PROCEEDINGS
of the American Academy of Forensic Sciences 70th Annual Scientific Meeting

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Meeting. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, engineering, immunology, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to "peer-review" each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues.

The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

Articles from the AAFS *Proceedings* should be officially cited in the following format:

Fenton T.W., Kendell A.E., DeLand T.S., Haut R.C. Determination of Impact Direction Based on Fracture Patterns in Human Long Bones. *Proceedings of the American Academy of Forensic Sciences*, 64th Annual Scientific Meeting, Atlanta, GA. 2012. H72.

Contents

S1 Raising the Bar in Forensic Science

Linton Mohammed, PhD, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014; Karen B. Rosenbaum, MD*, 49 W 24th Street, Ste 908, New York, NY 10010; Vernon M. Neppe, MD, PhD*, Pacific Neuropsychiatric Institute, 6300 Ninth Avenue, NE, Ste 353, Seattle, WA 98115; Allison Campbell, PhD*, American Chemical Society, 1155 16th Street, NW, Washington, DC 20036; Matthew F. Redle, JD*, 148 S Brooks Street, Sheridan, WY 82801; Roger W. Falcone, PhD*, University of California Berkeley, 366 LeConte Hall, #7300, Berkeley, CA 94720; Rick Jones, JD*, NACDL, 317 Lenox Avenue, 10th Fl, New York, NY 10027; Christopher R. Thompson, MD*, 10850 Wilshire Boulevard, Ste 850, Los Angeles, CA 90024; and Daniel A. Martell, PhD*, Park Dietz & Associates, 2906 Lafayette, Newport Beach, CA 92663*

The goals of the 2018 Interdisciplinary Symposium (IDS) are to provide attendees with an overview on how forensic science is viewed inside and outside the forensic arena and to present ideas on what the forensic science community can learn from the broader scientific community regarding transparency, research integrity, and a strong commitment to education.

This presentation will impact the forensic science community by providing attendees with the perspectives of scientists from major scientific organizations inside and outside of forensic science and from attorneys from leading legal associations. Attendees will receive information on how to address strengths and weaknesses in the forensic sciences and should then be able to apply this knowledge in their own research and casework.

The 2018 IDS will comprise several distinguished scientists from within and outside of forensic science. The speakers will address perceived research gaps in the forensic sciences and discuss how to close these gaps.

To complement the 2018 American Academy of Forensic Sciences theme, *Science Matters*. the theme of the 2018 IDS is *Raising the Bar.* This symposium will highlight collaboration with the broader scientific community as a means to strengthen forensic science. Popular television shows have had a generally positive impact (for forensic science) on how the public views forensic science and forensic scientists. Despite the public perception of the near-infallibility of forensic science to detect and solve crimes, there has been criticism of forensic science from the scientific and legal communities. The criticism often notes that there is too much emphasis on the forensic aspect of various disciplines and not enough emphasis on foundational sciences. The National Commission on Forensic Science (NCFS), in which many AAFS members were active, provided a forum for members of the broader scientific community to contribute to recommendations designed to foster the foundational sciences of forensic science and to strengthen the forensic science community. Although the NCFS was not renewed upon the expiration of its charter in the spring of 2017, collaboration with the broader scientific community remains an important objective of AAFS.

At the 2018 IDS, a distinguished panel of researchers and speakers from professional organizations in the broader scientific community will address their perceptions of the strengths and challenges of the forensic science community. The 2018 speakers include the current leaders of the American Chemical Society (ACS), the American Physical Society (APS), the American Academy of Psychiatry and the Law (AAPL), the National Association of Criminal Defense Lawyers (NACDL), the Criminal Justice Section of the American Bar Association (ABA), and an AAFS past president. These speakers will discuss the efforts of their respective organizations to strengthen forensic science and the importance of "outside" voices in the advancement of forensic science. For example, with the APS, that could involve a discussion of what forensic science can learn from the broader scientific community about transparency, research integrity, and a strong commitment to education.

The keynote speaker is Vernon M. Neppe, MD, Director of the Pacific Neuropsychiatric Institute in Seattle, WA, Adjunct Professor of Psychiatry and Human Behavior, St. Louis University School of Medicine, St. Louis, MO, and former Director, Division of Neuropsychiatry, University of Washington, Seattle, WA. Dr. Neppe has contributed internationally in the specialties of neuropsychiatry and behavioral neurology, psychopharmacology, forensic psychiatry, anomalistic psychology, and epileptology. A distinguished psychiatrist, author, playwright, and philosopher, Dr. Neppe's presentation will highlight the importance of groundbreaking paradigm shifts to the advancement of scientific theory and practice.

Forensic Science, Reliability, Admissibility

S2 Research in Science: How Young Scientists Can Shape a Better Future

Brianna B. Bermudez, BS, 9112 Surrey Road, NE, Albuquerque, NM 87109; Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695; Zain Bhaloo, MSc*, Canada Border Services Agency, 14 Colonnade Road, Ste 280, Ottawa, ON K2E 7M6, CANADA; Brittany N. Beyer, MS, Houston Forensic Science Center, 1301 Fannin, Ste 170, Houston, TX 77002; Alyssa J. Badgley, MS, Indiana State Police Laboratory, 550 W 16th Street, Ste C, Indianapolis, IN 46202; Jeremy M. Manheim, 605 Driftwood Drive, E, #200, Lafayette, IN 47905; Alexandria Anstett, MS, Customs and Border Protection, Newark, NJ; Dante Webb, BS, 113 Ellington Boulevard, #473, Gaithersburg, MD 20878; Ashley E. Foster, MAS, Texas Department of Public Safety, 5800 Guadalupe Street, Bldg U, Austin, TX 78757; Erin L. Houston, MS, 3223 Summerhill Lane, Columbus, OH 43221; Vienna C. Lam, BA, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Gail S. Anderson, PhD*, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Maria Susana Ciruzzi, PhD*, Hospital Nacional de Pediatría Prof. Dr. Garrahan, Combate de los Pozos 1881, Buenos Aires 1045, ARGENTINA; Josep De Alcaraz-Fossoul, PhD*, Arizona State University, West Campus - School of Math and Natural Sciences, 4701 W Thunderbird Road, Glendale, AZ 85306; Lindsay Glicksberg, BS*, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Pierre M.M. Guyomarc'h, PhD*, Université de Bordeaux, Allee George St Hilaire, Bat B8, Pessac 33615, FRANCE; Greg Hampikian, PhD*, Boise State University, Biology Dept, 1910 University Drive, Boise, ID 83725-1515; Cheryl D. Hunter*, 403 Pioneer Creek Drive, Florissant, CO 80816; Pamela L. Marshall, PhD*, Southern University at New Orleans, 6400 Press Drive, New Orleans, LA 70126; Michael A. Peat, PhD*, 6700 Woodlands Parkway, Ste 230-308, The Woodlands, TX 77381; Joseph A. Prahlow, MD*, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007; Dragan Primorac, MD, PhD*, 471 Wolcott Lane, Orange, CT 06477; Marcus Rogers, PhD*, Purdue University, 401 N Grant Street, West Lafayette, IN 47907; Elisa N. Shoff, BS*, Miami-Dade Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136; Peter R. Stout, PhD*, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002; Thomas W. Vastrick, BS*, 522 S Hunt Club Boulevard, Ste 217, Apopka, FL 32703; and Sheila Willis, PhD*, NIST, 100 Bureau Drive, Gaithersburg, MD 20899*

After attending this presentation, attendees will better understand the novel research being conducted by both young and leading scientists within a variety of forensic science disciplines and how important that research is to the field.

This presentation will impact the forensic science community by educating young scientists on the importance of scientific research and the effects it has on the community at large. This special session also provides students and scientists with the opportunity to network with professionals in a unique setting that focuses on bridging the gap between established professionals and researchers and those aspiring to enter and thrive in the field.

Calling all students, young researchers, and those new to forensic science! The Young Forensic Scientists Forum (YFSF) focuses on providing young professionals and students continued education in different aspects of forensic science at each AAFS Annual Scientific Meeting. Registration for the YFSF Special Session includes a day-long session on Tuesday and a Breakfast Session on Thursday. The full-day special session will highlight the novel and exciting research being conducted by Academy members and students. The YFSF also hosts Bring Your Own Slides (BYOS) and Bring Your Own Posters (BYOP) sessions that provide young professionals and students with the opportunity to present their research.

The 2018 YFSF Special Session, *Research in Science: How Young Scientists Can Shape a Better Future*, is a day-long session that will leave attendees invigorated and excited about the research being conducted by Academy members and students. Participants will have a more complete understanding of the variety of disciplines that make up the Academy. The selection of speakers represents nearly every AAFS section, which makes for a highly diverse and unique suite of presentations.

The morning session will include an assortment of topics ranging from how to become an AAFS member to how 3D imaging can be used to analyze fingerprints. Following a delicious lunch, included with registration, attendees will hear about the Innocence Network and case-driven research. This day-long session will conclude with a Q&A session in which attendees can engage speakers and panelists in an open discussion.

YFSF, Education, Research

BS1 Analytical Thinking Skills: Essential Training for 21st-Century Forensic Scientists

Mary Ellen O'Toole, PhD, George Mason University, 4400 University Drive, Fairfax, VA 22030; and Joseph A. DiZinno, DDS, 3613 Old Vernon Court, Alexandria, VA 22309*

The goals of this presentation are to: (1) provide attendees with an overview on creating a stand-alone analytical thinking course in graduate curriculums; (2) instruct attendees on structuring a course to address real-world forensic science problems; and, (3) inform attendees on teaching students a specific methodology to break down complex problems.

This presentation will impact the forensic science community by providing students the skills for working in the field in the 21st century.

Forensic science can be considered a three-pronged science designed to train students in theory, research, and application; however, students can face particularly significant challenges without analytical thinking skills and understanding how to apply them to real-world forensic problems.

While analytical thinking skills are important for all scientists, they are particularly critical for forensic science students who must be able to comprehend complex scientific theories, principles, and methodologies, synthesize all of their knowledge, and apply it in real-world situations with unpredictable challenges. To complicate this challenge, many forensic scientists are regularly expected to testify, under oath in court, as to the analytical thinking process they applied to the problem. A weakness or flaw in their analytical thinking or in the application of the science to real-world problems, and the subsequent flawed or weak explanations to the trier of fact, could result in a serious appellate issue for the case, which could summarily damage or even end a young scientist's career.[1]

Forensic scientists are also often asked to serve on multidisciplinary commissions, panels, etc., to collaborate on specific forensic science problems, identify causation, and recommend viable solutions.

Dr. Richard Bloom, a well-known psychologist and educator, created the *Taxonomy of Educational Objectives Book*, which identified levels of cognition ranging from basic comprehension of scientific theories and principles to much more complicated levels of cognition.[1] Later revised, the book identified analytical thinking, creativity, and evaluation as the highest levels of cognition requiring specific teaching methodologies in order to develop and maintain these skills.[2]

In their 1992 paper presented at the annual meeting of the American Educational Research Association, Franklin and Theall noted that college instructors in soft disciplines utilized a wider range of teaching behaviors than those utilized by instructors in science disciplines.[3] Twenty-two years later, Benton and Cashen opined that Science, Technology, Engineering, and Math (STEM) instructors relied predominately on lectures in their courses, rather than more advanced levels of instructional behaviors to help students reach higher levels of cognition, including analytical and creative thinking.[4] This study conducted a review of ten forensic science graduate programs. Five programs were Forensic Science Education Programs Accreditation Commission (FEPAC) -accredited, and five were not. Results indicated none of these programs included a stand-alone analytical thinking course in their curriculums.

Part 1: Demonstrate how to break down a real-life forensic science problem into its most basic component parts in order to identify causation. Students will see that most real-life forensic science problems are complicated and multilayered, and they need a method to break the problem into manageable parts.

Part 2: Students will learn how to develop hypotheses to test causation using research methodologies, both qualitative and quantitative.

Part 3: Using a collaborative and multidisciplinary framework, students will learn how to use analytical and creative skills to identify relevant conclusions and, from those conclusions, develop creative but scientifically sound recommendations for solutions.

Currently, many graduate forensic science programs do not offer stand-alone analytical thinking courses. These skills are either not directly taught or are minimally covered in other courses. Without a solid understanding of analytical thinking skills, forensic science students are not being adequately equipped to face career challenges in the 21st century.

Analytical, Challenges, Methodology

BS2 My Experiences as a Forensic Science Consultant for Crime Drama Television Series

Gregory E. Laskowski, MPA, Criminalistics Services International, LLC, 8021 Dottie Court, Bakersfield, CA 93308; and John Houde, Calico Press, LLC, PO Box 4648, Rolling Bay, WA 98061*

The goal of this presentation is to educate attendees on the processes that occur in the creation of a crime drama episode and why certain aspects of the "reality" of forensic science do not necessarily get translated to the screen. This presentation will discuss the real-life experiences of a forensic science consultant for such television shows as: *CSI: Crime Scene Investigation; CSI: Miami; Law and Order; BONES; Killer Instinct; Vanished; The Mob Doctor; Rizzoli and Isles; Drop Dead Diva; The Blacklist;* and *Rosewood*. Clips from various episodes of these shows will be presented with a discussion on what is real and what is "Hollywood Real." Attendees will be taken on a virtual tour of what happens in the writers' room and on the set.

This presentation will impact the forensic science community by providing attendees with a better understanding of the reason forensic science is portrayed in a certain manner on television crime dramas.

Forensic science flew under the radar for a number of decades. A brief spike in interest of the discipline occurred for a span of seven years from 1976 to 1983. *Quincy ME* was a very popular television show. It was Quincy played by Jack Klugman that fostered the career interest of this presenter. It was not until October of 2000 that the breakout television series *CSI: Crime Scene Investigation* hit the television airwaves. This megahit show took the world by storm. At one point, *CSI: Crime Scene Investigation* was the number-one rated show in the world and/or the most-watched television crime drama. Soon after, the television series led to a number of spinoffs: *CSI: Miami, CSI: New York*, and the much less-known *CSI: Cyber*, gathering number-one ratings for the CBS television network. Not to be outdone, the Fox Television Network launched its own hit forensic science series, *BONES*. On the cable networks, docudrama series such as *Forensic Files* aka *Medical Detectives, Cold Case Files,* and *Extreme Forensics* became extremely popular, with the HLN network broadcasting multiple episode reruns of *Forensic Files* nightly for six years after the original series ended. This presenter has had the distinct honor of having been featured in three episodes. Another hit television show, *NCIS*, and its spinoffs, *NCIS: Los Angeles*, and *NCIS: New Orleans*, feature forensic science components.

For the disciplines of forensic science, these television shows created a wave — perhaps a tsunami — of interest. Young people suddenly began to seriously look at career paths in forensic science. Colleges and universities began seriously looking at either creating or expanding programs in forensic science. During the 2000s, forensic science was in vogue. It was cool to work in a crime lab or be a crime scene investigator. Crime labs were seeing a tremendous uptick in applications for criminalist positions. Colleges and universities began to develop curricula to meet Forensic Science Education Program Accreditation Commission (FEPAC) guidelines. With success comes criticism, and, not surprisingly, the legal community and its allies in the legal educational community began their quest to diminish forensic science. The specter of the "CSI Effect" was raised because it was felt that forensic scientists, when testifying as expert witnesses, were seen as too believable by juries. Juries had unreasonable expectations when forensic science was not introduced in certain trials. Then, many disciplines were being questioned as to whether they were scientific or employing valid scientific techniques. Forensic science was now under the microscope.

For the past 17 years, I have served as a forensic consultant to such television shows as *CSI: Crime Scene Investigations, CSI: Miami, BONES, Rizzoli and Isles, Law and Order, Rosewood*, and *The Blacklist*, in addition to appearing on several forensic science-themed docudramas. As a television consultant, I would either respond to email questions from writers and producers, review scripts, work on-set advising the director or the set dresser, or explain how to perform a technique to the actors. While most of these shows have now been canceled, they do appear on cable television networks and appear to have a strong following. Binge watching these shows can be accomplished by live streaming or DVD rental. While no longer in the forefront of television series lineups, forensic science appears as an ancillary subject in television crime dramas, such as *The Blacklist* and *Lucifer*. So, to an extent, I still keep somewhat busy. Through the use of personal stories and video clips from some of these shows, this presentation will reveal both the real and farcical aspects of television crime dramas.

Forensic Science, Consultant, Television

BS3 The Lawyers Always Win

Roderick T. Kennedy, JD, PO Box 7041, Albuquerque, NM 87194-7041; and Gil Sapir, JD, PO Box 6950, Chicago, IL 60680*

The goal of this presentation is to reinforce the nature of science as transparent and objective. The legal system will ultimately turn to recognized criteria based in the scientific method and academic science to judge the utility and validation of forensic science. Forensic science can profit from associations that will quantify and qualify the limits of forensic examinations. This argues that there is no valid basis to resist examination of forensic science practice by traditional science and legal scholars.

This presentation will impact the forensic science community by demonstrating that it is ultimately the law and law-trained persons who determine the criteria for admissibility of forensic science evidence in court.

In 1923, the *Frye* case judged a challenge to a nascent technology purporting to detect deception in a subject.[1] *Frye* held that evidence produced from novel techniques based in scientific supposition must be judged by the general acceptance of a relevant scientific community related to the technique in question to be admitted. Polygraphy was sidelined; "general acceptance by a relevant community" became a criterion for the admissibility of novel scientific evidence. Physiologists and psychologists were considered the relevant touchstone for "expert testimony deduced from the discovery, development, and experiments thus far made."[1] Polygraphy is still judged by these objective disciplines, but not so much the polygraphers themselves.[2] The law has a suspicion of self-referenced validation.

In 2009 and 2016, failures of forensic claims to validity and reliability in their theories, applications, and results caused two blue-ribbon commissions to review the state of forensic science, and various pattern-matching disciplines specifically.[3,4] In the latter, the President's Council of Advisors on Science and Technology (PCAST) identified two gaps for these disciplines: (1) the need for clarity regarding the scientific standards for the validity and reliability of forensic methods; and, (2) the need to evaluate specific forensic methods to determine whether they have been scientifically established to be valid and reliable. It cast these concepts as "foundational validity" and "validity as applied."[5]

Forensic practitioners criticized these reports as reflecting the views of persons from outside the practice of forensic science. Citing "unprecedented (and unrelenting) challenges from legal professionals, research academics, and the popular press" promotes an idea that only those who practice the particular discipline can establish or judge its validity, not statisticians or scientists from academia, and most particularly, not lawyers.[6] These critics do not recall that forensic science itself is a collection of applied disciplines whose goal is to explain case phenomena in ways relevant and helpful to a court. For years, forensic science escaped much critical evaluation because its genesis, practitioners, and proponents in court were, for the most part, on the same side. This changed in the 1990s when an academically validated and objective scientific technique — DNA analysis — was used not to convict, but to exonerate persons who had been wrongfully convicted. In half of those cases, false and overstated forensic opinions contributed to the injustice. At that point, the legal profession began looking to objective scientific evaluation of claims to legitimacy to which some more subjective (i.e., pattern-matching) disciplines of forensic science laid claim. Prosecutors paid attention to avoid reversals and defense attorneys to call "foul" on unsupported testimony.

Wrongful convictions are a stain on the judicial system, which is self-policing. In cases in which trust in forensic science has been shaken, the law looks to established scientific practice to evaluate and change it. The Los Alamos National Laboratories teaches judges that foremost, science is an open process in which theories and methods must be open to testing by any interested party. The manner in which statistics can validate investigative conclusions compels the use of likelihood ratios, and expressions of limitations on conclusions become requisite to expert testimony. Academic scientists, therefore, inform us as to what validity, repeatability, and reliable process is, and what should be used in the important work of administering justice.

The practice and fate of the forensic sciences is in the hands of lawyers, who are its end consumers, and who are awakening to the need to validate forensic specialties that have been shown susceptible to bias, subjectivity, and lack of enforceable standards for practice. Admissibility of forensic results is in the hands of judges, who look to statisticians, behavioral scientists, and academic disciplines to quantify and qualify validity and reliability of forensic techniques and results. For forensic scientists to keep their research cards close to the vest ignores the open nature of science and sacrifices collaboration with academic scientists to develop acceptable standards for the practice. Forensics' validity in court can be admitted as valid and reliable within its limits, so long as the limits are properly expressed.[7] A bunker mentality that closes out scrutiny and validation can only result in the march of the law going around the bunker.

Law, Forensic Science, Admissibility

BS4 YFSF's Wake Up to Professional Development... and Bacon!

Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Amanda L.A. Mohr, MSFS*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Barbara L. Hovanec*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Brianna B. Bermudez, BS, 9112 Surrey Road, NE, Albuquerque, NM 87109*

After attending this presentation, attendees will have gained knowledge pertaining to professional development and understand how to better prepare themselves for a career in forensic science. Additionally, attendees will be informed of practical applications by professionals established within several disciplines of forensic science.

This presentation will impact the forensic science community by educating young scientists on the importance of personal and professional developments and on the positive effects they can have on the forensic science community. This breakfast seminar provides students and scientists with the opportunity to network with professionals in a unique setting that focuses on bridging the gap between established professionals and young scientists, both in higher education and in the beginning of their careers.

The Young Forensic Scientists Forum (YFSF) Breakfast Session is a morning session that will leave attendees motivated and enthusiastic about their future successes and accomplishments. This session will focus on bridging the gap between academics and early career growth. The goal is to provide young forensic scientists, whether students, near-graduates, or recent employees, with practical skills and knowledge associated with this transition period. Topics of interest will include the application and interview processes, early success and development as a scientist in a respective field, and the overall feelings and emotions that can often overwhelm young scientists. The speaker presentations will conclude with an open Q&A session, where attendees will be able to interact with the speakers to gain additional information.

The YFSF Breakfast Session will conclude, as always, with the popular résumé review session, pioneered by Academy scientists and peers from across several disciplines and career paths. This session is a rare opportunity for young professionals and students to discuss and improve their résumés with established professionals and leaders in the fields of forensic science. Attendees will sit down one-on-one with résumé reviewers to gain imperative knowledge regarding important aspects and areas to highlight or improve upon within their achievements and qualifications.

YFSF, Network, Forensic Careers

BS5 The Making of an Opioid Crisis in America? Why Research, Policy, and Practice Matter

Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709; Michael F. Rieders, PhD*, NMS LABS, 3701 Welsh Road, Willow Grove, PA 19090; Bruce A. Goldberger, PhD*, University of Florida College of Medicine, Dept of Pathology, 4800 SW 35th Drive, Gainesville, FL 32608; Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; Andrew M. Baker, MD*, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415; Agnes D. Winokur, MS*, DEA/Southeast Laboratory, 2205 NW 132nd Place, Miami, FL 33182; and Sabra R. Botch-Jones, MS, MA*, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Boston, MA 02118*

After attending this presentation, attendees will be able to analyze and discuss the features and characteristics of the opioid crisis in the United States. Attendees will also be able to summarize successful implementation of policies and practices at the federal, state, and local levels.

This presentation will impact the forensic science community by providing an open forum for forensic practitioners of many disciplines to discuss the impacts of the opioid crisis to the criminal justice system and how improved reporting, surveillance, research, analytical testing, technology, and policy can help mitigate the challenges of use and misuse of these drugs.

Nearly three million Americans reported a substance use disorder to prescription pain relievers or heroin in 2015, fueling a steady increase in fatalities to an estimated 91 United States deaths daily. These rates are not slowing. In fact, alarming increases in 2015 also resulted in drug overdoses becoming the leading cause of accidental death in the United States, with more than half attributed to heroin and prescription pain relievers (33,091 of 52,404 total drug overdoses).[1] Effective strategies begin with understanding the factors that drive the interrelated problems our nation faces with the ever-increasing opioid crisis in public health and the criminal justice system.

Law enforcement, medical professionals, laboratories, and legal agencies are battling with unmanageable caseloads, economic shortfalls, and challenges for safety, analytical preparedness, and basic education and training. Confronted with the fast-paced emerging drug life cycles, reliable surveillance and intelligence are needed more than they have ever been. The legislative quagmire is just as burdensome, as policy change cannot happen without the data to support change.

This breakfast seminar is an ongoing effort of the National Institute of Justice's Forensic Technology Center for Excellence and the American Academy of Forensic Sciences Synthetic Opioids Ad Hoc Committee to heighten awareness in our communities and encourage working together to bring about necessary research and positive changes to policy and practice. This seminar will offer a multifaceted perspective to the manner in which diverse criminal justice disciplines are addressing these challenges, sharing their knowledge, and advancing science, technology, and law. Dealing with the impacts of the opioid crisis to the criminal justice system requires better reporting, surveillance, research, technology, and policy than are currently in use. This type of forum is the kind of effective public safety strategies identified by the National Governors Association to reduce the illicit supply of and demand for opioids by implementing best practices and ensuring inter-governmental cooperation in criminal and death investigations as well as establishing and enhancing stakeholder coalitions.[2] The need to understand the epidemic and its effects goes beyond knowing your own profession — it takes a global perspective to fully act and make a difference.

L1 Post-Conviction DNA Testing in an Ever-Advancing DNA World

Lisa Mertz, MS, OCME, Dept of Forensic Biology, 421 E 26th Street, New York, NY 10016; Heather Nelson, MS*, OCME, 421 E 26th Street, New York, NY 10016; and Rachel S. Singer, JD*, Kings County District Attorney's Office, 350 Jay Street, Rm 1922, Brooklyn, NY 11201*

After attending this presentation, attendees will better understand the complexities and challenges faced in processing post-conviction DNA cases and will be presented with real-life case examples.

This presentation will impact the forensic science community by showcasing the need for the continued processing of post-conviction cases so forensic science can, through the development and deployment of new technologies, continue to serve both the criminal justice system and society.

DNA testing has become one of the most important forensic tools available in solving, prosecuting, and preventing crime. It is relied upon heavily in the justice system to aid in convicting the guilty and freeing the innocent; however, the usefulness of DNA testing has only been routinely demonstrated within the past decade because of advancements in DNA technology. Such advancements have led to a renewed interest in wrongful convictions. This interest is especially strong in those cases in which convictions are based solely on eyewitness accounts. With the implementation of new DNA technology, physical evidence at crime scenes can be reassessed to see what is possible in terms of examining evidence for biological fluids and/or biological material.

Post-conviction investigations face many of the same basic challenges as new investigations in terms of DNA testing; however, there are additional complexities. Processing a post-conviction case involves greater cooperation among law enforcement, the crime laboratory, and the district attorney's office. This is due to the fact that simply locating the items of evidence to be processed can be both time-consuming and challenging. Just as time-consuming and challenging is locating previous reports and previous laboratory testing results. From past reports and considering previously tested and untested pieces of evidence, if they are found, the crime laboratory can make a determination as to what DNA testing or additional testing is now plausible. Challenges are then faced in the processing of evidence that is old and may only result in the recovery of degraded DNA. Difficulties also arise when dealing with items of evidence that may have been unknowingly contaminated at the scene in a pre-DNA world where there was less emphasis on proper protective equipment. A DNA profile may be able to be recovered from the item of evidence tested; however, obtaining these elimination samples from witnesses or law enforcement personnel, who may have come into contact with the item, may be impossible. Oftentimes, processing post-conviction cases can encounter obstacles in obtaining funding. Laboratories are frequently backlogged with current cases and often do not have the funding to look back, vet, and process old cases.

With all the hurdles faced by crime laboratories, several post-conviction cases remain dormant, their probative evidence locked in unprocessed DNA to this day. The wrongfully convicted continue to serve their sentences in jail, harboring the hope that DNA will one day help them in their quest for justice. Similarly, the families of victims of violent crimes, in too many instances, remain deprived of the closure of knowing the true identities of actual perpetrators. This Luncheon Seminar will present post-conviction case examples that will highlight the challenges faced in processing such cases. This seminar will also showcase the need for the continued processing of post-conviction cases so forensic science can, through the development and deployment of new technologies, continue to serve the criminal justice system and society.

Post-Conviction, DNA, Advancing

L2 Understanding the Impact of Human Factors on Forensic Science: Case Studies in Fingerprint and Handwriting Examination

Melissa K. Taylor, BA, 100 Bureau Drive, Gaithersburg, MD 20899; Ted M. Burkes, BS*, FBI Laboratory, 2501 Investigation Parkway, Rm 2174, Quantico, VA 22135; Emily J. Will, MA*, PO Box 58552, Raleigh, NC 27658; Melissa Gische, MFS*, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; and David Kaye, JD*, Penn State Law, Lewis Katz Building, University Park, PA 16802*

After attending this presentation, attendees will better understand: (1) the general themes of human factors and organizational theory; and, (2) the findings and recommendations of the Expert Working Groups on Human Factors in Latent Print and Handwriting Examinations.

This presentation will impact the forensic science community by helping forensic professionals understand the impact of human factors on every aspect of the evidence examination process.

Forensic science plays a vital role in the criminal justice system by providing scientifically based information through the analysis of physical evidence; however, several high-profile cases in the United States and abroad have highlighted the fact that human errors can occur. Human error is an inevitable part of everyday life; however, in certain endeavors, such as forensic analysis, in which errors may lead to the loss of life or liberty, error prevention is imperative. Human factors analysis can advance the understanding of the nature of errors in complex work settings. The study of human factors is the scientific discipline concerned with the understanding of interactions among humans and other elements of a system and is the profession that applies theory, principles, data, and other methods to design in order to optimize human well-being and overall system performance. The forensic science community can benefit from the application of the substantial body of human factors research to advance the understanding of the nature of errors, enhance productivity and quality in forensic examinations, and reduce the consequences and likelihood of human error in the interpretation of evidence.

The National Institute of Justice and the National Institute of Standards and Technology have partnered to sponsor a series of expert working groups to examine the effects of human factors in forensic analyses and recommend practices to reduce the likelihood of error. Each discipline-specific working group will be comprised of experts from relevant forensic disciplines, statisticians, psychologists, researchers, and other scientific experts, in addition to representatives from the legal community, professional organizations, and other identified stakeholder groups. To date, reports, including recommendations, have been published in the areas of fingerprint and handwriting examinations. The next working groups in this series will focus on DNA mixture interpretation and tool mark examinations.

This presentation will provide the general themes of human factors and organizational theory. The findings and recommendations of the Expert Working Groups on Human Factors in Latent Print and Handwriting Examinations will be presented. A range of issues affecting forensic science disciplines in the areas of work environment, training, emerging technology, and research needs will also be covered.

This presentation will further assist forensic examiners in understanding the purposes and value of reporting and documenting examinations and will provide recommendations for standardizing the content of these materials. Presenters will discuss methods to improve trial and pretrial communications between relevant parties — the experts, lawyers, judges, and juries.

Human Factors, Handwriting Examination, Latent Print Examination

ES1 Science in the Public Eye: Diversity, Research, and Communication

Ryan Gabrielson, ProPublica, 4209 Shafter Avenue, Oakland, CA 94609; Aretha Marshall, BA*, Peacock Productions NBC News, 30 Rockefeller Plaza, 1968E, New York, NY 19119; Kevin Oliver, BA*, WNorml, PO Box 1691, Seattle, WA 99210; Michelle Richmond, BA*, New York, NY; Lucy A. Davis, BHS, LDH Consultants, LLC, 2944 N Mayo Trail, Pikeville, KY 41501; Anjali A. Ranadive, JD, SciLawForensics, Ltd, 1834 Overlook Ridge Road, Brookings, SD 57006; and Christine Funk, JD*, 213 4th Street E, Ste 400 - 417, Saint Paul, MN 55101*

The goal of this presentation is to provide information, based on the experience of national leaders in media, activism, and advocacy, regarding how the use of communication, research, and a commitment to diversity can move the objectives forward and enhance the view of forensic science in the public eye.

This presentation will impact the forensic science community by revealing how the national news media and political activists influence public opinion. The community can apply the experiences, perspectives, and skills demonstrated to implement new methods of accurately presenting the work of forensic scientists in a manner lay people can understand.

Program Description: "A reporter, an activist, and a producer walk into a bar … " Please join us for a slightly different twist on this year's meeting theme, *Science Matters*. The focus of the AAFS 2018 program is diversity, research, and communication in forensic science. By tapping resources from other professions, this presentation seeks to broaden the understanding of how media plays a pivotal role in the general public's *perception* of forensic science and the criminal justice system. This session's speakers come to the table (or bar) bringing their unique experiences regarding how to communicate the work of forensic scientists, their research, and their diversity to affect change in society.

Ryan Gabrielson is a journalist with the independent, non-profit investigative newsroom ProPublica that was awarded the 2017 Pulitzer Prize for public service. Mr. Gabrielson won the 2009 Pulitzer Prize for stories that exposed how immigration enforcement in Maricopa County, AZ, undermined both emergency response and law enforcement investigations. Mr. Gabrielson's reporting has called attention to the apparent failure of the criminal justice system to understand the difference between a presumptive roadside drug test kit and the certainty of confirmatory testing. This lack of communication between science, law enforcement, and the courts has resulted in countless people being unnecessarily detained as well as documented cases of wrongful conviction. Mr. Gabrielson's work has resulted in changes in policy and procedures in the criminal justice system throughout the country.

Aretha Marshall is an executive producer at Peacock Productions, NBC's non-fiction production company, and is responsible for all aspects of talent development, casting for content, and programming. She previously worked as the managing editor for *Dateline*, winning the 2010 Emmy for Outstanding Coverage of a Breaking News Story in a News Magazine. Ms. Marshall's recent work as Executive Producer of Booking on the History Channel's *Navy Seals: America's Secret Warriors* demonstrates the importance of having appropriate, knowledgeable people supplying facts to televised documentaries.

Kevin Oliver is a Washington state cannabis activist. Mr. Oliver is the executive director of the Washington state National Organization for the Reform of Marijuana Laws (NORML) and Political Action Committee (PAC). NORML's mission is to move public opinion sufficiently to legalize the responsible use of marijuana. During his career, Mr. Oliver has relied on grassroots organizing and providing information, based on data and research, to achieve legal reform and to ensure that consumers have access to safe, convenient, and affordable marijuana. In advocating individual legal rights, law reform, and best practices, he brings a different perspective to the forensic science point of view of cannabis identification and toxicology.

Michelle Richmond is a television news producer specializing in legal, crime, and justice news shows. She provided editorial guidance and post-production review for such non-fiction programs as MSNBC's *O.J. Simpson Chasing Freedom* and Lifetime's *JonBenet's Mother: Victim or Killer* to ensure the accuracy and quality of the productions. She also covered the Casey Anthony trail, analyzing witness testimony, motions, closing arguments, and jury instructions for news packages on *Good Morning America, World News Tonight,* and *Nightline*. Ms. Richmond routinely attends forensic conferences to develop storylines and content for news productions and brings in-depth knowledge regarding how forensic science is presented in the media.

Communication, Diversity, Research

W01 Proposed Revisions to the Federal Bureau of Investigation (FBI) Quality Assurance Standards – DNA

Kristy Kadash, PhD, Jefferson County Regional Crime Lab, 200 Jefferson County Parkway, Golden, CO 80401; Jocelyn R. Carlson, MS*, FBI, 2501 Investigation Parkway, Quantico, VA; Susannah Kehl, MS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Kristin Schelling, MS, 7320 N Canal Road, Lansing, MI 48913*

After attending this presentation, attendees will be informed of the proposed changes to the FBI Quality Assurance Standards for Casework and Databasing laboratories. Laboratory personnel will be aware of any changes to policies and procedures that may be necessary in order to comply with the new standards.

This presentation will impact the forensic science community by providing an opportunity to learn about the proposed changes to these quality standards in advance. All National DNA Index System (NDIS) -participating laboratories are required to adhere to and be audited against the revised standards when these standards become effective.

The Scientific Working Group on DNA Analysis Methods (SWGDAM) is revising and updating the Quality Assurance Standards (QAS) for Forensic DNA Testing Laboratories and the Quality Assurance Standards for DNA Databasing Laboratories. Upon completion, SWGDAM will forward the revised QAS to the Director of the FBI and recommend them for issuance. Once approved and an effective date is established, all NDIS-participating laboratories must adhere to and be audited against the revised QAS by the effective date.

The last major revision of the QAS occurred in 2009, with additional revisions issued in 2011. Many changes in technology, interpretation approaches, and casework applications have occurred since then. These include such topics as the development of sophisticated software programs for interpretation and statistics, the expansion of the Combined DNA Index System (CODIS) core Short Tandem Repeat (STR) loci, the emergence of legacy data, and the implementation of Rapid DNA technology. In addition, next generation sequencing and non-STR markers could be adopted in forensic casework or databasing laboratories in the near future. As a result, efforts have been made over the past two years to bring the standards up to date with the demands of today's laboratories and to look forward to tomorrow's needs. This has involved some restructuring and re-organizing of the QAS document and the associated audit document.

Information from past audits, the feedback posted on the SWGDAM Frequently Asked Questions website, and suggestions gathered from laboratories were used to clarify standards that have led to confusion for laboratories and auditors. Where appropriate, elements of the discussion sections of the audit document were incorporated into the standards to better ensure compliance. The goal of these revisions is a document that is adaptable to new advances in the field of human DNA identification yet strict enough to retain confidence that the highest quality testing results are being reported.

Workshop discussion will include the revision process, the revisions under consideration, and the anticipated timeline for approval, issuance, and compliance. This workshop will provide insight into the thought processes behind the proposed changes and will allow workshop participants to collaborate on methods to meet and ensure continued compliance to the standards within their laboratories.

This workshop is being provided with the goal of giving laboratories a closer look at the new QAS in order for participants to initiate preparations that may be needed in their laboratories to achieve compliance to these new standards.

DNA, Quality, Audit

W02 Heavy Petting: A Forensic Expert's Guide to Bestiality and Zoophilia

Brian J. Holoyda, MD, Saint Louis University, Dept of Psychiatry & Behavioral Neuroscience, 1438 S Grand Boulevard, St. Louis, MO 63104; Renee Sorrentino, MD*, Institute for Sexual Wellness, 53 Winter Street, Weymouth, MA 02188; Carl Wigren, MD*, Wigren Forensic PLLC, 509 Olive Way, Ste 1003, Seattle, WA 98101; Susan Hatters-Friedman, MD*, University of Auckland, Level 12, Room 599-12.003 Park Road, Auckland, NEW ZEALAND; John Allgire, BS*, Whatcom County Sheriff's Office, 311 Grand Avenue, Bellingham, WA 98225; Sara Moore, PsyD*, Institute for Sexual Wellness, 53 Winter Street, Weymouth, MA 02188; and J. Paul Fedoroff, MD, Royal Ottawa Hospital, 1145 Carling Avenue, Ottawa, ON K1Z 7K4, CANADA*

After attending this presentation, attendees will understand the history of human-animal sexual intercourse in various cultures across time as well as the development of laws around the world to prosecute this behavior. Attendees will learn current conceptualizations of bestiality and the related diagnosis of zoophilia from the psychiatric perspective. Lastly, attendees will be able to describe current approaches to the evaluation of bestiality cases from the point of view of a forensic pathologist and law enforcement officer.

This presentation will impact the forensic science community by improving the understanding of bestiality, a rarely discussed sexual behavior, and its relevance to the fields of forensic mental health, forensic pathology, and criminal investigation.

This multidisciplinary session featuring forensic mental health experts, a forensic pathologist, and a law enforcement officer will educate attendees about bestiality (i.e., human-animal sexual intercourse). The history of bestiality across cultures as well as the development of legislation to prosecute this behavior will be described. The body of literature on individuals who engage in bestiality will be reviewed, providing practical recommendations for psychiatric and medical evaluation and treatment. The Enumclaw horse sex case will be reviewed from a forensic pathologist's perspective and current practices and examples of the forensic investigation of such cases will be described.

Human-animal intercourse, or bestiality, has occurred since earliest recorded human history. Some ancient cultures were permissive of such behavior, most commonly in the setting of religious practice. On the other hand, many early civilizations punished individuals accused of having sex with animals. Over time, the majority of nations around the world have established legislation to punish individuals deemed to have engaged in bestiality. Various legal grounds for punishing acts of bestiality exist, including moral or religious proscriptions, treating animals as property, and considerations of animal rights.

Though many nations and states have severe sentences for violations of anti-bestiality law, the scientific community knows relatively little about the people who have sex with animals. Alfred Kinsey's original research indicated that human-animal sexual contact was a relatively common phenomenon, at least among farm-raised boys.[1] More recent research has identified various types of individuals who have sex with animals, including self-identified "zoophiles" who report being sexually attracted to or having relationships with their pets as well as incarcerated sexual offenders who report histories of bestiality in addition to other forms of animal cruelty. Case reports describe individuals with autism spectrum disorder who engage in sexual acts with animals, possibly as a component of restricted or atypical interests. Lastly, some individuals have sex with animals for secondary gain, such as financial compensation from pornography or sex shows.

Despite research providing an incomplete understanding of bestiality, there have been multiple efforts to categorize those who have sex with animals. In terms of psychiatric nosology, the *Diagnostic and Statistical Manual, Fifth Edition* classifies "zoophilic disorder" under the diagnosis of "other specified paraphilic disorder," which requires that an individual's sexual interest in animals causes distress or impairment or results in harm or risk of harm to self or others. Notably, the diagnosis may fail to capture all individuals who engage in sex with animals, depending on whether or not a clinician determines that bestiality incurs a risk of harm to others. In 2011 Aggrawal proposed a novel categorization of bestiality based on his necrophilia classification scheme, which he stated could be used for sentencing offenders, despite the lack of any evidence that his classification separated offenders based on their risk of violence or recidivism.[2] In 2017, Holoyda and Newman summarized the current understanding of bestiality in a classification scheme based on offenders' motivations.[3]

In 2005, the Washington state Enumclaw horse sex case brought bestiality into the public eye. A 2007 movie, *Zoo*, described the life and death of Kenneth Pinyan, an American man whose anal intercourse with a horse led to the perforation of the man's colon.[4] Subsequent to Mr. Pinyan's death, Washington state passed its own anti-bestiality bill. Though somewhat rare, law enforcement agencies do investigate reports of animal cruelty that involve bestiality. For example, in 2015, investigators identified two adult males who engaged in sexual intercourse with a mini-mare on a farm in Whatcom County, WA. Utilizing an online forum for individuals interested in bestiality, the detectives were able to obtain evidence incriminating the two defendants. Further analysis of the forum revealed ties to the original Enumclaw animal sex farm as well as another case in which a man was running a dog brothel in Sumas, WA.

Poorly understood and in need of further research, bestiality remains a taboo topic in much of the world. Despite the lack of scientific evidence, societies and law enforcement agencies have developed — and, in some cases, been forced to develop — legislation and investigative techniques to identify and punish individuals who have sex with animals. Further research will spur improved scientific and legal understanding and help guide legal bodies in their management of offenders.

