. Robert Hare.[1-3]

Psychopathy is a clinical construct loosely characterized by a cluster of severe affective, interpersonal, and behavioral components that include, but are not necessarily limited to, traits such as: superficial charm, egocentrism, glibness, conning/deceptiveness, pathological lying, poor behavioral controls, callous lack of empathy, and/or lack of remorse. Although related, psychopathy is often incorrectly equated with the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) diagnosis of Antisocial Personality Disorder (ASPD), a relatively heterogeneous categorical construct.

One of the many characteristics that distinguish psychopaths from non-psychopaths is the way they employ language in unusual ways.[4-7] Their words are sometimes perceived as hollow shells devoid of affective content, a phenomenon that Cleckley referred to as "semantic aphasia."[1] Language is the most common and reliable manner to convey our thoughts and emotions so that others can understand us.[8] Our words reflect who we are and how we relate to others. Researchers have long studied the semantics of subjects with various psychopathologies to glean more insights into them and their behaviors; however, such endeavors often proved tedious, time consuming, expensive, and often had problematic interrater reliability.[9] With the advent of more affordable and powerful computers, we can now empirically and reliably accomplish in seconds or minutes what may have previously taken months or years. One tool that circumvents the aforementioned issues is the LIWC software.[9]

LIWC (pronounced "Luke") is a transparent text analysis program developed by psychologist Dr. James Pennebaker and his students at the University of Texas at Austin.[9] It counts words and places them in psychologically meaningful categories.[10,11] These empirical dimensions have been extensively studied, well validated, and applied to detect meaning in a wide variety of circumstances, such as predicting mild cognitive impairment, detecting deception in written and spoken language, and understanding individual differences between attempters and completers of suicide.[12-16] To date, relatively few studies have used LIWC to understand psychopathy, and, as of this writing, no published research has used it to study serial killers.

The primary objective of this study is to perform an exploratory analysis using LIWC to study how one prototypical psychopathic serial killer (Bundy) used language within various contexts over time. The dataset includes transcripts of police interrogations, personal correspondence, courtroom testimony, and interviews with the press collected by this study from books, video footage, and original documents from state archives in both Florida and Washington. The goal of this presentation is to introduce attendees to the powerful and affordable potentials of using LIWC in forensic investigations by illustrating how it can reliably relate language patterns to psychopathology.

I18 The Psychopathological Profile of the Female Serial Killer: From Homicide to Cannibalism — The True Story of the "Soapmaker of Correggio"

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Paola Frati, PhD, Dept of Anat Histol Forensic and Orthop Sciences, University of Roma "La Sapienza," Viale Regina Elena 336, Roma 00161, ITALY; Valerio Riccardo Aquila, Via Dante Alighieri, Crotone, ITALY; and Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY*

After attending this presentation, attendees will better understand the role of the psychopathological profile in female serial killers and, in particular, the role that gratification plays in inducing the serial killer to commit murder.

This presentation will impact the forensic science community by highlighting that, for the female serial killer, a psychopathic personality and child sexual abuse are common features.

In most cases reported in the literature, serial killers are men. This study sought to analyze cases of female serial killers. A literature review was performed using the Pubmed NCBI search engine with "female serial killer" as the key word. There are few cases in the literature concerning female serial killers. This work seeks to tell the story of a female Italian serial killer.

An investigation of the mental processes with the analysis of her memoir, *Leonarda Cianciulli, An embittered soul's confessions,* attributed to this serial killer, was performed and the data compared. This study reports the case Leonarda Cianciulli. She was born in 1892, in Mantella, Italy. Her childhood was difficult: "I was a weak child … my parents treated me like a weight … I attempted to hang myself twice …." She had 17 pregnancies, but only four sons survived. These children became an obsession with her.

Cianciulli attended three friends, who were single, middle-aged women. The first victim was Faustina Setti. Leonarda told her she had found a husband for her. Since Faustina was semi-literate, Leonarda volunteered to help her write a letter. The same day, she killed her friend with an ax, then dissected the corpse. She wrote, "I threw the pieces into a pot … I made a lot of pastries … also Giuseppe (her son) and I ate them." The second victim was Francesca Soavi, who wanted to find an occupation. Cianciulli claimed to have found her a job and convinced her friend to write to her acquaintances regarding her departure. Leonarda rushed the woman with an ax and killed her. The third victim was Virginia Cacioppo, an opera singer who lived in poverty. Leonarda claimed to have found her a job. About her, Cianciulli said, "She ended up in the pot, like the other two ... after a long time on the boil, I was able to make some most acceptable creamy soap. I gave bars to neighbors and acquaintances."

After numerous investigations (victims' blood and dentures were found in her home), it was considered certain that the woman had committed the crimes. She was sentenced to 30 years in prison and 3 years in a criminal hospital. The woman, in the Aversa mental hospital, said, "I killed … only for mother's love." Cianciulli died of cerebral apoplexy in prison.

From a psychiatric point of view in serial killing cases, the murders are premeditated, based on obsessions that become an irresistible impulse to kill. The necessary conditions for homicide are the fantasy, the symbolism, the ritualism, and the compulsion. The killer takes with him/her something belonging to the victim. In fact, Cianciulli confessed that she killed the women, destroyed the bodies by boiling them, made soaps, and kept the blood to mix with milk and chocolate to make cookies for her sons, believing this would save them from a mysterious death. Leonarda identified herself with the goddess Thetis, who wanted to give her sons immortality. The victims always have features in common. The perpetrator has a criminal record and prefers victims who are geographically close. According to scientific studies, serial killers are victims of childhood traumas. In these murderers, psychopathological personality disorders, a desire for control, delusions of omnipotence, and sexual motives are common denominators.

This historic case is unique for manners; the sexual motive is absent, but it clearly represents a profile of the female serial killer. The feelings of parental abandonment and the sons' deaths caused frustrations and a desire to control of events. The choice of weapons, such as hatchets or axes, was related to her constitution of being a small woman who needed harmful weapons. The dissection of the bodies was performed for two reasons: to dissolve the traces and to retain fetishes as rituals.

Forensic Science, Female Serial Killer, Homicide

I19 Empathy for the Psychopathic Patient

Paulina Riess, MD, Bronx Lebanon Hospital Center, 1276 Fulton Avenue, Bronx, NY 10456; and Ahmed Albassam, MD*, Bronx Lebanon Hospital Center, 1276 Fulton Avenue, Bronx, NY 10456*

The goal of this presentation is to provide a brief review of the literature on this subject, along with the means to cross barriers of negative countertransference when navigating similar cases.

This presentation will impact the forensic science community by demonstrating how positive countertransference has been directly correlated to improved patient outcomes, particularly in psychiatry, as the therapeutic alliance remains a central focus in treatment.

Literature on this topic is extensive; however, literature on positive countertransference for criminals and psychopaths is scarce. Developing positive countertransference remains challenging for some clinicians when faced with particularly difficult patients. When clinicians are noted to struggle in their supervision to develop positive relationships with patients, supervisors recommend empathizing with such patients as a way of developing positive feelings toward them; however, certain patients, particularly psychopaths, challenge a clinician's ethics and fundamental beliefs. Hence, developing rapport with such patients remains difficult for many clinicians. Lastly, it is important to differentiate between what is positive countertransference induced by the patient's attempt to manipulate, appeal, and please the provider versus identification of true and genuine empathy on the provider's part.

The phenomenon of countertransference was first defined publicly by Sigmund Freud in 1910 as being the result of a patient's influence on the psychiatrist's unconscious feelings. The concept of countertransference was originally considered a barrier in psychotherapy, whether positive or negative. Freud originally thought it should be identified and rooted out; however, it is now considered very important in the therapy process. Otto Kernberg provided psychiatry with a totalistic way of looking at countertransference. When juxtaposed with Freud's theory, it encompasses the complete emotional reaction of the therapist toward his patient. Heinrich Racker linked countertransference with empathy. This study would like to implement Racker's model of countertransference for the purpose of this presentation.

Most of the available literature on this topic suggests that empathy for psychopathic patients among psychiatrists is quite rare and only occurs in the context of voyeuristic curiosity or envy of the criminal's ability to cross social and moral barriers. In this presentation, it is argued that genuine empathy for such patients is possible. Here is described the experience of two residents, both pursuing careers in forensic psychiatry, who provided care for such a patient with concordant rapport. This particular patient had a violent background with severe psychopathic traits; however, both providers were capable of appreciating the patient's pathology, and identifying his feelings of loss, isolation, illness, and decay. This presentation will also provide a brief review of the literature on this subject, along with the means to cross barriers of negative countertransference when navigating similar cases.

Psychopathy, Countertransference, Empathy

I20 How Just Is Manifest Injustice (MI)?: Evaluating the Use of Manifest Justice in the Washington State Juvenile Rehabilitation Administration

Nicole Sussman, MD, Cambridge Health Alliance, 9 Austin Park, Unit 2, Cambridge, MA 02139; Terry Lee, MD, University of Washington School of Medicine, 2815 Eastlake Avenue, E, Ste 200, Seattle, WA 98102; and Kevin Hallgren, PhD, University of Washington, 1959 NE Pacific Street, Box 356560, Seattle, WA 98195-6560*

After attending this presentation, attendees will be able to: (1) appreciate the juvenile justice system's mission to provide rehabilitation and treatment for youths, as well the existence of policies that support this mission (i.e., MI); (2) recognize the disproportionate minority contact and racial inequality in youth sentencing that exists within the juvenile justice system; (3) understand the circumstances that are contributing to the sentencing disparity identified with the use of MI and the importance of adequate community services for these youths; and, (4) inspire efforts to engage in advocacy for youths and families engaged in the juvenile justice system.

This presentation will impact the forensic science community by illuminating ongoing sentencing disparities within the juvenile justice system. The hypotheses generated to explain the findings of this study point to critical system-wide injustices that need to be addressed and better understood. Further research is needed to ensure laws are being used justly across all ethnic and minority groups.

Objectives: In the Washington (WA) State Juvenile Code, a provision called Manifest Injustice (MI) allows judges to sentence youths outside of the standard sentencing range guidelines. Racial inequality in juvenile justice sentencing is well established.[1] This investigation evaluates how MI is used across racial groups among WA youths involved in the Juvenile Rehabilitation Administration (JRA). It was hypothesized that MI would be used more frequently to decrease sentences of Caucasian youths and to increase sentences of minority youths.

Methods: De-identified and aggregated administrative data of the JRA residential population (n=436) was obtained for youths in custody on 1/11/16. The goal was to compare rates of JRA involvement and MI between racial minorities and Caucasian youths. Rate ratios were used to compare the proportions of WA state and JRA-involved minority youths who received MI Down or MI Up/In with Caucasian youths.

Results: African American (AA) youths were more than seven times as likely to be involved in the WA Juvenile Justice System than Caucasian youths (RR=7.85, p=<0.0001), while Mixed youths were three times more likely (RR=3.17, p=<0.0001), and Hispanic youths were 40% more likely (RR=1.40, p=0.0131). Although results did not meet statistical significance, there was a trend toward AA and Mixed youths having MI used to decrease their sentence less than Caucasian youths. AA youths were about half as likely to have MI used to increase or intensify their sentence compared to Caucasian youths (RR=0.49, p=.002), whereas Mixed youths were 42% less likely (RR=0.58, p=.04).

Conclusions: Finding that Caucasian youths were more likely than AA and Mixed youths to have their sentences increased or intensified was contrary to what was hypothesized. More AA youths reside in the urban and more liberal parts of the state where judges may be more progressive and less likely to use MI to intensify sentences. More diversion programs are available in the urban areas of the state, some target minority youths, and more AA youths are transferred to adult court; all of these actions reduce the likelihood of minority youths receiving sentence intensification. Judges in the rural areas of the state, which are Whiter and have fewer treatment resources, may be using MI to send youths into facilities to access treatment. It is imperative that community behavioral health services are available so youths and families can be justly served.

Juvenile Justice, Mental Health, Disparities

I21 Potential Effects of Legalized Recreational Cannabis on Youth

Jeramy R. Peters, DO, Oregon Health and Science University, 3181 SW Sam Jackson Park Road, Portland, OR 97239; and Joseph Chien, DO, VA Portland Health Care System, 3710 SW US Veterans Hospital Road, Portland, OR 97239*

After attending this presentation, attendees will appreciate the growing national trend toward legalization of recreational cannabis and understand the potential effects that acceptance of cannabis use and the growing cannabis industry may have on the vulnerable population of children and adolescents.

This presentation will impact the forensic science community by increasing awareness of the specific vulnerabilities of children and youths to cannabis products that are transforming due to a changing legal stance toward recreational use. Clinicians will be more aware of changes in Tetrahydrocannabinol (THC) concentration, means of consumption, and packaging that potentially have an impact of pediatric use of cannabis. Clinicians may be better able to counsel their patients on marijuana use and preventing inadvertent consumption of cannabis products by children.

Currently, recreational cannabis for adults is legal in eight states and the District of Columbia, and the list is growing.[1] This presentation explores current trends in legalization of recreational cannabis, the growing cannabis industry, and changes in THC potency and means of consuming that have resulted from this legal shift; however, a recent report by Han et al. examining data from the National Survey on Drug Use and Health from 2002-2014 found that youth cannabis use has been declining since 2011.[2,3] This data is in contradiction to what might be expected with increasing acceptance of cannabis use.

As more states begin to legalize recreational marijuana, it remains to be seen if this downward trend in youth cannabis use will continue. This presentation will examine how some of the marketing efforts of the cannabis industry for new forms of cannabis, such as edibles, are being packaged to appear nearly indistinguishable from candy products and may target children or be mistakenly consumed by children. The current trend of legalizing recreational marijuana use may have an adverse effect on the vulnerable youth population. The potential effects of the higher visibility of cannabis products, as well as higher potency products, is also explored in the context of research that suggests that younger populations may be more vulnerable to cognitive impairment and more susceptible to developing psychosis with cannabis use.[4]

Cannabis, Legalization, Adolescents

I22 Females Who Sexually Offend: Characteristics and Behaviors

Emily D. Gottfried, PhD, MUSC, Charleston, SC 29407; and R. Gregg Dwyer, MD, EdD*, Medical University of South Carolina, Community & Public Safety Psychiatry Division, 29-C Leinbach Drive, Charleston, SC 29407*

The goal of this presentation is to add to the empirical literature on sexual offending by females, given the paucity of such resources available to those involved in assessment, treatment, and prevention.

This presentation will impact the forensic science community by increasing empirically based understanding of females who sexually offend, which, in turn, will improve clinicians' abilities to effectively evaluate clients for diagnosis, treatment, and risk reduction.

Female sex offenders are an understudied population and are often regarded as being rare; however, as a recent meta-analysis reported, sex offenses committed by women are more prevalent than it previously appeared.[1] Specifically, Cortoni and colleagues reported that although only approximately 2% of sex offenses reported to law enforcement are perpetrated by women, victimization surveys report a much higher (approximately 12%) instance of sexual offending by women.[1]

This presentation will include data on 13 women who were convicted of sexual offenses and were assessed for civil commitment under the South Carolina Sexually Violent Predator (SVP) Act. The mean age was 32.85 (*Standard Deviation (SD)*=6.50, range 23-44) at time of assessment. The sample had one to two victims (*M*=1.23, *SD*=0.44) each and 30.8% had female-only victims, 61.5% had only male victims, and 7.7% had both female and male victims. The victims' ages ranged from 3 to 17, with the mean age of the offenders' youngest victim being 12.54 (*SD*=4.41). The convictions included Criminal Sexual Conduct with a Minor, Lewd Act on a Child, Criminal Solicitation of a Minor, Promoting Minor Prostitution, and Sexual Exploitation of a Minor. Two of the women had prior convictions for sexual offenses and four had prior convictions for felony offenses. Nine (69.2%) had victims who were unrelated, three (23.1%) had related victims, and one (7.7%) had both related and unrelated victims. None of the women had been diagnosed with a paraphilic disorder. Nearly 70% (*n*=9) had been diagnosed with a mental illness to include schizophrenia, bipolar disorder, anxiety disorder, substance use disorders, post-traumatic stress disorder, and an unspecified depressive disorder. More than 75% (*n*=10) reported experiencing childhood sexual abuse. Only one of the women was referred for further review for potential civil commitment under the SVP Act. A comparison with a matched set of male sex offenders will be included, noting similarities and differences, with discussion of likely etiologies of each.

Practical application of findings for diagnostic and risk assessments and treatment planning is presented. Next steps in developing this area of limited evidence base are outlined for consideration.

Female Sexual Offenders, Sexually Violent Predators, Women

I23 High-Functioning Autism and Violence Risk

Lindsay Howard, DO, Oregon Health and Science University, 3181 SW Sam Jackson Park Road, Portland, OR 97239; Will Frizzell, MD, Oregon Health and Science University, 3181 SW Sam Jackson Park Road, Portland, OR 97239; and Joseph Chien, DO, VA Portland Health Care System, 3710 SW US Veterans Hospital Road, Portland, OR 97239*

After attending this presentation, attendees will better appreciate how Autism Spectrum Disorder (ASD) may be an underrecognized condition requiring different approaches to the assessment and mitigation of violence risk. Attendees will also gain awareness of special considerations in the assessment and treatment of potentially violent patients with high-functioning autism.

This presentation will impact the forensic science community by helping clinicians who routinely assess patients for violence learn to incorporate assessments for autism spectrum disorder (i.e., Autism Spectrum Quotient). Clinicians will learn to utilize recommended strategies for mitigating risk specific to high-functioning autistic individuals.

This presentation describes a case of a man admitted to an acute inpatient psychiatry ward with vague symptoms of anxiety and difficulty controlling his anger, and indirectly alluding that he was a threat to harm himself or others. Prior to his admission, he had his first visit with his outpatient psychiatrist, where he reported that he was receiving "ideas" to harm himself and others. The outpatient psychiatrist diagnosed him with likely autism spectrum disorder and recommended he be hospitalized for further assessment. On admission to the inpatient ward, the patient was fixated on themes of government conspiracies and rights to bear arms, making it difficult to obtain a reliable history. He also reported trouble connecting with others, and on further evaluation, reported that he had been diagnosed as being on the autism spectrum as a child. The patient completed the Autism Spectrum Quotient, and scored in the low range of the autism spectrum (formerly Asperger's Disorder). He was treated with a low dose of risperidone (titrated to 1mg twice daily), which resulted in improved mood and less irritability. He no longer reported thoughts or messages to harm himself or others at the time of discharge, and a course of psychotherapy aimed at improving social skills was recommended.

The relationship between high-functioning autism and violence is poorly understood. Media representation of recent mass killers, such as perpetrators of the shootings in Sandy Hook Elementary School, Newtown, CT, in 2012 and Santa Barbara, CA, in 2015, would seem to suggest a link between violence and individuals who appear to be on the autism spectrum. Research to date has not supported this link. Daniel Im reviewed the literature to explore ASD and violence from 1943 to 2014 and found no conclusive evidence of a connection.[1] In this review, he did identify some risk factors specific to individuals with ASD that may increase violence risk among these individuals, such as problems with emotional regulation and deficits social-cognitive functioning. This presentation proposes that early identification of ASD may assist in preventing violence by allowing the identification and treatment of these unique risk factors, which otherwise may be missed if the diagnosis is not considered. Assessment and treatment strategies for patients with possible ASD who are at a risk for violence will be discussed.

Autism Spectrum Disorder, Violence, Risk Assessment

I24 Factitious Disorder Imposed on Another: A Life-Threatening Italian Case

Sara Simona Racalbuto, PsyD, Department of Pediatric Emergency, Turin, Piazza Polonia 94, Torino 10100, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Francesco Lupariello, MD*, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, A.O.U. "Città della Salute e della Scienza," Turin, ITALY; and Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will better understand Factitious Disorder Imposed on Another (FDIA), also termed Munchausen Syndrome by Proxy in some jurisdictions, which should be one of the possible differential diagnoses of recurring health issues in children.

This presentation will impact the forensic science community by emphasizing the importance of a multidisciplinary evaluation of suspected somatoform disorders perpetrated by caregivers.

FDIA continues to mystify health care professionals, law enforcement officials, and the judicial system.[1] Even though the first cases were described in 1977, it remains puzzling as to why a parent would want to induce fictitious symptoms and illnesses onto a child.[2] Many professionals do not consider FDIA as a diagnosis because the parent, usually the mother, is extraordinarily able to convince them that she is a "good" mother and wants the best for her child.[3]

This study reports a severe case of FDIA managed in the multidisciplinary unit dedicated to the evaluation of suspected abused children ("Bambi") of the "Ospedale Infantile Regina Margherita" in Turin, Italy. After an 11-year-old boy had several prior hospitalizations in multiple other facilities over a period of eight years, he was hospitalized in the Endocrinology Department by his mother. The child was treated for various problems, including Hirsprung Disease and diabetes mellitus type 1 with life-threatening ketoacidosis. He was also subjected to invasive procedures (cystoscopy with bladder neck incision, rectal biopsy, intestinal resection with coloanal anastomosis, and botulin toxin injections). In the consultation processes with the "Bambi" team, the mother and the boy were interviewed separately. The child described himself drawing "Pinocchio" (a notorious character known for being a liar). In interactions with the mother, he always appeared dominant, blackmailing, and manipulative. The mother displayed a facility with medical language, even though she was not a health professional, and strongly identified with the role of therapist. She also displayed tentative and inconsistent parental behaviors and inefficient coping skills. The mother conveyed that she was the only caregiver and refused support from her partner, who had left her and their children a few months earlier. The woman had always cared for sick relatives and showed pride for this role. Her whole life had been focused on the illnesses of others, and she displayed considerable expertise in working with the social workers to obtain economic and other welfare benefits. A discrepancy between the severity of the reported facts and the woman's emotional state was evident. A careful global assessment of clinical and family history found the heterogeneity of the child's symptoms and their escalation over time. There was a lack of correlation between the symptoms' progressions and therapies. There was always a temporal correlation between the stressful life events of the mother (death of her mother, abandonment by her husband) and the subsequent clinical deterioration of the child. Furthermore, when the woman was engaged in taking care of other relatives, the clinical condition of her son improved and his hospitalizations decreased.

After a comparison between the "Bambi" unit personnel (pediatrician, medical examiner, psychologist, and trained nurse) and physicians of the Endocrinology Department, the situation was referred to the judicial authority, formulating the hypothesis of FDIA. Thanks to a brief period of intense observation, it was documented that a ketoacidosis crisis had been induced by incongruous insulin delivery by the mother. The subsequent psychiatric evaluation confirmed the mother's diagnosis. The overall assessment of the case by a multidisciplinary team was fundamental to formulating the proper diagnosis of the mother's psychological pathology. For many years, the child had been a victim of this particularly subdued form of maltreatment and, upon several occasions, had been subjected to unnecessary life-threatening interventions. In fact, the child's false symptoms (in particular, the ketoacidosis crises) were an expression of the mother's need to maintain the only function she had in her life: to be a caregiver. The diagnosis was further complicated by the fact that the child was actually suffering from various diseases, which were overtreated by the mother.

This presentation provides attendees with a better knowledge of FDIA. This diagnosis should always be kept in mind when health care professionals evaluate cases of chronic pediatric diseases in the presence of an inappropriate correlation between symptoms and therapeutic efforts.[4]

Child Abuse, Differential Diagnosis, Munchausen Syndrome By Proxy

I25 Clinical Psychiatry and Neuropsychiatry in the Forensic Context

Vernon M. Neppe, MD, PhD, Pacific Neuropsychiatric Institute, 6300 Ninth Avenue, NE, Ste 353, Seattle, WA 98115*

The goals of this presentation are to: (1) educate mental health professionals in three important medicolegal areas; (2) provide greater understanding of Tardive Dyskinesia (TD) and of Traumatic Brain Injury (TBI); and, (3) demonstrate methods to practice better psychiatry and more properly evaluate patients clinically and forensically. This presentation will provide a greater understanding of clinical psychiatry and neuropsychiatry in the forensic context and consists of lectures on the forensic aspects of TD, TBI, and proper evaluations.

This presentation is applicable to all psychiatrists and mental health professionals. This presentation will impact the forensic science community by raising awareness of the need for careful clinical care, prophylaxis, and proper evaluations and will highlight principles generalized to other areas of civil and criminal forensic practice.

Psychiatric evaluations include appropriate examination, ongoing assessments, diagnosis, management, prognosis, attributions of proximate causality, and damages. Prior medical histories are critical. Forensic data has an even higher standard emphasizing causality attributions and prognoses.

Two key common illustrative medical conditions are: (1) Tardive Dyskinesia (TD) — a complex neuroleptic-prescription-induced, sometimes irreversible, movement disorder. Here, physicians commonly err in management, and the pharmaceutical industry may not properly put "warnings" on drug labels; and, (2) traumatic brain injuries — these could be repeated and catastrophic. Proper acute and chronic care is complex and sometimes additive to previous events.

TD is possibly the most well-known but often missed drug-induced neuropsychiatric forensic condition. TD is sometimes incurable and induced by long-term prescription neuroleptic treatment (antipsychotic medications as well as gastro-intestinal medications, such as metoclopramide). Civil litigation against prescribers (physicians, particularly psychiatrists) and the pharmaceutical industry is a common, major consideration. Several steps for ensuring ongoing proper clinical evaluation and management are often neglected, including early detection, appropriate follow-up, including testing, outside specialized expert referral, differential diagnosis, and recognition of patients at risk. Evaluations include an effective specific TD scale (Neppe's STRAW scale) with other formal examinations (AIMS, Simpson-Angus and possibly SCT Hans). Videotaping monitors progress. Management requires prophylaxis, early recognition, and ongoing interventions. It has been found that off-label, high-dose buspirone treatment (1989-2017 experience) is extraordinarily successful, efficacious, cost-effective, and safe. This study regards it as far preferable to expensive, tetrabenazine derivatives (e.g., valbenazine), with theoretically significant side-effects and ostensibly incomplete control long-term.

Traumatic brain injury (TBI) is very common with variable symptomatology: (1) non-recognition of the blow, but still having subtle changes; (2) concussion is common with several presentations, but sometimes incorrectly labeled; (3) unrecognized, seldom diagnosed yet treatable focal cerebral abnormalities; this includes particularly temporal or frontal lobes dysfunctions and uncommonly, subtle changes; (4) ranges through to prolonged deep coma, where acute lengthy hospitalization and rehabilitation is specialized. Management clearly varies acutely compared with the subacute and chronic residual phases; (5) recently, Chronic Traumatic Encephalopathy (CTE) with repetitive TBI has become increasingly recognized in contact sports and has major potential medicolegal implications; and (6) subtle differences must be recognized. To facilitate, the presentation has classified head injury forensically and clinically.

Some management nuggets include: (1) missing the subtle focal injuries can be disastrous in clinical and forensic consequences, and yet can be commonly helped with appropriate, but often unprescribed, medications (including anticonvulsants and azapirones); (2) cognitive rehabilitation (previously expensive and lengthy) has largely been replaced by appropriate computer programs facilitating easier, often effective, management and rehabilitation (important medicolegally); (3) certain less well-known tests, such as the Inventory of Neppe of Symptoms of Epilepsy and the Temporal Lobe (INSET) and Soft Organic Brain Inventory of Neppe (SOBIN) are very important, structured ways of monitoring symptoms clinically and in follow-up; (4) costly, sometimes beneficial, specialized evaluations (e.g., home ambulatory electroencephalography, head Magnetic Resonance Imaging (MRI) and Computed Tomography (CT) with contrast, **Positron Emission Tomography** (PET) scanning, Single-Photon Emission Computed Tomography (SPECT) scan, and polysomnography amplify diagnoses. Civil litigation may involve contradictory clinician and forensic roles.

Testing in Clinical and Forensic Psychiatry and Neuropsychiatry: Every clinical patient *could* be a potential forensic case, because a major basis of litigation is substandard care. Applying standardized techniques while recognizing individual differences facilitates the appropriate clinical and forensic evaluations. Treatments are sometimes necessarily off-label while repeatedly assessing progress and ongoing management revisions. Clinical and forensic evaluations must include appropriate diagnostic, symptom, and risk assessments. Particularly, medicolegally appropriate data correlations, all pertinent records (medical and psychosocial), and outsider validations by family members, friends, and sometimes law-givers are important. Standardized neuropsychological testing has significant strengths by applying comparative norms. Accounting for baseline data — education, background, and previous test exposures — is essential. Yet, unrecognized testing weaknesses can imply over-inclusiveness and ignore significant individual differences. The clinical neuropsychiatric evaluation with repetitive individualized longitudinal monitoring is essential. Repeated follow-ups, including reviewing critical neglected areas (e.g., subtle malingering, motivation and fatigue), are ideal. These evaluations also require individual clinical tailoring of broad structured psychiatric and neurological questionnaires. The Pacific Neuropsychiatric Institute (PNI) has developed and meaningfully applied many such medicolegal neuropsychiatric screens. These include the detailed "Diagnostic-Screen questionnaires" ("DS-10"), the INSET and SOBIN, plus the BROCAS Screening Cerebral Assessment of Neppe (SCAN) cognitive examination.

Tardive Dyskinesia, Traumatic Brain Injury, Evaluations

I26 Contribution of the Psychiatrist in the Evaluation of Fitness for Detention While in Custody in France

Arsene Gambier, MD, Institut Medico Legal, CHRU Tours, Tours 37044, FRANCE; Camille Rerolle, MD, Service de Medecine Legale, Hopital Trousseau, CHRU Tours, Tours 37000, FRANCE; and Pauline Saint-Martin, MD, PhD, Service de Medecine Legale, Hopital Trousseau, CHRU Tours, Tours 37000, FRANCE*

After attending this presentation, attendees will better understand the evaluation of fitness for custodial detention in France, which allows, in some cases, a direct intervention at the police station by a forensic psychiatrist.

This presentation will impact the forensic science community by illustrating the in-custody management of mental health issues of a police station in France.

Each year in France, several hundred thousand individuals who are suspected of having committed a criminal offence are arrested and retained in custody in a police station. As soon as the measure begins, the individual is allowed several defense rights, including the right to see a defense attorney and the right to have access to medical care at any moment while in the custody. A medical examination can also be solicited by the police officer or by a member of the individual's family. The physician is always appointed by the police officer.

These examinations are performed either by general practitioners or by emergency room doctors, but, in 2011, French forensic medical units were proposed to have a supplementary budget to perform these examinations in the geographic area closest to them. As a result, physicians with forensic training are performing these evaluations in some geographic areas. This report presents the organization of an institute that is located in an area of 600,000 inhabitants. Approximately 1,500 medical evaluations of persons in custody are performed each year. As French medicolegal physicians may have different professional courses, a psychiatrist is working full-time at the unit and is frequently solicited in this context.

In general, medical examinations are requested in five circumstances: (1) when the arrestee declares he/she is suffering from a particular disease and requires a specific treatment that needs to be continued during police custody; (2) when recent traumatic lesions need to be treated and recorded; (3) when the arrestee complains of acute symptoms that appeared during police custody; (4) when a mental disorder could lead to an involuntary hospitalization requested by a state representative — this usually concerns individuals whose behavior has disturbed public order; and, (5) when it is imposed by law — for minors, for instance. It should be noted that the individual may still refuse the examination.

Intervention of a psychiatrist to evaluate the fitness for detention is of particular interest in two situations, not exclusive from one another: (1) when the individual is suffering from alcohol and/or substance use; and, (2) when the individual needs a mental health assessment. In the first situation, the question of delivering a psychotropic medication may arise, either because the individual requests a substitutive treatment to avoid withdrawal symptoms or because the individual presents symptoms of anxiety or suicidal risk. In the second situation, the psychiatric interview allows determination as to whether or not there is a mental issue that could lead to the deliverance of a specific treatment or an observation in a psychiatric ward.

This report suggests that direct evaluation by a psychiatrist in the police station allows better collaboration with the police officers to perform surveillance and administer medication to these individuals. The psychiatric interview also provides a filter before a more complete evaluation in the emergency room (if this is necessary).

Forensic Science, Police Custody, Psychiatric Evaluation

I27 Impartiality and Forensic Psychiatry: How Forensic Psychiatry Specialists Consider the Concept of Impartiality

Tony Godet, Geneva University Hospital, rue G Perret Gentil 4, Geneva 14 1211, SWITZERLAND; and Gérard Niveau, MD, Geneva University Hospital, rue G Perret Gentil 4, Geneva 14 1211, SWITZERLAND*

The goal of this presentation is to determine knowledge and representation regarding impartiality and which factors could change this.

This presentation will impact the forensic science community by increasing knowledge of the factors that influence impartiality.

Introduction: When it comes to justice, an expert psychiatrist has a different role than a therapist. In the first case, the psychiatrist works only when asked by authorities to testify. Impartiality is a priority for the expert psychiatrist.[1] This survey was initiated to better understand how forensic psychiatry specialists consider the concept of impartiality and also asks which factors can influence impartiality.

Material and Methods: An online survey was created that included a clinical case, some general issues about impartiality, and questions on personal and professional specifications relating to the persons who answered. This survey was sent to psychiatrist members of the World Psychiatrist Association of the European Psychiatric Association and of the American Association of Forensic Psychiatry.

Results: One hundred thirty-one psychiatrists from 18 countries (66% from the United States) participated in this survey with a rate of 94.5% answers (103-131 answers by question). The sample consisted of 74% men and 94.5% of graduate psychiatrists. The average age was 53.4 years and the average forensic psychiatry experience was 18.3 years. More than 80% of the sample had an additional forensic psychiatry certification. In the clinical case, personal convictions were identified as a factor that called into question their impartiality in 80% of the cases. Impartiality pertains primarily to ethics and legal topics, according to the survey. The most important factors that influenced personal impartiality were: (1) being the treating psychiatrist of the assessed person in the past (97%); (2) personal past experiences (92%); and, (3) personal convictions (90%). The most frequent factors that strengthened personal impartiality were: (1) forensic psychiatric training (94%); and, (2) professional past experiences (77%). The most important factors that question legal impartiality were: (1) already being the treating psychiatrist of the assessed person in the past (93%); (2) personal convictions (78%); and, (3) already having performed a psychiatric assessment on the person (70%). Comparisons reveal very few differences between answers provided by men and women, the doctor's age had an influence on the factors questioning legal impartiality, and there were very few differences between the experienced psychiatrists and those who did not have a lot of experience. It was noted that the choice of factors that strengthen and call impartiality into question were influenced by the psychiatrists' work countries. Finally, the survey compared the different types of forensic psychiatric training. Results reveal that psychiatrists trained in forensic psychiatry within a general psychiatry program feel that personal convictions and being the treating psychiatrist for the assessed person in the past strengthen impartiality. Psychiatrists with additional training in forensic psychiatry consider impartiality more as an ethical notion and that additional training in forensic psychiatry strengthens impartiality. Psychiatrists who were supervised during their assessment consider that the fact that they have already completed a psychiatric assessment affects impartiality — that this could also question it *and* that professional past experience calls impartiality into question.

Conclusion: The psychiatrists sampled have a good knowledge of impartiality. The principal factors they identified as being able to affect, strengthen, and call into question are the same factors mentioned in scientific articles and international recommendations.[2] The high participation rate of American psychiatrists could be explained by a large diversity of organizations and the recognition of forensic psychiatry in European countries. As expected, having additional training in forensic psychiatry did not change the perception of impartiality. Moreover, years of experience in forensic psychiatry had a small influence on the answers, whereas psychiatrists older than 65 years of age were most likely to identify some factors that call impartiality into question.

Impartiality, Forensic Psychiatry, Psychiatric Assessment

I28 Racial Trauma: Its Mental Health Manifestations in Racial Minorities Involved in the Legal System and Incorporating Findings in Forensic Psychiatric Assessments

Donald R. Brown II, MD, USC Institute of Psychiatry and Law, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will be able to: (1) understand the concept of "racial trauma"; (2) realize how it could apply specifically to racial minorities involved in the legal system; (3) better understand its psychiatric manifestations; and, (4) value its importance in the forensic psychiatric assessment.

This presentation will impact the forensic science community by exposing how racial harassment and discrimination, in its numerous forms, against minorities in American society could lead to emotional and psychiatric manifestations due to traumatic stress. Awareness of this topic will enhance the efficacy of the forensic psychiatrist's evaluation and treatment plan. In some cases, it may also strengthen the therapeutic alliance between the treating psychiatrist and the client.

The information presented is obtained from previously conducted studies and literature that examined the link between cultural competency regarding racial discrimination and the criminal justice system. Additional sources include current events reported by the media that relate to perceived racial injustice. The fact that many members of racial minorities believe there is racial injustice makes it imperative that forensic psychiatric evaluators address and include these issues in their examinations.

Researchers have noted that, in recent decades, one area of inquiry that needs increased attention is racial discrimination, specifically as perceived by non-dominant group members (African, Latino, Asian, and Native Americans). Carter and Forsyth define racial discrimination as a "form of avoidant racism, reflected in behaviors, thoughts, and policies that have the effect of maintaining distance or limiting contact between dominant and non-dominant racial group members" and racial harassment as a "form of racism that involves feelings, thoughts, and actions intended to communicate a target's subordinate status due to membership in a non-dominant racial group."[1] Multiple studies have found that "between 40%-98% of racial minority participants reported that they had experienced racial discrimination."[1]

Currently, there are limited resources to assist psychiatrists in appropriately assessing racial trauma. Psychological reactions to racial discrimination often do not fit the specific criteria in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-V*) for post-traumatic stress disorder; however, researchers have documented statistically significant relationships between "perceived experiences with racism" and mental disorders, such as adjustment, stress reaction, mood, and anxiety.[1]

According to the United States Census Bureau, the 2010 population of Whites (72.4%) far outnumber Black (12.6%) and Latino (16.3%) populations. Yet, in the same year, the national prison population consisted of 38% Black and 22% Latino men and women.[2] Race has been used as a political and media tool and, consequently, has engendered fear within the dominant group toward the minority group and vice versa. This has been a contributing factor to the minority groups' overall distrust of the legal system. The following are some examples: the murder of unarmed Black males by law enforcement in which the perception in the Black community is that justice hasn't been served, the outcry for the construction of a "wall" between the United States and Mexico with mass deportation of illegal immigrants, or the imposition of a Muslim ban on entry to the United States from Islam-dominant countries. These events have led to severe emotional and psychiatric stress (racial trauma) in these target communities that should be identified.

This presentation seeks to: further analyze racial trauma; explore how these reactions to perceived racial injustice could be expressed emotionally, psychologically, cognitively, or behaviorally; and provide a guideline in performing a thorough forensic psychiatric evaluation. In addition, consideration of perceived racial trauma will ultimately lead to enhancing the therapeutic alliance between client and psychiatrist.

I29 Mental Wellness and Suicide Prevention Programming Among United States Police Agencies

Leslie Ethan Dodson, BA, Texas Tech University, 6110 36th Street, #14, Lubbock, TX 79407; Megan Thoen, PhD, Texas Tech University, Institute for Forensic Science, 4434 S Loop 289, Lubbock, TX 79414; Brandy Pina-Watson, PhD, Texas Tech University, Dept of Psychological Sciences, Box 42051, Lubbock, TX 79409; and Elizabeth Trejos-Castillo, PhD, Texas Tech University, Human Sciences, Human Development & Family Studies, Box 41230, Lubbock, TX 79409*

After attending this presentation, attendees will better understand the availability and use of police officer wellness promotion and suicide prevention programs implemented nationally as well as the perceptions of program effectiveness expressed by employing departments. Attendees will be able to identify and describe various difficulties encountered with, and the need for research within, the area of police mental wellness and suicide prevention.

This presentation will impact the forensic science community by discussing perceptions of effectiveness in mental wellness and suicide prevention programming utilized by police departments.

Officer suicide is a major issue affecting police: the 2015 President's Task Force on 21st Century Policing reported on the necessity of research in this area, stating officers were more than twice as likely to die from suicide as from homicide.[1] It has been recommended that training and programming should educate officers on emotional strength, and that the provision of relevant resources are essential to reducing officer suicide.[2] A dearth of research exists in the area of police mental wellness and suicide prevention, especially regarding wellness programs utilized by police departments. By better understanding the state of police officer wellness promotion, it may be possible to determine the most effective programming for officer wellness and suicide prevention. To date, there has not been a comprehensive list of available programs or an examination of their effectiveness.[3] This study is important to law enforcement as mental health issues may negatively impact cognitive abilities, job performance, and the likelihood of post-traumatic stress disorder and suicidal ideation.[1,4]

This presentation will examine data collected from a national sample of city police departments and sheriff's offices describing any mental wellness and/or suicide prevention programs implemented. Using the most recent Census of State and Local Law Enforcement Agencies, police departments and sheriff's offices with more than five full-time, sworn officers were compiled.[5] These departments were then stratified into three groups based on the number of full-time, sworn officers: 5-20 (small), 21-100 (medium), and 101+ (large). The ten largest departments, and those recognized for wellness programming by the Destination Zero Program of the National Law Enforcement Officers Memorial Fund, were targeted for sampling.[6] Other departments to be sampled were chosen randomly from within these strata. The phone interview, adapted from Kuhns, Maguire, and Leach, asked questions about available programming and perceptions of utilization and effectiveness of those programs.[3] Most respondents have been ranking officers with some mental health training or civilian psychologists/counselors employed by the agency. Data collection ended in December 2017. Thirty departments from each stratum (90 total) were targeted, and to date, 13 departments have been interviewed (response rate of 25.5%; 13 respondents out of 51 contacted).

Several logistical issues have arisen, most notably, difficulty in making contact with departments. The telephone-based recruitment procedure was chosen to avoid the non-response bias inherent in email or mail-based procedures.[7] Nevertheless, difficulties in making contact with the appropriate potential respondents within these departments have occurred (i.e., some departments were unfamiliar with who should be contacted for the request at hand, resulting in the need to contact multiple people from within one agency). Some agencies that declined to participate noted policy against research participation and/or not enough time or officers to respond to the interview; others did not provide a reason for the refusal or never responded to repeated requests for participation. Most respondents willing to participate expressed pride in their department's programming and had dedicated some effort to mental health issues in police work.

Preliminary data indicated peer support groups are the most common programs used; 61.5% of responding departments use them. These programs were considered to be the most highly effective of utilized wellness or suicide prevention programming as well. Some respondents considered peer support programs to be ineffective, citing stigma in asking for help, and thus the programs are being underutilized. Other employed programs identified by departments included employee assistance programs, resiliency training, wellness campaigns/symposia, and use of critical incident response teams. Most agencies recommended peer support programming of all programming utilized. Future directions for research, including further discussion of the methodological and practical implications for generating empirical knowledge, will be addressed.

I30 Determining Implicit and Explicit Attitudes of Hiring Non-Violent Ex-Offenders

Cristine S. Kilburn, MA, University of Central Oklahoma, 400 E Danforth Road, Apt 106, Edmond, OK 73034; and Nora Gayzur, PhD*, University of Central Oklahoma, 100 N University Drive, Box 85, Edmond, OK 73034*

After attending this presentation, attendees will better understand the everyday practices of hiring non-violent ex-offenders and the impact of employment opportunities available to those who have been convicted of a non-violent crime as compared to non-offenders.

This presentation will impact the forensic science community by explaining reductions in recidivism rates among non-violent ex-offenders (e.g., harsh penalties for drug charges). Offenders who are incarcerated for drug charges are in need of substance abuse treatments instead of imprisonment, while those found not guilty by reason of insanity need treatment for psychological disorders within a secure environment. Both populations have commonalities such as treatment, reintegration back into their community, and productiveness within their society. An integral part of success is gaining employment. The purpose of this study is to examine the implicit and explicit attitudes individuals have toward non-violent ex-offenders and the effect attitudes may have on the hiring process. Implicit and explicit attitudes would have the same impact on hiring decisions and could also aid in understanding discrimination in the hiring process.