Bestiality, Zoophilia, Sexual Offender

W03 Alternate Light Source (ALS) Photography: Ultraviolet (UV), Infrared Radiation (IR), Lights, and Filters

David G. Pauly, MFS, Methodist University Forensic Science Program, TruForensics, LLC, 3512 Gables Drive, Fayetteville, NC 28311; Mark Vecellio, MFS*, 83 Carter Drive, Sanford, NC 27332; Dyer Bennett, MS*, Sirchie, 100 Hunter Place, Youngsville, NC 27596; Steven L. Downs, MFS*, Methodist University, 5400 Ramsey Street, Applied Forensic Science, Fayetteville, NC 28311; and David Alford, BS*, Sirchie, 100 Hunter Place, Youngsville, NC*

After attending this presentation, attendees will understand how to properly image trace evidence by ALS, utilizing a Digital Single Lens Reflex (DSLR) cameras, ALS kits, and filters.

Professionals charged with processing crime scenes and forensic evidence are often expected to understand, but are not properly trained in, the use of ALS, including UV and IR. This presentation will impact the forensic science community by providing a broad understanding of the capabilities of standard and modified DSLR cameras in their ability to image evidence outside the visible spectrum.

While most crime scene and evidence photography is conducted in the visible spectrum of light, much of the most valuable evidence (biological fluids, trace hair/fibers, firearms/explosive residue, inks, etc.) must be visualized and thus imaged outside of the visible spectrum. This ALS photography session will expose attendees to UV and IR photography through instruction and hands-on practical exercises on the use of DSLR cameras, ALS, and specialized filters.

Crime scene and forensic photography within the visible spectrum of light remains the most utilized and thorough means of documenting crime scenes, autopsy findings, physical injury, and forensic evidence. Despite being the most utilized method of documentation, the lack of proper understanding, training, experience, and equipment results in photography being underutilized or at least not utilized to its fullest potential.

Whatever the level of understanding of photography may be in the visible spectrum, the crime scene professionals' understanding of photography in the ultra-violet and infrared spectrums, or spectra outside the visible, remains an elusive concept. With this lack of understanding comes missed opportunities to locate, visualize, and properly capture photographically evidence that is likely crucial in verifying that a reported crime occurred or to refute a false allegation.

After attending this presentation, attendees will understand how to properly visualize, and image evidence requiring the use of ALS, UV, and IR energy. Common types of evidence requiring the use of ALS for visualization and imaging include semen, saliva, urine, gunshot and explosive residue, fluorescent fingerprint powders, hairs/fibers, inks utilized in fraudulent document cases, and other trace evidence.

This workshop will include a short review of photography principles, including the exposure triangle, an introduction (or "tour") of the Nikon® D7000, and topic lectures by faculty members, followed by hands-on practical exercises.

Sufficient DSLR cameras, lenses, tripods, alternate light source kits, specific nanometer "barrier" filters, and props will be provided for every two to three attendees.

Forensic science professionals in all disciplines that are charged with imaging crime scenes, or forensic evidence, will benefit from this workshop. Jurors want and even expect to see high-quality images of crime scenes, injuries, and other physical evidence. All too often, images exposed in an attempt to capture the various forensic evidence found at crime scenes and other forensic settings are lacking in quality or do not meet the basic legal standards required. In response to these recognized deficiencies, this workshop has been designed for attendees to learn the basic legal requirements for introducing properly formatted images into the courtroom, including when to utilize RAW uncompressed (i.e., lossless) settings. Informal surveys of forensic science and law enforcement professionals have shown repeatedly that most law enforcement and crime scene photographers do not understand the nuances in compression levels, such as when to utilize JPEG vs. RAW in general crime scene work versus when capturing critical comparison or evidence-quality images.

ALS, Photography, UV and IR

W04 Applications of Raman Spectroscopy for Trace Evidence Examinations

Christopher S. Palenik, PhD, Microtrace, 790 Fletcher Drive, Ste 106, Elgin, IL 60123-4755; Edward M. Suzuki, PhD*, WA State Patrol Crime Lab, 2203 Airport Way, S, Bldg A, Ste 250, Seattle, WA 98134-2045; Andrew M. Bowen, MS*, US Postal Inspection Service, 22433 Randolph Drive, Dulles, VA 20104-1000; and Patrick Buzzini, PhD*, Sam Houston State University, Chemistry/Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77340*

This presentation focuses on applications of Raman spectroscopy for the analysis of various types of materials that may be encountered as trace evidence. This presentation is intended to provide trace evidence examiners with a better understanding of this underutilized analytical method, which has seen significant developments in instrument technology in the past couple of decades. After attending this presentation, attendees will gain: (1) a better understanding of the theory, principles, and instrumentation of Raman spectroscopy; and, (2) a greater appreciation of Raman spectroscopy's capabilities and limitations for the characterization, comparison, and identification of various types of trace evidence.

This presentation will impact the forensic science community by increasing participant knowledge and information as well as providing a framework upon which examiners can better utilize this method for casework and to correctly interpret the spectral data of their evidence.

The principles and applications of Raman spectroscopy for the analysis of various materials encountered as trace evidence are presented in this workshop. The emphasis is on spectral interpretation and explanations of the underlying reasons as to why Raman and infrared spectra differ. Because the two methods present data in formats that — superficially, at least — appear identical, the differences between the two methods are often a source of confusion.

All instructors of this workshop have experience as both trace evidence examiners and as researchers who have sought new applications of Raman spectroscopy. Collectively, the types of materials they have examined with this technique include textile fibers, paint, polymers, pigments and dyes, cosmetics, explosives, nanoparticles, and general unknowns. These instructors thus provide perspectives as both practitioners and researchers who have applied Raman spectroscopy for the analysis of a wide variety of materials.

Probably the most significant development that permitted the practical utilization of the very weak Raman effect, which consists of inelastic scattering from a sample, has been the advent of stable lasers, which provide intense monochromatic excitation sources. Use of such lasers for Raman spectroscopy began in the 1970s, and since that time, there have been a number of other significant developments in commercial Raman instrumentation. These include holographic gratings, Charge-Coupled Device (CCD) detector arrays, efficient notch and edge filters to remove Rayleigh scattering lines (without which Fourier Transform (FT) -Raman spectroscopy would not be possible), lasers covering a wide range of excitation wavelengths, and microscope attachments that allow spectral data to be collected from diffraction-limited spatial areas. These developments have transformed what was once a time-consuming analysis requiring hours to one in which data can now be obtained in minutes. More importantly, the lower laser power levels now permitted have expanded the range of materials from which useable Raman data can be obtained without destroying samples.

Because certain types of trace evidence may consist of very complex matrices, a battery of analytical techniques is typically employed to obtain more complete information about the sample. The types of information provided by a Raman analysis of various types of evidence are described, with particular emphasis on how this complements, supplements, or augments data obtained from other methods. Using Raman spectroscopy, trace examiners can probe very small areas of their evidence with minimal sample preparation in a non-destructive manner. Raman spectroscopy is thus ideally suited for the analysis of certain types of trace evidence, but it is currently an underutilized technique in the forensic science laboratory. This workshop is intended to help rectify this situation.

This project was supported by Award No. 2010-DN-BX-K236 and No. 2011-DN-BX-K557 awarded by the National Institute of Justice, Office of Justice Programs, United States Department of Justice.

Raman Spectroscopy, Trace Evidence, Identification

W05 Ohio's Assertive Approach to Scheduling Opioids and Fentanyl Analogs

Douglas E. Rohde, MS, Lake County Crime Laboratory, 235 Fairgrounds Road, Painesville, OH 44077; Eric S. Lavins, BS*, Cuyahoga County Medical Examiner's Office, Toxicology Dept, 11001 Cedar Avenue, Cleveland, OH 44106; Erin C. Reed, JD*, State of Ohio Board of Pharmacy, 77 S High Street, Columbus, OH 43215; Jon E. Sprague, PhD*, Center for the Future of Forensic Sci at BGSU, 39 College Park, Bowling Green State University, Bowling Green, OH 43403; Joseph A. Felo, DO*, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106; and Stanton W. Wheasler, BS*, Ohio Bureau of Criminal Investigation, 1560 State Route 56, SW, London, OH 43140*

After attending this presentation, attendees will: (1) recognize the role of state government in the scheduling of drugs; (2) understand the importance of rapid scheduling of drugs for law enforcement purposes; (3) identify the parts of the molecular structure of drugs that are responsible for pharmacological interactions; and, (4) realize the importance of communication and cooperation between forensic laboratories and government entities.

This presentation will impact the forensic science community by providing an in-depth examination of how one state is combating the opioid epidemic.

Opioid overdoses in the United States have quadrupled since 1999. Among the 47,055 drug overdose deaths in the United States that occurred in 2014, 28,647 (60.9%) involved an opioid. Opioids were involved in 33,091 overdose deaths in the United States. in 2015.[1]

Ohio was one of the five states with the highest rate of death due to drug overdose in 2015 (West Virginia: 41.5 per 100,000; New Hampshire: 34.3 per 100,000; Kentucky: 29.9 per 100,000; Ohio: 29.9 per 100,000; and Rhode Island: 28.2 per 100,000).[1] In response to the alarming trend in opioid deaths, government agencies in Ohio worked with forensic scientists across the state to combat this epidemic through rapid and novel legislation.

In 2016, confirmed cases of U-47700 opioid fatalities in Ohio initiated drug scheduling research to be conducted by the Ohio Attorney General's Bureau of Criminal Investigation (BCI). After BCI's research was provided to the State of Ohio Board of Pharmacy, the Board cast a swift and unanimous vote which classified U-47700 as a Schedule I opium derivative under rule 4729-11-02 of the Ohio Administrative Code.[2] The next day, Ohio Governor John Kasich signed an executive order authorizing the Board to take emergency action and subjecting U-47700 to criminal drug penalties as of May 4, 2016. This action occurred six months before the United States Drug Enforcement Administration placed U-47700 into Schedule I of the Controlled Substances Act on November 14, 2016.

Another combined effort in Ohio to combat the influx of newer drug analogs was the development of the "pharmacophore rule."[3] The Office of the Ohio Attorney General working together with the Ohio State Board of Pharmacy developed this unique method of establishing guidelines for the scheduling of newer drug analogs based upon the scientific principles of drug design.

Drugs elicit their mechanism of action through biochemical and physiological interactions with drug targets. The pharmacophore of a drug molecule is the portion responsible for producing a pharmacological response and provides the core scaffold to which functional groups are added. Functional groups provide atoms for interacting with drug targets, such as receptors. The binding of a drug to a receptor produces most of the pharmacologic and toxicologic effects of the drug.

The ''pharmacophore rule'' addresses the fentanyl analog problem at the level of pharmacology before the compounds have even been identified in forensic laboratories. The rule is written such that a forensic scientist can identify the basic structural elements required for a fentanyl analog to bind to the drug receptor. If the binding elements are met as outlined in the Ohio Administrative Code, a forensic scientist can report the fentanyl analog as a Schedule I controlled substance.

The ability of government entities in Ohio to rapidly schedule newer opioids, in addition to the ability of forensic scientists in Ohio to utilize the "pharmacophore rule" to immediately classify new fentanyl analogs as Schedule I drugs, allows for rapid action on the part of law enforcement officials in the state.

Opioid, Pharmacophore, Drug Scheduling

W06 Machine-Readable Technologies in Travel and Identity Documents

Joel A. Zlotnick, MSFS, US Department of State, 600 19th Street, NW, Ste 12.601, Washington, DC 20522; Linda L. Mitchell, BS, Forensic QDE Lab, LLC, 243 S Escondido Boulevard, #550, Escondido, CA 92025-4116; and Linton Mohammed, PhD, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014*

After attending this presentation, attendees will understand how contemporary machine-readable technologies used in travel and identity documents function and the circumstances under which the encoded data can be accessed using software and/or hardware readers.

This presentation will impact the forensic science community by describing novel travel and identity documents examination methods that revolve around document reader technology instead of microscopic and other conventional methods for the examination of questioned documents.

Drivers for the adoption of machine-readable security features in identity and travel documents generally include a desire for better facilitation and/or improved security. In context, facilitation means improved speed in the processing of documents and their bearers through border control environments and similar contact points, coupled with a reduced risk of typographical or clerical errors that result from human involvement in data entry. Security means the adaptation of machine-readable features to help a document authenticate itself to a machine reader and/or human inspector or the inclusion of biometric technologies that can bind the document to its bearer to reduce the risk of successful impostor fraud. The nature of machine-readable technologies used in travel and identity documents has changed considerably over the past four decades, and which technologies may be present in a particular document is a function of the document type, its intended usage, and the governing technological standards of the era in which the document was issued.

Passports, visas, birth records, identity cards, and other identity and travel documents have been manufactured with a diverse array of machine-readable technologies that are capable of very different functions. These include optical character recognition fonts, machine-readable text zones, magnetic stripes, barcodes, optical strips, and both contact and contactless smart chips. The function and usage of each of these technologies in the context of identity and travel documents will be described on a technical level, including how the technology encodes data, the limits of how much and the nature of the data that can be encoded, and how the feature may or may not facilitate biometric comparisons. Additionally, the technologies will be considered from the point of view of document design standards promulgated by the International Civil Aviation Organization (ICAO), the American Association of Motor Vehicle Administrators (AAMVA), and other bodies, and as they relate to the REAL ID Act of 2005 and the Western Hemisphere Travel Initiative.

Clearly, machine-readable technologies are not designed for human examination and most cannot be deciphered using conventional questioned document methods, such as microscopy; however, this does not mean that machine-readable document features are inaccessible to questioned document examiners. Although highly sophisticated document reading systems are being deployed for use in border control environments, expensive and complicated readers are not always necessary to access individual machine-readable technologies. Many machine-readable features can be decoded using inexpensive equipment ranging from small magnetic stripe readers to commercial barcode software to a variety of smartphone applications. Similarly, it is often not necessary to have a detailed knowledge of computer science or cryptography to obtain useful information from machine-readable technologies, particularly if the primary benefit of the technology is related to facilitation (as opposed to security). The final goals of this workshop are to describe straightforward methods for accessing machine-readable document features using low-cost tools and to explain when such an approach is likely or unlikely to be successful in regard to different circumstances.

Document, Security, Facilitation

W07 Data Standards, Archiving, and Analytics in Forensic Anthropology

Franklin E. Damann, PhD, DPAA CIL, 106 Peacekeeper Drive, Offutt AFB, NE 68113; Jeffrey James Lynch, MSc*, 501 Park Avenue, Apt 126, Omaha, NE 68105; Sachin Pawaskar, PhD*, University of Nebraska Omaha, 1110 S 67th Street, Omaha, NE 68182; Carl N. Stephan, PhD*, The University of Queensland, School of Biomedical Sciences, Saint Lucia, Queensland 4072, AUSTRALIA; Stephen D. Ousley, PhD*, Mercyhurst University, Dept of Anthropology/Archaeology, 501 E 38th Street, Erie, PA 16546; Nicholas P. Herrmann, PhD*, Texas State University, Dept of Anthropology, 266 ELA, 601 University Drive, San Marcos, TX 78666; Alexandria Frye, MA*, 1811 Medical Parkway, #836, San Marcos, TX 78666; Felix Engel, MA*, Albert Ludwigs University Freiburg, 29 Hebelstrasse, Freiburg, Baden-Württemberg 79104, GERMANY; Stefan Schlager, PhD*, and Albert Ludwigs University Freiburg, 29 Hebelstrasse, Freiburg 79104, GERMANY*

After attending this presentation, attendees will understand the benefits of a unified data architecture and ontology of forensic anthropology data, which enables the development and implementation of software applications for data analytics. Attendees of this session will join a community of users and will gain access to open source software for recording and managing biometric data in forensic anthropology.

This presentation will impact the forensic science community by providing access to an ecosystem of software applications for forensic anthropology that facilitates casework analyses. Casework efficiencies are realized through a common ontology, enabling data sharing and opportunities for new methods. The ecosystem of applications is based on open source software that fosters collaboration and community engagement via appropriate interfaces and Application Programming Interfaces (APIs).

Disparate and fractured datasets preclude collaboration among various research groups. The purpose of this workshop is to promote a unified data architecture and ontology for forensic anthropology. In doing so, the consistency, quality, and usability of skeletal data improves, providing for more robust reporting and analytics capability, and enhances collaboration and efficiency among globally distributed forensic scientists, researchers, networks, and infrastructures.

This workshop begins with a series of presentations introducing the concepts of: (1) a unified data architecture and its application to forensic anthropology; (2) a well-defined data ontology; and, (3) an overview of data analytics and project pipelines. These concepts are then reinforced through tutorials and hands-on demonstrations.

The Resource Description Framework (RDF) is a standard for data integration, serving as a formal representation of knowledge and a conceptual data model in knowledge management systems. The RDF-based data standard (i.e., RDFBones) is presented with research data from the Forensic Anthropology Center Texas State (FACTS). The Commingled Remains and Analytics (CoRA) is an open source software application for recording and managing data from skeletal specimens. CoRA is a web-enabled relational database built on the open source PHP Laravel framework. It was created to manage multiple data types obtained from skeletal specimens in a large commingled assemblage. In doing so, data attributes (i.e., metric and non-metric data) are then searchable and filterable to propose linkages among specimens associated to single individuals. During these presentations, attendees will gain access to software, create user accounts, and realize the benefits by performing data input and aggregation into various information systems and run complex data queries across various data types.

The later presentations build upon the previously introduced concepts by demonstrating the benefits through analytical packages developed for specific tasks. A short hands-on introductory session to R programming will be provided to introduce the basics of computer programming to attendees and ensure users can draw on extensibility functions of R and hacking R program source code for their own research purposes. The analytical packages OsteoSort, TDStats, Skelet-o-matic, and recent updates to FORDISC® will be discussed.

OsteoSort is an osteological sorting package for R (www.osteosort.net) and provides tools to conduct pair-matching, articulation, and association analyses on large commingled assemblages. A related package, OsteoShiny, provides a graphical user interface to OsteoSort. Hands-on demonstrations will involve conducting analyses within R and through the graphical interface.

TDStats is an R application for standardizing and automating facial soft tissue thickness analysis for craniofacial identification and is freely available from the craniofacial identification resource hub CRANIOFACIALidentification.com. It is built under an exploratory data analysis framework and heavily utilizes plots rather than statistical significance tests to encourage comprehensive understanding of the data to draw scientific inferences and generate enhanced central tendency statistics for use in casework. TDStats uses base tcl/tk for graphical user interfaces.

Skelet-o-matic is a Microsoft® Excel® macro-enabled program that enables inventory of skeletal remains and the automatic generation of a colored skeletal homunculus. As an Excel® spreadsheet with set cells for data values, completed inventory forms can be easily data mined in R.

FORDISC® software is used to assess sex and ancestry and estimate stature, and upcoming versions will add modules for: (1) age estimation using transition analysis; (2) ancestry estimation using macromorphoscopic traits of the skull; and, (3) ancestry estimation using dental morphology traits. These modules will be available as free standalone programs.

Tying separate and related analytical packages together demonstrates the utility and efficiencies gained in analytical processes linked via a computing ecosystem. By creating a community of forensic anthropology users who contribute data to unified data architecture patterns, human skeletal variation among spatially and temporally disparate collections becomes attainable.

Information Management, Data Analytics, Forensic Anthropology

W08 Innovative Teaching With Active Learning Methods — Implementation in Forensic Science Education

Gina Londino-Smolar, MS, IUPUI, 402 N Blackford Street, LD 326, Indianapolis, IN 46202; Amy N. Brodeur, MFS*, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R806, Boston, MA 02118; Matthew R. Wood, PhD*, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753; Catherine G. Rushton, EdD*, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; Mark Windschitl, PhD*, University of Washington, 115 Miller Hall, Seattle, WA 98195; Mark R. McCoy, EdD*, University of Central Oklahoma, Forensic Science Institute, 100 N University, Edmond, OK 73034; Caitlin E. Porterfield, MS*, Forensic Science Institute - UCO, 100 N University Drive, Edmond, OK 73034; Sandra Haddad, PhD*, Bay Path University, 588 Longmeadow Street, Longmeadow, MA 01106; John A. Williams, PhD*, Western Carolina University, Anthropology and Sociology, 101 McKee Hall, Cullowhee, NC 28723; and Adrienne L. Brundage, PhD*, 2001 Cobblestone Lane, Bryan, TX 77807*

After attending this presentation, attendees will be able to: (1) describe general principles of learning, including examples related directly to scientific disciplines; (2) identify and describe a variety of active learning methods; (3) distinguish between active and non-active learning methods; (4) cite examples of useful teaching methods dependent on the environment; (5) evaluate innovative teaching styles that could be incorporated into their classroom; and, (6) generate lesson plans that could be integrated into their classroom.

This presentation will impact the forensic science community by exploring a variety of teaching strategies to gain insight into a broader scope of active learning methods useful in forensic science teaching. Attendees will learn how these teaching methods can help forensic science instructors adapt their lesson plans to rapidly changing learning environments. By discussing multiple learning techniques and the application of teaching methods in forensic science education, attendees will be able to incorporate new tools into their forensic science classroom.

Many instructors still teach the way they were taught — lecture and test — without realizing that more active learning methods exist. This session, organized jointly by the Council of Forensic Science Educators (COFSE) and the Forensic Science Education Programs Accreditation Commission (FEPAC), will explore innovative teaching strategies currently being used in science education. The active learning methods presented are applicable to undergraduate and graduate level forensic science programs, educational workshops for forensic science practitioners, and forensic laboratory trainees. Active learning methods improve a student's critical thinking skills, problem-solving abilities, and long-term retention of the material. Such methods include flipped classroom techniques, large lecture teaching methods, service-based learning, gamed-based learning, direct experimentation, and a writing-based approach to scientific learning. Each discussion will include real classroom examples of how the teaching method is implemented within the forensic curriculum and how to apply the teaching methods to any discipline.

This presentation explores what learning scientists have discovered regarding how individuals process new knowledge, reason with information, problem solve, and engage in professional practices. Theories about "what counts" as knowledge and learning will be explored, including individual cognition, sense-making, and apprenticeship.

A "flipped" classroom employs recorded lectures to deliver information outside of class time. Class time can then be used for other learning activities, such as case studies, discovery-based activities, writing-to-learn exercises, class discussions, and in-class office hours.

Teaching 15-30 students is much different from teaching 300-400 students. Instructors want to engage students in the material. This presentation will focus on methods used in large lectures to engage students through active learning techniques. Topics will include group discussion, useful technology to engage attendees in presentations, and response systems in the classroom.

This workshop will provide a framework for utilizing service-learning projects as an active learning methodology in the forensic science classroom. Service learning offers transformative learning experiences to students by developing "beyond-disciplinary skills," broadening students' perspectives in relation to themselves and their community, integrating meaningful community service, and placing students at the "center of their own active and reflective learning experience."

Forensic science education naturally lends itself to game-based learning. The games can be a re-imagination of a board game or be based on current technology. Additionally, hands-on laboratories and case studies allow instructors to incorporate vastly different game components. Assessment of student mastery of the material can be accomplished simply by the student successfully completing the game. The knowledge, skills, and abilities students gain from the game would complement any current curriculum.

Discussion will include the use of small-group activities interspersed within the standard lecture format. The different outcomes of providing groups with very detailed instructions regarding how to conduct an experiment compared to groups given simplified instructions will be discussed. Items to be covered will include creating groups, design strategies, and methods of evaluation.

Scientific writing is one of the necessities of the working life, yet teaching this subject to students proves to be a challenge. A journal-based approach yields higher grades and greater involvement for the students and leads to higher impact learning. Such an approach will be outlined, using a custom journal aimed at undergraduate level research, peer reviewed, and edited by undergraduates in an upper division science writing course.

Forensic Education, Active Learning, Teaching Strategies

W09 Putting the Expert on Trial

Joyce L. deJong, DO, WMU Homer Stryker MD School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; Rudy J. Castellani, MD*, Center for Neuropathology, 1000 Oakland Drive, Kalamazoo, MI 49008; Carl J. Schmidt, MD*, Wayne County MEO/University of Michigan, 1300 Warren, Detroit, MI 48207; and Michael L. VanErp, JD*, Johnson & Wyngaarden, PC, 3445 Woods Edge Drive, Okemos, MI 48864*

After attending this presentation, attendees will: (1) recognize and understand the significance of various pediatric injuries; (2) understand the process of discerning inflicted from accidental injuries causing death; (3) appreciate the effective use of consultants in certain pediatric deaths; (4) realize the potential legal risks of providing opinions as practitioners and consultants; and, (5) be informed about appropriate practices to follow in the event of subsequent allegations of improperly practicing the forensic sciences and providing opinions.

This presentation will impact the forensic science community by clarifying the recognition and significance of various pediatric injuries, improving the determination of inflicted from accidental injuries, and preparing practitioners and experts for potential litigation against them for providing their opinions.

The juxtaposition of medical science and justice is fraught with challenges. Whereas scientific reasoning seeks to objectively explore theory with empirical observation, American justice is adversarial by design. This contrast is particularly problematic in homicidal abuse, with a helpless and preverbal victim on the one hand, and an accused caregiver on the other; one life lost and the other hanging in the balance. Adding to the incendiary environment is a recent Supreme Court dissent claiming that "doubt has increased within the medical community," which in turn has led to doubts about the existence of abusive head trauma in general. Assertions of flawed studies, circular reasoning, wrongful incarceration, and miscarriages of justice occur with regularity, on the part of doctors and lawyers alike. It is therefore not that surprising that the justice system on occasion might turn on the primary interpreters and put the forensic pathologist on trial; however, the educational value of such a case is immense.

This workshop is centered on the case of a 20-month-old toddler who was found dead in bed. Autopsy examination disclosed many hallmarks of abuse and the death was certified as homicide. The boyfriend of the deceased's mother was eventually charged and incarcerated; however, after receiving opposing opinions from experts for the defense, the prosecutor dismissed all charges with prejudice, after which four pathologists, the arresting officer, a municipality, a county, and a hospital were sued in federal court for due process violations, under auspices of the 4th, 6th, and 14th amendments of the United States Constitution.

This workshop will review the multiple aspects of medical science raised in this case, with strict adherence to the scientific method and quality of evidence — in effect a systemic review of all relevant literature. The topics will include: clinical and social context of child abuse, perpetrator data, cutaneous bruising in physical abuse, impact-related abusive head trauma vs. shaken baby syndrome, subdural hematoma, severe hemorrhagic retinopathy, mechanisms of parenchymal injury in pediatric head trauma, short distance falls, lucid intervals vs. pathological timing of injuries, brain injury biomechanics, second impact syndrome, coagulopathy (intrinsic versus drug-induced versus trauma-induced), and child abuse mimics. Included in this workshop will be an experienced attorney who devoted numerous hours to the civil case on the defense side researching case law, engaging in motion practice, and incorporating medical science. This attorney will explore in-depth the concept of qualified immunity, areas of inherent risk and exposure to due process and malpractice claims targeting forensic pathologists in child abuse and other cases, tactics and philosophies of personal injury lawyers, and strategies for pre-emptive protection of forensic pathologists in a hyper-litigious environment.

After considering the scientific underpinnings of the manner of death assessment, a number of additional questions will be raised for discussion, including, but not limited to, the following: (1) Is the American justice system capable of litigate medical science?; (2) What is the risk to forensic pathologists of certifying a child abuse case as homicide?; (3) What is the level of adherence to scientific principles by lawyers seeking damages and/or their retained experts?; (4) How often is medical science co-opted by retained experts relying on *ipse dixit* opinion and low evidence quality?; (5) What is the extent of the chilling effect on the willingness to properly certify manner of death and/or offer objective opinion as an expert if the scientific conclusion is homicidal child abuse?; (6) Are personal and pecuniary biases on the part of retained experts corrupting otherwise robust science in civil and criminal justice?; (7) Should expert panels be employed to litigate medical science instead of individual retained experts?; and, (8) What justice systems in other countries may serve as better models to deal with the juxtaposition of medical science and justice?

Child Abuse, Forensic Pathology, Jurisprudence

W10 A Multidisciplinary Approach to Dogfighting Cases

Rachel Touroo, DVM, 2015 SW 16th Avenue, Gainesville, FL 32608-1166; Amanda Fitch, MS*, American Society for the Prevention of Cruelty to Animals (ASPCA), 2015 SW 16th Avenue, Bldg 215, Rm VC-79, Gainesville, FL 32610; Randall Lockwood, PhD*, American Society for the Prevention of Cruelty to Animals (ASPCA), 2214 Tulip Drive, Falls Church, VA 22046; Terry Mills*, American Society for the Prevention of Cruelty to Animals (ASPCA), 520 8th Avenue, New York, NY 10018; Pamela Reid, PhD*, American Society for the Prevention of Cruelty to Animals (ASPCA), 520 8th Avenue, New York, NY 10018; and Jennifer Chin, JD*, American Society for the Prevention of Cruelty to Animals (ASPCA), 520 8th Avenue, New York, NY 10018*

After attending this presentation, attendees will: (1) possess a basic understanding of dogfighting within the United States, including the breeds of dogs utilized, housing, breeding, training and conditioning of dogs, the rules and procedures of a fight, and recognition of paraphernalia associated with this crime; (2) be familiar with investigative techniques specific to dogfighting; (3) recognize the unique aspects of dogfighting crime scenes; (4) understand evidence analyses typically associated with dogfighting case work; (5) recognize the pattern of injury and animal behavior consistent with dogs utilized in organized dogfighting; (6) understand the link between dogfighting and other violent crimes; and, (7) better understand major legal issues in dogfighting investigations and prosecutions.

This presentation will impact the forensic science community by enabling recognition of this clandestine crime and elucidating the most current research and techniques utilized when investigating and prosecuting dogfighting. Additionally, this presentation will illustrate the benefits of a multidisciplinary approach for the most favorable outcome to dogfighting criminal cases.

Organized dogfighting is intentional, severe abuse of animals. Although animal fighting is illegal in all 50 states and the federal Animal Welfare Act prohibits animal fighting ventures, this organized abuse of animals is still rampant throughout the United States and rarely occurs in isolation. Organized crimes, such as racketeering, illegal gambling, illicit drugs, and firearm offenses, are frequently associated with animal fighting.[1-3] Therefore, it is critical that law enforcement, veterinarians, prosecutors and others involved possess a basic understanding regarding the animals utilized, how they are maintained, trained and conditioned, fought, and the pattern of injuries and the behavior associated with these illegal fights.

In the United States, the American Pit Bull Terrier is the breed most commonly associated with organized dogfighting.[1-4] Dogfighting can be divided into three main categories: street fighting, hobbyist fighting, and higher level "professionals."[1,3,5] Dogs are prepared for a fight in a fairly routine pattern; however, this varies depending on the category in which they fall. A wide array of equipment, techniques, supplements, and drugs are used to condition a dog for a fight. It is of the upmost importance that those involved in the investigation and prosecution of this crime be familiar with these items and information that may be inferred from them. Dogfighting crime scenes are unique and ideally involve a multidisciplinary approach that includes a variety of experts.

In addition to the items of physical evidence that might be encountered on the crime scene, it is important to remember that the animals themselves are also evidence and may have important information to be considered. Veterinarians involved in the examination of live and deceased animals should be familiar with the wound patterns characteristic of this activity. Fighting dogs typically display scars and/or wounds caused by the teeth of their opponent; however, typically, not all dogs in a dogfighting yard will have wounds and/or scars present, due to age and/or use.[6] The extent and distribution of wounds and/or scars can be very informative. Initial research has demonstrated that there is a distinct pattern of injury associated with organized dogfighting, which has been differentiated from spontaneous dogfights.[6-7] Additionally, underlying fractures or other skeletal trauma is not uncommon and should be documented through advanced imaging or skeletal analysis of remains.

Normal canine aggression is highly ritualized, but a fighting dog is more likely to rush directly at its opponent without hesitation, target vulnerable areas of the opponent's body with deep-mouthed, hard bites, and continue to fight even if the opponent signals submission and defeat. Dogs seized in fighting cases should be systematically evaluated by experienced behavior specialists in order to document these unique behavioral characteristics, as this information can be used to support charges that the dogs were used for organized fighting.

Additionally, there are a variety of major legal issues involved in the investigation and prosecution of dogfighting, both at the state and federal level. Those involved in these areas should have a basic understanding of the issues at hand and how they may impact a case. This workshop will address the link between dogfighting and other crimes, provide attendees with a basic understanding of the animals utilized, how they are maintained, trained and conditioned, fought and the pattern of injuries and the behavior associated with these illegal fights as well as discuss major legal issues in dogfighting investigations and prosecutions.

W11 Some Like It Hot: A Forensic Analysis of Burnt Remains

Sara C. Zapico, PhD, FL International Univ, Dept of Chem and Biochem, Modesto A. Maidique Campus, OE116, 11200 SW 8 Street, Miami, FL 33199; Sarah Ellingham, PhD*, International Committee of the Red Cross, Baghdad Delegation, PO Box 3317, Al-Alwiya Post Office, Baghdad, IRAQ; Joe Adserias-Garriga, DDS, PhD*, c/ Balmes 62 30 la, Barcelona, SPAIN; Douglas H. Ubelaker, PhD*, Smithsonian Institution, Dept of Anthropology, NMNH, MRC 112, Washington, DC 20560; John Berketa, PhD*, University of Adelaide, 121 William Street, Norwood, South Australia 5067, AUSTRALIA; Steven A. Symes, PhD*, MS Medical Examiner's Office, MCL, 215 Allen Stuart Drive, Pearl, MS 39208; Ericka N. L'Abbe, PhD*, University of Pretoria, 9 Bophelo Road, Pretoria 0001, SOUTH AFRICA; and Christopher W. Schmidt, PhD*, University of Indianapolis, Dept of Anthropology, 1400 E Hanna Avenue, Indianapolis, IN 46227*

After attending this presentation, attendees will: (1) be introduced to fire scene investigation involving burnt human remains and their recovery; (2) recognize the micro- and macroscopical changes undergone by the body, skeletal, and dental hard tissues when subjected to fire; (3) understand the different techniques, approaches, and challenges for the identification of burnt human remains, including the practical issues; (4) learn what additional information about the incineration event can be gained through burnt bone analysis; and, (5) gain insights through the discussion of forensic casework.

This presentation will impact the forensic science community through the presentation of multidisciplinary and innovative approaches to tackle complex cases of burnt human remains with a more holistic approach to not only facilitate the identification of remains, but to also glean insight into the reconstruction of the incineration conditions.

Mass disasters, aircraft accidents, or motor vehicle collisions can involve fire; sometimes, a fire may have been set to destroy forensic evidence, including to prevent the identification of the deceased. When the fire affects a large area, it often cannot be extinguished for many hours or even days. As a consequence, some bodies are subjected to prolonged high temperatures and, in many cases, be reduced to extremely fragile skeletal elements. Thus, the identification of human remains subjected to incineration depends on the degree of destruction of the remains, which is affected by the intensity and duration of the fire. In fact, the loss of soft tissues destroys visual and fingerprint clues, leaving odontology, anthropology, and DNA as the only possible identifiers.

Subsequent to the destruction of skin and soft tissues, the skeletal remains exposed to fire or high temperatures undergo changes both on a macro- as well as a microscopical level. Macroscopically, high-temperature exposure modifies the bone structure in size, color, and shape. At the microscopic level, there are different changes in chemical and crystalline structures. All of these changes complicate the estimation of sex, age, and stature, challenging the accurate identification of the remains. The same changes are found in teeth. Although genetic identification can be an option in some circumstances, DNA extraction, yield, and quality is also affected by the intensity and duration of the fire.

Therefore, due to the fragility of skeletal and dental remains, the maximization of collection and stabilization are required at the very early stages of scene recovery; attention to detail and care throughout the analyses to maximize the extractable information is critical.

Based on these issues and challenges, a multidisciplinary team effort of forensic pathologists, anthropologists, odontologists, and analytical scientists is essential to facilitate the correct identification of the victims and to reconstruct the incineration conditions.

This workshop will illustrate this multidisciplinary effort, explaining the recovery of burnt human remains from the fire scene and the analysis of these remains at different levels — macroscopic, microscopic/biochemical, and genetic — to facilitate the identification of the victims, applying anthropological, odontological, and genetic techniques to finally illustrate the discussed approach and challenges through practical case studies.

Fire Scene, Burnt Remains, Forensic Identification

W12 Eric Zimmerman's Open Source Forensic Tools Library

Alan E. Brill, MBA, Kroll Cyber Security, 300 Harmon Meadow Boulevard, Ste 305, Secaucus, NJ 07094; Marla E. Carroll, BS, Forensic Video & Audio Associates, Inc, 6919 W Broward Boulevard, Ste 222, Plantation, FL 33317; and Eric Zimmerman, BS*, Kroll Associates, Inc, 600 Third Avenue, New York, NY 10016*

After participating in this workshop, attendees will better understand the challenges facing digital forensic software developers to both design and maintain open source tools and will understand how to prepare and use an open source digital forensic toolkit to conduct examinations. Attendees will better understand the relative advantages of commercial forensic packages and open source tools and where they can be used in concert to impact the work of digital forensic examiners. Those attending will learn the specific capabilities and methods of use of one of the most well-known open source libraries of digital forensic software. Issues vital to those who would develop and maintain forensic software, such are architecting through plug-ins to evolve functionality as opposed to monolithic executables, will be discussed as well as how that architecture can allow forensic examiners to expand the tools' capabilities by developing plug-ins to meet their particular casework needs and challenges. Finally, this session will help forensic examiners better understand how growing complexity and evidence volumes are making the ability to perform triage and focus on those elements most likely to be relevant to the investigation. This session will help the forensic community understand the balance between thoroughness and timeliness that is the hallmark of real-world cases that our examiner community faces every day.

This presentation will impact the forensic science community by demonstrating that freely available, open source forensic tools and forensic libraries can help both public and private sector organizations.

Software initially developed to support investigations into online sexual exploitation of children (which in one year resulted in the rescue of at least 45 children, the execution of 300 search warrants, and 222 arrests of suspects) was recognized as having value to the forensic community as a whole and was evolved into an open source library. Challenges faced in child trafficking and child pornography investigations — such as the need to quickly and efficiently parse hundreds of thousands of files when time and resources are limited — have become challenges for all forensic examiners as typical storage drives have come to contain hundreds of thousands of system, application, and user files. Attendees will also learn how open source forensic software can be created and modified as new operating system versions and forensic challenges arise. These tools are now used by thousands of forensic examiners in more than 50 countries; this workshop will help make the knowledge of how to employ these important tools available to forensic investigators worldwide. Because of the use of both open source and plug-in architecture, forensic examiners can develop and publish their own plug-ins to the benefit of the forensic community as a whole.

Tools, Computer, Open Source

W13 Moving From the Combined Probability of Inclusion (CPI) to Probabilistic Genotyping for DNA Mixture Interpretation

Michael D. Coble, PhD, NIST, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8314; and Daniele S. Podini, PhD*, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the current limitations of interpreting DNA mixtures using "binary" approaches in which alleles are either "included" or "excluded" from analysis. Attendees will develop an understanding and overview of probabilistic approaches that consider missing data (allele drop-out) or spurious alleles (allele drop-in) to interpret DNA profiles.

This presentation will impact the forensic science community by providing an overview of the limitations of current statistical approaches and promises for the future of DNA mixture interpretation for forensic DNA analysts, DNA technical leaders, laboratory directors, prosecutors, defense attorneys, and judges.

This workshop is targeted to attendees that have not committed to a probabilistic genotyping software but would like to have an introduction to improve their knowledge base.

Several high-profile closures of forensic DNA laboratories in the United States over the past few years have now focused the forensic DNA community on the challenges associated with the interpretation of mixtures. Many of these challenges involve the use of the CPI or the Combined Probability of Exclusion (CPE) on complex mixtures where allele drop-out is reasonable. In 2010, the Scientific Working Group on DNA Analysis Methods (SWGDAM) published a set of guidelines for autosomal Short Tandem Repeat (STR) interpretation, updated in January of 2017. The SWGDAM guidelines, along with the recommendations of the International Society for Forensic Genetics (ISFG) in 2006, have recommended the use of a stochastic threshold to consider the possible loss of alleles in a DNA profile (i.e., allele drop-out).

With the recent improvements in both STR multiplex chemistry and Capillary Electrophoresis (CE) instrumentation, the interpretation of highly complex mixtures such as "touch" items with (1) two or more contributors, and/or (2) low-level contributors with possible dropout has become a greater challenge for the analyst to interpret. Methods that treat alleles probabilistically instead of with a threshold-based approach have gained acceptance around the world over the past few years as a way forward for DNA mixture interpretation. The statistical output of a probabilistic genotyping software is the Likelihood Ratio (LR), which evaluates the evidence under two mutually exclusive hypotheses.

This workshop is targeted for laboratories considering a move to a probabilistic genotyping system for mixture interpretation or for individuals in the legal community wanting to learn more about this approach compared to the current methods of interpretation. This workshop will begin with a general review of probability, provide an introduction of the LR, and examine the limits of CPI, the modified Random Match Probability (RMP), and the binary LR. This workshop will work specific examples by hand, so attendees are encouraged to bring a calculator or have a calculator app on their smartphone. Finally, attendees will examine two approaches to probabilistic interpretation: the discrete (semi-continuous) and the fully continuous methods of interpretation.

DNA Mixture Interpretation, Likelihood Ratio, Probabilistic Genotyping

W14 Pharmacogenomics — Uses in Forensic and Clinical Toxicology

Laura M. Labay, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Gwendolyn McMillin, PhD*, ARUP, 500 Chipeta Way, Salt Lake City, UT 84108; Wendy R. Adams, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Jorge McCormack, MD*, Pediatric Cardiology Associates, Mednax Medical Group, 625 6th Avenue, S, Ste 120, St. Petersburg, FL 33701; Alan H. Wu, PhD*, San Francisco General Hospital, 1001 Potrero Avenue, Rm 2M27, San Francisco, CA 94110; Jeffrey M. Jentzen, MD*, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109; and William H. Anderson, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to develop effective approaches for the development and validation of genetic assays for drug monitoring applications, identify the benefits associated with pharmacogenetic testing and understand their relevance to the practice of medicine, and utilize toxicology and pharmacogenetic test results in conjunction with other case histories for decisions regarding cause- and manner-of-death determinations.

This presentation will impact the forensic science community by illustrating the benefits and utility of pharmacogenetic testing. Case studies will be provided to assist attendees with the interpretation of toxicology and pharmacogenetic test results and explain how these findings can impact death investigation outcomes.

The purpose of this presentation is to familiarize participants with the study of pharmacogenomics and to cultivate an understanding about how an individual's genotype affects an individual's health status and influences their response to drugs. Without the benefit of an analytical test to help provide guidance, it is challenging at best, and perhaps not even possible, to predict who will benefit from a medication, who will not respond at all, and who will experience symptoms associated with an adverse drug reaction. To provide a working knowledge of pharmacogenomics, speakers will detail the development, validation, and utility of predictive genetic tests, address how genetic makeup influences drug metabolism, disease states and their progression, and describe how test results can have implications for cause- and manner-of-death determinations.

Pharmacogenetics is the specialized area of pharmacology concerned with the effect of genetic influences on reactions to medications and other drugs. In essence, genetic variability means that not all people within a population will react to the same drug in the exact same manner. Incorporation of genetic test outcomes into the prescribing process is one important aspect of personalized medicine and can improve efficacy while minimizing adverse drug reactions and therapeutic failures. Alternate uses involve the identification of genetic abnormalities associated with a life-threatening or a lethal outcome. Taking into account the possibilities for why this type of testing must be performed, laboratories need to identify those genetic factors (e.g., enzyme polymorphisms) that are most relevant to creating a personalized treatment approach to the practice of medicine, then develop and validate those testing procedures. This workshop will enable attendees to understand how metabolic and genetic influences affect the overall health of an individual, specifically in regard to drug metabolism, drug-drug interactions, and the disease process. In addition to using genetic testing results prior to prescribing a drug, test results can also be applied to interpretation of toxicology results in conjunction with provided case history. This becomes relevant to death investigations in which one main goal is to determine an individual's cause and manner of death. Was a drug purposely consumed in an overdose amount or was the individual as a direct consequence of their genotype unable to properly metabolize the drug? Can genetic testing be used in the event of a negative autopsy to identify a familial disease that contributed to death? Overall, this workshop will provide a thorough overview of pharmacogenomics from start to finish and provide an introduction to pharmacogenomics, cover development and validation of laboratory testing, and address where and how this genetic approach can be applied to both patient treatment and the death investigation process. Finally, this workshop will benefit attendees by broadening their approach when interpreting toxicology results.

Pharmacogenomics, Pharmacogenetics, Toxicology

W15 Postmortem Monocular Indirect Ophthalmoscopy (PMIO)

Patrick E. Lantz, MD, WFU School of Medicine, Dept of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Candace H. Schoppe, MD*, Southwestern Institute of Forensic Sciences, 2355 N Stemmons Freeway, Dallas, TX 75207*

After attending this presentation, attendees will be able to: (1) differentiate between direct and indirect ophthalmoscopy, noting advantages and limitations of each technique for the postmortem detection of retinal hemorrhages; (2) discuss the fundal location of retinal hemorrhages relative to their projected aerial image during monocular indirect ophthalmoscopy; and, (3) accurately draw retinal abnormalities observed during monocular indirect ophthalmoscopy on a fundal diagram and capture the projected aerial image with a smartphone.

This presentation will impact the forensic science community by providing an overview of PMIO, promoting skill acquisition, evaluating practical training, and facilitating imaging techniques with fundal diagrams and a smartphone.

Postmortem examination of the retina has relied on ocular enucleation. In most medical examiner/coroner jurisdictions ocular evisceration is not a standard autopsy procedure unless child abuse is suspected, thus creating observational bias when citing the prevalence of postmortem fundal findings such as retinal hemorrhages (subinternal limiting membrane, flame-shaped or splinter, and dot/blot), perimacular retinal folds, retinoschisis, and postmortem artefactual retinal folds.

PMIO permits examination of the decedent's posterior fundus and portions of the peripheral retina. The required equipment necessary for PMIO is relatively inexpensive and, when compared to direct ophthalmoscopy, the technique is less affected by corneal clouding, lens opacity, or vitreous hemorrhage. PMIO uses a focal light source and an aspheric, convex condensing lens. An excellent source of paraxial illumination is a smartphone or a surgical or procedural headlamp using a halogen or xenon light source. The headlamp light source creates a collimated beam of light and permits the examiner to stabilize the condensing lens with both hands. Current aspheric lenses range from +14 to +40 diopters and come in different diameters permitting a field of view of 35°–55°. Postmortem corneal opacity may cause the fundus to appear hazy; however, by gently removing the epithelial layer of the cornea, the emergent image is usually of adequate quality to readily detect lesions such as fundal hemorrhages and retinal folds.

Learning how to perform and become proficient at PMIO can be perplexing and intimidating. Most pathology residents and forensic pathology fellows have limited exposure to indirect ophthalmoscopy. Because the projected aerial image is inverted and laterally reversed, precise descriptions or recordings of fundal abnormalities can be challenging. Unlike binocular indirect ophthalmoscopy with a teaching mirror attachment, an instructor and the fellow or resident cannot view the projected aerial image simultaneously during PMIO. To address these learning obstacles, it is necessary to develop tools and models to facilitate skill acquisition. An hour or two with an inexpensive ocular model can shift the learning curve of the resident, fellow, or forensic pathologist substantially to the right in how to correctly position the light source and hold the indirect lens.

This workshop consists of an initial discussion and didactic presentation reviewing the technique of PMIO, highlighting the optics, equipment, and examples of abnormal fundal findings found at autopsy by PMIO, and the use of a smartphone to capture the projected aerial image. Next, attendees will have a realistic learning experience by practical hands-on training with a procedural headlamp, an aspheric indirect lens, and simple ocular models containing a variety of retinal abnormalities observed at autopsy. Attendees will receive assistance in positioning the procedural headlamp, holding the indirect lens, viewing the projected aerial image, and accurately recording the retinal abnormalities on fundal diagrams and their smartphones. Attendees with smartphones can practice still image acquisition and video recording of fundal images produced by PMIO and will learn how to hold and stabilize the smartphone while imaging the fundal findings in the ocular models.

Following practice visualizing and diagramming numerous fundal images, attendees will have the option of being evaluated with a series of unknowns. Self-assessment of technical skill training and review of the unknown retinal findings concludes the workshop. Attendees will be provided fundal diagrams and articles on PMIO.

Indirect Ophthalmoscopy, Retinal Hemorrhage, Smartphone

W16 Forensic Image Processing

Marcus Borengasser, PhD, Department of Defense, 3205 Lago Vista Drive, Melbourne, FL 32940; Kathleen L. Rettich, MS, 1371 Indian Oaks Drive, Melbourne, FL 32901; Richard Vorder Bruegge, PhD, FBI, OTD, Bldg 27958A, Pod E, Quantico, VA 22135; and Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS*

The goal of this presentation is to provide a working knowledge of forensic image processing to enable an analyst to apply the optimum image processing algorithms to surveillance video and digital photography.

This presentation will impact the forensic science community by providing basic forensic image processing skills for the analyst. Surveillance video is nearly ubiquitous and a successful analyst is one who is familiar with forensic image processing and how to use it.

Contrast: A histogram can provide information about the amount of contrast in an image. Since image contrast is the difference in brightness between pixel values in a scene, the shape of the histogram is directly related to image contrast. For example, an image with a high level of contrast will have a broad-shaped histogram, but an image with low contrast will have a narrow histogram.

Pixel values in an image can be redistributed to a different range in an output image (i.e., histogram modification). This process has the effect of "stretching" or "compressing" the intensity range in the output image. If the pixel values are stretched to the full available range, then all pixel intensity values are utilized. This process can optimize the contrast and brightness of the output image.

Spatial Filters: Spatial filtering, or convolution, is an aspect of image processing. The process of filtering involves a moving window of array coefficients (i.e., weights). The size of an array, or kernel, is usually an odd number of pixels such as 3 x 3, 5 x 5, or 7 x 7. As the kernel is incrementally positioned through an image, the value of the pixel at the center of the kernel is multiplied by the value of the corresponding pixel in the image. For a given kernel position, all the kernel values are multiplied similarly and summed to produce a new output image. The next kernel step associates the next image pixel with the center of the kernel, and this process continues for the entire image.

The value of an output pixel from spatial filter is a function of the adjacent pixels in the original image. Spatial filters can be used to isolate the high and low frequency components of an image. High frequency components can be removed by either a low-pass filter or a rank filter.

Low-Pass Filters: Low-pass spatial filters are typically used to minimize Gaussian, or random noise. Ideally, the frequency of the noise is different from the frequency of the information in the image. The output pixel from a low-pass filter is a weighted sum of the adjacent pixels in the input image.

Edge Operations: Edge operations are types of spatial filtering in which each pixel is replaced with a weighted sum of the adjacent pixels. The type of edge operation is controlled by the weights that are applied to each of the adjacent pixels. For example, vertical or horizontal edge detection can be performed by choosing specific weights. There are two general objectives for edge operations: (1) increase image contrast; and, (2) detect edges within an image.

Smoothing: Image noise suppression via smoothing is a fundamental procedure in image enhancement. The trade-off for noise suppression is image blurring, which can be problematic for edges in a digital image. Noise suppression is usually accomplished with an averaging filter or a Gaussian filter.

Image Processing, Surveillance Video, Digital Photography

W17 An Introduction to Lean Fundamentals and Six Sigma Operational Improvement

Timothy D. Kupferschmid, MFS, MBA, NYC Office of Chief Medical Examiner, 421 E 26th Street, New York, NY 10016; Joanie Brocato, PhD*, 376 E Airport, Baton Rouge, LA 70806; and Linda Razzano, MS*, OCME, Dept of Forensic Biology, 421 E 26th Street, New York, NY 10016*

After attending this presentation, attendees will better understand the common tools and techniques used in a Lean Six Sigma (LSS) project to increase productivity and efficiency of the laboratory without increasing employees or purchasing new equipment or software.

This presentation will impact the forensic science community by introducing participants to a logical, step-wise procedure to greatly improve the understanding (through actual data collection) of the current laboratory system and to provide a structured method to eliminate waste and make improvements for a more efficient and effective laboratory process.

Attendance at this full-day workshop will introduce the participants to the LSS philosophy of continuous improvement and its methodology to achieve rapid and lasting process improvements while producing a positive culture change. Attendees will receive lectures and take part in practical exercises that will demonstrate the principles of LSS and clarify how the adoption of this philosophy can have a marked improvement in laboratory throughput. Finally, attendees will be presented with the LSS projects of modern crime laboratories. Participants will learn by using the Define, Measure, Analyze, Improve, Control (DMAIC) process, a system the labs were able to develop that increased productivity and morale without compromising quality.

LSS methodologies are used globally to improve testing laboratory processes, reduce turnaround time, increase productivity, and enhance morale. This approach also upholds the highest regulatory compliance while actually increasing quality.

The term Lean has its origins in "lean production" or "lean manufacturing" and was widely developed, implemented, and disseminated by Toyota®, although Toyota® learned its roots from Henry Ford. Lean is more than a set of tools to improve efficiency. It is a philosophy that understands that value must be interpreted from the customer's viewpoint. In order to add value, waste — those activities that don't add value — must be eliminated or minimized. This is accomplished by creating continuous flow of value-adding activities to increasing throughput.

The DMAIC process is the Six Sigma methodology used to discover the current state of the laboratory, the location of its primary bottlenecks, and the waste inherent in the production system. It is used to create a process in which samples flow through the laboratory in an efficient and proficient manner. Six Sigma is a rigorous performance improvement approach that uses a customer-focused and data-driven understanding of process variation and process capability.

Both Lean and Six Sigma supports quality management systems, including accreditation programs by the American National Standards Institute-American Society of Quality (ANSI-ASQ) National Accreditation Board (ANAB), the American Association for Laboratory Accreditation (A2LA), the American Board of Forensic Toxicology (ABFB), the National Association of Medical Examiners (NAME), and others.

Concurrently, the organizational culture will change to one of identifying problems and finding solutions to those problems. The quality of the work product will increase by designing quality checks throughout the process and by having all scientists perform their work in a similar standard way. Finally, employee morale will increase by creating a positive teamwork atmosphere and having each employee perform at their designed level.

Lean, Six Sigma, Process Improvement

W18 Domestic Violence and Child Abuse Deaths

David J. Zeliff, MFS, 102 Glacier Way, Stafford, VA 22554; Rick Malone, MD*, PSC 475, Box 1842, FPO, AP 96350, JAPAN; Donald Hayden, MFS*, 292 Harbour Lane, Richmond Hill, GA 31324; Edward Mazuchowski II, MD, PhD*, 115 Purple Heart Drive, Dover AFB, DE 19902; Sarah Mannix*, AFOSI, 8049 Galla Knoll Circle, Springfield, VA 22153; Michelle Miller, PsyD*, CID, 6616 Comet Circle, Apt 400, Springfield, VA 22150; Jessica Ann Veltri, MS*, US Army CID, 22nd Military Police Battalion CID, Bldg 3148, 2nd Division Drive, Joint Base Lewis-McChord, WA 98433; and Brian L. Janysek, MFS*, 2521 Hunter Mill Road, Oakton, VA 22124*

After attending this presentation, attendees will understand the biomechanics of accelerative/blunt force injury in infants and children; the dynamics of Munchausen Syndrome by Proxy; multiple descriptions of child interview techniques; psychological analysis, which can be conducted in child death investigations; and the Fatality Review Board (FRB) process within the United States Department of Defense. This session will also include homicide presentations by special agents and crime scene investigators who process domestic violence and child abuse death crime scenes.

This presentation will impact the forensic science community by providing insight into the many disciplines utilized in domestic violence deaths. The presentations will leave a lasting impact on attendees through the intricate details of each topic, discussing the criminal, physiological, and psychological aspects of domestic violence.

A group of psychologists, a forensic pathologist, and forensic science special agents, all bringing decades of forensic science and federal law enforcement experience, will present technical material pertaining to Munchausen Syndrome by Proxy, child interviews, accelerative/blunt force trauma, and psychological analysis used in solving domestic violence investigations. This group will present an FRB process that brings together subject matter experts and leaders to reduce the number of deaths in a community using a multi-modal approach. Special agents will provide three separate case presentations of domestic violence deaths they investigated, sharing their insight of the forensic science process in domestic violence homicides.

Features of Munchausen Syndrome by Proxy (now referred to as Factitious Disorder Imposed on Another in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) will be described. Typical case findings will be discussed, along with offender psychological characteristics and implications for investigation and interview strategies. Illustrative examples will also be used from past cases.

A case presentation from a 2013 child death involving a 14-month-old male murdered while in the care of his grandmother will be reviewed. The boy, born from an incestuous relationship between the subject's daughter and husband, became a victim of the subject's anger. The initial autopsy report listed the cause and manner of death as undetermined and the case grew cold; however, 18 months after the child's death, the case was renewed by investigators, resulting in the manner of death changing to homicide and prison time for subject.

A history of child interviews and research conducted in the past 30 years will also be discussed. This segment will explore the type and value of open-ended questions and the amount of information gained when compared to traditional direct questions, and elements that are necessary in all structured child interviews will be discussed.

The Army FRB will then be presented. The FRB conducts a review of all domestic violence and child abuse deaths in order to establish trends or patterns that may help in formulating training or preventative methods for the future. An overview of recent trends in regard to child abuse deaths will also be provided, as will recommendations, then the importance of utilizing the results of FRBs in order to establish processes and training that help in the reduction of these types of deaths will be examined.

The biomechanics of accelerative and blunt force injuries in infants and children will be discussed, with a focus on head and neck injury. Landmark articles and "controversies" over the past several decades will be discussed. Additionally, the classification of a death as Sudden Unexplained Infant Death and the necessary documentation will be reviewed.

Next, the response by special agents to a suspected double homicide and suicide will be presented. The subject was a spouse of a service member and the mother of the two victims, ages 3 and 18 months. In the weeks leading up to the deaths, the subject was observed exhibiting increasingly erratic behavior, incoherent conversations, and religious paranoia. Investigators utilized scene reconstruction to replace displaced items as well as to conduct a bloodstain pattern analysis and shooting incident reconstruction.

The final case review details a 28-day-old infant death. The topics discussed will include a review of the mother's pre-incident behaviors, all circumstantial evidence pertaining to the case, analysis of the 911 call, video reenactment, and post-incident behaviors.

Child, Violence, Death

W19 The Evolution of Fire Investigation From the Perspective of Science: Why Science Matters in the Search for Justice

Paul Messner, JD, 980 Dry Ridge Mt. Zion Road, Dry Ridge, KY 41035-7672; John J. Lentini, BA*, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036; George A. Codding, JD*, International Association of Arson Investigators, 6086 Simmons Drive, Boulder, CO 80303; Terry-Dawn Hewitt, LLM*, McKenna Hewitt, 820 S Monaco Parkway, #185, Denver, CO 80224-3703; and Daniel Madrzykowski, MS*, UL Firefighter Safety Research Institute, 6200 Old Dobbin Lane, Ste 150, Columbia, MD 21045-5887*

After attending this presentation, attendees will have an understanding of how: (1) past anecdotally based methods resulted in potentially erroneous convictions; (2) scientific research discredited those methods; (3) applicable standards have evolved as a result; and, (4) science-based research in many disciplines continues to improve our understanding of fire science and its proper application in fire investigation.

This presentation will impact the forensic science community by explaining the importance of empirical scientific research as well as how and why the results of such research must be applied when investigating fire scenes, analyzing fire debris and other evidence, and crafting valid conclusions in any investigative discipline.

Numerous organizations, academics, and fire investigators have contributed to an ever-growing body of empirical research in fire science, some of which contradicted many previously accepted anecdotally derived fire behavior beliefs; however, this scientific information, even when available for use in fire investigations, has not always been applied nor always accepted in contemporary court proceedings. This workshop will look at the methods, processes, and reasoning used in past fire investigations and compare them to countervailing science-based analyses elucidated, primarily, during post-conviction appeals. Faulty fire investigations are not limited to criminal matters; they are equally likely to affect insurance-related civil litigation; however, criminal court records and information are more accessible and, since the fire investigation techniques are the same, this workshop uses mostly (though, not exclusively) criminal case examples.

To illustrate the effect that empirical, scientific research has had on fire investigations, the fatal arson conviction of Adam Gray will be examined.[1] Gray was arrested in March 1993 following a fire in the back of a house that killed two people. Investigation indicated the fire had been intentionally set and there was a confession from Gray. Two fire investigators found alligator charring and deep burn patterns at the scene and concluded that was evidence of a hot fire set with an accelerant. A milk jug found in the alley behind the home was believed to contain the accelerant. A gas station clerk said Gray bought gas shortly before the fire. In his confession, Gray admitted purchasing gasoline and dousing the enclosed second floor back porch and stairs. Gray was convicted of arson and murder; he was 14 years old. On appeal, Gray contended that his conviction was based on a coerced confession, faulty laboratory analysis, and flawed fire behavior conclusions. Despite the proffer of research-based evidence, a trial-level judge denied Gray's motion for a new trial. The charges against Gray were only dropped in May 2017 after prosecution and defense jointly sought dismissal from an appellate court.[2]

These contrasts will be further illustrated by examining other fatal arson convictions subsequently affected by science-driven changes, including Angela Garcia, Katherine Bunch, Earnest Ray Willis, and Han Tak Lee.[3-6]

Presenters will also examine the following: how science-based research significantly altered fire science concepts and fire investigation; how the research is driving standards development by the National Fire Protection Association (NFPA), the American Society for Testing and Materials (ASTM), and others; the role of certifying organizations, such as the International Association of Arson Investigators (IAAI) and others, in promoting acceptance of science-based concepts; recent and on-going research using computer simulation, electron microscopy, Gas Chromatography/Mass Spectrometry (GC/MS), and real-world live-fire experimentation by Underwriters Laboratories, the Bureau of Alcohol, Tobacco, Firearms and Explosives, and other entities; human bias issues affecting cause determinations and their use in court proceedings; and contemporary issues of reliability, validity, and accuracy of fire investigations and their acceptance in court proceedings.

Since trial court judges are evidentiary gate keepers, determining, as a matter of law, who is qualified to be an expert witness and whether an expert's opinion is admissible, throughout the workshop speakers will explore questions pertaining to admissibility: Should fire investigators be subjected to *Daubert* challenges? What qualifies a fire investigator to be considered an expert witness? Are fire investigators "forensic science practitioners" or "forensic scientists"? Does it matter? What constitutes an admissible origin and cause determination?

Fire/Arson Investigation, Wrongful Convictions, Fire Science Research

W20 Fentalogs: The Chemistry, Pharmacology, and Toxicology of Illicit Fentanyl and Emerging Opioids

Amanda L.A. Mohr, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; Lionel Raymon, PhD*, 25041 SW 207th Avenue, Homestead, FL 33031; Robert A. Middleberg, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Audrey M. Williams, PhD*, 7000 E Avenue, L-091, Livermore, CA 94550; Erin Artigiani, MA*, University of Maryland, Center for Substance Abuse Research, College Park, MD 20740; Timothy Wiegand, MD*, University of Rochester Medical Center, 601 Elmwood Avenue, AC-3, Rochester, NY 14642; Paul Wax, MD*, University of Texas Southwestern, 5323 Harry Hines Boulevard, Dallas, TX 75390; Erin M. Worrell, BSc*, Cuyahoga County Medical Examiner's Office, 11001 Cedar Avenue, Cleveland, OH 44106; Nicole A. Yarid*, King County Medical Examiner's Office, 325 Ninth Avenue, Seattle, WA 98104; and Alex J. Krotulski, MS*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the origination of fentanyl and fentanyl analogs and describe their pharmacology as well as identify and implement methods for the safe handling of these compounds. In addition, attendees will be able to describe methods used to profile and disseminate information on emerging opioids, assess the findings of fentanyl and fentanyl analogs in casework, and implement appropriate analytical techniques used in their identification

This presentation will impact the forensic science community by providing current information on the opioid epidemic with a specific focus on fentanyl and fentanyl analogs and their chemistry, pharmacology, and toxicology seen in forensic casework.

The opioid epidemic, which has recently proliferated to include fentanyl and its analogs, is a serious public health concern as many users are unknowingly ingesting these drugs under the misconception they are using heroin. The rate with which these compounds are being illicitly and clandestinely synthesized creates a major challenge for seized drug, forensic, and clinical toxicology laboratories in identifying the compounds and developing methods for their analysis. Fentanyl and fentanyl analogs or "fentalogs," many of which are several times more potent than traditional opioids, have been implicated in several case reports and adverse events associated with overdoses. Limited information related to their pharmacology, often embedded in the pharmaceutical patents from which they are derived, further complicates interpretation related to these cases. In just the past year, case reports of fentanyl analogs, including furanyl fentanyl, carfentanil, butyryl fentanyl, para-isobutyryl fentanyl, cyclopropyl fentanyl, acryl fentanyl, and the reemergence of 3-methylfentanyl, have been implicated in postmortem and Driving Under the Influence (DUI) cases, demonstrating the high rate of turnover and overall prevalence.

This workshop will provide background information related to origin of fentalogs, history derived from the patents where they are originally described, the pharmacology related to receptor binding, and potency. The actual and perceived risk of accidental overdoses of first responders, police officers, and laboratory personnel encountering these substances will be presented, and current recommendations regarding the safe handling of these substances will be discussed. Additional topics included in this workshop will focus on early detection and dissemination of the identity of novel opioids, methodologies used in profiling seized drug materials, and analytical approaches for detecting and confirming the presence of fentanyl-related analogs. This workshop will conclude with case reports, including toxicological data for incidents involving fentanyl and its analogs.

Fentanyl Analogs, Novel Opioids, Opioid Epidemic

W21 Macromorphoscopic (MMS) Traits: Data Collection and Analysis

Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824; Kelly R. Kamnikar, MA*, Michigan State University, 355 Baker Hall, 655 Auditorium Road, East Lansing, MI 48824; and Amber M. Plemons, MA*, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824*

After attending this presentation, attendees will: (1) understand the history and theoretical concepts of ancestry estimation via cranial morphology, particularly in reference to MMS traits; (2) have gained experience scoring macromorphoscopic traits in human crania using recently developed software; (3) have learned the basic strategies of various statistical procedures to estimate ancestry with MMS trait scores; and, (4) have acquired working knowledge of the application of MMS trait data in casework.

This presentation will impact the forensic science community by providing up-to-date methodologies and theoretical considerations in ancestry estimation using MMS trait data. Additionally, attendees will learn how to record, analyze, and report MMS trait data using the appropriate statistical framework. Attendees will be introduced to a worldwide reference dataset that permits ancestry estimations beyond the historical three-group classifications used in ancestry estimation from cranial morphology.

This presentation will focus on MMS trait data collection and analysis, particularly as these slight variations in cranial form relate to the estimation of ancestry from human skeletal remains. The once-subjective nature of MMS data has shifted to more objective methods through the introduction of standard data collection protocols; however, observer experience, expertise, and training still impact data collection. To that end, attendees will gain a deeper understanding of MMS trait analysis by understanding where and how biases can be introduced.

Following a general introduction, a series of lectures provided by scholars in MMS trait analysis will outline MMS trait manifestations, trait distributions, and illuminate aspects of ancestry estimations from different viewpoints and through multiple forms of analysis. Previously, approaches to ancestry estimation using MMS traits did not detail the various manifestations, or character states, of each trait. Instead, these approaches relied on extreme expressions and trait lists. In other words, analysts needed an expert-level surety of human variation. Attendees will be guided through the complete analytical process performed in forensic casework. Using a variety of examples and hands-on material, attendees will learn to assess MMS trait data using standardized data collection protocols. In concurrence with this training, attendees will become familiar with newly developed data collection software freely available to practitioners. Statistical procedures will be reviewed, both theoretically and practically, which have been deemed most appropriate for MMS trait data analysis. Attendees will then learn to effectively report ancestry classifications using a worldwide reference sample using observed trait scores and statistical analyses.

Lecturers will conclude the session by demonstrating the ways in which MMS data have been applied in current research. This will include geographic patterning of MMS traits, observer error, and potential secular change inherent in MMS data. Becoming familiar with and understanding these nuances allows practitioners to make more meaningful interpretations of ancestry classifications using MMS data.

Estimating ancestry from the skull need not be difficult. In much the same way students first learn metric analysis (e.g., “GOL is measured between these two landmarks and entered into a computer program to obtain an estimate”), macromorphoscopic trait analysis requires visual learning and a hands-on approach. The goal of this session is to increase the utilization of an empirical method to ancestry estimation via cranial morphological traits in the forensic sciences by training a subset of the community to correctly perform the method. In turn, this information can then be disseminated to colleagues and students.

Ancestry, Macromorphoscopic Traits, Human Variation

W22 Science Matters to Everyone: Victims, Offenders, and the Public

Anjali A. Ranadive, JD, SciLawForensics, Ltd, 1834 Overlook Ridge Road, Brookings, SD 57006; Joanna L. Collins, MFS*, LINUS Investigations & Consulting, 20079 Stone Oak Parkway, Ste 1105-215, San Antonio, TX 78258; Gerald M. King, JD*, 151 4th Street, SE, Rochester, MN 55904*

The goal of this presentation is to educate attendees regarding systemic issues in forensic science and the strides being taken to address them.

This presentation will impact the forensic science community by exploring how the criminal justice system can or should respond in the face of backlogs, lab scandal, error, and publicity involving forensic science.

For a number of years, the forensic science community has grown and advanced and the demand for forensic evidence in courtrooms has dramatically increased. As a result, the forensic community has faced challenges: (1) involving discoveries that the strength of the forensic evidence testified to at trial may not have been as strong or as certain as was thought; (2) working through backlogs in testing, such as sexual assault kits; or, (3) in some cases, regarding simply untruthful or deceptive analysts, which has led to laboratory shutdowns and more.

This workshop will look first at the impact of increased volume and demand for forensic services that has impacted communities; specifically, the impact of backlogs in sexual assault kits. This has led to the re-traumatization of victims and to offenders being on the street to offend again. Speakers will then address the responses that have been developed, recommendations for best practices in the handling of sexual assault kits, how to work in a multidisciplinary fashion using a trauma-informed approach to reduce backlogs and streamline the processing of sexual assault kits and notification of victims.

In addition to backlogs, forensic science faces challenges stemming from the fact that what is known in forensic science is evolving. New technology and new revelations about a forensic discipline or even an unethical forensic scientist can lead to questions concerning the integrity of convictions relying on this evidence. This workshop will focus on the changes that have taken place in this area surrounding arson cases. When assumptions used to determine whether a fire was an intentional fire were discovered to be erroneous, the integrity of convictions came to light. The justice system had to determine what to do regarding the integrity of convictions that had been secured and how to go about addressing issues as they arise. The lessons learned within arson review provide guidance for addressing conviction integrity in all areas. Speakers will discuss what a conviction integrity unit is within a prosecutor's office, what should be considered when creating these units, including partnerships among stakeholders, and will address the state response in Texas, including the creation of a Science Advisory Work (SAW) group.

When carried over into the tapestry of the trial, where the various portions of the cloth of justice are woven into a final piece, science, medicine, dentistry, and jurisprudence result in a single verdict. When a conviction is sewn together from flawed fabric, the victim, the defendant, the courts, the justice system, and society itself suffer. One of the most often-questioned areas of forensic evidence involves bitemark evidence. Such cases may have relied on flawed analysis and/or questioned testimony to establish guilt. As the discipline consensus changes regarding the reliability, reproducibility, and significance of the data, the question remains as to how the witness can and should respond to prior convictions and practice pre-emptive analysis to prevent potential future miscarriages. Less highly publicized, but no less challenging, are cases in which the medical "gold standard" of the autopsy is challenged. Forensic pathologists, like everyone else, are subject to flawed analyses and conclusions resulting from human shortcomings and/or advances in understanding. These might involve inaccurate/incomplete interpretations of findings (both inclusion and exclusion), improved analytic methodologies, additional testing, etc. Handling situations in which the data doesn't match the testimony must be addressed — both as a forensic pathologist during the death investigation and as an expert witness on the stand.

Finally, the news media and public perception come into play. High-profile cases with extensive media attention can also lead to analytical errors, flawed understandings, hasty conclusions, and more. Media exposure may have immediate real and lasting effects; for example, by contaminating a potential jury pool necessitating a change in venue, sequestration, and the like. More subtle, but perhaps more lasting, could be the contamination of the public perception of the case, such that results of the trial are questioned and an acquittal is viewed with skepticism with the result being that a jury's verdict (guilty or innocent) remains in question, damaging public confidence in the jury system, sprouting conspiracy theories, and so forth.

Sexual Assault, Conviction Integrity Unit, Errors

W23 Cardiovascular Pathology for Medical Examiners and Coroners: Basic and Advanced Techniques for the Investigation of Sudden Cardiac Death

Peter T. Lin, MD, 200 First Street, SW, Rochester, MN 55905; Joseph J. Maleszewski, MD*, Mayo Clinic, 200 First Street, SW, Rochester, MN 55905; Marie Christine Aubry, MD*, Mayo Clinic, 200 First Street, SW, Rochester, MN 55905; and Ross Reichard, MD, Mayo Clinic, Div-Anatomic Path, Hilton 11, 200 1st Street, SW, Rochester, MN 55905*

After attending this presentation, attendees will: (1) understand basic cardiac anatomy relevant to the investigation of sudden cardiac death; (2) be able to apply basic and select advanced cardiac dissection techniques useful for the investigation of sudden cardiac death; (3) identify situations in which postmortem genetic testing may be useful; (4) appreciate the challenges of interpretation of genetic testing results with respect to determining mechanism of death, underlying cause of death, and contributory cause of death; and, (5) recognize situations in which consultation with a cardiovascular pathologist is warranted.

This presentation will impact the forensic science community by providing up-to-date knowledge and practical techniques in cardiovascular pathology and molecular genetics that will assist medical examiners, coroners, death scene investigators, and others involved in the investigation of sudden death.

The spectrum of cardiovascular disease which may present in the forensic setting ranges from common entities such as coronary artery atherosclerosis and hypertension to less common entities such as infective endocarditis or viral myocarditis, and more esoteric entities such as various congenital heart diseases, the dilated, hypertrophic, and arrhythmogenic forms of cardiomyopathy, arrhythmia syndromes such as Long QT syndrome or catecholaminergic polymorphic ventricular tachycardia (CPVT), and aortopathy syndromes such as Marfan Syndrome or Loeys-Dietz Syndrome. It is especially important for medical examiners and coroners to be familiar with inheritable cardiovascular diseases, which may be treatable in surviving family members, thereby directly fulfilling the ultimate goal of quality death investigation — to help the living.

The diagnosis of many cardiovascular diseases at autopsy has become increasingly complicated. Critical morphologic information suggestive of a particular disease may be observed at the time of autopsy, but confirmation of the disease usually requires a comprehensive evaluation incorporating medical history, scene investigation, and multiple diagnostic modalities, which may include histologic examination, microbiology testing, enzymatic assays, and genetic testing. The increasing use of postmortem genetic testing in the evaluation of sudden unexplained death in the young is a particularly challenging area for medical examiners and coroners and is potentially subject to error due to misinterpretation of genetic variants whose significance is unknown. The failure to consider the presence of inheritable disease and retain appropriate specimens for genetic testing or subspecialist consultation remains a persistent risk for medical examiners and coroners who are not familiar with the spectrum of cardiovascular disease which may present in a forensic setting.

This workshop is intended to be a practical introduction to the investigation of sudden cardiac death. The presenters include practicing cardiovascular and forensic pathologists with extensive experience in autopsy pathology, death investigation, surgical cardiovascular pathology, and molecular genetics. The basic foundations of cardiovascular pathology, including normal cardiac anatomy and histology, normal anatomic variants, and standard cardiac dissection methods, will be reviewed. Advanced dissection techniques will also be taught, including long-axis cuts (four-chamber and left ventricular outflow cuts), base of heart dissection for demonstrating valvular heart disease, gross dissection and histologic examination of the cardiac conduction system, and histologic examination of valves, myocardium, and aorta. Both common and rare entities in the differential diagnosis for sudden cardiac death will be discussed, including atherosclerotic coronary artery disease, hypertensive heart disease, hypertrophic cardiomyopathy, dilated cardiomyopathy, arrhythmogenic cardiomyopathy, inherited arrhythmia syndromes, and inherited aortopathy syndromes.

The role of genetic testing in the diagnosis of inherited cardiomyopathy, arrhythmia, and aortopathy syndromes will also be discussed, including the challenges associated with the interpretation of genetic test results that are equivocal for pathogenicity, or when pathogenic variants are discovered in the setting of alternative and equally compelling causes of death. A framework for communication of results to families will also be provided. Guidelines for specimen retention and cardiovascular pathology subspecialist consultation will also be discussed. This session will incorporate didactic lectures, informal question-and-answer sessions with questions solicited from the audience, and hands-on tutorials utilizing 3D scanned and printed models.

Forensic Pathology, Cardiovascular Pathology, Sudden Cardiac Death

W24 Think Tank on the Leading Edge of Forensic Science: Drones, Autonomous Vehicles, Big Data/Big Problems, National Security Globalization Into Protrusionism Privacy, Dirty Bombs, and Microbial Forensics

Laura L. Liptai, PhD, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Van Ypenburg 6, The Hague, Zuid-Holland 2497 GB, NETHERLANDS; Erwin Van Eijk, MS*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS; Kimho Himberg, PhD*, Police University College, Vaajakatu 2, Tampere Vaajakatu 2, FINLAND; David O. After attending this presentation, attendees will understand how the rapid rate of change in society may impact several fields in forensic science.

This presentation will impact the forensic science community by demonstrating how the rate of change in society provides new challenges for forensic science. The development of designer drugs as well as the rapid development of methods to extract information from large amounts of data should be considered and perhaps prompt needed changes in laws. The issues with investigation of Chemical, Biological, Radiological, and Nuclear (CBRN) as well as driverless cars, drones, and the insights of cybercrimes and globalization with privacy issues will be discussed.

A wide variety of developments that will impact forensic science have been identified within the Think Tank Committee of the Forensic Sciences Foundation, Inc. The goal of this presentation is to describe how new developments may impact forensic scientists in their work. Practical examples will be presented on national security globalization into privacy issues, driverless cars, drones, microbial forensic, nuclear forensics, cybercrime, and big data. This presentation will impact the forensic science community by providing an overview of some of the new developments in forensic science and by opening a forum for the discussion of issues that arise regarding such developments.

Digital cameras were invented in 1975. As with all exponential technologies, the 10,000 pixels were a disappointment until digital became superior and went mainstream in a matter of years. This will now happen with artificial intelligence, health, autonomous cars, education, 3D printing, agriculture, jobs, and … yes, forensics.

The amount of data that is available from digital investigation, and from sensors, is rising each year and the question is whether a statistical analysis of this data can be presented in court. Biometric algorithms are improving and analyzing large amounts of video and images in combination with location data and other data available provide the possibility of making summaries of the data that can be presented in court. When applying these methods, users should also be aware of the limitations and error rates of the algorithms used. Additionally, the use of Bayesian conclusion scales is under discussion and national security globalization appears to yield privacy issues.

We see the developments of Unmanned Aerial Vehicles (UAVs) and drones and the forensic issues with finding digital traces as one of the topics. The driverless car is also performing in the real world. Will we skip level 3 autonomous vehicles (human intervention) and go directly to level 4?

Another important topic is the investigation within a CBRN crime scene and the interrogation of CBR agents presenting a variety of problems. Primary among those at the scene is an intense degree of political scrutiny and a high thermal burden. How do you accurately take high-value samples when you are in a Level A "spacesuit," how do you know where the samples are, and what should you prioritize in the 20 minutes of air you have at the scene? The European Commission Generic Integrated Forensic Toolbox (GIFT) is answering these questions and can share some of this data.

The Chemical Forensics International Technical Working Group (CFITWG) was created in 2017 to address science and capability gaps for the source attribution of weaponized chemicals by chemical means (e.g., impurity profiling and stable isotope ratios). Source attribution can tell how and where a weaponized chemical was made to help find perpetrators or facilitators of chemical attacks or detect the illicit proliferation of chemical precursors. This presentation will provide a brief overview of chemical forensics research and review how the CFITWG will strive to prevent and deter chemical attacks through collaborative efforts among members and partners.

The use of microbial communities in entomology is important. Current research focuses on the structure and function of antemortem and postmortem microbial communities using microbiomes as spatial and temporal evidence. In the past year, developments have advanced in understanding the relationships between decomposing remains, microbial communities, and the environment.

How do we manage multiple terabytes of data, containing millions of traces? How can a case investigator obtain meaningful information from all the data in the case, in a quick and simple manner, without compromising on forensic validation of the methods, the various data, and privacy protection? Additionally, the amount of data in the average case is needed by more than one team, dispersed through the town or country, and as such can no longer be worked on by a single investigator. Furthermore, knowledge dissemination concerning new methods discovered is difficult and ineffectual. At the Netherlands Forensic Institute, a big data digital analytics platform has been developed that is in use by the Dutch police force. This presentation will focus on the lessons learned about scaling the platform, the cases, and enhancing the platform with newer analytic methods. Finally, this workshop will close with research examples of deep learning and forensic multimedia investigation.

To keep pace, laboratories need to be innovative in their approach to monitoring the market for peer-reviewed literature and markets, building in-house libraries and databases, and investigating many other channels of intelligence in anticipation of possible new threats as well as helpful techniques.

Driverless Cars and Drones, National Security, Microbial Forensics

A1 Investigating the Accuracy of Additive Manufacturing Skeletal Samples for Evidence Reconstruction

Rachael M. Carew, MSc, Viale Muratori 185, Modena, MO 41124, ITALY; Ruth M. Morgan, PhD, University College London, UCL Centre for the Forensic Sciences, 35 Tavistock Square, London WC1H 9EZ, UNITED KINGDOM; and Carolyn Rando, PhD, University College London, Institute of Archaeology, 31-34 Gordon Square, London WC1H 0PY, UNITED KINGDOM*

After attending this presentation, attendees will be aware of the problems inherent within 3D modeling and additive manufacturing (3D printing) in forensic anthropology and will recognize that these issues are pertinent to forensic science reconstruction approaches and, in particular, the presentation of 3D prints as evidence in court.

This presentation will impact the forensic science community by alerting attendees to the uses and limitations of additive manufacturing from Computed Tomography (CT) scans in a forensic context. Recommendations and thought-provoking findings could initiate discussions and collaborations toward further exploration into the use of models for reconstruction purposes in anthropology and wider forensic disciplines.

This research investigates the metrology of 3D modeling and 3D printing osteological samples from CT scans. It is expected that such models will be sufficiently accurate for anthropological comparisons, but the extent of the effect of modeling parameters is currently unknown.

There are two documented cases in which 3D prints of human remains have been used in United Kingdom courts of law.[1,2] In one of these cases, lawyers cast doubt on the reliability of a 3D-printed cranium, as the process has not been validated in a forensic context.[2] This type of evidence can be utilized after a virtual postmortem (avoiding disruption of remains), from antemortem clinical CT data, or in cases in which the subject survives. Studies have begun to validate these techniques, such as the reliability of obtaining accurate anthropological measurements from CT reconstructions of certain skeletal elements and the accuracy of 3D printing in medicine/anatomy, but further research is needed.[3-6]

Three dry osteological samples (a cranium, clavicle, and first metatarsal) were CT scanned using a multi-detector Toshiba Acquillon™ ONE. 3D models were segmented and converted into Stereolithic (STL) files for printing. First, the parameters applied in the virtual model generation were investigated for quality. Second, two additive manufacturing methods, Selective Laser Sintering (SLS) and Fused Deposition Modeling (FDM), were tested on three printers, and a statistical comparison of anthropometric measurements taken from the original samples, the virtual models, and the 3D prints was undertaken.

The results of this study indicate that: (1) the threshold values (labels) used in virtual model segmentation affect the quality of the model, as does the amount of smoothing employed; (2) there was no statistically significant difference between the clavicle and first metatarsal 3D prints and the original dry bone (p values >0.05), except for one of the clavicle FDM prints; (3) the cranium 3D print was not statistically distinguishable from the virtual model (p values >0.05) following removal of inconsistent cranial measurements, but the cranium 3D print was statistically significantly different when compared to the source bone ($p < 0.05$); (4) the virtual models had mean Absolute Errors (AE) of 1.6mm±0.9mm for the cranium, 1.5mm±0.7mm for the clavicle, and 1.1mm±0.7mm for the first metatarsal; and, (5) the 3D prints produced using SLS technology had smaller respective AE, with 1.4mm±0.9mm for the cranium, 1.2mm±0.2mm for the clavicle, and 0.7mm±0.5mm for the first metatarsal.

This empirical research provides initial data to validate the process of additive manufacturing in forensic anthropology. The data demonstrated that accurate 3D prints can be produced from CT-scanned bones, but with limitations. Segmentation of the virtual model was found to be a crucial step for producing accurate models, and it is thought that applying additional smoothing could help. Further exploration of additive manufacturing and samples that exhibit trauma, pathology, and taphonomy will progress toward producing best practice guidelines and validation of the technique.

Additive Manufacturing, Metrology, Evidence Reconstruction

A2 Radiographic Image Analysis and the Estimation of Age at Death in Adult Males

Andrew C. Seidel, MA, Arizona State University, Human Evolution/Social Change, PO Box 872402, Tempe, AZ 85287-2402; Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007; and Joel K. Simcoe, Maricopa County Office of the Medical Examiner, 701 W Jefferson Street, Phoenix, AZ 85007*

After attending this presentation, attendees will understand how the analysis of digital radiographs of the pubic bone can be used to estimate age at death for male decedents.

This presentation will impact the forensic science community by providing data indicating that digital radiographic images of the male os pubis can be reliably used to place individuals within intervals of age at death comparable to those of more commonly employed methods based on morphological changes of the pubic bone.[1,2] The techniques developed in this research can be used to estimate age at death from pubic bones where details of the symphyseal face have been damaged or otherwise obscured and, with refinement, may eventually enable age-at-death estimation without excision and maceration of the pubic bone.

This research was conducted using the Hartnett-Fulginiti collection curated at the Forensic Science Center in Maricopa County, AZ. This collection is comprised of more than 600 specimens of pubic symphyses from decedents of known sex, age at death, and ancestry. A training sample, composed of 100 pubic bones from male decedents ranging in age from 18 to 91 years, was selected to provide roughly equal representation from each of the seven morphological phases of the Hartnett-Fulginiti method for the estimation of age at death.[2] Although preference was given to the left os pubis, the right was used when the left was damaged or otherwise unsuitable for analysis.