In 2015, the Bureau of Justice Statistics stated there were approximately 6,741,400 individuals (approximately 2.7%) under some form of correctional supervision (e.g., parole, probation). In 2011, nearly 660,000 people were released from prison. In mid-October 2015, the Federal Bureau of Prisons released another 6,000 offenders to help with the dilemma of population overcrowding and reduced the time served for non-violent offenders with harsh sentencing for some drug-related offenses.[1] The drop in numbers has been attributed to lower incarceration rates (down 2.3%), as well as a community supervision decrease (down 1.3%).[2] Another reason for the decrease in prison populations was overcrowding in prisons. Attitudes that people have toward ex-offenders have a significant impact on their lives, including social inclusion and employment. Attitudes can be explicit (consciously aware) or implicit (unaware), and each type of attitude may or may not affect behavior in the same way.[3,4,5] Wilson, Lindsey, and Schooler demonstrated that explicit and implicit attitudes can have different outcomes on behavior.[6] Explicit attitudes have been shown to have a greater influence on well-thought-out decisions. Conversely, implicit attitudes are more difficult to control and monitor; thus, these affect decisions when a person does not know what the response should be. Former President Barack Obama supported a law reform for hiring practices involving ex-offenders. The "Ban the Box Campaign" would ban the criminal information questions from federal employment in the *initial* hiring stage.[7] There are 25 states, (including Oklahoma), and more than 150 counties and cities across the United States that have adopted the "Ban the Box" from the initial job application, which delays background checks until a later stage in the hiring process. The Fair Chance Act protects ex-offenders' rights to have their employment history based on experience rather than viewed as an ex-offender on the first page of an application. The act provides ex-offenders the same chance as everyone else who is applying for the same position.[8]

In conclusion, this study could educate employers on the significance of implicit attitudes and their impact. Many people are not aware of how influential these attitudes can be. If they are aware of the impact, they may think more conscientiously about employment decisions. Hopefully, this study will also influence interviewees to request a reason for their employment denial; which is usually offered in the application paperwork.

Attitudes, Offenders, Employment

I31 A Complex Case of Psychosis and Factitious Disorder

J. Brandon Birath, PhD, Olive View-UCLA Medical Center, 14445 Olive View Drive, Dept of Psychiatry, Sylmar, CA 91342; Stacie Collins, MD, Olive View-UCLA Medical Center, 14445 Olive View Drive, Sylmar, CA 91342; and Davin Agustines, DO*, Olive View-UCLA Medical Center, 14445 Olive View Drive, Sylmar, CA 91342*

The goals of this presentation are to highlight the diagnostic challenges of recognizing factitious disorder and to separate this diagnosis from malingering and psychosis in a clinical setting.

This presentation will impact the forensic science community by improving the ability of clinicians to understand and recognize the diagnostic challenges in separating factitious disorder from malingering and psychosis. This presentation will also improve the ability of clinicians to manage this disorder.

Factitious disorder is a *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-V*) -classified condition characterized by an individual's intentional deception of medical professionals and others to present themselves or another as ill, injured, or otherwise impaired, motivated by a desire to assume the "sick role."[1] Factitious disorder can pose as a diagnostic challenge, as the patient will often go to great lengths to convince others they are ill, whether by feigning symptoms or by self-inflicting illness or injury, often leading to unnecessary and, in some cases, costly and invasive tests and procedures.[2,3] After medical illnesses have been ruled out, factitious disorder may also be confused with other psychiatric disorders, including somatic symptom disorder and conversion disorder (both of which can be distinguished from factitious disorder by the absence of intentional falsification of symptoms) or malingering (characterized by patients feigning symptoms for secondary gain).[1]

Due to the fact that factitious disorder remains so diagnostically elusive, the exact prevalence is unknown. Studies have suggested that between 0.3% and 1% of patients admitted to general medicine services, who also have had consults placed to psychiatry, may actually have had diagnoses of fictitious disorder.[3-5] The majority of patients with factitious disorder present feigning medical conditions, with endocrinologic, dermatologic, and cardiac complaints being the most prevalent.[6] Among patients on psychiatric units, studies have estimated between 0.5% and 8% may have diagnoses of factious disorder with a primary psychological complaint.[7,8] This occurs most commonly with co-morbid diagnoses of substance use disorder, depression, and cluster B personality traits.[6,9-11] There have also been past reports describing factitious disorder patients presenting with primary symptoms of bereavement and post-traumatic stress disorder.[12-15] Factitious disorder patients presenting with primary symptoms of psychosis are less common, though there have been sporadically documented case series and reports.[16,17] This study presents a diagnostically challenging case of a patient with an unusual presentation of factious disease, with primary presenting symptoms in psychotic and somatic spheres.

Mental Health, Psychosomatics, Malingering

I32 Criminological Analysis of Human Smuggling and Migrant Trafficking Into Italy

Laura Volpini, PhD, Via Dei Sulpici, 62, Rome 00174, ITALY; and Federica Mondani, EUNAVFORMED Op SOPHIA, Via Guido D'Arezzo 10, Roma 00187, ITALY*

After attending this presentation, attendees will understand the identification and criminal characteristics of human traffickers, as well as the organizational structure of trafficking operations into Europe.

This presentation will impact the forensic science community by elucidating the findings of a recent study investigating migrant smuggling and human trafficking operations into Europe in an effort to propose empirically based identifiers to assist naval intervention. Furthermore, this presentation will define the role of the forensic and mental health advisor in operations designed to thwart these crimes.

With increasing frequency, migrants have been entering Europe. The use of human traffickers is a common method used by migrants to achieve these goals, despite being subjected to dehumanizing treatment and perilous journeys. Previous studies regarding human trafficking have primarily highlighted that the smuggling of migrants is operationalized within a stable, hierarchical, and transnational structure, using non-banking, intermediary, financial circuits called Hawala as payment. These organized crime efforts have been difficult to study because of variable investigative methods. In addition, traffickers make efforts to avoid detection, and migrants, typically instructed to avoid identification photographs, are difficult to identify.

The goal of this research study, conducted on behalf of the European Union Naval Force Mediterranean/Operation Sophia (EU NAVFOR MED), was to identify criminological aspects of migrant smuggling and the characteristics of traffickers in order to aid in halting human trafficking in Italy.

This study examined a large number of relevant court cases and reviewed national and international literature on the topic with the goal of identifying potential criminal traffickers, from a criminological perspective, during the first moments of migrant survivor rescue. This study found that traffickers are generally male, between 25 and 35 years of age, speak several languages, have good persuasive communication skills, live in shelters, have legal residency paperwork, and are sometimes married.

This study also proposes a scientific investigative protocol, based on holistic and systemic methods, to better characterize and study the *modus operandi* and style of the perpetrators of these crimes. Strategic investigation may be conducted on two levels, direct and indirect, while migrants are detained and recovering from rescue.

A direct investigative approach involves the use of digital audio and video recordings of survivor behaviors; these materials are often requested by the judicial authorities. Alternatively, an indirect investigative approach focuses on interviews of survivors, specifically women with minor children, who generally have fewer ties to the traffickers. This method would be managed through the use of behaviorally trained forensic consultants.

This study proposes that forensic consultants, used to evaluate these survivors, employ a questionnaire that evaluates the communication methods used by traffickers. The Self-Administered Interviews (SAI) questionnaire was found to be most efficient for this task. In addition, a direct interview to reconstruct the context and the actions of traffickers would be helpful using a Cognitive Interviewing (CI) technique. This technique provides validation for the concerns of migrant survivors and provides investigators with a wealth of information on human traffickers.

The use of these investigative methods in a systematic manner will aid in accumulating relevant data regarding this phenomenon.

Criminological Analysis, Human Smuggling, Smuggling

I33 Live Streaming Suicide and Murder on Facebook®: Can Someone Be Held Liable?

Chris Chen, MD, 655 S Hope Street, Unit 1101, Los Angeles, CA 90017*

After attending this presentation, attendees will better understand the unique legal considerations related to the live streaming of suicide or murder on the social media site, Facebook®. Attendees will also become familiar with freedom of speech on social media platforms and the associated liability.

This presentation will impact the forensic science community by: (1) presenting a review of the current laws regarding the liability of live streaming suicide and murder; and, (2) discussing the possibility of a duty by the social media site and viewers to protect others and prevent harmful acts.

Facebook® Live is a service that allows Facebook® users to create and broadcast real-time videos to their followers. It became publicly available in January 2016. Since then, a string of suicides and some murders have been broadcast over Facebook® to a wide audience. These incidents raise questions regarding legal liability related to freedom of speech, trauma inflicted on viewers, and obligations to protect and prevent persons from engaging in harmful behavior.

Does Facebook® have a legal responsibility to censor disturbing content, such as live broadcasts of suicide or murder? The first amendment gives Facebook® and its users the right to freedom of speech; however, there are instances when freedom of speech does not protect all content. For example, obscene content (material that offends the sexual morality of its viewers) is federally banned from the internet. Although suicide and murder do not fall under this category, is there another category that would ban such disturbing content?

If such videos are not monitored and removed from viewing on Facebook®, can Facebook® observers of these acts of suicide and murder sue the media site for trauma inflicted while watching these videos? There have been cases in which relatives present at the time of death successfully sued for emotional distress after witnessing their family member being killed; however, in these lawsuits, the negligent infliction of emotional distress required that the plaintiff was physically near the scene of the incident. Negligence has been hard to prove and often unsuccessful in cases viewing death from a distance as well as on televised media.

After many suicides were live streamed, Facebook® launched tools for viewers to report suicides. Given this ability, would the viewer have a legal obligation to report suicidal behavior? The law traditionally does not impose a general duty on the public to prevent another person from taking his/her own life; however, the case of a "special relationship" (e.g., mental health professional-patient relationship) can give rise to a responsibility where none would otherwise exist. For example, if a psychiatrist were to see a patient live streaming suicidal behavior, then the psychiatrist potentially would have a duty to protect the patient. If it is a murder that is being live streamed, certain states require any person who reasonably believes that he/she has observed the commission of a murder to notify a Peace Officer.

Facebook® currently has teams designing artificial intelligence algorithms for identifying users who may be at risk for suicide before it becomes too late. If this algorithm could match or even surpass a physician's diagnostic abilities, what duties would Facebook® owe to the individuals its algorithm identifies or overlooks? Could Facebook® be found negligent if it does not do enough to prevent suicide?

This presentation will review the literature on live streaming suicide and murder with respect to key legal considerations that pertain to liability for viewers and media sites. In addition, possible recommendations toward reducing the incidents of harmful behavior that is live streamed will be provided.

Live Streaming, Death, Liability

I34 Do Evidence Submission Forms Expose Latent Print Analysts to Task-Irrelevant Information?

Brett Gardner, PhD, 205 Douglas Avenue, Apt 2, Charlottesville, VA 22902; Sharon Kelley, PhD, Institute of Law, Psychiatry, and Public Policy, 1230 Cedars Court, Ste 108, Charlottesville, VA 22903; Daniel C. Murrie, PhD, Institute of Law, Psychiatry, & Public Policy, University of Virginia, Box 800660, Charlottesville, VA 22908; and Kellyn Blaisdell, BA, University of Virginia, Institute of Law, Psychiatry, & Public Policy, 1230 Cedars Court, Ste B, Charlottesville, VA 22902*

The goals of this presentation are to educate attendees regarding the nature and quantity of potentially biasing, task-irrelevant information routinely requested by crime laboratories before latent print analyses are conducted and to provide insight into appropriate countermeasures.

This presentation will impact the forensic science community by providing results of a study examining the type and relevance of information requested by evidence submission forms in laboratories across America. Further, this presentation will apply the recent literature demonstrating contextual effects in forensic sciences to the evidence submission process and offer recommendations for countermeasures.

In 2009, the National Academy of Sciences (NAS) released their congressionally mandated Report, *Strengthening Forensic Science in the United States: A Path Forward.*[1] Detailing a variety of problems in the wide-scale practice of forensic science, this influential Report prompted media attention and widespread calls for reform. The concern that forensic science findings may be influenced by *contextual effects* (i.e., extraneous data and pressures that are unnecessary and potentially biasing to scientific analysis of fingerprints, firearms, DNA, and other evidence) was a primary identified problem. For example, forensic scientists who perform circumscribed procedures such as analyzing latent fingerprints may receive superfluous information regarding the criminal suspect or crime scene details; such contextual information is unnecessary to the task of comparing fingerprints and has the potential to bias the examiner toward a particular finding.

Concerns regarding contextual effects are clearly consistent with a rich body of research in cognitive and social psychology.[2] Moreover, several seminal studies specifically addressing contextual effects among forensic science procedures recently raised concerns throughout the forensic science community.[3-5] Although limited, this growing body of research has substantial implications for policy and justice — many advocates have already urged substantial reforms.[6]

One of the primary recommendations offered in the NAS Report was to identify sources of bias and develop appropriate "countermeasures."[1] This current study sought to clarify the nature and quantity of potentially task-irrelevant information that is routinely requested before latent print analyses are conducted in forensic laboratories. Moreover, this study seeks to identify explicit requests for potentially biasing information in order to provide insight into appropriate "countermeasures."

In this study, 183 crime laboratories accredited by the American Society of Crime Laboratory Directors – Laboratory Accreditation Board (ASCLD-LAB) for the analysis of latent prints were first identified. An additional 24 laboratories accredited by ANSI-ASQ National Accreditation Board (ANAB) (a unified list of accredited laboratories was not available at the time of data collection) were identified in addition to three other laboratories that were either unaccredited or had recently stopped conducting latent print analyses. This study only identified laboratories accredited in latent print analysis for simplicity, clarity, and due to recent research specifically demonstrating significant contextual effects in latent print analyses.[3,7] Each laboratory was asked to provide a blank evidence submission form used in latent print analysis requests. Two weeks after the initial request, a reminder email request was sent to all laboratories that did not respond. All remaining laboratories are now being contacted by telephone to personally request blank evidence submission forms.

To date, 76 laboratories responded to this study's request and the provided submission forms represent at least 105 laboratories across America. The submission forms from 68 laboratories were sufficient to be fully coded. These forms represent at least 97 laboratories in 39 states. Descriptive analyses focus on information requested by submission forms regarding the offense, suspect, victim, and other seemingly task-irrelevant and potentially biasing subjects. For example, approximately 96% of all forms request information regarding the type of offense, whereas only 20% specifically request a police or incident report be provided. Approximately half of all forms request information regarding the suspect's race and criminal history. Moreover, while some task-irrelevant prompts appear to have practical purposes (e.g., approximately half of the forms request information regarding the location of the offense and most request suspect's name), others have no overt practical purpose (e.g., victim sex and race). Moreover, approximately 18% of forms request seemingly task-irrelevant information that appears likely to bias latent print analysts (e.g., "Is suspect serious violent felon?"; "Please indicate if item was the probable-cause evidence in your case"). This presentation will provide much more descriptive information regarding the type of task-irrelevant information being requested and exposed to latent print analysts.

In conclusion, this presentation will discuss the potential influence of task-irrelevant information currently being requested before latent print analyses are performed. This presentation will also relate current findings to extant literature demonstrating contextual effects in forensic sciences and latent print analysis specifically.[3,5,7] Finally, there will be discussion regarding methods of achieving the correct balance of information necessary for latent print analysis (e.g., case management, linear sequential unmasking, Laboratory Information Management Systems (LIMS)) to prevent subconscious bias.

Contextual Effects, Bias, Latent Print Analysis

I35 Jury Instructions on Insanity Acquittal Disposition

Jennifer Piel, MD, VA Puget Sound, 1660 S Columbian Way, MS-116-MHC, Seattle, WA 98108*

The goals of this presentation are to: (1) provide a summary of federal and state laws on jury instructions on insanity acquittal disposition; (2) review the primary reasons for and against jury instructions on what happens to a person acquitted by reason of insanity; and, (3) review the empirical evidence on juror knowledge concerning insanity acquittal disposition.

This presentation will impact the forensic science community by reviewing the arguments for and against jury instructions on insanity acquittal disposition and will provide attendees with a review of the empirical research on juror knowledge concerning the consequences of a successful insanity defense.

Jurors generally know that persons found guilty of a crime are punished and persons found not guilty are set free. Although jurors may not be aware of sentencing guidelines applied to a particular defendant, they generally have a basic understanding regarding the range of criminal punishments afforded to persons found guilty of a crime and understand that most convicted defendants serve time in jail or prison.

Perhaps less obvious to jurors is what happens to defendants who are found Not Guilty by Reason of Insanity (NGRI). Because of uncertainty regarding NGRI disposition, some jurors may believe that criminally insane defendants are set free upon an NGRI verdict or may have unreasonable expectations about the duration of confinement.

An important topic concerning the insanity defense is what jurors should be told about the disposition of a defendant acquitted NGRI. In the federal system, jurors are not told about the consequences of an insanity verdict under *Shannon v. United States.*[1] State courts are divided on the issue.

This presentation will review the current status of jury instructions — in the federal system and among the states — on the consequences of an NGRI verdict. The most recent legal cases on this topic will be discussed. The role of the jury will also be reviewed. Historically, juries have decided on guilt without knowledge of the consequences to the defendant.

In this presentation, principle arguments for and against a jury instruction on NGRI disposition will be reviewed. Some courts address this issue by emphasizing the differences between the role of the jury and that of the judge — that judges are responsible for applying the law and imposing sentences, not the jury.[2] Other state courts have held, at least as a matter of policy, that a jury instruction on NGRI disposition is necessary to prevent juror confusion and misguided verdicts. In states that have both NGRI and Guilty but Mentally Ill verdicts, instruction(s) about the verdicts and disposition outcomes are likely to be particularly important to reduce juror confusion.

Of particular interest, this presentation will provide a review of the empirical evidence on juror knowledge regarding insanity acquittal disposition. Although the studies are limited in number and scope, they provide relevant information concerning juror knowledge and attitudes about the insanity defense. The weight of the studies confirms juror misunderstanding about a defendant's disposition upon an insanity acquittal. In one study, a juror commented that he voted for a guilty verdict (in contrast to NGRI) because he "did not want a mad dog released."[3] This comment exemplifies the reason to give an instruction on the consequences to the defendant following acquittal by reason of insanity.

Insanity, Jury Instruction, Diisposition

I36 Compassionate Care for the Criminal Courts

Karen B. Rosenbaum, MD, 49 W 24th Street, Ste 908, New York, NY 10010*

The goal of this presentation is to educate defense attorneys, district attorneys, judges, and mental health professionals who work with the criminal court system on the benefits of compassionate care and enhancing empathy in a system that is traditionally adversarial.

This presentation will impact the forensic science community by integrating concepts in contemplative science with issues in forensic science.

People who are involved with the criminal justice system are under an extreme amount of stress. Defendants are facing possible lengthy incarcerations, defense attorneys are often overworked and underpaid, and judges have an overwhelming number of cases on their docket. Prosecutors are concerned with protecting the community and are not usually as interested in issues pertaining to a suffering individual who has committed a crime. When a defendant is mentally ill and needs treatment to be able to become competent to stand trial, this can delay cases for months and sometimes years. Legal professionals who are not trained in mental illness often have a difficult time understanding how mental illness can affect criminal responsibility and could interfere with someone's ability to understand their charges and assist in their own defense.

Mental health professionals and officers of the court often speak different languages. Issues pertaining to the law are focused on responsibility and blame. Psychiatrists and other clinicians are more concerned with diagnosis and cure and how to help someone out of their suffering.

Concepts from Compassionate Care in contemplative science may be helpful in laying common groundwork between mental health professionals and legal professionals that could benefit their own wellbeing as well as their understanding of mentally ill criminal defendants.

There are numerous studies on the psychological and neurological health benefits of meditation, yoga and other relaxation techniques that could help educate professionals in the criminal justice system on how to take care of their emotional health in a manner that results in more energy and understanding for another's suffering. Teaching officers of the court to take time to engage in self-care could help them develop the capacity to better understand and appreciate people who are mentally ill and suffering. Meditating and slowing down at times during the day could also be helpful.

Numerous case examples illustrate the need for better understanding of the difficulties mentally ill people face when they are in the criminal justice system. Enhanced empathy does not change the adversarial nature of the court system, but could provide each side with more information in order to better understand each position and the individual's unique set of circumstances. As a result, they work together to help the defendant/client receive appropriate treatment/rehabilitation. Ultimately, this allows the criminal court system to function in a fairer and more efficient manner.

Contemplative, Criminal, Court

I37 The Patient Can Leave: Involuntary Hospitalization of Non-Psychiatric Patients Who Lack the Capacity to Refuse Medical Treatment

Thomas Rodriguez, MD, LAC+USC Forensic Psychiatry, PO Box 86125, Los Angeles, CA 90033*

After attending this presentation, attendees will have gained knowledge of California's current laws regarding involuntary hospitalization of medically ill patients who do not meet criteria for an involuntary psychiatric hold.

This presentation will impact the forensic science community by illuminating the quandary the medical professional may be in when a patient who lacks capacity to refuse treatment chooses to leave the hospital. As most of these cases involve individuals with cognitive impairment, this will become an even greater issue as the proportion of the aged population increases.

Generally, there is no legal mechanism to hospitalize medically ill patients against their will unless they are psychiatrically ill, have a legal conservatorship, or have certain contagious diseases. Possible solutions to this dilemma will be discussed.

The need for involuntary hospitalization occasionally arises for medically hospitalized patients. Most of these cases pertain to patients with an acute mental illness. In California, if a person is mentally ill and a danger to self and/or others, or gravely disabled (unable to provide food, clothing, or shelter), the patient can be involuntarily hospitalized for psychiatric treatment for a 72-hour period. California law allows for additional periods of involuntary hospitalization of psychiatric patients, if indicated.

However, at times there are medically ill patients who do not have a psychiatric illness but may require involuntary hospitalization for medical treatment purposes. An example may be a patient with delirium who lacks the capacity to refuse treatment and wants to leave the hospital. When an individual requires inpatient medical treatment, but lacks the capacity to refuse the treatment, a petition can be filed under California Probate Law. If the court finds that the patient lacks capacity, the court can authorize treatment and appoint an individual to make health care decisions on behalf of the patient for that specific medical problem.

It is important to recognize that when this health care decision-making is granted to another, the law does not explicitly grant that individual the authority to involuntarily hospitalize the patient against their will. Consequently, the patient could choose to leave prior to administration of the treatment. Given this situation, staff members at some hospitals are instructed to refrain from physically restraining these patients if they try to leave the hospital. The hospital is in a difficult situation. If they prevent the patient from leaving, they are doing so illegally. If they allow the patient to leave, they are possibly exposing the patient to a serious threat to their physical health.

The situation mentioned above presents medical professionals with a significant dilemma. Changes to hospital policy or legislation could provide much needed direction.

This presentation will provide a general overview of California statutes related to involuntary psychiatric hospitalization, guardianships, conservatorships, and other protective proceedings. A case example will be used to illustrate the application of these laws and current hospital policies.

Involuntary Hospitalization, Capacity, Leaving

I38 Capacity to Consent to Psychiatric Treatment in Ontario, Canada: Perspectives From a Forensic Psychiatry Program

Sebastien S. Prat, MD, St. Joseph's Healthcare - McMaster University, Forensic Psychiatry Program, W 5th Campus - 100 W 5th Street, Hamilton, ON L8N 3K7, CANADA; and Joseph Ferencz, MD, St. Joseph's Healthcare, Forensic Psychiatry Program, 100 W 5th Street, Hamilton, ON L8P 3K7, CANADA*

After attending this presentation, attendees will: (1) understand the legal concepts of the capacity to consent to treatment in Ontario, Canada; (2) understand the challenges that clinicians have when someone is refusing psychiatric treatment (including risk of violence); and, (3) be able to discuss ethical aspects of forcing someone to receive psychiatric treatment.

This presentation will impact the forensic science community by increasing awareness of a different legal framework and what the impact is on both the patients and the community.

Introduction: Pharmacological treatment can be one of the major components of the mental stability of individuals suffering from a psychotic disorder or a bipolar disorder; however, as per the nature of their psychotic or mood symptoms, these patients may lack insight into their condition and refuse to take psychiatric medication. In that situation, these persons may remain acutely psychotic or manic for months and even years if no action is taken to force medication. Most of the legislation authorize but limit the use of forced treatment. The most common method in place is when a Substitute Decision Maker (SDM) is named; in that case, the SDM will make the decision on behalf of the patient as he has the capacity to understand the nature of the mental disorder and the consequences of taking or not taking psychiatric medication. Also, many legislations allow the patient to appeal the decision of the physician who found his/her patient incapable of consenting to treatment.

In Canada, each province and territory has developed its own legal framework for consenting to treatment. In Ontario, the legal process is deemed under the Consent and Capacity Act. It appears that the Ontario process has the particularity of not allowing any treatment until the appeal process is extinguished, either because of the patient not having appealed the decision within the allowed time or because no further appeal is possible (the last decision from the Supreme Court of Canada). Some legal procedures may be quick (a few weeks) and some may be extremely long (one or more years), during which time the patient remains acutely unwell. The individuals in favor of such a procedure often argue that each patient should be allowed a freedom of choice.

Methods: In the St. Joseph's Healthcare Forensic Psychiatry Program, patients who have gone the route of appealing the decision of capacity to consent to treatment were identified. Several factors were reviewed, such as how long the process took place, how far the patient appealed the decision, and the change of their mental status before and after receiving treatment (including their risk factor, their aggressive incident, and their access to privileges)

Results: Ten patients were identified who appealed their treatment capacity. Only three of them went to the Supreme Court of Canada. The longest appeal was 1.5 years. All had a significant decrease of their aggressive incidents after receiving treatment and were allowed to use off-unit, unaccompanied privileges shortly thereafter.

Discussion: The data related to the significant behavioral improvement after receiving treatment was expected; however, obtaining these data may help provide some guidance to enhancing a different legal process and help these patients recover more quickly. It also raises ethical questions and legal issues, notably when these patients are part of the forensic system and their main psychiatric disorder is associated with an offense. All of these points will be detailed in the presentation.

Capacity to Consent, Psychiatric Treatment, Forensic Psychiatry

J1 An Examination of Highly Deceptive Counterfeit Currency

Khurram W. Mahmood, MPhil, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 53700, PAKISTAN; Sehrish Mohsin, MS*, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 53700, PAKISTAN; Muhammad Irfan Ashiq, PhD*, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 54500, PAKISTAN; Bushra Iftikhar, MPhil*, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 53700, PAKISTAN; Nadeem-Ul-Hassan Khan, MPhil*, Punjab Forensic Science Agency, Thokar Niaz Baig, Lahore, Providence of Punjab 53700, PAKISTAN; and Mohammad A. Tahir, PhD*, Punjab Forensic Science Agency, Thokar Niaz Baig, Multan Road, Lahore, Punjab, PAKISTAN*

After attending this presentation, attendees new to the field will have gained a useful learning experience regarding security features present in Pakistani currency notes, while practicing questioned document examiners will have a better understanding of those security features that require special attention when dealing with the detection of high-technology counterfeit currency.

This presentation will impact the forensic science community by illustrating various security features that have been emulated to a high degree of success by counterfeiters and those qualities that could not be replicated.

Counterfeiting of currency has been occurring for ages, and there has been a continuing race between certifiers and counterfeiters for all that time. The state always attempts to introduce security features cannot be forged in their currency notes, but the problem of counterfeits has persisted. Counterfeiters attempt to duplicate the overt features and appearance of genuine currency notes and include at least some of the required security features in their counterfeit products. The original security features that require uncommon high-technology facilities cannot be duplicated in the same way as they appear in genuine notes; however, the introduction of sophisticated color printers, color photocopiers, and scanners in the early 1990s brought a dramatic shift in counterfeiting technology. This new technology has made it possible for counterfeiters to produce imitation currency of a higher quality. A number of counterfeit detection methods are being used by crime laboratories and other law enforcement agencies, but some are time consuming, some are imprecise, and some are destructive. In this presentation, a non-destructive method of counterfeit Pakistani currency note detection that does not involve specialized equipment, except for the readily available video spectral comparator and stereomicroscope, will be demonstrated.

A case study involving the examination of Rupees 5000 and Rupees 1000 Pakistani currency notes for their genuineness was performed in a non-destructive manner by using a Video Spectral Comparator (VSC6000) and a stereomicroscope. Both reference and questioned currency notes were examined for all available security features, including Ultraviolet (UV) -luminescent features, intaglio printing, watermarks, denomination printed with see-through register, and the flag printed with Optically Variable Ink (OVI). This comparative study revealed that the questioned currency notes included security fibers, security thread, see-through register, watermarks, UV-luminescent printing, and the OVI-printed flag appeared similar to those in genuine currency notes, but the quality of the watermark, UV-luminescent printing, and positioning of the see-through register was found to be different. A detailed examination of the inks used to produce micro-printed features revealed that a four-color printing process had been used instead of monochromatic printing inks and the rainbow printing process. Keeping in view all previous observations from counterfeit currency notes submitted at different time intervals for examination, it can be concluded that micro-printing features and rainbow printing are the most difficult to be introduced into counterfeit currency notes, so these features must be observed carefully by the examiners.

Counterfeit Currency, Questioned Documents, Security Features

J2 Questioned Document Examination of Two-Source Traced Forgery in Signatures: A Case Study

Zumrad Usman Bhutta, MS, Chak 84 South Branch Sargodha, Sargodha, Punjab 40100, PAKISTAN; Iqbal Mehmood, BSc*, Director General National Police Bureau, G-6 Markaz, Islamabad 44000, PAKISTAN; Saqib Sultan Al Mehmood*, National Forensic Science Agency, House No. 4, Street No. 1, Sector G-6/3, Islamabad 44000, PAKISTAN*

After attending this presentation, attendees will have learned how to examine two-source tracing in signatures. Traced forgery is performed using tracing paper, carbon paper, transmitted light, indented tracing, or a scanned image, but two-source signature tracing in questioned documents has great importance in solving questioned documents signature cases.

This presentation will impact the forensic science community by introducing a unique case study in which two-source signature tracing in questioned documents was analyzed with the comparison of known routine signatures of the deceased.

Pakistan has been affected by the worst form of terrorism and militancy. The scourge of terrorism has taken its toll on every aspect of life. One of the better ways to help overcome these difficulties is through education, and, in particular, high-level research and development in the field of forensic sciences. Signatures have great importance today, as every person signs his or her name or mark once, twice, or numerous times a day. Signature forgery can occur in many ways, including freehand simulation, tracing, and image transfer. Alternatively, a signature may be written with some disguise with a view to disavowing it at a later time.

Due to the regular use of signatures, the problem often arises of determining whether these signatures are genuine, disguised, or traced. Signature forgery means changing any signature with the intent to deceive, which could be accomplished in a number of ways. One of the methods most often used is discussed in this case study, that of two-source traced forgery, which means reproducing an exact copy of the genuine signature by using two sources of an original signature. In this type of forgery, most signatures that are traced have two parts. One part of the signature is traced from a document with an original signature and the second part is traced from another document with a second original signature to reveal the natural variation in signatures. Traced forgery is performed by using tracing paper, carbon paper, transmitted light, indented tracing, or scanned images. The forensic questioned document examiner examines every detail of the traced signature and concludes whether or not the questioned signature exhibits the characteristics and mathematical measurements with respect to the specimen and admitted routine signatures. In this presentation, a case will be discussed in which questioned signatures were examined and conclusions provided when the questioned author was deceased; the forensic document examiner relied only on admitted routine signatures. The comparison/examination of questioned signatures was performed, followed by the comparison/examination of the admitted routine signatures in order to locate the origin of the questioned signatures. The result in this particular case revealed that the disputed signature exactly superimposed with a slight adjustment with the admitted routine signature.

Signatures, Tracing, Forgery

J3 The Significance of Electrostatic Detection Apparatus (ESDA) in the Determination of Tampering

Nadeem-Ul-Hassan Khan, MPhil, Punjab Forensic Science Agency, Thokar Niaz Baig, Lahore, Providence of Punjab 53700, PAKISTAN; Saqib Iqbal, MPhil, Punjab Forensic Science Agency, Govt of the Punjab, Thokar Niaz Baig, Lahore, Punjab 53700, PAKISTAN; Kamran Ghafoor, PharmD, Punjab Forensci Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab, PAKISTAN; Sadaf Iqbal, MPhil, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 53700, PAKISTAN; Muhammad Irfan Ashiq, PhD, Punjab Forensic Science Agency, Old Multan Road, Thokar Niaz Baig, Lahore, Punjab 54500, PAKISTAN; and Mohammad A. Tahir, PhD*, Punjab Forensic Science Agency, Thokar Niaz Baig, Multan Road, Lahore, Punjab, PAKISTAN*

After attending this presentation, attendees will better understand the importance of ESDA in determining alleged tampering in cases in which the conventional use of a video spectral comparator does not produce promising results sufficient to prove alleged tampering.

This presentation will impact the forensic science community by demonstrating the use of ESDA as a significant tool in the determination of tampering in cases in which no significant visually apparent signs of tampering were present.

Background: One of the most demanding fields of forensic document examination is proving alleged tampering in a disputed document using a variety of techniques. When examining a piece of writing for alleged tampering, one of the items the examiner looks for is any difference in the writing instrument/ink used. This will consequently result in one of two findings: the writing instrument(s) used in the area of the questioned writing is similar/same, or more than one (different) writing instrument has been used. In the latter scenario, the interpretation is usually easier, whereas in the former, there may be no tampering or tampering using the same or similar writing instrument. The examination may become complicated when the suspected tampered area of writing involves writing instruments having ink composition that is similar enough to evade differentiation by commonly used non-destructive methods. Such disputed documents prove to be more demanding for the document examiner, and the use of alternate techniques accompanied by problem-solving approaches becomes essential.

Method: This presentation discusses a case that involves successful detection of tampering (alteration) in a disputed notebook. The case presented a common problem involving the use of the same or very similar inks/writing instruments for tampering that the conventional use of a Video Spectral Comparator (VSC6000) was unable to prove tampering in the disputed notebook. Based on preliminary optical examination of the disputed entry, the examiner was sure that "something" was suspicious about the questioned entry in the disputed notebook and continued to investigate. The questioned entry was also examined from the rear using a VSC6000 to discover any information, but resulted in failure. At last, the examiner processed the page underneath the disputed page of the notebook by using ESDA^2. Use of ESDA^2 resulted not only in a number of findings sufficient to prove tampering in the questioned notebook but also provided probative evidence to the investigation.

Conclusion: Use of ESDA^2 seems to be an ideal technique in cases in which no significant visually apparent signs of tampering are present. Tampering (alteration) done with the same and/or a similar type of ink/writing instrument but lacking normal and natural writing flow, consistent writing pressure, and involving suspicious pen lifts may be successfully revealed by using ESDA^2.

Tampering, ESDA, VSC

J4 Rubber (Hand) Stamps: A Long-Term Study Into Stamp Wear and Damage, Stamp Impression Variation, and Incompatible Inks

Tobin A. Tanaka, BS, Canada Border Services Agency, Government of Canada, Ste 280-14 Colonnade Road, Ottawa, ON K2E 7M6, CANADA*

After attending this presentation, attendees will be familiar with: (1) examples of stamping impression variation in addition to the progressive wear/damage to stamps over a long period of time; and, (2) the effect that an incompatible ink has on polymer stamping materials.

This presentation will impact the forensic science community by providing information concerning: (1) the preliminary results of long-term experiments regarding progressive wear/damage to rubber (hand) stamps; (2) the variation in stamp impressions; and, (3) the effects of incompatible inks on polymer stamping materials.

The topic of stamp wear/damage, stamp impression variation, and incompatible ink effects is described in different examination standards and some publications; however, there is less published on the documented progression of wear/damage to stamps and the degree to which variation in stamp impressions may occur from different stamping actions.[1-4] Similarly, there is little published on the progressive damage to stamp dies over a period of time when an incompatible ink has been used.

Part 1 of this study involves getting stamp impressions from different-sized stamps and from different individuals. Three different sizes and types of stamp were used: a large-area rubber stamp (38mm by 72mm), a self-inking round rubber stamp (diameter 24mm), and a mass-produced, factory-made stamp with a combination of date and selectable word (55mm by 5mm). Each of these stamps used a separate inking pad.

To obtain impressions with variation from the stamping process, a variety of volunteers were sought. The volunteers were attendees at two forensic science meetings: the Australasian Society of Forensic Document Examiners Inc. (ASFDE Inc.) Meeting held in Melbourne, Australia, during May 2017, and the International Association of Forensic Sciences (IAFS) Meeting in Toronto, Canada, during August 2017. Impressions were made by attendees of the meetings during different times onto pre-numbered and configured sheets designed for each stamp type. Variation was present due to the differences in the biomechanics of stamping from participants and from the number of impressions taken in a session. For example, in some stamping sessions, participants made many impressions in a short period of time; this is in contrast to when a single impression was made.

The collection of additional stamp impressions is ongoing, with an opportunity to participate at this meeting by making impressions. Only the number of impressions made on a given day will be recorded, with no information about anyone making impressions retained.

Part 2 of this study is an experiment to determine the effect of an incompatible ink on polymer stamping materials over a long period of time. Incompatible inks are those with chemical formulations that may degrade stamping materials for which they were not designed. This experiment involves different stamps that are not part of the wear/damage and variation study. One stamp and one unmounted die for both polymer and rubber-stamping materials were made using the same graphics. Impressions were made on a regular basis using a fast-drying (alcohol-based) ink. Alcohol-based inks are not designed to be used with polymer stamps but can be used with rubber-based stamps. An equal number of impressions were produced over the period of approximately one year with the polymer and rubber stamps; ink was applied to the unmounted dies, but no impressions were taken.

The presentation on Part 1 of the study will focus on the variation in impressions with secondary discussion on the observed wear/damage. For the Part 2 experiment, the degree of degradation for the polymer stamp compared to the rubber stamp will be presented and discussed.

Rubber (Hand) Stamps, Document Examination, Variation

J5 An Analysis of Indented Writing Impressions in Questioned Documents Using Flatbed Scanners in Pakistan

Zumrad Usman Bhutta, MS, Chak 84 South Branch Sargodha, Sargodha, Punjab 40100, PAKISTAN; and Saqib Sultan Al Mehmood*, National Forensic Science Agency, House No. 4, Street No. 1, Sector G-6/3, Islamabad 44000, PAKISTAN*

After attending this presentation, attendees will better understand how to decipher indented writing on different types of paper without using the Electrostatic Detection Apparatus (ESDA). Indented writing on documents has great importance in solving questioned documents cases. Therefore, in this research lecture, different techniques will be discussed relating to how results can be obtained without using an ESDA.

This presentation will impact the forensic science community by demonstrating a non-destructive process that leaves no marks on the document and has significant results.

Pakistan has been affected by the worst form of terrorism and militancy. The scourge of terrorism has taken its toll on every aspect of life. One of the better ways to help to overcome these difficulties is through education, and, in particular, high-level research and development in the field of forensic sciences. Indented writing may have significant value in resolving questioned document issues. As the term implies, indented writings are non-visible indentations applied to a sheet of paper positioned below the page actually written upon. While a specialized laboratory instrument can be used by document examiners to recover indented writing, the indentations may be made visible by using side light and flatbed scanners with the use of software. This is a non-destructive process in which the questioned documents do not have any type of change or effect. In this study, different types of techniques were used on different weights of paper.

Forensic document examination is the application of forensic science in analyzing questioned documents. Indented writing impressions can be seen by using an angled, oblique light with high intensity, or more accurately, by using the ESDA; however, because of the limited resources in Pakistan, the accessibility of costly equipment such as the ESDA in forensic labs in all provinces of Pakistan is limited. This suggests that an instrument with equal performance and lower price should be a substitute. In this study, various types of papers found at crime scenes that had indented impressions were analyzed using the ESDA and commercial flatbed scanners with image enhancement software (Adobe® Photoshop® CS-8). This study was divided into three experiments: (1) dissimilarity of interleaving paper; (2) paper quality test; and, (3) variation of writing pressure. The results of this study reveal that flatbed scanners can be used as an alternative instrument for recovery and revealing of indented writing impressions.

Questioned Documents, Indented Writing, Adobe® Photoshop® (CS-8)

J6 The State of the Art in Computational Forensic Document Examination

Timothy Campbell, BSc, Canada Border Services Agency, 14 Colonnade Road, Ste 280, Ottawa, ON K2E7M6, CANADA*

The goal of this presentation is to provide attendees with a better understanding of the document research work being conducted that may not initially have a forensic intent but may ultimately be applicable to further development of the profession.

This presentation will impact the forensic science community by alerting practitioners to tools and techniques they would not normally find within the forensic community.

Forensic Document Examination (FDE) is a broad discipline that, while necessarily being firmly tied to traditional technologies, is greatly affected by modern advancements in instrumentation and analytical techniques. FDEs are quite familiar with databases for examined subject matter, such as inks and typewriters, and digital tools, such as laser microscopes, spreadsheets, and advanced image enhancement; however, there is another parallel world of work conducted on documents in academia that FDEs should find beneficial.

The Pattern Recognition (PR) research community has been working on applying PR techniques to document and handwriting problems as they have been presented in the world of archiving and commerce. While these subjects tend to focus on digitizing historical tomes or modern business documents, a subset of PR researchers have worked on automating handwriting authorship determinations, the same analyses that FDEs claim as expertise.

The International Association for Pattern Recognition (IAPR) has a number of Technical Committees (TC); number 11 (TC11 – Reading Systems) concerns the analysis and recognition of document-based information, namely image processing, Optical Character Recognition (OCR), and handwriting recognition. TC11 publishes the *International Journal on Document Analysis and Recognition*. There are two recurring conferences and one workshop which are held biannually and in alternate years.

The International Conference on Document Analysis and Recognition (ICDAR) is held on odd calendar years and is geared primarily, but not exclusively, toward non-handwriting document issues. On even years, the International Conference on Frontiers in Handwriting Recognition (ICFHR) is held, as is the main TC11 workshop, Document Analysis Systems (DAS).

Smaller workshops held in conjunction with these conferences have included Historical Image Processing (HIP), the International Workshop on Camera-Based Document Analysis and Recognition (CBDAR), the International Workshop on Multilingual OCR (MOCR), and the International Workshop on Robust Reading (IWRR). New for 2017 are the Historical Book Analysis (HBA) workshop and the First International Workshop on Computational Document Forensics (IWCDF). Additionally, the Automated Forensic Handwriting Analysis (AFHA) group was well-attended by FDEs when it was co-located with the meeting of the American Society of Questioned Document Examiners (ASQDE) in 2014.

These gatherings typically make use of competitions whereby interested parties will acquire a common dataset of known ground truth and apply their algorithms against the problem at hand. Winners are announced after the submissions have been evaluated for efficiency and accuracy.

In addition, the forecast of the paperless office has largely failed to materialize and the amount of hardcopy documents used in society remains large, while we have simultaneously seen a swelling of digital document quantities. Outside of PR, the task of organizing and navigating such cross-media collections is a point of important research as institutions see the reduction of librarians as a cost-cutting measure, while the work is downloaded to the subject matter expert. Researchers are at work integrating large collections and speeding the re-finding of hardcopy documents through searching a digital collection. Moreover, as cases grow in size and complexity, such interfaces could aid the FDE in an examination capacity so that comparing handwriting and other features across thousands of documents becomes a more attainable feat.

These products and techniques may prove useful to FDEs in future casework situations or in the organization of vast reference materials and databases. A review of the state-of-the-art in computational document forensics is presented, in addition to a recap of known technologies, highlighting capabilities and limitations. The potential uses of such advanced computational tools will be discussed.

Documents, Computation, Pattern Recognition

J7 Deployment of the Counterfeit Detection Training Electronic Learning Course

Joel A. Zlotnick, MSFS, US Department of State, 600 19th Street, NW, Ste 12.601, Washington, DC 20522; and Tyra S. McConnell, MSFS, US Department of State, 600 19th Street, NW, Washington, DC 20552*

After attending this presentation, attendees will be aware of the deployment strategy for the Document Security Features electronic learning course and how government agencies may request access.

This presentation will impact the forensic science community by providing a resource for comprehensive, broad, and scalable training on security feature technologies used in passports, identity cards, birth records, and other security documents worldwide.

In the United States Department of State, the Bureau of Consular Affairs and the Bureau of Diplomatic Security have developed a broad strategy for deployment of fraud document detection training to a geographically diverse mix of consular and law enforcement staff that must assess a broad range of national identity and travel documents. To address this need, the Bureaus jointly authored and deployed the e-learning course Document Security Features to audiences throughout the Department of State in 2017.