Digital radiographs of each specimen were taken from a fixed distance and with constant settings. The resulting images were subjected to analysis in which characteristics of the distribution of gray values (mean, standard deviation, minimum, maximum, median, mode, skew, and kurtosis) were recorded. In an attempt to control for individual variation in size and shape, image analysis was constrained to the triangular area defined by the upper and lower bounds of the symphyseal face and the most medial point on the margin of the obturator foramen. Recorded characteristics were evaluated for their correlation to age at death, and a subset of six variables (comprised of standard deviation, maximum value, skew, kurtosis, and the constructed metrics of range and signed difference between mean and median) was selected for a k-means clustering analysis. Although Hartigan's Rule suggested that 13 clusters was the optimal clustering solution for this data, this resulted in several clusters that were based around a small number of individuals, and a clustering solution of nine was adopted instead. Each of the nine clusters was defined by the location of its centroid and described by the mean, standard deviation, and range of the within-cluster age-at-death distribution.

To test whether radiographic image analysis could produce viable age-at-death estimates, the six variables listed above were recorded for a secondary sample of 57 randomly selected males ranging in age from 22 to 84 years. The six-dimensional Euclidean distance between each new individual and the centroids of the nine previously defined clusters was calculated, and individuals were assigned to the cluster whose centroid they were nearest to. The frequency with which the ages of the individuals in the secondary sample fell within intervals constructed around the mean age of each cluster was then recorded. Results indicate that overall, an individual's true age at death was within 17 years of the mean age of the cluster to which they were assigned in 75.4% of the trials. Although a 34-year age interval is large, it is nearly equivalent to those employed by widely used morphological techniques for the estimation of age at death.[1,2] Moreover, the majority of the individuals whose ages were not in the predicted interval were either very young or very old. For individuals whose age at death was between 25 and 75 years, true age at death was within 17 years of the assigned cluster's mean in 87.8% of cases and, for 81.5% of individuals between the ages of 40 and 60 years, true age at death was within ten years of the assigned cluster's mean.

Although preliminary, these results suggest that image analysis of radiographs of the male os pubis can be employed for the estimation of age at death. With further refinement, the utility of this technique for both younger and older individuals may be increased. Moreover, further exploration of the uses of radiographic image analysis may eventually obviate excision and maceration of the pubic bone for the development of a biological profile.

Age-At-Death Estimation, Pubic Bones, Radiographs

A3 Landmark and Measurement-Based Data Assistant (LAMbDA): A Pedagogical Tool for Cranial Landmark Data Collection

Kelly R. Kamnikar, MA, Michigan State University, 355 Baker Hall, 655 Auditorium Road, East Lansing, MI 48824; Amber M. Plemons, MA, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; and Alexis C. Goots, MA, 5757 Barton Road, North Olmsted, OH 44070*

After attending this presentation, attendees will be familiar with the Landmark and Measurement-based Data Assistant (LAMbDA) interactive website, which can be used as a pedagogical and/or reference tool for aiding in the collection of cranial landmark data. Additionally, attendees will understand the need for standardized cranial landmark definitions and a centralized data repository of definitions and diagrams for cranial landmark data collection in forensic anthropological analyses.

This presentation will impact the forensic science community by addressing inconsistencies within standardized definitions for all cranial landmarks. This information will be located in an online repository that includes standardized cranial landmark definitions, their locations, exceptions to certain definitions, depictions and photographs, and currently available reference material. A document repository is especially useful for learning and/or practicing a skill by allowing the user to easily access all related material in one location.

Cranial landmark data is one of the most informative components of data collection in forensic anthropological analyses. This data is used in more refined analyses to estimate sex and ancestry as components of the biological profile. When learning data collection procedures for landmark digitization, users refer to various sources for standardized definitions and diagrams. Definitions of some landmarks can be found in the literature, but there is not an available definition for every cranial landmark. Therefore, word-of-mouth definitions are transmitted from instructors to students, further emphasizing the need for a comprehensive and standardized list of cranial landmarks. Additionally, discrepancies between landmark definitions across separate sources can contribute to interobserver error. Further, unclear or imprecise definitions in reference material can lead to differences in interpretation of a given definition. This error can lead to flawed reference data (e.g., via multiple contributors to reference data in FORDISC®) or incorrect measurements through misidentification of landmarks, ultimately impacting classification.

Currently, cranial landmarks are defined across at least ten references, yet a single complete reference for all landmarks used in forensic anthropology does not exist. LAMbDA serves as a repository for all cranial landmark definitions, with accompanying diagrams and depictions. The LAMbDA website (www.locatelambda.org) features a 3D, interactive digital model of the human cranium labeled with cranial landmarks. Pop-up definitions of each landmark appear when the cursor is scrolled over the landmark. These definitions come from their original references when definitions are clear and consistent. Cranial landmarks previously undefined, with inconsistent definitions across references, or those that lack precision, are defined by the authors and approved by a panel of experts on this topic. The website includes 2D photographs demonstrating proper placement of cranial landmarks on bone exhibiting anatomical variants, such as lambdoidal and bregmatic ossicles. LAMbDA is designed to be compatible with 3Skull, as this program uses the most comprehensive list of 108 cranial landmarks; however, the website can be used to aid with data collection using other software programs, such as CRANID. Each written definition includes the landmark's associated measurements to aid in the interpretation of landmark placement. This presentation's goal is to provide LAMbDA as a pedagogical tool both in the classroom and in practice to assist students and practitioners in collecting standardized cranial landmark data for forensic anthropological analyses.

Forensic Anthropology, Digital Reference Tool, Standardization

A4 A Test of Quantitative Age-At-Death Estimation of the Pubic Symphysis Using the forAge Program

Audrey D. Schaefer, BA, 2211 Chapel Valley Lane, Timonium, MD 21093-2935; and Jessica Galea, BA, Texas State University, 225 Ramsay Street, #321, San Marcos, TX 78666*

The goal of this presentation is to test the method of age-at-death estimation from the pubic symphysis proposed by Slice, Algee-Hewitt, Stoyanova, and colleagues on the Texas State Donated Skeletal Collection.[1-3] After attending this presentation, attendees will understand some of the implications of this novel age-at-death estimation technique to better interpret the results from forAge analysis.

This presentation will impact the forensic science community by helping shed light on avenues for amending or expanding on this novel age-at-death estimation technique.

This preliminary test of the objective age-at-death estimation methodology, as proposed by the aforementioned authors, examined the accuracy and bias of age-at-death estimation provided by the forAge program.[1-3] The forAge program performs shape analyses of 3D surface models, calculates surface parameters, and outputs an age-at-death estimation. After attending this presentation, attendees will understand some implications of this novel age-at-death estimation technique to better interpret the results from forAge analysis.

The left pubic symphysis of 50 modern White males and females from the Texas State Donated Skeletal Collection and 12 male casts from the original Suchey-Brooks method were scanned using the NextEngine® 3D Desktop Scanner following the methods of Stoyanova et al.[3] The individuals ranged in age from 18 to 94 years old, with a mean age of 60.88 years.

Excess data were removed to isolate the symphyseal surface in ScanStudio™ v2.0.2. The surfaces were divided into three groups for analysis: (1) original surface scans (with holes); (2) edited surface scans (holes filled); and, (3) Suchey-Brooks cast surface scans. Surfaces with holes were filled in MeshLab v2016.12 and saved as separate files. Scans were then exported as ASCII PLY files and uploaded into the forAge program.

Point estimates generated by forAge were analyzed for accuracy, bias, and correlation against reported age at death. Differences in age-at-death estimates between surface scans with and without holes were compared using paired *t*-tests. Lastly, paired *t* -tests compared the means of age-at-death estimates from the Suchey-Brooks casts scanned by this study and between this study and Stoyanova et al.[3]

Analysis of the Original Surface Scans exhibited high inaccuracy in age-at-death estimation, with a bias toward under-aging individuals more than 40 years old and over-aging individuals less than 40 years old. This study revealed greater levels of inaccuracy in age-at-death estimation compared to Stoyanova and colleagues.[1-3]

Surface scans with fluctuating surface topography tended to produce holes in the mesh. Analyses comparing age-at-death estimates between original surface scans with holes and edited surface scans with no holes resulted in no significant differences. Thus, this study advises against filling holes in the surface scans.

Scans of the Suchey-Brooks male pubic symphysis casts were used to test for interobserver error between the two contributors of this study and between the first contributor of this study and the Stoyanova study.[3] The age-at-death estimates between the two contributors of this study exhibit no significant differences except in one shape measure. The age-at-death estimates collected by the first contributor were significantly different for each shape measure compared to those published by Stoyanova et al.[3]

The disparities between this research and Slice, Algee-Hewitt, and Stoyanova et al. may best be explained by the differences in the sample distribution, which had more individuals more than 40 years of age, while the previous studies had more individuals less than 40 years of age.[1-3] High inaccuracy may be due to the inability of the shape measures to account for minute differences in the surface topography of older individuals, such as increased porosity and excess bony growth. Since the same standardized casts were scanned in these analyses, the significant differences observed in age-at-death estimation from the casts may be explained by differences in scan parameters and image processing (i.e., bracket vs. single scans). Overall, this research may shed light on avenues to amend or expand on the original research.

A5 The Glenoid Cavity in Sex Estimation Among Contemporary Filipinos: Preservation and Accuracy Rates

Matthew C. Go, MA, University of Illinois at Urbana-Champaign, 607 S Mathews Avenue, 109 Davenport Hall, Urbana, IL 61801; Jana Andrea D.S. Santos, BA*, University of the Philippines Diliman, Albert Hall, Lakandula Street, Quezon City, Metro Manila 1101, PHILIPPINES; Anne Marie R. Valera, BA*, University of the Philippines Diliman, Albert Hall, Lakandula Street, Quezon City, Metro Manila, PHILIPPINES; Giswinne van de Wijdeven, MS*, stenen brug 2a, Landgraaf, Limburg 6372 AP, NETHERLANDS; and Nicole Marie C. Vesagas, BA*, University of the Philippines Diliman, Albert Hall, Lakandula Street, Quezon City, Metro Manila 1101, PHILIPPINES*

The goal of this presentation is to demonstrate the utility of the scapula in determining sex among contemporary Filipino skeletons and to highlight the importance of population-specific methods for biological profile estimation.

This presentation will impact the forensic science community by presenting a method that can be applied to an underresearched yet important population. This presentation will also further validate the reliability of the scapula as a means for sex estimation.

Methods of biological profile estimation from skeletal remains are known to be population specific. The degree of sexual dimorphism, rate of senescence, and formulas for stature differ from population to population. Furthermore, the different components of the biological profile often rely on each other. Knowing the sex, for example, further calibrates later estimates of age and stature. Research into Filipino skeletal variation has been relatively scarce owing to the until-recent absence of appropriate reference collections.[1] Such a paucity of methods for estimating the Filipino biological profile is unfortunate, given the country's large population sizes, widespread diaspora, frequent exposure to natural disasters, and rampant violence.

The glenoid cavity of the scapula has previously been used to estimate the sex of unknown individuals.[2] In this study, the effectiveness of the glenoid cavity in estimating sex among contemporary Filipino skeletons was evaluated using metric measurements of the glenoid height and breadth. The performance of these measurements was then tested using discriminant functions developed from Thai, Greek, and Mexican populations.[3-5] Discriminant analysis was also conducted on the Filipino sample. The rate of preservation of the glenoid cavity was further qualified in order to assess the utility of this feature in forensic contexts.

The state of preservation of glenoid cavities from 124 individuals housed at the Archaeological Studies Program, University of the Philippines Diliman were observed. More than 71%-75% of glenoid cavities examined by sex and side were fully intact or had marginal erosion that did not affect measurement, often even when there was significant postmortem damage to the scapular body. From this larger sample, 70 adult individuals (35 males and 35 females) were selected and measured by three different observers. Statistically significant differences between Filipino males and females were found using a paired *t*-test at an alpha level of 0.05 (t=-5.44, p=0.00). Using multivariate discriminant functions from Mexican and Greek populations, correct classification of females was 100% and of males was 8.6%. Using the Thai discriminant function yielded classification success of 34.3% for females and 100% for males. Filipino-specific linear discriminant analysis produced a cross-validated overall correct classification rate of 82.9% (F=80.0%; M=85.7%).

These results indicate that the glenoid cavity is a robust skeletal feature that resists degradation. Further research into this feature is warranted, given the probability of its preservation within forensic contexts. Additionally, the degree of sexual dimorphism of the glenoid cavity is highly variable between populations. The poor success of Filipino males using Mexican and Greek formulas speaks to relatively reduced sexual dimorphism within this population. The Thai formula yielded better classification for Filipino males but not females; however, the successful performance of the Filipino discriminant analysis confirms the utility of the glenoid cavity in sex estimation, but is heavily population specific.

Forensic Anthropology, Scapula, Philippines

A6 Reliability and Validity of the Walker and Klales, et al. Methods

Mackenzie Walls, Forensic Anthropology Program, Washburn University, 1700 SW College Avenue, Topeka, KS 66621; Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621; Kate M. Garvin, PhD, Des Moines University, Dept of Anatomy, 3200 Grand Avenue, Des Moines, IA 50312-4198*

After attending this presentation, attendees will better understand the reliability and validity of two commonly used morphoscopic sex estimation methods.

This presentation will impact the forensic science community by reporting observer consistency in scoring commonly used skull and pelvis traits and investigating the role that experience level plays in obtaining accurate sex estimations.

To have forensic utility, methods must be both valid and reliable. Validity refers to how well a method measures what it is supposed to (i.e., accuracy) and reliability refers to the ability to produce consistent results. External validity and reliability of methods must be assessed prior to their incorporation into standard operating procedures, and, to comply with *Daubert* standards, forensic methods must be tested and potential error rates published. As a result, there has been a push to translate traditional qualitative methods into quantitative methods, in which morphoscopic traits are assigned ordinal scores; however, these scoring methods do not eliminate method subjectivity completely, and thus it is important to assess validity and reliability in these trait scoring methods.

Two popular sex estimation methods, Walker and Klales, et al., provide an ordinal scoring method for traits of the skull and pelvis, respectively.[1,2] Walker utilizes the nuchal crest, glabella, supraorbital margin, mental eminence, and mastoid process. Klales et al. utilizes the ventral arc, subpubic contour, and medial aspect of the ischio-pubic ramus.[1,2] The validity and reliability of these methods have been tested only a handful of times since their incorporation into forensic casework, and the results have varied. Recognizing the need for updated standards in the field, trait data have been collected from more than 2,500 individuals as a part of a National Institute of Justice (NIJ) grant to: (1) assess the reliability and validity of these methods; (2) evaluate the impacts of population differences, secular change, and asymmetry on sex estimation; and, (3) create a free morphological database for sex estimation using these traits/methods: MorphoPASSE. This presentation addresses the first of these goals: trait scoring validity and reliability.

Three observers with varying levels of experience (expert/grant Principal Investigator (PI), experienced, and inexperienced) collected ordinal score data using the Walker and Klales et al. traits. This interobserver sample consisted of 222 individuals from the Hamann-Todd (HTH) and Bass skeletal collections. The expert observer scored the individuals twice, with a year between scoring events for intraobserver analyses. Additional trait data were contributed by four other researchers, with various levels of experience, thereby facilitating additional tests of observer error. Their data were collected from the HTH (n=174), Bass (n=57), and the Operation Identification and donated collections at Texas State University (n=57) and included individuals also scored by the grant PI. Interobserver error was assessed using the Intraclass Correlation Coefficient (ICC), while intraobserver error was assessed with quadratic weighted Kappa (wK). Sex classification accuracy was evaluated using the logistic regression equations provided in the original publications.

Intraobserver agreement was nearly perfect for the pelvis and substantial for the skull. The ICC indicated excellent levels of agreement between the three observers that scored the entire sample of 222 individuals, with the exception of the orbital margin (good agreement). The expert and experienced observer achieved higher agreement than the inexperienced observer, indicating that experience does play a role to some degree. When the additional contributed trait data were included in analyses, excellent agreement was obtained between the three expert observers for all traits except the mental eminence. Classification accuracy was high for all three experience levels for the pelvis (96.6% expert, 93.6% experienced, and 78.2% inexperienced), but was generally lower, with a high sex bias, for the skull regardless of experience (73.5% expert, 61.4% experienced, and 70.7% inexperienced). In conclusion, the reliability results indicate general consistency in trait scoring among observers, while the validity results suggest that experience plays a larger role in the accurate application of the methods than has been previously reported; observers with a great deal of experience can expect much higher sex classification accuracy than observers with less experience.

This research was funded by an NIJ Grant. Opinions, points of view expressed in this research, and products discussed represent a consensus of the authors and do not necessarily represent the official position, policies, or endorsement of the United States Department of Justice or the NIJ.

After attending this presentation, attendees will have a clearer understanding of the extent to which stratigraphy can be an important piece of evidence for the interpretation of forensic archaeological sites.

This presentation will impact the forensic science community by highlighting: (1) the frequent subtlety and complexity of stratigraphic information at forensic archaeological sites; and, (2) the importance of professional archaeological knowledge and experience to the successful recognition and correct interpretation of such stratigraphic cues. Further, it will emphasize that due to these two factors, forensic sites requiring mapping and excavation are best processed with the direct involvement of trained forensic archaeological professionals who have an understanding of how to record and interpret stratigraphic evidence.

Steno's Law of Superposition (1669) essentially states that older layers of soils and sediments underlie younger layers. A related principle, the Law of Cross-Cutting Relationships, states that sediment layers must necessarily be older than any deposit or intrusion that disturbs them. These are simple concepts that, when practically applied, can be extraordinarily complex. Though Steno's Laws are foundational principles of archaeology, they are not commonly associated with the forensic sciences; however, in the context of forensic archaeology, particularly when dealing with forensic scenes that have developed over an extended period of time, understanding these elementary principles of soil and sediment stratigraphy can be a crucial element of site interpretation.

The goal of this presentation is to illustrate the assertion that forensic anthropological professionals must have a strong knowledge of stratigraphic interpretation or risk being led astray and reaching incorrect conclusions during site excavation. To that end, this presentation will present six forensic archaeological excavation case studies in which astute interpretation of site stratigraphy constituted a significant line of evidence toward the successful excavation of the forensic scene and, in some cases, the recovery and identification of a missing individual. The discussed sites were excavated by Defense POW/MIA Accounting Agency teams searching for the remains of missing United States service members from three major wars. Each site is unique and necessitated a distinctive style of archaeology due to a number of factors. Soil and sediment types vary widely from one geographical location to another; no two sites are alike, and even within an individual site, formation processes can vary extensively from one area to another. Sites presented include those with very deep stratigraphic profiles, such as aircraft crash craters, others with little to no stratigraphic development, such as disturbed surface scatters, and unusual sites where the depositional environment is unclear or highly complex, such as ice fields or glaciers. Despite these differences, all of these sites share the distinctive aspect of having formed over long periods of time (typically 45 to 75 years). The comparatively protracted time depth of these sites often means more complex site formation processes are at work than would typically be found on more recent forensic archaeological sites. Relevant site formation processes, such as erosion, bioturbation, fluvial deposition, and human scavenging activities, will be examined.

A clear understanding of stratigraphy and the archaeological methods used to detect, interpret, and record formation and disturbance patterns in layers of soil and sediment is one of the many things that sets apart archaeological professionals from untrained amateurs. This is one of the primary reasons it is so important to have forensic sites excavated by experienced forensic archaeologists rather than by well-meaning but untrained and inexperienced non-archaeological professionals. An ability to detect, interpret, and record stratigraphy is a fundamental skill used by forensic archaeologists, and one that must be honed through a variety of field experiences; it is nearly impossible to learn in a classroom setting. Stratigraphy tells a story that can only be read through careful excavation.

Forensic Archaeology, Stratigraphy, Defense POW/MIA Accounting Age

A8 Analysis of Interobserver and Intraobserver Error Associated With the Use of 3D Laser Scan Data of the Pubic Symphysis

Jieun Kim, PhD, 24 E Liberty Street, Apt 45, Savannah, GA 31401; Bridget F.B. Algee-Hewitt, PhD, Stanford University, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020; Detelina Stoyanova, PhD, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306; Cristina Figueroa-Soto, MA, The University of Tennessee, 254 S Stadium Drive, Knoxville, TN; and Dennis E. Slice, PhD, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306-4120*

After attending this presentation, attendees will understand the intraobserver and interobserver error related to collecting and editing 3D laser scans of skeletal material, as well as the repeatability of three new age estimation methods that use bone shape data extracted from the laser scans.

This presentation will impact the forensic science community by providing best practice guidelines for using laser scanners, scanned images, and coordinating data in forensic casework that will contribute to the standardization of 3D image processing procedures between different forensic practitioners and labs. It will also provide validation for the age estimation methods discussed here.

In age-at-death estimation based on visual assessment, objective evaluation and correct diagnosis of age-related skeletal traits are crucial, as these factors determine whether the aging methods can achieve their full potential — producing the most accurate and reliable age estimates. Nevertheless, the traditional, phase-based age estimation methods have been reported to yield inconsistent age estimates both within and between observers.[1,2] The reasons for these discrepancies lie in the fact that accurate macromorphoscopic analysis heavily depends on the correct interpretation of qualitative trait descriptions, conformity of the bone, and experience of the observer.

Recently, Slice and Algee-Hewitt and Stoyanova et al. have introduced three novel, fully computational aging methods using 3D laser scans of the pubic symphysis that minimize subjectivity in age estimation by reducing the effects of observer experience in the age-indicator/trait assessment and methodological bias; however, the reproducibility of these methods has not been fully explored or quantified.[3-5] This is of concern because there is potential for introducing error in the first two steps of data processing — when the scans are taken and edited at different times by different observers. In response to this concern, the current study evaluates the repeatability of these novel methods by assessing intra-scan variation, within, and between, observer differences in scan editing and its impact on age estimation.

The test data used in this study represent replicate scans of the Suchey-Brooks' (SB) male casts, taken using a 3D desktop laser scanner. The upper and lower stages of each of the six phases were scanned three times by a single observer (n=36). Four different observers with various experience levels and training backgrounds independently edited the triplicate of the SB scans using the scanner's accompanying software, such that the symphyseal face is extracted from the surrounding bones. From these isolated faces, x, y, and z coordinates were retrieved and analyzed via the Subarachnoid Hemorrhage (SAH) Score method, the Thin Plate Splines/Bending Energy (TPS/BE) method, and the Ventral Curvature (VC) method to compute shape measures.[3-5] These measures were subjected to single-variable and multivariate regression models to obtain age estimates for each replicate scan per observer. Finally, using the shape measures and final age estimates, a series of the Intraclass Correlation Coefficient (ICC) were calculated to evaluate within- and between-observer reliability in scan editing. Additionally, extra editing conditions were tested to simulate the situation in which the practitioner misidentifies age-related traits due to unfamiliarity with the scan editing protocol. A set of the SB casts was edited with different widths of the margin (2mm vs. 4mm vs. 1cm) left around the symphyseal face and with/without the pubic tubercle, which may impact the VC values as it protrudes ventrally. Possible effects of these conditions on age estimates were evaluated using the paired t-test.

This study produced high ICC values (0.75-1.0), demonstrating that the raw scans were edited consistently within and between observers and that the derived shape measures and age estimates were in excellent agreement among observers. Moreover, despite the simulated improper editing of the scans with various margin widths remaining, the methods were robust enough to self-correct and produce consistent and accurate age estimates ($p > 0.05$), with the exception of the faces with 1cm margin. Interestingly, the inclusion of the pubic tubercle for the shape analysis did not necessarily yield inaccurate age estimates for the VC method, while it produced statistically significant mean differences between the documented chronological age and age estimates of the SAH score method, TPS/BE method, and the two multivariate regression models ($p < 0.01$). These results demonstrate high repeatability of the computational methods regardless of the observer's level of experience or training background and support using a 3D laser scanner and scanned images to aid in resolving the issue of subjectivity.

Age-At-Death Estimation, Observer Error, 3D Scans

A9 Analysis of Osteon Pull-Out and Collagen Degradation to Establish Fracture Timing

James Luong, MSc, 800 N 25th Street, Middlesboro, KY 40965; Sadaf Fakhra, MSc, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37742; Natalie R. Langley, PhD, Mayo Clinic School of Medicine, Dept of Anatomy, 13400 E Shea Boulevard, SC-AB-01-313B, Scottsdale, AZ 85259; Beatrix Dudzik, PhD, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and MariaTeresa A. Tersigni-Tarrant, PhD, Saint Louis University School of Medicine, Center for Anatomical Science, 1402 S Grand Boulevard, M306, St. Louis, MO 63104*

After attending this presentation, attendees will understand the phenomenon of osteon pull-out, the effects of collagen degradation on pull-out morphology, and the utility of these morphological changes in distinguishing peri-mortem versus postmortem traumatic events.

This presentation will impact the forensic science community by documenting morphological differences between fracture-induced osteon pull-out during the peri-mortem and postmortem intervals.

It is hypothesized that the histological appearance of peri-mortem fractures exhibits greater degrees of osteon pull-out due to elasticity imparted by Type I collagen. As the organic collagen fibers degrade postmortem, the characteristics of pull-out differ due to the concomitant reduction in elasticity. This study provides a basis for further investigation into the use of osteon pull-out and histological morphology to distinguish between peri-mortem and postmortem fractures.

Fractures may exhibit characteristic features of peri-mortem injuries as long as they occur while the bone is reasonably elastic. The extended time during which bone maintains its elasticity after death creates an exaggerated peri-mortem interval in bone and limits the capacity of macroscopic fracture evaluation to delimit peri-mortem versus postmortem events. Fracture morphology associated with peri-mortem events is related to moisture content, mineral matrix ratios, and osteon fracture patterns.[1,2] This study evaluates fracture microstructure with Scanning Electron Microscopy (SEM) and correlates the histologic features with Accumulated Degree Days (ADD) and collagen degradation.

Thirty-two foot bones (16 metatarsals and 16 phalanges) from a non-reproducing pig (*Sus scrofa)* were obtained on the same day of slaughter. One metatarsal and one phalanx were selected to represent an ADD of 0. Cross-sectional samples were harvested from these two bones at mid-diaphysis with an autopsy saw. These samples were then washed in a phosphate buffer solution and fractured with a quick snapping force. Fractured pieces were fixed using osmium tetroxide, ethanol, and hexamethyldisilazane, then mounted on SEM stubs and sputter coated with gold. The remaining samples were catalogued, tied in porous cloth, and placed in a cage to decompose in an outdoor setting. ADD was recorded using daily temperature averages for Middlesboro, KY, with a minimum threshold temperature of 57°F. Samples spanning a postmortem interval of 0-1,043 ADD were fractured at regular intervals. Histologic morphology was examined with SEM, and postmortem collagen degradation was analyzed with mass spectrometry. Bone material was prepped according to established analytical platform protocols and analyzed using high-resolution (0.2ppm-3ppm mass error) data acquisition with an Orbitrap™ mass spectrometer.[3,4]

The mass spectrometry analysis of collagen revealed expected degradation with advancing ADD. The average OD_{550} of the two initial specimens resulted in an absorbance of 0.36 compared to the final specimen, which yielded an absorbance of 0.23, a difference of approximately 36.1%. Analysis of SEM images revealed significant differences in osteon appearance occurring at approximately 70% of initial collagen levels. Samples containing 70% or less of intact collagen demonstrated marked structural failure along canaliculi channels compared to samples with >70% of intact collagen. This preliminary data suggests that as collagen degrades with increasing ADD, the osteon pull-out mechanism becomes inadequate at dispersing force, and structural failure occurs along canaliculi channels, which may be a source of structural weakness. SEM analysis of fracture morphology coupled with mass spectrometry quantification of collagen degradation may offer a method for more precise interpretation of fracture timing.

Bone Histology, Scanning Electron Microscopy, Skeletal Trauma

A10 Quantitative Population Differences in Anterior Zygomatic Projection (ZP)

Chelsea C. Cataldo-Ramirez, BA, 3636 Calle Quebracho, Thousand Oaks, CA 91360; Heather M. Garvin, PhD, Des Moines University, Dept of Anatomy, 3200 Grand Avenue, Des Moines, IA 50312-4198; and Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will better understand the variation of anterior ZP within modern populations and its use in identifying unknown individuals of Asiatic/Native American ancestry.

This presentation will impact the forensic science community by expanding the knowledge of craniofacial trait variability used during ancestry estimation. Additionally, this presentation will demonstrate the value of updating traditional methods by incorporating contemporary technology, such as 3D virtual models.

Within forensic anthropology, qualitative methods have historically been favored for estimating the ancestry of unknown individuals. This leaves room for subjectivity when assessing traits and can potentially lead to misclassifications. Anteriorly projecting zygomas have traditionally been viewed as a trait indicative of Asiatic heritage (including Native Americans), but the trait is poorly defined and recent validation studies have demonstrated its vulnerability to high interobserver error.[1,2] In an effort to reduce subjectivity in describing ZP, two non-metric methods have been proposed to measure this projection, one commonly referenced to Rhine and the other from Bass.[3,4] In Rhine, the angle of projection is measured by dropping a line "from the middle of the upper margin of the orbit to the middle of the lower margin [that] produces an angle … with the Frankfort plane" using a 90° sectioning point to define projecting, vertical, or receding zygomas. In the Bass method, the observer holds the skull with the occipital region in their hand and the facial area up. A pencil is then placed across the nasal aperture and the observer inserts their index finger between the zygomatic and the pencil. If the observer cannot fit their finger in that space, the zygomatics are considered projecting. The Rhine method is qualitatively assessing an angle, while Bass is visually assessing an absolute distance, yet both use the terminology "zygomatic projection." The current study investigates the applicability of the available methods of assessing ZP and quantitatively examines the relationship between ancestry and ZP.

For both the Rhine and Bass techniques, two interpretations of each method were metrically assessed utilizing 3D virtual cranial models. All analyses were conducted via the use of Geomagic® studio software and ImageJ. This allowed for the crania to be automatically aligned to standardized orientations for viewing and facilitated the incorporation of inter-planar distance measurements, which are necessary to quantitatively test the original qualitative methods. The sample consists of 231 3D cranial models of United States White (n=73), United States Black (n=38), Arctic Native American (n=79), and Plains Native American (n=41) individuals.

Two interpretations of the ZP angle were tested following Rhine and two inter-planar distances between the nasal aperture and the zygoma were tested following the text and figures presented in Bass. To test for differences in group means, Analyses of Variance (ANOVAs) were run on all measurements of ZP, with two-way ANOVAs then conducted to examine the effects of ancestry and sex on each measurement. Tukey's post hoc tests were then performed to identify which groups displayed differences. Lastly, to provide more details on group differences and evaluate group classification rates, logistic regression was performed on all measurements of ZP that yielded significant ancestry differences ($p < 0.05$).

In each assessment, the Arctic Native Americans demonstrated the most anteriorly projecting zygomas, providing support to the general assumption that individuals of Asiatic ancestry have more anteriorly projecting zygomas than other populations, although significant differences were not always obtained. Of the interpretations tested, the inferior zygomatic inter-planar distance performed best at classifying between Arctic Native Americans and other groups when using binary logistic regression. This yielded correct classification rates between 70% and 98%. ZP was also found to be mildly sexually dimorphic, with females having more projecting zygomas than males within the same population. This study demonstrates that quantitatively modifying the current methods of ZP assessment through the use of 3D software can lead to information gains unobtainable through existent qualitative methodologies. Furthermore, this study examines the use of standardized terminology within the field of forensic anthropology and highlights the benefits of investigating alternative interpretations to traditional methodologies.

Biological Profile, Ancestry Estimation, Cranial Traits

A11 The Use of the Mastoid Triangle for Sex Estimation

Natalie L. Andras, John Carroll University, 1 John Carroll Boulevard, University Heights, OH 44118*

After attending this presentation, attendees will better understand the use of the mastoid triangle for sex estimation in adult individuals.

This presentation will impact the forensic science community by providing insight into a method for sex estimation using metrics of the mastoid triangle. In addition, this presentation demonstrates the need for additional research into the use of the mastoid triangle for sex estimation.

Sex estimation is a key parameter of the biological profile because it allows for sex-specific methods to be employed in the estimation of other aspects of the biological profile. Previous studies utilizing the mastoid process for sex estimation have focused on both metric and non-metric traits of the mastoid process itself; however, Paiva and Segre measured the area of the mastoid triangle, defined as the area between asterion, mastoidale, and porion, and found significant sex differences.[1] Subsequent studies have found significant differences between males and females using dimensions of the mastoid triangle; however, no studies have examined the use of shape differences of the mastoid triangle for sex estimation. The goal of the present research is to metrically examine size and shape differences of the mastoid triangle between males and females.

A total of 200 adult individuals of known sex were sampled from the Hamann-Todd Collection housed at the Cleveland Museum of Natural History: 100 males and 100 females. Using a digitizer, three coordinates were collected from the left side of the cranium: Asterion (AST), Mastoidale (MS), and Porion (PO). Three Interlandmark Distances (ILDs) were calculated to explore size differences, and Geometric Morphometric Analyses (GMA) were conducted to explore shape differences. Classification accuracy was assessed using jackknifed Linear Discriminant Function Analysis (LDFA) of the ILDs, Procrustes Coordinates (PCoords) generated from the GMA, and Principal Components (PCs) generated from the principal component analysis.

Using LDFA of all three ILDs, correct classification between the sexes was 72.5% (females 73%, males 72%). Using separate ILDs, classification accuracy between the sexes was highest using LDFA of MS-PO (overall 71.35%; females 73.7%, males 69%), followed by AST-MS (overall 67.5%; 66% females, 69% males), and AST-PO (overall 63.3%; females 59.6%, males 67%). In addition, males were significantly larger ($p < 0.05$) than females for all three ILDs. Classification accuracy between the sexes using LDFA of the PCoords was 70.5% (females 67%, males 74%), which is similar to and slightly less than the size analysis. The first two PCs accounted for 99.9% of the variance, and classification accuracy between males and females using LDFA and these two PCs was 65.5% (females 68%, males 63%).

The results of this study demonstrate statistically significant differences between the mastoid triangle of males and females. Classification accuracy was highest using the ILDs; however, the results using the PCoords were comparable. The results of this study are similar to previous studies, which found significant differences between the mastoid triangle of males and females; however, classification accuracy using AST-PO differs from Jain et al.'s reported 45% classification accuracy.[2] This may be due to variability in the location of asterion between individuals and populations.[3] Combining the size and shape analyses from this preliminary study with the measurement of mastoid area or including measurements of both the left and right mastoid triangles in the analyses have the potential to produce even higher classification accuracies.

Sex Estimation, Mastoid Triangle, Geometric Morphometrics

A12 The Impact of Asymmetrical Leg Lengths on Adult Stature Estimation

Megan E. Ingvoldstad, PhD, DPAA Laboratory, 106 Peacekeeper Dr, Offutt Air Force Base, NE 68113*

After attending this presentation, attendees will have learned that left/right total leg length asymmetries are commonly encountered in forensic anthropological casework. Guidance will be provided on how best to estimate stature when asymmetries are present to avoid the production of inaccurate estimates and the erroneous exclusion of decedents as matches to their skeletal remains.

This presentation will impact the forensic science community by encouraging bilateral measurement taking whenever possible and selection of a 99% Prediction Interval (PI) when total leg length asymmetry reaches ≥0.7mm. This practice can prevent inaccurate stature estimates and the erroneous exclusion of decedents from their skeletal remains.

The skeletal elements required to execute Fully's anatomical method of stature estimation are often not present, are incomplete, or are damaged, precluding its use. Thus, forensic anthropologists often use regression formulas to estimate stature from limb bones. As previous research has revealed that: (1) stature estimates calculated from two or more long bones are superior to those calculated from one; (2) lower limb bones correlate more strongly with stature than upper limb bones; and, (3) asymmetry between sides is relatively minor, the left (by convention) femur and fibula (highest r-squared value combination in FORDISC®) are often used to estimate stature at the Defense POW/MIA Accounting Agency (DPAA) laboratory.

A review of recent DPAA identifications reveals that stature estimations using the left femur and left fibula are occasionally slightly inaccurate due to total length asymmetries between the left and right legs. In extreme cases, estimates calculated from one limb match an identified individual's reported stature, while estimates calculated from the opposite limb exclude the remains as a match. Realizing that conventional selection of the left leg could be resulting in inaccurate stature estimations in cases of asymmetry, this research was undertaken to investigate: (1) if statistically significant asymmetries exist between left and right total leg lengths; and, (2) if the longer total leg length more accurately reflects measured stature as it represents an individual's greatest height potential when standing up straight.

To address these questions, stature data was collected from adult individuals identified at the DPAA Laboratory between 2001 and 2017. Ultimately, this sample was composed of 70 males of European, African, Native American, and Hispanic descent ranging in ages at death from 18 to 40 years (average=21.9 years, standard deviation=3.66 years). Twenty-two individuals served in World War II and 48 in the Korean War. To be included, the remains must have had left and right femora and fibulae present for analysis, the remains must be atraumatic and complete, and both left and right sides must have been measured by the assigned forensic anthropologist.

Using element lengths documented in the case notes, each individual's stature was estimated using FORDISC® 3 and the appropriate Trotter MStats male database. First, the maximum lengths of the left femur and left fibula were used to calculate a 95% Prediction Interval (PI). Second, the maximum lengths of the right femur and right fibula were used to calculate a 95% PI. These PIs were then assessed for absolute difference and checked against the individual's antemortem stature (obtained by healthcare professionals during military medical evaluations) for accuracy. Stature estimates that did not include the identified individual's antemortem stature were run again using 99% PIs and checked to see if the identified individual's antemortem stature was captured.

Although left/right total leg length asymmetries up to 16mm were observed in 61/70 cases, results indicate that: (1) mean total leg lengths are not significantly different; (2) when there are left/right total leg length asymmetries, the taller leg does not consistently produce the more accurate stature estimate; and, (3) when a disparity between left and right legs ≥7.0mm is encountered, increasing the PI from 95% to 99% ensures the individual's living stature is captured. Implementing this practice among the current sample improved stature estimate accuracy (90% to 100%).

Overall, these findings reinforce the idea that although mean total leg lengths are not significantly different, bilateral asymmetry can be significant enough to affect stature estimates.

Biological Profile, Stature, Bilateral Asymmetry

A13 The Utility of Postcranial Non-Metric Traits in Ancestry Analysis

Micayla C. Spiros, MSc, 110 W Grant Street, Apt 26B, Minneapolis, MN 55403; and Carolyn Rando, PhD, University College London, Institute of Archaeology, 31-34 Gordon Square, London WC1H 0PY, UNITED KINGDOM*

After attending this presentation, attendees will be familiar with a novel approach to analyzing postcranial non-metric traits and how these variations may be used to estimate the ancestry of individuals in a forensic context.

This presentation will impact the forensic science community by addressing a notable gap in forensic anthropological literature regarding the usage of postcranial non-metric traits, which will assist in future approaches to ancestry estimation.

This research project sought to create a visual method for scoring a suite of postcranial non-metric traits, to define and illustrate the traits being used in the method, and to compare these postcranial non-metric traits between ancestral groups.

To begin, a categorical scoring method was created to analyze the usability and frequency of post-cranial non-metric variation between ancestral groups.[1] Based on a comprehensive survey of the literature, 11 different traits were used in this study. Due to discrepancies in the definitions and photographs of these traits throughout various studies, new definitions, trait states, and illustrations were created. Next, these 11 traits were observed and recorded on a sample of 210 specimens from the Robert J. Terry Anatomical Skeletal Collection, including American Black (n=105) and American White (n=105) individuals. Frequency distributions were calculated after data collection to depict the differences between the American Black and American White as different ancestral groups. After creating contingency tables for each trait, Chi-square tests were utilized to determine statistically significant differences between the two ancestral groups. Using these contingency tables, correspondence analysis was run using code modified from previous cranial non-metric trait analysis to create two-dimensional biplots visually demonstrating the relationships between American Blacks and American Whites.

Results indicate that, of the 11 traits analyzed, five had statistically significant differences between the two ancestral groups when running Pearson's Chi-square test with a significance level of $p < 0.05$. These traits include the spinous process bifurcation for both the third and fourth cervical vertebrae (C3: $x2$=60.9738, df=2, $P < 0.00001$; C4: $x2$=39.96, df=2, $P < 0.00001$), septal aperture ($x2$=13.6159, df=1, P=0.0035), third trochanter ($x2$=17.3744, df=1, P=0.000031), vastus notch ($x2$=4.3063, df=1, P=0.0379), and the anterior and middle calcaneal facets ($x2$=26.5157, df=3, $p < 0.00001$). These results were mirrored in both the frequency charts and, in turn, the correspondence analyses.

While the frequencies and Chi-square results of these traits are not enough to be used in isolation, this analysis of a non-metric postcranial trait list identifies the necessity for further research in these traits and their associations with ancestry estimation. This creation of the postcranial trait list will enhance the ability to visually ascertain ancestry. Further documentation of more populations paired with additional statistical analyses will allow forensic anthropologists to rely on scientifically tested data rather than relying on personal experience of visually estimating ancestry.

Ancestry, Non-Metric Variation, Postcranial Skeleton

A14 Testing the Reliability of Ancestry-Specific Juvenile Age Estimation Methods Using the Diaphyseal Length of the Humerus

Hugo Cardoso, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Laure Spake, MA*, Simon Fraser University, 8888 University Drive, Burnaby V5A 1S6, BC, CANADA; Luis Rios, MA, Fernando Garrido 6 48, Madrid 28015, SPAIN; and John Albanese*, University of Windsor, Dept of Sociology, Anthropology and Criminol, 401 Sunset Avenue, Windsor, ON N9B 3P4, CANADA*

After attending this presentation, attendees will have a better understanding of population variation in long bone length and how ancestry-specific age estimation methods based on humerus length do not necessarily improve the accuracy over other methods, particularly when the ontogenetic environment is not considered.

This presentation will impact the forensic science community by demonstrating that size is not ancestry specific, and that the reliability of juvenile age estimation methods based on long bone length is not necessarily conferred by matching the ancestry of the individual under investigation with the ancestry of the individuals in the sample used to develop the method.

Little work has been conducted on whether juvenile age estimation methods perform well beyond the population that was used as a reference. The accuracy of juvenile skeletal age-at-death estimation methods is known to be tied to the similarity between the method's reference sample and the target population. This similarity has been most often described in terms of "biological/genetic proximity" or ancestry and is the basis for advocating population-specific methods; however, similarity of growth environments has been less considered. The purpose of this presentation is to test two recently published juvenile skeletal age estimation methods (Stull et al., based on modern South African children; and Cardoso et al., based on 18th- to early 20th-century children from Portugal and England) on a diverse sample of known-age juvenile remains.[1,2]

Humerus diaphyseal length was collected from a sample of 81 known-age juvenile skeletons, aged between birth and 12 years. The data combines archaeological, anatomical, and forensic reference collections in the United States, Canada, and South Africa. Ages were estimated using Stull and colleagues and Cardoso and colleagues prediction models.[1,2] Mean residuals and mean absolute residuals were calculated to evaluate method accuracy and precision. To further evaluate reliability, 95% range inclusion frequencies were calculated as the percentage of individuals whose real age fell within the estimated 95% confidence interval.