Document Security Features is composed of a series of electronic learning modules that cover a variety of anti-counterfeiting and anti-alteration technologies used in documents, including substrate features used in paper and plastics, printed security features, specialty inks, optically variable devices, and features based on lens technologies. Users are trained to recognize and authenticate these technologies independently of document type or the issuing source agency. Because this broad scope familiarizes users with discrete technologies rather than their specific deployments in individual national documents, users can rapidly assess and self-train on the security features in an unfamiliar document even where no additional background information can be obtained.

It is in the interest of both Bureaus to encourage better understanding of document security technologies within other government agencies at the United States federal, state, and local levels, and also among our partners in the international community. One of the key advantages of e-learning is that once the training is developed, delivery can be scaled in ways that are simply impossible for classroom-based training, because no instructors, classrooms or scheduling logistics are required. Accordingly, once the internal Department of State deployment was completed, the Bureaus commenced work on a second version of Document Security Features that could be offered to external audiences.

The external version of Document Security Features includes information on all of the same topics as the internal version, though some content has been adjusted for non-Department of State audiences. During this presentation, the course content, teaching format, and exercises will be demonstrated using the externally approved version of Document Security Features. For government agencies interested in using Document Security Features to train their own staff, procedures for requesting a copy and completing the required Memorandum of Understanding with the Department of State will be discussed.

Counterfeit, Training, E-Learning

J8 Security Document Artwork That Resists Reverse Engineering

Joel A. Zlotnick, MSFS, US Department of State, 600 19th Street, NW, Ste 12.601, Washington, DC 20522; Jordan C. Brough, MFS, HSI Forensic Laboratory, 8000 Westpark Drive, Ste 325, McLean, VA 22102; and Troy J. Eberhardt, BS, 14931 Greymont Drive, Centreville, VA 20120-1519*

After attending this presentation, attendees will understand how design strategies for security document artwork can play a key role in the prevention of artwork reverse engineering by sophisticated traditional counterfeiters.

This presentation will impact the forensic science community by demonstrating novel strategies for the design of artwork in security documents and how forensic examination of document artwork could be impacted in the future if there is some adoption of this novel design paradigm.

Counterfeiting can be accomplished via one of two basic workflows: digital and traditional. The easier scan-and-print workflow of digital counterfeiting has made counterfeiting easier and more accessible to criminals with limited graphic art skills because it does not require counterfeiters to redraw document artwork, manufacture printing plates, or operate a printing press; however, digital counterfeiting processes are only capable of simulating document artwork using inkjet or toner devices. This places limitations on the quality of the counterfeits that can be produced by digital counterfeiting because the printing process characteristics of the letterpress, intaglio, and lithographic printing processes used to produce genuine security documents cannot be fully replicated with computer printers, office copiers, or multifunction devices.

In contrast, traditional counterfeiters follow a more sophisticated and technically demanding workflow that has the potential to produce counterfeits of higher quality. Traditional counterfeiters try to mimic not just the basic appearance of the document but also the combination of printing processes used in its manufacturing. Before any redrawing or replication of document artwork can proceed, traditional counterfeiters must reverse engineer the artwork to determine how many different printing plates were used, the specific artwork featured on each plate, and other production parameters. Once the counterfeiter understands how a genuine document was printed, it becomes possible to replicate the document artwork, even if executing the replication is made more difficult because of printed security features such as line art, spot colors, microprinting, guilloche patterns, split fountain printing, latent images, transparent register, and similar features.

The security artwork strategies described above all increase the difficulty of either generating the artwork or physically printing the artwork on press. Importantly, not one of these strategies is deliberately targeted at the prepress process of separating the individual printing plate images, which means that a number of theoretical strategies that do target this particular process remain largely unexplored in the contemporary practice of security document design. If a counterfeiter is unable to determine the number of printing plates used or the specific artwork present on each plate, then there is no pathway toward accurate replication of the individual plate artwork. At best, the counterfeiter abandons the attack or, at worst, must compromise the quality of the counterfeit. The question is how to use design to force traditional counterfeiters to face these complications.

To understand how a genuine document was printed, traditional counterfeiters rely on a series of four visual cues that are present in the artwork of most historical and contemporary security documents. These cues include the printing of different colors of ink from each separate plate, the use of continuous line patterns that can be traced, delivery of complete artwork visual elements from a single printing plate, and the use of different artwork styles on different printing plates. Therefore, purposefully designing artwork that does not contain these four cues can produce security designs that can be originated and printed by genuine document issuers, but which are very challenging to reverse engineer if starting only from the printed hardcopy document, as a counterfeiter must. Such designs are essentially the opposite of the four cues described above; they contain the same color of ink on each printing plate, continuous line patterns are eliminated or minimized, most artwork elements require multiple plate images to produce, and the same basic artwork style is used across all printing plates.

This presentation will describe these design techniques, provide examples of security artwork concepts that comply with these principles, and explain ramifications for forensic examination of security document artwork.

Counterfeit, Artwork, Design

J9 Distinguishing Characteristics of Robotic Writing

Aurora Dumitra, MS, NYPD Forensic Investigations Division Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432; Anna Guzowski, BS, NYPD Forensic Investigations Division Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432; Alynka Jean, BS, NYPD Forensic Investigations Division Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432; Melvin Shaw, MS*, NYPD Forensic Investigations Division Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432; Grace L. Warmbier, BS, 1189 Martha Place, Franklin Square, NY 11010; and Patricia Zippo, BS, NYPD Forensic Investigations Division Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432*

After attending this presentation, attendees will be familiar with the characteristics observed in machine-simulated writing.

This presentation will impact the forensic science community by alerting the forensic document examiner of the advances of robotic writing technology and the features that distinguish robotic writing from genuine handwriting.

Robotic handwriting has been long in the making, dating back to the 18th century. Since the 1940s when the Robot Pen became commercially available, autopen devices with advanced features have been used to reproduce an exact copy of a person's signature. In the field of forensic document examination, the term "autopen" has become a standard for all signature-duplication machines. These autopen devices are used to replicate signatures of government officials and also major corporate companies, so these influential leaders and business people can apply their time elsewhere without removing the touch of personalized correspondence and the authenticity of official documents.

Today, in an era of rapid proliferation of digital devices, handwriting has become an unconventional, vintage skill. But, with the advent of new technology, it is possible to mimic an individual's handwriting to generate customizable written documents with the use of digitization, mechanics, and software programming. Programming and mechanics work together to encompass pen positions, speed, and letter form, then integrate that into writing onto paper via a robot. The robot can simulate pen movements, including pen lifts and touches, by operating along three linear axes that move simultaneously. To an untrained eye, the product of this machine is a document that can be mistaken for a genuine, handwritten correspondence by the individual whose handwriting is being simulated.

To reveal the distinguishing characteristics of such technical reproductions of one's handwriting, a study was conducted. Robotic writing samples of six individuals were compared to known, genuine writing samples of the same individuals, including directed and collected samples. Distinct features observed in the robotic samples included even pen-pressure, variable sequence of up strokes and down strokes, and the superimposition of letter forms. Examination, comparison, and evaluation of these features in both the questioned and known samples revealed substantial and significant dissimilarities and resulted in an opinion of non-genuineness.

Technology can certainly assist humans, but it cannot entirely replace humans in the area of writing. Handwriting is an acquired, perceptual motor skill requiring the melding of the mind and body. A person's handwriting is made up of a complexity of habitual patterns and can be identified based on the presence of individualizing features. Careful examination of the structural features as well as dynamic features of a particular writing can aid an examiner in recognizing when a robot is being used. This presentation will confirm the inconsistencies between the human hand and the robotic arm.

Questioned Documents, Robotic Writing, Autopen

J10 An Analysis of Forensic Document Examiner (FDE) Aptitude in Determining and Comparing Velocity Rates of Handwritten Strokes

Michael Caligiuri, PhD, University of California, Dept of Psychiatry, 9500 Gilman Drive (0603), San Diego, CA 92093; Linton Mohammed, PhD, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014; and Carl R. McClary, BA*, 2600 Century Parkway, Ste 410, Atlanta, GA 30345*

After attending this presentation, attendees will better understand the aptitude of FDEs in comparing and determining the velocity of handwritten strokes. This presentation will provide training information for journeyman and trainee FDEs.

This presentation will impact the forensic science community by providing empirical data on the aptitude of FDEs in discriminating velocity of handwritten pair samples. This discrimination is one part of the examination process and can be vital when determining genuineness in handwriting and signatures. The results will provide insights into the ability of FDEs in this area of examination, and the study will be an impetus for future research.

Proper evaluation of the speed of a written stroke is an important parameter for FDEs in determining whether or not signatures or handwriting are genuine. FDEs make this evaluation based on line gradation, variations in pen pressure, and initial and terminal strokes. FDEs have been shown to make reliable evaluations of line speed from early generational photocopied samples and from online samples. This study was conducted by extracting 60 original handwritten letters ("l") from a large database of 16-bit digitized samples and presenting them to 50 forensic document examiners in the form of sample pairs. Each pair included samples of the letter "l" selected to range in known stroke velocity from 10mm/s to 150mm/s. The average velocity of a handwritten stroke is 100mm/s. Pairwise comparisons of letters executed at various speeds were then presented to the FDEs who were asked to provide an opinion as to which of the two samples of the pair was faster. The opinions were a forced call and no inconclusive opinions were allowed. FDE judgments were evaluated to determine the reliability of the FDEs in the task of comparing line velocity using blinded repeat pairs.

The FDEs evaluated the line velocity using online samples. Once these examiner classifications were performed and results received, they were evaluated against the known velocity differences between the sample pairs. That point along the continuum of velocity difference scores where 95% or more of the FDEs accurately selected the faster sample served to operationalize the Just Noticeable Difference (JND). Further analyses were performed to examine effects of years of experience on the magnitude of the JND.

This study processed FDE judgments for accuracy and their ability to identify the JND in perceived stroke velocity based on ground truth of known velocities. This study has implications for validating claims by FDEs about reliably estimating handwriting speed. Identifying the perceptual JND for stroke velocity is relevant to questions of whether experienced FDEs can distinguish important features in handwriting that fall within or outside the writer's natural variation.

This study provides information on the ability of FDEs to determine the velocity of handwritten strokes and their ability to differentiate strokes based on velocity ratings from digitized samples. It should also provide training samples for FDE journeyman examiners and trainees and an impetus for other studies to expand on this one.

Forensic Document Examination, Velocity, Kinematics

J11 The Influence of Terminal Illness and Prescription Medications on Patient Signatures

Jan Seaman Kelly, BA, 9360 W Flamingo Road, #110-400, Las Vegas, NV 89147*

After attending this presentation, attendees will have a better understanding of the influences that opiate pain killers, benzodiazepines, and illnesses may have on a patient's handwriting or signatures.

This presentation will impact the forensic science community by educating attendees that opiate and benzodiazepine drugs act on the brain and nerves, producing a calming effect in relieving pain or anxiety that may result in the patient's signature containing characteristics of distortion. In cases involving such a deviation, attendees will understand the importance of obtaining contemporaneous signatures and a list of medications the patient (writer) was taking.

Every forensic document examiner is aware of the complexities within an individual's handwriting. All physical repetitive actions, including handwriting and the execution of signatures, are achieved through the Central Nervous System (CNS) using the neuromuscular system. Eighty percent of the cerebral cortex is used to produce a handwritten text.[1] Naturally written handwriting and signatures contain a combination of characteristics that can individualize the writing to a specific writer; however, the central nervous system is susceptible to prescription medications designed to relieve pain, anxiety, depression, etc. The patient's writing or signatures may be distorted when under the influence of prescription medications that act on the CNS. Obtaining information regarding the health of the writer and his or her prescribed medications taken during the timeframe of the production of the signature can assist the forensic document examiner in understanding the physiological process involved in the production of distorted writings or signatures.[2]

A 69-year-old male patient was diagnosed with terminal small-cell carcinoma of the lungs on May 3, 1996, and was advised he had four to six months left to live. The patient was asked if he would provide at least one signature each day during his illness as this would assist forensic document examiners in understanding the influence of illness and medications reflected in his known signatures. The patient agreed and the following information was to be recorded: date and time of each signature; the date, time, and name of medication; and the patent's comments regarding pain or anxiety.

Sixty-five signatures were recorded, with the last one written two weeks prior to the patient's death on June 22, 1996. The patient's pain was managed with a variety of opiate pain killers. Benzodiazepines were prescribed to relieve the patient's anxiety and depression. A comparison of the timeline of pain, anxiety, and prescription medications to the timeline of the signatures will provide forensic document examiners with the opportunity to gain a better understanding of the influence these factors may have on the writings and signatures executed by terminally ill patients.

Prescription Medications, Central Nervous System, Signatures

J12 Measuring the Frequency Occurrence of Handwritten Numerals

Thomas W. Vastrick, BS, 522 S Hunt Club Boulevard, Ste 217, Apopka, FL 32703; Ellen M. Schuetzner, BA, 6348 N Milwaukee Avenue, #161, Chicago, IL 60646-3728; and Kelsey Osborn, Forensic Science Institute, University of Central Oklahoma, 100 N University Drive, Edmond, OK 73034*

The goal of this presentation is to provide attendees with objective pre-established frequency of occurrence proportions that provide the soundest foundation for authorship determination and probability estimations.

Pre-established frequency of occurrence proportions is generally acknowledged to be the most objective form of rarity determination available to the forensic document examiner. This presentation will impact the forensic science community by addressing the issue of handwritten numerals and is designed to serve as a sister study to "Measuring the Frequency Occurrence of Handwriting and Handprinting Characteristics" published in January 2017 in the *Journal of Forensic Sciences*.[1]

This presentation describes the results of a statistical research study. The motivation was to strengthen the statistical basis for overall handwriting comparisons in conjunction with the previous paper on which this study expands.[1] Multiple studies and recommendations for purposes of strengthening forensic science have highlighted the need for more comprehensive foundational studies.[2-4] In response to these and other requests, the objectives of this study were to develop statistically valid frequency occurrence proportions for handwritten numeral specimens from sampling representative of the United States adult population for the purposes of providing forensic document examiners with additional objective, statistical information for reliability and measurement validity and to provide courts with additional foundational and supporting data.

This study produced an initial set of 32 handwritten numeral features that were subsequently reduced to 25 characteristics (78%) that passed an Attribute Agreement Analysis (AAA) and were utilized in this study. By passing an AAA, these characteristics are shown to be unambiguously identified by forensic document examiners. Handwriting specimens from 1,197 participants were collected based on the parameters set forth by Johnson et al.[1] Meeting the prescribed population representation through paring led to the selection of 849 numeral specimen forms that closely approximate the demographic proportions represented in the United States. The analysis of these specimens yielded 25 specific frequency occurrence proportions. This study relied on the same protocols applied by Johnson.[1]

There are several studies relative to numeral characteristics.[5-7] Ahola delved into frequency of occurrence in Canada but used a modest, non-stratified sampling number and concentrated on styles of numerals as opposed to specific design structures referenced herein.[5]

Forensic document examination, along with its sister disciplines within the forensic sciences, is undergoing exponential changes in the basic fiber of its foundation. One such change is the recognition that objective, pre-determined frequency of occurrence proportions is the most objective form of weighing the significance of characteristics noted in an examination. In recognition of this, much time has been spent in establishing estimates and this work must continue.

The product of this study is data. Forensic document examination must now collectively decide the best ways in which to utilize this data. Johnson provided several suggestions and ideas, but ultimately it will require a discipline-wide consensus as to the best way to move forward. Frequency occurrence issues are now appearing in reports and in court testimony, so the need for some levels of standardization is becoming increasingly important.

This study is the second in what is anticipated to be a series of studies. The purpose of this study is to fill a gap from the original study in which none of the numeral characteristics passed the AAA. It is anticipated that the next study will further fill gaps from the first two studies. Subsequent to that, it is imperative that these studies be maintained and expanded. By the collection of additional specimens and the identification of additional characteristics that pass AAA, forensic document examination will have an ever-increasingly valuable tool for use in casework and in presenting to courts the foundational research that provides the basis from which we operate.

Frequency Occurrencce, Statistics, Numerals

J13 Initials: Value for Identification

Jane A. Lewis, MFS, 544 E Ogden Avenue, Ste 700-289, Milwaukee, WI 53202*

After attending this presentation, attendees can expect to better understand the identification value of initials in 21st-century handwriting.

This presentation will impact the forensic science community by increasing appreciation for the individuality and limitations of the examination of initials representing abbreviated signatures that forensic document can expect to encounter in their casework today.

A paucity of research on 21st-century initials along with a case involving disputed initials on a loan application motivated this study. Computer keyboarding, diminished teaching of cursive writing to school children, and more use of hand printing in modern writing may have an impact of the use of initials in everyday business documents. This study was conducted to determine the individuality of handwritten initials and their similarities or differences when compared to the capital letters representing the first letter of each name in a signature. Initials are condensed signatures. Forensic document examiners use the same methodology in examining initials as they do for signatures and extended hand printing or cursive writing. Appreciation for the individuality of initials and their consistency or departure from the first letter of each name in a signature will help forensic document examiners correctly identify or eliminate writers of initials in disputed documents.

Forms using letter-sized paper were created to collect four initial samples and two signature samples from each writer in 2017. Sections requesting age, gender, and country of origin of the writer were also included. The goal was to collect samples from at least 200 writers. Evaluation of the collected forms revealed the individuality of many of the basic letter forms of initials in cursive and hand-printed styles. Individuality was also revealed in the punctuation, connectedness, spacing, and size of initials that forensic document examiners can expect to see in cases. Sets of initials composed of two to three letters were compared to the signatures by the same person to discover instances of consistency and differences between the two in basic letter construction, spacing, size, slant, and punctuation.

This study sought to provide an evaluation of modern initials, their general format, and individuality. It also sought to illustrate that initials can conform closely to the capital letters of a signature, but also may be constructed quite differently. This study revealed that the number of letters in a group of initials and their complexity will determine their value for identification. Forensic document examiners must also consider that since letters used to write initials do not always conform to the capital letters of each initial of a signature, known initials must be collected for comparison purposes in casework involving questioned initials.

Initials, Handwriting, Identification

J14 Competency for Chinese Handwriting Examination

Chi Keung Li, PhD, Government Laboratory, Ho Man Tin Government Offices, 88 Chung Hau Street, Kowloon, HONG KONG SAR*

The goals of this presentation are to: (1) introduce the basic principles and methods for the examination of Chinese handwriting to the international forensic community; (2) introduce activities organized to assist the in sharing of the latest developments; and, (3) evaluate the competency of the practitioners.

This presentation will impact the forensic science community by allowing overseas document examiners to better understand the principles and methodology in Chinese handwriting examination and how to demonstrate their competency in this area.

Chinese characters were invented approximately 4,000 years ago, and, unlike English words that are composed of linearly arranged discrete units (alphabet letters and characters), all Chinese characters are written within a framework of an imaginary box with component radicals arranged in a two-dimensional array. Do these disparities in structure and formation between Chinese and Latin-script writing give rise to significant differences in the methods of examination between the two types of handwriting?

Chinese handwriting and signatures are used by more than 1.3 billion people all over the world; document examiners will have the chance to encounter cases involving the examination of Chinese handwriting and signatures. Extensive studies on the examination of English handwriting and signatures can be found in the literature, whereas publications on the identification of Chinese handwriting are relatively limited. Would it be possible for a document examiner who is unfamiliar with Chinese characters to apply the principles of identification and elimination of authorship described in the various literature sources for the examination of English handwriting to the examination of Chinese handwriting?

Hong Kong is an international city where both English and Chinese writing are used in commercial and legal documents. Document examiners of the Government Laboratory, Hong Kong Special Administration Region (HKSAR) have ample opportunity to examine both Chinese and English handwriting and are provided with the opportunity to compare the methodology used in mainland China and overseas. A series of research projects on the examination of Chinese handwriting has been conducted since the late 1980s. In this presentation, the basic principles and methods for the examination of Chinese handwriting will be introduced to the international forensic community.

This presentation will include a review of Chinese handwriting examination that includes: (1) a brief introduction to the history and development of Chinese characters; (2) methods of Chinese handwriting examination as compared to the examination of English handwriting; (3) the significance of various writing characteristics in Chinese handwriting useful for the identification and differentiation of authorship; (4) methods of disguise in Chinese handwriting; and, (5) a study into the individuality of Chinese handwriting.

Numerous international reviews on forensic science stressed the importance of competency and expertise of the forensic practitioners. How can document examiners demonstrate their competency for conducting Chinese handwriting examination? Over the decades, various activities have been organized with a view to providing an analytical forum for participants in the field of document examination to evaluate the competency of participants and share the latest development for seeking further development. Activities such as Chinese handwriting workshops and proficiency testing programs will also be described in this presentation.

Competency, Chinese Handwriting, Proficiency Testing Programs

J15 Research on the Mechanism of Paper Burning by Thermal-Gravimetry and the Handling Methods for Charred Documents

Da Qin, PhD, Insitute of Forensic Science, MPS, PRC, MuXiDi South 17, West City District, Beijing 100038, CHINA*

After attending this presentation, attendees will understand the mechanism of paper burning, which can be summarized by four stages. Additionally, a new handling method with softening and flattening solutions will be introduced.

This presentation will impact the forensic science community by increasing knowledge regarding charred document examination, especially on the use of suitable handling methods based on the stage of the charred paper.

In questioned document examination, a charred document is a piece of burned paper or its fragments containing a message. The examination of such a document and deciphering the writing thereon are important for gaining information, usually demanding a careful application of certain scientific methods and techniques because of its unstable property. To address this issue, the mechanism of paper burning needs to be studied in order to discover the essential and key factors. Here, Thermal-Gravimetry (TG) was applied to investigate five types of paper with their TG and Derivative Thermo-Gravimetric (DTG) curve observed at different atmospheric conditions. The results demonstrated that the shape of curves, albeit similar, varied with the physical and chemical composition of paper. In the burning process, dehydration and de-polymerization are the two main pathways for cellulose — the major ingredient of paper. The heating rate indicated little influence on the curves while the type of atmosphere was strongly influential. The reason is due to the lack of tar oxidation when nitrogen is used as the atmospheric environment. At a moderate temperature, de-polymerization prevails and the tar can be observed. With increasing temperatures, the tar and cellulose are further decomposed, leading to products of a high boiling-point. According to the results, the charred document can be classified as one of dehydrated, tarred, charred, and ashed: (1) Dehydrated — below 100°C, paper is slightly yellow. In this stage, water absorbed in cellulose is gradually lost, and the basic physical property stays intact; (2) Tarred — from 150°C to 250°C, paper color changes from yellow to brown, the edges become curly, and the dimension diminishes. In this stage, although cellulose is not completely decomposed, tar is obtained through de-polymerization; (3) Charred — from 250°C to 350°C, paper changes from dark brown to black and becomes much curlier. In this stage, residual tar continues to oxidize, thus solid char can be observed; and, (4) Ashed — above 350°C, paper color turns from gray-white to ash. In this stage, char continues to oxidize, leaving the high boiling-point products, mainly the filler materials (mostly Calcium Carbonate ($CaCO_3$)).

Except for the ashed document, the other three can be handled and deciphered to collect information. A new softening solution (glycerinum-water) and flattening solution (polyvinylpyrrolidone-ethanol) with a new handling method can be used for subsequent examinations. The results of this study may provide a fundamental method for examining and deciphering charred documents.

Charred Document, Thermal-Gravimetry, Handling Method

J16 The Evaluation of Method Parameters Affecting Magnetic Flux Measurement of Toners as a Screening Tool for Casework Application

Carrie Polston, BA, Sam Houston State University, Chemistry and Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77341; Williams Mazzella, PhD, University of Lausanne, ESC-IPS, BCH, Lausanne-Dorigny, 0 CH-1015, SWITZERLAND; Martin Furbach, MS, Universite de Lausanne, Ecole des Sciences Criminelles, Le Batochime, Universite de Lausanne, 1015, Lausanne, SWITZERLAND; and Patrick Buzzini, PhD, Sam Houston State University, Chemistry and Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand the potential use of a quantitative magnetic flux measuring device to differentiate between black and white toner-printed documents from different sources. Attendees will gain an understanding of the magnetic characteristics exhibited by toner-printed documents and learn how to employ magnetic flux measurement techniques during comparative examinations between questioned and reference printed texts.

This presentation will impact the forensic science community by providing a method for quickly screening black and white toner-printed documents, reducing the need for more time-consuming or destructive methodology.

This study was created to address questions raised by previous research into magnetic properties of toner. Specifically, this research addresses questions related to the optimization of instrumental parameters to maximize repeatability of results and ensure that variability due to the user may be minimized.

Toward this goal, a trial was conducted on seven randomly selected samples from incoming mail collected between April 2007 and January 2016 at the University of Lausanne, Switzerland. A series of three trials were conducted across the span of one week, and a total of 63 magnetic flux measurements were collected from each of three different areas of text per sample. The text areas were selected to include one sample that completely filled the sensor area, one that filled approximately half of the sensor area, and an intermediate sample with an area between the two extremes. The area of each measurement was determined individually using image processing software, and the units were normalized to nWb flux/mm^2 of toner to facilitate comparison.

The primary objective was to determine if the placement of the text within the sensor field affected the precision of measurements. The hypothesis for the experiment based on instrument manuals was that if the text occupied the periphery of the sensor area, there would be distortions in the measurements and the results would become increasingly inaccurate and repeatability would decrease. This is because the sensor is unable to completely image the vector for the magnetic induction of the pixels at the periphery, which leads to inaccurate interpretations of the numerical value for the flux field for those peripheral pixels. The secondary objective was to optimize the protocol for the area determinations. It was determined in a previous study that the mean gray value of the pixels selected appeared to have an impact on reproducibility of measurements. If the standard deviation of the mean gray value was greater than 1 for a sample set, the variance of the results for that sample set appeared to increase. The hypothesis for this linkage was tested by performing the area determinations for the same sample set of interest until the variance for the nWb flux/mm^2 was observed to stabilize at its lowest possible value.

The results of this study indicate that repeatability of magnetic flux measurements of toners can be improved by selecting text areas that do not intersect with the peripheral edges of the sensor and by maintaining a mean gray value standard deviation of .25 or less within the same sample set. This finding is useful to aid in optimizing a method that can be used in a forensic laboratory setting, which will allow for quick screening of toner-printed documents without the need for further testing, which may be destructive.

Questioned Documents, Toner, Magnetic Flux

J17 The Application of t-Stochastic Node Embedding and Random Forest Statistical Methods to Classify Raman Spectra of Inkjet Printer Inks for Purposes of Identification and Production of Investigative Leads

Patrick Buzzini, PhD, Sam Houston State University, Chemistry and Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77341; James M. Curran, PhD, University of Auckland, Dept of Statistics, Private Bag 92019, Auckland 1142, NEW ZEALAND; and Carrie Polston, BA, Sam Houston State University, Chemistry and Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will gain knowledge regarding the application of a relatively novel statistical approach to Raman patterns gathered *in situ* from micrometric colored spots of inkjet-printed documents from different sources.

This presentation will impact the forensic science community, with an emphasis toward questioned document examiners, by evaluating the utilization of a statistical approach to extract information from Raman patterns for investigative purposes. Although the main goal of this research is the improvement of the current examination of inkjet-printed counterfeit banknotes, the proposed approach is definitely relevant to areas of forensic science where spectroscopic data are used.

The printing process by means of inkjet technology involves the production of a constellation of ink spots of micrometric size. Raman spectroscopy proved to be a suitable method for rapidly obtaining a chemical signature *in situ* from the three main colored components (cyan, magenta, and yellow) of inkjet printer inks. The present step of this study seeks to evaluate whether the statistical methods of t-Stochastic Node Embedding (t-SNE) and random forest are suitable for classification to produce investigative leads in cases in which a suspected printer needs to be developed based on its detected Raman profiles.

One hundred fifty Raman spectra were captured from the cyan, magenta, and yellow spots of ten inkjet printer ink samples provided by the Treasury Obligations Section of the United States Secret Service, using a Near-Infrared (NIR) laser wavelength at 785nm. Given that inkjet ink samples generate Raman spectra that often can be differentiated on the basis of the presence of minor peaks only, a sensible classifier is then required for conducting spectral comparisons.

t-SNE is a dimension reduction technique that is primarily used for visualization of high-dimensional data. This technique seeks to preserve low-dimensional (potentially non-linear) groupings that may exist in high-dimensional data. Linear methods such as Principal Component Analysis (PCA) are unable to preserve these non-linear relationships. The method proceeds by converting Euclidean distances to conditional probabilities that represent similarities. These probabilities are computed in the original dimension and in the proposed low-dimensional representation. The optimal lower dimensional representation is the one that minimizes a well-known information theoretic criterion known as the Kullback-Leibler divergence. Van der Maaten and Hinton proposed a variation to t-SNE in which the Gaussian distribution used to compute the probabilities with a Student t-distribution is replaced and the joint probability distribution of pairs of points (rather than the conditional probabilities of one point given another) is used.[1] Both of these proposals lead to improved performance. The method of random forest is an ensemble approach to classification in which a group of low-dimension classifiers can be combined to provide a strong classifier (or learner). A random forest takes random subsets of the available variables to produce a tree, then aggregates (usually by averaging) the classifications over the trees to produce a classification.

The t-SNE visualization and PCA biplots of the Raman data reveal that in general, measurements from the same source (ink cartridge) cluster together. These methods also reveal observations that are behaving poorly. It is interesting to contrast the plots for all dye colors using t-SNE and PCA methods. As one might expect, the PCA plots emphasize the gross differences between the dye colors, whereas the t-SNE plots emphasize the clusters of samples within colors. Inspection of PCA biplots (using pairs of the first three principal components) reveal strong local structure aligned with the source of the measurement; that is, measurements from the same source appear to be close together in Euclidean space. This is an indication that classification techniques should be able to make a reasonable classification; in nearly each case, there are five measurements on each of ten sources. A 60:40 split for training and testing of a random forest model was used. The overall classification rate varied between 75% and 95%, providing at least initial evidence that this technique is a promising classifier for the samples of this study.

Inkjet, Raman, Statistics

J18 Inks Examination Using a Combination of Video Spectral Comparator (VSC) Spectra and Color Deconvolution

Yi Hui Ngor, Health Sciences Authority, 11 Outram Road, Singapore 169078, SINGAPORE; and Nellie Cheng, BS, Health Sciences Authority, 11 Outram Road, Singapore 169078, SINGAPORE*

The goal of this presentation is to conduct ink examinations using a combination of VSC spectra and color deconvolution.

This presentation will impact the forensic science community by providing Forensic Document Examiners (FDEs) a quantifiable means to examine inks and to better discriminate different inks.

Ink examination is usually performed either by: (1) using non-destructive methods such as visual and microscope examination and VSC examination; (2) destructive methods such as Thin-Layer Chromatography (TLC), Raman spectroscopy; or, (3) a combination of both non-destructive and destructive methods. If possible, FDEs would prefer non-destructive over destructive methods in their examinations. Often, the infrared reflectance and luminescence examinations using VSC are sufficient to differentiate the inks; however, issues arise when the difference observed in VSC results is subtle and requires examiners to interpret and determine if these subtle differences (e.g., a small difference in intensity of luminescence of the inks) are sufficient to determine if the inks are different or insufficient not to exclude them. It is this type of interpretation that differs from examiner to examiner that, in the end, could result in different conclusions between examiners. Yet, without using destructive methods such as TLC or Raman spectroscopy, which could provide a more conclusive finding, it is difficult for examiners to make any effective conclusion solely based on observations of when the inks exhibit subtle differences in luminescence at the various VSC settings.

With the goal of resolving the ambiguity that may arise due to the subtle differences observed for inks, a combination of two non-destructive methods of VSC spectra and color deconvolution is proposed. These two methods utilize different working principles and, hence, are complementary to each other in the examination of inks.

VSC spectra: The inks are subjected to various settings of the VSC under both the reflectance and luminescence modes and the results are then tabulated in the format of spectra. The spectra provide examiners a more objective interpretation of the results based on the profiles of the spectra and do not require examiners to agree or disagree if the extent of luminescence is sufficient or not to determine if they are different.

Color deconvolution: The inks are scanned, then processed using the image processing tool, which helps to separate the color of the different inks. The image processing tool utilizes mathematical algorithms that can define each image pixel as a vector of red, green, and blue components, then uses these vectors to help make subtle color differences obvious.

By using the combination of the spectra obtained by VSC and color deconvolution, examiners would have a more quantifiable means in the interpretation of results.

Inks Examination, VSC, Color Deconvolution

J19 The Evolution of Documents and Their Security Submitted for Examination Using a Video Spectral Comparator (VSC®80)

F.L. Jim Lee, Jr., MS, Summit Forensic Document Examination Lab, PO Box 207, Eden, UT 84310; and Darren Corbett, BS, Foster & Freeman Ltd, Vale Park, Evesham Worcestershire, UNITED KINGDOM*

This goal of this presentation is to discuss how the type of documents encountered by questioned document examiners has changed over the last few decades. The increasing pace of developments in security features and the corresponding advances in Video Spectral Comparators (VSCs) for their examination will be examined, as will how these changes affect document examiners today and how they may be affected in the future.

This presentation will impact the forensic science community by alerting attendees to the evolution of documents and to the progress in the development of VSC instrumentation for the examination of falsified and/or altered documents.

After attending this presentation, attendees will understand how a new technology that allows Video Spectral Analysis (VSA), especially using the VSC®80, can enhance and facilitate the investigation and examination of altered security documents, such as identity documents, banknotes, travel documents, and security features, as well as the more routine questioned document problems submitted for forensic document examination to the laboratory, such as those involving alterations due to erasures and additions made to questioned documents.

Personal computers, such as desktops, laptops, and notebooks, have become a part of the VSC systems — initially, this was primarily a method to save images or connect to a printer, but increasingly by taking over control of the instrument by automating tasks, recording settings, monitoring lamps, running self-diagnostic tests, etc. With many instrument capabilities now controlled by software, they can constantly evolve. It is therefore more important than ever for forensic document examiners to keep up to date with technology and its capabilities.

At the same time, digital camera technology has progressed rapidly, as have the associated hardware- and software-driven capabilities, enabling the achievement of higher resolutions, faster operation speeds, and greater image quality. Document security features and devices have followed a similar path. As some types of optically variable features such as holograms lost their effectiveness against ease of compromise, security printers introduced new technologies, such as anti-Stokes inks, micro-taggants, and others. Documents have become more sophisticated. To appreciate this, one has only to compare the latest driver licenses with those issued ten years ago.

Threats have become more sophisticated also — counterfeit driver's licenses, easily available online, are able to match most security features. VSCs closely follow these trends. They are supplied to a great variety of end users, such as Departments of Motor Vehicles, banks, lotteries, universities, insurance companies, and security printers, as well as to the more traditional forensic document examiners. This presentation will conclude with the revealing of a new VSC and its capabilities for the examination of security features in documents — the VSC®80.

Documents, Security, Video Spectral Comparator

J20 A Physical-Chemical Study of Crossed Line Intersection

Daniela Djidrovska, Interpol, 200 Quai Charles de Gaulle, Lyon 69006, FRANCE*

The objectives of this presentation are to answer the many questions regarding whether or not: (1) non-visible ink migration can be used for ink dating; (2) fading of luminescence can be used to determine the production time gap (Dt) between two intersecting lines; and, (3) there is the possibility of identifying luminescent compounds by utilizing various chemical methods.

This presentation will impact the forensic science community by providing a proposed methodology that will enable forensic experts and investigators around the world to conduct examinations at globally accepted standards.

The INTERPOL Counterfeit Currency and Security Documents Branch (CCSD) is responsible for establishing programs that provide forensic support, operational assistance, and technical databases to assist the 190 member countries of INTERPOL regarding counterfeit currency, security documents, and addressing border security issues by improving the integrity of travel and security documents.

The CCSD frequently encourages the incorporation of science into its police work and recognizes the importance of science in the development of technology and investigations. The Physical-Chemical Study of Crossed Line Intersection project began in 2010 at the initiative of the CCSD and in partnership with the International Academy for Handwriting and Documents (AIEED). This project provides a proposed methodology that will enable forensic experts and investigators worldwide to conduct examinations at globally accepted standards. Gaining a better understanding of the sequencing of line-crossings will help forensic document examiners to identify falsified documents, which will assist criminal investigations and combat and prevent future crimes.

For this project, inks were chosen in which migration of ink components has already been observed as well as such inks with unknown behavior. Non-intersecting lines can also be considered for migration studies, if they are positioned close to each other and if luminescence appears in this area. In some cases, invisible migration can be measured/observed outside of intersections.

Shared with participants at the regular INTERPOL meetings on Physical-Chemical Study of Crossed Line Intersection, the "proof of concept," which was established following a year-long forensic analysis of the protocol conducted by laboratories in 13 countries, is to now be tested in the field with the goal of training forensic document examiners to assist in fraud or forgery investigations. This project will foster the development of new research in this domain and expertise to facilitate knowledge-sharing between international laboratories.

This study has been presented to nearly 120 forensic document examiners from 54 INTERPOL member countries who have been regularly attending working group meetings at the INTERPOL Secretariat General.

Migration, Luminescence, Ink Dating

K1 Drivers Under the Influence of Alcohol and Drugs: An Eight-Year Retrospective Analysis in a Southern Italian Region

Anna Carfora, University of Campania "L. Vanvitelli," via Luciano Armanni, 5, via Santa Maria di Costantinopoli, 16, Naples 80138, ITALY; Carlo P. Campobasso, MD, PhD, University of Campania, Dept Experimental Medicine, via Santa Maria di Costantinopoli, 16, Napoli 80138, ITALY; Raffaella Petrella, University of Campania "L. Vanvitelli," via Santa Maria di Costantinopoli, 16, via Luciano Armanni, 5, Naples 80138, ITALY; Paola Cassandro, University of Campania "L. Vanvitelli," via Santa Maria di Costantinopoli, 16, via Luciano Armanni, 5, Naples 80138, ITALY; and Renata Borriello, University of Campania "L. Vanvitelli," Via L. Armanni,5, Naples 80138, ITALY*

After attending this presentation, attendees will better understand the Italian trend of alcohol and drug use among motor vehicle drivers involved in Road Traffic Crashes (RTC).

This presentation will impact the forensic science community by providing alcohol and drug results of biological samples collected from 1,797 drivers at the request of police from 2009 to 2016 that were processed at a major forensic toxicological laboratory in southern Italy.

Operating a motor vehicle while Driving Under the Influence Of Alcohol (DUIA) or Drugs (DUID) is considered a crime worldwide because of the risk to traffic safety. Based on the recent report by the National Institute for Statistics (ISTAT) in Italy, there were 173,892 traffic accidents resulting in personal injury in 2015. From 2013 to 2015, an average of four to six deaths and 20 injured drivers per 100,000 people were recorded by ISTAT in the Campania region, the third most-populous region in Italy. This region has a population of 5,869,965 people, with 4,434,136 inhabitants living in the Naples metropolitan area alone, the second most-populated metropolitan area in Italy, after Milan.

A recent Italian Road Traffic Law (IRTL) (L. 41/2016) just updated the crimes related to DUIA and DUID with the penal sanctions having been generally increased. If a driver causes the death of one person and injury to another, he can be punished with 18 years in prison and at least 5 years disqualification from driving. In the Campania region, the Forensic Toxicology Unit (FTU) of the University "Luigi Vanvitelli" of Campania represents the "reference laboratory" of the entire region, performing all of the confirmation toxicological analyses for medicolegal purposes. The toxicology lab is accredited to perform the analytical work on postmortem samples as well as on hospitalized drivers injured because of RTC. According to the sampling protocol established by the current IRTL, when drivers are injured in an RTC, a medical evaluation must be performed first. Immunochemical screening tests on biological samples must follow in order to find evidence of alcohol/drug effects on the driver's performance. Only positive blood and urine samples collected from injured drivers are forwarded to the FTU for confirmation of the toxicological analyses.

To assess the trends in the use of alcohol and drugs among motor vehicle drivers, a retrospective analysis was performed based on drivers involved in RTC and admitted to 16 Emergency Departments (ED) located in the different provinces of the Campania region from 2009 to 2016. An additional goal of the study was to collect data useful to the improvement of toxicological analytical work and preventive policies with regional relevance. Confirmation tests of positive toxicological screening analyses were performed on biological samples (blood/urine) collected from 1,797 hospitalized drivers. The analyses were performed on a total of 780 blood samples: 609 cases were referred for suspected DUIA and 171 cases for suspected DUIA and DUID; 1,017 urine samples were also collected from DUID cases when the blood test was denied by drivers. All blood and urine samples were collected at admission to the ED within two hours of the accident. Blood Alcohol Concentration (BAC) on whole blood was analyzed by Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID). Qualitative and quantitative analyses for drugs were accomplished by Gas Chromatography/Mass Spectrometry (GC/MS) or Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

Results: BAC greater than 0.5g/L (the legal limit in Italy) was observed in 91.5% of drivers suspected for DUIA and in 93% of drivers suspected for DUID. In particular, BAC >1.5g/L were found in 308 suspected cases of DUIA out of 609 (50.5%) and in 66 suspected cases of DUID out of 171 (38.6%). RCT occurred mostly in drivers with BAC >1.5g/L, while in cases of DUID, BACs between 0.5g/L and 1.5g/L were most common. Toxicological analyses for drugs in blood were negative in 51 drivers out of 171 DUIA and DUID cases total (29.8%). Cocaine and Δ^9-Tetrahydrocannabinol (Δ^9THC) were the drugs most commonly associated with alcohol, followed by poly-drug abuse, a combination of different drugs among which, again, cocaine and THC were the most represented, followed by methadone and Benzodiazepine (BDZ). Among positive urine analyses, 11-nor-9-Carboxy-Δ^9-Tetrahydrocannnabinol (THCCOOH) was the most frequently identified compound, alone or in association with other drugs, followed by poly-drug>cocaine>BDZ>opiates. It is worth mentioning that negative confirmation tests were obtained in 14.5% of the drivers previously recognized as positive in screening analyses. Therefore, an improvement in the protocols currently applied to DUIA and DUID assessment is needed, and confirmation tests on the blood should be considered mandatory in demonstrating a violation of the Road Traffic Act.

Driving Under the Influence, Blood Alcohol Concentration, Road Traffic Crashes

K2 Surface-Enhanced Raman Spectroscopy (SERS) -Based Screening Test for Synthetic Cannabinoids in Oral Fluid

Irene Conticello, BS, University of Bologna, Dept of Chemistry "G. Ciamician," Via Selmi 2, Bologna 40126, ITALY; Chiara Deriu, MS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Thaddeus Mostowtt, MFS, 403 Lakeview Drive, Apt 101, Weston, FL 33326; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand SERS and how it can be used to retrieve structural information from small molecules at very low concentrations. Attendees will also understand how this approach can be applied to the detection of xenobiotics in oral fluid.

This presentation will impact the forensic science community by demonstrating how SERS is a fast, selective, and sensitive approach for synthetic cannabinoids screening, as an alternative to immunoassays.

Synthetic cannabinoids are New Psychoactive Substances (NPS) that represent a worldwide issue due to unknown toxicological effects and widespread use among the young population. Moreover, the rapidity by which these compounds are modified and introduced into the illegal market makes it difficult to detect them using standard screening methods, such as immunoassays. Indeed, cross-reactivity between different species and false negative responses severely limit this approach.

SERS has been shown by this study to have great potential to solve these problems by providing a sensitive and selective screening approach that can provide fingerprint signals from xenobiotics at toxicological concentrations. This was achieved on benzodiazepines, both as standard solutions and in spiked urine matrices, and more recently, on standard solutions of synthetic cannabinoids. The latter included JWH-018, JWH-030, JWH-073, JWH-081, JWH-122, JWH-175, AM-2201, MAM-2201, with typical Limits of Detection (LODs) ranging from 20ng/mL for JWH-018 to 140ng/mL for JWH-081 and AM-2201. By translating this strategy to biological matrix analysis, the forensic and emergency medical field would benefit from a sensitive and selective alternative to current immunoassays. Because the procedure provides a spectral fingerprint, SERS can be seen as a complementary tool to other structure elucidation techniques, such as mass spectrometry.

SERS is a surface spectroscopy that amplifies Raman scattering by several orders of magnitude via the addition of metallic nanoparticles capable of producing Localized Surface Plasmon Resonance (LSPR). In this method, citrate-reduced gold nanospheres were prepared as LSPR-bearing substrates and later aggregated through the addition of $MgCl_2$. The aggregation process red-shifts the frequency of the LSPR and produces strong electromagnetic fields where the particles interact. The result is a rapid method for detection with exceptional sensitivity.