Results do not lend support to the argument that ancestry-specific methods are more accurate, but seem more consistent with the ontogenetic environment hypothesis. Stull and co-worker's method is based largely on modern South African children, both "Black" and "Colored." It consistently performs best in the Forensic Data Bank sample, which is comprised largely of "Whites." Cardoso and co-workers' method is based on significantly stunted European children and consistently performs best in the Dart collection, which is comprised entirely of "Blacks." These findings have important implications for age estimation of juvenile skeletons in forensic contexts.

Juvenile Skeletal Age, Inter-Population Variation, Ancestry

A15 A Revision of the Histological Age Estimation Formula From Stout for Sternal Rib Ends

Nicole M. Weiss, BS, The Ohio State University Dept of Anthropology, 4034 Smith Lab, 174 W 18th Avenue, Columbus, OH 43210*

After attending this presentation, attendees will understand how forensic anthropologists use histological methods to estimate age at death and how the accuracy of these methods may be improved.

This presentation will impact the forensic science community by providing a revised regression equation to improve the accuracy of histological estimation of age at death from cross sections of sternal rib ends.

Given the lack of macroscopic features in highly fragmentary skeletal remains, histological methods may be employed to estimate age at death if complete skeletal elements are not available. These methods are based on the assumption that bone remodeling events accumulate throughout one's lifetime, meaning the bones of older individuals generally contain more osteons, the result of remodeling, than those of younger individuals.

Previous research by Stout and colleagues described a formula for histological age estimation based on Osteon Population Density (OPD) for cross sections of the sternal end of the fourth rib from an autopsy sample of 60 individuals (mean age=39.2 years, age range=11-88 years).[1] Though the original publication reported that age estimates produced by the histological prediction equation differed from known age at death by 8.8±0.98 years, reexamination of the original equation using individuals from the same collection revealed that age estimates differed from known age at death by 22.54±2.30 years.[1]

This current work seeks to revise the original formula, taking into consideration osteon area and osteon circularity in addition to OPD to create more accurate age estimates. OPD, defined by Stout and colleagues as the number of osteons per unit area, was calculated with the aid of a Merz counting reticle.[1] Osteon area is defined as the amount of bone in the boundary of an intact osteon in millimeters and osteon circularity is the quantification of how similar an osteon's shape is to a true circle, ranging from 0 to 1.[2,3] Osteon area and circularity were measured using ImageJ software to trace the cement line, or outside boundary, of each osteon. Data on OPD, osteon area, and osteon circularity were collected from the entire cross section of the rib. Given that information on known age at death for 14 individuals had been misplaced since the original publication, a subsample of the original autopsy sample was used to develop the revised equation, including 46 individuals (17 females, 29 males) of known age (mean age=43.3 years, age range=15-83 years). The formula was generated using multiple regression analysis in which the dependent variable was age and the independent variables were OPD, osteon area, and osteon circularity. OPD and osteon area were found to make statistically significant contributions to the age estimation formula ($p < 0.05$). Osteon circularity did not significantly contribute to the age estimates, and the final formula was developed using only OPD and osteon area as independent variables.

Age estimates produced by the revised equation differed from known age at death by 10.18±1.25 years, indicating that the revised formula was more accurate for estimating age than was the original formula. To test the accuracy of the revised equation, a "test set" approach was used in which a subset of individuals (*N*=16) was removed and the equation was calculated from those individuals who remained (*N*=30). Age at death was estimated for those individuals removed from the sample, and results revealed that age estimates produced by the "test set" equation differed from known age at death by 10.99±2.48 years, indicating accuracy comparable to the equation generated from all 46 individuals. Therefore, it is recommended that the revised formula be used for histological age estimation of rib cross sections in place of the previously described formula.

Forensic Anthropology, Skeletal Histology, Age Estimation

A16 An Examination of Pelvic Scarring as a Determinant of Parturition Status

Helen M. Brandt, BA, University of Indianapolis, 1400 E Hanna Avenue, Indianapolis, IN 46227; Stephen P. Nawrocki, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227-3697; and Krista E. Latham, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227*

The goals of this presentation are to: (1) develop a better understanding of the effects of parity and sex on pelvic bone scarring; and, (2) recognize the significant causal relationship between childbirth and dorsal pubic pitting.

This presentation will impact the forensic science community by providing a statistically rigorous study of pelvic scarring using a large modern skeletal sample and controlling for other relevant independent variables. This study helps to resolve the contradictory findings of prior studies, provides new guidelines for the determination of sex and parity from pelvic scars, and establishes a platform for future research on the processes that cause those scars.

Scars of parturition, or pelvic scars, have been examined frequently to explore their utility as indicators of childbirth and sex. Many studies found a significant association between the presence and/or severity of pelvic scars and parity, while others found no such relationship. The traits commonly considered to be indicators of parity are dorsal pubic pitting, the height of the pubic tubercle, the preauricular sulcus, and the interosseous groove. The goal of this current study is to examine these traits in a sample with known parity status, combining traditional qualitative scoring with quantitative measurements and using multivariate testing to separate the influence of parity from other independent variables. The null hypothesis is that parity does not independently affect the expression of pelvic scarring when sex, body size, and age at death are controlled.

Both male and female skeletons were assessed for the presence and degree of pelvic scarring. A sample of 530 identified, primarily Euroamerican individuals was drawn from the Texas State University Donated Skeletal Collection, the Maxwell Museum Documented Skeletal Collection, and the William M. Bass Donated Skeletal Collection. Sex, age at death, and ancestry was recorded for all specimens, and all females had known (self-reported) parity status. Coxa height was used as an indicator of overall body size. The presence and severity of dorsal pubic pitting, the preauricular sulcus, and the interosseous groove were scored traditionally using ordinal scales, and the width, depth, and length of pubic and preauricular pits were also measured with sliding calipers. The type of preauricular sulcus and interosseous groove present ("groove of pregnancy" or "groove of ligament") was recorded. The height of the pubic tubercle was measured using a contour gauge and sliding calipers, and retroauricular surface rugosity was scored ordinally to assess whether this area is also affected by childbirth.

Each of the examined pelvic traits was analyzed individually for its relationship to parity using IBM® Statistical Package for the Social Sciences (SPSS) Advanced Statistics 23.0. The independent effects of sex, age at death, and body size were assessed with binary logistic and ordinal regression for the non-metric traits and analysis of covariance for the metric traits. These powerful multivariate tests allow for a more reliable and precise interpretation of the effects of parity than has been attempted by previous works.

The results clearly demonstrate that only dorsal pubic pitting (presence, number, width, and volume) has a significant relationship with parity. Nulliparous females display a higher frequency of pitting than males, and the number and severity of pits increases in females with the number of births; however, parity's influence on pubic scarring is not as important as that of sex. Females with pitting are ~85% likely to have had at least one child, but females without pitting are only ~30% likely to be nulliparous. The preauricular sulcus and interosseous groove are strongly determined by sex and thus can serve as effective sex indicators, while variance in the height of the pubic tubercle can be attributed to body size and sexual dimorphism. The retroauricular surface increases in rugosity with age and body size and is more rugose in females, but is not influenced by parity.

These results challenge recent arguments for the lack of a causal relationship between dorsal pubic pitting and parity; however, because the effect of parity is secondary to that of sex, the practical applications for determining parity status from an unidentified decedent are limited. Furthermore, these results reinforce claims that the preauricular sulcus, interosseous groove, and pubic tubercle are caused or influenced by processes other than childbirth. All pelvic scars can be used effectively for sex determination.

Forensic Anthropology, Scars of Parturition, Dorsal Pubic Pitting

A17 Stature Estimation Using Measurements of the Cranium for Populations in the United States

Kelsey Kyllonen, MA, 1200 Green Tree Road, #202, Fredericksburg, VA 22406; Terrie L. Simmons-Ehrhardt, MA, Virginia Commonwealth University, School of World Studies, 312 N Shafter Street, Richmond, VA 23284; and Keith L. Monson, PhD, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the accuracy and limitations of estimating stature for populations in the United States using only cranial measurements.

This presentation will impact the forensic science community by providing a method of estimating the stature of an unknown individual using cranial measurements if no other skeletal elements are present.

Stature estimation is part of the process of developing a biological profile for an unidentified individual. This is usually accomplished by measuring the lengths of the available long bones and calculating a stature range for the unidentified individual using published sex- and ancestry-specific regression equations. Stature can be estimated using measurements from other bones if long bone measurements are not available for an individual, but the estimated stature ranges generated from these equations are typically larger than those utilizing long bone measurements. Human crania are easily recognizable even to the untrained observer and are sometimes recovered in the absence of other skeletal material. The height of the cranium from points basion to bregma directly relates to stature, suggesting that this measurement and other cranial measurements could be used to estimate stature when no other skeletal elements are present.[1] Although stature estimation equations using various cranial measurements have been developed for several regional populations in various countries, no stature estimation equations utilizing standard cranial measurements exist for common populations in the United States. The purpose of this study is to develop and test stature estimation equations for four populations in the United States.

Seventeen standard cranial measurements were obtained from both a cranial Computed Tomography (CT) dataset and the Forensic Data Bank for Black, White, and Asian males and females and Hispanic males, for a total of 513 individuals.[2-4] Only individuals with either self-reported stature or stature measured at the time of the CT scan were included in this study, and all individuals were between the ages of 18 years and 60 years. Correlation coefficients and both simple and multiple linear regression equations were calculated for each of the 17 cranial measurements. Weak-to-moderate correlations with stature were observed for several cranial measurements in each population group, but none of the cranial measurements for any population demonstrated a strong correlation with stature.

The simple regression equations were tested using a separate dataset consisting of 94 individuals from the William M. Bass Donated Collection for which both cranial measurements and stature information (either self-reported or measured) are available. Stature ranges were developed from 95% confidence intervals calculated using the method by Giles and Klepinger.[5] Actual stature for these individuals fell within the calculated stature range for their respective regression equations 91%-97% of the time, but the calculated stature ranges for all individuals were very broad (±14-20cm). When individuals were tested using equations from groups other than their own, method accuracy dropped dramatically (41%-60%). The results of this study indicate that stature can be estimated using cranial measurements as long as the sex of the individual has been correctly assessed; however, this method produces broad stature ranges and should only be used if no other suitable skeletal elements are present.

Stature Estimation, Cranial Measurements, Linear Regression

A18 Histological Variables at Multiple Locations and the Effect on Age Estimation

Victoria M. Dominguez, MA, The Ohio State University, Skeletal Biology Research Lab, Columbus, OH 43210; Nicole M. Crowe, BS, The Ohio State University, 1645 Neil Avenue, 279 Hamilton Hall, Columbus, OH 43201; Angela L. Harden, MA, 5445E Briardale Lane, Dublin, OH 43016; and Amanda M. Agnew, PhD, The Ohio State University, 306 Atwell Hall, 453 W 10th Avenue, Columbus, OH 43210*

After attending this presentation, attendees will: (1) appreciate the importance of sampling location in the human rib for accurate results utilizing histological age methods; and, (2) understand how differences in bone remodeling along the length of the rib may help or hinder successful application of rib aging methods.

This presentation will impact the forensic science community by demonstrating the need for in-depth analysis of the variance of histological structures. Increased understanding of the rib's bone biology will serve to improve sampling procedures and accuracy of histological aging methods.

Current histological methods for estimating adult age at death were developed exclusively from cross sections of the mid-shaft sixth rib; however, in forensic practice, it is not uncommon for histological samples to come from fragmented or previously segmented ribs, leading to uncertainty of sampling location.[1,2] The potential for error increases when the sampling location on the rib is uncertain and utilizing a section beyond the mid-shaft (either anterior or posterior) may result in erroneous age estimates.

Additionally, Frost recommended a minimum of 50mm^2 of cortical bone be read when assessing skeletal remodeling, which has resulted in the common practice of reading two to three serial sections in the ribs and averaging the results to account for local variation.[3] Problems have arisen when there is not enough bone to create or insufficient time to properly analyze multiple serial sections. This study sought to determine the importance of the mid-shaft distinction for age assessment by analyzing histological variables at multiple sampling locations along the length of the rib.

Histological sections were obtained from a single left or right sixth rib from five male postmortem human subjects (82-90 years, *Standard Deviation* (*SD)*=6.24 years). Three seriated sections were taken from each of three locations, posterior (25%), middle (50%), and anterior (75%), resulting in a total of nine sections from each individual (45 sections in total). All slides were imaged at 100x magnification and observed on the microscope using bright field and polarized light at 200x magnification. The following histological variables were quantified and analyzed: (1) Osteon Population Density (OPD): $[OPD_{(Intact)} + OPD_{(Fragmentary)}]$/Ct.Ar; and (2) Cortical Area (Ct.Ar.) per mm^2.

Ct.Ar was manually traced and measured from still images using a digitizing tablet in ImageJ software, while OPD was collected live from the microscope. Statistical analyses were performed using Statistical Package for the Social Sciences (SPSS) 24.

Serial sections were compared using a repeated measures Analysis Of Variance (ANOVA), which revealed no significant differences between Ct.Ar or OPD in any of the serial sections at the three locations. For the location comparisons, paired *t*-tests were used to examine OPD and Ct.Ar. at the anterior, middle, and posterior sites. Preliminary results indicate that OPD does not differ significantly between the anterior and middle locations (p=0.762) or between the anterior and posterior locations (p=0.131), although the middle and posterior locations are significantly different (p=0.05). Results for Ct.Ar revealed that there are significant differences between all three locations (anterior-middle: $p < 0.001$, anterior-posterior: $p < 0.001$, and middle-posterior: p=0.002).

Overall, results indicate that there is no significant difference in OPD and Ct.Ar between serial sections; however, significant differences exist between location sections for all variables analyzed. Due to histology's two-dimensional approach to bone, a three-dimensional structure, the absence of significant differences in the observed variables between serial sections is not surprising. Significant differences in Ct.Ar. at all locations reflect variation in the loading environment along the length of the rib. Though Ct.Ar. differences between the anterior and middle sites are significant, they are small by comparison to the differences between either of those locations and the posterior section. This may explain the observed trend of a lower OPD in the posterior sections than in the other locations.

These results suggest that it may be possible to obtain accurate age estimates using only one slide, rather than averaging multiple serial sections. Furthermore, these results indicate the importance of a mid-shaft location in histological age estimation; however, if the sampling location is uncertain, a more anterior section should be taken, as the histomorphology of the anterior rib is more consistent with that of mid-shaft. Future studies should explore Ct.Ar. and OPD in a more diverse sex and age sample to determine if the pattern observed in this study is consistent throughout the population.

A19 Using Structure From Motion Photogrammetry to Quantify Volume Gain and Loss During the Human Decomposition Process

Kathleen Flor-Stagnato, BA, 225 Craddock Avenue, Apt C, San Marcos, TX 78666; Susan Sincerbox, BS*, 625 Creekside Way, Apt 1246, New Braunfels, TX 78130; and Nicholas P. Herrmann, PhD, Texas State University, Dept of Anthropology, 266 ELA, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will better understand the basics of using photogrammetry to quantify volume gain and loss in human cadavers. Additionally, attendees will understand the typical decomposition process for human remains in central Texas.

This presentation will impact the forensic science community by presenting a new method that can be used to quantify volume gain and loss during human decomposition. Quantifying general trends (i.e., bloat) with respect to influential variables (i.e., body size and ambient temperature) will assist in producing more precise reconstructions of the progression of human decomposition, promoting accuracy and precision of postmortem interval estimates.

This research investigates the use of Structure from Motion (SfM), a type of digital photogrammetry that creates 3D models from photographs, for estimating the total body volume of individuals in the fresh, bloated, and post-bloated stages of decomposition. This project seeks to quantify parameters of volume gained during bloat and lost following collapse of the abdominal cavity to better understand how the progression of early decomposition events is affected by ambient temperature, as measured by Accumulated Degree Days (ADD), and body size.

This project utilized ten human cadavers procured through the Forensic Anthropology Center at Texas State's Willed Body Donation Program. Donor bodies were excluded from the study if the donor was being treated with chemotherapy prior to death, if the donation was not in the fresh stage of decomposition at the time of placement at the Forensic Anthropology Research Facility, if the donation was autopsied or presented with significant thoracic trauma, or if tissue samples were harvested from the donation for concurrent projects during the period of study. These criteria were selected so that the entire bloat process could be observed and to ensure that bloat proceeded "naturally" by minimizing potential antemortem disruption of the microbiome and preventing gas and fluid loss through autopsy or traumatic injury sites. After placement, donations were monitored daily. Flexible fiberglass tape measures placed under the body were used to monitor the circumference of the neck, chest, and abdomen. The presence of bloat indicators (e.g., protrusion of the tongue, inflation of the scrotum, and swelling of the head and neck) and purge occurrence and location were noted.

Three SfM models of the cadavers were created; one on the initial date of placement, one during the three days encompassing the period of maximum bloat as determined by the cadaveric measurements, and one after the collapse of the abdominal cavity. Photographs were taken using an Olympus® OM-D EM-5 Mark II 16-megapixel camera, on manual settings. Two different photograph collection methods were used to ensure proper camera calibration in Agisoft PhotoScan™. First, a "flat" project was completed by taking photos parallel to the ground surface and the body being photographed. Subsequently, a "dome" project was completed to ensure that the entire surface of the individual was collected completely. The photographs for the dome project were collected by moving around the individual, taking photos at four elevations. These elevations were approximately 6 feet, 5 feet, 3 feet, and .5 feet from the ground surface. Overlap of at least 66% between each photograph for the dome project was ensured by moving no more than 30 degrees between each photo station.

Photos were processed and optimized in Agisoft PhotoScan™ software, which was also used to measure the volume of each model. The model was scaled using ground control points shot in with a total station, which were placed near the head, hands, and feet of each individual. Percentage increase from the date of placement to the date of maximum bloat was calculated for all physical circumferences and model-generated volume for each donation to account for variation in initial body size. Tukey mean-difference plots were then constructed in R to assess agreement between methods, comparing the change in each circumference to the corresponding change in volume. ADD to maximum bloat and abdominal collapse, determined using physical measurements and volumes, were calculated using temperature data collected from an on-site weather station. Frequency distributions were constructed and descriptive statistics calculated for each group to describe the central tendency and dispersal of the data. ADD was also regressed against percentage change in physical measurements to determine how much variation in bloat is explained by temperature. Additional statistical methods may be employed as needed.

This project will contribute detailed quantitative data on variation in bloat, which is influenced by characteristics of both the individual and the immediate environment, and add to the body of knowledge about the decomposition of human remains. Postmortem interval estimation is a critical component of medicolegal death investigations, as it can aid in narrowing a list of missing persons and facilitating identification.

Photogrammetry, Decomposition, PMI

A20 The Use of the Mandibular Symphysis for Estimating Ancestry

Ginesse A. Listi, PhD, LSU Geography & Anthropology, 227 Howe-Russell Bldg, Baton Rouge, LA 70803*

After attending this presentation, attendees will understand whether or not metric variation in the mandibular symphysis can be used to estimate ancestry in unidentified skeletal remains.

This presentation will impact the forensic science community by exploring a new metric method in the mandible for estimating ancestry from unidentified skeletal remains.

Maxillary prognathism is one of a suite of traits in the cranium that can be useful for differentiating between Sub-Saharan African and European ancestries in unidentified skeletal remains ("Black" and "White" individuals, respectively). While various metric and morphoscopic traits in the mandible also have been assessed for ancestry estimation, the projection of the mandibular symphysis that corresponds to maxillary prognathism has not been evaluated. Morphologically, this projection would include the area encompassing the anterior alveolar border, the incisive fossa, and the mental protuberance. This study assesses this projection for its potential in ancestry estimation using dimensions of the mandibular symphysis as a proxy.

Data were collected from 597 mandibles from the Terry Collection; 167 were measured twice to test for intraobserver error. Sliding calipers were used to take three measurements of the mandibular symphysis in the sagittal plane. Measurement endpoints included: infradentale prime, defined as the midpoint of a line tangential to the anterior-most projection of the alveolar processes of the central incisors; deep fossa, the posterior-most indention of the incisive fossa; and pogonion. Measurements consisted of: X, the distance from infradentale prime to deep fossa; Y, from infradentale prime to pogonion; and Z, from deep fossa to pogonion. Because endpoints are Type II landmarks prone to subjectivity, each measurement was taken three times per mandible, and the average was recorded.

A random sample of 75 individuals from each demographic group (Black and White, males and females) was selected for statistical analysis (N=300). Intraobserver error for each measurement was assessed on a random sample (n=63) using a paired t-test. None of the measurements exhibited significant differences (a=.05); therefore, all measurements were used in subsequent calculations and statistical analyses.

In addition to measurements, two indices and the incisive fossa angle were calculated to further explore symphyseal morphological variation. The indices included the "Symphyseal Index," derived by the formula $I_{symphysis}$=x/z, and the "Z index," derived by I_z=z/y. The incisive fossa angle was calculated using the inverse cosine function: A_{sulcus}=arccos $[(x^2+z^2-y^2)/2xz]$. Statistical analyses (Students' t-tests, linear regression) were used to assess variation in the measurements, indices, and incisive fossa angle between the sexes and ancestry groups. For all tests, significance was determined if p <05.

Results of the t-tests reveal significant differences between the sexes for two out of three measurements (Y: t=5.674, p=.000; Z: t=6.219, p=.000); therefore, subsequent statistical analyses were conducted with the sexes separated. For males, significant differences were found between Black and White individuals in four of six variables: X (t=-8.153, p=.000), Y (t=-4.626, p=.000), $I_{symphysis}$ (t=-6.793, p=.000), and I_z (t=7.665, p=.000). For females, all variables revealed significant ancestry differences: X (t=-6.843, p=.000), Y (t=-6.424, p=.000), Z (t=-2.389, p=.018), $I_{symphysis}$ (t=-4.958, p=.000), I_z (t=5.635, p=.000), and A_{sulcus} (t=2.416, p=.017).

Regression analyses show similar results. For males, the same four variables are significant (X, Y, $I_{symphysis}$, and I_z): adjusted R-squares are .305, .120, .233, and .279, respectively. For females, all variables are significant: adjusted R-squares are .235, .213, .031, .137, .171, .033 for X, Y, X, $I_{symphysis}$, I_z, and A_{sulcus}, respectively.

This study demonstrates that a relationship exists between the dimensions of the mandibular symphysis and both sex and ancestry. Sex differences are not unexpected. A larger mental protuberance impacts pogonion, thus affecting all variables except X, and possibly accounting for the stronger predictive values of these variables in males. For ancestry, the superior portion of the symphysis (X) shows the strongest relationship in both males and females, followed by I_z, which represents the proportion of the lower symphysis to the entire symphyseal length; however, despite the association to ancestry, results indicate that simple linear measurements do not adequately capture symphyseal variation to the extent needed for prediction. Future analyses that use geometric morphometrics to quantify symphyseal curvature may yield better predictive results that can be used in forensic contexts.

Ancestry Estimation, Mandible, Forensic Anthropology

A21 Scavenging Patterns in Hawaii: An Archaeological and Skeletal Case Study

Robert Kalani Carreira, BA, University of Hawaii - West O'ahu, 91-1001 Farrington Highway, Kapolei, HI 96707; Jennifer F. Byrnes, PhD, University of Hawaii - West O'ahu, 91-1001 Farrington Highway, Kapolei, HI 96707; and William R. Belcher, PhD, University of Hawaii - West O'ahu, 91-1001 Farrington Highway, Kapolei, HI 96707*

After attending this presentation, attendees will better understand the taphonomic processes associated with specific scavenging behavior.

This presentation will impact the forensic science community by providing vital insights into the complexities of scavenging patterns to assist in executing a forensic recovery and analysis of skeletal material.

The current state of taphonomic research in Hawaii, specifically related to mammalian fauna, is minimal, at best. The remains of an unidentified decedent were discovered on the surface of a forensic site, necessitating archaeological recovery methods on the island of Kauai. This investigation and recovery operation provided an opportunity to examine a specific case of scavenging activities and reconstruct the depositional history within the context of a natural setting.

An archaeological recovery was performed by conducting a pedestrian survey of the adjacent areas surrounding the majority of the skeletal remains. Azimuth mapping techniques were used to record the recovered skeletal remains and non-osseous evidence. Visible pig trails transecting the recovery site were also documented using Global Positioning System (GPS) track recording. All materials were collected in accordance with crime scene protocols. In a laboratory setting, peri-mortem and postmortem alterations to skeletal elements were observed and recorded by gross examination in conjunction with microscopic magnification of bone surfaces.

Skeletal elements from the lower spine, left lower limb, and sternum were found to be dispersed in a broad, patterned distribution, extending as far as 24m from the primary concentration of skeletal material. Skeletal analyses revealed evidence of pits, punctures, furrows, crushing, and scoring over many of the bone surfaces. Multiple areas of bone reduction were also observed, in conjunction with previously mentioned trauma. Peri-mortem and postmortem alterations were primarily concentrated at proximal and/or distal ends of long bones, in addition to peripheral margins of flat and/or irregular bones. The majority of the unrecovered skeletal elements consisted of ribs, small bones of the hands and feet, and some vertebral segments.

Feral, domesticated pig (*Sus scrofa*) trails transecting various areas of the recovery site correspond with the distribution pattern of recovered material, including both the main concentration and more broadly disbursed skeletal elements. Elements of unrecovered/missing skeletal material are consistent with previously recorded observations found in literature on mammalian scavenging patterns. Much of the peri-mortem and postmortem bone deformations analyzed were characteristic of tooth marks associated with both canid and suid (pig) scavenging. Pit, puncture, and scoring marks located on the superior region of the right scapula and anterior surfaces of the right calcaneus and cuboid are consistent with marks left by the canine and carnassial teeth of a canid. Crushing marks made by opposing teeth found on rib fragments, in addition to broad linear punctures and deep furrows found on the epiphyseal ends of the left femur, are consistent with scavenging patterns of suid. Other trauma, while consistent with tooth marks left by scavengers, could not be specifically assigned to an animal family. Recovery of a nearly complete piglet skeleton further suggests this area was important ground for local suid sounders.

Knowledge of the local fauna is often vital to the success of a forensic recovery. Knowing and understanding faunal scavenging patterns that potentially and often contribute to the formation of a site can aid the investigator in predicting and recognizing distribution patterns of material. In addition, this knowledge can be key in assisting the investigator with the forensic analysis of peri-mortem and postmortem changes to the skeletal elements.

Forensic Anthropology, Taphonomy, Hawaii

A22 Anatomy and Biological Anthropology: Time for a Family Reunion?

Natalie R. Langley, PhD, Mayo Clinic School of Medicine, Dept of Anatomy, 13400 E Shea Boulevard, SC-AB-01-313B, Scottsdale, AZ 85259; and Lauren Butaric, PhD, Des Moines University, 3200 Grand Avenue, Des Moines, IA 50312*

The goal of this presentation is to acquaint attendees with the academic history of anatomy and biological anthropology in the United States and the nature of anatomy education among biological anthropology graduates. The results of a survey regarding anatomy education, training, and teaching experience among biological anthropology graduates will be discussed.

This presentation will impact the forensic science community by increasing awareness of biological anthropologists' educational training and competencies in the anatomical sciences (anatomy, histology, neuroanatomy, and osteology).

Biological anthropology and anatomy are separate degree programs today, but they share an integrated past. This academic history can be traced to Harvard, where George Dorsey graduated with the first PhD in anthropology in the United States, having received much of his training and mentorship from anatomists. In 1928, at the anthropology section meeting of the American Association for the Advancement of Science, Ales Hrdlička proposed the formation of a new professional society in physical anthropology, and the American Association of Physical Anthropologists (AAPA) was born. Two years later, the first meeting of the AAPA was held in Charlottesville, VA, in conjunction with the American Association of Anatomists annual meeting. More than 50% of founding members were anatomists and physicians, while only eight members were anthropologists. Biological anthropology programs gradually separated from anatomy departments to join the cultural, archaeological, and linguistic fields, following Boas' four-field approach. This movement of physical anthropology programs out of anatomy departments and into anthropology departments changed the foundational education of many physical anthropologists. Today, training varies depending on educational paths and research interests. Still, biological anthropologists increasingly fill faculty positions in non-anthropology departments, including anatomy faculties at medical schools and health sciences education programs, as well as applied positions in medical examiners' offices and government agencies. This study investigated anatomical sciences among biological anthropology master's and doctoral graduates and its implications for career paths.

A 22-question anonymous online survey was administered to biological anthropologists who obtained, or are in the process of obtaining, a graduate degree (Institutional Review Board (IRB) Application #17-001956, determined to be exempt from the requirement for IRB approval (45 CFR 46.101b, item 2) by the Mayo Clinic Internal Review Board). The survey was distributed to potential participants via several email listservs, including the Anthropology Section of the American Academy of Forensic Sciences. Questions surveyed anatomy education and training, graduate teaching experience in the anatomical sciences, the relevance of anatomy education to current and future career and research pursuits, and opinions regarding the need for anatomy training among biological anthropology graduates.

The 305 survey respondents were mostly anthropology graduates, and the majority had PhDs (88% anthropologists; 58% PhDs). The majority of the survey respondents obtained their degrees in the United States (65% of PhD and 75% of master's degree respondents). Europe, Canada, Central and South America, Asia, and Australia were also represented. Fifty-eight percent work/attend school in anthropology/social sciences departments, 16% in anatomy departments, and 5% in biology departments. Most were employed at research universities (65%); 24% reported teaching responsibilities in health sciences programs (medical, dental, and/or allied health professions programs). The majority (72%) of employed respondents consider anatomy knowledge essential to their current position. Sixty-seven percent report that it is relevant to their teaching load, and 72% consider it relevant to their research. Only 36% of PhDs reported that anatomy was/is a *required* course, but 72% of PhD graduates took an anatomy course (63% took gross anatomy with cadaveric dissection). Fewer graduates took histology, embryology, or neuroscience courses, as these are rarely required to obtain a graduate degree in anthropology and are not necessary for the career paths pursued by most graduates. Most respondents (76%) agreed that an anatomy course should be required in biological anthropology graduate programs; 49% agreed that anatomy should be offered as an elective, but not required. Nearly all (94%) respondents reported feeling that their educational training adequately prepared them to teach human osteology. Nearly half (49%) of the respondents reported feeling adequately prepared to teach gross anatomy with or without cadaveric dissection.

Responses indicate biological anthropologists still value, seek, and receive anatomy training, making these graduates uniquely suited to positions requiring an anatomical knowledge base and skillset; however, the nature and amount of anatomy training varies depending on educational paths and career interests.

Anatomy, Biological Anthropology, Survey

A23 The Forensic Application of Skeletal Stress Indicators: A Correlation Study of Linear Enamel Hypoplasia (LEH), Harris Lines, Cortical Bone Loss (CBL), and Stature

Justin Goldstein, MA, 108 Ludlow Street, Apt 3B, New York, NY 10002*

After attending this presentation, attendees will understand how the analysis of multiple skeletal stress indicators can be simultaneously incorporated into forensic biological profiles.

This presentation will impact the forensic science community by expanding upon current studies of skeletal stress by addressing unresolved questions concerning the differences between manifestations of skeletal stress in recent, forensic populations versus in more traditional studies of prehistoric populations. Understanding the relationship between LEH and other postcranial stress pathologies in recent populations would help forensic anthropologists gain a more comprehensive foundation for incorporating skeletal stress into biological profiles. This research uses data obtained from the Hamann-Todd skeletal collection, which can be used as a proxy for recent, forensically relevant populations.

Skeletal stress indicators have provided important bioarchaeological insights into prehistoric populations, but are rarely used in forensic contexts. Incorporating LEH — a readily visible, non-specific indicator of stress — into current forensic biological profiles has proved a promising method for identifying and repatriating the remains of undocumented migrants in Southern Arizona; however, the relationship between LEH and other postcranial stress markers is unknown.[1] Harris lines, a postcranial indicator of stress associated with LEH in prehistoric remains, may be equally useful in this effort since both LEH and Harris lines can be linked to nutritional stress events during life; however, current studies focusing on correlations between Harris lines and LEH have been conducted on prehistoric populations rather than contemporary populations and yield mixed results.[2-7] Work on prehistoric samples also associates Harris lines with CBL and stunted stature within stressed populations.[4] In Neolithic contexts, these stress indicators have been associated with periods of agricultural transition, but analogous lifestyle changes are not seen in forensically relevant populations today.[8]

This study, therefore, considers the relationships between LEH, Harris lines, CBL, and stunted stature in the Hamann-Todd collection, a recent (1900s) skeletal population. One hundred twenty-five individuals (74 males and 51 females) ranging in age from 1-72 years were scored for LEH. Known statures provided by the Hamann-Todd collection were recorded, and tibiae from all individuals were radiographed and assessed for the presence of Harris lines. Cortical bone thickness was measured as a percentage of total bone width at the midshaft of each tibia using the same radiographs. All measurements were then recoded into binary to denote the presence ("1") and absence ("0") of skeletal stress. LEH and Harris lines were recoded based on the visual assessments. Stature and CBL were respectively recoded by plotting residuals for each age group and identifying outliers more than two standard deviations away from each group's mean. Multiple regression models and correlation analyses were run on the entire dataset as well as on each defined age group. Unlike previous studies on these indicators in prehistoric contexts, sex differences in trait correlations were also considered.

Results suggest that future studies should consider the interaction between these measures histologically at higher resolutions. Based on the intertrait correlations produced between Harris lines and cortical bone thinning (ranging across current age groups from -0.289 to -0.559), this study tentatively supports the hypothesis that Harris lines may be more indicative of periods of increased growth velocities rather than periods of malnourishment and arrested growth. Future forensic work on skeletal stress should incorporate histological measures of cortical bone. No significant differences in trait expression were found based on sex (p=0.260). Additional results from the same data condensed into new age groups (0-18 years, 19-34 years, 35-49 years, and 50+ years) are pending.

In conclusion, this study finds that incorporating non-specific stress indicators into forensic analyses requires the independent consideration of traits coupled with an in-depth analysis of life history events. While not practical for all forensic case work, this approach may aid the identification and repatriation of individuals with sparse antemortem data, such as undocumented migrants or long-unidentified individuals.

Linear Enamel Hypoplasia, Skeletal Stress, Cortical Bone

A24 The Use of High-Resolution Micro-Computed Tomography (micro-CT) for Quantifying Vascular Pore Networks Across Whole Cross Sections of Human Cortical Bone

Mary E. Cole, MA, Ohio State University, Dept of Anthropology, 4034 Smith Laboratory, 174 W 18th Avenue, Columbus, OH 43210-1106; and Sam D. Stout, PhD, Ohio State University, Dept of Anthropology, 4034 Smith Laboratory, 174 W 18th Avenue, Columbus, OH 43210-1106*

After attending this presentation, attendees will appreciate how regional patterns of cortical bone loss may be visualized and quantified in 3D space using high-resolution micro-CT.

This presentation will impact the forensic science community by demonstrating that high-resolution micro-CT facilitates extraction of vascular pore networks from within complete, thick cross sections of human bone tissue. Tracking how vascular pore structures accumulate and expand across the human lifespan has future forensic applications, including: (1) assessing whether porosity-related bone fragility could have played a role in an accidental or non-accidental fracture; and, (2) distinguishing fragments of bone types based on pore structure, which appears to be sensitive to age, strain mode, fragility, and human/non-human origin.

Bone remodeling takes place throughout life but declines with age. Osteoclast cells tunnel into old or damaged bone and osteoblast cells fill this tunnel with new bone, leaving a central pore to conduct a blood vessel. Osteoblasts' capacity for bone formation slows with age. They cannot keep pace in filling the resorbed spaces, which accumulate as large pores. Lowered mechanical strains trigger further resorption to expand and connect existing pores. Vascular pores concentrate stress, providing a target for microscopic damage to initiate and propagate into a spontaneous fracture.

Research into pore structure has been limited in either axial or lateral dimensions. Two-dimensional histological sections of bone can describe how pore cross sections, but not their three-dimensional structures, vary between regions of bone tissue. High-resolution three-dimensional imaging often limits the specimen dimensions laterally (e.g., synchrotron X-ray imaging) or axially (e.g., confocal laser scanning microscopy). This research implements three-dimensional vascular pore visualization of a whole cross section of a human rib with high-resolution micro-CT.

The sample chosen for this pilot study was a fresh cadaveric fourth right-side rib from a 72-year-old female. In order to fit within a single field of view in the scanner at an approximate resolution of 5µm, a midshaft segment of the rib was cut to 1cm and further quartered along its medial, lateral, superior, and inferior long axes. These rib segments were scanned in air using a SkyScan 1172-D High Resolution Desktop Micro-CT with source voltage of 59kV, camera pixel size of 8.87µm, and voxel size of 4.88µm. In Avizo Fire 8.1, the four rib segments were geometrically transformed to their original positions, extracted and united using the Segmentation Editor, then exported as an image sequence of cross sections. In ImageJ, the Slice Geometry plugin of BoneJ was used to annotate each cross section with the major axis, which divides the cutaneous (skin-side, low-strain) and pleural (lung-side, high-strain) regions of the rib.[1,2] Cross sections were imported back into Avizo Fire 8.1, where the major axis guided the creation of masks for these regions to extract them independently. Vascular pore structures were extracted from each region in the Segmentation Editor, then exported as cross sections.

The Analyze Particles tool in ImageJ was used to calculate pore number and area for each cross section, mirroring analysis of two-dimensional cross sections. The pleural region (high strain) had fewer (mean=52+/-5.4, range=31 to 71) but larger pores (mean=0.0074+/-0.0029mm^2, range=0.0030 to 0.020mm^2). The cutaneous region (low strain) had more numerous (mean=85+/-6.7, range=66 to 103) but smaller pores (mean=0.0046+/-0.0022mm^2, range=0.002 to 0.011mm^2). Both regions had similar total pore areas (pleural mean=0.387+/-0.161mm^2, range=0.159 to 1.036mm^2; cutaneous mean=0.392+/-0.196mm^2, range=0.171 to 0.915mm^2). The Analyze Particles plugin of BoneJ was used to extract pore volumes.[1] Again, the pleural region had fewer (2,923) but larger volume (mean=0.00247+/-0.0272mm^3, range=2.79x10^{-6} to 0.956mm^3) pores compared to the cutaneous region's more numerous (5,841) but smaller volume pores (mean=0.00125+/-0.0222mm^3, range=2.79x10^{-6} to 1.343mm^3).

High-resolution micro-CT is an accessible and effective technology for three-dimensional imaging of vascular pore structures across whole, thick cross sectional regions. These preliminary results suggest using this technology for further investigation into trade-offs between pore volume and number that are sensitive to strain mode during life.

Skeletal Histology, Three-Dimensional Imaging, High-Resolution MicroCT

A25 The Effect of Cranium Orientation on Positive Identification Using Frontal Sinus Radiographs

Alyssa R. Harrison, BS, Mercyhurst University, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand the effect that variations in angle between antemortem and postmortem radiographs have on positive identification using the frontal sinus. This presentation will also outline the appropriate orientation for taking postmortem radiographs of the cranium for comparison to antemortem radiographs.

This presentation will impact the forensic science community by determining the margin of error for skull positioning to ensure positive identification using the frontal sinus, adding to the research previously conducted on courtroom admissibility. Furthermore, this presentation reinforces the standard orientation for postmortem radiographs of the skull as utilized by forensic radiologists and anthropologists.

Although many forensic disciplines have come to accept the qualitative analysis of frontal sinus outlines as an appropriate means of identification, these methods do not meet current evidence admissibility standards. Efforts have been made within recent years to update and improve frontal sinus methods to meet admissibility guidelines by empirically testing their uniqueness and developing more quantitative methods, but there are still many sources of potential error that have yet to be thoroughly examined. A study by Silva et al. began addressing the potential error that variations in angle between antemortem and postmortem radiographs have on the comparison of frontal sinus shapes; however, the quantitative methodology utilized by Christensen, using Elliptic Fourier Analysis (EFA), was not addressed in the Silva et al. study.[1-3] This study sought to evaluate how different angulations in cranial orientations during radiography may introduce variation in frontal sinus shape as interpreted from two-dimensional X-ray images and how these variations may affect positive identification results when Christensen's EFA methodology is applied.

This research utilized 16 crania from the Mercyhurst University Donated Skeletal Collection. The crania were radiographed 18 times each at five-degree increments in both the vertical and horizontal planes, resulting in a total sample of 288 radiographs. The frontal sinus outlines from these radiographs were then traced in Photoshop® and analyzed using EFA and principal components analysis. Euclidean distances were calculated from principal component scores within individuals and between individuals to test whether an individual's frontal sinus could be matched regardless of orientation during radiography. A logistic regression model was created to determine the probability of an individual's frontal sinus outlines matching.

Observability of frontal sinuses was affected by as little as five degrees in some individuals. The mean of the Euclidean distances from within individuals was smaller than the mean from between individuals with a statistically significant difference between the means ($p < 0.001$). The logistic regression model indicated that the highest posterior probability was only 80%, even when two of the sinus outlines matched exactly in shape space (Euclidean distance of 0). These results suggest the logistic regression model has a real, but limited, discrimination between matches and non-matches. Posterior probabilities greater than 0.5 were considered as matching; only 66% of the sample was correctly classified as matching or non-matching using the logistic regression equation.

Overall, these results suggest that orientation during radiography can have a significant impact on the accuracy and reliability of frontal sinus comparisons for positive identification. As such, it is important for both clinicians and forensic radiologists and anthropologists to pay close attention to the positioning of the skull during radiographs to ensure minimal variation in orientation. This orientation requires that postmortem radiographs be taken with the orbitomeatal line (from the upper margin of the external auditory meatus to nasion) perpendicular to the X-ray film in order to most accurately match the orientation utilized by clinicians during antemortem radiographs.

Positive Identification, Frontal Sinus, Admissibility

A26 A Study on the Asymmetry Between the Left and Right Human Pubic Symphysis for Age-at-Death Estimation Based on 3D Laser Scans and Computational Methods

Detelina Stoyanova, PhD, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306-4120; Bridget F.B. Algee-Hewitt, PhD, Stanford University, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020; Jieun Kim, PhD, 24 E Liberty Street, Apt 45, Savannah, GA 31401; and Dennis E. Slice, PhD, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306-4120*

The goal of this presentation is to investigate how asymmetry observed between the left and right pubic symphyseal surfaces of one individual affect the accuracy of age-at-death estimates produced by the use of novel techniques involving 3D laser scans and computational algorithms.

This presentation will impact the forensic science community by demonstrating that an accurate and reliable age-at-death estimation can be achieved with either the left or right human pubic symphysis, independent of individual factors that are potentially unknown to the forensic investigator, such as the weight or stature of the person in question. Attendees will be presented with a number of the many advantages that modern laser scanning technology has to offer to the field of forensic anthropology. Particularly, attendees will be familiarized with new computational techniques used for age-at-death estimation from the adult skeleton and show how, with these methods, they can produce accurate and reliable age estimates even in cases when one pubic symphyseal surface is missing or damaged.

There is a well-established tradition of using the human pubic symphysis for age-at-death estimation.[1] Therefore, anthropologists have devoted considerable effort to refining and improving the methodology.[2-4] In recent years, there has been a growing interest to better understand, capture, and quantify the link between the morphology of the symphyseal surface and age.[5,6] The currently accepted practice for age-at-death estimation using the pubic symphysis is based on the visual inspection of the skeletal element and its comparison to images, casts, and/or written descriptions that are associated with pre-defined age intervals. Such methodologies are relatively easy to apply but are prone to high interobserver and intraobserver error as they are highly dependent on the scientists' experience and expectations.[7] With the advancement of current data acquisition and analytic technologies, researchers have begun to look for new ways to study age indicator morphology and infer chronological age. Most recently, new methods for age-at-death estimation of the pubic symphysis have been developed that use 3D laser scan data and computational methods that seek to eliminate the element of subjectivity in estimation.[8-10] The methods include two surface analysis algorithms, one ventral outline measure, and two multivariate-regression models that combine each surface measure with the outline score. These models were calibrated on 3D scans of left or right pubic symphysis selected at random. These new computational methods have been shown to be at least as accurate and reliable as the traditional techniques and have the potential to allow for better understanding of the morphology of the symphyseal surface.

This study further investigates the utility of these methods by focusing on the issue of asymmetry. Data was generated from 88 White males with known ages at death, for whom both the left and right pubic symphysis were scanned; the three measures and five age estimates were produced using the aforementioned computational algorithms and the accuracy of the age estimate produced by each side was analyzed. The effect of the individuals' height, weight, and calculated body mass index must be taken into consideration. The results demonstrated that both sides are equally reliable in estimating the age at death of the individual. Neither side proved to be consistently less accurate. Further, regression models were built using only left or only right scans to demonstrate that neither side models the age-progressive changes better than the other. Overall, the difference in age estimates between the left and right estimates are less than five years for more than half of the data and nearly all estimates are less than 15 years apart. For individuals with notably asymmetric sides, the difference in estimates was not associated with advanced age, weight, height, or body mass index. The findings indicate that in situations in which one side of the pubic symphysis is damaged or missing, the side that is available can be used with the same level of confidence. Further, the fact that the computational algorithms produce consistent results regardless of the weight and stature of the individual means that scientists can apply these techniques to casework situations when no soft-tissue or personal life history information is available.

Pubic Symphysis Asymmetry, Age-At-Death Estimation, Computational Methods

A27 Preauricular Sulcus (PAS) and Parity Status: A Possible Correlation? A Test on a Documented British Collection

Sarah E. Canty, BSc, Liverpool John Moores University, James Parsons Bldg, Byrom Street, Liverpool, Wiltshire L3 3AF, UNITED KINGDOM; Matteo Borrini, PhD*, Liverpool John Moores University, School of Natural Science & Psychology, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM; Constantine Eliopoulos, PhD, Liverpool John Moores University, School of Natural Science & Psychology, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Silvia Gonzalez, PhD, Liverpool John Moores University, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will better understand the correlation between the PAS and parity status in humans.

This presentation will impact the forensic science community by providing further tests on the use of PAS morphology to examine parity status.

At previous AAFS Annual Scientific Meetings, a new grading system was presented to assess the morphology of the preauricular sulcus and examine its link to both parity status and sex. The grading system has five grades ranging from 0 (no PAS present) to a grade 4 (a deep, pitted sulcus). The grading system focuses on the changes in depth rather than the size or shape of the PAS. The system was developed using two British medieval populations. Although these populations were undocumented, they had previously been aged and sexed by both researchers and other forensic anthropologists using established methods and techniques.

This study presents a new test of the grading system on a documented modern British collection, the Spitalfields Collection at the Natural History Museum (London). A sample of 78 female individuals were selected; the parity statuses for all the individuals has been reconstructed using archival records and coffin plates.

The results confirmed the previous tests on the historical populations: the majority of the individuals (all female) present a PAS, 93%, supporting the use of the PAS as a sexual indicator. In addition, grade 1 is present in 16% of the sample, grade 2 in 29%, grade 3 in 33% and grade 4 in 15%.

The parity status of the individuals was also analyzed in correlation with the grading system; however, in this sample, no correlation between grade and parity status was found, despite previous analysis on another modern British collection of 35 individuals from St. Bride's Church, (curated through the Museum of London) where a correlation was observed.

The two populations are from a similar temporal and geographical period, and the differences between the results provide an interesting aspect to the discussion of the effect of parity status on the PAS.

Although the two collections present differences in the parity status/PAS correlation, they agreed on the sexual dimorphism of the sulcus, present in 98% of the females. For the St. Bride's collection, male individuals have also been examined (n=183), and it was demonstrated that only 51% had a PAS and no grade 3 or 4 sulci were found.

Although these two collections exhibit a discrepancy over the effects of parity status on the PAS, the study confirms that this anatomical trait is sexually dimorphic and can be used as an indicator of sex for biological profiling. Furthermore, this study demonstrated the reliability of the new PAS grading system as a tool for biological profiling in both forensic and archaeological cases.

Biological Anthropology, Parturition, Parity Status

A28 Forensic Fractography of Bone: A New Approach to Skeletal Trauma Analysis

Angi M. Christensen, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824; Michael A. Smith, PhD, 2501 Investigation Parkway, Chemistry Unit, Quantico, VA 22135; Jodi Blakely Webb, MS, FBI Laboratory, 2501 Investigtation Parkway, Quantico, VA 22135; Maureen Bottrell, MS, FBI Laboratory, Trace Evidence Unit, Quantico, VA 22135; and Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with how fractography can be used to assess skeletal fractures in forensic anthropological trauma analysis, increasing the accuracy of trauma interpretations.

This presentation will impact the forensic science community by enhancing the analysis of skeletal trauma using a new method of fracture examination that is reliable, easy, and inexpensive.

Fractography is the study of fracture surface characteristics and their relationship to crack propagation. This science is routinely used in forensic examinations of materials such as glass, ceramics, metals, and plastics to identify the initiation point and nature of the material's failure. Fracture surfaces of brittle materials typically display features reflecting the speed and stability of the propagating crack front. Generally, crack initiation sites are relatively featureless, becoming more featured with increasing crack speed and instability. These changes can be seen as arrangements of ridges and lines with specific orientations with respect to the moving crack front.

The fracture surfaces of bone also reveal information about fracture initiation and propagation, yet the science of fractography has rarely been applied to bone in forensic anthropological contexts. It is hypothesized that the science of fractography can be applied to forensic skeletal analysis to provide additional information about the bone's failure and the trauma event. Here, the application of fractographic principles to the analysis of fractured femoral cortical bone is tested to determine the utility of fractography in the forensic analysis of skeletal trauma. The bone samples consisted of 12 biomechanically fresh human femora that underwent controlled three-point bending as part of a previous study.

Several methods for enhancing visualization of the fracture surface were assessed, including magnification, oblique lighting, various contrast media (including powders, inks, and sputtered gold films), casting/molding, and Computed Tomography (CT) scanning. Such coatings and treatments are often used in other forensic fractography analyses to decrease reflection and increase contrast; in particular, bone's light color can result in reflections and low contrast that interfere with visualizing surface details. Dual-contrast fingerprint powder applied to the bone fracture surface combined with oblique lighting and low-magnification microscopy (1-4x) was determined to result in optimal visualization of the features. Moreover, this approach is relatively easy, inexpensive, and reversible.

The fractured femur specimens were then examined by seven assessors (three forensic anthropologists with no previous experience with fractography and four forensic fractographers with no previous experience examining bone). For each specimen, assessors documented the presence or absence of fractographic features, including bone mirror, arrest ridges, bone hackle, wake features, and cantilever curl. In addition, the assessors recorded their conclusions regarding the direction of crack propagation based on the presence, location, and orientation of these features.

The results strongly indicate that fractographic features observed in bone can be used to determine the location of fracture initiation and the direction of crack propagation. Interobserver error in identifying the presence of features was insignificant (p=0.244), and there was 100% agreement between all assessors for all specimens regarding crack propagation direction. Multiple correspondence analysis also revealed good agreement between the fractographic features and the fracture initiation site. Experience may play a role in identifying fractographic features, and greater precision is found in the identification of more features when the cortical area is greater.

Fractographic analysis of bone can be used to reliably determine the point of fracture initiation and the direction of fracture propagation by assessing the bone for the presence, location, and orientation of surface features. These features can generally be observed with the unaided eye, although they are further enhanced using oblique lighting, contrast medium application, and low-power microscopy. This approach is reliable and can be easily and inexpensively applied in forensic anthropological examinations. Fractographic analysis should be used in conjunction with the examination of other fracture characteristics to provide a more thorough and accurate analysis of the bone's failure and the trauma event.

Forensic Anthropology, Fractography, Trauma Analysis

A29 A Retrospective Study of Intentional Body Dismemberment in New York City: 1996-2016

Bradley J. Adams, PhD, New York OCME, 520 1st Avenue, New York, NY 10016; Christopher W. Rainwater, MS, New York OCME, 520 1st Avenue, New York, NY 10016; An-Di Yim, MA, University of Illinois, Dept of Anthropology, 109 Davenport Hall, 607 S Mathews Avenue, Urbana, IL 61801; and Helen S. Alesbury, BS, 1244 Pacific Street, Apt 2B, Brooklyn, NY 11216*

After attending this presentation, attendees will better understand various aspects of dismemberment cases in an urban setting.

This presentation will impact the forensic science community by providing a baseline for the comparison of dismemberment data originating from a large metropolitan area.

A detailed review of autopsy records, case photographs, and (when present) anthropology reports was conducted at the New York City Office of Chief Medical Examiner to locate cases of intentional body dismemberment. The initial list of cases was compiled based on database searches including terms "dismember(ed)," "dismemberment," "disarticulate(d)," "disarticulation," "amputate(d)," "amputation," "decapitate(d)," and "decapitation." More than 700 cases were reviewed based on these search parameters. Only cases involving intentional body dismemberment by another individual were included in the final dataset. In addition, there had to be complete separation of a major body part for the case to be included in the study (i.e., separation of bones without complete separation of the soft tissue was not counted). Additionally, the removal of ears, noses, and genitalia did not meet the criteria for inclusion in this study since these dismemberment locations involve only soft tissue/cartilage and would not be observable on remains in an advanced state of decomposition. After the vetting process, 75 different case numbers were found that pertained to intentionally dismembered bodies. Through DNA or anthropological re-association, 21 of these cases could be linked to other cases. After the consolidation of cases was completed, it was determined that a total of 54 dismembered bodies were discovered within New York City (NYC) between 1996 and 2016.

Data were collected on type of dismemberment: disarticulation, transection, or a combination of both. Disarticulation indicates that dismemberment was achieved by cutting between bones at joints. This is usually accomplished with a knife. Transection indicates that cuts were made through a bone. Transection usually occurred by sawing or chopping. In some cases, multiple implements were used and disarticulation and transection were observed on the same body. The results reveal that 54% of body dismemberment involved transection only (29/54), 35% involved disarticulation only (19/54), and 11% involved a combination of both (6/54).

Data were collected on the number of body parts represented after dismemberment. In 48% of the cases (26/54), the entirety of the body was never recovered. Due to missing elements, it was not possible to determine the total number of cuts or the full extent of the dismemberment locations in many of the cases. The total number of parts ranged from a low of 2 (e.g., decapitation only) to an extreme example in which the entire body was defleshed and nearly all of the individual bones were disarticulated. Frequent locations for dismemberment were the neck, shoulders, and hips.

Annual trends indicate that there was an average of 4 cases per year, with a high of 15 cases in 2005 and a low of 0 cases in 2016. These values indicate the year that the dismembered body parts were recovered. In most instances, the body parts were discovered soon after death, but, in several cases, the parts were not discovered until years after death. The frequency of body part discoveries by NYC borough reveals that Brooklyn has the highest percentage at 33% (25/75), followed by the Bronx at 27% (20/75), Queens at 23% (17/75), Manhattan at 13% (10/75), Staten Island at 3% (2/75), and 1 body part from outside NYC that linked to a NYC case (1/75). In some instances, these values represent the discovery of body parts from the same person that were spread between different boroughs.

Possible reasons for dismemberment include making the body more manageable for transport/disposal and attempting to hinder identification efforts. In a few NYC cases, the dismemberment was associated with body packing and intentional cutting of the decedent was conducted to retrieve drugs hidden inside their body. In other cases, the dismemberment may simply be an aggressive act to disfigure and mutilate the victim. It is theorized that NYC may experience a higher number of dismemberment cases than other large cities due to the density of the population and added difficulty of body transport and disposal, but currently there are no other United States studies available for comparison. Retrospective studies of dismemberment trends in other large metropolitan cities would provide an interesting comparison to the findings within NYC.

Dismemberment, Sharp Force Trauma, New York City

A30 Determining Common Skeletal Injury Locations Based on Manner of Death (MOD)

Cortney N. Hulse, MA, 4719 Revolution Road, Chubbuck, ID 83202; Kyra E. Stull, PhD, University of Nevada, Reno, Dept of Anthropology, 1664 N Virginia Street, Stop 0096, Reno, NV 89557; and Laura D. Knight, MD, Washoe County Regional Medical Examiner's Office, 990 E 9th Street, Reno, NV 89512*

The goal of this presentation is to inform attendees of common injury patterns associated with specific modes and causes of death.

This presentation will impact the forensic science community by discussing how these findings will assist attendees in better interpreting patterns of injury across the body and to help substantiate estimation of MOD in forensic casework.

Data was collected from the Washoe County Medical Regional Medical Examiner's Office (WCRMEO) to document specific injury locations based on the MOD and trauma class and explore which anatomical locations presented with the highest frequencies. This presentation will impact the forensic community by providing corroboration for trauma interpretations based on injury location, by increasing our understanding of the circumstances surrounding the death event, as well as informing scientists of influential future research directions.

The justification for the majority of trauma research is that it is assumed to be a common injury location and, therefore, will impact forensic anthropologists and other similar practitioners. For example, numerous studies explore cranial bone reactions to blunt force trauma, utilizing tools that resemble hammers, baseball bats, and other common weapons used in cases of homicide. The goal of the current study is to quantify the frequency of trauma on the skeleton based on MOD and trauma classes (i.e., blunt force, sharp force, or ballistic) as well as determine whether significant differences were observed.

Deceased individuals recorded in the WCRMEO VertiQ case-reporting database were included in the study if: (1) they have a documented MOD consistent with accident, homicide, or suicide; (2) they have a documented Cause Of Death (COD) consistent with some type of traumatic skeletal injury and not a drug, soft tissue disease state, or disease-related complication; and, (3) were more than 18 years of age. Only cases from January 2016 to July 2017 that had been designated "closed" at the time of data collection were included, which resulted in a total sample size of 300 individuals. Variables collected from the WCRMEO autopsy reports for each individual included age, sex, weight, height, body mass index, ancestry, MOD, COD, and specific skeletal trauma location. All fracture locations were recorded as present or absent for each bone and the general location on each bone (i.e., left/right, proximal/midshaft/distal). Frequency distributions of fracture location based on MOD were created as well as frequency distributions of fracture location based on trauma class, as interpreted from COD. Chi-square tests were conducted to explore the relationship between fracture location and MOD.

Interpretation of the frequency distributions of MODs suggested that cranial injuries were most common with suicides and accidental deaths. On average, greater than 50% of suicides resulted in fractures to the cranium. Ribs, the appendicular skeleton, and the innominates were most often affected by an accidental death. An MOD of homicide resulted in similar amounts of trauma (26%) appearing on both the cranium and thoracic area; however, unlike the aforementioned studies within the field, no MOD homicide reported a COD of blunt trauma. When examining frequencies of COD, sharp force trauma most frequently affected the ribs (62%) and ballistic trauma most frequently affected the cranium (70%). Blunt force trauma had a slightly higher occurrence on the ribs overall, where 55% of blunt force trauma cases resulted in lateral rib fractures; however, a substantial portion (28%) of blunt force trauma also appeared on the cranium. Chi-squared tests revealed that some of these location frequencies had a statistically significant relationship with MOD ($p < 0.05$).

The results from this research demonstrate that MOD has a significant correlation with the location of trauma. Recognizing common injury location does not directly influence the trauma interpretation, but rather provides information regarding the death event and corroborates any findings from the trauma analysis. These findings will assist forensic scientists to better interpret patterns of injury across the body and help substantiate estimation of MOD in forensic casework. Additionally, these findings will direct future forensic anthropological research by providing data on the anatomical areas presenting with the highest frequency of trauma per MOD and COD.

Trauma Analysis, Frequency Tables, Cause of Death

A31 Butterfly Fractures in Medicolegal Investigations

Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, MCL, 215 Allen Stuart Drive, Pearl, MS 39208; Ericka N. L'Abbe, PhD, University of Pretoria, 9 Bophelo Road, Pretoria 0001, SOUTH AFRICA; and Mark M. LeVaughn, MD, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208*

After attending this presentation, attendees will have acquired knowledge regarding bending bone fracture patterns in adult long bones. Broken bones have been studied for more than 100 years, yet little research has applied and validated fracture patterns in medicolegal investigations.

This presentation will impact the forensic science community by contributing to the knowledge of fracture biomechanics and the utility of evaluating the direction of bending bone failure in a medicolegal environment as well as aiding attendees in the interpretation of long bone fractures. Blunt trauma is addressed as a whole, with an emphasis on: (1) the application of bone trauma interpretation in practice; (2) the significance of the identification of a blunt butterfly fracture pattern; and, (3) the recognition of biomechanical modes of failure. A Pedestrian Vehicle Accident (PVA), a common medicolegal occurrence in which the expertise of a forensic pathologist and anthropologist is needed, will be used as an exemplar for the discussion.

More than 30 years ago, anthropologists began to work hand-in-hand with forensic pathologists, which marked the beginning of a new relationship in forensic science that emphasized bone trauma diagnoses based in biomechanics. Autopsy became the ideal environment to apply and validate bone trauma research.[1] The identification of the modes of bone failure and the features of tension and compression of tubular bone fractures were shown to be accurate in determining bending direction of reconstructed bone and became standard practice in forensic anthropology.[2-4]

Recently, experimental research in three-point bending has exhibited considerable variation in butterfly fracture patterns and has urged caution in using these fractures in establishing bending direction:

"If practitioners consider only the presence and orientation of complete butterfly fractures, they may be unable to accurately interpret impact direction and all trauma cases."[5]

This introduces confusion in bone trauma analysis, whether blunt or ballistic, as all are based on biomechanical principles of bone failure. The recognition of these features in bone is usually based on visual patterns, such as blunt butterfly fractures, with the intent of immediately establishing bending direction. So where does the confusion lie in explaining and interpreting blunt butterfly fractures? And, how does this affect our current application and interpretation of long bone fractures in medicolegal investigations?

Obviously, interpretation of processed bone has limitations, as demonstrated by an exemplar of a broken leg from a PVA. In this case, it will be demonstrated how soft tissue and context makes the determination of bending and Point Of Impact (POI) possible. POI requires prior knowledge, despite claims in the historic literature. With prior knowledge and context, an analyst can reconstruct a bone fracture for pattern analysis and can further separate these bones for macroscopic examination of tensile and compressive failure. The above-mentioned experimental research on three-point impacts also concluded that surfaces of broken bone accurately indicated areas of tension and compression.[5]

This presentation contextualizes bending bone fractures within the framework of current knowledge and discusses the application of this knowledge to a medicolegal environment. This study contends that the variable morphology observed in a butterfly pattern is attributed to the continuous adjustments and failures of bone bending. With enough energy, tension failure forms in a bone shaft, with shear and compressive forces guiding or diverting fractures. Bone's ability to resist compression energy directs initial fractures longitudinally along the shaft. Eventually, complete fractures are formed as fractures approach the side of compression.

Therefore, the blunt butterfly fracture pattern indicates initial failure, which eventually progresses into or toward maximum compression failure. The overall morphology of the fracture pattern reveals general direction of bending, while discerning the actual contour of the bone in cross section assists in establishing bending direction of that bone at that location.[6]

An anthropologist must remain forensically conservative in his/her analytical approach to trauma analysis, particularly when prior knowledge or context is not available. A blunt butterfly fracture pattern can assist in establishing bending direction of the bone; however, an analyst must be cognizant of variation in fracture morphology and must not purely rely on these features for interpretation of an injury. Anthropologists need to be cognizant of the intrinsic features of bone, the biomechanical principles of bone failure, and the application of this body of knowledge to a medicolegal investigation.

Blunt Butterfly Fractures, Biomechanics, Fracture Direction

A32 Early Signs of Direct Fracture Repair and Indirect Intramembranous Fracture Repair Without Indications of Endochondral Ossification in the Ribcage

Katie M. Rubin, MS, University of Florida, CAPHIL, PO Box 103615, Gainesville, FL 32610; and Michala K. Stock, MA, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610*

After attending this presentation, attendees will better understand the early stages of osseous healing and their macroscopic manifestation on dry skeletal material.

This presentation will impact the forensic science community by highlighting the need to carefully examine all fractures, including minute incomplete fractures associated with major fractures, for slight irregularities indicative of short-term survival after a traumatic event.

Partially skeletonized human remains were discovered beneath a structure that had collapsed several months prior. Associate Medical Examiner Dr. Kyle Shaw of Florida's District 5 Medical Examiner's Office evaluated the scene and remains; he referred the latter to the University of Florida C.A. Pound Human Identification Laboratory (CAPHIL) for additional analysis. Assessments at the CAPHIL indicated that the remains were those of a middle- to older-aged adult female of primarily European ancestry. Analyses also revealed the presence of several complete and incomplete fractures of the anterior rib cage. All fractures to right ribs 2-7 and left ribs 2-5 were consistent with an anterior loading (compression) event. These fractures were examined under 7-80x magnification using a stereoscope. Although most complete fractures revealed no indications of healing and were consistent with peri-mortem trauma, several incomplete fractures, including those directly associated with a complete fracture, revealed indications of very early osseous repair. Small spicules of new bone were present adjacent to larger incomplete fractures and bridge smaller incomplete fractures. In both cases, bony spicules were oriented perpendicularly to the long axis of fracture. The large majority of new bone present cannot be visualized on plain film radiography.

While there is extensive literature on the cellular and molecular changes underlying early fracture repair, there is a dearth of literature addressing the gross, anatomical appearance of early fracture healing in human skeletal material. Immobilized, highly mechanically stable fractures, including stress fractures and incomplete fractures, may demonstrate a high degree of direct healing and indirect intramembranous ossification.[1] For both direct repair and indirect intramembranous repair, bone formation at fracture sites begins prior to (and on rare occasions, in lieu of) endochondral ossification of a soft callus.[2] In direct healing, the cells in the local cortical bone build new lamellar bone and Haversian systems without intermediary woven bone.[3] This type of repair occurs only at fracture gaps of less than ~1mm with low interfragmentary strain (i.e., fractures that do not require calluses for stabilization).[3] In indirect healing, the intramembranous hard callus is deposited without a precursor onto the existing bone surface from the subperiosteal layer and forms adjacent to fracture margins before progressing toward the fracture line.[4] In non-human animal studies, intramembranous bone deposition usually begins by day three post-fracture.[5] In contrast, woven bone deposition in endochondral ossification may not begin until ~14 days post-fracture.[6]

Despite the mix of fractures with and without indications of healing in the rib cage of the forensic case examined by the CAPHIL (a mix observed even along the margins of a single fracture area), it is likely most of the fractures occurred as a result of a single, compressive event. Death occurred after the body initiated direct and intramembranous fracture healing at the incomplete (mechanically stable) fracture locations, but prior to any endochondral ossification at the complete (mechanically unstable) fracture sites. Although individual variation and a lack of studies on timing of these fracture repair stages in humans render an exact timetable difficult to establish, these findings suggest the individual died very shortly, but not immediately, after injury. In this particular case, these findings may have implications for cause of death. This case study illustrates the importance of careful examination of *all* fracture surfaces via light microscopy. Further, this case study highlights the need for future studies/autopsy series designed to elucidate macroscopic changes associated with fracture repair and the timing of ossification in human adults. Such findings would not only aid forensic scientists reconstructing the last days of someone's life, but would augment clinical understandings of human skeletal repair as well. In addition, because bone is one of the few truly regenerative tissues, better understanding of the initiation of bone regeneration in humans could have an important impact on tissue engineering.

Fracture Healing, Trauma, Tissue Regeneration

A33 Initiation and Propagation of Fractures in Blunt Impacts to Unconstrained Human Cadaver Heads

Mariyam I. Isa, MA, Michigan State University, Dept of Anthropology, 655 Auditorum Drive, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; Alexis C. Goots, MA, 5757 Barton Road, North Olmsted, OH 44070; Elena O. Watson, BA, 5929 Fredricks Road, Sunbury, OH 43074; Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; Feng Wei, PhD, Michigan State University, 965 Fee Road, Rm A-414B, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics Laboratories, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be informed about cranial fracture initiation and propagation in blunt impacts to upright, unconstrained cadaver heads.

This presentation impacts the forensic science community by adding to their current understanding of the relationship between location of fracture production, propagation of fracture, and implement type in cases involving blunt cranial trauma.

Previously, this research group presented the results of blunt cranial impacts performed on entrapped human cadaver heads at the American Academy of Forensic Sciences meetings.[1,2] High-speed footage of these experiments support Gurdjian's predictions that: (1) cranial fracture can initiate either at or peripheral to the impact site; and, (2) variables, including implement shape and impact energy, influence the location of fracture initiation and propagation.[3] Fenton et al. and Isa et al. report that fractures tend to initiate peripherally in impacts with larger, broader implements and at the point of impact with smaller, more focused implements.[1,2] As these experiments were performed on heads fully constrained within a rigid medium (plaster of Paris), it remains unclear how fractures would initiate and propagate in impacts to more realistically constrained heads.

The current study investigated fracture initiation and propagation in blunt cranial impact experiments designed to simulate a blow to the head of an upright individual. Nineteen unembalmed male cadaver heads were impacted using a new, custom-built pneumatic impact system. Three aluminum impactors were selected for this study to approximate the shapes of objects commonly implicated in forensic cases: a brick (3" diameter flat), a bat (2.5" diameter cylinder), and a hammer (1" diameter flat). Twelve impact experiments (n=4 for each implement) were performed at a base energy level: 91.8J±18.7J for brick impacts, 112.1J±3.7J for bat impacts, and 105.3J±19.5J for hammer impacts. Seven impact experiments (n=2 brick; n=2 bat; n=3 hammer) were performed at approximately 1.6-1.8 times the base energy level (153.6J±50.0J for brick impacts, 137.1J±39.3J for bat impacts, and 172.0J±10.6J for hammer impacts).

Impacts were delivered at the mid-parietal, inferior to the parietal boss, on heads placed in an upright position. Prior to impact, specimens were secured at the C4 vertebra to a mounting plate using an adjustable clamping mechanism. Heads were positioned for impact via breakaway tethers attached to a collar fastened around the neck. A high-speed camera captured fracture initiation and propagation at 10,000fps.

A key result of the base energy-level experiments was the observation of peripheral fracture initiation in impacts with all three implements. These results indicate peripheral initiation is not just possible, but likely following a blunt impact to an unconstrained head. A second key finding was that for all three implements, at least one of four experiments generated fractures that initiated peripherally and did not propagate back to the impact site. As a result, 4/12 experiments (2/4 brick, 1/4 bat, and 1/4 hammer impacts) produced fractures concentrated somewhere other than the impact site (primarily in the temporal and sphenoid).

Initial results also indicate that both implement shape and impact energy influence the location of fracture initiation and propagation in unconstrained heads. At the base energy level, experiments with brick and bat implements tended to generate peripherally initiating linear fractures that propagated back toward and/or away from the impact site. At a higher energy, brick and bat implements produced linear fractures that initiated at the point of impact and propagated away. In contrast, high-energy hammer impacts produced peripherally initiating linear fractures that propagated back toward the impact site.

The present study sought to investigate the issue of fracture initiation and propagation in blunt impacts to unconstrained adult heads. High-speed photography revealed fractures initiating peripherally with all three implements impacted at the base energy level. In some cases, peripherally initiating fractures also traveled away from the point of impact, resulting in fractures located distant from the point of impact. Practitioners, therefore, should be advised that the location of linear fractures does not necessarily correspond with the location of impact.

Haut, PhD, Michigan State University, Orthopaedic Biomechanics Laboratories, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will better understand relationships between Point Of Impact (POI) -involved implement and fracture patterns from single, blunt cranial impacts to unconstrained human cadaver heads.

This presentation will impact the forensic science community by contributing to ground-truth data in support of assessing implement shape and POI in cases involving blunt cranial trauma.

Previous research has demonstrated that implement shape influences location and pattern of fractures in controlled impacts to fully constrained adult human heads and developing porcine specimens.[1-3] This current study further investigated the effects of implement shape on fracture patterns in experimental impacts to upright, unconstrained human heads. This study explored two major questions relevant to analyses of blunt cranial trauma: (1) Do different-shaped implements produce distinct fracture patterns?; and, (2) Can fracture patterns be used to estimate the POI? For 12 experimental cases in which implement and POI were known, these questions were explored through analyses of fracture patterns, defect size, and spatial relationship between fractures and the known POI.

Twelve adult male cadaver heads were impacted with a pneumatic impact system that allowed for controlled energy impacts to unconstrained specimens. Single impacts were administered to the mid-parietal, inferior to the parietal boss, with three implements that approximated a hammer (1"-diameter cylinder with a rounded surface; n=4), a baseball bat (2.5"-diameter cylinder with a curved surface; n=4), and a brick or broad, flat implement (3"-diameter flat disk; n=4).

Following single impacts, ectocranial fracture patterns were diagrammed and photographed. To observe endocranial outcomes, adjusted craniotomy cuts were conducted on the crania after maceration. Relevant data collected were: type of fractures present, spatial relationship between fractures and known POIs, and approximate size of any circular-type defects.

Energy to fracture and overall peak force were not statistically different between implements. For all three implements, the average fracture energy was 12.44J±6.04J, and the average overall peak force was 5221N±1936N.

The results of fracture patterns and their relationship with POI revealed trends by implement. In 3/4 impacts with the hammer implement, focal and circular depressed fractures circumscribed the POI. Endocranially, these impacts also generated corresponding internally beveled, delaminated “bone plugs” concentrated under the POI. Such endocranial defects were largely absent in the bat and brick impact experiments. In 3/4 impact experiments with the bat, curvilinear fractures occurred around the POI; however, they did not completely encompass the POI and exhibited an oval shape. The brick implement produced more variable fracture patterns. Half (2/4) of these impacts resulted only in linear fractures located remote from the POI in adjacent bones. In the other two brick impacts, large concentric fractures formed around the POI.

Circular-type defects were produced in 3/4 hammer, 3/4 bat, and 2/4 brick impact experiments. The hammer implement produced defects with the smallest average diameter (29mm±1.15mm.) These defects were of a consistent size, slightly larger than the implement diameter. The brick implement produced the largest defects (59mm±7.07mm); defects were typically smaller than the diameter of the implement. The bat produced defects of an intermediate size (34mm±15.72mm); however, defect sizes were inconsistent and overlapped in range with defects produced by the other two implements. These results indicate that defect size may assist in making a general distinction between small and large implements (i.e., hammer vs. brick), but it may not be possible to infer implement size based on defect size alone.

The results of this study reveal emerging trends in cranial fracture patterns associated with implement shape and suggest some baseline parameters for locating POI. In this experimental sample, an approximately circular defect, particularly in association with an endocranial bone plug, served as an effective indicator of POI. In contrast, when fracture patterns consisted only of linear fractures without the presence of round defects (1/4 hammer, 1/4 bat, 2/4 brick), impact location was obscured.

Blunt Force Trauma, Cranial Fracture Patterns, Trauma Analysis

A35 Estimating Points of Impact in Multiple Blunt Force Cranial Trauma: Lessons From Experimental Impacts

Alexis C. Goots, MA, 5757 Barton Road, North Olmsted, OH 44070; Mariyam I. Isa, MA, Michigan State University, Dept of Anthropology, 655 Auditorum Drive, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; Elena O. Watson, BA, 5929 Fredricks Road, Sunbury, OH 43074; Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; Feng Wei, PhD, Michigan State University, 965 Fee Road, Rm A-414B, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics Laboratories, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will gain awareness of: (1) the influence of implement shape on fracture patterning in multiple, blunt cranial impact experiments; and, (2) the implications of this study for fracture pattern interpretation in a medicolegal setting.

This presentation will impact the forensic science community by presenting ground-truth data for multiple cranial impacts with known implements and known number and location of impacts.

The forensic literature is conspicuously lacking in guidelines for locating points of impact and, thus, accurately estimating number of impacts in cases involving blunt cranial trauma. The current study investigates the related issues of estimating locations and number of impacts in a series of multiple blunt force impact experiments on human cadaver heads. Research questions included: (1) Can fracture patterns be used to accurately locate all points of impact?; and, (2) How might implement shape influence practitioners' ability to make this assessment?

Controlled impact experiments were performed on 12 unembalmed, unconstrained human cadaver heads using a pneumatic impact system. Three aluminum impactors were selected to investigate implement effects on fracture patterns: a hammer (1"-diameter flat implement; n=4 specimens), a baseball bat (2.5"-diameter cylinder; n=4), and a brick (3"-diameter flat implement; n=4). Three impacts were delivered to each head: first to the mid-parietal, second to the anterior parietal, and third to the posterior parietal. After each impact, fractures were photographed and diagrammed. Following this series of three impacts, each cranium was macerated and a modified craniotomy cut was made to enable ectocranial and endocranial assessment of fracture.

Input energy for the impact experiments was 105.33J±19.48J for the hammer implement, 112.06J±3.70J for the bat, and 91.81J±18.7J for the brick. Energy differences between implements were non-significant.

The results indicated that sole reliance on ectocranial fractures may lead to an incorrect assessment of location and even a possible overestimation of the number of impacts. In contrast, assessment of only endocranial fracture, in this case internally beveled "bone plugs," may underestimate impact number.

Combined ectocranial and endocranial data provided clear indication of impact location for most impacts with the hammer implement. Nine of 12 impact sites exhibited circular fractures circumscribing the Point Of Impact (POI) ectocranially, 8/12 impact sites exhibited endocranial bone plugs, and 6/12 impact sites exhibited both. One or both features were present in association with known POI at 11/12 impact sites.

The bat produced semicircular fractures partially circumscribing the POI in 5/12 impacts, bone plugs in 3/12 impacts, and both features in 2/12 impacts. One or both features were observed in association with the known POI in 6/12 impacts. In all four specimens, at least one impact site was obscured due to the absence of circular fractures around the POI, presence of linear fractures distant from the POI, and/or lack of bone plugs associated with the POI.

The brick produced semicircular fractures surrounding the POI in 5/12 impacts, bone plugs in 1/12 impacts, and both features in 1/12 impacts. One or both features were observed in association with known POI in 5/12 impacts. In all four specimens, at least one impact site was obscured because: (1) fractures were linear and initiated at sutures adjacent to the POI (2/4 specimens); (2) new fractures intersected with fractures generated in previous impacts (4/4 specimens); and/or, (3) few endocranial defects were observed (4/4 specimens).

The results of this study suggest that practitioners should consider both endocranial and ectocranial data when assessing cranial blunt force trauma. In this experimental set, ectocranial circular defects and endocranial "bone plugs" were consistently observed in association with known points of impact. These features were observed in most hammer impacts, but only about half of the bat and brick impacts. This indicates that implement shape can affect assessment of impact location and, potentially, the number of impacts to an adult human head.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. Blunt Force Trauma, Cranial Fracture Patterns, Trauma Analysis

A36 Introducing MorphoPASSE: The Morphological Pelvis and Skull Sex Estimation Database

Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621; and Stephanie J. Cole, MS, University of Nevada, Reno, Dept of Anthropology, 1664 N Virginia Street, Stop 0096, Reno, NV 89523*

After attending this presentation, attendees will be familiar with MorphoPASSE, a free interactive database for estimating sex in unidentified adults.

This presentation will impact the forensic science community by providing a new computer-based, statistical database program for sex estimation that is multivariate and combines two skeletal regions.

According to a recent survey administered to current American Academy of Forensic Sciences Anthropology Section members, most practitioners prefer to use both qualitative and quantitative methods when estimating sex from unknown skeletal remains; however, when only one method is used, qualitative methods are preferred nearly twice as often as metric methods.[1] Benefits of morphological methods include ease of use, efficiency, no need for specialized equipment, and applicability to fragmentary remains. Unfortunately, many of the qualitative methods used for sex estimation are based on subjective interpretations of skull and pelvis traits.

Studies by Walker and Klales et al. attempted to remedy the aforementioned shortcomings of morphological methods by: (1) providing modified descriptions of commonly used traits; (2) creating standardized illustrations with systematic ordinal scales; and, (3) including statistical analyses for a number of morphological skull and pelvis traits.[2,3] This was conducted to reduce the level of subjectivity and better conform to the scientific expectations presented in the *Daubert* proceedings and the National Academy of Sciences (NAS) Report. The Walker method utilizes glabella, nuchal crest, supraorbital margin, mastoid process, and the mental eminence, while the Klales et al. method utilizes the ventral arc, medial aspect of the ischio-pubic ramus, and the subpubic concavity/contour.[2,3] The eight traits included in these two methods continue to be the most popular morphoscopic traits for sex estimation, according to the Klales survey.[1] Both methods have been well received in the anthropological community and are currently being used nationally and internationally for forensic casework. To facilitate easier application of these methods and sex classification combining the methods, research was undertaken with the goal of developing a free database program.

Data were collected from more than 2,500 individuals from various United States and international collections to: (1) examine the reliability and validity of both methods; (2) examine the impact of experience in applying the methods; and, (3) determine the effects of population variation, secular change, and asymmetry on the methods. This research has culminated in the development of the free, interactive morphological database Morphological Pelvis and Skull Sex Estimation, known as MorphoPASSE. MorphoPASSE allows forensic practitioners to analyze sex in their unknown cases in a manner compliant with *Daubert*. Practitioners enter ordinal scores of an unidentified individual into the program based on the traits available for scoring (i.e., the program does not require complete remains or use of all traits). Then, these trait scores are compared to the known samples in the database for sex classification, either by selecting a specific population and/or temporal period in order to compare the unknown individual to the most appropriate reference sample or by using the generic logistic regressions equations created from the entire sample when the other parameters are unknown. MorphoPASSE then provides the user with posterior probabilities and associated error rates for sex classification that the user can then include in forensic case reports.

A publicly available user manual and website (www.MorphoPASSE.com) have been created to accompany the database. The first portion of the manual contains detailed descriptions of the traits, with reference to the original publications, and detailed instructions on scoring the traits in light of the results from this research. The second portion of the manual contains specific instructions for using the database and interpreting the sex classification results generated from the program. Since each forensic case presents with a different suite of traits, the statistical software package will provide a graphical user interface to simplify the entry of variables associated with each case. The package interfaces with R to conduct the statistical tests and the results are displayed in a user-friendly format. The score data from this research is available in numerous formats, including a CSV file and an R package.

This research was funded by a National Institute of Justice (NIJ) grant. Opinions, points of view expressed in this research, and products discussed represent a consensus of the authors and do not necessarily represent the official position, policies, or endorsement of the United States Department of Justice or the NIJ.

A37 Computational Anatomy: What Prospects for Forensic Anthropology?

Rémi Agier, CREATIS Research laboratory of Medical Imagery, 7 Avenue Jean Capelle O, Villeurbanne 69100, FRANCE; Remy Prost, PhD, CREATIS Research Laboratory of Medical Imagery, 7 Avenue Jean Capelle O, Villeurbanne 69100, FRANCE; Razmig Kechichan, CREATIS Research Laboratory of Medical Imagery, 7 Avenue Jean Capelle O, Villeurbanne 69100, FRANCE; Sébastien Valette, CREATIS Research Laboratory of Medical Imagery, 7 Avenue Jean Capelle O, Villeurbanne 69100, FRANCE; Laurent Fanton, MD, PhD, Hospices Civils de Lyon, Institut de Medecine Legale, 12 Avenue Rockefeller, Lyon 69008, FRANCE; and Angelique Franchi, MD, Hospices Civils de Lyon, Service de Medecine Legale, Faculté de Médecine, Lyon 69008, FRANCE*

After attending this presentation, attendees will be able to consider the prospects of using computational anatomy in forensic anthropology.

This presentation will impact the forensic science community by drawing the attention to sex determination by computational anatomy and by developing an automatic method to simplify the anthropological approach.

The steady advances in medical imaging are the source of many complex images stored in hospitals. Unfortunately, after an image of the patient is obtained for a specific diagnosis, this image is usually discarded, without further analysis. Hence, there are many images stored in hospitals that could be further analyzed to extract knowledge on human anatomy. Computational anatomy is a recent research field which seeks to help practitioners in their daily practice by analyzing many individuals, which yields large-scale statistics on human anatomy.[1]

The purpose of this study is to assess the relevance of computational anatomy for forensic anthropology, in particular for sex determination.

Toward this goal, a novel groupwise registration algorithm was used, based on a keypoint detection, and was able to register several hundreds of full body images in a common space. This algorithm is fully automatic and can robustly register one hundred images within a few hours.

Preliminary results will be presented for 83 Computed Tomography (CT) scans of living individuals from the VISCERAL database.[2] The first results will focus on the hip bone for sex determination, which is known to be one of the most dimorphic regions between men and women. Experiments demonstrate that the well-known criteria for sex discrimination (e.g., the opening angle of the pubic symphysis or the greater sciatic notch) are well preserved in the mean images of men and women. Moreover, the results with the Probabilistic Sex Diagnosis (DSP: Diagnose Sexuelle Probabiliste) method (a tool using worldwide variability in hip bone measurements) will be shown by manually placing only 20 anatomical landmarks in the common space.[3] Sixty-two percent of individuals had been correctly estimated, 37% had been undetermined, and 1% of individuals had been determined with error of sex. The placing of landmarks manually is difficult and insufficiently accurate. Further analysis will address the skull and femur.

Currently, the limiting factor is the population size and a future goal will be to significantly increase the size to improve global accuracy. The long-term objective is to automatically computer generate local points of interest in the common space image. This new approach provides an automated profiling method to determine the sex of an individual and possibly her/his age, origins, and body measurements in future works.

Computational Anatomy, Forensic Anthropology, Sex Determination

A38 Risen From the Ashes: An Exploratory Study for Developing New Methods of Analyzing Cremated Human Remains

Anthony W. Hudson, 603 New Walters Mill Road, Providence, NC 27315*

After attending this presentation, attendees will better understand potential new methods of recreating pertinent biological profile information, specifically the estimation of sex, of remains that have undergone cremation or burning.

This presentation will impact the forensic science community by providing results from an exploratory study of an area with little current or previous research. This presentation will add to research being conducted in the field of forensic anthropology by demonstrating how biological profile estimates are affected by a burning episode and how potential new methods may contribute to more accurate assessments of sex when human remains have undergone burning.