This presentation will focus on the development of an optimal extraction technique to detect synthetic cannabinoids in oral fluids. Fortified oral fluid samples were pretreated via centrifugation in the presence of methanol, which yielded protein sedimentation. Throughout the course of this work, thiocyanate anions were found to be a critical interfering species, as they strongly interact with the colloidal gold. Therefore, a variety of different desalting procedures were examined prior to SERS analysis, including ion exchange and solid phase extraction. The SERS signal was also increased through various wash steps conducted on the gold colloid, prior to its use as an enhancing substrate. This reduced residual citrate molecules carried over from the synthetic process, leaving the nanoparticle's surface more available for analyte adsorption.

The optimized methodology was developed using JWH-018 as a model target drug, then extended to other naphthoylindole synthetic cannabinoids. Detection was achieved using a portable Raman spectrometer operating at 785nm. This new procedure has great potential in forensic analysis, both as a more specific and flexible replacement for immunoassay and as an orthogonal method for analysis that is compatible with downstream mass spectral detection.

Major support for this research has been provided by an award from the National Institute of Justice. Points of view in the document are those of the authors and do not necessarily represent the official view of the United States Department of Justice.

SERS, Synthetic Cannabinoids, Oral Fluid

K3 Will the Real "Molly" Please Stand Up? N-Ethyl Pentylone-Related Deaths in Alabama

Rachel C. Beck, PhD, University of Alabama at Birmingham/Jefferson County Coroner and Medical Examiner Office, SP 286, 620 19th Street, S, Birmingham, AL 35249; Susan Kloda, 619 S 19th Street, Birmingham, AL 35233; Jennifer Whiddon, BS, University of Alabama at Birmingham, 620 19th Street, S, Birmingham, AL 35249; Daniel W. Dye, MD, Jefferson County Coroner/Medical Examiner Office, 1515 6th Avenue, S, Rm 220, Birmingham, AL 35233; Daniel Atherton, MD, Cooper Green Hospital, 1515 6th Avenue, S, Ste 220, Birmingham, AL 35233; and C. Andrew Robinson, Jr., PhD, University of Alabama, Laboratory Medicine Division, Dept of Pathology, Birmingham, AL 35233-7331*

The goals of this presentation are to: (1) review n-ethyl pentylone-proposed pharmacology; (2) describe the n-ethyl pentylone case facts; and, (3) recognize the increasing prevalence of n-ethyl pentylone and the potential trend of combining it with cocaine.

This presentation will impact the forensic science community by increasing knowledge and awareness of n-ethyl pentylone through communication of its increasing prevalence as observed in the Birmingham, AL, area and highlighting the potential new drug trend of combining n-ethyl pentylone and cocaine.

Hypothesis: N-ethyl pentylone, a Novel Psychoactive Substance (NPS), has been observed in high concentrations and mixed with cocaine, which may represent a new drug combination (i.e., speedball (cocaine and heroin), twisters (crack and methamphetamine), el diablo (cocaine, heroin, and marijuana)).

Statement of Content/Methods: Three death cases were investigated by the Jefferson County Coroner and Medical Examiner's Office (JCCMEO) between February and May of 2017; each involving n-ethyl pentylone. N-ethyl pentylone (i.e., bk-EDBP, ephylone, Mercedes, Mitsubishi, Lacoste) is classified as a psychostimulant related to cathinone. Stimulants modulate neurotransmitters (i.e.; serotonin, dopamine, and norepinephrine) through increased release or reuptake inhibition. Being structurally related to cathinone, n-ethyl pentylone is proposed to modulate multiple neurotransmitters with overdoses resulting from serotonin syndrome. Effects related to n-ethyl pentylone use range from euphoria, increased alertness, and talkativeness to agitation, tachycardia, hyperthermia, rhabdomyolysis, hypoglycemia, renal failure, and cardiac arrest. Users describe routes of administration as insufflation, intravenous, and oral with the onset of effects occurring within 30 minutes and lasting three to five hours. Due to its current legal status, n-ethyl pentylone can be purchased via the internet in either powder or pill form and has been observed as a component of Neuregulin 1 (NRG-1) and as "Molly."

The first n-ethyl pentylone case encountered by the JCCMEO was a 34-year-old White male who had been observed using "Molly." According to the witness, the decedent became erratic and paranoid. The decedent was later located underneath a car in an auto garage with the scene in disarray -— overturned items, including chairs and stepladders, and papers scattered around the room. The second occurrence was a 34-year-old Black male. This decedent was at a party when he entered into cardiac arrest and was transported to the emergency room. The decedent transpired a few hours later. The third n-ethyl pentylone case was a 25-year-old Black male found lying in the street suffering multiple gunshot wounds. According to neighbors, the decedent was in a feud with the suspect. In all three cases, postmortem specimens (blood, urine, vitreous, bile, liver, and brain) were collected and submitted to the toxicology laboratory. Analyses performed included: volatiles testing, immunoassay screening, and Gas Chromatography/Mass Spectrometry (GC/MS) confirmation/quantification.

Summary of Results: Postmortem toxicology results for the first n-ethyl pentylone encounter were trace levels (<0.01mg/L) of cocaine and cocaethylene and n-ethyl pentylone at 0.953mg/L. Cause Of Death (COD) and Manner Of Death (MOD) were reported as "Acute n-Ethyl Pentylone Toxicity" and "Accident," respectively. The toxicology results for the second occurrence were cocaine at 0.033mg/L, fentanyl at 0.003mg/L, n-ethyl pentylone at 0.121mg/L, methamphetamine at 0.938mg/L, and amphetamine at 0.086mg/L. COD and MOD for case 2 were "Multiple Drug Toxicity from Methamphetamine, Cocaine, Fentanyl, and n-Ethyl Pentylone" and "Accident," respectively. The third case was the result of multiple gunshot wounds (COD) and determined to be a homicide (MOD) but resulted in toxicological findings, including trace levels of hydrocodone, alprazolam at 0.030ng/mL, and n-ethyl pentylone of 0.045mg/L.

Conclusion: Presented here are the first three occurrences of deaths related to n-ethyl pentylone by the JCCMEO. With these deaths occurring in such a short time period, it is shown that the prevalence of n-ethyl pentylone is increasing in the Birmingham area. Furthermore, a potentially deadly combination of n-ethyl pentylone and cocaine has been observed in two of the cases, with both psychological (paranoid and agitated) and physiological (cardiac arrest) effects witnessed. In short, n-ethyl pentylone is a dangerous NPS that should be included in toxicological analyses.

N-Ethyl Pentylone, Novel Psychoactive Substances, Molly

K4 Carfentanil-Induced Fatalities: A Case Series

Nicholas J. Corsi, BSc, Oakland County Medical Examiner's Office, 1200 Telegraph Road, Bldg 28 East, Pontiac, MI 48341; Prashanti Boinapally, PhD, MSU Department of Epidemiology and Biostatistics, 909 Fee Road, Rm B601, East Lansing, MI 48824; James C. Anthony, PhD, MSU Department of Epidemiology and Biostatistics, 909 Fee Road, Rm B601, East Lansing, MI 48824; and L.J. Dragovic, MD, Oakland County Medical Examiner's Office, 1200 Telegraph Road, Bldg 28 East, Pontiac, MI 48341*

The goal of this presentation is to investigate several fatalities associated with carfentanil and to provide a template for medical examiner offices to monitor "designer" opioid deaths through standardized toxicological screening.

This presentation will impact the forensic science community by providing novel carfentanil toxicity levels, considering that the human biological effects of the illicit opioid are unknown.[1]

Carfentanil is a μ-opioid receptor agonist that induces respiratory compromise and central nervous system depression. Its potency is 10,000 times greater than morphine.[2] Used as an elephant tranquilizer, the schedule II drug has concealed itself within the street drug market in North America. Fatalities continue to climb, considering there has been only one published instance of human exposure to an illicitly manufactured version of carfentanil with a successful medical outcome.[3]

This case series will investigate 17 fatal intoxications involving carfentanil, considering the postmortem findings, autopsy results, and toxicological screenings.

A retrospective review of 2,807 deaths was conducted through the Oakland County Medical Examiner's Office database to investigate all potential deaths of carfentanil use. Every public carfentanil-related death in Oakland County, MI, over a six-month period is included in this study. Postmortem specimens for toxicology measurement were extracted from the matrix source of the femoral artery, except for instances of heart blood when no femoral blood was present. Each decedent received a volatile screen through a fentanyl enzyme-linked immune absorbance assay test kit. With a positive confirmation of a fentanyl metabolite, an expanded postmortem, forensic, quantitative blood test was ordered through the National Medical Services Laboratories (NMS Labs). Carfentanil spectra was matched through a spectral library and measured through Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). A standardized case review form was used to characterize each carfentanil-positive death. All available medical and legal history was reviewed to interpret the death.

Sixty-one percent of the decedents were below the age of 35 years. Other than two females, every decedent was male. The cause of death deemed by the medical examiner was drug abuse (n=0), drug intoxication (n=6), and drug overdose (n=1). The manner of death was undeterminable in 16 of the cases, with one exception of suicide by overdose. Only five of the decedents had pre-existing medical conditions that could be speculated as contributory to cause of death. The rest of the decedents were otherwise healthy individuals with no anatomical evidence of trauma or pre-existing disease. Eight of the decedents underwent endotracheal intubation and six were administered naloxone. Five cases were found with a syringe in hand or within arm's reach. Of 11 chronic substance users, seven either actively abused heroin or used within the past six months per family members and friends. Four presented with biventricular hypertrophy and three possessed left ventricle myocardium hypertrophy. The mean combined lung weight was 1,536 grams. Every case possessed moderate to severe pulmonary edema, with remarkable pulmonary congestion. As reported by NMS Labs, every case presented with a unique panel of drugs with a mean carfentanil concentration of 0.384ng/mL. It was previously suggested that 20 micrograms of carfentanil could induce death, although the concentrations reported in the bloodstream at time of death were as low as 10ng/mL.[4] Five cases were found to have 6-monoacetylmorphine, with a mean concertation of 17.66ng/mL. U-4700 was found in conjunction with carfentanil in three instances.

There has been only one other study which provided results from a comprehensive and sensitive screening method, through Ultra High-Performance Liquid Chromatography (UHPLC) -Ion Trap-MSn, to identify carfentanil.[5] That study only provided detection results, without quantification values. The methods presented in the current study could be employed as a template for other medical examiner offices, as LC/MS/MS can reduce toxicological discrepancies between cases and detect low concentrations.

Hopefully, the cases presented in this study will provide a foundation for further studies examining carfentanil's toxicological characteristics. Future studies are warranted to investigate the epidemiological trends of this perilous opioid.

Carfentanil, Postmortem Concentration, Overdoses

K5 An Assessment of the Incorporation of Amphetamine and Diazepam Into Human Head Hair for the Preparation of Hair Reference Material

Jennett M. Chenevert, BS, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199; Ashley N. Kimble, BS, 9581 Fontainebleau Boulevard, Miami, FL 33172; and Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199*

After attending this presentation, attendees will better understand the process of preparing Hair Reference Material (HRM) with incorporated xenobiotic substances.

This presentation will impact the forensic science community by contributing to a body of research targeted at better understanding the interactions between drugs of abuse with different physiochemical properties and hair that would be considered during routine analysis in forensic laboratories.

HRM is essential for the development and validation of methodologies used in forensic hair analysis. At present, HRM containing selected xenobiotic substances is only available on a limited basis. In addition, most xenobiotic substances relevant to forensic casework are not available as incorporated drug standards in human head hair. Additionally, little is known about the incorporation process that occurs when human head hair is soaked in a xenobiotic-containing buffer solution. This body of work demonstrates the intentional incorporation of Amphetamine (AMP) and Diazepam (DZP) into human head hair for the development of "in-house" HRM by exploring the relationship between time and the concentrations of drug detected in the incorporation buffer solution, daily hair extracts, and solutions used to wash daily hair aliquots. The hypothesis was that, over time, the concentration of xenobiotic detected will decrease in the buffer solution, increase in the hair extracts, and remain relatively constant in the wash solutions.

Purchased human head hair was soaked in 1X Phosphate-Buffered Saline (PBS) spiked with either AMP or DZP at 800pg/mL for five days (120h). Each day, aliquots of hair and spiked PBS solution were taken to monitor incorporation. The hair aliquots were washed using both organic (2-propanol) and aqueous (1X PBS) solvents, then pulverized using a Retsch® MM200 ball mill. Subsequently, the pulverized hair was incubated in a mixture of organic and aqueous solvents (methanol:cetonitrile: 2mM ammonium formate in water; 1:1:2) for 18h to extract incorporated drug from the matrix. After incubation, the samples were centrifuged to separate the hair particulates from the solvent mixture containing recovered drug. The resulting solution was subjected to online Solid-Phase Extraction (SPE) cleanup and Liquid Chromatography/Triple Quadrupole/Tandem Mass Spectrometry (LC/QqQ-MS/MS) analysis. Mass Spectrometry (MS) analysis was performed on the spiked PBS solutions, extracted samples, and wash solutions. A 1µL injection of each sample was introduced to an Agilent® 1290 Infinity Flexible Cube to perform online SPE. A reversed-phase LC column (Agilent® ZORBAX® Rapid Resolution High-Definition Eclipse Plus C18, 2.1 X 50mm, 1.8µm) was used as the analytical column on an Agilent® 1290 Infinity® HPLC system. A gradient elution was used over 8min using 5mM ammonium formate in water with 0.1% formic acid (A) and methanol with 0.1% formic acid (B). Analysis was performed with positive mode Electrospray Ionization (ESI) on an Agilent® 6460 QqQ-MS instrument.

Quantitative results demonstrated the successful incorporation of AMP and DZP into blank human head hair. Contrary to the hypothesis, the amount of drug extracted from the hair aliquots was not significantly different between the 24h and 120h time points for either drug. Final incorporated drug levels were approximately five-fold higher for AMP than DZP. The organic wash did not remove a significant quantity of AMP, but did remove DZP from the surface of the hair. The three aqueous washes each removed AMP from the hair surface, with decreasing concentration in each wash. In contrast, the organic wash and the first of the aqueous washes removed DZP, while subsequent aqueous washes did not remove any additional drug. These results suggest that the maximum transfer of drug from the incorporation buffer into hair occurs within the first 24h of incubation for both drugs. In addition, AMP may be more prone to contaminating the surface of the hair or it may be more loosely bound to the hair matrix than DZP. The differences between incorporation, decontamination, and extraction of these two drugs may be attributed to differences in their physiochemical properties.

Hair Analysis, Hair Reference Material, Incorporation of Xenobiotics

K6 A Mass Spectrometric Approach to the Analysis of Covalent Modifications of Blood Proteins by Drugs of Abuse

Richard A. Gilliland, MSFS, 12605 SW 9th Street, Miami, FL 33184-2330; and Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199*

After attending this presentation, attendees will better understand *in vitro* formation of covalent protein modifications formed by reactive drug metabolites, as well as the Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analytical approach required for detection of these adducts.

This presentation will impact the forensic science community by demonstrating that covalent protein adducts formed *in vitro* provide the necessary framework for an *in vivo* detection method under development for the retrospective detection of drugs of abuse in human blood.

Hemoglobin (Hb) and serum albumin (SA), two prevalent proteins in human blood,- contain unbound cysteine thiol moieties, creating a nucleophilic site with the potential for covalent modification by reactive chemical species. These covalent modifications, called "adducts," are stable entities that accumulate during acute and chronic exposure and remain covalently bound for the life-span of the protein. Despite their current use as exposure markers for a variety of compounds, the use of adducts in assessing exposure to drugs of abuse has not yet been explored. The goal of this work is to examine the *in vitro* adduct-forming capability of selected drugs of abuse with Hb and SA to provide additional proof of principle for the development of a real-world detection and monitoring analysis method. Use of protein adducts as biomarkers of drug exposure will allow for an increased window of detection, from several days to several months, as compared to current blood analysis methods. The drugs examined in this study cover a wide range of abused drugs, including cocaine, methamphetamine, and Δ^9-THC, and have all been shown in previous work in the laboratory to form adducts with glutathione and/or other thiol-containing peptides.

For this research, a new assay procedure was created to facilitate recovery of modified protein by combining published methods with existing methodology used in the lab. The new assay utilized a dialysis membrane to maintain separation of proteins of interest from the microsomal components, while allowing for small molecules (i.e., stable and reactive metabolites) to pass through, resulting in a decrease in the number of steps required to extract the modified protein of interest. For the metabolism/adduction assay, each drug was added to a plastic microfuge tube with residual solvent removed via vacuum centrifuge. Human liver microsomes were added to the tube and combined with Nicotinamide Adenine Dinucleotide Phosphate (NADPH) in the presence of a regeneration system containing glucose-6-phosphate and glucose-6 phosphate dehydrogenase, in sodium phosphate buffer (pH 7.4). The protein of interest was then added; the tube was incubated at 37°C for 18h, then centrifuged. An aliquot of supernatant was removed and added to a clean LC/MS vial for analysis. Instrumental analysis of modified protein was performed using positive Electrospray Ionization (ESI) on an Agilent® 1290 Infinity® Ultra High-Performance Liquid Chromatography (UHPLC) coupled to an Agilent® 6530 MS and chromatographic separation utilized an Agilent® ZORBAX® Rapid Resolution HD Eclipse® Plus C8 column. Data were collected using full MS scan mode, to allow for necessary analysis of all protein components. The mobile phases used were as follows: (1) water with 0.1% trifluoroacetic acid; and, (2) 95% acetonitrile, 4.9% water, 0.1% trifluoroacetic acid. The total run time was 16 minutes with a 2-minute post-run for column re-equilibration. Initial analysis of MS data obtained was performed using Agilent's® MassHunter™ Qualitative Analysis software, followed by MassHunter™ BioConfirm software for protein deconvolution and proteomic analysis of adducts formed.

The use of protein adducts for retrospective drug detection represents a novel and useful advance in drug testing and analysis. The characterization of covalent adducts formed *in vitro* shown in this research provides the necessary framework for future examination of a more complete set of abused drugs. The confirmation and subsequent analysis of these covalent protein adducts reinforces the need for the development of a real-world applicable method to screen for drug exposure utilizing a longer window of detection than is currently available for most drugs and matrices.

Protein Adducts, Drugs of Abuse, LC/MS

K7 Hydrogen Sulfide (H_2S) Poisoning in the Workplace: Toxicological Investigations in a Fatal and Non-Fatal Accident

Elvira Ventura Spagnolo, MD, University of Palermo, Via Del Vespro, 129, Palermo 90127, ITALY; Antonina Argo, University of Palermo, Via Del Vespro 127, Palermo 90100, ITALY; Cristina Mondello, MD*, Department BIOMORF, University of Messina, via Consolare Valeria, 1, Messina 98123, ITALY; Stefania Zerbo, MD, University of Palermo, Via Del Vespro, 127, Palermo 90100, ITALY; Luigi Cardia*, via M Amari 1, Messina, ITALY; Alberto Marchese, Department of Law - University of Messina, via Pietro Castelli, 1, Messina, Sicily 98121, ITALY; Aurora Vesto, PhD, Università "Dante Alighieri" Reggio Calabria, Via del Torrione 95, Reggio Calabria, ITALY; and Nunziata Barbera, MD, University of Catania, Via S Sofia 87, Catania 95123, ITALY*

After attending this presentation, attendees will understand that in cases of occupational asphyxiation, it is important to both conduct a complete postmortem toxicological analysis and to perform accurate scene investigations supported by environmental-toxicological monitoring.

This presentation will impact the forensic science community by highlighting the usefulness of the measurement of thiosulfate that represents an important step in a toxicological investigation of H_2S poisoning because it can supply information regarding the time of death and toxicokinetics.

H_2S is a toxic gas involved in deaths in the workplace. Few cases have been reported in the literature and the accident occurs predominantly in the sour gas industry and in other industrial settings.

The reported case regards fatal and non-fatal intoxications due to H_2S asphyxiation involving six seamen who were working on a ferryboat.

Accident scene reconstruction revealed that three workers had to remove the waste fluid from a bilge of the ferryboat. The first victim unscrewed bolts of the bilge manhole and in a few minutes fell unconscious. Two other seamen who saw what happened asked for help and approached the subject, but they too fell unconscious. Three other workers arrived to move the three unconscious seamen and only one had a protective mask. The first victim died in the workplace, the second one died in the ambulance, while the third one died in the emergency room. Of the remaining three workers, one had a severe pulmonary edema that required intensive treatment, the second had pulmonary injuries also involving the heart, and the third, who wore the mask, had lung injuries.

Toxicological environmental analyses were performed two hours after the accident on air samples from the bilge, the area in front of the bilge manhole, and on the waste fluid collected from the bottom of the bilge. The analyses revealed high levels of H_2S in all specimens.

Autopsies were performed after 48 hours and the findings were the same for all the victims, showing edema of the lungs and multi-organ congestion.

Toxicological analyses were performed both on venous blood taken from the living subjects on arrival at the emergency room and on femoral blood and urine taken during autopsy to evaluate the presence of volatile hydrocarbons, carbon monoxide, hydrogen cyanide, and H_2S. Results from the surviving workers were negative and, in particular, H_2S concentrations were below the quantification limit, being already biotransformed and eliminated in the urine, either in the form of unmodified sulfide or as thiosulfate. In the deceased workers, the toxicological investigation was positive for high levels of H_2S; thus, thiosulfate research was performed to distinguish between the H_2S concentrations in blood secondary to lethal poisoning and those produced by a putrefactive phenomena. Thiosulfate evaluation revealed significant levels in femoral blood (45.7µg/ml) and even more in the urine (510.1µg/ml) belonging to the first decedent. Lower levels were observed in samples from the second decedent (blood: 35.5µg/ml; urine: 10.4µg/ml). Even lower levels were determined in the blood of the third decedent (21.5µg/ml) and no measurable concentrations were in the urine.

These findings demonstrated that the seamen died from asphyxia due to H_2S poisoning. Moreover, the toxicological results allowed for the evaluation of several different survival times. In fact, the first seamen survived for a longer time because metabolism of much of the inhaled sulfides had occurred and a high amount of metabolite (thiosulfate) had eliminated in the urine. The second worker survived briefly and was able to metabolize a smaller amount of sulfides and to eliminate a small amount of thiosulfate in the urine. Finally, the third survived for a very short time because the urine thiosulfate was negative.

This presentation also highlights the importance of safety devices used as well as compliance to the relative Italian legislation.

Hydrogen Sulfide, Toxicological Analysis, Occupational Accident

K8 The Development of a Rapid Multi-Target Screening Method for Emergency Toxicology by Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Hee-Sun Chung, PhD, Graduate School of Analytical Science and Tech, Chungnam National University, 99 Daehak-ro, Yuseong-gu, Daejeon 305-764, SOUTH KOREA*

After attending this presentation, attendees will understand a rapid simultaneous screening method using GC/MS and LC/MS/MS for the determination of multiple toxicants in urine samples collected from intoxicated patients in emergency rooms.

This presentation will impact the forensic science community by informing attendees of the rapid method for simultaneous screening of multiple toxicants by GC/MS and LC/MS/MS that were established to determine targeted and unknown toxicants in urine.

From February 2015 to March 2017, 265 urine samples were collected from the Chungnam University Hospital emergency room. Urine samples were cleaned by using Waters® Ostro™ (pass-through type) and examined by GC/MS and LC/MS/MS. After analysis by GC/MS, the library search for unknowns was conducted by in-house mass spectral databases with the Automated Mass spectral Deconvolution and Identification System (AMDIS). In addition, Chemstation® software was mobilized to identify toxicants. For LC/MS/MS analysis, the 3200 QTRAP® LC/MS/MS and Cliquid® software was used for a simultaneous multi-targeted screening.

A rapid multi-target screening method by GC/MS and L/-MS/MS was developed to determine toxic substances in urine. By using Ostro™ extraction and an in-house database, it was possible to screen urines for toxic substances within three hours. With this method, 265 urine samples were examined and it was noted that zolpidem, acetaminophen, and citalopram were detected in 49, 29, and 16 cases, respectively, and those were the most frequently encountered drugs in emergency room patients. The targeted and unknown toxicants were well searched by in-house and commercial mass spectral databases in all specimens studied. AMDIS & Chemstation® software were used for GC/MS analysis and Cliquid® 2.0 software was used for LC/MS/MS analysis.

The rapid multi-target screening methods by GC/MS and LC/MS/MS developed in this study proved to be applicable to the actual hospital poisoning samples. This method can be efficiently used to detect toxic substances within three hours in emergency cases.

Multiple Toxicants, Targeted and Unknown Toxicants, Emergency Toxicology

K9 A Concentration of Biomarkers in Vitreous Humor for the Estimation of Postmortem Interval (PMI) in South Korea

Hee-Sun Chung, PhD, Graduate School of Analytical Science and Tech, Chungnam National University, 99 Daehak-ro, Yuseong-gu, Daejeon 305-764, SOUTH KOREA*

After attending this presentation, attendees will understand which biochemical markers in vitreous humor can be measured by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for the PMI and the correlation between the levels of biochemical markers and PMI in South Korea.

This presentation will impact the forensic science community by examining the correlation between the concentrations of Hypoxanthine (Hx), potassium, and time after death. This will be useful information for the estimation of PMI.

To choose the possible biomarkers for PMI, concentrations of Hx and lactic acid in vitreous humor were measured by LC/MS/MS. Hx is the terminal stage of purine catabolism in man and is known to be highly correlated to PMI. Also, in mammalian cells, lactate is formed from pyruvate in carbohydrate metabolism under anaerobic conditions. Lactic acid is chiral, consisting of two optical isomers. Because L-lactic acid is known to be correlated with PMI, it was targeted in this study.

A vitreous humor was collected from a cadaver with a known time of death between 18 hours and 103 hours at the National Forensic Service (NFS) in Korea. Twenty-one samples were comprised of 16 males and 5 females with an age range of 27-84 years. Vitreous humors were extracted by a solid-phase extraction with Oasis® MAX cartridges. Agilent® 1260 infinity HPLC system and Sciex® 3200 QTRAP® MS were used for the quantification of Hx, uric acid, and lactic acid in vitreous humor. Chromatographic separation was performed by using 0.1% formic acid in water and methanol as the mobile phase. The Multiple Reaction Monitoring (MRM) of ion transitions monitored was m/z 137.0>110.0, 119.0 for Hx and 5-(p-methylphenyl)-5-phenylhidantoin 267.2>163.3 as the Internal Standard (IS). Lactic acid was separated into L-lactic acid and D-lactic acid by derivatization, and (+)-O,O`-diacetyl-L-tartaric anhydride (≥97%) (DATAN) were used as derivatization reagents. The MRM of ion transitions monitored was m/z 308.0>89.0 for L-, D-lactic acid and L-lactate-3,3,3,-d3 308.1>92.1 as IS for lactic acid.

Analysis of 21 vitreous humor samples revealed that the concentration of Hx ranged from 327μM to 1,780μM and well correlated with the PMI. The Hx concentrations increased gradually until 96 hours, indicating the concentration of Hx and time after death are well matched. The differences in HX concentration between gender and age were not noted. The concentration of potassium was also well related with PMI, while creatinine, Blood Urea Nitrogen (BUN), sodium (Na), and chlorine (Cl) were not correlated with PMI. Lactic acid was separated into L-lactic acid and D-lactic acid through its derivatives.

The correlation between the concentrations of Hx, potassium, and time after death will be very useful information for the estimation of PMI.

Postmortem Interval, Hypoxanthine, Potassium

K10 Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) Extraction of Novel Psychoactive Substances (NPS) From Biological Matrices

Ashley N. Kimble, BS, 9581 Fontainebleau Boulevard, Miami, FL 33172; and Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199*

The goal of this presentation is to describe the findings of using QuEChERS as a quicker and less expensive alternative for the extraction of NPS from biological matrices. This presentation will cover a broad range of drug classes and the trends observed. An optimized extraction method that encompasses as many NPS as possible will also be presented.

This presentation will impact the forensic science community by presenting an alternative to currently used extraction techniques for NPS that includes added benefits, such as decreased costs and time spent on sample preparation.

This presentation is intended to demonstrate the potential of QuEChERS ("catchers") as an extraction technique for various NPS in biological fluids (urine and whole blood). Although extraction techniques for common drugs of abuse are well studied, developing extraction methods specifically targeting NPS is needed due to the high prevalence of NPS in forensic casework. A validated screening/confirmatory triggered Multiple Reaction Monitoring (tMRM) method for 826 NPS by Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) recently developed in the lab is being used to analyze all extracts for this study. The method allows for the screening of a wide variety of NPS drug classes and metabolites, with a focus on synthetic stimulants and cannabinoids due to their current importance in forensic toxicology casework.

Most biological fluids require an extraction step before analysis to avoid unwanted matrix effects and to protect instrumentation. Some commonly used extraction/purification techniques are Solid Phase Extraction (SPE), Liquid-Liquid Extraction (LLE), and dilute/crash and shoot. These techniques can be expensive, time consuming, and may not eliminate all matrix effects. Extraction methods ideally should be inexpensive and relatively fast to allow for high throughput in forensic toxicology labs.

QuEChERS has the potential to be a desirable alternative to these techniques because it can decrease overall costs, matrix effects, and time. QuEChERS was originally developed to simplify and speed up sample prep to extract pesticides from fruits and vegetables. QuEChERS uses a dispersive SPE (d-SPE) technique that increases the sample's contact with the sorbents. This increased contact allows for a more effective extraction than classic SPE. It is specifically designed for highly aqueous matrices and, therefore, can be a very useful technique for forensic toxicology work. While QuEChERS has been previously used as a technique for extracting common drugs of abuse from urine and blood, to date it has not been applied to extraction of NPS on this scale.

In this study, a modified Bond Elute kit was utilized. Blank human urine spiked with 29 different NPS at three different concentrations (5ng/mL, 20ng/mL, and 80ng/mL) was used for this work. The mixture included NPS from different drug classes, including synthetic cannabinoids, synthetic cathinones, tryptamines, and phenethylamines. The range of concentrations was selected to test the utility of the technique for authentic samples, which may contain very low concentrations of these compounds. The extraction process consisted of two major steps: a drying step with salts, followed by d-SPE. First, 3mL of the spiked urine was combined with 3mL acetonitrile, followed by the addition of salts (magnesium sulfate and sodium acetate) to dry the sample, which was then centrifuged at 4,400rpm for 5min. Then, 1mL of the acetonitrile layer was used for d-SPE. The acetonitrile was added to a centrifuge tube containing primary secondary amines, magnesium sulfate, and CI8 and centrifuged at 4,400rpm for 5min. A 100µL aliquot of the resulting supernatant was diluted with 100µL of internal standard mix and 300µL of High-Performance Liquid Chromatography (HPLC) water for analysis by LC/QqQ/MS. The total time for extraction was 15min, which is an improvement over most other extraction methods. An Agilent® 1290 Infinity® HPLC system and Agilent® 6460 QqQ/MS with Jet Stream Technology ESI was used with an Agilent® ZORBAX® Rapid Resolution HD Eclipse® Plus C18 column for LC/MS/MS using the tMRM method.

Results demonstrate that QuEChERS is a promising technique for the extraction of tryptamines, phenethylamines, and synthetic cannabinoids, all of which exhibited recoveries >85% at all three concentration levels. This work is being continued with whole blood and additional NPS to further assess the technique's potential. QuEChERS is capable of extracting NPS from multiple drug classes in a single urine specimen and represents an appealing alternative to other extraction methods due to fewer transfer steps, quick extraction time, and decreased cost.

QuEChERS, Novel Psychoactive Substances, LC/MS

K11 A Validated Method for the Quantitative Determination of Zolpidem, Zopiclone, and Zaleplon (ZZZ Drugs) in Blood, Stomach Contents, and Liver by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Madison R. Schackmuth, BS, 1235 S Josey Street, Apt 271, Huntsville, TX 77340; Rachel Marvin, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; and Erica Bakota, PhD, Harris County Institute of Forensic Science, 1861 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand a validated method for the quantitation of ZZZ drugs in blood, stomach contents, and liver by basic Liquid-Liquid Extraction (LLE) and LC/MS/MS.

This presentation will impact the forensic science community by describing a method validation to rapidly and simultaneously confirm all three ZZZ drugs with matching deuterated internal standards (zolpidem-D6, zopiclone-D4, and zaleplon-D4).

Zolpidem, zopiclone, and zaleplon are sedative hypnotics.[1] Due to their rapid onset of action and short half-lives, ZZZ drugs have become the standard alternative to short-acting benzodiazepines for the treatment of onset and maintenance forms of insomnia.[2] ZZZ drugs are GABA agonists and their poly-use with benzodiazepines, ethanol, or other Central Nervous System (CNS) depressants can increase impairment and lead to toxicity or death.[3] If taken in compliance, the drugs should exist at or below therapeutic concentrations with little to no residual effects upon waking. ZZZ drugs are commonly detected both independently and in conjunction with benzodiazepines and ethanol in Driving Under the Influence of Drugs (DUID) and postmortem cases.[4] Current methods for the detection of ZZZ drugs in blood are generally performed with Ultra High-Performance Liquid Chromatography-Tandem Mass Spectrometry (UHPLC-MS/MS) either in tandem with benzodiazepines or are not quantitative for all three analytes.[1,3,5] The goal of this work was to validate a method for the quantification of zolpidem, zopiclone, and zaleplon by LC/MS/MS.

Both acidic and basic LLE methods were investigated during method development. The basic extraction yielded higher area counts, more uniform peak symmetry, and easier isolation of the organic layer. The basic extraction method utilized saturated sodium borate (pH 12), ethyl acetate, and matching deuterated internal standards. An Agilent® 1290 Infinity® II Stack and 6460 Triple quadrupole/Mass Spectrometry (QqQ/MS) system was employed in positive electrospray ionization mode with Multiple Reaction Monitoring (MRM) transitions selected by the Agilent® Optimizer program. Separation was achieved on an Agilent® InfinityLab Poroshell 120 EC-C18 column (3.0mm x 100mm, 2.7µm) with a 0.6mL/min flow rate of 0.1% formic acid in H_2O (A) and 0.1% formic acid in CH_3CN (B). The gradient was initialized at 20% B for 0.8min, increased to 45% B over 0.8min, and 95% B over 1min. An isocratic hold was placed at 95% B for 1.5min, followed by a decrease to 20% B over 0.3min, for a total run time of 4.7min. Method validation was conducted according to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines.

Seven non-zero calibrators were used to establish a 10ng/mL-1,000ng/mL working range with a 1/x weighting factor. Standard residual plots indicated that zopiclone was best fit with a linear model while zolpidem and zaleplon required a quadratic model. Studies assessing the limit of detection are currently underway and the Limit Of Quantitation (LOQ) was set at the lowest non-zero calibrator (10ng/mL) as ZZZ drugs tend to be found, in blood, at concentrations exceeding the lowest calibrator.[2,6] Carryover following the 1,000ng/mL calibrator was determined to be 0.35%, 0.23%, and 1.28% of the LOQ for zolpidem, zopiclone, and zaleplon, respectively. Three concentration levels (25ng/mL, 400ng/mL, 750 ng/mL) in triplicate were used to determine the bias and precision. Bias and precision were calculated at ≤15% for all three analytes, concentrations, and matrices, with the exception of zopiclone in stomach contents at 17.3% CV. Ion suppression was assessed by a post-extraction spike of mobile phase and negative blood, stomach content, liver, and urine matrices at low and high Quality Controls (QCs). Although ion suppression was present at values exceeding SWGTOX guidelines, it had no impact on accuracy or precision of quantitation. No significant interferences were present in mobile phase samples spiked with common drugs of interest (fentanyl, opiates, cocaine, diphenhydramine, trazodone, buspirone, PCP, 3-MeO-PCP, dextromethorphan, ketamine, duloxetine, venlafaxine, tramadol/ nortramadol, amitriptyline/ nortriptyline, clozapine, doxepin/nordoxepin, fluoxetine/norfluoxetine, olanzapine, quetiapine/norquetiapine). The selected MRM transitions were not triggered by endogenous compounds in negative human blood, stomach contents, liver, or urine matrices. Bias and precision of dilution integrity fell ≤20% and was monitored by preparing a 1,500ng/mL ZZZ calibrator and diluting in triplicate (x25, x10, x4) in negative blood. The preceding validation method meets the requirements of SWGTOX guidelines.

Wilkinson, Las Vegas Metropolitan Police Department, Forensic Laboratory, 5605 W Badura Avenue, Ste 120B, Las Vegas, NV 89118*

After attending this presentation, attendees will understand the need to consider relevant factors before performing retrograde extrapolation in DUI trials.

This presentation will impact the forensic science community by increasing awareness that retrograde extrapolation must be performed with caution to ensure that a reliable calculation is obtained. Data from a Las Vegas Metropolitan Police Department (LVMPD) drinking study will be used to illustrate this point.

In the Illinois case of *People v. Floyd*, the defendant was convicted of aggravated DUI and resisting arrest.[1] The defendant's DUI conviction was later reversed and remanded for a new trial by the appellate court. The decision to reverse the conviction was due to an assumption made by the State's expert witness while performing retrograde extrapolation that the defendant was in the post-absorptive phase without considering all relevant factors. Although the ruling recognizes that it does not "[create] a blueprint or a bright-line rule for the admissibility of retrograde extrapolation evidence," it emphasizes the fact that retrograde extrapolation must be carefully conducted.[1]

To demonstrate this point, a drinking study involving 12 subjects (6 males and 6 females), between the ages of 23-35 years, was conducted. Nine of 12 subjects consumed food within 2.5 hours of the start of drinking. Two subjects consumed food more than four hours prior to the start of drinking, and the time of the last meal was not provided for one subject. Hard liquor was consumed over 1.5-3 hours. Three blood draws were taken from each subject approximately 1, 2, and 3 hours following the end of drinking.

Each blood sample was collected in a 10mL gray-stoppered glass blood tube and was stored at 2ºC-8ºC from the time of collection to the time of analysis. The blood samples were analyzed using a dual column headspace gas chromatograph with two flame ionization detectors. The method was validated following the Scientific Working Group for Forensic Toxicology (SWGTOX) standard practices.

A plot of Blood Alcohol Concentration (BAC) as a function of time was generated for each subject, and the elimination rate was determined through linear regression analysis. Of the 12 subjects, 2 appeared not to be in the post-absorptive phase at the time of the first blood draw. Elimination rates for these 2 subjects were determined through linear regression analysis using only second and third blood draw data. Mean elimination rates of 0.020g/100mL/h (range: 0.015g/100mL/h-0.024g/100mL/h) and 0.018g/100mL/h (range: 0.007g/100mL/h-0.027g/100mL/h) were obtained for male and female subjects, respectively.

For retrograde extrapolation, the elimination rate and rate range considered were 0.015g/100mL/h and 0.010g/100mL/h-0.035g/100mL/h.[2] Assuming that each subject was in the post-absorptive phase at the time of the first blood draw, extrapolating to that time using the second blood draw data overestimated the BAC of one subject. This was the case whether the 0.015g/100mL/h or 0.010g/100mL/h-0.035g/100mL/h elimination rate/rate range was used. Furthermore, retrograde extrapolation to the time of the first blood draw based on the third blood draw data, using the 0.015g/100mL/h elimination rate, marginally overestimated BACs of 2 subjects; however, similar retrograde extrapolation using the 0.010g/100mL/h-0.035g/100mL/h elimination rate range did not overestimate any BAC.

Based on the LVMPD drinking study data and the *People v. Floyd* appellate ruling, it may not always be appropriate to assume that a subject is in the post-absorptive phase at the time of the incident. The BAC may be overestimated if relevant factors, such as the drinking scenario, food consumption, and circumstances surrounding the incident, are not considered. Retrograde extrapolation is an effective tool in determining the BAC at an earlier time when it is carefully conducted.

K13 The Identification of Five Kratom Alkaloids Using High Resolution Mass Spectrometry

Stephanie Basiliere, BS, 3019 Sam Houston Avenue, Apt G302-2, Huntsville, TX 77340; Kelsie Bryand, MS, PO Box 2525, Huntsville, TX 77340; and Sarah Kerrigan, PhD, Sam Houston State University, 1003 Bowers Boulevard, SHSU Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will be able to identify and separate kratom alkaloids using Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS). The influence of mobile phase additives and adduct formation will be discussed and common fragmentation pathways of corynanthe-type alkaloids will be explored.

This presentation will impact the forensic science community by highlighting the importance of mobile phase selection, optimization of ionization conditions, and structural identification of fragment ions using high-resolution MS.

Mitragynine (MG) (9-methoxycorynantheidine, kratom) and 7-hydroxymitragynine (MG-OH) are naturally occurring corynanthe-type indole alkaloids present in the leaves of *Mitragyna speciosa*. This flowering plant of the *Rubiaceae* genus contains more than 20 alkaloids, of which mitragynine is the principal pharmacologically active component, with 7-hydroxymitragynine being a minor psychoactive constituent. Mitragynine and 7-hydroxymitragynine are μ-opioid agonists. Kratom also contains two diastereoisomers of mitragynine (speciociliatine and speciogynine) and paynantheine. Although these three compounds are not known to be psychoactive, their presence in biological specimens may indicate kratom use. Although not yet federally regulated, kratom's dual stimulant and opiate-like effects are somewhat unique, making it an ideal candidate for misuse among recreational drug users.

Separation and identification of MG, MG-OH, Speciociliatine (SC), Speciogynine (SG), and Paynantheine (PY) in biological samples presents a significant analytical challenge. LC/qTOF/MS is a high-resolution MS technique that offers high sensitivity and significant benefits in terms of mass accuracy and structural identification. Mobile phase composition and optimization of the ionization conditions is essential in order to achieve high sensitivity and adequate chromatographic separation. Tandem Mass Spectrometry (MS/MS) spectra can provide valuable structural information. Characterization of fragmentation pathways and identification of ions is important for new assay development.

During the development of an analytical method for MG, MG-OH, PY, SC, and SG in urine, a total of three mobile phase additives were evaluated in deionized water/acetonitrile: 0.1% formic acid; 10mM ammonium formate, and 5mM ammonium acetate. Chromatographic resolution, ionization efficiency, and the formation of adducts were investigated. Fragmentation pathways for MG, MG-OH, PY, SC, and SG were elucidated. MS/MS spectra were used to identify fragments and make mass assignments. Ultimately, this process plays an important role in the selection of highly specific precursor ion transitions. A total of three transitions were selected for each of the compounds.

The most abundant product ions for all compounds were associated with C-ring cleavage and the loss of the substituted piperidine (D-ring) between C2 and C5. The abundance and specificity ultimately led to this being selected for quantitation purposes for MG (399→174), MG-OH (415→190), SC (399→174), SG (399→174), and PY (397→174). Variations of C-ring cleavage predominated for all other major product ions, as well as formation of intact substituted piperidine ions.

Chromatographic separation and mass spectral acquisition are particularly important analytical variables due to the potentially large number of structurally similar alkaloids and diastereoisomers found in *M. speciosa*. LC/qTOF/MS and other high-resolution MS techniques are particularly useful for complex analytes such as these.

Kratom, Fragmentation, LC/qTOF/MS

K14 Conformational Considerations of Ethylenediamine Opioids AH-7921 and U-47700

John L. Krstenansky, PhD, KGI School of Pharmacy, 535 Watson Drive, Claremont, CA 91711; Alexander Zambon, PhD, KGI School of Pharmacy, 535 Watson Drive, Claremont, CA 91711; Thomas Hsu, PhD, Keck Graduate Institute, 535 Watson Drive, Claremont, CA 91711; Jayapal Mallareddy, PhD, KGI School of Pharmacy, 535 Watson Drive, Claremont, CA 91711; and Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be able to recognize potentially confounding spectra attributable to conformational preference or slow conformation interchange of the amide bond in the AH- and U-series opioids.

This presentation will impact the forensic science community by informing attendees regarding spectroscopic issues that arise from conformational aspects seen in the related AH-7921 and U-7700 series opioids.