Reconstructing the biological profile of remains that have undergone burning or cremation often proves to be a difficult task due to the nature of damage that is incurred when bone is exposed to fire, such as warping, heat-induced fracturing, and alterations to bone shape.[1] These changes are compounded by the relatively small amount of literature available on the topic. This often forces the forensic anthropologist to rely on more traditional methods of assessing the biological profile since there are few cremation-specific methods available. While these methods can be applied successfully in many cases, it would be desirable to utilize methods designed specifically for cremated remains.

The basis of this research comes from data collected for a master's thesis in 2016 utilizing 49 cremations from the William M. Bass Donated Skeletal Collection housed at the University of Tennessee, Knoxville. Forty of the cremations were unprocessed (not pulverized after cremation) and the remaining nine cremations were processed. Each of the unprocessed cremations was carefully analyzed to determine which skeletal elements consistently survived cremation and whether they would be useful for identifying potential new methods of estimating biological profile. All skeletal elements deemed to be potentially useful were measured to determine if size sexual dimorphism was present. More traditional methods of estimating biological profile were also tested to determine which methods returned the most accurate estimates. Age was estimated for the unprocessed cremations using methods created by Brooks and Suchey, Buckberry and Chamberlain, Lovejoy et al., Meindl and Lovejoy, and Todd.[2-7] Sex was estimated using robusticity of the skeleton, the heads of the humeri and femora, as well as morphological traits of the skull and pelvis.[8] The weight of cremains was also used to estimate sex for both the processed and unprocessed remains using studies performed by Bass and Jantz, Van Deest et al., and Warren and Maples.[9-11] Stature was estimated using the Steele method of partial bone length reconstruction and Trotter's formulas for estimating stature from lone bone lengths.[12,13] The estimates were then compared with known demographic data of the individuals to assess which methods returned the most accurate estimates of the biological profile.

It was determined that a total of six skeletal elements/portions displayed size sexual dimorphism and may be useful for constructing new methods of estimating sex of cremated remains. These were the heads of the humerus, femur, and radius, the mandibular condyles, the first sacral vertebra, and the ischial tuberosities. Each of these elements/portions survived frequently in the cremations studied and could be measured and/or observed for size dimorphism. After assessing the results of the traditional methods of estimating biological profile, it was determined that sex was best able to be estimated using morphological traits of the skull and pelvis. Age at death was most accurately estimated using the Lovejoy et al. and Meindl and Lovejoy methods of assessing the auricular surface, and stature was best estimated using the Steele and Trotter methods paired together.[4,5,12,13] Ancestry was unable to be estimated for any of the cremations studied.

In conclusion, it was determined that it does appear feasible to develop new specific methods of estimating sex for remains which have undergone burning. While new methods of estimating age at death, ancestry, and stature could not be developed, it was determined that traditional methods can be used to accurately estimate age at death and stature for burned remains. This is important to the field of forensic anthropology as it demonstrates that there is potential to develop cremation-specific methods of estimating biological profile, which may lead to more accurate estimates of age at death, sex, and stature for remains which have undergone burning.

Cremation, Human Remains, Forensic Anthropology

A39 Estimating Sex With Outline Shape Analysis of the Trochlear Constriction and the Olecranon Fossa

Saskia Ammer, MSc, Jestelstrasse 2, Munich, Bavaria 80999, GERMANY; and João Pedro Valente de Oliveira Coelho, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL*

The goal of this presentation is to demonstrate that using statistical modelling combined with outline shape analysis accomplishes a more accurate and unbiased sex estimation of the distal humerus than the non-quantitative visual assessment methods commonly used.

This presentation will impact the forensic science community by introducing attendees to a revised method for estimating the sex of an individual by using the distal humerus while turning the geometric morphometrics approach into a more accessible and easier-to-utilize interactive online application that allows users to control the principal component parameters.

Forensic anthropologists are often asked to establish a biological profile of human remains. Regularly, the skeletal remains are very damaged and the bones commonly used for sex estimation cannot be consulted. Fortunately, the distal aspect of the humerus is usually relatively well preserved due to its compact morphology. Therefore, this research will be particularly useful to researchers working with fragmented remains.

Several studies have investigated whether it is possible to estimate the sex of an individual by examining the distal humerus. A method using visual assessment of the morphology was developed by Rogers, with average accuracies ranging from 74%-91%.[1] Tests of this method in different populations have correctly classified 74%-82% of the individuals.[2-5] An attempt at a landmark-based geometric morphometrics reinterpretation of the method by Vance and Steyn reports accuracies between 78%-91%.[6]

A total of 80 female and 71 male humeri were analyzed using the 21st-Century Identified Skeletal Collection at the University of Coimbra (CEI/XXI) in Portugal. For this preliminary study, only the left humeri were evaluated. All specimens were photographed in a standardized position from the posterior view by placing the subject on a flat table and the camera directly above the olecranon fossa.

Using TPSdig2, a software program used for landmarks and outline digitization, an open curve and a closed outline were marked.[7] The first evaluated the constriction of the trochlea, with the curve reaching from the most medial inferior aspect to the most lateral inferior aspect of the trochlea. The second described the outline of the olecranon fossa and was recorded clockwise, starting from its most inferior aspect.

All the analyses were performed using the R programming language and the Momocs package developed by Bonhomme et al.[8,9] All coordinates were superimposed using Generalized Procrustes Analysis (GPA) as first proposed by Gower.[10] GPA allows multivariate statistical analyses on the shape of objects. This is possible, since GPA can superimpose shapes by iteratively rotating, translating, and scaling them until a consensus is reached.

Using 16 sampled points, natural six-degree polynomials fits were calculated for the open curve of the Trochlear Constriction (TC). An elliptical Fourier transformation was used to analyze the closed outline of the Olecranon Fossa (OF). This retained 99% of the harmonic power, which, in this case, resulted in six harmonics. Next, both sets of data were processed with the same statistical algorithms. Principal Component Analysis (PCA) was used to reduce the dimensionality of data and to visualize the morphospace.

Subsequently, Linear Discriminant Analyses (LDA) models were created using the principal components to estimate the sex from shape configurations. These classification models were trained on a $K=n$-1 cross-validation scheme to avoid overfitting.

After selecting the best predictive model, it was implemented into a web app, which was developed using the Shiny package for R.[11] This follows the recent trend in forensic anthropology, which attempts to make complicated statistical models more accessible and easier to utilize through interactive online applications.[12-14]

The two shape configurations exhibited strikingly different degrees of sexual dimorphism when evaluated using LDA with leave-one-out cross-validation. The trochlear construction performed poorly, with only 60.9% of the individuals being attributed to the correct sex; however, the olecranon fossa exhibited high sexual dimorphism, and the LDA model presented an accuracy rate of 92.1%. Thus, this character alone, using outline-based morphometrics, performs better than the combination of all four features of the visual assessment method proposed by Rogers.

Outline Shape Analysis, Sex Estimation, Distal Humerus

A40 The Utility of Clavicular and Humeral Non-Metric Sex Assessment Methods in Japanese and Thai Individuals

Sean D. Tallman, PhD, Boston University, Depts of Anatomy and Neurobiology and Anthropology, 72 E Concord Street, L1004, Boston, MA 02118*

After attending this presentation, attendees will understand how select non-traditional, non-metric traits of the clavicle and humerus can be used in a statistical framework to ascertain the sex of Japanese and Thai individuals.

This presentation will impact the forensic science community by providing population-specific clavicular and humeral sex assessment methods for use when the traditional non-metric traits of the pelvis and cranium are absent.

Sex is one of the most important components of the biological profile as it can exclude roughly half of the population and it dictates the methods used in age, ancestry, and stature estimations. While the non-metric traits of the pelvis and cranium are used regularly and reliably in forensic and bioarchaeological sex assessment, trauma, taphonomic alterations, and incomplete recovery may preclude their inclusion in the biological profile. Therefore, it is necessary to develop, validate, and refine sex assessment methods on other sexually dimorphic regions of the skeleton that may be variably preserved, including the clavicle and humerus. The infero-medial clavicle serves as an attachment point for the costoclavicular ligament, and it is hypothesized that males more frequently show an excavation (rhomboid fossa) in this area. Sexually dimorphic differences in the distal humerus are attributed to differing female and male carrying angles; however, these non-traditional sex assessment methods were developed, validated, and refined in North America on individuals of African and European descent. Until relatively recently, Asian populations have remained understudied in forensic anthropological research, which is problematic in worldwide forensic contexts.

This study explores the expression of clavicular rhomboid fossae and distal humeral morphology in 1,397 Japanese and Thai individuals, 17 to 96 years of age. The Japanese sample is composed of 209 individuals from the late 19th to early 20th centuries (Chiba University) and 572 individuals from the modern era (Jikei University) (*f*=219; *m*=562). The Thai sample is composed of 616 individuals from the modern era (Khon Kaen and Chiang Mai Universities) (*f*=198; *m*=418). The rhomboid fossa of the medial clavicle was assigned an ordinal score based on the degree of expression and presence or absence. Similarly, the sexually dimorphic traits of the distal humerus (trochlear constriction, trochlear symmetry, olecranon fossa shape, and angle of the medial epicondyle) were assigned an ordinal score based on their "female-like" or "male-like" expression. Percentages, probabilities, and chi-square statistics were calculated to determine if differences exist between the sexes and populations. Subsequently, binary logistic regression equations and Chi Square Automatic Interaction Detection (CHAID) decision trees were calculated to identify the distal humeral traits that perform best in differentiating females and males. Additional non-parametric tests examined the effects of age and intraobserver error.

Overall, the results indicate that the methods developed on non-Asian populations exhibit reduced discriminatory power when applied to the Japanese and Thai populations. Concerning the clavicle, the majority of females and males (56.9%–97.4%) lack a rhomboid fossa; however, the presence of a fossa indicates male with a probability of 70%–91%. The left clavicle is more sexually dimorphic than the right. Concerning the distal humerus, 42%–85% of the individuals were correctly classified using the traits individually, while 68%–94% were correctly classified using a population-specific composite scoring method. Males were more correctly classified, and the angle of the medial epicondyle performed the best, while trochlear constriction performed worst. Further, the clavicular and distal humerus traits are influenced by age at death, population, and intraobserver error, thereby possibly complicating their use in sex assessment.

Though less accurate than the pelvis or cranium, this study demonstrates that clavicular and humeral morphology can be used in the absence of traditional non-metric traits to estimate the sex of Japanese and Thai individuals. Moreover, the findings underscore the importance of developing population-specific sex assessment methods for diverse Asian populations, as the Japanese and Thai are somewhat less sexually dimorphic than non-Asian populations and differ from each other.

This research was funded by the National Science Foundation and the Japanese Society for the Promotion of Science (1414742), and the National Institute of Justice (2014-DN-BX-0002).

Sex Assessment, Non-Metric Traits, Asia

A41 Resolving Commingling and Past Accounting at Cabanatuan Prison Camp Cemetery

Mary S. Megyesi, PhD, DPAA-CIL, 590 Moffett Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will understand the unique history of the World War II Cabanatuan Prison Camp assemblage and learn about some of the challenges in identifying individuals from this highly commingled context. In addition, using some specific examples within this assemblage, this presentation will inform attendees how identifications (and past mis-identifications) can be resolved with a multidisciplinary approach using anthropological, historical, and DNA analysis.

This presentation will impact the forensic science community by highlighting both the complications and the strategies used to solve commingled human remains cases.

Cabanatuan Prison Camp was one of several Japanese-run Prisoner Of War (POW) camps located on Luzon Island in the Philippines. It was occupied from June 1942 until the end of WWII in September of 1945. There were 2,763 confirmed casualties of American POWs at Cabanatuan. Several factors have influenced the degree of commingling present in the Cabanatuan skeletal remains and have created unique challenges to identifications.

A brief history of the Cabanatuan remains illustrates several different points in which commingling of the remains occurred. The initial burial system at Cabanatuan was a series of mass graves where all individuals who died within a 24-hour period were interred together. Each mass grave received a "Common Grave" (CG) number, and this number is still used today to reference the original provenience of the remains. After the war, the American Graves Registration Service (AGRS) exhumed the Cabanatuan Prison Camp cemetery. The remains were inventoried, preliminary anthropological analysis was performed, and many (300+) individuals were identified. The unidentified were interred temporarily at the United States Army Air Forces Cemetery in Manilla. Beginning in approximately 1947, the Cabanatuan remains at the United States Army Air Forces Cemetery were disinterred (again), processed, and more identifications were completed (1,000+). A review board in 1951 recommended that due to the commingling present, all remaining unknowns be buried in what is now the Manilla American Cemetery and Memorial (MACM) in the Philippines. Historians estimate between 990 and 1,006 unresolved casualties from Cabanatuan are currently at the MACM.

Common Grave 717 was originally associated with 14 individuals who died, according to Cabanatuan prison camp records, on November 19, 1942. Four of these individuals were identified in the late 1940s during the initial analysis of the Cabanatuan remains. The remaining ten individuals were buried as unknowns in the early 1950s at the MACM. In August of 2014, these ten caskets from CG 717 were disinterred from MACM and sent to the Defense POW/MIA Accounting Agency Laboratory in Hawaii for anthropological analysis and identification. The ten caskets from CG 717 are extremely commingled and, as of May 2017, there are 15 mitochondrial DNA (mtDNA) sequences represented in the ten caskets. These include sequences that are consistent with individuals who were previously identified out of CG 717 in the late 1940s, in addition to sequences that are consistent with the historical roster of individuals associated with CG 717.

The commingling present in the Cabanatuan assemblage includes individuals who were identified and resolved soon after WWII and individuals who were unresolved, or "unknown." This particular circumstance creates anthropological and historical complexity for these cases. For instance, given a set of remains from a resolved individual, how do we navigate an identification for those remains, and the set of (now unknown) remains that were buried after an erroneous identification several decades ago? Identifying the commingled remains of Cabanatuan entails revisiting identifications made under completely different operational and scientific standards of the late 1940s.

Using a specific example from an individual associated with CG 717, this presentation examines how commingling of both resolved and unresolved individuals requires an approach that uses anthropological, historical, and DNA data. In addition, it offers some lessons about past mis-identifications, and insight into how to best move forward with our current identification practices for commingled remains.

Commingled, Cabanatuan, Identification

A42 Procedures for Sorting Small-Scale Cases of Commingled Remains: An Integrative Approach Using Morphological, Metric, and Chemical Methods

Colleen F. Milligan, PhD, California State University, Chico, Dept of Anthropology, 400 W First Street, Chico, CA 95929-0400; Eric J. Bartelink, PhD, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; and Alexandra Perrone, MA, 2590 California Park Drive, Apt 13, Chico, CA 95928*

After attending this presentation, attendees will better understand the range and order of procedures for resolving commingled remains cases, including case studies that utilized morphological, osteometric, and non-destructive chemical methods.

This presentation will impact the forensic science community by demonstrating how using a range of methods for sorting commingled remains can produce optimal outcomes for medicolegal cases.

Methods for sorting commingled human remains have a long history in physical anthropology and include the determination of the minimum number of individuals and other quantitative measures for establishing how many individuals are represented within commingled and/or incomplete skeletal assemblages. Over the past decade, the Human Identification Laboratory at California State University, Chico (CSUC HIL) has developed a protocol for resolving small-scale commingling cases, including remains recovered from various scene contexts. This presentation discusses the CSUC HIL commingled remains protocol and presents four commingled case studies to highlight how the application of both low-tech and high-tech methods can successfully sort commingled remains prior to their return to next of kin for final disposition.

All methods for resolving commingled remains are based on the assumption that any two or more individuals vary on a number of different variables, including shape (morphology), size (osteometrics), taphonomic signatures, genetic markers, and chemical composition. Well-tested methods include physical matching and reconstruction of fragmented bones and teeth, visual pair matching of bilateral skeletal elements and tooth antimeres, physical matching of joint congruence of articulating skeletal elements and loose teeth with alveolar sockets, assessment of taphonomic patterns (e.g., staining, animal scavenging, and fragmentation patterns), and DNA profiles. More recently, the use of osteometric sorting and elemental analyses, such as X-ray fluorescence, has been introduced as a means for sorting commingled remains.

The CSUC HIL commingled protocol requires that analyses begin with a complete inventory of all remains and a sort by anatomical position. Where needed, analysis proceeds, beginning with skeletal reconstruction, followed by visual pair matching, osteometric sorting, and assessment of joint congruity. Assessment of taphonomic patterns can provide useful information to complement these methods; however, it can also be misleading if all remains were exposed to similar environments and, by extension, similar postmortem modifications. DNA results, if available, serve as a cross-check against the morphological and osteometric commingling assessment. For any remains that cannot be sorted through these methods, portable X-Ray Diffraction (pXRF) can be used to assign isolated skeletal elements to a particular individual. This application is most appropriate for two-person commingling scenarios. The most effective means for sorting commingled remains using pXRF is to scan a large sample of skeletal elements sorted to each individual through other means (e.g., reconstruction, visual pair matching, DNA), then to construct 95% confidence intervals for chemical concentration values. Concentration values for seven chemical elements (Silicon (Si), Phosphorus (P), Potassium (K), Calcium (Ca), Manganese (Mn), Iron (Fe), and Cobalt (Co)) provided the best discriminating power based on earlier research developed through the CSUC HIL. If the segregated bone groups from each individual do not overlap in their confidence intervals for at least one chemical element, unsorted skeletal elements can be assigned to the individual whose confidence interval includes the chemical concentration values. Thus, pXRF is a valuable tool for sorting commingled remains, but may not discriminate between individuals in all cases.

The use of multiple methods in the identification sequence helps to maximize the correct identifications of individual skeletal elements, especially in instances where a cross-check with DNA analysis is limited. Four recent case studies are used to highlight the utility of the CSUC HIL commingled remains protocol, including an outdoor surface context, a buried context, a fire scene, and a cold case representing several commingled individuals. Each of the case studies represents a different scene context, different length of time between recovery and identification, and different relationships between the individuals. They address issues associated with taphonomic damage, familial relationships, and detection of the number of individuals in group sizes larger than two. The goal of this presentation is to show how flexibility and diversity in the identification methods can aid in reducing the limitations often associated with commingled cases.

Forensic Anthropology, Commingled Remains, Portable X-Ray Fluorescence

A43 How Large Is Too Large? The Effect of Assemblage Size in Reassociating Commingled Remains

Kyle A. McCormick, PhD, Defense POW/MIA Accounting Command, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853*

The goal of this study is to examine osteometric reassociation accuracy as assessed through correct classification rates on commingled assemblages of varying sizes.

This presentation will impact the forensic science community by addressing a largely unexamined aspect of resolving commingling — size of the commingled assemblage.

Commingled assemblages present a common situation in osteological analysis in which discrete sets of remains are not readily apparent, thereby hindering biological profile construction and the identification process. Osteometric sorting has been shown to be a reliable and relatively objective method for resolving commingling.[1] Two statistical and probabilistic osteometric reassociation approaches have been successfully applied to resolving commingling: frequentist and Bayesian.[1,2] This study focuses on the latter approach.

To accomplish the goal of this study, linear measurements of the femur from 435 individuals were analyzed from the William M. Bass donated skeletal collection. Individuals were randomly removed from the total sample, acting as a closed-population commingled assemblage. The smallest commingled assemblage examined in this study was two individuals. The next smallest assemblage was five individuals and assemblage size was increased by increments of five to a maximum of 50 individuals. One femur was chosen from the commingled assemblage as the independent variable, with the possible matching femora representing the dependent variable. Using the remaining total sample, Bayesian regression via Hamiltonian Markov Chain Monte Carlo was used to estimate a range of possible dependent variable values. These values were smoothed into a probability density function using kernel density estimation, and the possible matches were evaluated against this distribution to calculate predictive probabilities. The femur with the highest predictive probability was considered the best match. This process was repeated 100 times for each commingled assemblage size.

As expected, there is a general inverse relationship between correct classification rates and commingled assemblage size. Accuracy decreased as the commingled assemblage size increased, with the two-individual assemblage showing the highest correct classification at 98%, and the fifty-individual assemblage showing the lowest at 76%. Interestingly, accuracy did not decrease markedly as the commingled assemblage size increased. A 50-individual commingled assemblage represents a 2,400% increase compared to a two-individual assemblage, with only a 22% decrease in classification accuracy. These results show that a Bayesian approach to resolving commingling is powerful across a large range of commingled assemblage sizes.

Commingling, Osteometric Reassociation, Bayesian Modeling

A44 Commingling Among Unidentified Remains Stored at Mortuary Facilities in Bosnia and Herzegovina (BiH)

D. Sarzinski, MSc, International Commission on Missing Persons, Alipašina 45a, Sarajevo, BOSNIA and HERZEGOVINA*

After attending this presentation, attendees will be informed regarding the extent of commingling (and associated issues) among the unidentified human remains disinterred in the period of 1996-2016 and stored at mortuary facilities in Bosnia and Herzegovina.

This presentation will impact the forensic science community by providing information regarding commingling during exhumations as well as in mortuary facilities, particularly with regard to obtaining new identifications within the assemblage. The need for thorough analyses with regard to defining skeletal sets and establishing Minimum Number of Individuals (MNI) will be demonstrated, and the framework for re-association of skeletal elements based on DNA and skeletal morphology as assessed through standard osteological measurements will be discussed. Most importantly, the implemented system of meticulous case management will be discussed as a method for prevention of further commingling within the mortuary facilities.

In May 2013, the State Prosecutor of Bosnia and Herzegovina issued an order to commence the process of the anthropological examination of human remains stored within mortuaries and memorial ossuaries across Bosnia and Herzegovina. Through coordination of the International Commission on Missing Persons (ICMP) and state and regional participants, the No Name (NN) Project was created and implemented to ascertain the exact number of cases, review the history of each case, determine each case's current status, and issue recommendations for a national system for organization, storage, and management of all unidentified remains.

As of June 2017, a total of 2,548 cases containing a total of 5,673 skeletal sets have been reviewed by ICMP's anthropologists, indicating a pervasive level of commingling. Commingling in these cases was caused by a variety of factors: interment in caves or pits where numerous taphonomic forces were active; grave robbing and/or displacement (the repeated exhumation and reburial cycles intrinsic to secondary and tertiary mass graves); or through inadequate case management in the mortuary facility itself. In order to address the issue of commingling, the ICMP developed and implemented a thorough process of case review through the assessment of previously accumulated documentation and the use of scientific examination techniques for each case. Divided into several phases, ICMP's NN Project tackled the issue of commingling through determination of skeletal sets present in each case**,** defining them as a discrete set of remains belonging to one individual (ascertained through DNA matching, fracture matching, anthropological features, and visual pair matching) supported by additional findings. A total of 170 reviewed cases were determined to contain only skeletal elements designated as "ossuary," a category encompassing the commingled remains that cannot be associated with a skeletal set that has a successful or pending DNA sample and that will not be subject to DNA testing; these cases cannot be resolved currently, primarily due to the financial constraints of DNA testing.

Out of more than 2,000 DNA samples extracted from commingled or under-sampled skeletal remains during the project, 101 new matches with blood reference samples were obtained from 72 cases, out of which 39 cases had some degree of commingling. This number is likely to increase as many DNA samples are still pending extraction and processing. The examination phase of the project is scheduled to end in September 2017, when a complete summary of obtained results will be made available.

The NN project in Bosnia and Herzegovina illustrates the importance of a comprehensive and integrated approach to the analysis of commingled remains, fulfilling obligations to identify missing persons in the most meaningful and scientifically possible manner.

Commingling, Identification, Mortuary Review

A45 The Accuracy of Visual Pair Matching of the Humerus of a Large-Scale Commingled Assemblage

Carrie B. LeGarde, MA, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113*

After attending this presentation, attendees will understand the reliability and interobserver variability of visual pair matching of the humerus.

This presentation will impact the forensic science community by illustrating that visual pair matching by anthropologists can be confidently relied upon, particularly by those with experience with commingled human remains.

Commingled human remains pose a particularly difficult challenge for identification, particularly when the commingling is large-scale. DNA analysis is often heavily relied upon to segregate these remains into discrete individuals, but this can be time consuming and costly. Anthropological methods, such as pair matching, can be employed when possible to limit the number of elements that require DNA sampling. The purpose of this study was to determine the accuracy rates of visual pair matching for multiple observers with a variety of educational and experience levels.

The sample for this study involves left and right humeri (n=287 and n=293, respectively) from the commingled remains of the USS *Oklahoma,* which are currently being segregated and identified by the Defense POW/MIA Accounting Agency (DPAA). The humerus was chosen for this study for two reasons: (1) there is a relatively high degree of bilateral asymmetry exhibited as compared to other long bones, which could make visual pair matching more difficult; and, (2) all left and right humeri in the assemblage were sampled for DNA analysis, which could allow for the accuracy of pairs to be determined. Although less than half the DNA testing has been completed, accuracy was determined for those that have been tested. Five anthropologists completed this study with osteological experience ranging from 2 to 13 years, with the following education levels represented: post-BA (n=1), post MA (n=1), and post-PhD (n=3). Experience with segregating Commingled Human Remains (CHR) was also considered and separated into three categories: none (n=1), minimal (n=2), and experienced (n=2).

All left and right humeri were placed on ten tables for analysis. The observers were instructed to pair left and right humeri using four categories based on confidence level: (1) match (confident); (2) probable match (fairly confident); (3) possible match (not confident); and, (4) no match. Methodology for pair matching was not specified, but observers were instructed to document their process to examine differences in methodology. Only results for those categorized as "match" are given below. Additionally, matches between observers were compared and examined for congruency.

The amount of time required to complete the pair matching assessment ranged from 35 to 55 hours, but methodology was similar for all observers. The total number of visual pair matches ranged from 88 to 156. The observer with no CHR experience paired the least and all other observers paired between 144 and 156 humeri. The accuracy of pair matching for the five observers ranged from 80% to 100%, with the two experienced CHR observers having the highest accuracy (98% and 100%), followed by the observer with no CHR experience (96%). This reveals that the least experienced observer was more conservative by pairing the fewest humeri (by nearly half), but demonstrated high accuracy for the visual pair matches made. Accuracy was not found to correlate with level of education.

These preliminary results reveal that visual pair matching has relatively high accuracy, regardless of education or experience level; however, this accuracy increases with experience. Results suggest that visual pair matching by anthropologists experienced with commingled human remains are exceptionally accurate and can be relied upon with confidence. These results are preliminary and may change as additional DNA results are received.

Pair Matching, Humerus, Commingled Human Remains

A46 Osteometric Sorting of Commingled Upper Limb Bones

Ioanna Anastopoulou, BSc, University of Athens, School of Medicine, 75 M Asias Street, Athens 11527, GREECE; Fotios A. Karakostis, MSc, Eberhard Karls University at Tübingen, Rumelinstrasse 23, Tübingen, Baden-Württemberg 72070, GERMANY; Konstantinos Moraitis, PhD, University of Athens, School of Medicine, 75 M Asias Street, Athens 11527, GREECE; and Matteo Borrini, PhD*, Liverpool John Moores University, School of Natural Science & Psychology, Byrom Street, Liverpool, AE L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will understand the utility of using metric methods for sorting commingled human remains.

This presentation will impact the forensic science community by providing a statistically valid means of sorting commingled remains when traditional non-metric methods need to be supplemented.

Long bones of the arm and scapula are reported to be reliable for sex determination and stature calculation.[1,2] Therefore, in a commingled context, it is crucial to assess that these bones correspond to the same individual. In this framework, the present study sought to develop a number of functions for sorting commingled human scapulae, humeri, ulnae, and radii using linear measurements of these bones' articular surfaces.

For this purpose, a number of linear measurements was performed: the maximum height and breadth of the glenoid fossa, the maximum vertical head diameter and the maximum anterior-posterior head breadth of the humerus, the capitulum-trochlea breadth, the maximum olecranon breadth, the minimum olecranon breadth, the ulnar radial notch height, the maximum head diameter of the radius, and the vertical radial head height. All 222 individuals included in the study belong to the Athens Collection.[3] This skeletal collection consists of individuals of known sex, age, occupation, and cause of death. They lived in the second half of the 20th century in Athens, Greece, and their biological age ranged between 20 and 99 years.

Simple and multiple linear regression analyses produced a total of 11 equations (7 simple and 4 multiple regression equations) as the best statistical models for predicting measurements of one skeletal element using measurements of another. The standard error of the estimate ranged between 0.88mm-1.59mm for the simple regression formulas and 1.41mm-1.58mm for the multiple regression formulas. Pearson's correlation coefficient ranged between 0.69-0.93 (sig. <0.05) showing statistically significant strong positive correlations among measurements. The coefficient of determination (r2) scored overall higher in multiple regression analyses (0.71-0.86) compared to simple regression analyses (0.47-0.83). Sex and bilateral asymmetry did not have a statistically significant effect on the methods accuracy.

In conclusion, the regression equations developed in this study were found to be suitable for sorting commingled upper limb skeletal elements. The development of similar methods for other joints of the human skeleton would be beneficial for the anthropological analysis of commingled remains.

A47 The Use of Portable X-Ray Fluorescence (pXRF) Spectrometry for a Large Commingled Assemblage

Larkin F. Kennedy, PhD, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113-4006; and Stephanie Fuehr, MA*, 3710 Harney Street, Apt 301, Omaha, NE 68131*

After attending this presentation, attendees will understand the potential application of trace elemental concentrations in bone as measured by pXRF to large commingled skeletal collections when used in conjunction with other segregation techniques, as well as the pitfalls of its use stemming from taphonomic alteration.

This presentation will impact the forensic science community by serving as a further means of segregation in extensively commingled skeletal assemblages and will discuss approaches to combining elemental concentration data with other segregation techniques. These methods also have the advantage of being relatively inexpensive, rapid, and non-destructive.

Commingled skeletal assemblages present a challenge to the accurate segregation of skeletal remains, particularly when individuals from the loss incident share demographic similarities. PXRF has been shown to be useful in segregating individuals in small commingled assemblages, though its utility has not been established in larger scale cases. Developed methods use intraskeletal similarities in the trace elemental composition of bones (including some of the following: potassium, calcium, iron, magnesium, phosphorus, zinc, strontium, lead, sodium, silicon, titanium, vanadium, chromium, manganese, cobalt, nickel, and copper) to chemometrically group skeletal remains based on the relative concentrations of each element; however, many of these concentrations may be affected by taphonomic processes. This research compares elemental concentrations as measured by the pXRF at the bone surface to those measured on internal cortical bone exposed by previous DNA sampling. These data were also compared to trace element concentrations present in the surrounding burial environment. Trace elements with measurements that are much higher at the bone surface are likely to have been taphonomically affected, as are skeletal remains that exhibit an element concentration profile matching that of the burial environment. Additionally, pXRF analysis of these remains alongside standard reference materials with known elemental concentrations may be able to provide accurate measures of individual trace elements that can then be better compared across the skeleton. This research will use the resulting trace elemental concentrations in multivariate analysis to create groups that can be used in conjunction with other segregation methods.

The sample represents the remains of close to 400 men lost aboard the USS *Oklahoma* on December 7, 1941. After multiple identification attempts in the late 1940s, these remains were buried in the National Memorial Cemetery of the Pacific, Honolulu, HI. Their recent disinterment revealed extensive commingling with an estimated minimum number of 390 individuals, based on mitochondrial DNA profiles. Preliminary analysis of three bones, each from four individuals (a humerus, a femur, and an innominate) identified the potential for the use of specific trace elements in segregating remains. One individual displayed high concentrations of potassium and iron, another was characterized by relatively high values of titanium, and another by steady values in strontium, lead, and zinc. The fourth exhibited large fluctuations between measurements obtained at the bone surface and from exposed cortical bone. High concentrations of iron, the presence of vanadium and chromium, and variability in trace elements such as potassium and zinc imply that the composition of these skeletal remains may have been affected by taphonomic processes.

This study will present methods for integrating these chemometric data into visual examination and the use of DNA sequence information for a large commingled assemblage. This research will explore methods for increasing the accuracy of measurement for trace elements throughout this assemblage to better differentiate those useful for segregation of individuals and those indicative of taphonomic alteration.

A48 Estimating the Number of Individuals in a Large Commingled Assemblage of Known Size

Andrea Palmiotto, PhD, DPAA, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; Carrie A. Brown, PhD*, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113; and Carrie B. LeGarde, MA, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113*

After attending this presentation, attendees will understand the differences between methods that estimate the number of individuals in a skeletal assemblage and which method best estimates the true population size of a large commingled assemblage.

This presentation will impact the forensic science community by assessing the results of different methods that estimate population size in skeletal assemblages and highlighting a standardized method to inventory data in large commingled assemblages.

Estimating the number of individuals in a commingled assemblage is vital for planning purposes, including budgeting, resource allocation, analytical approaches, and the direction of future recovery efforts; however, the estimate is affected by factors inherent to the assemblage (e.g., fragmentation, preservation, and recovery rates) and the estimation methods themselves (e.g., variability of methods results in numerous estimates, lack of testing on assemblages of known size, and inconsistent inventory terminology).

Minimum Number of Individuals (MNI), Grand Minimum Total (GMT), and Most Likely Number of Individuals (MLNI) estimate the number of individuals in an assemblage. MNI determines the fewest possible individuals needed to account for the physical remains that are recovered and is traditionally estimated by the reported completeness of the most common element. GMT and MLNI use pair matching, with the former producing an MNI estimate based on counts of paired and unpaired bones and the latter using the maximum likelihood estimate of the total number of individuals that may have originally comprised an assemblage.[1] Previous assessments of MLNI typically have focused on smaller assemblages (<50 individuals) in which the original loss population was unknown; MLNI has not been tested on larger assemblages of known size. For all quantification methods, an accurate inventory of the assemblage is a crucial step, since this affects the accuracy of the estimate.

The December 7, 1941, attack on Pearl Harbor resulted in 429 casualties from the USS *Oklahoma*; 394 of these individuals were not identified at the time. The remains of these individuals are known to be severely commingled; the first disinterred casket, containing five "sets" of remains, yielded 95 unique mitochondrial DNA (mtDNA) sequences. The USS *Oklahoma* project, which seeks to individually identify the USS *Oklahoma* casualties, has an assemblage of nearly 13,000 skeletal elements with nearly 5,000 samples submitted for DNA analyses.

This study examines MNI, GMT, and MLNI estimates using inventoried elements and DNA results to date from the USS *Oklahoma* project. The inventory of the USS *Oklahoma* assemblage used both a descriptive system (e.g., distal portion present) and the zonation method of Knüsel and Outram, with slight modifications.[2] Part of the DNA strategy for the USS *Oklahoma* project included sampling all crania, humeri, and tibiae, enabling the calculation of both MNI and MLNI. MNI was calculated using the most frequent element, zones, and the number of duplicated elements per mtDNA sequence (n=308 mtDNA sequences to date). GMT and MLNI were calculated using visual pair matching of all humeri in the assemblage (*left*=287, *right*=293).

For the cranium, MNI is estimated as 356 individuals (Zone 5, occipital). For the postcranium, MNI is 336 (right femur, distal) and 354 (right femur, Zone 1). By duplicated element per mtDNA sequence, MNI is 394. Based on the humeri, MNI is: 289 (right humerus, distal); 298 (Zone 5); and 369 (GMT); and MLNI is calculated as 399±15 individuals.

In this assemblage, MNI by mtDNA and MLNI provide estimates that are identical or nearly identical to the original population size. GMT is the next most accurate method, followed by MNI based on zones. The least accurate estimator is MNI based on traditional descriptive inventory terms. While MNI by mtDNA sequence is currently very accurate, the sequencing is not yet complete for the project and it will likely take several years to process all 5,000 samples. Thus, this does not represent the timeliest or most cost-effective strategy. MLNI, while also very accurate in this study, has the potential to overestimate when the associated interval is considered, and both MLNI and GMT necessitate pair-matching across the entire assemblage. If this is not possible, the zonation method is more accurate than traditional MNI, and it provides a means to reliably assess fragmented remains, especially if recovery rates are poor or fragmentation is high. Finally, MLNI assessments corroborate previous findings on a larger scale than previously tested.

Commingled Skeletal Remains, MNI, Zonation Method

A49 Using Biological Data to Inform a DNA Sequencing Strategy

Carrie A. Brown, PhD, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113; and Jeffrey James Lynch, MSc, 501 Park Avenue, Apt 126, Omaha, NE 68105*

After attending this presentation, attendees will be familiar with a successful approach using antemortem and postmortem biological data to prioritize DNA sequencing for a large commingled assemblage.

This presentation will impact the forensic science community by outlining a strategy to prioritize DNA sequencing of elements that fall >1 standard deviation from sample means for stature and age estimates, which can then be used to identify individuals prior to completion of all DNA analyses, reducing the missing person pool and the time families wait for notification.

Large commingled assemblages present unique challenges for identification. Unlike individual cases, the segregation of remains into discrete individuals can be difficult and time-consuming, even when DNA is incorporated. Using antemortem data and postmortem estimates from skeletal remains, this study outlines an effective and biologically informed strategy to prioritize DNA sequencing in a large commingled assemblage.

The assemblage is from the USS *Oklahoma* identification project and is comprised of nearly 13,000 skeletal elements; nearly 5,000 were sampled for DNA analyses. The remains are extensively commingled, with the first casket exhumed containing elements representing approximately 25% of the USS *Oklahoma* casualties unidentified following the incident (*n*=394). Analyses of the assemblage, including DNA sequencing, are concurrent with identifications being made.

All elements were inventoried and, as applicable, measured and epiphyseal fusion and pubic symphysis development recorded following McKern and Stewart.[1] The calculation of stature point estimates by element was automated for the entire assemblage using OsteoSort and linear regression equations from Trotter's Black and White male combined dataset in FORDISC® 3.[2] Only elements sampled for DNA analyses with a stature point estimate or age data were included. Antemortem data was drawn from military records of the unidentified USS *Oklahoma* casualties. Frequency distributions and descriptive statistics for antemortem data and postmortem estimates were produced using R, with the exception of epiphyseal fusion since mean ages per stage are not provided by McKern and Stewart.[1]

The frequency distributions for antemortem stature and postmortem stature point estimates are normal and nearly identical — in inches (mean, standard deviation, *n*): antemortem (68.56, 2.31, 374); humerus (68.26, 1.86, 507); radius (68.44, 1.47, 325); ulna (68.35, 1.49, 328); femur (68.17, 1.97, 642); tibia (67.08, 1.88, 573); and fibula (68.45, 1.97, 360). Antemortem age and pubic symphysis postmortem point estimates are skewed to the right, but also similar — in years: antemortem (24.49, 6.40, 394); and pubic symphysis point estimate (24.31, 5.21, 405). For casualty individuals, 160 have stature and/or age that is >1 standard deviation from the antemortem means.

Because of the demonstrated similarity between antemortem data and postmortem estimates, prioritization was defined in four tiers based on standard deviations of the point estimates from the means: Level 1 — stature estimate >2 standard deviations (*n*=89); Level 2 — age estimate $\leq$20 years and $\geq$30 years (*n*=247); Level 3 — Stage 3 fusion (~21 years, *n*=106); Level 4 — stature estimate 1-2 standard deviations from the mean (*n*=501); and total on priority list, *n*=943. Due to the antemortem age distribution, epiphyses that fuse in the mid- to late-20s were not prioritized (e.g., medial clavicle). When elements were found in multiple priority levels, the element was given the higher of the ranked priorities. It should be noted that all cranial and dental samples were sequenced prior to other elements in order to aid with Minimum Number of Individuals (MNI) estimation and dental identifications.

This prioritization strategy has thus far resulted in segregation from the large commingled assemblage of 20 of the 160 individuals whose biological data are >1 standard deviation from antemortem age and/or stature means. These individuals will be identified prior to the completion of DNA sequencing for the entire project, which would not be feasible if relying solely on processing samples in the order they were received. The ability to make identifications can be important for family members, especially when a large period of time exists from incident to identification, as well as the forward progress of the project, as each identification further reduces the pool of missing persons. This also can be applied when sampling elements for DNA. One limitation to this approach is the lack of or incomplete antemortem data, which will affect the ability to develop informed priors.

Commingled Skeletal Remains, DNA Sequencing Strategy, Biological Data

A50 A Multidisciplinary Approach to Identifying Unaccounted Service Members From the Battle of Tarawa in 1943

Rebecca J. Wilson-Taylor, PhD, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; Anthony J. Koehl, PhD, Defense POW/MIA Accounting Agency, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; Audrey L. Scott, PhD, Defense POW/MIA Accounting Agency, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853; Willa R. Trask, Defense POW/MIA Accounting Agency, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853; and Heli Maijanen, PhD, DPAA, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will better understand the interdisciplinary approach necessary to resolve unknown commingled remains associated with a World War II battlefield.

This presentation will impact the forensic science community by highlighting the collaborative efforts and multiple lines of evidence required to identify United States service members from the commingled Battle of Tarawa assemblage.

In November 1943, United States forces captured Betio Island, Tarawa Atoll, Republic of Kiribati (previously the Gilbert Islands), which contained a Japanese-controlled landing strip essential to the United States Pacific campaign. The battle resulted in more than 1,100 United States and more than 6,000 Japanese and Korean casualties on a ~381-acre island; many individuals were buried in temporary mass graves. Approximately ~48% (~500) of all United States burials were recovered after World War II, including Unknowns (Minimum Number of Individuals (MNI)=114) interred in 94 caskets at the National Memorial Cemetery of the Pacific (NMCP). Since World War II, local residents, Defense POW/MIA Accounting Agency (DPAA) recovery teams, and non-governmental organizations have regularly recovered human remains from Betio Island. The Tarawa commingled assemblage consists of remains from past and ongoing field recovery operations and disinterred Unknown Tarawa casualties from the NMCP. The actions of hasty, but necessary, interment after the battle with later disinterment, transport, and reinterment resulted in the loss of identity and commingling of the Tarawa casualties.

Commingled projects have largely relied on DNA analysis for segregation and identification of remains; however, the Schofield Central Identification Laboratory (Schofield-CIL) treated the Tarawa remains with embalming powder prior to their interment at the NMCP, which blocks primer-binding locations. Next Generation Sequencing (NGS) improves the ability to yield DNA sequence from chemically treated remains, but the average time for NGS results combined with the amount of samples required to rectify commingling can take years. In addition, low Family Reference Sample (FRS) coverage of ~68% for both mitochondrial and nuclear references complicates Tarawa identifications. In order to counter these limitations, dental record comparisons and historical records were used to create initial short lists of potential individuals in lieu of DNA as the first step.

These historical or dental short lists serve as the basis for all subsequent analyses (e.g., chest radiograph (CXR) comparisons, development of the biological profile, and osteometric sorting). Antemortem chest radiographs are available for ~25% of all Tarawa casualties, thus providing an additional line of evidence for identification. When a potential CXR match is made from the short list, DNA sequence data obtained from earlier field accessions, which are comprised of primarily small bones of the hands and feet, are examined for association with NMCP disinterments.