The published Structure Activity Relationships (SAR) for the AH-7921 series opioids demonstrate a preference for N-monosubstituted benzamides with hydrogen attached to the amide nitrogen. These types of analogs should favor a *trans* amide bond preference.[1] Conversely, U-47700 analog (SAR) indicates a preference for a methyl group on the corresponding amide nitrogen, which allows for *cis* and *trans* amide conformations.[2] The hypothesis is that this preference may be due to each series having the opposite amide bond configuration when bound to the mu-opioid receptor. Preliminary molecular modeling studies that explore this hypothesis by looking at preferred conformations for examples for each of the series and the potential for overlap of key functional groups between the AH-series and the U-series compounds will be presented.

The studies presented will highlight issues that an analyst may encounter that may cause confusion due to data that could be misinterpreted as a mixture. For example, peak doubling in the Nuclear Magnetic Resonance (NMR) due to slow interchange between *cis* and *trans* amide conformations may mislead one into thinking the sample is impure. It has long been documented in the literature that unsymmetrically N,N-disubstituted alkyl amides can exhibit both *cis* and *trans* amide bond conformations due to the lower barrier for rotation and diminished steric preference compared to N-monosubstituted alkyl amides.[3]

Analogs within the AH-7921 and U-47700 series will be analyzed by a variety of methods, including NMR, Gas Chromatography/Mass Spectrometry (GC/MS), Infrared (IR), Raman, etc., particularly regarding indications of conformational preference and potential for rotational interchange. It is well known that simple N-monosubstituted amides that are not conformationally restrained prefer the *trans* amide configuration. The AH-7921 analogs fall into this category. The U-47700 analogs are N,N-disubstituted alkyl amides and demonstrate both *cis* and *trans* configurations as evidenced in their NMR spectra, since the rotational interchange of the amide bond is slower than the NMR time scale. The conditions and the degree to which this phenomenon is observed will be described. The binding of the respective *cis* vs *trans* isomers to the mu-opioid receptor is not known, but it is likely one of the isomers would be preferred by the receptor over the other just as any flexible drug molecule binds to its receptor with a preferred conformation. Also, it is known from structure activity relationships for the U-series analogs that small changes in structure can lead to significant changes in receptor selectivity (e.g., phenylacetamides as kappa-receptor agonists vs. benzamides as mu-receptor agonists).[2]

In conclusion, occasionally even simple compounds can present the analyst with potentially confusing data, so awareness of not only stability issues (e.g., UR-144 degradation in the GC), but also conformational influences on chromatography and spectroscopy is important.

Synthetic Opioids, AH-7921, U-47700

K15 The Transformation of Drug/Metabolite Ratios: An Objective Assessment of Toxicity

Oneka T. Cummings, PhD, Ameritox, LLC, 486 Gallimore Dairy Road, Greensboro, NC 27409; Frank Wallace, BA, Ameritox, LLC, 486 Gallimore Dairy Road, Greensboro, NC 27409; Erin C. Strickland, PhD, Ameritox, LLC, 486 Gallimore Dairy Road, Greensboro, NC 27409; Ronald C. Backer, PhD, 6815 S Highway A1A, Melbourne Beach, FL 32951; and Gregory L. McIntire, PhD, Ameritox, 486 Gallimore Dairy Road, Greensboro, NC 27409*

After attending this presentation, attendees will be aware of the use of a simple mathematical transformation of urine test results to afford an objective assessment of toxicity through the ratio of drug to metabolite (e.g., fentanyl to norfentanyl). Comparison of postmortem drug(s) to metabolite ratios from urine to a large database of such ratios from urine drug testing can help provide this objective assessment of toxicity.

This presentation will impact the forensic science community by demonstrating that the mathematical transformation described in this report can provide a tool to help with the assessment of toxicity in postmortem examinations. These data are necessarily from urine in which "normal" population data exists from pain medication testing. This will require a testing paradigm shift in postmortem samples in which often only the parent drug is tested in various bodily fluids.

Forensic assessment of toxicity is often subjective. For example, it is expected intuitively that fentanyl concentrations from postmortem samples are higher than corresponding therapeutic levels, whether in blood or urine. In fact, many forensic laboratories only test for fentanyl and not the metabolite, norfentanyl. Ruan et al. suggested that the absolute value of the ratio of norfentanyl to fentanyl could be related to the probability of "acute fentanyl toxicity."[1] This work reports that a simple logarithmic transformation of the ratio of parent drug concentrations to metabolite concentrations from a large body of therapeutic test results in urine can afford a stable database for comparison with forensic (postmortem) sample results treated the same way. The stable database for comparison is readily available from urine data obtained during pain medication monitoring testing.[2] Similar databases from blood testing are not available. While this approach can work for any number of potentially toxic drugs, the transformed ratios of fentanyl to norfentanyl in urine from several postmortem cases were compared with the "normal" therapeutic distribution of such transformed ratios to confirm this model/hypothesis. Urine fentanyl/norfentanyl data from overdose cases reported by Coopman et al., Peer et al., and Poklis et al. were similarly transformed to compare with the existing pain monitoring population (Figure 1).[3-5] There is some apparent overlap between the populations, but the overdose population is higher than the "normal" therapeutic results as predicted by Cummings et al.[6] Additional fentanyl/norfentanyl urine data from postmortem samples is expected to more clearly delineate that population of results in contrast to the therapeutic distribution. Thus, this simple transformation of the test results can provide an indicator of toxicity. Of course, the total setting of the death must be taken into consideration, but this approach could serve as an additional tool for forensic scientists in their investigations.

K16 The Electroanalytical Identification of 25I-NBOH and 2C-I Via Differential Pulse Voltammetry: A Rapid and Sensitive Screening Method to Avoid Misidentification

Jose Gonzalez-Rodriguez, PhD, University of Lincoln, Joseph Bank Laboratories, Green Lane, Lincoln LN6 7DL, UNITED KINGDOM; and Ana B. Andrade, PhD, SQS 108 Bloco F apto 506, Asa Sul, Brasilia, Distrito Federal 70347060, BRAZIL*

The goal of this presentation is to present a new electrochemical method to identify 25I-NBOH, a new, potent serotonin 5-HT2A receptor agonist usually identified in blotter paper.

This presentation will impact the forensic science community by introducing a new, selective, and sensitive method for the identification of 25I-NBOH, a compound that is usually misidentified by routine Gas Chromatography/Mass Spectrometry (GC/MS) methods.

Recently, a new potent serotonin 5-HT2A receptor agonist was identified in blotter paper seizures in Brazil.[1] This compound, named 25I-NBOH, is a label molecule that undergoes degradation when examined under routine GC/MS conditions, leading to misidentification as it degrades into 2C-I, an amphetamine-type stimulant.[2] The prevalence of this substance on the Novel Psychoactive Substances (NPS) market can be underestimated under GC/MS conditions, the most widely and routinely utilized analytical technique for drug sample analyses, as it can misidentify 25I-NBOH because of its degradation into 2C-I (and corresponding 2C for the other members of the series).[2] Despite many attempts in adjusting GC/MS conditions and even changing the extraction solvent, Coelho Neto et al. stated that degradation could not be avoided.[2] The degradation takes place inside the GC/MS injector and appears to be caused by the high temperature inside the injector with the degradation products reacting with the alcohol used in the extraction procedure.[2] Another recent study described the analytical determination of phenethylamines derivatives; compounds of the NBOMe group via cyclic and differential pulse voltammetry.[3] Noting that 25I-NBOH has only a single modification regarding 25I-NBOMe, a substitution of a metoxy group for a hydroxy group in the position 3 of the secondary aromatic ring, a very sensitive and specific method to identify 25X-NBOH avoiding misidentification as 2C-X of this class of compounds was developed.

The voltammetric behavior of 25I-NBOH and 2C-I were investigated and their electroanalytical characteristics determined. The investigation of the electrochemical behavior by Cyclic Voltammetry (CV) using a carbon Screen-Printed Electrode (SCPE) showed two oxidative waves observed at +0.74 V and +1.09 V for 25I-NBOH and one single oxidative wave at +1.20 V for 2C-I. The first oxidative peak is a result of the electrochemical oxidation of the secondary amine present in the NBOH compound and the second oxidative wave is due to the halogen oxidation to a hydroxyl group and subsequent oxidation to a ketone (quinone/catechol equilibrium). The effect of scan rate (v) on the peak current (ip) and the peak potential (Ep) upon the electrochemical oxidation of both drugs were also examined. The slope values observed were close enough to the theoretically expected value of 0.5 for a purely diffusion-controlled current. The pH analyses revealed a linear dependence in the order of magnitude to that expected for a monoelectronic/monoprotonic reaction. To achieve unmistakable identification, differential pulse voltammetry was also used. The method uses the electrochemical oxidation of these molecules to produce an analytical signal that can be related to each compound concentration with an average lower limit of quantitation of 0.01mg/mL. The analytical identification for 25I-NBOH, 25I-NBOMe, and 2C-I was performed using the second oxidation wave, although the first oxidation wave was used in the quantification analysis.

A novel, fast, and sensitive electrochemical method for detection of 25I-NBOH using SCPE was achieved and all method characteristics demonstrated the method to be analytically valuable. The method is selective enough to identify the three compounds individually, even given the great similarity in their structure. The method is selective and achieved full differentiation between 25I-NBOH, 2C-I, and 25I-NBOMe.

K17 Death From Poppy Tea Consumption

Lauren N. Fox, MSFS, OCME, 4312 District Drive, Raleigh, NC 27607; Ruth E. Winecker, PhD, OCME, 3025 Mail Service Center, Raleigh, NC 27699-3025; and Sandra C. Bishop-Freeman, PhD, OCME, 4312 District Drive, Raleigh, NC 27607*

After attending this presentation, attendees will understand the toxicological implications of home brewing poppy beverages and the biological concentrations associated with these types of deaths.

This presentation will impact the forensic science community by increasing awareness of the toxicity of this natural high by educating forensic investigators, pathologists, and postmortem toxicologists.

The historical practice of brewing poppy tea for its opioid-like effects is making a comeback with modern-day substance abusers. Whether it is brewed as an attempt to get high, as a source of natural pain relief, or to alleviate opioid withdrawal symptoms, the desired effects among users include euphoria, sedation, or the lessening of any negative symptoms of withdrawal, such as anxiety, nausea, and sweating.

This study presents three postmortem cases with opiate toxicology results that can serve as excellent case studies for debate on the hazards of poppy-drink ingestion. Enough attention has not been given to the dangers of this practice due to the variability of the morphine content of the opium exuded from the plant. While internet tea recipes offer guidance, differences in poppy seed/pod cultivation, washing, and infusing time are some of the reasons why beverages may contain different alkaloid concentrations from brew to brew. Variability in individual opioid tolerance in addition to other drugs also taken will impact the degree of toxicity of the opiates in the tea.

Free opiates (morphine, 6-acetylmorphine, codeine, hydrocodone, oxycodone, hydromorphone, and oxymorphone) in blood and urine are analyzed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) following Solid Phase Extraction (SPE) using a method validated against the Scientific Working Group for Forensic Toxicology (SWGTOX) validation standard. The blood concentrations of free morphine and codeine were 0.94mg/L and 0.11mg/L in case one, 0.62mg/L and 0.034mg/L in case 2, and 0.16mg/L and 0.010mg/L in case 3, respectively. Urine was submitted to the laboratory for two of the three cases. The urine concentration of morphine and codeine in case 1 were 10mg/L and 0.98mg/L and in case 2 were 13mg/L and 1.7mg/L, respectively. None of these cases were positive for 6-acetylmorphine. The minor opium alkaloids thebaine and laudanosine were identified by routine basic drug extraction in the urine of cases 1 and 2.

A review of the scene evidence from all three cases will help practitioners understand the investigatory clues leading to probable poppy drink consumption.

Poppy Tea, Poppy Seed, Forensic Toxicology

K18 The Impact of Storage Temperature, Glucose, and Microorganisms on Blood Alcohol Concentration in Non-Decomposed Whole Blood

S. Sharee Lambert, Emporia State University, 1 Kellogg Circle, Emporia, KS 66801; Melissa M Bailey, PhD, Emporia State University, 1 Kellogg Circle, Campus Box 4050, Emporia, KS 66801; and Carrie Hodges, MLS, Kansas Bureau of Investigation, 2001 SW Washburn Avenue, Topeka, KS 66604*

After attending this presentation, attendees will have a better understanding of how storage temperature, time, and the presence of excess glucose, bacteria, fungi, and yeast have an impact on Blood Alcohol Content (BAC) in non-decomposed whole blood.

This presentation will impact the forensic science community by illustrating the effects of glucose and microorganism contamination on BAC over a six-month storage period.

The presence of microorganisms has been studied in biological matrices, particularly in urine, but to date there are no comprehensive, longitudinal studies that demonstrate the impact of microorganisms and excess glucose in whole blood. Current research has revealed that some bacteria and yeasts, particularly *Candida albicans*, can produce ethanol in blood samples through a fermentation pathway. Additionally, storage of samples in warmer temperatures can increase the bacteria's ethanol production.[1] Conversely, degradation of ethanol in blood alcohol samples can be caused by storage temperature, time of storage, and sample volume.[2] Currently, an international standard for the collection, handling, storage, and testing of blood alcohol samples has not been established. If samples need to be re-analyzed or significant time elapses between evidence receipt and analysis, the samples must be stored correctly to ensure accurate results.[3] This study illustrates the effects of sample volume, storage temperature, and presence or absence of excess glucose and microorganisms on BAC over a six-month period.

Two sets of stock solutions of seven different ethanol concentrations were prepared in defibrinated sheep's blood: 0g/dL, 0.05g/dL, 0.08g/dL, 0.10g/dL, 0.15g/dL, 0.20g/Dl, and 0.30g/dL. D-glucose was added to one set of stock solutions in sufficient quantity to result in a blood glucose measurement of at least 240mg/dL. The appropriate blood was then added to 10mL gray-stoppered BD Vacutainer™ blood collection tubes in varying amounts (2.5mL, 5mL, 7.5mL, and 10mL) by removing the stopper and adding the blood via a syringe. For each BAC, four groups of eight samples were prepared. Group 1 included tubes of each volume as described, with and without excess glucose stored at room temperature (25°C). Group 2 was stored refrigerated at 4°C. Groups 3 and 4 were inoculated with a mixture of *Saccharomyces cerevisiae, Candida albicans, Acinetobacter johnsonii, Fusarium oxysporum,* and *Staphylococcus aureus* to simulate microbe contamination by improper collection (these strains were chosen as some of the most abundant on skin and/or having been indicated as common sources of contamination).[4] All four sets were made at each BAC for monthly analysis (months 0-6), for a total of 1,568 tubes. Each month, samples were analyzed in duplicate with an internal standard of 0.005% 2-butanone in water by an Agilent® 7820AGC and 5977EMS with headspace after instrument calibration, with 0.10g/dL standards run every 24 vials. Additionally, samples from each BAC level were streaked on blood agar plates and incubated to determine viability of the bacteria, yeasts, and fungus. If excess glucose was present, tubes inoculated with the microorganism mixture produced ethanol. Refrigerated samples experienced less degradation than samples stored at room temperature. Sample volume affected the rate of decomposition; smaller sample volumes experienced greater amounts of sample degradation. At BAC greater than 0.20g/dL, the microorganism survival rate was lower.

The results of this study indicate that the presence of microorganisms, particularly in the presence of excess glucose, can negatively affect the accuracy of ethanol analysis and that storage conditions and sample collection conditions, if known, should be considered when analyzing BAC data obtained from casework.

BAC, Contamination, Longitudinal

K19 An Analysis of Drugs and Their Metabolites in Saliva and Urine Using Various Swabs in Conjunction With Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Nicholas L. Drury, BSc, The George Washington University, 510 21st Street, NW, Apt 216, Washington, DC 20006; Nicholas T. Lappas, PhD, The George Washington University, Mount Vernon Campus, 2100 Foxhall Road, LO5 Somers Hall, Washington, DC 20007; and Mehdi Moini, PhD, The George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will be able to: (1) understand the application of DART®-MS to the analysis of illicit drugs and their metabolites on various swabs used in routine drug testing applications; (2) understand the pros and cons of toxicology analysis of buccal swabs and urinary swabs by DART®-MS; and, (3) understand the effects of swab composition, drug type, drug polarity, and collection time on the sensitivity of drug detection in biological samples.

This presentation will impact the forensic science community by improving examiner knowledge of the variables involved in the analysis of oral fluid and urine for the detection of drugs of abuse using DART®-MS as a detection technique for swab analysis.

Hypothesis: Application of DART®-MS is gaining momentum in the forensic sciences due to its fast analysis time and minimal sample preparation. In toxicology casework, various swabs may be used for oral fluid collection and analysis. Though not popular, urine may also be sampled by a swabbing technique after being donated by the testee to concentrate any drugs present in the urine onto the swab tip.[1-3] These swabs may vary in their performance based on the method used for identification of drugs on these swabs, the composition of the swabs (hydrophobicity/hydrophilicity of the fibers), the physical properties (solubility, acidity/basicity, etc.) of the drug, and other factors.

Methods: Positive ion mass spectra were acquired using a DART® ion source interfaced to an AccuTOF™ mass spectrometer. To test the utility of swab sampling techniques for the analysis of drugs by DART®-MS, four different types of swabs were used: CVS™ brand cotton swabs, 155C rayon swabs, and two polypropylene applicators, 4508C FLOQSwabs™ and 4504C FLOQSwabs™, with different tip shapes. Solutions of lidocaine, procaine HCl, diphenhydramine HCl, and quinine monohydrochloride dihydrate were prepared in concentrations ranging from 1mg/ml to 1ng/ml. Specificity, Limit of Detection (LOD), and Linear Dynamic Range (LDR) were established for each swab variant. Next, the method was applied to multiple illicit drugs and metabolites, including cocaine, Δ^9-tetrahydrocannabinol, benzoylecgonine, and 11-nor-9-carboxy-Δ^9-tetrahydrocannabinol. These drugs were used to determine the correlation between: (2) swab fiber polarity; (2) drug polarity; and, (3) sensitivity. These drugs were spiked into synthetic urine or synthetic oral fluid in concentrations ranging from 100ug/ml to 1ng/ml. Each swab was submerged in the solution for 3s and analyzed via DART®-MS.

Results: There was a positive correlation between swab fiber polarity, drug polarity, and sensitivity of drug analysis. When urine or oral fluid solutions of polar drugs were sampled with polar rayon or cotton swabs, sensitivity was an average of ~10X-20X compared to polypropylene applicators. When urine or oral fluid solutions of non-polar drugs were sampled with the non-polar polypropylene applicators, sensitivity was ~10X-20X lower. When polar drugs in urine or oral fluid were sampled by the swabs, peak intensities were greatest for non-polar swabs, followed by more polar swabs. Non-polar drugs gave the highest peak intensity when cotton swabs were used. The two polypropylene applicators are composed of the same fibers, but have different tip shapes; 4508C is slightly more rounded than 4504C, and 4508C always had a higher peak intensity versus 4504C, showing the impact that swab tip shape has on sensitivity. The application of these techniques to the analysis of various synthetic drugs will be presented.

K20 The Concentration and Distribution of Methamphetamine (MA) and Amphetamine (AM) in MA-Related Postmortems

Seung Kyung Baeck, PhD, National Forensic Service, Pusan Institute, 50 Keumho-ro, Mulgeum-eup, Yangsan-si 50612, SOUTH KOREA; Heejin Yang, National Forensic Service, Pusan Institute, 50 Keumho-ro, Mulgeum-eup, Yangsan-si 50612, SOUTH KOREA; Yujin Park, PhD, National Forensic Service, Pusan Institute, 50 Keumho-ro, Mulgeum-eup, Yangsan-si 50612, SOUTH KOREA; Heesang Lee, National Forensic Service, Pusan Institute, 50 Keumho-ro, Mulgeum-eup, Yangsan-si 50612, SOUTH KOREA; and Jiyoung Jo, National Forensic Service, Pusan Institute, 50 Keumho-ro, Mulgeum-eup, Yangsan-si 50612, SOUTH KOREA*

The goal of this presentation is to inform attendees that concentrations of MA and AM in the blood could be estimated with the postmortem concentrations in Bile Juice (BJ), when Peripheral Blood (PB) or Cardiac Blood (CB) cannot be taken.

This presentation will impact the forensic science community by presenting a study that is expected to play a major role in estimating the postmortem concentration of MA and AM in MA-related death cases.

MA is a frequently abused drug in southern parts of South Korea due to the nature of the port area. Also, MA-related deaths often occur in this area more than in other areas of South Korea. This study compared the concentrations and distributions of MA and AM in MA-Related Postmortems (MRPs). Gastric content (GS), CB, PB, BJ, and urine were analyzed in 20 autopsy cases of MRPs.

A Forensic Toxicant Screening Test (FTST) for medicine, pesticides, and cyanide in GS, CB, and urine was conducted by Gas Chromatograph/Mass Spectrometry (GC/MS) or liquid chromatograph/tandem mass spectrometry.

A Forensic Drug Screening Test (FDST) for MA, delta-9-carboxytetrahydrocannabinol, cocaine, and benzodiazepine in urine was conducted by immunoassay, and ethyl alcohol screening in PB by GC. MA and AM, if detected by the FDST, were subsequently confirmed and quantified by re-extraction and re-analysis in CB, PB, and BJ by GC/MS.

The postmortem MA and AM concentrations (mg/L) ranged from 0.42-204.10 (average 18.46) and 0.001-8.70 (average 0.68) in CB (n=15), 0.11-194.40 (average 13.29) and 0.001-7.30 (average 0.54) in PB (n=15), and 0.09-149.40 (average 27.46) and 0.001-4.20 (average 0.83) in BJ (n=9). The ratios of CB to PB (n=12) for MA and AM were 0.79-6.59 (average 1.92) and 0.21-6.67 (average 1.87), BJ to PB (n=8) were 0.77-10.50 (average 4.62) and 0.58-12.67 (average 5.36).

These data suggest that the postmortem MA and AM concentrations in CB are approximately two times (average 1.92 and 1.87) higher than those in PB, and four to five times (average 4.62 and 5.36) higher in BJ. The CB and BJ to PB ratios less than five are consistent with little to no propensity for postmortem redistributions; these data demonstrate that MA and AM are unlikely to exhibit significant redistributions.

According to these detection ratios, the concentrations of MA and AM in the blood could be estimated with those in BJ of the postmortem, which cannot take PB or CB.

Therefore, this study expects to play a major role in estimating the postmortem concentration of MA and AM in MA-related death cases. Additionally, it could assist in or predict the interpretation of MA intoxications and redistributions for the MRPs.

Methamphetamine, Postmortem, Concentration

K21 The Effects of Kambo: The First Case of Sudden Death in Forensic Literature

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Forensic Pathology Dept, Ospedale Colonnello D'Avanzo, Foggia I-71100, ITALY; Simona Magi, PhD, University of Ancona, Ancon , ITALY; Pasqualina Castaldo, PhD, University of Ancona, Ancona, ITALY; Graziella Viscomi, Prosecutor's Office, Courthouse of Catanzaro, Piazza Falcone e Borsellino, Catanzaro 88100, ITALY; Salvatore Amoroso, University of Ancona, Ancona, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the effects of Kambo as a concurrent cause of death in users with heart disease.

This presentation will impact the forensic science community by explaining Kambo's biological effects and the need to control its sale.

Kambo is a substance obtained from the skin secretions of a frog, *Phyllomedusa bicolor*. The secretions are used during a purification ritual common in some regions of South America. After the skin is burnt, the secretions are applied, causing a type of poisoning in a process not yet fully understood. No fatalities associated have yet been reported. In the case reported, the biological effects of Kambo with the potential to cause death were analyzed.

A 42-year-old man was found dead in his house. The external examination showed recent burns on the left arm. A wooden stick, approximately 10cm long and burnt on one end, was found near the body. A plastic box labeled "*Kambo Sticks*" was also found. From his medical history, it emerged that the man was a chronic consumer of this substance. There was no history of drug use nor a family history of sudden premature death or ischemic heart disease.

A toxicology analysis was performed on biological fluids for alcohol, prescription medication, and illicit drugs. A toxicological study was also conducted on the Kambo sticks and on biological fluids (blood and vitreous humor). The analysis consisted of reverse phase High-Performance Liquid Chromatography (HPLC) and mass spectrometry with TripleTOF® 5600+ System. Internal analytical standards were used for the research of dermorphin, deltorphin A, phyllocaerulein, phyllokinin, sauvagine.

The heart exhibited left ventricular concentric hypertrophy. There were also apparent petechiae on the subpleural area and a subconjunctival hemorrhage. Histological examination revealed moderate coronary artery disease with a reduction of approximately 65% of the left coronary branch by the atheroma. The brain displayed intraparenchymal microhemorrhages. The lungs had subpleural petechiae and bullous emphysema, with fibrotic thickening of the septal interstitium and sporadic micro-granulomas. The myocardium exhibited fragmented myofibrils and areas with marked inter-myofibrillar connective tissue.

The toxicological screening was negative for cannabinoids, opiates, cocaine metabolites, benzodiazepines, and ethanol. The investigations performed on the sticks found in the house demonstrated the presence of deltorphin A, phyllocaerulein, and phyllokinin; however, regarding biological fluids, deltorphin A was isolated exclusively in blood.

Kambo is comprised of a peptide mix. The peptides contain opioids including dermorphin and deltorphins, vasoactive molecules including phyllocaerulein, phyllomedusin, phyllokinin, sauvagine, and antimicrobials including dermaseptins. The peptides affect the body both at a central and peripheral level. The effects of each peptide are not yet fully understood. In the case reported, the man died suddenly after the substance was applied. In this case, as noted by the clinical data reported by the family doctor, the young man didn't appear to have any diseases or symptoms, and didn't take any medicine for treatment or other drugs intravenously. From the testimony of his mother, death happened approximately 30 minutes after the application of the drug. The autopsy revealed a left ventricular hypertrophy. By analyzing the action of these peptides on the body, it is possible to assume that the chronic consumption of some of the cardioactive peptides could lead to the development of left ventricular hypertrophy. Coronary artery disease was also found, most likely associated with the man's lifestyle (smoker and overweight). Certainly, the more likely effect would be hypotension. Death might therefore result from hypoperfusion of the heart which, in this case, could well be exacerbated by the increased left ventricular mass and moderate coronary artery disease. In a heart exhibiting moderate coronary artery disease and left ventricular hypertrophy, this generated an acute cardiac ischemia and consequent ventricular fibrillation. The following pressure peak generated was demonstrated by diffuse cerebral micro-hemorrhages, subpleural petechiae, and subconjunctival hemorrhage. The positive results of the toxicological investigation made it possible to state that the substance could be one of the concurrent causes of death. It is also important to consider that this substance can easily be ordered and obtained from many websites without any controls and/or prescriptions.

Forensic Science, Kambo, Sudden Death

K22 An Evaluation of Alcohol Concentrations in Samples Referred to the Forensic Laboratory in Baghdad

Atheer Jawad Al-Saffar, Al-Nahrain University, Al-Mansor, Baghdad, IRAQ; Haider K. Al-Rubai, MSc, Forensic DNA Center for Research and Training, Karrada, Baghdad, IRAQ; Enas Muataz Al-Qazzaz, BPharm, Medico-legal Institute, House #19/1, Al-Mutahna District 712/13, Baghdad, IRAQ; and Muataz Abdulmajeed Al-Qazzaz, PhD, University of Al-Nahrain -College of Medicine, House #19/1, Al-Muthana District 712/13, Baghdad, IRAQ*

After attending this presentation, attendees will be aware of the minor impact of the problem of alcohol drinking in causing and contributing to the cause of death in all autopsy cases in Baghdad. The goal of this paper is to detect and measure the concentration of alcohol, tackle this issue, and reveal its scope.

This presentation will impact the forensic science community by revealing the size of the problem of alcohol intake in contributing to or causing death.

Alcohol is one of the world's leading risk factors for morbidity, mortality, and disability. In 2012, 5.9% of all global deaths were attributed to alcohol and 5.1% of all global diseases and injuries were attributed to its use as well. Its effect was more pronounced from neuropsychiatric disorders.[1] Annually, 88,000 people die from alcohol-related causes in the United States and it is considered the fourth-leading preventable cause of death. It is blamed for 31% of all driving fatalities.[2]

Alcohol is also related to many crimes. In 2013-2014, 53% of violent crimes were committed under the effect of alcohol, including assaults, wounds, sexual offenses, homicides, criminal damages, theft, and robbery.[3]

This study was a prospective study within the first six-month period of 2015 on postmortem blood samples referred to the main forensic toxicology laboratory in the medicolegal directorate in Baghdad for the detection and measurement of alcohol; 5ml to 10ml of blood was withdrawn for each sample and a Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID) from Agilent 7890A was used.[4]

A fifty-milligram percentage of alcohol was considered the cut-off point and every result above 50% was considered to be a positive sample. In general, traumatic death was predominant among all victims.[5] From the total 1,275 samples, only 112 (8.8%) were positive, with males more than five times more frequent than females. There was a significant relation to alcohol intake with traumatic causes of death, yet in only 13 victims were the concentrations fatal.

This study also revealed that traumatic causes of death decreased significantly with advancing age. Only 12 positive samples were attributed to natural causes of death. In those victims, alcohol probably factored with their diseases in precipitating death.

Alcohol drinking is a minor problem, as it was detected in a small group of all cases, yet its association with traumatic death was significantly higher than natural death and its consumption was more than five times higher in males. Only in a limited number of cases was the concentration fatal.

Alcohol, Ethanol, Postmortem

K23 The Evaluation of Direct and Indirect Biomarkers of Ethanol Consumption: A Likelihood Ratio (LR) Approach to Identify Chronic Alcohol Misusers for Forensic Purposes

Eugenio Alladio, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano (Turin) 10043, ITALY; Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY; Agnieszka Martyna, PhD, Department of Analytical Chemistry, Szkolna 9, Katowice, Polska 40-007, POLAND; Alberto Salomone, PhD, Regione Gonzole 10/1, Orbassano (TO), ITALY; Valentina Pirro, PhD, Purdue University, Dept of Chemistry, 560 Oval Drive, West Lafayette, IN 47907; Grzegorz Zadora, Institute of Forensic Research, Westerplatte 9, Krakow 31033, POLAND; and Paolo Garofano, MD, PhD, Laboratorio Genetica Forense - CAD, Regione Gonzole 10/1, Orbassano (TO) 10043, ITALY*

After attending this presentation, attendees will understand how to interpret and evaluate the values of direct biomarkers of ethanol consumption to be detected in hair and keratin matrix for forensic purposes.

This presentation will impact the forensic science community by informing attendees that the LR models proved to be capable of significantly discriminating non-chronic from chronic alcohol consumers.

The determination of direct ethanol metabolites, such as Ethyl Glucuronide (EtG) and Fatty Acid Ethyl Esters (FAEEs), to be quantified in keratin matrix samples is indicated as the gold-standard approach to efficiently identify chronic alcohol drinkers.[1,2] Even if cut-off values have been established by the Society of Hair Testing (SoHT) to interpret EtG and FAEEs results, it has been documented that several confounding factors may alter the correlation between alcohol consumption and biomarkers' concentration in hair (e.g., cosmetic treatments).[3] As a consequence, the adoption of the traditional univariate interpretative approaches seems not to be the best option, as it may lead forensic experts and physicians to infer misleading conclusions, thus triggering the possibility of employing alternative multivariate data interpretation approaches.

Due to the fact that the LR models overcome the drawbacks of the traditional univariate approaches, as no cut-off values are involved during the process of evidence evaluation, several LR models have been developed and tested.[4] In the practice, LR values reveal the support to be delivered to the evaluated propositions and LR results can be expressed by means of verbal scales. An LR approach evaluates the Evidence (E) in case of two different, and mutually exclusive, hypotheses by examining the collected data. In the present case, the first hypothesis (H1) is that the individual under examination is a non-chronic alcohol consumer. Otherwise, the second hypothesis (H2) states that the examined subject is a chronic alcohol misuser. At the current stage, the collected data consists of direct (FAEEs, EtG) biomarkers of alcohol consumption from more than 150 scalp hair samples of different individuals, representing both chronic and non-chronic alcohol drinkers target categories. Different multivariate LR models have been evaluated and their ability to discriminate chronic alcohol misusers from non-chronic alcohol consumers were examined. The performance of each model was evaluated in terms of rates of correct classification (%) and empirical cross-entropy parameters. Since satisfactory reduction of information loss have been observed, together with correct classification rates close to 100%, LR validated models proved to be capable of discriminating non-chronic from chronic alcohol consumers. Similar results have been observed when employing further multivariate data analysis strategies such as Partial Least Squares Discriminant Analysis (PLSDA).[5]

Chronic Alcohol Drinkers, Hair Samples, Likelihood Ratio

K24 2017 Novel Illicit Opioids: Trends and Toxicological Insights

Donna M. Papsun, MS, NMS Labs, Willow Grove, PA 19030; Melissa Friscia, MSFS, CFSRE, 2300 Stratford Avenue, Willow Grove, PA 19090; Jennifer L. Turri, MS, W3901 Johnson Road, Vulcan, MI 49892; Sherri L. Kacinko, PhD, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the changes in novel illicit opioid positivity in forensic casework over a 6- to 12-month time period in 2017.

This presentation will impact the forensic science community by detailing trends in the use of novel illicit opioids in 2017, including change in positivity over time, user demographics, and quantitative data from casework, all of which underscore the need for comprehensive toxicological testing with a dynamic scope for novel opioids and vigilance by investigators, forensic scientists, and legislators.

Novel illicit opioids are a major component of the opioid epidemic that has become a major public health crisis. Increased misuse and diversion of pharmaceutical fentanyl in the early 2000s has given way to exponential growth since 2013 with the appearance of illicitly synthesized fentanyl and the introduction of additional novel illicit opioids, such as U-47700, furanyl fentanyl, and carfentanil, which have subsequently been identified in toxicological casework. Toxicological identification involved either Liquid Chromatography/Time Of Flight (LC/TOF) or fentanyl-based immunoassay screening and targeted confirmations using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) or a Gas Chromatography/Mass Spectrometry (GC/MS) database match.

Positivity data was obtained from toxicology casework (death investigation, impaired driving, and hospital admissions) in which the commonly encountered novel opioids furanyl fentanyl, U-47700, carfentanil, butyryl fentanyl, para-Fluoroisobutyryl Fentanyl (FIBF), and acryl fentanyl were detected in blood samples (Table 1). Percent positivity indicates the proportion, relative to the totals for these drugs encountered by month.

	January		**February**		**March**		**April**		**May**		**June**		**TOTAL**
	N	%Pos	N	%Pos	N	%Pos	N	%Pos	N	%Pos	N	%Pos	
Furanyl Fentanyl	122	41.4	178	49.3	164	39.0	114	39.6	120	33.7	90	28.1	**788**
U-47700	34	11.5	31	8.6	53	12.6	47	16.3	68	19.1	45	14.1	**278**
Carfentanil	79	26.8	51	14.1	31	7.4	46	16.0	51	14.3	73	22.8	**331**
Butyryl Fentanyl*	6	2.0	17	4.7	45	10.7	18	6.3	23	6.5	7	2.2	**116**
FIBF*	34	11.5	28	7.8	55	13.1	29	10.1	63	17.7	80	25.0	**289**
Acryl Fentanyl	20	6.8	56	15.5	72	17.1	34	11.8	31	8.7	25	7.8	**238**
TOTAL	**295**		**361**		**420**		**288**		**356**		**320**		**2040**

Table 1: *Change in positivity from January 2017 to June 2017.*

**%Pos = %Positivity for month specified. *Butyryl Fentanyl and FIBF are not differentiated from their isomers isobutyryl fentanyl and para-fluorobutyryl fentanyl, respectively.*

During the same time period, a total of 5,589 fentanyl cases were encountered, in addition to 2,458 cases containing the heroin metabolite 6-monoactylmorphine. Carfentanil, furanyl fentanyl, and U-47700 became popular in 2016 and maintained popularity in 2017. Positivity of furanyl fentanyl has been declining as positivity for acryl fentanyl and FIBF have been increasing from 6.8% to 7.8%, and 11.5% to 25%, respectively, in casework between January and June. Several other fentanyl variants are also being detected in toxicology casework to a lesser extent. 3-methyl fentanyl has continued to be seen (70+ detections total) in 2017, after re-appearing in 2016 following a roughly 30-year hiatus. There have also been sporadic detections of valeryl fentanyl (*n*=1), 4-methoxybutyryl fentanyl (*n*=1), and fluoro fentanyl analogs (*n*=20). An additional "U" series compound, U-49900, has been confirmed in two postmortem cases and both cases were also positive for Tetrahydrofuran Fentanyl (THF-F), a new fentanyl derivative first seen in 2017. Additionally, methoxyacetyl fentanyl (*n*=7) and cyclopropyl fentanyl (*n*=1) are being detected with increasing frequency as of July 2017.

These new substances challenge the forensic toxicology and chemistry communities because they pose all the same risks of routine opioids while going undetected. The data also illustrates the short cycle time of many of these drugs as they can come and go before a toxicology laboratory can develop and validate a method for their detection. In addition, the potency of these derivatives and correspondingly low concentrations in biological fluids challenge the capabilities of routine analytical methodology, forcing laboratories to seek new technologies to keep abreast of the trends.

Novel illicit opioids have been confirmed by the reporting laboratory in 42 states and Canada. Although certain states, especially the Northeast United States, have greater prevalence for certain compounds, they are not isolated to one part of the country. The forensic science community in general needs to be aware of the impact of novel illicit opioids.

Opioids, Novel Psychoactive Substances, Methoxyacetyl Fentanyl

K25 The Morphine in Your Pantry — Understanding the Overdose Risk of Home-Brewed Poppy Seed Tea

Deborah L. Powers, BA, SHSU Department of Forensic Science, Huntsville, TX 77341; Stephen A. Erickson, MD, #3 Natural Resources Drive, Little Rock, AR 72205; and Madeleine J. Swortwood, PhD, Sam Houston State University, Huntsville, TX 77341*

After attending this presentation, attendees will understand the risks involved with consuming home-brewed poppy seed tea, including death. Attendees will learn that regardless of extraction conditions, it is possible to rinse opium alkaloids from poppy seed coats by home-brewing methods. In particular, attendees will learn that it is possible to rinse lethal amounts of morphine from unprocessed poppy seeds at home.

This presentation will impact the forensic science community by demonstrating the need for further consideration regarding the legality of purchasing unprocessed poppy seeds in bulk.

Morphine, codeine, and thebaine are naturally occurring opiates found in the latex of the opium poppy (*Papaver somniferum*). This latex is harvested worldwide for both licit and illicit opioid production. Poppy seeds are commonly harvested for baking, and opium alkaloids are transferred onto poppy seed coats during the harvesting process. Bulk, unprocessed poppy seeds can be purchased online with no current legal repercussions.

Recently, a medical examiner reported the case of a 24-year-old male who died of morphine intoxication with aspiration pneumonitis; however, neither licit nor illicit sources of morphine were found at the scene. It was suspected that the decedent ingested a lethal amount of morphine from home-brewed poppy seed tea. A 5-pound bag of poppy seeds and a 33-fluid-ounce bottle filled with seeds and water were found at the scene.

Due to the recent increase in poppy seed tea-related deaths, this research proposed that lethal amounts of morphine could be extracted from poppy seeds by home-brewing methods. Codeine concentrations were investigated because codeine is another opium alkaloid with analgesic properties, and codeine and morphine can have compounding effects when both drugs are taken simultaneously. Thebaine concentrations were investigated because, although it has no analgesic properties, its presence in biological specimens is indicative of poppy seed consumption.

No studies to date investigated opium alkaloid content that can be extracted from poppy seeds by home-brewing methods. For this reason, 22 samples of poppy seed products were purchased from online sources and extracted with four home-brewing methods representative of recipes found on drug user forums. Poppy teas were produced in room temperature and heated water, with and without lemon juice (acid) modifier over 10min with gentle agitation.

Extracts were analyzed in triplicate, and morphine, codeine, and thebaine were quantified in these extracts by liquid chromatography-tandem mass spectrometry using a validated analytical method. Precision and accuracy were 4.2%–7.7% and 92.3%–103.4%, respectively, with minimal matrix effects (95.1%–103.7%). Morphine, codeine, and thebaine concentrations were <1mg/kg–2,788mg/kg, <1mg/kg–247.6mg/kg, and <1mg/kg–124mg/kg, respectively. Many samples yielded morphine levels that would correlate to lethal concentrations if moderate volumes of tea were consumed. Yield varied between all extractions for all analytes in all samples.

Forensic Science, Forensic Toxicology, Poppy Seed Tea

K26 Carfentanil-Related Deaths in Wayne County, Michigan: Epidemiology and Toxicology

Denice M. Teem, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Daniel S. Isenschmid, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Carl J. Schmidt, MD, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the toxicological and epidemiological aspects of a series of 129 carfentanil-related fatalities in Wayne County, which includes the city of Detroit, MI.

This presentation will impact the forensic science community by providing attendees with the carfentanil concentrations observed in medicolegal death cases related to the drug in addition to the demographic information associated with the decedents, which will assist with the interpretation of drug concentrations in future carfentanil deaths.

Introduction: Carfentanil, a synthetic opioid with an analgesic potency estimated to be 10,000 times that of morphine and that is approved for veterinary use in the sedation of large animals, was analytically confirmed in blood samples from 129 death investigation cases investigated by the Wayne County Medical Examiner's Office between August 2016 and June 2017. Details of the findings in these cases are presented and discussed.

Methods: All cases presented were submitted to NMS Labs in Willow Grove, PA, for comprehensive toxicological analysis by a Liquid Chromatography/Time Of Flight/Mass Spectrometry (LC/TOF/MS) screen for approximately 250 drugs and their metabolites, which includes carfentanil and several other emerging novel opioids in an additional secondary targeted accurate mass database. Confirmatory testing for carfentanil was performed by quantitative Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) with a quantitative reporting limit of 0.10ng/mL and limit of detection of 0.03ng/mL. Carfentanil-positive cases were reviewed for other drug findings, as well as demographic case data.

Results: Carfentanil concentrations ranged from 0.1ng/mL to 14ng/mL (*N*=127) with two cases <0.1ng/mL. The mean and median concentrations were 0.75ng/mL and 0.44ng/mL, respectively. It was found that 87% of cases had a carfentanil concentration less than or equal to 1.0ng/mL. There were only three cases in which carfentanil was the only drug detected. In 87.6% of cases, another opioid was detected, including morphine (57%), fentanyl (43%), 6-acetyl morphine (38%), furanyl fentanyl (28%), and U-47700 (12%). Other common findings were ethanol (50%), cocaine and/or benzoylecgonine (45%), cannabinoids (31%), and alprazolam (21%). Death locations were at home (37%), at a scene (32%), or in a hospital (31%). Naloxone was detected in 78% of hospital deaths compared to 17% at home and 7.3% at a scene. Decedent demographics were mostly male (73%) and White (63.5%). Black or African American (32.5%) and other (4%) were slightly underrepresented compared to overall Wayne County demographics (52% White, 31% Black or African American, 7% Other). Total cases peaked between November 2016 and February 2017, after which there was a sharp decline in deaths related to carfentanil. In one case, an antemortem whole blood specimen was collected at the hospital approximately 14 hours prior to death. The antemortem blood and postmortem femoral blood concentration was 0.93ng/mL and 0.34ng/mL, respectively. The half-life of carfentanil in female elands was reported to average 7.7 hours.[1] This single human case appeared to have a half-life of 8.1 hours. While there are certainly caveats to this extrapolation of kinetic data, it does suggest that a one-time dose of naloxone (half-life 64 +/- 12min) would be insufficient as an antagonist. To various degrees, all of the reported cases involved police, first responders, investigators, morgue assistants, and pathologists. There was not a single incident of any adverse effects to any individual in any case involving incidental exposure to carfentanil.

Conclusions: Carfentanil was detected as an opioid of abuse in 129 cases Wayne County, MI, between August 2016 and June 2017. Although it was detected with other opioids in more than 80% of cases, it contributed to the cause of death in all cases that were considered drug-related fatalities. The decrease in the incidence of carfentanil toward the end of the reporting period suggests the possibility of new novel opioids that may be contributing to drug-related deaths.

K27 A Field Performance of the DrugTest 5000® and DDS®2 Onsite Oral Fluid (OF) Devices by Oregon and Vermont Drug Recognition Experts (DREs)

Marilyn A. Huestis, PhD, Huestis & Smith Toxicology, LLC, 683 Shore Road, Severna Park, MD 21146; Amanda L.A. Mohr, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the field performance of the Draeger DrugTest 5000® (DT5000®) and Alere™ DDS®2 Onsite OF devices compared to Mass Spectrometry (MS) OF confirmatory tests and understand the usefulness of drug tests in Driving Under the Influence of Drugs (DUID) cases.

This presentation will impact the forensic science community by informing attendees regarding the use of onsite OF tests in identifying drug use.

Background: OF is easily collected and tested at the roadside to rapidly identify recent drug intake. Collection is non-invasive and gender neutral, with results available in minutes rather than hours for urine or invasive blood collection. During this delay, blood drug concentrations may decrease greatly, especially Δ9-Tetrahydrocannabinol (THC), hampering identification of recent drug consumption.

Methods: OF was collected with the DT5000® in Oregon ((OR), N=57) and Vermont ((VT), N=35), and the DDS®2 (N=23) in VT. Only one device was utilized per individual. Cutoff concentrations and performance for the combined OR and VT DT5000® data and the VT DDS®2 data are in the tables below. NMS Labs performed confirmation testing on OF collected with Immunalysis™ Quantisal® devices. All OR samples were collected in DUID cases, while 49 VT cases were from a court-ordered rapid intervention program and 9 from DUID cases.

Results:

DT5000 (OR & VT)

Drug, cutoff ng/mL	TP	FN	FP	TN	Sensitivity %	Specificity%	Efficiency %	PPV %	NPV %
THC, 5	47	1	0	44	97.9	100	98.9	100	97.8
Cocaine, 20	5	0	1	85	100	98.8	98.9	83.3	100
Amphetamine, 50	23	7	2	60	76.7	96.8	90.2	92	89.6
Methamphetamine, 35	34	0	2	56	100	96.6	97.8	94.4	100
Benzodiazepines, 15	2	0	0	90	100	100	100	100	100
Opiates, 20	31	1	3	56	96.9	94.9	95.6	91.2	98.2
Methadone, 20	3	0	0	89	100	100	100	100	100
Overall	145	9	7	480	94.2	98.6	96.9	95.4	98.2

DDS®2 (VT)

Drug, cutoff ng/mL	TP	FN	FP	TN	Sensitivity %	Specificity %	Efficiency %	PPV %	NPV %
THC, 25	3	2	0	15	60	100	90	100	88.2
Cocaine, 30	2	0	0	21	100	100	100	100	100
Amphetamine, 50	3	0	3	17	100	85	87	50	100
Methamphetamine, 50	0	0	0	23	n/a	100	100	n/a	100
Benzodiazepines, 20	0	0	0	23	n/a	100	100	n/a	100
Opiates, 40	3	1	1	18	75	94.7	91.3	75	94.7
Overall	11	3	4	117	78.6	96.7	94.8	73.3	97.5

Discussion: For the DT5000® device, sensitivity, specificity, and efficiency exceeded 94.9%, except for the amphetamine assay, which had 7 FN tests. This could have been due to the much lower 10ng/mL OF amphetamine confirmation test, and the 2 FP tests could have been due to cross-reactivity of the DT5000® antibodies with other sympathomimetic amines. For 641 OF samples and seven drug classes, the DT5000® had sensitivity, specificity, and efficiency of more than 94.2%, with high Positive Predictive Values (PPV) and Negative Predictive Values (NPV) of ≥95.4%. The DDS®2 device had 78.6% sensitivity, 96.7% specificity, and 94.8% efficiency, with a high NPV of 97.5% and a lower PPV of 73.3%. The poorer THC DT5000® results may be the result of a higher THC cutoff or that there were only five confirmed positive THC samples or that different individuals were tested. The amphetamine assay specificity was problematic with a PPV of only 50%. Although there were many cocaine tests for the DT5000® evaluation, there were too few positive cocaine, benzodiazepines, and methadone cases to draw conclusions about sensitivity, and for the DDS®2, there were only 11 positive cases in the entire set. For DUID cases, PPV is important because of the consequences on the driver from an FP test. There were only 1.1% FP tests for the DT5000® and 3.0% FP for the DDS®2. In drivers with negative field tests or when results are inconsistent with observed intoxication, supplemental tests should be ordered because the onsite OF devices test for a limited number of drug classes.

Conclusion: The devices achieved good specificity, with better sensitivity for the DT5000® as compared to the DDS®2 device. In addition, savings on cost of transport time, officer time, phlebotomist costs, and a reduction in the number of witnesses required for testimony may be substantial.

Oral Fluid, Onsite, DUID

K28 An Analysis of Ethanol in Blood and Oral Fluid Samples From Dosed Individuals by Headspace Gas Chromatography

Emily R. Parchuke, BS, Cedar Crest College, 701 Harrison Street, Apt 426, Allentown, PA 18103; Matthew R. Wood, PhD, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753; Marianne E. Staretz, PhD, Cedar Crest College, Dept of Chemical & Physical Science, 100 College Drive, Allentown, PA 18104; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will better understand the application of headspace gas chromatography to the determination of ethanol in blood and oral fluid. Attendees will also understand the relationship between ethanol concentrations in blood, oral fluid, and breath samples during a human dosing study.

This presentation will impact the forensic science community by providing evidence of a validated method for the analysis of both blood and oral fluid. The validated method was utilized in the analysis of samples from individuals dosed with ethanol in order to assess the viability of oral fluid as a matrix in Driving Under the Influence (DUI) applications. The use of headspace gas chromatography for this toxicological analysis allows for minimal sample preparation and little devaluation of the column with repeated usage.

Oral fluid has become a matrix of interest for forensic toxicological analysis, mainly for the qualitative and quantitative analysis of various drugs of abuse. Oral fluid is an ideal matrix for forensic analysis due to its lack of invasive collection procedure and ease of collection and monitoring, making the sample difficult to adulterate.[1-3] The findings of this study have the potential to impact current policy and forensic sample collection in suspected DUI cases. The use of oral fluid as a forensic specimen that is collected carside after probable cause of driving while impaired has been determined to have the potential to improve the quality and accuracy of the forensic toxicological analysis. The ability to collect oral fluid at the scene can potentially reduce the lag time between the traffic stop and obtaining the toxicological sample.

A method for the analysis of ethanol in blood and oral fluid was developed. In this study, a Perkin Elmer® HS-Clarus® 580 headspace gas chromatograph with two flame ionization detectors and a TurboMatrix™ 40 autosampler was utilized. A single headspace injection was split between two columns, Elite-BAC1 (30m x 0.32mm x 1.8µm) and Elite-BAC2 columns (30m x 0.32mm x 1.2µm). Helium carrier gas at a flow rate of 12.30mL/min was utilized, and the column temperature was set to 70°C. The method was validated using aqueous solutions, bovine blood, human blood, and human oral fluid with Lower Limit of Detection (LLOD) and Lower Limit of Quantification (LLOQ) values of 0.01% for ethanol. Calibration curves demonstrated good linearity for the BAC1 and BAC2 column where the r^2 values exceeded 0.999.

A controlled dosing study was performed utilizing subjects who consumed a pre-determined amount of wine (11.5%) to reach a target blood alcohol concentration of 0.05g/dL. Blood, breath, and oral fluid samples were collected from subjects prior to the consumption alcohol. Blood and breath samples were collected every 15 minutes over 3 hours; oral fluid samples were collected every 5 minutes for the first 30 minutes post-consumption and every 15 minutes following for 3 hours. Blood and oral fluid samples were prepared using 3mL of internal standard (0.016% *n*-propanol), 300µL of sample, and ¼ teaspoon of NaF/NaCl salt mix. Breath samples were measured with a portable breath-testing device. Results revealed the ethanol concentration profiles correlated well between blood and oral fluid. The Pearson correlation values between samples of oral fluid and blood were 0.92–0.97.

In conclusion, the validated method for the analysis of ethanol in blood and oral fluid samples illustrates the utility of oral fluid samples as a matrix in DUI investigations. The ease of collection of oral fluid and the fast and simple sample preparation for analysis makes this method viable for implementation in a forensic toxicology laboratory for analysis of DUI samples.

Forensic Toxicology, Blood Alcohol, Oral Fluid

K29 Alcohol Extrapolations: Scientific, Legal, and Ethical Considerations

Ashraf Mozayani, PharmD, PhD, Texas Southern University, 3100 Cleburne Avenue, Houston, TX 77004*

After attending this presentation, attendees will better understand the various methods for performing alcohol extrapolation, issues with using only the Widmark formula, and the scientific and legal expectations when performing alcohol extrapolations.

This presentation will impact the forensic science community by discussing a more scientifically robust approach for performing alcohol extrapolations by accounting for individual differences in volume distribution and elimination rates, thus representing Blood Alcohol Concentration (BAC) extrapolations as a range of values rather than a single point estimate.

Forensic science laboratories are often faced with Driving Under the Influence of Drugs (DUID) and Drug-Facilitated Sexual Assault (DFSA) cases involving alcohol. Forensic toxicologists and the justice system are frequently faced with questions pertaining to the BAC, or level of intoxication, experienced by an individual at a particular time in which an incident occurred. Direct measurements of the blood are typically taken at a time after the incident occurred and forensic toxicologists are frequently tasked with the determination (estimation) of the actual BAC at the time the incident occurred using a combination of chemical analyses of the blood or breath and any of the various empirically derived extrapolation methods. Many experts attest to BAC extrapolations using the original Widmark factor for estimating volume distribution without consideration for successive improvements to the formulas by Watson, Forrest, Ulrich et al., and Seidl et al., as well as assumptions that all of the alcohol had been absorbed at the time of the incident and the individual exhibits an average rate of elimination.[1-5] These simplistic assumptions and use of a single coefficient by Widmark are likely due to perceptions of the complexity to employ the more complicated algorithms, which account for gender, age, weight, height, water content, and Body Mass Index (BMI) as well as typical variations in absorption and elimination rates.

While simplistic, the single-point BAC result derived by limiting the calculation to a single method does not reflect the entire range of possible values at the time of the incident. Limiting the calculation to an average of the physiological ranges without consideration of a bounded interval of possible BAC values does not address individual differences and, therefore, could present incomplete and potentially misleading information to a fact-finder when evaluating whether a specific individual's BAC was greater than a statutory level at a particular time prior to the direct measurements. A more scientifically robust approach to alcohol extrapolations by expressing the full range of possible BAC values not only does provide a more thorough representation of the BAC, it provides a standardized framework for evaluating results across different laboratories, and cases in which assumptions and input parameters may otherwise vary. In *State v. Read*, the courts ruled that evidence is inadmissible if unfairly prejudicial — if it has the capacity to skew the truth or prejudice the truth finding process itself.[6] In "The Admissibility of Novel Scientific Evidence: *Frye v. United States*, a Half Century Later," Giannelli states that "the major danger of scientific evidence is its potential to mislead a jury; an aura of scientific infallibility may shroud the evidence and thus mislead the jury to accept it without critical scrutiny."[7] In *State v. Fausto*, the court asserted that, "When a witness is sworn in, he or she most often swears to 'tell the truth, the whole truth, and nothing but the truth.' In other words, a witness may make a statement that is true, as far as it goes. Yet there is often more information known to the witness, which if provided, would tend to change the impact of the information already provided."[8]

A review of court rulings clearly demonstrates the expectation, albeit the requirement, for clear expert testimony that in no way misleads a jury. The ANSI-ASQ (American National Standards Institute-American Society of Quality) National Accreditation Board's (ANAB's) document, *The Guiding Principles of Professional Responsibility for Forensic Service Providers and Forensic Personnel,* also speaks to the use of clear communications and the presentation of expert testimony that is not misleading to the judge or jury.[9] This presentation will discuss the methods for performing alcohol extrapolation, issues with using only the Widmark formula, and scientific and legal expectations when performing alcohol extrapolations.

Alcohol Extrapolations, Legal, Scientific Formula

K30 Quantification of Minor Blood Cannabinoids and Their Utility as Recent Cannabis Use Markers in Driving Under the Influence of Drugs (DUID) Investigation Cases

Ayako Chan-Hosokawa, MS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Marykathryn Tynon Moody, MSFS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Loan Nguyen, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Bingfang Yue, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; and Marilyn A. Huestis, PhD, Huestis & Smith Toxicology, LLC, 683 Shore Road, Severna Park, MD 21146*

After attending this presentation, attendees will be able to adopt and validate a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for quantitation of minor cannabinoids, including Cannabidiol (CBD), Cannabigerol (CBG), and Cannabinol (CBN). As CBG and CBN were reported as recent cannabis use markers, attendees will be able to apply the findings to improve the interpretation of recent cannabis use.

This presentation will impact the forensic science community by providing information on a quantitative method for minor cannabinoids as recent cannabis-use markers and their utility to aid in the interpretation of blood cannabinoid results in DUID cases.

It has been demonstrated that cannabinoid blood concentrations following smoking are not well correlated with effects because their concentrations are a function of various factors (dose, potency, route of administration, users' experience level, frequency of drug use, etc.), making interpretation of results challenging. Determination of the presence of minor cannabinoids in blood can add value to the interpretation by providing a time frame on last cannabis use.

This study describes a sensitive LC/MS/MS method for quantification of minor cannabinoids (CBD, CBG, and CBN). Cannabinoids were extracted from 100µL of whole blood using liquid-liquid extraction, separated in a two-dimensional LC system with an Agilent® Poroshell 120 PFP (4.6mm x 5mm; 2.7µm) as a guard column and an Agilent® Poroshell 120 Bonus RP (2.1mm x 50mm; 2.7µm) as an analytical column, in a 5min run time and detected by an AB SCIEX™ 6500 system with turbo ion spray operating in positive ion mode with scheduled mass spectrometric Multiple Reaction Monitoring (MRM). The method validation protocol was based on the Scientific Working Group for Forensic Toxicology (SWGTOX) guideline to include linearity, Limit Of Detection (LOD), Lower Limit Of Quantitation (LLOQ), precision and accuracy, interfering substances, extraction efficiency, matrix effect, stability, dilution of samples, matrix matching, and carryover.

The calibration for CBD, CBG, and CBN was linear from 0.1ng/mL to 50ng/mL. Minimum extraction efficiency and the maximum observed matrix effect were 97.4% and 2.8% suppression, respectively. The method also met validation criteria for precision and accuracy at the LLOQ, low and high controls, dilution of samples, matrix matching, interference, and carryover.

Between January and March 2017, NMS Labs received 2,787 cases for a basic DUID panel consisting of TEN common drugs of abuse. Cannabinoids were presumptively positive by Enzyme-Linked Immuno-Sorbent Assay (ELISA) in 52% (*n*=1,450) of cases and the presence of Δ^9-tetrahydrocannabinol (THC) was further confirmed in 1,202 cases (83%) by LC/MS/MS with a Reporting Limit (RL) 0.50ng/mL. Of those cases, 98 samples with positive THC at various concentrations were additionally tested for CBG, CBN and CBD using the method described. Table 1 summarizes these findings.

	CBG (ng/mL)	CBN (ng/mL)	CBD (ng/mL)
Mean (±SD) (ng/mL)	0.44 (±0.51)	0.28 (±0.15)	0.25 (±0.33)
Median (ng/mL)	0.26	0.23	0.12
Range (ng/mL)	0.10 – 3.3	0.10 – 0.74	0.10 – 1.1
% positive	74 (*n*=72)	67 (*n*=66)	10 (*n*=10)

Table 1. *Blood concentrations and positivity rates for CBG, CBN, and CBD*

To assess the correlation between concentrations of THC and three minor cannabinoids, the correlation coefficient (*r*) values were calculated and analyzed. The analysis demonstrated that both CBG and CBN have *r* values greater than Critical Values when *p*=0.05, suggesting a statistically significant positive correlation between THC and CBG as well as THC and CBN. The results from the same analysis between THC and CBD and CBG and CBN showed no correlation.

CBD had a significantly lower positivity rate compared to CBG and CBN. This, partly because of its short detection window and the various concentrations depending on the growth environment and strains, excluded CBD as a reliable recent cannabis use marker.

Using the incident and blood collection times provided in 42 cases with positive CBG and/or CBN at a RL of 0.1ng/mL, the calculated time difference (Δt) ranged from 0.033 to 5.4 hours. Of those cases, 11-hydroxy-THC (11-OH THC) was positive above RL of 1.0ng/mL in 39 cases (93%) with the mean and median concentrations of 5.1ng/mL and 3.9ng/mL, respectively (range: 1.4-22).

The detection windows were also evaluated for CBG and CBN at the previously studied RLs. Of 72 CBG-positive cases, a majority (>90%, *n*=65) were in between 0.1ng/mL and 1.0ng/mL; CBG was above 1.0ng/mL in seven cases with an average Δt of 1.1 hours (*n*=3; time information provided). Smoking higher doses of cannabis may explain the longer detection window for CBG in this study compared to the previously reported 0.5hr. Of 66 CBN-positive cases, six cases had CBN above 0.5ng/mL (RL 0.1ng/mL) with an average Δt of 0.78 hours (range; 0.68–1.13 hours, *n*=5; time information provided). This was consistent with the previous finding.

Recent Cannabis Use Markers, CBG, CBN

K31 A Study of an Active-State CB1 Receptor Model and JWH Synthetic Cannabinoids

Caroline Spencer, BS, 2000 Lexington Pointe Drive, Apt 4K, Oxford, MS 38655; Pankaj Pandey, PhD, University of Mississippi, 145 Martindale, University, MS 38677; Robert J. Doerksen, PhD, University of Mississippi, 145 Martindale, University, MS 38677; and Murrell Godfrey, PhD, University of Mississippi, Chemistry & Biochemistry, Coulter Hall, Rm 115, University, MS 38677*

After attending this presentation, attendees will better understand the interactions between synthetic cannabinoids from the JWH family with an active-state CB1 receptor model.

This presentation will impact the forensic science community by contributing to the understanding of essential interactions between specific substituents of JWH synthetic cannabinoids with specific CB1 receptor residues through molecular modeling. The knowledge of these key interactions can help forensic chemists predict the structure of new and undiscovered families of synthetic cannabinoids.

Synthetic cannabinoids have emerged onto the drug scene as an alternative to illegal marijuana.[1] Like delta-9-tetrahydrocannabinol (THC), the main psychoactive ingredient in marijuana, synthetic cannabinoids interact with G-coupled protein receptors found in the brain, immune system, and peripheral organs.[2] There have been two cannabinoid receptors identified: CB1 and CB2. The binding of THC and synthetic cannabinoids to the CB1 receptors that are prevalent in the brain, activating the receptors, is believed to be the cause of the drugs' psychoactive effects. In the 1990s, John W. Huffman et al. developed a large series of synthetic cannabinoids. (These compounds were all given the name JWH-XXX, after Huffman.) Many JWH compounds have been found to have similar effects as THC, functioning as CB1 receptor agonists.[3] These JWH compounds are seen in many synthetic cannabinoid or "Spice" drugs and have become an important area of research in the forensic science community.

In this study, an active-state CB1 receptor model, prepared by the Doerksen lab, was used to compare the ligand-receptor interactions between the CB1 receptor, the JWH synthetic cannabinoid family, and the THC compound. This study was conducted using Schrödinger's Maestro molecular modeling software. Synthetic cannabinoids from the JWH family were selected based on their affinity to bind to the CB1 receptor. The docking of the ligands to the receptor took place after both the synthetic cannabinoid ligands and CB1 receptor model were prepared for docking and a grid of the active site was generated. In order to increase understanding of the interactions between cannabinoids and the CB1 receptor, parameters can be set to provide the five best possible poses, or positions, for the ligands. Once the ligands were docked to the CB1 receptor model, the interactions were thoroughly analyzed. The information collected from this study includes: (1) the amino acid residue interactions with the ligands and the bond distances of these interactions; (2) the docking score of each ligand and each pose; and, (3) estimated binding affinities. This study revealed: the specifics of the interactions, such as the presence of π-π stacking; which interacting residues are hydrophobic, charged, or polar; and whether solvent exposure was important for parts of the molecules.

Results from this study reveal which residue interactions with the CB1 receptor are important for the JWH compounds and how these interactions vary between compounds within this family. Identifying the key interactions between the synthetic cannabinoids and the CB1 receptor is a step toward a better understanding of the effects of these drugs, including toxicity and potential for abuse. The long-term goal is to develop a database and computer program to help predict new structures and different classes of synthetic cannabinoids that have not previously been identified. Future research will include studying all classes of synthetic cannabinoids and other synthetic drugs in addition to the metabolites of these substances.

Synthetic Cannabinoid, CB1 Receptor, Molecular Modeling

K32 The Evaluation and Preservation of Urine Specimens in Forensic Toxicology

Meaghan Ringel, BS, 8480 Limekiln Pike, Apt 410, Wyncote, PA 19095; Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038; Gail Audrey Ann Cooper, PhD, OCMENYC, 520 First Avenue, New York, NY 10016; and Karen S. Scott, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will better understand how the pH of urine changes over time, the effect temperature has on pH change, the need for a preservative in urine samples, and the recommended minimum concentration of preservative required to stabilize urine pH. This research will directly benefit stability studies conducted on urine samples, as well as benefiting forensic and clinical laboratories analyzing for illicit substances in urine.

This presentation will impact the forensic science community by providing urine pH stability for 200 days as well as urine pH stability at room temperature from a multitude of participants to illustrate how variable the matrix is. Attendees will also understand the effects of added buffers, as well as preservatives, in varying concentrations in order to maintain the pH of a urine sample. The results of this study will allow toxicologists to better understand why some of their extractions have failed and also allows urine samples to be stored for longer periods of time to decrease the number of samples canceled for matrix stability problems. These results were evaluated for clinical and postmortem situations so a standardized method could be applied to both fields.

Urine is a commonly encountered matrix when screening for illicit substances in Driving Under the Influence of Drugs (DUID) cases within forensic laboratories and for clinical testing within hospital laboratories. Once a sample is received, after a period of storage, it generally undergoes an extraction procedure to remove any interferences from the matrix prior to instrumental analysis. Solid phase extraction techniques require pretreatment of samples to achieve an appropriate pH so the analyte of interest is in the appropriate form. This is generally achieved by use of a buffer. If the sample is not in the proper form, poor or no recovery may be a result.

During method development for a range of cathinones, it was determined that the pH of urine was changing over time and affecting these processes. It was determined that as the time a sample remained at room temperature increased, so did the urinary pH. This was hypothesized to be due to the breakdown of urea and creatinine into ammoniated compounds. This hypothesis was tested using Nessler's reagent and the Jaffee test. Nessler's reagent was used to measure the amount of urea present in a sample by scanning all wavelengths and reporting the absorbance at a specific wavelength. The Jaffe test was conducted in the same manner, but this test measured the amount of creatinine present in a sample. Appropriate calibration curves were made and urine samples were monitored over time to determine how the levels of these two compounds changed.

The addition of an appropriate preservative or buffer that can be added to urine to stabilize the pH of the matrix was investigated to help decrease the number of failed extractions and increase the stability of drugs present in urine over time. Sodium fluoride at 0.2% and 2.5% weight by volume (w/v) were added to urine samples and the pH was monitored to see if this was appropriate. Buffers of varying molarity were also evaluated. Samples were monitored in duplicate when stored in both the refrigerator and at room temperature for a period of 200 days. It was found that sodium fluoride at 0.2% w/v helped to maintain the pH with the necessary pH range required for successful extraction for a period of 90 days. Urine samples containing sodium fluoride at 2.5% w/v were found to be significantly less stable than that of the 0.2% w/v, but more stable than that of unpreserved urine. Without the addition of the preservative, urine pH is only stable for approximately two weeks. With the implementation of this research into case work, laboratories have the potential to extend the viability of the matrix and decrease the number of specimens canceled due to matrix instability. This research also provides the potential for detecting illicit substances for longer periods of time because pH is not adding to the degradation.

Urine, pH, Preservative

K33 Novel Stimulants N-Ethyl Pentylone and Dibutylone: Case Reports, Quantitative Confirmation, and Metabolic Profile Determination

Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Donna M. Papsun, MS, NMS Labs, Willow Grove, PA 19030; Bruno De Martinis, PhD, Arcadia University, 1001 Easton Road, Apt 307 M, Willow Grove, PA 19090; Amanda L.A. Mohr, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to evaluate N-ethyl pentylone and dibutylone concentrations in postmortem and Driving Under the Influence of Drugs (DUID) cases. In addition, attendees will be able to describe the metabolic biotransformation of N-ethyl pentylone and dibutylone and identify the metabolites in toxicological casework.

This presentation will impact the forensic science community by characterizing biomarkers of two emerging stimulants and providing analytical data for use in qualitative and quantitative interpretation.

Novel stimulants, like other Novel Psychoactive Substances (NPS), have been subject to various chemical modifications resulting in the appearance of a rapid succession of novel substances. Information related to the metabolism of these substances is often limited due to the lack of *in vitro* and/or *in vivo* studies, or unreported identification in authentic human specimens. In addition, uncharacterized chromatographic retention times, lack of identified target ions, and undetermined recreational or toxic concentration ranges create challenges for analytical detection and toxicological interpretation.

N-ethyl pentylone and dibutylone have been identified as emerging stimulants in impaired driving and death investigation casework, as well as in recreational drug users. The metabolic pathways of neither have been previously characterized.

Separate *in vitro* incubations of N-ethyl pentylone and dibutylone were performed with pooled human liver microsomes in duplicate over three days. Biotransformations identified for N-ethyl pentylone included demethylenation, ketone reduction, and hydroxylation. Biotransformations identified for dibutylone included demethylenation, ketone reduction, hydroxylation, and N-demethylation, forming butylone. After characterization of *in vitro* metabolic pathways, *in vivo* verification of these metabolites was accomplished using authentic specimens from toxicological casework or drug user studies.

Blood specimens (*n*=20) were quantitatively analyzed for N-ethyl pentylone by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) from postmortem cases (*n*=12), DUID cases (*n*=5), and cases with unspecified history (*n*=3). The mean (± Standard Deviation (SD)), median, and range for N-ethyl pentylone concentrations are shown in Table 1. One postmortem blood specimen was positive for pentylone (200ng/mL), a species not identified as a metabolite during microsomal incubations. In total, five metabolites of N-ethyl pentylone were confirmed in these specimens.

	Postmortem Cases (*n*=12)	**DUID Cases (*n*=5)**	**Unspecified Cases (*n*=3)**	**Overall (*n*=20)**
Mean	247 (±259)	41 (±26)	813 (±618)	280 (±374)
Median	155	34	1,140	95
Range	12-833	21-87	100-1,200	12-1,200

Table 1: *N-ethyl pentylone concentrations (ng/mL).*

Blood (*n*=4), urine (*n*=3), and vitreous (*n*=1) specimens were quantitatively analyzed for dibutylone and butylone by LC/MS/MS. All specimens were analyzed from postmortem cases (*n*=4), with overlap in specimens collected from the same individual. Specific case concentrations are shown in Table 2. In total, five metabolites of dibutylone were confirmed in these specimens.

	Blood (*n*=4)		**Urine (*n*=3)**		**Vitreous (*n*=1)**	
	Dibutylone	**Butylone**	**Dibutylone**	**Butylone**	**Dibutylone**	Butylone
Case 1	383	130	3100	69	250	108
Case 2	<10	385	16500	3060	-	-
Case 3	61	<10	2140	149	-	-
Case 4	1400	600	-	-	-	-

Table 2*: Dibutylone and butylone concentrations (ng/mL).*

N-ethyl pentylone and dibutylone were detected in combination in blood specimens (*n*=5) from death investigation cases. In four cases, mean (±SD), median, and range for N-ethyl pentylone concentrations were 479 (±316), 545, and 38-790ng/mL, respectively, and for dibutylone were 18 (±14), 12, and 10-40ng/mL, respectively. One additional blood specimen was positive for N-ethyl pentylone at 50,000ng/mL and dibutylone at 14ng/mL. Butylone was quantitatively confirmed in only two cases, above the analytical threshold.

Additional NPS identified in these cases included methylone, dimethylone, ethylone, 4-fluoroamphetamine, 4-chloro-alpha-PVP, acryl fentanyl, tetrahydrofuranyl fentanyl, carfentanil, para-fluoroisobutyryl fentanyl, U-47700, and U-49900. Causes of death included drug overdose, homicide, suicide, and vehicular crash. Reports of suspected "Molly" and "bath salt" use were noted in two cases. Specimens originated from Pennsylvania, New Jersey, New York, Florida, Texas, Utah, Vermont, Illinois, Missouri, and the District of Columbia. The majority of individuals were male (86%).

A comprehensive analytical approach is necessary to confirm novel stimulants and NPS in biological specimens, as drugs are often found in combination. Specimen concentrations for novel stimulants can vary, as high as µg/mL; therefore, appropriate dynamic range, detection limits, and dilution capabilities should be assessed. Rapid identification of biomarkers can be useful in the determination of unique and/or common metabolites between related substances, possibly providing additional information about ingestion and prolonging detection windows.

N-Ethyl Pentylone, Dibutylone, Postmortem

K34 Pharmacokinetic and Pharmacodynamic Differences Between Paramethoxymethamphetamine (PMMA), Paramethoxyamphetamine (PMA), 3,4-Methylenedioxymethamphetamine (MDMA), and Amphetamine in a Mouse Model

Robert Kronstrand, PhD, National Board of Forensic Medicine, Dept of Forensic Toxicology, Artillerigatan 12, Linkoping SE 58758, SWEDEN; Mikael Andersson, PhLic, National Board of Forensic Medicine, Artillerigatan 12, Linkoping 58758, SWEDEN; and Hanna Göthe, MSc, National Board of Forensic Medicine, Artillerigatan 12, Linkoping 58758, SWEDEN*

After attending this presentation, attendees will be able to describe the pharmacokinetics of PMMA and related drugs. Attendees will also recognize the differences in behavior the drugs induce in a mouse model.

This presentation will impact the forensic science community by adding pharmacokinetic and pharmacodynamics data for PMMA and related drugs in a mouse model.

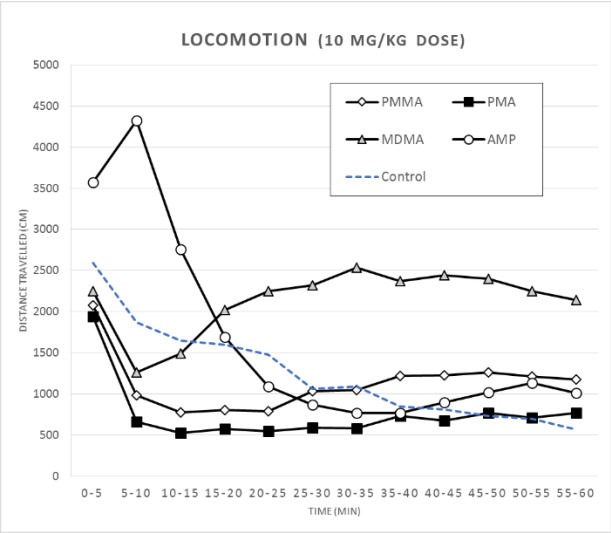
Background: Controlled study data regarding the pharmacology of PMMA and PMA in humans are lacking, but some data is available for the rat, pointing toward MDMA-like effects. Also, studies have suggested there is a delay in brain uptake that may trigger the user to take another dose because of absence of effect.

Goals: The goals of this study were to investigate the pharmacokinetics of PMMA and PMA in a mouse model and to compare their pharmacodynamics with MDMA and amphetamine.

Methods: The experiments were approved by the Animal Ethics Committee in Linköping, Sweden. Male C57/BL6 mice, 8-12 weeks old, weighing 25±1g were used for the experiments. The behavioral experiments were performed in an open field model. A video camera recorded the movements of the mouse during 60min and the movements were analyzed using EthoVision XT 9. Total distance travelled and time spent in the central zone were measured. In the behavior experiments, the animals (*N*=10) were dosed via intraperitoneal injection (i.p.) with either 0, 1, 5, or 10mg/kg of each substance immediately prior to the open field session.

Two pharmacokinetic experiments were conducted. First, dose concentration relationships were investigated using the same doses as in the behavior experiments with animals (*N*=5) sacrificed at 60 minutes. In addition, blood and brain kinetics were investigated for PMA and PMMA at 5mg/kg and 10mg/kg, respectively. The higher PMMA dose was chosen to increase the possibility of also measuring PMA formed from PMMA. Samples were obtained at 5, 10, 20, 40, 60, 80, and 120 minutes after injection.

Blood and brain concentrations of the substances were determined by Ultra High-Performance Liquid Chromatography-Tandem Mass Spectrometry (UHPLC-MS/MS) using an AB Sciex™ 4500 coupled to a Shimadzu® LC-30AD liquid chromatograph. The column used was an Acquity® UPLC® BEH Phenyl (2.1mm x 50mm, 1.7µm). In brief, 100µL whole blood was fortified with internal standard, precipitated, then further diluted 10 times before analysis. The whole brain was weighed and homogenized in 0,075% HFo in acetonitril/ethanol (90:10), an aliquot fortified with internal standard and then diluted 20 times.



Results: There was a good positive correlation between dose and both blood and brain concentrations for all four substances with Pearson's *r* between 0.90 and 0.99.

The kinetics of PMA and PMMA were slightly different. PMMA distributed equally fast to blood and brain whereas PMA demonstrated a delay in maximum brain concentrations. Also, the disappearance of PMA from the brain was slower than for PMMA. The brain concentrations correlated well with the effects from the behavior experiments, with a longer duration of locomotor suppression for PMA. As can be seen in the figure, both PMA and PMMA resembled MDMA in their temporal pattern but with less pronounced effect, whereas amphetamine exhibited quite the opposite. The time spent in the center zone is a measure of anxiety. The only significant result was PMA at the 10mg/kg dose, which acted anxiolytic with more time spent in the center zone.

Conclusion: The findings suggest that the behavior effects are correlated to brain concentrations of PMMA and PMA and that the effects resembled those of MDMA, rather than amphetamine.

PMMA, Open Field, Pharmacology

K35 The Development of a High-Resolution Mass Spectrometry (HRMS) Library and Method Validation for Screening and Confirmation of 800+ Novel Psychoactive Substances (NPS) by Liquid Chromatography/Quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS)

Melanie Eckberg, MSFS, Florida International University, 11200 SW 8th Street, OE 324, Miami, FL 33199; and Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199*

After attending this presentation, attendees will better understand the development of a compound database and spectral library containing more than 800 NPS, metabolites, and related compounds from a wide variety of drug classes with a particular focus on synthetic cannabinoids and stimulants. In addition, this presentation will demonstrate the use of standard mixtures rather than individual compounds to validate a comprehensive screening/confirmation method for the detection and identification of these NPS in biological fluids using LC/qTOF/MS.

This presentation will impact the forensic science community by presenting a developed HRMS library that can be used to help identify NPS.

NPS are of great interest to forensic toxicology labs due to their potentially high potency and ability to evade detection by many current screening methods. These compounds can also be rapidly developed to avoid current scheduling laws, causing a need to develop comprehensive detection methods covering a wide variety of drug classes.

An Agilent® 1290 Infinity® HPLC system and Agilent® 6530 QTOF-MS with Jet Stream technology Electrospray Ionization (ESI) source was used for this research. A total of 826 compounds to be included in the final method were analyzed using Flow Injection Analysis (FIA) to create an HRMS library with spectral data collected at three collision energies (10eV, 20eV, and 40eV) for each compound. Once the spectral data were collected, all compounds were run through an Agilent® ZORBAX® Rapid Resolution HD Eclipse® Plus C18 column (3.0mm x 100mm; 1.8µm particle size) to obtain retention times. LC was performed with a gradient of 95% A (5mM ammonium formate in HPLC water with 0.1% formic acid) and 5% B (methanol with 0.1% formic acid) from 0min–1min, increasing to 90% B over 1min–9.5min, then held at 90% B for the remainder of the 20min run. All retention times were used to create the final method for validation. The collected HRMS data and retention times were curated into a database/library using the MassHunter™ Personal Computer Database Library (PCDL) Manager software. Each compound entry also contained the following information: compound name, chemical formula, monoisotopic mass, chemical structure, and International Union of Pure and Applied Chemistry (IUPAC) name. Chemspider and Chemical Abstracts Service (CAS) numbers were also included, when available. The developed HRMS library is used to help identify NPS in real-time analysis, as well as to retrospectively search previously collected data.

In order to fully validate the method, calibration curves were created for each drug standard. Completing individual calibration curves for each of the 826 NPS included would be extremely time consuming and inefficient; therefore, an approach using a series of standard calibration mixes was investigated. Validation of the proposed method for 826 compounds involved the creation of 25 mixes containing between 29–37 different compounds each. The compounds selected for each mix were selected so that no compounds had the same retention time and had a minimum of 0.2min between compound peaks in the mix. Seven different calibration levels were chosen for method validation: 1, 2, 5, 10, 20, 50, and 100ng/mL. All calibrators also included an internal standard "supermix" made of 22 deuterated standards representing multiple NPS drug classes. Calibrations were performed with both methanol-based and spiked matrix (urine) mixtures for method optimization. For calibrations completed in urine, a simple "dilute and shoot" approach was used in which a 1:5 dilution was directly injected into the instrument.

To date, individual calibration curves have been created for nine different NPS mixtures representing nearly 300 of the 826 proposed NPS for the final validated method. LC chromatograms were analyzed using MassHunter™ QTOF Quantitation software. This approach was capable of identifying all compounds in each mixture. The results of these experiments clearly demonstrate the value of using standard mixes for method validation in comprehensive toxicological analysis in conjunction with an HRMS library. Work is continuing to create calibration curves for the remaining compounds using mixtures containing a maximum number of compounds to limit the number of mixtures needed for full validation.

LC/qTOF/MS, Novel Psychoactive Substances, Method Validation

K36 6-Monoacetylmorphine (6-MAM) Positivity: A Comparison of Two Methods

Jolene Bierly, MSFS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Laura M. Labay, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand the impact of methodology and reporting limits on the ability to confirm heroin use through the detection of 6-MAM in forensic cases.

This presentation will impact the forensic science community by comparing the ability of two different methods to confirm heroin use through the evaluation of 6-MAM positivity.

With opiate use and abuse increasing, laboratories are under increased pressure to distinguish licit opiate use from illicit use; however, confirming the presence of heroin (6-diacetylmorphine) can be challenging due to the pharmacokinetics of the drug. Heroin is rapidly metabolized to 6-MAM and eventually to morphine. Confirming 6-MAM is essential to determining the presence of heroin in body fluids. Laboratory methodology and reporting limits can vary greatly in their ability to confirm and quantitate 6-MAM. This work compares the ability of a Gas Chromatography/Mass Spectrometry (GC/MS) method with a reporting limit of 10ng/mL and a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method with a reporting limit of 1ng/mL to confirm and quantitate 6-MAM.

Method: Antemortem Driving Under the Influence of Drugs (DUID) and postmortem blood specimens submitted for opiate confirmation by GC/MS from April 2013 through April 2014 were reviewed. These results were compared to blood specimens submitted for opiate confirmation by LC/MS/MS from April 2014 through April 2015. Submissions in which 6-MAM confirmation was not performed for various reasons and cases that were none-detected for morphine were excluded. Percentages were rounded to the nearest whole number using conventional rounding rules. Statistical analysis was performed using student *t*-tests assuming unequal variance and that the populations were independent.

Results: A total of 14,932 cases that were submitted for opiate confirmation between April 2013 and April 2015 were included in this review. The overall 6-MAM positivity based on method increased from 15% by GC/MS to 32% by LC/MS/MS, an increase of 18% ($p < 0.05$). Submissions were also evaluated based on submission type: DUID (n=3,072) or death investigation (n=11,859). 6-MAM values ranged from 10ng/mL to 160ng/mL (mean 31ng/mL) by GC/MS confirmation and from 1ng/mL to 6,000ng/mL (mean 27ng/mL) by LC/MS/MS confirmation in DUID cases. 6-MAM positivity increased from 4% by GC/MS to 16% by LC/MS/MS, an increase of 12% ($p < 0.05$). Further investigation revealed that 87% of the DUID 6-MAM confirmations on LC/MS/MS were below 10ng/mL during this time period. Death investigation 6-MAM values ranged from 10ng/mL to 26,000ng/mL (mean 65ng/mL) on GC/MS and from 1ng/mL to 830ng/mL (mean 17ng/mL) on LC/MS/MS. 6-MAM positivity increased from 16% by GC/MS to 38% by LC/MS/MS, an increase of 22% ($p < 0.05$). In addition, 64% of the 6-MAM confirmations on the LC/MS/MS were below 10ng/mL in death investigations.

Conclusion: A comparison of these two methods demonstrated that a GC/MS method with a reporting limit of 10ng/mL could fail to confirm a large majority of heroin use in DUID and death investigation cases. In this particular review, a 6-MAM positivity rate increase of 18% was observed between the two methods.

Heroin, LC/MS/MS, GC/MS

K37 The Development and Validation of a Method for the Analysis of Novel Emerging Opioids

Marykathryn Tynon Moody, MSFS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Stephanie Kumor, MA, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Parul Shah, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Donna M. Papsun, MS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe a Scientific Working Group for Forensic Toxicology (SWGTOX) - compliant approach to method validation for the analysis of designer opioid compounds in a variety of forensic samples using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) technology.

This presentation will impact the forensic science community by demonstrating the capability of an analytical method that can be used to simultaneously analyze 17 novel emerging opioid compounds, many of which have only recently appeared on the market.

In recent years, an increasing number of novel opioids have appeared on the illicit drug market and have been linked to the growing opioid crisis in the United States. In 2015, butyryl fentanyl was ranked in 12th place of the most frequently identified narcotic analgesics category in the National Forensic Laboratory Information System (NFLIS). By mid-year 2016, butyryl fentanyl was replaced by furanyl fentanyl, U-47700, and 3-methylfentanyl, which were ranked 12th, 13th , and 14th, respectively.

A method is described for the analysis of 19 of the most current novel opioid drugs in whole blood and serum, and 17 analytes in urine using LC/MS/MS. Blood and serum were analyzed quantitatively for butyryl fentanyl/isobutyryl fentanyl, MT-45, AH-7921, furanyl fentanyl, para-fluorofentanyl, ortho-fluorofentanyl, para-fluorobutyryl fentanyl/FIBF, 4-methoxybutyryl fentanyl, 4-ANPP, alpha-methyl fentanyl, 4-methylphenethyl acetyl fentanyl, U-47700, U-50488, acryl fentanyl, valeryl fentanyl, carfentanil, and beta-hydroxythiofentanyl. Urine samples were analyzed qualitatively for butyryl fentanyl/isobutyryl fentanyl, MT-45, AH-7921, furanyl fentanyl, para-fluorofentanyl, ortho-fluorofentanyl, para-fluorobutyryl fentanyl/FIBF, 4-methoxybutyryl fentanyl, 4-ANPP, alpha-methyl fentanyl, 4-methylphenethyl acetyl fentanyl, acryl fentanyl, valeryl fentanyl, carfentanil, and beta-hydroxythiofentanyl. The isomer pairs butyryl fentanyl/isobutyryl fentanyl and para-fluorobutyryl fentanyl/FIBF are not chromatographically separated in this method and are reported as a pair.

The method was validated according to a SWGTOX-compliant procedure, which for the quantitative portion evaluated precision and accuracy, limit of detection, lower limit of quantitation, linearity, stability in matrix and on-instrument, robustness, an evaluation of interfering compounds, matrix matching, dilution integrity, carry-over, matrix effect, and extraction efficiency. The validation for the qualitative portion of the method evaluated precision around the decision concentration (cut-off) stability in matrix and on-instrument, sensitivity and specificity, robustness, evaluation of interfering compounds, matrix effect, and extraction efficiency.

Sample preparation consisted of protein precipitation followed by solid phase extraction using Agilent® Plexa™ PCX 3mL/60mg extraction columns. The analytical method consisted of separation using a ZORBAX® RX-SIL (3mm x 100mm, 1.8 micron) column coupled with an Optimize EXP filter (0.2 micron) and a gradient elution utilizing ammonium formate, pH 4.0 (Mobile Phase A), acetonitrile (CH3CN), LC/MS grade (Mobile Phase B and weak wash), and formic acid in deionized water, 0.1% (strong wash). The analysis was performed on a Waters® ACQUITY® TQD MS/MS with a Waters® ACQUITY® Ultra Performance LC system.

This method produced data that met the acceptance criteria established for the validation. The quantitative portion of the analysis produced controls within 25% of target value, while the qualitative portion produced 94.1% sensitivity and 100% specificity during the validation. During the validation, it was determined that all analytes were stable in blood at room temperature for at least two weeks, and at refrigerated and frozen conditions for 30 days, with the exception of acryl fentanyl, which was only stable for one day at room temperature and one week refrigerated. In serum, it was determined that all analytes were stable at room temperature for at least two weeks, and 30 days refrigerated and frozen, except acryl fentanyl, which was stable for two days at room temperature, and MT-45, which was stable for one week at room temperature. In urine, it was determined that all analytes were stable for a minimum of one week at room temperature, and 30 days refrigerated and frozen.

Designer Opioids, Forensic Toxicology, LC/MS

K38 A Semi-Quantitative Retrospective Method Validation for Three Synthetic Cannabinoids With Analytical Confirmation in Toxicology Casework

Stephanie Kumor, MA, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Kristopher W. Graf, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Sherri L. Kacinko, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to discuss the importance of implementing analytical testing methods that allow for quick updates for continuously evolving synthetic cannabinoids and will be able to understand the benefits of performing a retrospective method validation to determine the concentrations of these analytes in biological fluids.

This presentation will impact the forensic science community by describing a retrospective method validation protocol used to determine semi-quantitative results of the synthetic cannabinoids 5F-AMB, 5F-ADB, and FUB-AMB, the most commonly seen analytes in toxicology casework from May 2016 through July 2017.

Since 2009, synthetic cannabinoids have presented a challenge to toxicology laboratories. As new compounds become available within the recreational drug market, labs are required to update their analytical methods to stay relevant. The development and validation of quantitative methods can be a long and demanding process, especially when there is a lack of deuterated internal standard for every analyte in the panel. Development of a qualitative confirmation method allows for faster incorporation of new compounds. Since these newer drugs are not part of many laboratories' routine testing procedures, there is limited information available on their expected levels in casework, making interpretation difficult; however, observed concentrations in biological fluids can help provide insight into the toxicity of these compounds. Therefore, a retrospective method validation of a qualitative method was performed for three compounds with a high positivity rate to acquire semi-quantitative data.

The qualitative assay was developed to detect 5F-AMB, 5F-ADB, and FUB-AMB, in addition to 24 related synthetic cannabinoids. During method development, it was noted that running a calibration curve improved the precision around the cut-off concentration; however, the quantitative controls for several analytes were not meeting the stringent requirements required by quantitative validations. Therefore, the method was validated qualitatively according to laboratory Standard Operating Procedure (SOP), including the evaluation of the cut-off concentration, sensitivity/specificity, carryover, matrix effect, interfering substances, and stability. Whole-blood samples were extracted using a liquid-liquid extraction, and analytes were detected using positive mode Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Separation was achieved on a BEH C18, 2.1mm x 100mm column with mobile phases consisting of water containing 0.1% formic acid and an acetonitrile and methanol mixture (80:20).

A retrospective method validation was performed based on laboratory SOP and Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines. The Limits Of Quantitation (LOQ) were 25pg/mL for 5F-AMB and FUB-AMB and 50pg/mL for 5F-ADB. Linearity was established across two ranges (25-200pg/mL, and 50-400pg/mL) using five calibration points (n=5) with correlation coefficients ≥0.990 for all analytes and all back-calculated calibrators within 13% of target. The three synthetic cannabinoids were measured at three different concentrations for 15 separate days to provide acceptable between-run precision (13.5% Coefficient of Variation (CV)) and accuracy (±10.6%).

Based on the results of the retrospective method validation, all data that was still available on the laboratory instruments was reprocessed to determine the concentrations of 5F-AMB, 5F-ADB, and FUB-AMB. Data was included for all runs that met the following criteria: calibration curve correlation coefficients >0.990; back-calculated calibrators within ±20% of target and controls within ±20% of target. In this data set, there were 15, 97, and 112 cases above the limit of quantification for 5F-AMB, 5F-ADB, and FUB-AMB, respectively. Of these, 47% 5F-AMB, 24% of 5F-ADB, and 38% of FUB-AMB were below the reporting limit of the qualitative assay and thus had been reported "None Detected." The concentrations of all cases that fell within the calibration range are provided in the table below.

Analyte	Concentration (pg/mL)	# Cases >ULOQ
5F-AMB	68 ± 54 (n=10)	5
5F-ADB	200 ± 90 (n=52)	45
FUB-AMB	100 ± 60 (n=74)	38

The development of a qualitative method to detect synthetic cannabinoids allows for ease of updating the scope to remain relevant within the designer drug market. The ability to obtain semi-quantitative data through a retrospective method validation offers the forensic toxicology community information concerning the toxicity and expected concentrations of 5F-AMB, 5F-ADB, and FUB-AMB in whole blood samples.

Synthetic Cannabinoids, Retrospective Validation, Semi-Quantitation

K39 Fully Automated Detection and Quantification of Insulin Analogs by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) in Postmortem Vitreous Humor

Kevin M. Legg, PhD, 2300 Stratford Avenue, Willow Grove, PA 19090; Laura M. Labay, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be informed about the current state of insulin analysis and the challenges surrounding its detection by LC/MS/MS in forensic samples. In addition, attendees will be able to implement a forensically validated LC/MS/MS method.

This presentation will impact the forensic science community by providing a novel approach for the simultaneous detection and quantification of human insulin and five pharmaceutical analogs and by describing its application in a series of forensic death investigations.

The analysis of biological specimens for the presence of exogenous insulin is of special interest in select postmortem investigations. Like other drugs and chemical agents, insulin may be implicated or suspected in the cause of a death; however, toxicological analysis is challenging due to complexities associated with immunoassay screening (cross-reactivity between endogenous and pharmaceutical analogs), challenges regarding multistage sample preparation (protein precipitation coupled to solid phase extraction or antibody immunopurification), as well as difficulties with mass analysis (poor fragmentation, low specificity transitions, analog/isotope coelution, and a reliance on low-flow microbore or nanobore chromatography). As a consequence, the determination of insulin in postmortem cases is not routinely performed. The work described here enables unambiguous differentiation of human insulin as well as five pharmaceutical analogs, including insulin glargine, glulisine, lispro, aspart, human, and detemir, through the use of robotic immuno-microchromatography coupled with insulin β-chain detection by LC/MS/MS.

Insulin extraction was performed on the Agilent® AssayMAP Bravo robotic platform using protein-G cartridges. Before extraction, 150µL of human vitreous humor is diluted 1:1 with Phosphate Buffer Saline (PBS) and fortified with porcine insulin as an internal standard. Cartridges are primed and conditioned with PBS prior to loading two mouse anti-insulin monoclonal antibodies (Santa Cruz SC-377071 and BioRad 5329-3806) to generate anti-insulin immunoaffinity microchromatography cartridges. Diluted vitreous humor is then loaded onto the immunoaffinity cartridges, washed sequentially with 4xPBS, 1xPBS, and 20% acetonitrile in 50mM ammonium bicarbonate, and eluted with 2% acetic acid into an existing volume of 40mM Tris(2-Carboxyethyl)Phosphine Hydrochloride (TCEP-HCL) in 30% acetonitrile. Following a brief incubation, insulin beta chains are analyzed in positive Multiple Reaction Monitoring (MRM) mode on an Agilent® 6495 triple quadrupole mass spectrometer coupled with a 1290 series Ultra High-Performance Liquid Chromatography (UHPLC). Chromatographic separation is performed using an Agilent® RRHD 300Å SB-C18 1.8µm, 2.1mm x 50mm analytical column with a stepwise gradient at 0.4mL/min over nine minutes.

Method validation was performed in accordance with the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for Standard Practices for Method Validation in Forensic Toxicology. All analogs performed within criteria for acceptable performance. Parameters evaluated included linear range (500pg/mL–25,000pg/mL), limit of quantitation (500pg/mL), limit of detection (500pg/mL for insulin detemir and 125pg/mL for all other analytes), accuracy and precision (within and between run Coefficient of Variation (CV) <20%), interference, carryover, and stability (4°C and -20°C up to 30 days). In addition to the validation results, samples from five cases involving a suspected death by insulin have been analyzed. Of these, one case was positive for insulin aspart (743pg/mL) and one for insulin lispro (2,003pg/mL). A summary of the case history as well as an interpretation of findings will be discussed.

Insulin, LC/MS/MS, Overdose

K40 The Effect of Sample Preparation Techniques on Matrix Effects and Absolute Recovery of Opiates in Liver Tissue Using Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS): Part 1

Casey Spencer, BS, Virginia Commonwealth University, Box 843079, Richmond, VA 23284-3079; Jean A. Heneks, BA, 3211 W Franklin Street, Apt 1, Richmond, VA 23221; Justin L. Poklis, BS, Virginia Commonwealth University, Dept of Pharmacology & Toxicology, 410 N 12th Street, Rm 746, PO Box 980613, Richmond, VA 23219-0613; and Carl E. Wolf II, PhD, Virginia Commonwealth University - Health, PO Box 980165, Richmond, VA 23298-0165*

After attending this presentation, attendees will better understand the effectiveness of the various sample preparation techniques for the extraction of opiates from liver tissue in order to determine which method may be suitable for their own implementation.

This presentation will impact the forensic science community by increasing knowledge regarding sample preparation techniques for the forensic pathology and postmortem toxicology communities. Many sample preparation techniques are primarily designed for the extraction of drugs from blood or urine, and the adoption of these techniques for difficult matrices, such as liver tissue, has occurred without complete understanding of the effects of the matrix on the analysis of the analyte(s) of interest.

In this presentation, an evaluation of the effect of sample preparation techniques on matrix effects and absolute recovery of opiates in liver tissue will be presented. In postmortem toxicology, the concentration of drugs in the blood is often used to assist in the determination of the cause and the manner of death; however, central cavity drug blood concentrations can be unreliable because of the phenomenon of postmortem redistribution. This can be combated by evaluating liver concentrations, as drug concentration in liver is fairly stable after death. While liver is a valuable tissue for postmortem toxicology, the protein, fat, and phospholipid components of the matrix can interfere with analysis, and thus the drug must be isolated from the matrix prior to analysis. If proper and effective sample preparation and clean-up are not performed, matrix effects, such as ion enhancement or suppression, can hinder analysis and affect recovery of the drug. To limit matrix effects, it is necessary that the preparation technique used has the ability to extract the analyte as completely as possible while limiting the extraction of any interfering compounds.

There are many different approaches to sample preparation for drug extraction. The three traditional types of techniques are Solid-Phase Extraction (SPE), Liquid-Liquid Extraction (LLE), and filtration. A growing number of simple and rapid sample preparation techniques have become commercially available in recent years. These new techniques are commonly based on the traditional techniques but have added features to improve the extraction process. While these newer techniques have the ability to make sample preparation both easier and faster, there are still limitations. A majority of the user guides and technical notes for these new products focus on either blood or urine sample matrices. There is limited published data regarding tissue matrices, such as liver. For these techniques to be effectively used for liver samples, the matrix effects, absolute recovery, and process efficiency for extractions from liver must be evaluated.

These sample preparation techniques were evaluated for matrix effects and recovery by extracting opiates from homogenized liver tissue. Liver tissue was homogenized in saline at a ratio of 1:4. Homogenates were fortified with six opiates, at two concentrations (n=6), and their respective isotopic derivatives. The opiates analyzed were codeine, hydrocodone, hydromorphone, morphine, oxycodone, and oxymorphone. Three sets of samples were analyzed: neat, fortified before, and fortified after. Sample preparation was performed following manufacturer's guidelines (Waters® Oasis™ PriME HLB cartridge, Biotage® ISOLUTE® SLE+, and Biotage® ISOLUTE® PLD+) and using a laboratory validated LLE technique. Samples were analyzed using a previously validated UPLC-MS/MS method.

Results varied greatly between the methods evaluated. For Waters® Oasis™ PriME HLB, the observed matrix effects were between -35% and +5%, and recoveries were between 100% and 122%. For Biotage® ISOLUTE® SLE+, the observed matrix effects were between -18% and 0%, and recoveries were between 86% and 109%, with the exception of morphine, which had recoveries between 30% and 32%. For Biotage® ISOLUTE® PLD+, the observed matrix effects were between -16% and +50%, and recoveries were between 55% and 94%. For LLE, the observed matrix effects were between -59% to -37%, and recoveries were between 39% and 82%.

Liver is a difficult matrix to analyze. Sample preparation is not as simple as it is for blood or urine. It was observed that not all sample preparation techniques are effective or reliable for the extraction of opiates from liver tissue. Of the techniques evaluated, the Biotage® ISOLUTE® SLE+ was more effective at removing matrix effects and improved recovery.

Opiates, Liver, Sample Preparation

K41 The Identification of Adulterants in Preliminary Drug Analysis

Bianca Olivieri, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816; Mark Maric, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816; and Candice Bridge, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand the implications of drug adulteration for urinalysis and how commercially available and common household adulterants can affect results in preliminary drug screening techniques, such as Enzyme-Linked Immunosorbent Assay (ELISA).

This presentation will impact the forensic science community by demonstrating how these immunoassay-based screening techniques are prone to producing false positive and negative results in the presence of adulterants. Adulteration of urine samples can circumvent current preliminary screening protocols (i.e., ELISA) and even common adulterant test strips. These results may affect criminal proceedings that are reliant on drug tests to determine convictions, compliance in probation, and court-based treatments.[1]

Despite drug abuse being one of the major issues that has plagued society for centuries, the technology to detect drugs and their metabolites in bodily fluids has only been accessible for less than 50 years.[2] Drug testing always begins with a screening technique in the form of immunoassays, such as ELISA, and adulterant testing strips may also be utilized to ensure the sample has not been manipulated.[3] Although response accuracy of immunoassays have increased drastically over the years, they only remain accurate approximately 95% of the time for the detection of drugs of abuse and their corresponding metabolites in urine samples.[4] This value decreases when samples have been adulterated.[2]

Approximately 30 urine samples were collected from anonymous volunteers. Each participant was required to complete surveys detailing the frequency of their drug use in the week prior to providing a sample. Based on this information, samples that may contain significant concentrations of common drugs of abuse and their metabolites were identified (i.e., THC, cocaine, amphetamine, and benzodiazepines). Aliquots of these urine samples were adulterated at different levels (i.e., 5, 10, 25, and 50% volume/volume (v/v)) with common and commercially available adulterants, including bleach, vinegar, eye drops, Drano®, nitrite, table salt, hydrogen peroxide, and hand sanitizer. Preliminary research using ELISA revealed that some adulterants (e.g., bleach, eye drops, Drano®) drastically reduce the concentrations of detectable drugs/metabolites in comparison to the unadulterated urine samples.

Adulterant test strips were also utilized to determine if, and at what level, they were able to detect when a urine sample had been tainted. Preliminary data revealed that most of the adulterants were not able to be detected at concentrations less than or equal to 10% v/v. Eye drops, specifically those that contain benzalkonium chloride, were not detected in the adulterated urine samples, even at high levels. This is of great concern, considering that eye drops drastically reduced the detection of THC, cocaine, and amphetamine by ELISA. These results suggest that new pre-screening techniques may need to be identified to combat and detect the presence of adulterants in urinalysis.

ELISA, Adulterant Test Strips, Adulterants

K42 Using Medical Examiner Case Narratives to Improve Opioid Overdose Surveillance

Emily Hurstak, MD, UCSF/ZSFG, Box 1364, San Francisco, CA 94143; Phillip O. Coffin, MD, SF Department of Public Health, 25 Van Ness Avenue, Ste 500, San Francisco, CA 94102; and Nikolas P. Lemos, PhD, University of California - San Francisco, 333 E Amado Road, Box 217, Palm Springs, CA 92262-6451*

After attending this presentation, attendees will appreciate how using additional sources of information to classify opioid overdose cases can result in increases in the number of heroin-related classified deaths and in the identification of non-heroin, injection-related opioid analgesic deaths.

This presentation will impact the forensic science community by offering new tools for the characterization of opioid overdose deaths and the identification of meaningful subgroups of opioid users who can be targeted by public health programming.

Opioid overdose is a leading cause of death in the United States. While opioid analgesics were responsible for the rapid increase in overdose mortality during the 2000s, deaths due to heroin and fentanyl have increased sharply in recent years. Surveillance of the national opioid overdose epidemic demonstrate that the types of opioids causing overdose are evolving. For example, fentanyl mixed with or sold as heroin or other prescription opioids increases the risk of overdose death and complicates interpretation of postmortem toxicology. Opioid overdose surveillance systems report rates and counts classified by the type of opioid involved. Opioid types are extracted from the International Classification of Diseases (ICD) codes on death certificates, which may result in under-estimation or misclassification of specific opioid types.[1] Up to one-quarter of death certificates with drug overdose listed as the cause of death do not include the specific drugs implicated. Failure to include opioid type can result in substantially underestimated counts of overdose deaths involving opioid analgesics. Current opioid overdose mortality surveillance methods do not capture the complexity of the overdose epidemic. Most rely on death certificates which may underestimate heroin overdose deaths. In addition, categorizing deaths using characteristics beyond the type of opioid implicated in the overdose, such as the route of administration, can provide information to design and evaluate targeted public health interventions.

Methods: This study reviewed California Electronic Death Reporting System designations of cause of death and San Francisco Office of the Chief Medical Examiner postmortem toxicology reports and investigative case narratives for all unintentional deaths attributed to opioids occurring in the county of San Francisco from 2006 to 2012. Using these data sources, this study created enhanced classification systems for heroin-related and injection-related opioid overdose deaths and compared demographic, death scene, and postmortem toxicology characteristics between these groups.

Results: This retrospective analysis resulted in the identification of 816 unintentional opioid overdose deaths during the time period of interest. This study classified 152 of these deaths (19%) as "standard" heroin deaths (designated by the case medical examiner or confirmed by the presence of 6–monoacetylmorphine). An "expanded" classification of heroin deaths using data from postmortem toxicology reports and case narratives added 20 additional heroin deaths (+13% increase), accounting for 21% of all opioid deaths. Based on case narratives, 205 deaths (25%) were injection-related, 60% of which were attributed to heroin. A combined classification of enhanced heroin and injection-related deaths accounted for 31% of opioid overdose deaths during this period.

Conclusions: Using additional sources of information to classify opioid overdose cases resulted in a modest increase in the count of heroin-related deaths, but identified a substantial number of non-heroin injection-related opioid analgesic deaths that would otherwise have gone amiss. This current study reveals that including the route of administration in the characterization of opioid overdose deaths will identify meaningful subgroups of opioid users who can be targeted by public health programming.

This study was supported by a National Institute on Drug Abuse (NIDA) grant.

Opioid Overdose, Injection Drug Use, Heroin

K43 Prescription Drug Degradation in a Simulated Postmortem Blood Model

Jared Castle, BSc, 10 Allan Street, Prospect, South Australia 5082, AUSTRALIA; Danielle Marie Butzbach, PhD, Toxicology, Forensic Science SA, GPO Box 2790, Adelaide, South Australia 5001, AUSTRALIA; Claire Lenehan, PhD, Flinders University, GPO Box 2100, Adelaide, South Australia 5001, AUSTRALIA; Stewart Walker, PhD, Flinders University, Phys Sci, For & Analytic Chem, GPO Box 2100, Rm 304, Adelaide, South Australia 5001, AUSTRALIA; Frank Reith, PhD, The University of Adelaide C/O CSIRO Land and Wate, Waite Institute, Adelaide 5064, AUSTRALIA; Sam P. Costello, PhD, The Queen Elizabeth Hospital, 28 Woodville Road, Adelaide 5011, AUSTRALIA; and Paul Kirkbride, PhD, Flinders University, GPO Box 2100, Adelaide 5001, AUSTRALIA*

The goal of this presentation is to demonstrate the stability of prescription medications in an environment of optimal microbial activity, such as may be encountered in decomposed postmortem specimens.

This presentation will impact the forensic science community by providing fundamental information in regard to the stability of two important classes of drugs during the postmortem interval and throughout all stages of the analytical process. This information will assist attendees in the interpretation of antidepressant and antipsychotic drug concentrations measured in postmortem specimens.

Hypothesis/Proposition: Degradation of xenobiotics by micro-organisms is a complication that must be accounted for by forensic toxicologists analyzing postmortem specimens. This phenomenon is especially of concern prior to specimen collection, as during the postmortem interval (between death and autopsy), environmental conditions may favor microbial activity. Prescription medications (e.g., antidepressants and antipsychotics) are commonly observed in casework. Therefore, it is important to establish whether medications can degrade during this period to ensure accurate quantitation and detection of degradation products in toxicology screening methods. This study utilizes a "simulated postmortem blood" model enriched with microorganisms to investigate prescription drug stability.

Methods: The "simulated postmortem blood" model was constructed by directly inoculating antemortem blood (sourced from the Australian Red Cross Blood Service) with microorganisms from pooled stool samples of nine healthy donors. Antipsychotics investigated were in the structural classes of phenothiazines, tricyclics, thioxanthenes, butyrophenones, phenylpiperazines, and benzo(iso)thiazolepiperazines. Antidepressants investigated were tricyclics, Norepinephrine Reuptake Inhibitors (NRIs), and Noradrenergic and Specific Serotonergic Antidepressants (NaSSAs). These drugs were spiked into the model samples and non-inoculated controls. Risperidone was included in all experiments as a known microbially labile "positive" control. Preserved samples with 2% weight by volume (w/v) sodium fluoride were also prepared concurrently for both the model and non-inoculated controls. An Agilent® 1100 Series LC-UV was used to quantitatively monitor drug degradation over the course of a week's incubation of the samples at 37°C and extended incubations at room temperature, 4°C, and -20°C. Microbial communities were profiled throughout the experiments to determine which species were present in the initial inoculations and how communities changed over time with respect to sample environment, drugs present, temperature, and the presence of preservatives.

Results: Successful inoculation of viable microorganisms from the pooled stool samples was confirmed by the degradation of risperidone to its established bacterial degradation product, 2-hydroxybenzoylrisperidone, in unpreserved "simulated postmortem blood" samples. No degradation of risperidone was observed in the non-inoculated controls, which was consistent with prior studies performed to assess its stability in blood. After a week at 37°C, minimal losses were reported for all other investigated antipsychotics with none exhibiting significantly enhanced degradation in the "simulated postmortem blood" samples compared to the non-inoculated antemortem blood controls. In non-inoculated unpreserved samples, losses of up to 50% were observed for the phenothiazine antipsychotics after 38 days at 37°C. Experiments are currently ongoing for antidepressant drugs and extended incubation samples. At the time of presentation at the AAFS 2018 Annual Scientific Meeting, antipsychotic drugs will have been incubated at room temperature, 4°C, and -20°C for seven months. Results and analysis of microbial communities for 37°C experiments will also be completed later in 2017.

Conclusion: The simulated postmortem blood model allowed for the investigation of drug degradation as caused by a wide variety of relevant microorganisms; however, microorganisms sourced from unhealthy individuals, those taking any drugs or medications, and invasive species that may enter the body after death were not targeted in this study. Therefore, the potential for the postmortem degradation of these drugs cannot be excluded in all cases.

Drug Degradation, Putrefaction, Prescription Drugs

K44 Strange Bedfellows: Fentanyl Mixed With the Antiquated Poison Strychnine

Daniel Atherton, MD, Cooper Green Hospital, 1515 6th Avenue, S, Ste 220, Birmingham, AL 35233; Rachel C. Beck, PhD, UAB/Jefferson County Coroner/Medical Examiner's Office, SP 286, 620 19th Street, S, Birmingham, AL 35249; and Brandi C. McCleskey, MD, Jefferson County Coroner/Medical Examiner's Office, 1515 6th Avenue, S, Birmingham, AL 35233*

After attending this presentation, attendees will be familiar with two overdose deaths in which toxicological analysis detected strychnine in addition to fentanyl. These cases highlight the diverse methods often employed by clandestine laboratories in the production of illicit drugs.

This presentation will impact the forensic science community by providing two examples of cases of fentanyl overdoses in which strychnine was also detected. Attendees will find it an interesting juxtaposition of a modern synthetic drug with an antiquated natural poison. These cases also emphasize the wide spectrum of drugs the modern toxicologist could encounter.

The potent synthetic opioid fentanyl was first developed in the 1960s, having been derived from the structurally related drug meperidine. After discovering its potent effects, fentanyl was and is used regularly for palliative purposes. Illicit use of fentanyl began in the 1970s and continues to grow. Like all opioids, overdose deaths related to fentanyl have also increased dramatically in recent years. This growing demand has, in turn, been met by an increased supply and has also spurred greater diversity in techniques employed by clandestine laboratories in the illicit preparation of fentanyl. Presented here are two unusual death cases in which it is proposed that the illicit fentanyl was prepared with strychnine.

A 59-year-old White male was complaining of heartburn and vomiting one evening and was later found dead in his bed. Autopsy revealed changes related to hypertension, but no specific anatomic cause for death. Toxicological analyses of iliac blood reported fentanyl (0.003mg/L), strychnine (<0.025mg/L) and heroin metabolites: 6-monoacetylmorphine (0.006mg/L), morphine (0.159mg/L), and codeine (0.011mg/L). Death was attributed to heroin and fentanyl toxicity. Four days later, a 29-year-old Black male in another city, but in the same county, was discovered dead on his living room floor. The decedent had recently been released from prison and had also been treated at a hospital for pneumonia. Autopsy did not detect any residual pneumonia in the lungs or other anatomic cause for death. Toxicological analyses of iliac blood detected fentanyl (0.008mg/L), olanzapine (<0.025mg/L), and strychnine (<0.025mg/L). Death was attributed to fentanyl toxicity.

Strychnine is a potent alkaloid classically derived from the seeds of the *Strychnos nux-vomica* tree, which grows in warm climates in southern Asia and Australia. Strychnine was first isolated from the *Strychnos* genus in 1753, though the toxic effects of the *nux-vomica* bean had been well known in India and China for centuries before that. It is primarily used as a pesticide to kill small vertebrate pests such as rodents and has restricted availability in the United States due to the potential for deaths of animals for which it is not intended. Consumption of strychnine causes generalized muscle spasms. At lower doses, this can be restricted to tachycardia, cramping, rigidity, and agitation. Higher doses can lead to seizures, hypertension, cyanosis, and opisthotonus (dramatic back spasms causing arching of the back and neck). Death can occur from resultant cardiac arrest, respiratory failure, or brain damage.

In neither of these two cases was strychnine determined to be at sufficient levels to have contributed to death, especially given the presence and concentrations of the opioids. Nonetheless, its presence in these two cases underscores the diverse methods employed by clandestine laboratories in the production of illicit opioids and also illustrates an unusual marriage of a historic natural poison with more modern, synthetic drugs such as fentanyl.

Fentanyl, Strychnine, Opioids

K45 An Investigation Into the Analysis of Fentanyl in Postmortem Blood Using Biocompatible Solid-Phase Microextraction (BioSPME).

Chandler Marie Grant, MS, 5330 Covenant Court, Allentown, PA 18106; Thomas A. Brettell, PhD, Cedar Crest College, Dept of Chemical & Physical Science, 100 College Drive, Allentown, PA 18104; Samuel D. Land, MD, Forensic Pathology Associates/HNL, 1255 S Cedar Crest Boulevard, Ste 3800, Allentown, PA 18103; and Marianne E. Staretz, PhD, Cedar Crest College, Dept of Chemical & Physical Science, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will better understand how BioSPME can be an alternative extraction method for fentanyl in postmortem blood.

This presentation will impact the forensic science community by providing an extraction method that is faster than current analytical methods. BioSPME coupled with Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) allowed for minimal sample collection, preparation, and shorter analysis time in the analysis of postmortem blood samples from overdose victims.

The abuse of opioids, particularly fentanyl, has become a slow-motion mass disaster over recent years in the United States. Due to the frequent abuse of opioids, there has been an increase in drug-related deaths.[1] Forensic pathologists are responsible for collecting various postmortem samples that are then sent to a toxicology laboratory to be analyzed for drugs, such as fentanyl. This process can be time consuming and may result in a backlog, which could hinder a criminal investigation. A solution could be BioSPME using coated fibers that can be directly injected into a biological matrix and absorb any drug present without the interference of macromolecules, thus allowing for a faster analysis time.

A method has been developed to analyze fentanyl in postmortem blood using BioSPME followed by GC/MS and LC/MS/MS analysis. BioSPME fibers were conditioned, directly injected into blood, washed, filtered, desorbed into solution, dried down, and reconstituted. The extracted samples were screened by GC/MS and subsequently analyzed by LC/MS/MS. GC/MS was performed using splitless injection on a Rxi-5Sil MS column (30.0m x 0.25mm, 0.25μm) in the Selected Ion Monitoring (SIM) mode. Samples were confirmed using an AB SCIEX™ 3200 QTRAP® triple quadrupole MS with an Electrospray Ionization (ESI) source in the positive ion mode. LC was performed on a Shimadzu® LC system using an Ascentis® Express Biphenyl column (50mm x 2.1mm, 2.7µm) with the weak mobile phase of 0.1% (volume/volume (v/v)) formic acid in water and the strong mobile phase of 0.1% (v/v) formic acid in acetonitrile. The flow rate was 0.30mL/min, column temperature was 30ºC, injection volume was 1μL, and an analysis time of seven minutes per sample. This method was developed using bovine blood, then applied to 43 postmortem blood samples from overdose victims from the Lehigh County Coroner's Office in Allentown, PA.

In conclusion, the use of BioSPME as an extraction method allows for minimal sample preparation and collection for the detection of fentanyl in postmortem blood.

BioSPME, Forensic Toxicology, Fentanyl

K46 Fatal Hydromorphone Overdose in a Child: A Case Report

Teri L. Martin, MSc, Centre of Forensic Sciences, 25 Morton Shulman Avenue, Toronto, ON M3M0B1, CANADA*

The goal of this presentation is to describe the circumstances and postmortem toxicology results in a case of fatal hydromorphone toxicity in a child.

This presentation will impact the forensic science community by contributing to the forensic literature regarding hydromorphone blood concentrations in children. Furthermore, this case provides support for comprehensive drug screening in pediatric deaths.

Hydromorphone is a semi-synthetic opioid analgesic that is approximately eight times more potent when compared to morphine. It is prescribed for the treatment of post-operative or chronic pain; however, it may also be encountered in forensic casework as a drug that is used recreationally. Toxicity due to hydromorphone is dependent on an individual's tolerance, but can include stupor, hypotension, muscle flaccidity, coma, and respiratory depression.

The decedent in this case was a 13-month-old child found vital signs absent in her crib. Emergency medical services were notified, but she was pronounced dead upon arrival at the hospital. Prior to being put to bed the night before her death, she was described as "fussy" and lethargic. The autopsy described a well-developed, well-nourished child, with no significant injuries to head, neck, or torso, and no anatomic cause of death. Heart blood, femoral blood, liver, and stomach contents were submitted for toxicological analysis. Comprehensive drug screening was performed according to a pediatric death protocol used in the province of Ontario, Canada. This protocol comprised: Gas Chromatography/Nitrogen Phosphorous Detection (GC/NPD) and Gas Chromatography/Mass Spectrometry (GC/MS) screen for chemically basic drugs; immunoassay for acetaminophen, salicylates, barbiturates, benzodiazepines, cannabinoid metabolites, cocaine metabolite, opioids (morphine, hydromorphone, codeine, hydrocodone, levorphanol), oxycodone, and fentanyl; Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis for benzodiazepines; and headspace Gas Chromatography/Flame Ionization Detector (GC/FID) for ethanol and other volatiles.

The only toxicologically significant finding in the case was hydromorphone, which was tentatively identified in heart blood by immunoassay and confirmed in femoral blood by a quantitative LC/MS/MS method. The concentration of hydromorphone was determined to be 60ng/mL. Additional case information revealed a variety of prescription and over-the-counter medications used by adults in the home, including hydromorphone in both sustained-release (24mg) and immediate-release (1mg) formulations. The medication history for the deceased included infant acetaminophen drops and a mouthwash preparation comprised of diphenhydramine, aluminum hydroxide and magnesium hydroxide antacid, and lidocaine, prescribed for the treatment of mucositis, mouth pain, and/or oral ulcer.

The scientific literature is of limited assistance with respect to the toxicological interpretation of postmortem blood hydromorphone concentrations in children. Only one previously published case of pediatric overdose provides information on postmortem blood concentrations in children.[1] In that case, postmortem peripheral and heart blood concentrations of 30ng/mL and 60ng/mL, respectively, were measured in a 3-year-old who was determined to have accidentally ingested hydromorphone. Clinical studies are also rare, but provide information on plasma concentrations in children receiving hydromorphone therapeutically. For example, an average plasma concentration of 4.7ng/mL was reported for ten children receiving 2mg hydromorphone intravenously.[2] By comparison, oral administration of a 5mg sustained-release preparation to a 7-year-old child every 12 hours produced a plasma concentration of 1.48ng/mL.[3]

Based on the clinical history, autopsy results, and toxicology findings, the coroner determined the cause of death in this case to be hydromorphone toxicity. The manner of death was undetermined.

Hydromorphone, Child, Overdose

K47 An Accidental Death Due to Paraquat Poisoning: An Unusual Case Requiring Toxicologist, Pathologist, and Investigator Collaboration

Erin E. Walsh, MS, Miami-Dade County Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136; Elisa N. Shoff, BS, Miami-Dade Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136; Sean Hurst, MD, District 21 Medical Examiner Office, 70 S Danley Drive, Fort Myers, FL 33907; George W. Hime, MS, Miami-Dade Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136; and Diane Boland, PhD, Miami-Dade Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136*

After attending this presentation, attendees will better understand the toxicological and pathological findings that indicate death due to paraquat toxicity and how knowledge of the circumstances of death can aid in differentiating between a possible diquat toxicity case and a paraquat toxicity case.

This presentation will impact the forensic science community by demonstrating the necessity of a seamless working relationship between the forensic pathologists, forensic investigators, and toxicologists to understand unusual postmortem cases.

In December 2015, a 38-year-old White female presented to the hospital after accidently drinking from a water bottle that contained weed killer and vomiting twice. The decedent and her husband owned a cleaning business and had obtained the weed killer from the landscaping company at their apartment complex and stored it in a water bottle. The decedent and her husband advised the hospital staff that they believed the liquid to be diquat dibromide and were unsure how much the decedent had consumed before spitting out the liquid.

The hospital staff consulted the Poison Control Center who recommended that the decedent be observed for nine hours before she could be safely discharged. The decedent was treated and discharged later that day. Two days later, the decedent presented to a different hospital after continuing to vomit and complaining of nausea and a burning sensation. Despite medical intervention, her condition deteriorated, and she expired in January 2016, four weeks after the initial ingestion.

Autopsy findings were significant for consolidation of the lungs (right lung weight: 700 grams, left lung weight: 710 grams) with necrosis and purulent exudate. Microscopically, the section of lung exhibited dense pulmonary fibrosis with associated intraparenchymal and intra-alveolar hemorrhages. Delayed pulmonary fibrosis is a characteristic pathological finding in paraquat poisoning that is not seen in diquat poisoning.

A sample of the unknown liquid the decedent drank was submitted to the Miami Dade County Medical Examiner Department (MDME) Toxicology Laboratory for analysis in addition to antemortem samples taken during the decedent's second hospital visit. Toxicological screening of the unknown liquid by Gas Chromatography/Mass Spectrometry (GC/MS) indicated that 4,4-bipyridine was present in the sample. No other analytes were detected in the unknown liquid. 4,4-bipyridine is used as a precursor to paraquat. This finding caused the MDME Toxicology Laboratory to question if the decedent had consumed diquat, as she thought, or if she had consumed paraquat.

Due to the fact that paraquat and diquat could not be distinguished from one another by GC/MS, a fit-for-purpose method was developed by high-performance Liquid Chromatography/Ion Trap/Mass Spectrometry with MS^n capability (LC/Ion Trap/MS^n) to differentiate these two analytes. Analysis of an antemortem urine sample, dated five days after the initial ingestion, by LC/Ion Trap/MS^n indicated that paraquat was present in the sample. The detection of paraquat in a urine sample five days after ingestion is consistent with the literature, which indicates that paraquat can be detected in the urine for up to 26 days after an acute ingestion.

Based on the decedent's history, the sequence of terminal events, autopsy findings, and toxicology findings, the forensic pathologist determined that the cause of death was complications of paraquat toxicity and the manner of death was an accident. This case is a prime example of the necessary working relationship and the ability to share information between the forensic pathologists, forensic investigators, and toxicologists to allow the forensic pathologist to determine a cause of death.

Paraquat, Diquat, Postmortem

K48 Postmortem Tissue Distribution of Synthetic Cathinones

Lindsay Glicksberg, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Ruth E. Winecker, PhD, OCME, 3025 Mail Service Center, Raleigh, NC 27699-3025; Caitlin E. Miller, MS, LA County Dept of Medical Examiner-Coroner, Forensic Laboratories, 1104 N Mission Road, Los Angeles, CA 90033; and Sarah Kerrigan, PhD, Sam Houston State University, 1003 Bowers Boulevard, SHSU Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand tissue distributions and the potential for some synthetic cathinones to exhibit significant Postmortem Redistribution (PMR).

This presentation will impact the forensic science community by increasing the fundamental understanding of synthetic cathinone distribution in postmortem toxicological samples and the influence of PMR.

Postmortem toxicology results can provide crucial information in death investigations regarding the cause and manner of death; however, postmortem drug concentrations may not always reflect antemortem concentrations. Drugs may also undergo PMR, resulting in significant differences between central and peripheral blood. To assess PMR, Central to Peripheral (C/P) blood ratios can be calculated. PMR can be somewhat predicted using drug properties, including volume of distribution, lipophilicity, and p*Ka*. Blood and tissue distributions have been studied for many common illicit drugs, but this information is still limited for synthetic cathinones, a class of designer drugs that has been increasing in popularity over the past decade. In this presentation, postmortem tissue distributions and C/P ratios for select synthetic cathinones from cathinone-positive fatalities will be presented.

Postmortem samples from 60 cathinone-positive cases were included in the study. A total of 210 specimens were evaluated, including liver, urine, vitreous humor, and blood collected from the aorta, inferior vena cava, iliac, subclavian, and femoral vessels. Quantitative analysis was performed using blood or urine calibrators with matrix-matched controls. Samples were analyzed using a previously published and validated procedure for the determination of 22 synthetic cathinones in urine and blood using Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS). A total of nine isotopically labelled internal standards were used. The principal compounds of interest were methcathinone, 3-fFuoromethcathinone (3-FMC), 4-Fluoromethcathinone (4-FMC), ethcathinone, ethylone, methedrone, buphedrone, butylone, mephedrone, eutylone, 4-Methylethcathinone (4-MEC), 3,4-Methylenedioxy-α-Pyrrolidinobutyrophenone (MDPBP), pentedrone, pentylone, 3,4-Dimethylmethcathinone (3,4-DMMC), α-Pyrrolidinopentiophenone (α-PVP), 4-Ethylmethcathinone (4-EMC), 4-Methyl-α-Pyrrolidinobutiophenone (MPBP), Methylenedioxypyrovalerone (MDPV), pyrovalerone, and naphyrone.

Of the 22 cathinones in the assay, 9 were identified in at least one case: α-PVP (*n*=18), methylone (*n*=17), ethylone (*n*=15), MDPV (*n*=6), pentylone (*n*=3), methedrone (*n*=2), 4-MEC (*n*=1), butylone (*n*=1), and MDPBP (*n*=1). Concentration ranges in blood, urine, and liver, respectively, were <2 to 1,090ng/mL, 33 to 7,580ng/mL, and 14 to 663ng/g for α-PVP; <2 to 202 ng/mL, 2 to 38,064ng/mL, and 28 to 5,731ng/g for methylone; <2 to 2,743ng/mL, 32 to >20,000ng/mL, and 10 to 18,893ng/g for ethylone; 3 to 80ng/mL, 4 to 5,210ng/mL, and 64 to 840ng/g for MDPV; <5 to 322ng/mL in blood and 122 to >5,000 in urine for pentylone. Where possible, average C/P ratios were determined as follows: methylone (4.0, range 2.39-6.0, *n*=4), ethylone (2.9, range 0.5-9.2, *n*=6), pentylone (2.0, *n*=1), α-PVP (1.2, range 0.5-1.9, *n*=8), methedrone (1.1, *n*=1), MDPV (1.0, *n*=1), and butylone (0.7, *n*=1). Although C/P ratios were highly variable, some cathinones appeared to have significant potential for redistribution. Generally, the highest C/P ratios were observed in methyenedioxy-type cathinones bearing secondary amines. Although the pyrrolidine-type cathinones are less polar and subsequently more lipophilic, they are less basic than their secondary amine counterparts. Vitreous humor was only available in a small number of cases, but concentrations in vitreous were comparable to peripheral blood within this limited population. Although the concentration range of forensic interest was wide, the results also highlight the need for low limits of detection and quantification.

Tissue distributions and C/P ratios are presented and compared with existing literature. Variability of C/P ratios and the potential for cathinones to degrade *in situ* and during storage significantly complicates their interpretation. Of the 60 cases submitted, 50 cases had at least one specimen test positive for a synthetic cathinone. The results highlight the potential for some cathinones to exhibit PMR, the importance of collecting multiple specimens, and the interpretation of results within the full context of investigative information.

Synthetic Cathinones, Postmortem Redistribution, LC/qTOF/MS

K49 Acute Intoxications With Phenibut (ß-Phenyl- γ -Aminobutyric Acid), an Emergent Psychoactive γ -Aminobutyric Acid (GABA) Agonist

Erin L. Karschner, PhD, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover Air Force Base, DE 19902; John J. Kristofic, BS, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover Air Force Base, DE 19902; Jeffrey D. Chmiel, MS, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover Air Force Base, DE 19902; Neal C. Goebel, PhD, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover Air Force Base, DE 19902; and Jeff Walterscheid, PhD, Armed Forces Medical Examiner System, Division of Forensic Toxicology, 115 Purple Heart Drive, Dover Air Force Base, DE 19902*

After attending this presentation, attendees will be familiar with the behavioral and physiological effects of the psychoactive compound known as phenibut. Attendees will also understand the importance of updated screening libraries for the detection of Novel Psychoactive Substances (NPS).

This presentation will impact the forensic science community by raising awareness regarding phenibut abuse and by providing examples of screening and confirmation techniques for this analytically challenging substance.

Phenibut is an analogue of the inhibitory neurotransmitter γ-aminobutyric acid (GABA) and the antispasmodic baclofen. Neuromodulation occurs when phenibut binds to GABA receptors, primarily at $GABA_B$. While not licensed for medical use in the United States, phenibut has been prescribed in Russia since the 1960s for the treatment of anxiety, alcohol withdrawal, and insomnia. It is currently available on the internet as a nutritional supplement and marketed as a nootropic, anxiolytic, and euphoriant, where typical doses range from 500mg to 2g. Phenibut tolerance develops rapidly, similar to other GABA receptor modulators. Tolerance may precipitate substantial dose increases. Additionally, co-administration with other GABA modulators, such as ethanol, may result in more pronounced pharmacological effects. In this submission, two unrelated cases involving phenibut intoxication are presented.

Case 1: A 21-year-old male was found unconscious in a dormitory hallway. The subject was minimally responsive, slurring his words, and walking into walls when emergency personnel arrived. The man vomited, his condition deteriorated, and he was transported to the hospital. The attending physician described his aggressive and combative behavior as excited delirium. He assaulted medical staff, was restrained, and remained in the hospital for two days.

Case 2: A 21-year-old male was unconscious and unresponsive in a dormitory stairwell the morning after a night of drinking with friends. Two individuals were sent to retrieve the man and found him staggering and slurring his speech. The man was taken to his dorm room, where he laid down and fell asleep. His roommate attempted to wake him 1h later, but he appeared incoherent and confused. Medical personnel applied multiple sternum rubs to revive the individual. He jolted awake, appeared disoriented, and his pupils were non-reactive to light stimulus. He was transported to the hospital where toxicology revealed no drugs or alcohol.

Urine from each case was submitted to the Armed Forces Medical Examiner System (AFMES) Division of Forensic Toxicology. Both specimens were negative for ethanol by gas chromatography/flame ionization detection and for amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, opioids, phencyclidine, and sympathomimetic amines by immunoassay. In addition, both cases screened negative for alkaline-extractable drugs by gas chromatography/full-scan mass spectrometry. After case histories were reviewed, a non-targeted liquid chromatography/quadrupole time of flight/mass spectrometry drug screen was added. In Case 1, phenibut and ondansetron were detected in the urine. Phenibut, naloxone, and ondansetron were detected in the urine from Case 2. Phenibut was confirmed in the urine from both cases by liquid chromatography/tandem mass spectrometry.

Unknown to the lab at time of analysis, the individual in Case 1 later admitted to self-medicating with an internet-purchased supplement for his social anxiety and attention-deficit hyperactivity disorder. On the date of the incident, he self-reported ingesting 20g of phenibut, causing him to vomit shortly thereafter. He then ingested an additional 10g in an attempt to account for the amount he regurgitated. The individual in Case 2 was interviewed after discharge and stated he drank wine, beer, and champagne the night prior to the incident. He did not recall any events 8h prior to medical intervention in his dormitory room. The individual also admitted to purchasing phenibut from the internet, but did not provide information concerning the amount ingested or if the dose was co-ingested with alcohol.

In summary, two acute intoxications with phenibut that emphasize the difficulties encountered during extraction and instrumental analysis are presented. If proper analytical techniques are not available, methods are not current, or history is incomplete, it is possible to overlook phenibut and other NPS. In these cases, history was a key factor in directing additional testing. Intoxication effects corroborated previous reports of somnolence/stupor, confusion, agitation, nausea, and vomiting. These cases underscore the need for vigilance when evaluating casework and promote the use of comprehensive screening techniques that may reveal rare, but significant, findings.

Phenibut, NPS, QTOF

K50 A Forensic Characterization of Bacterial and Fungal Organisms in Traditional Chinese Herbs

Julia Grzymkowski, 1200 W Marshall Street, 242A, Richmond, VA 23220; Justin L. Poklis, BS, Virginia Commonwealth University, Dept of Pharmacology & Toxicology, 410 N 12th Street, Rm 746, PO Box 980613, Richmond, VA 23219-0613; Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Michelle R. Peace, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will be aware of the potential presence of toxic microorganisms in Chinese herbal products used for medicinal purposes.

This presentation will impact the forensic science community by potentially being used to identify unknown specimens of herbs, provide provenance of the herbs themselves, and help reconstruct toxicological episodes that result in medical emergencies or death.

Traditional Chinese Medicine (TCM) is one of the oldest healing methods used in Chinese culture, often referred to as "formula." TCM's herbal formulations are prescribed for a variety of illnesses, based on symptoms presented. Herbal remedies are selected based on Chinese ancient literature and individual experiences of patients or doctors. Use of TCM in the United States has increased because herbal remedies are believed to be less expensive and more effective with less adverse effects in comparison to traditional pharmaceutics. Therefore, sales have increased, despite articles and case studies that have demonstrated the dangers, such as injury and death, related to TCM, stemming from improper labelling, toxic contaminants, and, in some cases, the presence of pathogenic bacteria.

Objective: The purpose of this study was to conduct a molecular and biochemical survey of microorganisms of 11 Chinese herbal products purchased from a traditional medicine shop in Beijing, China. Bulk analysis of microbial/fungal lipids from the herbs was conducted using a rapid method for extraction of cellular fatty acids and derivatization into Fatty Acid Methyl Esters (FAMEs) prior to profiling with Gas Chromatography/Flame Ionization Detector (GC/FID).

Methods: Eleven over-the-counter Chinese herbs were purchased from Tong Ren Tang in Beijing, China. These herbs were chosen based on reported pharmacological activity: sedative and hypnotic (Suan Zao Ren, Fu Ling, Sha Yuan Zi, and Di Long); anticonvulsant (Gou Teng, Tian Ma, and Jiang Can); and analgesic (Yan Hu Suo, Chuan Duan, Wu Yao, and Mo Yao).

Approximately 100mg of the herbal product was placed in 1x Phosphate Buffered Saline (PBS). A 100µL aliquot of the solution was spread onto Tryptic Soy Agar (TSA) with and without blood supplements (50mg/L). Plates were then incubated overnight at 30°C. Colony growths were photographed, harvested, and subjected to FAME profiling.

FAME profiling of the herbal products was performed using GC/FID equipped with a series of analytical standards to detect and quantify fatty acids between 9 and 20 carbons in length.

Products were incubated with methanolic potassium hydroxide (5% KOH, 95% CH_3OH). The methyl esters were then extracted into hexane and analyzed. The individual fatty acids were identified by their retention time through comparison to reference standards.

Results: Strains within the *Bacillus* group were identified in nearly all 11 of the herbal samples. These included *B. subtilis* and *B. cereus*, as well as *B. megaterium*, *B. circulans*, and *B. atrophaeus.* Organisms belonging to the *Bacillus* ACT group (anthracis, cereus, thuringiensis) were identified in 5 out of 1 herb cultures as evidenced by the large ratio of 15:0 iso to 15:0 anteiso fatty acid biomarkers. A gram-positive, aerobic bacteria related to the *Bacillus* group*, Paenibacillus thiaminolyticus*, was also detected. This bacteria differs from *Bacillus* ACT and has been reported to cause bacteremic infections in humans. All of the herbal specimens also exhibited fungal biomarkers such as polyunsaturated 20:4 ω6,9,12,15c, and 18:3 ω6c (6,9,12). The presence of fungal biomarkers would be consistent with the origin of some herbal samples such as Jiang Can, silkworm larvae that are claimed to have been killed with the fungus *Beauveria bassiana*; however, in others, they could represent contamination of fungal spores.

Conclusion: The characterization of microorganisms present in these traditional Chinese herbs was successful through analysis of their FAME profiles and by the presence of particular and unique fatty acids. The bacterial and fungal identification can potentially be used to identify unknown specimens, provide provenance of the herbs themselves, and help to reconstruct toxicological episodes that result in medical emergencies or death.

Chinese Herbs, FAME Analysis, GC/FID

K51 The Role of Toxicology in Child Custody Disputes

Sherri L. Kacinko, PhD, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to discuss the importance of good laboratory practices, the pharmacology of drugs in analysis, and the interpretation of specimens in child custody cases.

This presentation will impact the forensic science community by describing the role of toxicology in child custody disputes.

Two cases are presented which highlight the importance of validated testing and interpretation of results in child custody cases. For both cases, a private toxicology lab (Lab A) was contacted and asked to review the analytical work performed at other laboratories, review the reported findings, and/or comment on opinions provided by other scientists.

Case 1: The mother of three children was accused of exposing them to Gamma Hydroxybutyrate (GHB), diazepam, and cocaine. Lab A performed hair testing; Lab B performed blood and segmented hair analysis on the mother and all the children; and Lab C tested urine, hair, and blood form both parents and the children. In total, more than 50 different tests were performed at Lab C. The following results will be discussed: diazepam in blood and urine specimens from both adults; diazepam in hair of all tested individuals at concentrations of 39.3ng/mg–215ng/mg; GHB in hair of all tested individuals at concentrations of 76.3ng/mg–225.5ng/mg; and methylecgonine in one hair segment from child 1 at a concentration of 39.3ng/mg. Despite testing hair specimens covering the same time range with reporting limits well below the results reported by Lab C, Labs A and B had no positive findings.

Despite the fact that analytical data was not available for review, the following inconsistencies between the known disposition of analytes in biological matrices and previously reported findings were identified: diazpeam was reported in blood and urine specimens in the absence of nordiazepam or temazepam though the reports indicated these analytes were in the scope of testing; diazepam concentrations in hair were approximately 1,000 to 10,000 times higher than the concentrations reported in women with known dosing regimens of the drug and at least five times higher than those reported in a drug abuser; nordiazepam was reported in the hair despite published studies that indicate that nordiazepam concentration typically exceeds those of diazepam in this matrix; GHB concentrations reported in this case were 76ng/mg–225ng/mg while one reported case of an individual given multiple doses had a maximum hair concentration of 1.66ng/mg; and, methylecgonine levels reported in the hair segments were at least 25x higher than what has been reported in patients who were administered cocaine, and neither cocaine nor benzoylecgonine were detected.

Case 2: A father was accused of exposing two children to phensuximide. Lab D performed testing on a powder found in the home and reported no drugs found. The data was forwarded to a chemical engineer (Dr. X, who concluded that the powder was 88% phensuximide. Subsequently, urine specimens were collected from the children and analyzed by the chemical engineer at Lab E, who indicated in a deposition that the urine samples contained succinimide and phenol, which he concluded were metabolites of phensuximide, proving exposure.

The data from Lab D and multiple reports, letters, and the deposition of Dr. X were provided to Lab A for review; no data was made available from Lab E. Based on the review of the available data and the deposition of Dr. X, it appeared as if Dr. X concluded that a large peak in Lab D's data was phensuximide based on the results of Lab D's in-house library search, which identified the peak as phensuximide with a match factor of 50; however, comparison of the spectrum of the unknown to the spectrum of phensuximide proved that this conclusion was not valid. Additionally, there is no literature or metabolic pathways that support the conclusion that succinimide or phenol are metabolites of phensuximide. A review of the data and comparison to known mass spectra led to the preliminary conclusion that the large unknown peak from the brown powder that smelled like cinnamon was cinnamaldehyde and none of the testing performed provided any evidence of phensuximide exposure.

Child Custody, Hair Testing, Jurisprudence

K52 A Segmental Analysis of Endogenous Gamma-Hydroxybutyric (GHB) Acid in Human Hair

Jennifer Thomas, PhD, 3110 Spring Drive, Alexandria, VA 22306; Erin Waddell Lloyd, PhD, 2501 Investigation Parkway, Quantico, VA 22135; Christopher C. Donnelly, BA, ORISE, 2121 Aquia Drive, Stafford, VA 22554; Mark L. Miller, PhD, FBI Lab, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; Madeline A. Montgomery, BS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Roman Karas, BS, 2501 Investigation Parkway, Chemistry Unit, Quantico, Virginia 22135-0001; and Marc A. LeBeau, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will be informed about a validated Liquid-Liquid Extraction (LLE) and Liquid Chromatograph/Tandem Mass Spectrometric (LC/MS/MS) method for the detection of GHB in human head hair. The validated method uses multi-point calibration curves and quality control samples. The research presented also investigates segmental analysis of hair samples and inter- and intra-variation among individuals.

This presentation will impact the forensic science community by providing information regarding endogenous GHB concentrations in hair. The research presented will address baseline levels of GHB within and between individuals to determine if a background threshold can be established for an unexposed population. Segmental analysis of hair samples will provide information regarding the variation of endogenous concentrations within an individual over a period of time that corresponds to hair growth rates.

GHB has been used in drug-facilitated crimes and is also a popular recreational drug of abuse. Ingestion of this drug may induce euphoria, amnesia, dizziness, and unconsciousness, depending on dosage. Because GHB is a natural chemical found in humans, it can be difficult to separate naturally occurring levels from levels following ingestion. GHB poses an additional challenge to the forensic community in that it is rapidly excreted by the body. Hair analysis is a good alternative to blood and urine due to the longer detection window available to establish the involvement of drugs in reported crimes. The scientifically accepted mean growth rate of human head hair is 1cm per month, which can be used to estimate the time period of ingestion. This research utilizes segmental hair analysis to determine baseline GHB concentrations among non-GHB users and to evaluate variability along the length of the hair. Knowing how much variation is present within an individual will help determine if an individual can serve as their own control in cases of ingestion.

Before collecting hair samples, a full quantitative validation was performed for the extraction procedure. The parameters assessed were: accuracy, precision, calibration model, carryover, interferences, Limit Of Detection (LOD), Limit Of Quantitation (LOQ), and processed sample stability. Due to the endogenous nature of GHB in hair, ionization suppression/enhancement experiments were not completed. Instead, the study relied on the deuterated GHB to compensate for any suppression or enhancement that may occur. Accuracy and precision were found to be within ±20% at low (1.2ng/mg), medium (4.0ng/mg), and high (9.6ng/mg) concentrations. A linear model was obtained from 0.4ng/mg to 12ng/mg and no carryover was observed in unspiked synthetic hair samples following injections of 12ng/mg or 24ng/mg GHB. No interfering signals (not including background GHB) were observed in hair extracts. The LOD and LOQ of the method were experimentally determined to be 0.4ng/mg. Lastly, extracts were observed to be stable after eight days while being stored at ≤14°C.

To evaluate the baseline GHB concentrations, hair collected from non-GHB users was segmented into 1cm increments based on proximity to the scalp. The segments were washed with organic solvents, cryogenically ground, and digested with sodium hydroxide. After digestion, the samples were neutralized with sulfuric acid and extracted via LLE with ethyl acetate. The extracts were then evaporated to dryness, reconstituted in mobile phase, and filtered for analysis by LC/MS/MS to determine the levels of GHB present. Initial results for 37 non-GHB users reveal an average baseline GHB concentration of 0.90ng/mg, with a minimum of 0.43ng/mg, maximum of 3.49ng/mg, and median of 0.84ng/mg. The average variation within individuals was 13%. Work continues on the processing of additional hair samples from other non-drug users.

GHB, Hair Analysis, LLE

K53 A Wastewater Analysis for Tobacco and Drug Detection in New York City

Alethea Jacox, MS, John Jay College of Criminal Justice, 524 W 59th Street, Rm 5.66.02, New York, NY 10019; Nicole Centazzo, BS, John Jay College of Criminal Justice, 524 W 59th Street, Rm 5.66.02, New York, NY 10019; Bonnie-Marie Frederick, MS, John Jay College of Criminal Justice, 524 W 59th Street, Rm 5.66.02, New York, NY 10019; Jasmine Gayle, MS, John Jay College of Criminal Justice, 524 W 59th Street, Rm 5.66.02, New York, NY 10019; and Marta Concheiro-Guisan, PhD, John Jay College of Criminal Justice, 524 W 59th Street, Rm 5.66.02, New York, NY 10019*

After attending this presentation, attendees will understand the utility of wastewater analysis to monitor tobacco and drug exposure in a certain community and will know how to perform the analysis of these types of samples by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

This presentation will impact the forensic science community by demonstrating the applicability of utilizing wastewater analysis by LC/MS/MS to investigate tobacco and drug use in different communities in an urban location.

Recent changes in the drug scene, such as the current issues with prescription opiates and fentanyl, among other substances, have sparked an increased interest in new tools to monitor what drugs are coming onto the market in a faster, more efficient manner than conventional population surveys. Wastewater analysis is an innovative approach to testing the drug consumption in a geographical area by analyzing human excretion products (biomarkers) in wastewater, which is essentially a large urine pool. Wastewater can provide independent, low-cost, reliable, and nearly real-time information. This methodology has not been fully explored in the United States.

A method was developed to determine tobacco (nicotine and cotinine), cocaine (benzoylecognine, cocaethylene, and cocaine), amphetamines (methamphetamine, MDMA, MDA, and amphetamine), opiates (6-monoacetilmorphine, morphine, codeine, oxymorphone, oxycodone, hydromorphone, hydrocodone, fentanyl, norfentanyl, methadone, EDDP), and cannabis (delta-9-tetrahydrocannabinol, 11-nor-9-carboxy-tetrahydrocannabinol, and 11-nor-9-carboxy-tetrahydrocannabinol-glucuronide) biomarkers in 50mL of wastewater. Wastewater samples were filtered, extracted using mixed-mode cation cartridges, and analyzed by LC/MS/MS using positive Electrospray Ionization (ESI). All compounds were analyzed on a Kinetex® C18 column (with 0.1% formic acid in water and 0.1% formic acid in acetonitrile as mobile phases) using two different gradients (one for cannabinoids and another for the remaining compounds). Each compound was monitored by two Multiple Reaction Monitoring (MRM) transitions. Method validation included linearity (5ng/L-1,000ng/L for all compounds, except 10-1,000ng/L for tobacco biomarkers), limit of detection (1ng/L-10ng/L) and quantification (5ng/L-10ng/L), imprecision (<20%), accuracy (80%-120%), matrix effect and extraction efficiency, interferences, and auto-sampler stability. This study applied this method to wastewater samples collected from wastewater treatment plants in New York City (The Bronx, Brooklyn, Queens, and Manhattan) throughout one year. Wastewater samples were collected into Environmental Protection Agency (EPA) -certified sample containers and stored at −20°C until analysis.

This study emphasizes the method of analysis, particularly the use of LC/MS/MS in terms of its sensitivity and selectivity, as a means to detect licit and illicit drugs in wastewater samples. It also provides a means by which new drug trends could be tracked by testing wastewater, thus providing real-time results in different boroughs within New York City.

Wastewater, Cannabis, Opiates

K54 Postmortem Pediatric Toxicology

Robert A. Middleberg, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, University of California - San Francisco, 333 E Amado Road, Box 217, Palm Springs, CA 92262-6451; Richard C. Harruff, MD, PhD*, King County MEO, 325 Ninth Avenue, Box 359792, Seattle, WA 98104; Carl J. Schmidt, MD*, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; and Thomas G. Rosano, PhD*, Albany Medical Center, Pathology & Lab Medicine, 43 New Scotland Avenue, Albany, NY 12208*

After attending this presentation, attendees will gain an appreciation for the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and case-specific sense.

This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

In this 19th Annual Special Session within the Toxicology section, pediatric cases involving toxicological findings will be discussed. As a relative dearth of interpretive information exists involving toxicological findings in the pediatric population, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation or issue-specific concern, including pharmaco-toxicokinetic data and other relevant ancillary information, followed by audience participation to provide interpretive clarity around case-specific impacts of the toxicological findings. This session, attended by various sections of the Academy, allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause of death in children.

Four cases will be presented that highlight the difficulty in assessing the role of toxicants in each case or the lengths to which one must go, in some cases. Richard Harruff, MD, PhD, Carl Schmidt, MD, Thomas Rosano, PhD, and Robert Middleberg, PhD, will be reviewing cases from their years of experience as forensic pathologists and toxicologists, respectively, that highlight the issues and confounders in the pediatric population.

Dr. Harruff will discuss a case involving colchicine. This esoteric substance in relation to the pediatric population has a number of therapeutic uses based on being an inhibitor of mitosis, including one of the primary treatments for gouty arthritis. The case presentation will address potential means of exposure, post-exposure effects, and consequences of colchicine exposure in the pediatric population.

Dr. Schmidt will discuss the case of twins who were administered lidocaine-containing teething gel. The toxicokinetics and toxicodynamics of this commonly used local anesthetic and cardio-active substance will be reviewed in relation to adverse outcomes, especially in the pediatric population. The risks associated with use of teething gels, in particular, will be emphasized.

Dr. Rosano will present a case involving the death of an 18-month-old who came in contact with liquid nicotine intended to be used in electronic cigarettes. This case will highlight how the child came in contact with the material, surrounding factors leading to exposure, the signs and symptoms after exposure, and postmortem toxicological findings. Finally, the outcome of the investigations will be addressed.

Dr. Middleberg will discuss the difficulties associated with assigning manner of death in pediatric cases. Special emphasis will be placed on the issues surrounding child endangerment versus homicide and the difficulties associated with the distinction. An open discussion regarding whether there is ever a way to readily move from child endangerment to homicide in toxicologically related cases will take place.

Pediatric, Postmortem, Toxicology

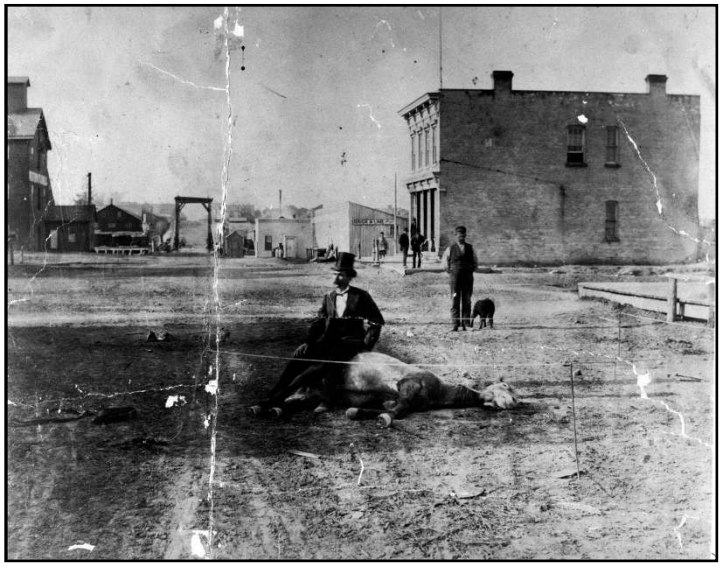
LW1 The Dead Horse Investigation — Forensic Photo Analysis Meets Genealogy

Colleen M. Fitzpatrick, PhD, 18198 Aztec Court, Fountain Valley, CA 92708*

After attending this presentation, attendees will better understand how forensic photo analysis, used in conjunction with genealogical research techniques, has been used to extract important investigative information from a historical "crime scene" photo about which very little prior information was available. Although photo-identification techniques from the forensic community were initially applied to the picture, by combining them with genealogical methods, it was possible to extract much more information from the photo, which could then be integrated into a cohesive narrative. Attendees will learn genealogical photo-identification techniques they may not have been aware of, but that can be used to enhance the investigative power of forensic analysis.

This presentation will impact the forensic science community by demonstrating the synergy that exists between forensic and genealogical investigations. This presentation will broaden understanding of how a seemingly irrelevant detail can be detected by one set of tools and analyzed by another, leading to an appreciation of the complimentary nature of the two disciplines.

The hat, the horse, the man, the scene … the mystery. Who was he and why was he photographed in a top hat and tails sitting on a dead horse in the middle of 8th Avenue in Sheboygan, WI?



When the Sheboygan Dead Horse Picture was published in 2007 by the *Sheboygan Daily Press* newspaper, numerous theories were advanced to explain the bizarre scene. Perhaps the image depicts the aftermath of the tornado that struck Sheboygan while a horse show was in town in 1901. Maybe the owner of a Sheboygan tannery is pictured staking his claim to the hide after someone's horse died in the street. No one seemed able to offer a satisfactory explanation.

Using a combination of forensic and genealogical photo-analysis techniques, much information concerning the time and place the photo was taken has been derived. Based on the type of lens used to take the picture and the presence or absence of certain shadows, it was possible to determine an earliest and latest year for the photo. The appearance of an unusual sundial in the picture provided the exact time of day and the day of the year. Assuming the streets were deserted because the photo was taken on a Sunday, the weather played a crucial role in further narrowing the year to only two possibilities.

Combined forensic and genealogical analysis indicates the picture was taken at 4:52 p.m. on August 10, 1873 or 1879.

Neither the man nor the horse have been identified. No arrests have been made in the case.

Forensic, Photograph, Analysis

LW2 Three Complementary Analyses of Ansel Adams' *Moonrise, Hernandez, New Mexico*

Roderick T. Kennedy, JD, PO Box 7041, Albuquerque, NM 87194-7041*

The goal of this presentation is to illustrate an interdisciplinary investigation of an iconic photograph to demonstrate a deeper context and meaning of the image.

This presentation will impact the forensic science community by demonstrating a greater appreciation for alternative methods of viewing photographic evidence, revealing layers of interpretation not previously contemplated, either by its creator or subsequent observers.

Ansel Adams created his most popular and iconic photograph with the single click of a shutter. *Moonrise Over Hernandez, New Mexico* was taken in late 1941, although it likely did not see the light of day until 1943 when it was published in the *U.S. Camera 1943* annual, preceding a 1944 show at the Museum of Modern Art, where it was exhibited. Ian Jeffrey, curator of the Phaidon Press' *The Photography Book*, said this about the work: "In this, one of the most epic of Adams' landscapes, humanity is signaled by a field of scattered crosses in the near foreground. The settlement itself makes an irregular diminishing rhythm from left to right, in contrast to the flowing horizontals of the mountain range and the swift, painterly markings in the sky. The whole of this musicality is related to the imperceptible slowness of the moon rising."[1]

This photograph is the subject of many stories, from Adams' jumping out of a car on Route 84 to capture the last moments of fading daylight, with or without his new-fangled light meter, or whether the photography was really captured at f32 with a one-second exposure.[2] At any rate, the hurried roadside process resulted in only a negative being created, and Adams did not record the exact date and time the picture was created.

While not discounting Jeffrey's poetic license about the musicality of the photograph's composition (Adams had studied piano), the legend of the image has created a miasma around the possible facts of its creation, all of which can be subject to further investigation and interpretation using different modalities, which will be discussed during this presentation.

First, the collecting of first-hand accounts, both near-contemporaneous and later, of how the photograph was captured by Ansel Adams will be presented. Hopefully, historical consensus can provide both depth and breadth to the circumstances of Adams' actions, including using the new technology of hand-held light meters.

Second, as the image gained in popularity, the question of just when it had been taken took on some importance. Two astronomers have pegged the date and time variously on October 31, 1941, and November 1, 1941. The calculations and celestial tables may track the moon; however, history suggests both the movement of the road after 1941 and the fact that Adams may have taken the photograph from the top of his station wagon.[3] Scientific measurements frequently depend on contextual information; perhaps the answers emanating from the High Altitude Observatory in Boulder, CO, and *Sky and Telescope* magazine will be found wanting for lack of an adequate background.

Finally, all of these discussions are divorced from the cultural aspects of the photograph, which contains the depth and breadth of human experience to fulfill the promise of the detailed image. The crosses and gravestones in the cemetery alit in the setting sun, the houses behind, the woods, the rivers, and the churches in the picture all tell their story without which a full understanding of *Moonrise Over Hernandez, New Mexico* may not be clear to the viewer.

Photography, Anthropology, Astronomy

LW3 A Review of Changing Crime Patterns and the Development of Forensic Science in Ireland

Sheila Willis, PhD, Forensic Science Ireland, Garda HQ, Phoenix Park, Dublin, IRELAND*

After attending this presentation, attendees will better understand how various techniques became acceptable and which techniques suited particular cases.

This presentation will impact the forensic science community by presenting the changes in the use of explosives, the variation in drugs abused, and the increased capability developed due to the availability of DNA.

This presentation reviews some case histories and uses them to outline the changing patterns in crime and the developments in forensic science from 1979 to 2017.

Following this presentation, attendees will appreciate the manner in which forensic science developed in one Common Law country and will have received an overview of the way in which crime pattern changes prompted changes in the management and resource allocation of forensic science services.

The forensic science service consisted of 5 people in 1979 and had grown to more than 100 in 2017. During this period, the nature of organized crime changed from one in which subversive crime and ordinary crime were quite separate to one in which the boundaries are more difficult to decipher. The rapid increase in drug abuse in the early 1980s began with the abuse of heroin in the poorer sections of the inner city to the situation today in which the full range of drugs are abused across all sections of the population countrywide. The ease of availability of drugs caused a drop in the number of armed bank robberies, as did improvements in bank security. Until the 2000s, the challenge for forensic science was quantity, but this changed with the so-called "head shop" phenomenon. The analytical challenges of dealing with new psychoactive substances are particularly focused on the acquisition of suitable reference material.

The "Troubles" in Northern Ireland affected crime patterns in the Republic of Ireland, and this presentation will trace the changing use of explosives throughout the period. While the Good Friday Agreement put an end to most of the subversive crime, the effect continues to this day with a more widely spread use of explosives within the criminal world than previously experienced. The nature and type of explosives changed according to availability of materials and the challenge for the forensic science community was a lack of information in a pre-internet era.

Over time (from the mid-1990s on), as with most laboratories, resources were diverted from particulate trace evidence to DNA. The focus in the introduction of DNA tended to be on the technology; thus, the lessons from traditional trace evidence did not necessarily transfer to the DNA area. High successes using this technology masked this issue for many years.

Historical, Case Histories, Technique Development

LW4 The 2014 Killing of Five Babies in Oulu, Finland, and the Neonatal Line (NNL) Investigation as the Definitive Bottom Line

Vivian Visnapuu, University of Turku, Turku, WA 20520, FINLAND*

After attending this presentation, attendees will better understand the NNL investigative method, which can be used in newborn homicide cases.

This presentation will impact the forensic science community by informing attendees of the NNL investigative method that can be applied to newborn homicide cases.

Background: Police arrested a 35-year-old woman after discovering five decomposed human fetuses in a basement cabinet of her apartment in Oulu, Finland, in 2014. The woman said she thought all the babies had been born dead. The woman had put the remains of her five newborn infants in buckets and plastic bags between 2005 and 2013 and transported them from place to place. The police began a forensic investigation immediately. The remains were so damaged that a forensic pathological investigation was infeasible, so two independent experts conducted osteological investigations. A forensic odontological investigation was conducted, as was an NNL investigation, which was the crux of this case. Also, a psychiatric assessment of the woman was administered pursuant to an order of the District Court of Oulu.

Material and methods: The delivery-related NNL appears in the enamel of primary teeth and first permanent molars at birth and is a marker of the live birth process.[1-4] It varies in width and location, is different in each deciduous tooth type, and is indicative of gestation time.[5,6] It is unclear what triggers determine NNL at birth. NNL separates pre- and postnatal enamel and dentin and varies in location in different tooth types. Four primary teeth from each fetus were investigated by histological methods and light microscopy.[6,7] The teeth were preserved in 100% alcohol. Samples were run through a rising alcohol series (70%, 90%, and 100%), embedded in resin (Technovit1®/alcohol 50%/50%), and in 100% Technovit® twice. Sections of 20 microns were made by buccal-lingual/palatial and axial cutting and, when no wear appeared, through incisal middle and cusp tip/underlying dentin horn.[7,8]

Results: All the infants' gestational ages were 38-40 weeks per the results of odontological investigation and 38 weeks per the results of osteological investigation.[1,5] NNL was observable in all infants' cases and at least 1-4 days of enamel formation after NNL was observable in each investigated primary tooth.[5] This means that all the infants were born alive and all lived 1-4 days; however, the cause of death was not possible to investigate because the remains were so badly damaged.

The conclusion of the psychiatric assessment was that the woman was criminally responsible. After the psychiatric assessment, the judgment of the District Court of Oulu was a verdict of five counts of murder and five counts of violence of grave peace; a life sentence was imposed. The defendant was not content with the judgement and appealed to the Rovaniemi Court of Appeal, which commuted the sentence to five counts of manslaughter and a 12-year sentence. The Oulu District Prosecutor was not satisfied and appealed to the Supreme Court of Finland in August 2016.

Neonatal Line, Primary Tooth, Killing Babies

LW5 A Forensic Examination of 19th-Century Archaeological Remains

Thomas J. David, DDS, 1000 Johnson Ferry Road, Bldg H, Marietta, GA 30068*

The goal of this presentation is to educate attendees on the importance of forensic information in determining the identity of archaeological remains.

This presentation will impact the forensic science community by demonstrating the power of forensic examinations by multiple disciplines in narrowing the field of possible identities of unknown individuals.

In March of 2012, construction workers accidently uncovered an unmarked grave during a renovation project at a private home in Deadwood, SD. The remains were contained within a wooden casket that was damaged by a backhoe during excavation of the reconstruction site. Because this site was part of Deadwood's first cemetery, state archivists and Deadwood Historic Preservation officials were on hand and exhumed the burial. After the exhumation of the remains, officials discovered the skeleton was nearly entirely intact. Subsequent examination of the dentition revealed many unusual features for someone from the 1870s. Preservation officials and archivists did not know the identity of this individual and decided to undertake a forensic examination of the remains in an attempt to identify this person.

Initially, the remains were sent to a forensic anthropologist, who determined that the individual was a White male who was in his late teens to early twenties at the time of death. Additionally, the forensic anthropologic analysis determined this individual was 5'6" to 5'11" in height and the skeleton revealed no indication of violent trauma. Subsequently, there were additional forensic examinations, including odontology, DNA, and elemental and isotopic analyses. Several of the forensic analyses supported and/or corroborated other forensic findings concerning the possible identity of the individual and where he lived during his lifetime.

Although this person has not been identified, the list of possible identities was initially narrowed using death records of individuals that fit the ancestry, age range, height range, and non-violent death circumstances. Subsequently, the list was narrowed based on the likely origin of distinctive, expensive dental restorations. Other dental evidence pointed to a different location later in life, but before he died in Deadwood. This information was corroborated by isotopic analyses. DNA analyses were able to extract a full profile from the skeleton and teeth. Additionally, Single Nucleotide Polymorphism (SNP) analysis was able to determine that this individual was not only a White male, but also that he was likely from Western Europe, specifically the British Isles, and had red hair and brown eyes. As a result of this inquiry, officials in South Dakota decided to produce a documentary that outlined the conclusions of the investigation. In May of 2017, South Dakota Public Broadcasting released the documentary *Deadwood Pioneer: A Face From the Past*. This presentation will discuss the forensic conclusions drawn from this investigation and what remains to be accomplished to identify this 1870's "Deadwood Pioneer."

Archaeological, Exhumation, Identification

LW6 The Dark Side of the Show: Investigating Mysterious Aspects of Traditional American Sideshows

Matteo Borrini, PhD, Liverpool John Moores University, School of Natural Science & Psychology, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will appreciate the possible contribution that forensic science can provide to understanding apparently mysterious aspects of traditional American sideshows.

The presentation will impact the forensic science community by providing examples of different disciplines applied to cold cases and old pieces of evidence. This presentation will also suggest a new method of presenting science to young generations of students based on traditional American sideshows, offering the opportunity for reflection on ethical issues related to the use of human samples.

In the American tradition, a sideshow is a secondary production associated with a circus or a fair. These attractions entertained the audience by exhibiting living "human oddities" (a "freak" show) or unusual animals, stuffed abnormal creatures, and exotic paraphernalia (a museum show).

Some of the most popular living performances (working acts) exhibited fire eating, sword swallowing, and lying on a bed of nails. These stunts can be used as interesting examples of physical and physiological principles that can be appreciated by modern generations of students. These attractive cases are not only appropriate for a better understanding of scientific aspects, but also help people preserve part of the American tradition.

An example of how it is possible to use one of the brightest stars of the vaudeville stage to understand physics concepts is represented by Annie May Abbott. During her performance, the small lady, known as the "Little Georgia Magnet," was able to resist the combined efforts of four men to move her while she stood on one foot. She also could lift all four men while they were on a chair by simply touching the chair. The application of balance, leverage, and force vectors to anatomical knowledge help solve the source of this apparently inexplicable strength.

If the living stunts can be only analyzed through the contemporary newspapers and pictures, some of the most unusual specimens from museum shows are still available in public and private collections. An example is the human mummy Sylvester (still present in the Ye Olde Curiosity Shop in Seattle, WA), who recently underwent a virtual autopsy to discover his origin and identity.

Furthermore, the history of sideshow abounds with real and fake mummies. Fiji mermaids and alleged human shrunken heads were a must-have for any impresario of a "freak" museum. The luckiest ones, such as Frank Hansen, a Minnesota showman who claimed ownership of a frozen Bigfoot-like creature, were able to present a giant hairy man preserved in ice.

Two mummies that have a strong link to the forensic sciences belonged to Elmer McCurdy and Julia Pastrana. Elmer, a thief, was killed in a shoot-out with police and his mummified body traveled for 40 years throughout the United States as a sideshow attraction. The body then vanished without a trace until it was discovered in The Pike amusement zone in California and identified via a forensic investigation.

Julia Pastrana, a woman affected by hypertrichosis and gingival hyperplasia, was employed as a living attraction in a "freak" show and was advertised as a hybrid between human and an ape. Married to her manager, Theodore Lent, she had a baby with the same pathological condition. During a European tour, they both died a few days after childbirth and their bodies were mummified by the impresario to be displayed in a glass cabinet. After the show ended, Julia's body went through several difficulties, was stolen and recovered, and then stored at the Oslo Forensic Institute. In 2013, it was finally buried at her birthplace in Mexico.

In conclusion, the story of Julia Pastrana, as well as the decline of the human oddities shows and the legal actions that forbid this attraction, offers the possibility of evaluating the modern approach to rare and disfiguring pathological conditions. These ethical considerations currently become more important, considering the recent revival of reality television shows on the topic.

This review of some of the most iconic and mysterious aspects of the traditional American sideshows is an opportunity to apply forensic science to cold cases and to teach science in a different and more attractive way, with a stronger ethical attention to human remains.

Cold Cases, Education, Forensic Anthropology

LW7 The Phoenix Canal Murders + Forensic Genealogy = Solved!

Colleen M. Fitzpatrick, PhD, 18198 Aztec Court, Fountain Valley, CA 92708*

After attending this presentation, attendees will understand how Y-chromosome DNA (Y-DNA) analysis methods borrowed from the genetic genealogy community led to an arrest in a 25-year-old serial killer case when all other investigative methods had failed. Although the techniques described have been used successfully by the genetic genealogy community for many years for surname studies, they are relatively new to law enforcement. Attendees will better understand a novel identification technique they may not yet be aware of, but that has the potential for immediate use by the forensic community for solving cold cases and identifying John Does in the absence of a Combined DNA Index System (CODIS) hit.

This presentation will impact the forensic science community by demonstrating the successful resolution of a cold case through the use of techniques borrowed from genetic genealogy. This presentation will broaden the understanding of various types of metadata that can be extracted about an unknown perpetrator from a match between his Y-DNA profile and public genetic genealogy databases, leading to an appreciation of genealogical Y-chromosomal Short Tandem Repeat (Y-STR) testing as an alternative source of generating investigative leads for cold cases.

One evening in 1991, Angela Brosso went for a bicycle ride along the Arizona Canal in Phoenix, AZ. She never returned home. Her body was found nearby in a vacant lot a few days later. Melanie Bernas went for a bicycle ride along the same canal in early 1992. She never returned either. Her body was found floating in the canal a few days later. The Canal Murders were apparently random killings in which the perpetrator had no connection to his victims, limiting the effectiveness of conventional investigative techniques. Over the years, numerous suspects were investigated, but with no success. There was no CODIS hit to the DNA from the crime scenes.

The Phoenix Canal Murders remained unsolved until 2014, when the Phoenix Police Department asked for the comparison of the Y-DNA collected from the crimes to genetic genealogy Y-STR profiles posted on public websites. Using in-house software to interrogate thousands of public genealogical databases, a Y-DNA match was found to a small group of Millers of Irish origin. This narrowed the list of suspects from perhaps 2,000 individuals to just 5. This led the authorities to arrest Brian Patrick Miller, who is to be tried for the murders of both women.

The Phoenix Canal Murders are only one example of how cold case investigations are benefitting from the use of genealogical resources. A match between a forensic Y-profile and a profile found in a genetic genealogy database can advance a cold case investigation in many ways. Perhaps the most interesting is that forensic genealogy, used in conjunction with DNA phenotyping, is making it possible to predict the appearance, ethno-ancestry, and last name of a killer, based on DNA alone.

Included in this presentation are results from other cases that have benefitted by comparisons to the ~300k Y-STR profiles posted online by the genealogy community; these results are based on surprising leads generated for ethnicity, nationality, and geographic origins, even in the absence of a surname match.

Phoenix, Canal, Genealogy

Program Committee Financial Disclosure – 2018

As a sponsor of continuing education, the American Academy of Forensic Sciences must insure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation; and, (2) with any commercial supporters of the activity. (Significant financial interest or other relationship can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) AAFS has an established policy regarding conflicts of interest that includes decisions the Program Committee members may make in selecting content for the Annual Scientific Meeting Program. By serving on the committee, regardless of role, each member has agreed to comply with Section 1.4.7. of the *AAFS Policy and Procedure Manual.*

To serve on the 2017-18 Program Committees, it is required that relevant AAFS staff members, program committee members, and reviewers complete a Financial Disclosure form before they are provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so that learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve. The executed Faculty Disclosure Forms are on file in the AAFS Office.

Presenting Author Financial Disclosure – 2018

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s); however, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS Office.

A

Discloses no financial relationships with commercial entities.
Emily J. Will, MA - L2
Discloses no financial relationships with commercial entities.
Andrew S. Williams, MD - H35, W20
Discloses no financial relationships with commercial entities.
John A. Williams, PhD - E109, W08
Discloses no financial relationships with commercial entities.
Karl E. Williams, MD - B81
Discloses no financial relationships with commercial entities.
Mary R. Williams, MS - B128
Discloses no financial relationships with commercial entities.
Sheila Willis, PhD - B82, F35, LW3, S2
Discloses no financial relationships with commercial entities.
Lori J. Wilson, PhD - E75
Discloses no financial relationships with commercial entities.
Teresa V. Wilson, PhD - A141
Discloses no financial relationships with commercial entities.
Rebecca J. Wilson-Taylor, PhD - A50
Discloses no financial relationships with commercial entities.
Melissa Wils-Owens, BS - H79
Discloses no financial relationships with commercial entities.
Allysha P. Winburn, PhD - A72
Discloses no financial relationships with commercial entities.
Mark Windschitl, PhD - W08
Discloses no financial relationships with commercial entities.
Hannah Wines, BS - B106
Discloses no financial relationships with commercial entities.
Carl Johan Wingren, PhD - E32
Discloses no financial relationships with commercial entities.
Agnes D. Winokur, MS - B81, BS5
Discloses no financial relationships with commercial entities.
Denise Wohlfahrt, BS - H26, H52
Discloses no financial relationships with commercial entities.
Emily Wolak, DO - H137
Discloses no financial relationships with commercial entities.
David A. Wold, DDS - E99
Discloses no financial relationships with commercial entities.
Matthew R. Wood, PhD - W08
Discloses no financial relationships with commercial entities.
Robert E. Wood, DDS, PhD - G4, G5
Discloses no financial relationships with commercial entities.
Charlotte J. Word, PhD - F17
Discloses no financial relationships with commercial entities.
Erin M. Worrell, BSc - B81, E49, W20
Discloses no financial relationships with commercial entities.
Travis J. Worst, PhD - B27
Discloses no financial relationships with commercial entities.
Thomas Wortman, BS - B95
Discloses no financial relationships with commercial entities.
Jessica Wright - C1
Discloses no financial relationships with commercial entities.
Alan H. Wu, PhD - W14
Discloses no financial relationships with commercial entities.
Richard T. Wyant, MS - B99
Discloses no financial relationships with commercial entities.
Timothy Wysozan, BS - H102
Discloses no financial relationships with commercial entities.

Y

Nicole A. Yarid - H47, H86, H124, W20
Discloses no financial relationships with commercial entities.
Stephen J. Yerka, MA - A143
Discloses no financial relationships with commercial entities.
Hatice Yilmaz, BSc - F1, F2
Discloses no financial relationships with commercial entities.

Julia Yip, BS - A134
Discloses no financial relationships with commercial entities.
Jessica Yopak, BA - A125
Discloses no financial relationships with commercial entities.
Carmen Young - B8
Discloses no financial relationships with commercial entities.
John L. Young, MD - I9
Discloses no financial relationships with commercial entities.
Jorn Chi-Chung Yu, PhD - B127
Discloses no financial relationships with commercial entities.
Nandar Yukyi, MA - A63
Discloses no financial relationships with commercial entities.
Laura Yurka, MA - A78
Discloses no financial relationships with commercial entities.

Z

David J. Zeliff, MFS - W18
Discloses no financial relationships with commercial entities.
Xiang Zhang, MD - H22, H23
Discloses no financial relationships with commercial entities.
Eric Zimmerman, BS - W12
Discloses no financial relationships with commercial entities.
James Zjalic, BSc - C8
Discloses no financial relationships with commercial entities.
Joel A. Zlotnick, MSFS - J7, J8, W06
Discloses no financial relationships with commercial entities.
Walter F. Zoller, DMD - G38
Discloses no financial relationships with commercial entities.

Presenting Author Index – 2018

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2018 Annual Scientific Meeting. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Anthropology	J	Questioned Documents
B	Criminalistics	K	Toxicology
C	Digital & Multimedia Sciences	LW	Last Word Society
D	Engineering Sciences	BS	Breakfast Seminar
E	General	ES	Evening Session
F	Jurisprudence	L	Luncheon
G	Odontology	S	Special Session
H	Pathology/Biology	W	Workshop
I	Psychiatry & Behavioral Science