If there are elements that match the FRS on file for a potential service member from the dental short list or a chest radiograph match, these elements are compared to the disinterred remains via articulation, osteometric sorting, and pair-matching. These methods use osteometric data to compare elements statistically, enabling the association and segregation of field accessions and NMCP disinterred remains. Through the association/segregation process, a biological profile of the remains is developed for sex, age, ancestry, and stature, which are compared to antemortem records of the proposed individuals. This data provides a means of exclusion and inclusion between those individuals on the short list, thereby facilitating identification.

The Tarawa Project has successfully identified 18 of the NMCP Unknowns using this process. Seven of these cases involved matching remains from field excavations to remains disinterred from the NMCP using this strategy. The initial reliance on other, non-DNA driven methods for casualty associations has freed the NGS DNA sampling queue for cases in which an effective dental short list cannot be generated.

These efforts have allowed this study to determine possible relationships between disinterred remains and field recoveries, focus the DNA sampling strategy employed, and determine future recovery locations on Betio Island. Thus, identifications being made from the Tarawa Project rely on the totality of evidence and interdisciplinary collaborations from geneticists, historians, archaeologists, odontologists, and anthropologists; no one scientist works in a vacuum.

Commingled Human Remains, Tarawa, Anthropology

A51 A Comparison of Bullet Type on Cranial Gunshot Exit Wounds

Elizabeth A. DiGangi, PhD, Binghamton University, Dept of Anthropology, PO Box 6000, Binghamton, NY 13902; Elizabeth A. Evangelou, MA*, Binghamton University, 7210 Ditmars Boulevard, East Elmhurst, NY 11370; Tessa Somogyi, MA*, Binghamton University, Dept of Anthropology, 4400 Vestal Parkway, E, Binghamton, NY 13902; Jessica E. Sanger, BA, 3 Spurr Avenue, Binghamton, NY 13903; Daniel Castellanos, MA*, 37 Haendel Street, Apt 2, Binghamton, NY 13905; Donald Poon, BA*, Binghamton University, Dept of Anthropology, 4400 Vestal Parkway, E, Binghamton, NY 13902; and Kevin E. Sheridan, PhD*, Binghamton University, Dept of Anthropology, 4400 Vestal Parkway, E, Binghamton, NY 13902*

After attending this presentation, attendees will better understand that bullet type (full metal jacket vs. jacketed hollow point) has the potential to have a significant effect on the amount of resultant damage to human skulls.

This presentation will impact the forensic science community by discussing the importance of experimental research in trauma analysis, especially regarding gunshot trauma, while demonstrating that such research using human remains can be conducted respectfully and in a manner designed to obtain the maximum amount of data.

Gunshot wound interpretation, especially of the skull, has been extensively studied in forensic anthropology. Most studies have taken a retrospective approach, whereby information from autopsy reports or forensic anthropology reports are mined for data regarding predictive patterns. This approach is problematic due to the number of extrinsic variables present. These variables include factors such as velocity of the projectile, distance of the weapon to the victim, type of firearm, bullet caliber, and bullet construction. In retrospective studies, there is no way to know what many of these variables were, rendering the results less reliable. Further, while research attempts have been made at elucidating these variables for existing cranial gunshot wound cases, current recommendations advise against determining or estimating anything about weapon type, caliber, or distance when analyzing skeletonized remains with gunshot trauma due to the number of confounding variables.[1] An experimental approach is therefore recommended as such variables can be controlled for, with the goal of eventually enabling variable estimation.

Therefore, this project experimentally tested the effect that bullets of two different constructions (jacketed hollow point vs. full metal jacket) have on human skulls in terms of fracture pattern and amount of damage, as assessed by centimeters of total fracture and exit wound morphology. These different bullet types are designed to either fully penetrate with no fragmentation (full metal jacket) or penetrate and expand upon contact (hollow point). The hypothesis was that damage caused by hollow point ammunition will be greater, which has implications for fracture interpretation.

Forty-five donated human heads were obtained from an anatomical tissue supply company, specifically for the purpose of trauma research. A specialized shooting stand was designed to support each head at the height of an average adult male, and each head was shot once either in the frontal or temporal bone, using a revolver with a $1^{7}/_{8}$-inch barrel loaded with 0.38 caliber bullets. Bullet type (jacketed hollow point vs. full metal jacket) was distributed randomly yet evenly between individuals. Following the experiment, heads were autopsied and macerated using standard procedures.

The interaction between bullet type and exit wound for those individuals with entrance wounds in the frontal bone was tested using a chi-square analysis. Preliminary results reveal that there is a significant difference between impacts with jacketed hollow point bullets vs. full metal jacket bullets in that the former do not cause exit wounds, while the latter do (p=021).

This has implications for gunshot wound fracture analysis, in that these results reveal bullet construction can significantly affect exit wound morphology. Future research will include analysis of fracture pattern differences by bullet type and the interaction between bullet type and entrance wound location.

Gunshot Wounds, Fracture Analysis, Forensic Anthropology

A52 Ancestral Variation and Postcranial Metrics for Three United States Populations: Implications for Stature Estimation

Bridget F.B. Algee-Hewitt, PhD, Stanford University, 162 Mosher Way, Palo Alto, CA 94304*

After attending this presentation, attendees will be aware of the influence of trihybrid ancestry on post-cranial metrics and stature within major United States populations and when group affiliation is unknown.

This presentation will impact the forensic science community by providing opportunities for improving stature estimation models for contemporary United States populations by using long bone measurements and estimated quantities of three-way continental ancestry.

The purpose of this study is to produce trihybrid estimates of continental ancestry for three of the major United States populations in order to: (1) test for associations between the proportions of ancestry, long bone measurements, and recorded stature; and, (2) determine if any of the three vectors of ancestry estimates contribute useful information to statistical models for the prediction of stature from upper and lower limb bone measurements. A sample of 934 males of recorded Black, Hispanic, and White identity, with matched cranial/postcranial metrics and forensic/cadaveric stature data, was selected from the Forensic Anthropology Data Bank. Of this total sample, 593 cases, with birth years ≥1930, were used in parallel analyses to address the issue of secular change in long bone measurements.[1,2] The proportions of African, European, and Native American ancestry for each individual were generated from the unsupervised model-based clustering of a standard set of craniometrics.[3] Four hypotheses are evaluated using these data: (1) estimates for each of the African, European, and Native American ancestry components are correlated with length measurements for the six limb bones and with recorded stature, when the sample is partitioned by population; (2) similar trends are observed when all cases are pooled and population affiliation is presumed unknown prior to analysis; (3) birth year, as a proxy for secular change, affects the outcome of these analyses; and, (4) stature estimation can be improved by including percent ancestry estimates in regression models using single bone measurements.

To investigate associations among ancestry composition and skeletal metrics, Pearson correlation coefficients, *r*, were calculated between each of the three vectors of ancestry estimates, the six limb bone lengths, and the recorded statures. Population-specific test results indicate that Black individuals showing less admixture with Europeans and Native Americans tend to have longer limb bones but shorter statures. Hispanic individuals with more Native American ancestry tend to have shorter limb bones and shorter statures, while those individuals with more African ancestry tend to have taller statures. Both larger quantities of African and European ancestry are associated with longer bone lengths for the Hispanic cases. White individuals in the Forensic Data Bank (FDB) are found to have low admixture (≈8%), as such correlation coefficients are small; however, their consistent direction suggests that greater metrics and taller stature are associated with European ancestry.

Results for the pooled data analysis find that all long bone metrics increase as African ancestry increases. The lengths of the humerus, femur, tibia, and fibula decrease with increased Native American ancestry just as the radius and ulna decrease with increased European ancestry. Stature is positively correlated with European ancestry and most negatively correlated with Native American ancestry. Trends similar to the individual population analyses are observed for the sample with birth years ≥1930. Yet, differences are noted in the ancestry proportions of the Black and Hispanic birth year subsets: in accordance with prior findings, the quantities of African and Native American ancestry are reduced, respectively.[4,5] This shift toward greater European admixture produces a change in magnitude, but not in direction, of the correlation coefficients.

To determine the effect of trihybrid ancestry on stature estimation, stepwise selection via Bayesian Information Criteria (BIC) and Akaike's Information Criteria (AIC) was applied to identify the best-fitting least squares regression models with significant ancestry component(s) and bone-ancestry interaction effects for each long bone measurement. Model improvement was gained with the inclusion of one ancestry component for all long bone regressions for the White sample, for all regressions except the fibula for the Black sample, and for regressions using the radius, ulna and fibula for the Hispanic sample. When populations were pooled, the best-fitting models include one (humerus, femur) or two (radius, ulna, tibia, fibula) ancestry component effects and one bone-ancestry interaction (ulna, radius) term.

These analyses demonstrate how: (1) quantifying variation in ancestral contributions is important to understanding within-population differences in both long bone measurements and statures; (2) population-specific trends are consistent when cases are pooled; (3) trends observed with the full sample are recapitulated with the birth year subset, indicating minimal influence of secular change on these trends; and, (4) the improvements gained in regression model fit suggest that future work on stature estimation equations may benefit from considering estimates of trihybrid ancestry, which can be computed from standard cranial measurement or forensic DNA data.

Trihybrid Ancestry, Long Bone Measurements, Stature Estimation

A53 A Comparison of Historical and Present-Day Skeletal Analyses of Unidentified Remains Recovered From Europe During World War II

Katherine Skorpinski, PhD, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt Air Force Base, NE 68113; and Ian Spurgeon, PhD, Defense POW/MIA Accounting Agency, 241 18th Street, S, Ste 800, Arlington, VA 22202*

After attending this presentation, attendees will be aware of accuracies and limitations of historical skeletal analyses of unidentified remains from World War II as they pertain to identification efforts, as well as the value of interdisciplinary collaboration between historians and anthropologists to interpret historical records.

This presentation will impact the forensic science community by identifying patterns in inaccuracies of historical skeletal inventories and biological profile estimations made using methods available in the 1940s.

The goal of this presentation is to compare historical documentation of remains recovery and analysis from World War II with current-day anthropological analyses of the same remains to determine possible sources of commingling and discrepancies in biological profile estimates, which may have originally rendered the remains as unidentifiable.

Defense POW/MIA Accounting Agency (DPAA) anthropologists and historians compared the historical records and current-day forensic anthropology reports of unidentified remains recovered in Europe during or shortly after World War II (n=34). Personnel from the American Graves Registration Command (AGRC) interred, disinterred, and processed the remains in the 1940s — sometimes multiple times — but could not establish identifications; the remains were subsequently buried as unknowns. Due to significant advances in DNA analysis and anthropological techniques, DPAA recently disinterred these unknowns for reanalysis in an attempt at identification. Variables examined in this study include degree of commingling and estimated biological profile.

Of the 34 cases examined, six involved some degree of commingling not documented in the historical record (18%). Commingling in these cases generally involved duplication in minor skeletal elements or fragments of elements. In some circumstances, these cases were buried in the same temporary cemetery or recovered in proximity to one another. Discrepancies between multiple historical dental and skeletal charts were also noted for four other cases (12%), suggesting possible commingling; however, upon accession at DPAA, anthropologists found no evidence of commingling with these cases.

DPAA anthropologists also compared historical biological profile estimates with modern reanalyses. AGRC technicians provided age estimates for 18 of the 34 sets of remains. Historical age estimates overlapped current estimates for 15 cases (83%), 10 of which indicated the method used for estimating age. For cases with discrepancies in age estimates, two of the three were historically overestimated while the other was underestimated. The two overestimations were made by the same analyst. For cases with historical stature estimates (n=28), 24 fell within current estimated stature ranges (86%). Stature was historically overestimated for individuals currently assessed to be of African ancestry and historically underestimated for shorter individuals. These variations arise from differences in formulas used to estimate stature, as historical skeletal measurements were similar to modern measurements. For remains with historical ancestry assessments (n=9), discrepancies occurred in three cases (33%) in which the current assessment was African or probable African, and the historical assessment was European.

Discrepancies between current and previous skeletal analyses may be due to limitations in facilities and personnel during the massive repatriation efforts of the late 1940s. During recovery operations in Europe, AGRC field teams frequently gathered and transported multiple sets of remains (sometimes dozens) from a battlefield at a time. These efforts taxed the capabilities of recovery teams, who often did not complete the necessary documentation of recoveries until days or weeks afterward. The first careful examination of the remains usually did not occur until delivery at a central identification point — some of which processed more than 2,000 sets of remains during the course of a year. Training and experience level for technicians performing the skeletal analyses also varied, as evidenced by two problematic historical age estimates made by the same technician.

Additionally, trends suggest limitations with anthropological methods used at the time. Stature equations used during the war appear problematic for shorter individuals, as well as non-European ancestry groups; however, historical stature estimates for Europeans of average height or taller were consistent with modern stature estimates. Further, historical age estimates that included a justification for the estimate were also consistent with modern age assessments. Although the identified discrepancies can complicate the use of historical analyses for identification and likely contributed to the initial inability to identify these remains, the identified patterns in consistencies and inconsistencies with current analyses can be used to aid in assessing possible candidates for identification for unidentified remains.

Historical Records, Commingling, Biological Profile

A54 An Assessment of Ancestry and Sex Estimation Using FORDISC® 3.1

John Albanese, University of Windsor, Dept of Sociology, Anthropology and Criminology, 401 Sunset Avenue, Windsor, ON N9B 3P4, CANADA; Abegail Dagdag, University of Windsor, Dept of Sociology, Anthropology and Criminology, 401 Sunset Avenue, Windsor, ON N9B 3P4, CANADA; Carmen Skalic, BA, University of Windsor, Dept of Sociology, Anthropology and Criminology, 401 Sunset Avenue, Windsor, ON N9B 3P4, CANADA; and Hugo Cardoso, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will better understand the problems with estimating ancestry from skeletal remains and the problems resulting from the approach of linking sex estimation to ancestry estimation.

This presentation will impact the forensic science community by discussing: (1) how cranial measurements are used to illustrate problems with ancestry estimation methods; (2) how a change in terminology from race to ancestry has not solved any underlying problems with the methods; and, (3) how linking sex to ancestry severely compromises the accuracy of sex estimation.[1]

Thomas and colleagues found an "accuracy rate" of 90.9% for ancestry estimation for a sample derived from an historical review of Federal Bureau of Investigation (FBI) records.[2] One of their goals with the historical review was to assess how various methods have provided information that was potentially useful in a forensic investigation; however, as they noted, methodological issues with how they included/excluded cases for analysis (n=99) have likely resulted in the inflation of the true allocation accuracy. In the research presented here, an experimental approach was pursued using FORDISC® 3.1 to provide a better estimate of expected allocation accuracy. A realistic scenario was created for the Detroit-Windsor boarder area to address one question: How often would FORDISC® provide estimates of ancestry and sex that would be useful in a forensic investigation?

Nine standard cranial measurements that are resistant to taphonomic changes were used from a test sample of 105 documented cases from the Terry and Coimbra Collections that reflect the demographic composition of the region and potentially real forensics cases: Western European-born individuals, European Americans, and African Americans. One additional provenienced (Late Archaic) First Nations (Amerindian) cranium from this region was also assessed. Cases were selected by one researcher and analyzed blind by another. The estimated ancestry matched pre-mortem records only 48% of the time and sex was estimated correctly 75% of the time; however, FORDISC® 3.1 does not allow for the separation of ancestry from sex estimation and the software provided correct estimates of sex and ancestry in only 39% of the cases. Thus, in 61% of the cases, FORDISC® provided erroneous information that would have compromised efforts for identification. Furthermore, a well-known problem with discriminant function analysis, the statistical approach used by FORDISC® and other methods, is that it will force an allocation into one of the selected groups even if the unknown is not a member of any of those groups. Posterior and typicality probabilities are intended to deal with this lack of "none of the above" problem by flagging these cases with probability scores of less than 0.05. The results from this research indicated that in most of the erroneous cases, the variously calculated probabilities failed to flag these cases and instead suggested confidence in the erroneous allocations. For example, the 4,000-year-old Late Archaic cranium was classified as "Black Male" with a posterior probability of 0.314, and three variously calculated typicality probabilities ranging from 0.960 to 0.963.

The results from this research indicate that renaming of race as ancestry methods does not solve any problems with these methods and linking sex estimation to ancestry undermines sex estimation.

Biological Profile, Ancestry Estimation, Sex Estimation

A55 A Multidisciplinary Approach to Identification and Repatriation at Mount Austen, Guadalcanal

Megan E. Ingvoldstad, PhD, DPAA Laboratory, 106 Peacekeeper Dr., Offutt Air Force Base, NE 68113; and Kimberly A. Maeyama, PhD, DPAA Laboratory, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will understand how historical, spatial, archaeological, anthropological, genetic, and isotopic analyses are synthesized by the Defense Prisoner of War/Missing in Action Accounting Agency (DPAA) personnel to streamline identifications and repatriations from an extensively commingled Solomon Islands battlefield site.

This presentation will impact the forensic science community by illustrating how a multidisciplinary approach can lead to identifications and repatriations within a Commingled Human Remains (CHR) project. This multidisciplinary approach specifically provides a useful method for sorting CHR originating from numerous nations.

From December 1942 to February 1943, Allied troops attempted to dislodge an entrenched Japanese position at Mount Austen, Guadalcanal. As a result, Japanese, American, Australian, New Zealander, Fijian, and Solomon Islander combatants overlapped spatially. Many of these individuals experienced fragmentation-causing skeletal trauma, and burials, which may have prevented further commingling, were not performed. Additionally, the Mount Austen site is now more than 75 years old and current occupants modify the site daily. The general area is also characterized by steep slopes, and downhill erosion exacerbates fragmentation and commingling of human remains.

While all large and fragmentary CHR projects endeavor to re-associate numerous portions of multiple individuals, the Solomon Islands Unidentified Project (SUP) specifically struggles to distinguish American from non-American remains, often without the use of morphological traits due to poor preservation. To efficiently and economically approach this challenge, a process was developed to manage the large quantities of evidence recovered from this battlefield, streamline American identifications, and repatriate the remains of combatants from other countries.

A detailed review of historical and archival documents pertaining to the Mount Austen battlefield loss was first completed by DPAA historians. From these efforts, a list of missing individuals was generated — 19 United States service members among at least 900 unaccounted-for Japanese. Battle timelines and troop movements were next georeferenced to better understand the context of the loss incident. DPAA archaeologists use this spatial data to target the most likely areas where missing United States members could be, and subsequent surveys and excavations have resulted in seven large accessions of human remains; there are also more than 25 additional accessions in the laboratory from unilateral turnovers allegedly related to the same loss incident.

Once evidentiary materials are received by the laboratory, the project anthropologist separates biological from material evidence, administratively removes non-evidence, designates group remains, marks remains with provenience data, sorts skeletal elements by size, reconstructs, makes pair-match determinations, nominates for DNA guided by the minimum number of individuals, builds individuals by genetic sequence, synthesizes provenience data by individual, and considers the haplogroup of each genetic sequence. An East Asian sequence is repatriated to Japan, while a sequence matching a United States Family Reference Sample (FRS) is processed for identification. A Caucasian or inconclusive sequence not matching an FRS is nominated for isotopic analysis as isotopic composition may aid in separating an American from a non-American service member.

After various results are consolidated, the project anthropologist provides feedback for the Mount Austen site archaeologists. Specifically, they identify exact locations where possible United States remains have been found to increase the likelihood of recovering additional American remains during the next excavation.

At present, all SUP remains currently in the DPAA Laboratory have been analyzed according to this method with numerous repatriations performed, several possible American sequences identified, and specific battlefield areas targeted for additional recovery operations. Through a combination of historical, spatial, archaeological, anthropological, genetic, and isotopic analyses, efforts to locate and recover United States remains from the large, commingled Mount Austen battlefield site are progressing.

The views of these authors do not reflect those of the Department of Defense or the Unites States government.

Commingled Human Remains, Fragmentary, Identification

A56 A Test of the (hu)MANid Classification Software on a Sample of United States White and Black Mandibles

Kelsey A. Carpenter, MS, Mercyhurst University, Dept of Applied Forensic Sciences, Erie, PA 16546; and Heather M. Garvin, PhD, Des Moines University, Dept of Anatomy, 3200 Grand Avenue, Des Moines, IA 50312-4198*

After attending this presentation, attendees will understand how the newly created (hu)MANid software performed when classifying sex and ancestry on a large sample of mandibular data.

This presentation will impact the forensic science community by testing the performance of this new software to evaluate its utility in forensic cases and by providing documented accuracy rates.

A recent publication by Berg and Kenyhercz describes a newly available statistical software program that can be utilized by practitioners to estimate sex and ancestry from the human mandible.[1] The software program, (hu)MANid, is available through the web or can be downloaded to be run with the statistical program R. It allows the researcher to input a combination of metric and morphoscopic variables from the mandible, from which either a Linear Discriminant Analysis (LDA) or Mixture Discriminant Analysis (MDA) can be performed to compare and classify the unknown mandible into one of the 15 reference groups within the program's database (total n~1750). Given the recent release of this software, there are not yet any published validation studies analyzing the accuracy of the assigned classifications.

In this study, morphoscopic and metric data were collected from a sample of 230 adult mandibles from United States White and Black males and females, and analyzed using the (hu)MANid web-based software program. Bigonial width, bicondylar width, and mandibular length had previously been collected from the physical specimens. The remaining metric variables (mandibular body height, chin height, minimum ramus breadth, maximum ramus height, and dental arcade width) and five morphoscopic variables (chin shape, shape of the lower border of the mandible, ascending ramus profile, gonial angle flare, and posterior ramus inversion) were collected following the descriptions provided in the "Definitions and Diagrams" tab of the software program from 3D virtual models of the specimens. The virtual mandibular models were created from 3D surface scans collected with a NextEngine® desktop scanner from individuals in the Hamann-Todd, Terry, and Bass Donated skeletal collections. All metric and morphoscopic data were collected using GeoMagic® Studio. The data collected from each specimen were run through the (hu)MANid program using the two different methods (LDA and MDA), first with all variables included, then using a Forward Wilks stepwise procedure, and both were compared to all 15 modern comparison groups and also to only the United States White and Black 20th-century samples. Altogether, eight separate analyses were run on each of the 230 specimens. The resultant group classifications were compared to the actual sex, ancestry, and combined ancestry/sex of the individual, and percentage of correct classifications was calculated.

In all cases, the MDA analyses outperformed the LDA analyses, and slightly better accuracy rates were obtained when all variables were entered (compared to using a Stepwise procedure). When performing an MDA on all available variables and comparing to all 15 modern reference groups, sex was assigned correctly in 76% of individuals, ancestry was correct in 52%, and both sex and ancestry were correctly estimated in 40%. Although these values may appear low, when considering that they were compared to 15 groups and the *a prior* classification rate would be less than 7%, 40% is a major improvement. An accuracy rate of 76% for sex estimation is also higher than most reports of sex estimation from the mandible, although lower than reported values for sex estimation from other regions of the skeleton. When the comparisons were limited to the United States White and Black reference groups, accuracy rates did not increase significantly: MDA on all variables resulted in 75% correct sex, 57% correct ancestry, and 41% correct sex/ancestry group. United States Blacks were much more likely to be assigned to the correct sex/ancestry group (77% correct, compared to only 7% correct for the United States White individuals). Overall, the (hu)MANid program performed relatively well, considering that all input variables are from the mandible. Although the program still needs to be tested on a sample of modern forensic cases, it exhibits great potential as a sex and ancestry classification tool.

Sex Estimation, Ancestry Estimation, Mandible

A57 Comparing Socio-Economic and Population-Level Differences and Quantifying Their Impact on Subadult Age Estimations

Samantha M. Gonzalez, 820 N Virginia Street, #4, Reno, NV 89501; and Kyra E. Stull, PhD, University of Nevada, Reno, Dept of Anthropology, 1664 N Virginia Street, Stop 0096, Reno, NV 89557*

The goal of this presentation is to inform attendees on the impacts of socio-economic and population differences on growth and development markers and, subsequently, subadult age estimation. A comparison of diaphyseal dimensions and dental formation from individuals between birth and ten years of age from two economically and genetically diverse countries will advise forensic practitioners on the potential utility of global, rather than population-specific, models.

This presentation will impact the forensic science community by providing insight into the developmental onset of economic and population differences and at what age the differences need to be considered prior to estimating a subadult biological profile.

Subadult age estimation is usually the sole contribution to the subadult biological profile. It is regularly stated that there need to be population-specific methods; however, it is not known at what age the population differences become apparent, or at least influential, to age estimations. Similar to population differences, another concern is the socio-economic status of reference groups. Growth data is recognized as being heteroscedastic, meaning that as individuals increase in age, the variation also increases. Based on the nature of heteroscedastic data, if there are minimal differences in the first few years of life, it should be possible to build global models, or apply models derived from one population and to others. The purpose of this study is to compare the skeletal and dental formation of two economically and genetically diverse populations as a means to determine if differences in growth and development exist and, if so, to quantify their magnitude.

Long bone lengths and dental formation stages for the maxillary and mandibular first and second molar were collected from a modern sample of subadults from South Africa and the United States. Individuals were between the ages of birth and ten years of age. First, simple visualizations were used to display the growth and development trends for each age indicator and variable per population. Second, point estimates were created for each individual variable using multivariate adaptive regression splines and age as the response variable. Ranges and means of the differences between the fitted values and true chronological age provided insight into the accuracy of each variable. By visualizing the discrepancies between the estimated ages based on dental formation and long bone length, we can also obtain an idea of which variable is more or less sensitive to the environment and/or population differences.

Visual comparisons confirmed very similar trends for long bone lengths and molar development, especially in the youngest individuals (<5 years). Differences between the groups increase as age increases. In the youngest ages, South African subadults have longer diaphyseal dimensions than their United States counterparts. As age increases (~3-4 years) of age), the median values become more similar and eventually the United States subadults (>6 years) exceed the South African children. Mean differences for the estimated and true chronological age in the regression models is close to zero for both South African children and United States children for the femur diaphyseal lengths (-0.02, -0.003, respectively) and the first molar (-0.04, -0.03, respectively). No differences were found when dental age and skeletal age were visualized to explore differential sensitivities; there was an even spread of predicted age both below and above the ideal fit line.

The findings of this study prove that minimal skeletal and dental differences are expressed in economically and genetically diverse young, modern subadults, which suggests anthropologists could apply methods developed on one population to other populations. The results will substantially impact the field, considering the paucity of modern skeletal remains around the world from which to derive population-specific methods. Furthermore, by increasing the application of scientifically and statistically sound techniques, we can also increase the number of positive identifications.

Diaphyseal Dimensions, Dental Formation, MARS

A58 Age Estimation of Hispanic Children Using the London Atlas

David C. McCloe, DDS, 4225 Millersport Highway, Buffalo, NY 14228; Sakher J. AlQahtani, PhD*, College of Dentistry, King Saud University, Riyadh 11545, SAUDI ARABIA; Marcio da Fonseca, DDS, University of Illinois at Chicago, 801 S Paulina Street, Chicago, IL 60612; Michael D. Colvard, DDS, PhD, UIC DMRT Office, College of Dentistry, University of Illinois at Chicago, 801 S Paulina, Rm 569-C, Chicago, IL 60612; and Ian Marion, DDS, University of Illinois at Chicago, 801 S Paulina Street, Chicago, IL 60612*

After attending this presentation, attendees will be familiar with the technique of estimating the age of children using dental radiographs. They will also be introduced to new population data for age estimation using The London Atlas of Tooth Development and Eruption.[1]

This presentation will impact the forensic science community by contributing a new data set to the bank of population-specific age estimation data. The accuracy of the results reinforces the principle that age estimation can be pragmatically accomplished using a universal tool rather than requiring population-specific methods.

Many different age estimation methods exist and studies have shown varying levels of accuracy, depending on the population group tested. The goal of this study was to test the accuracy of The London Atlas for age estimation of Hispanic children and to determine if there is any difference in age accuracy between males and females.

This study was a retrospective cross-sectional review of records of healthy Hispanic children from ages 6 to 15.99 years who had digital panoramic radiographs taken at the University of Illinois at Chicago College of Dentistry, Chicago, IL, between January 1, 2000, and January 15, 2016. A report of all patients marked as of Hispanic ethnicity or as Spanish speaking who had a panoramic radiograph taken between the ages of 6 and 16 years since January 1, 2000, was generated. After the list was generated, it was randomized to remove any order and was then screened by the primary investigator. The exclusion criteria were radiographs that were unclear and/or distorted, and patients who had hypodontia, hyperdontia, gross pathology (e.g., taurodontism, microdontia, amelogenesis imperfecta, dentinogenesis imperfecta, tumors, abscesses, fractures, etc.), previous orthodontic treatment, and/or severe malocclusion. Chronological age was blinded from the primary investigator and age estimation was performed using The London Atlas of Tooth Development and Eruption on the left side of both upper and lower jaws. Inter- and intra-examiner reliability tests were performed on 34 randomly selected radiographs.

There were 332 panoramic radiographs evaluated. In all age groups, 34 radiographs (from 17 males and 17 females) were reviewed, except for the age bracket 6–6.99 years, for which only 26 radiographs meeting the exclusion criteria were available. The intra-examiner comparison yielded a Cohen's Kappa of 0.793 and the inter-examiner comparison yielded a Cohen's Kappa of 0.764, which indicated good reliability in the use of The London Atlas. The mean age estimated of the entire sample by The London Atlas (11.44 years) was greater than the mean chronological age (11.09 years), which was statistically significant ($P < .001$). The mean difference between chronological and estimated ages for males was 0.30 years and for females was 0.40 years, but the difference between sexes was not significant ($P = .324$). One hundred sixty-two radiographs (49%) were estimated to the exact age interval, while 45 (14%) were under-estimated and 125 (38%) were over-estimated. Two hundred and forty radiographs (72%) were estimated to a value within one year of the actual age.

There was no difference in age estimation prediction accuracy between Hispanic males and females, but an age overestimation was seen. The London Atlas accuracy is suitable for use in forensic investigation.

Age Estimation, Radiographs, Children

A59 A Geometric Morphometric Analysis of Contemporary Hispanic Populations From Mexico and Colombia

Sergio Calle, BA, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02120; Sean D. Tallman, PhD, Boston University, Depts of Anatomy and Neurobiology and Anthropology, 72 E Concord Street, L1004, Boston, MA 02118; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will have gained a more precise understanding of geometric morphometric analysis and its applicability to ancestry estimation in Hispanic populations.

This presentation will impact the forensic science community by illustrating that a greater degree of classification beyond Hispanic may be possible using geometric morphometric methods that provide a statistically grounded model to differentiate two Hispanic populations.

In contexts such as natural disasters, humanitarian efforts, and forensic investigations, the timely and accurate development of the biological profile is vital to the identification of decedents. An essential but problematic aspect of the biological profile is the estimation of ancestry. Geometric morphometric analyses are germane to forensic ancestry estimation because they employ a statistically sound approach, derived from W.W. Howells' well-defined landmarks that focus on craniometric shape differences independent of size; however, many of the current methods pose a challenge because the term "Hispanic" is frequently utilized to represent world-wide Hispanic populations with the untested assumption that all individuals from North, South, and Central America, and the Caribbean are skeletally homogenous.[1-3] Additionally, comprehensive studies of Hispanic populations are severely limited due to the lack of robust reference data. The continued use of unrefined methods is problematic when employed in areas where remains are likely to be of Hispanic origin. As such, this study tests the hypothesis that two contemporary populations from Latin America (Colombia and Mexico) will demonstrate significant craniometric shape variability and provides population-specific forensic ancestry estimation methods.

This study explores geometric morphometric population variation and differentiation in 422 Colombian and Arizona Migrant individuals, 18 to 102 years of age. The Colombian sample is composed of 191 individuals from the late 20th and early 21st century (University of Antioquia). The Migrant sample is composed of 231 border crossers from the Pima County Office of the Medical Examiner (PCOME) in Tucson, AZ. The PCOME reports that the majority of migrants who die along the United States-Mexico border are from Mexico, and, as such, this group will represent a contemporary Mexican population.[4] MorphoJ, a program written for geometric morphometric analyses, was used to interpret the data in order to understand shape variation between the samples.[5] A Generalized Procrustes Analysis (GPA) was performed to scale, rotate, and transform the data into a common coordinate system. Males and females were pooled together in order to maximize the sample size. Subsequently, a Canonical Variate Analysis (CVA) was run in order to maximize the differences among the groups and isolate the key features contributing to the variation.

Mahalanobis distances were produced from the CVA and indicated statistically significant differences between the Migrant group and the Colombian group ($p < .001$). The plot produced by the CVA graphically displays the separation between the Colombian and Migrant group. The results support the hypothesis that morphological differences exist between the Colombian and Migrant decedents, who are more likely Mexican nationals. Therefore, a greater level of classification accuracy beyond "Hispanic" is possible using geometric morphometric methods.

This study supports the notion that a higher level of forensic identification may be possible using a geometric morphometric approach for Hispanic populations. Both the Colombian and Migrant samples demonstrate variability in form that underscores the importance of introducing geometric morphometric methods into the forensic toolkit. Moreover, this study demonstrates that Hispanic populations are not skeletally homogenous due to unique admixtures from the three primary ancestral groups (European, African, and Native/Asian) and differing population histories. Therefore, within a statistical framework, geometric morphometric methods can derive accurate identifications by assessing ancestry in a meaningful way using the morphological variation present in the human cranium.

This research was funded by Boston University's Department of Anatomy and Neurobiology.

A60 The Frequency of Asymmetry in Non-Metric Craniofacial Trait Expression and Its Effect on Ancestry Assessment

Samantha W. Coberly, Arbor Park, 309 SW 16th Avenue, Apt 106, Gainesville, FL 32603*

After attending this presentation, attendees will better understand the range of asymmetry within a forensic population.

This presentation will impact the forensic science community by emphasizing the importance of considering asymmetry when assessing ancestry and determining if the current method is the proper way to deal with asymmetry of traits.

The purpose of this study is to better understand the frequency of asymmetry in the craniofacial traits used to assess ancestry and to determine the effect of asymmetry, if any, on the results of the assessment.

Ancestry assessment is important in the creation of a biological profile of an unknown decedent. Non-metric trait frequencies have been compiled over time within forensic anthropology and are commonly used to analyze ancestry trait expression.[1] One of the most popular studies conducted on trait frequencies between and within groups was published by Hefner.[2,3] It has been established that many craniofacial traits are asymmetric.[4,5] Although Hefner briefly addresses asymmetry, noting that some traits (i.e., Inferior Nasal Aperture (INA)) exhibit it, and suggests scoring the left side in these cases; he does not go into the effects it may have on ancestry.[7]

Identified individuals curated at the C.A. Pound Human Identification Laboratory were assessed for the 11 non-metric traits described in Hefner. Of the 40 individuals, 15 were female and 25 were male. Ten of the 40 were of primarily African ancestry, 29 of primarily European ancestry, and one of primarily Asian ancestry. Six of the 11 traits (Anterior Nasal Spine (ANS), INA, Malar Tubercle (MT), Nasal Overgrowth (NO), Transverse Palatine Suture (TPS) and Zygomaticomaxillary Suture (ZS) have the possibility of asymmetry due to being bilateral. The right and the left of each of these six bilateral traits were scored independently. A final ancestry assessment was made for both the left and right sides of each individual independently and, based on a simple majority of ancestry group trait expressions, each expression was assigned to the group with the highest frequency of that trait expression; for the purpose of this research, MT was not used in the final ancestry assessment due to incorrect frequency data in the Hefner 2009 article.[6] The right- and the left-sided final ancestry for each individual was compared.

The results indicate that more than half of the individuals (22) had at least one asymmetric trait for a total of 26 asymmetric traits. Four individuals had two asymmetric traits; none had more than two. Thirteen of the 26 asymmetries (50.0%) were found in the ZSs, four in the INSs, (15.4%), three in the NOs (11.5%), three in the MTs (11.5%), two in the ANS (7.7%), and one case was found in the TPS (3.9%). Of the 22 individuals with asymmetry, only three (14%) were classified into different ancestry groups for the right versus the left. In each of those three cases, one side resulted in Asian ancestry classification and the other side as European classification. With two of the cases, the left side was the correct ancestry, and in the third, it was the right side. All three of these individuals self-identified as White. Using a z-test, no significant difference (p=115) in the frequency of asymmetry between the ancestry groups was found. Males and females exhibited asymmetry with approximately similar numbers (53% in females and 56% in males).

A tentative conclusion can be made that asymmetry occurs most often in the ZS and least often in the TPS. Earlier studies concluded that the ANS had only small deviations.[7] In this study, only two individuals had ANS deviations large enough to warrant a different trait expression in the right than in the left. This study suggests asymmetry can affect non-metric ancestry assessment, although this is uncommon. This finding is in line with other studies, which have noted that trait asymmetry is minimal.[4] Using the left side when analyzing bilateral traits worked two-thirds of the time and there does not appear to be a reason to discontinue using this methodology. Note that the sample size is small and that the ancestry assessment was simplified from what it would be in an actual forensic case. Further testing will be needed to fully understand the degree of asymmetry in craniofacial traits and their effect on ancestry.

Asymmetry, Craniofacial Traits, Ancestry

A61 Non-Metric Traits of the Mandible in Ancestry Estimation

Sarah Schwing, BA, BS, 5328 Mill Stream Drive, Saint Cloud, FL 34771; and Michala K. Stock, MA, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610*

After attending this presentation, attendees will be more knowledgeable on the subject of ancestry estimation via non-metric traits of the mandible, briefly reviewing similar research, a discussion of metric versus non-metric methods of assessment, and examining why the mandible holds potential as an ancestry-discriminating bone.

This presentation will impact the forensic science community by examining and discussing the usefulness of eight non-metric traits of the mandible in ancestry estimation and by suggesting traits to be considered in future research.

Ancestry represents a fundamental aspect of the biological profile. Therefore, when seeking to identify unknown human remains, ancestry plays a crucial role in minimizing the number of potential missing persons matches.[1,2] However, ancestry is routinely cited as the most difficult aspect of the biological profile.[2-6] As this assessment relies heavily upon the use of non-metric skeletal traits that are often clinal in nature, categorizing and standardizing these traits remains a challenge for forensic anthropologists.[4]

The traits most useful in ancestry estimation are housed within the mid-facial cranium.[1-3,7-9] This small and particularly fragile region of the skeleton has received substantial attention and research efforts with regard to ancestry estimation.[9] The mandible and post-cranial elements are less often used in ancestry estimation and, accordingly, the literature on these regions is less robust. As the mandible is more durable than many bones of the mid-face, it is more likely that this bone will be recovered in medicolegal investigations and can be assessed for ancestry.[9] The mandible also offers a plethora of traits, which can be helpful when the bone is found fragmented or incomplete. Furthermore, the mandible creates a functional unit with the mid-facial cranium, the most reliable region for ancestry estimation. As such, the mandible may also house traits fruitful in this assessment.

This study investigates the expression of eight non-metric traits of the mandible, including: pinching of ascending ramus, chin shape, chin profile, undulation of inferior border, shape of sigmoid notch, gonial eversion, height of coronoid process, and rocker jaw. These traits were scored among a sample of 470 3D surface scans, which originated from individuals of African, European, and Native American ancestries. Two-tailed *t*-tests were used to assess the significance of scores among pooled sexes, pooled ancestries, collections (within each ancestral group), and sex within each ancestry. A subset of these *t*-tests was supplemented with chi-square tests of independence to further assess the significance of these traits.

The results of these analyses suggest that pinching of ascending ramus, chin shape, chin profile, and undulation are useful ancestry discriminating traits (chi-square p-values: 0.045, <0.001, <0.001, <0.001, respectively). In this study, Europeans stood apart in regard to chin shape and chin profile, with a square/bilobate chin shape and protruding chin profile occurring most frequently among this population (53.9% and 54.6%, respectively). Similarly, Native Americans exhibited fewest occurrences of undulation (combined slightly undulated and undulated frequencies at 41%), supporting existing notions of Native Americans displaying very robust mandibles, and Africans far out-numbered Europeans and Native Americans in incidences of round chin shapes (68.9%) and displayed the greatest number of receding chin profiles (24.3%).

As pinching of ascending ramus, chin shape, chin profile, and undulation revealed significant results in *t*-tests and chi-square tests in this study, these variables should be investigated in future research. This study serves to indicate that morphological differences do exist between African, European, and Native American ancestral groups and encourages additional future research on non-metric traits of the mandible.

Ancestry Estimation, Non-Metric Traits, Mandible

A62 Using Basicranial Landmarks to Estimate Ancestry in an American Sample

Nicole D. Siegel, DVM, Northeast Ohio Medical University, Dept of Anatomy & Neurobiology, 4209 State Route 44, Rootstown, OH 44272-0095; and Adam Kolatorowicz, PhD, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752*

After attending this presentation, attendees will appreciate the utility of cranial base landmarks in identifying human skeletal remains.

This presentation will impact the forensic science community by providing an alternate metric method for estimating ancestry from fragmentary crania.

The cranium is one of the most informative and widely used areas of the human skeleton in establishing the sex and ancestry of human remains. Standard methods of cranial morphometrics in forensic anthropology include the use of landmarks and features on the ectocranial surface of the vault and the face.[1] These methods largely require intact crania. In a forensic setting, the cranium is often damaged and the traditionally used landmarks are obscured or destroyed.[2] When fragmentary or unable to be reconstructed, the cranium is often not used for identification purposes in these cases.[3-5] As a result, potentially valuable information contained within the remaining unexamined portions of the cranium is discarded. For example, in the case of fatal fires, the cranium is often deemed unusable because the typically evaluated areas for anthropological analysis (vault, face, and mandible) are damaged or missing; however, the cranial base is protected by the neck musculature, and oftentimes presents with fragmentary remains. The cranial base is a relatively underused region of the cranium in forensic anthropological analysis and is only recently being rigorously evaluated for its utility in the prediction of ancestry and sex.[6-9] This project tests the hypothesis that there are differences in cranial base shape between American White and Black individuals by comparing cranial base landmark data with standard ectocranial landmark data.

A total of 73 landmarks of the endocranial and ectocranial surfaces were registered using a MicroScribe® G2X portable coordinate measuring machine from 245 adult crania in the Hamann-Todd Human Osteological Collection and the William M. Bass Donated Collection. Landmarks were divided into four subsets: endobasicranial (18 landmarks), ectobasicranial (18 landmarks), all basicranial (36 landmarks), and ectocranial (43 landmarks). The first three subsets include uncommon landmarks, while the ectocranial set includes landmarks commonly used in a FORDISC® analysis.[10] First, landmarks were subjected to a generalized Procrustes analysis to bring them to a common coordinate system. Second, a discriminant function analysis with cross-validation was performed to assess the efficacy of landmark subsets in accurately classifying the crania. Finally, sensitivity, specificity, negative predictive value, and positive predictive value were calculated to further assess individual model performance. All analyses were performed in MorphoJ v1.06d with α=0.05.[11]

All discriminant models exhibited statistically significant differences in mean landmark configuration between ancestral groups ($p < 0.001$). The ectocranial subset had the highest classification rate of 88.6%, followed by ectobasicranium (82.0%), basicranium (78.8%), and endobasicranium (77.9%). Overall, the models have higher specificity (range 83.9%-91.6%) than sensitivity (range 67.3%-83.3%) and are able to more accurately classify White individuals than Black individuals. Positive predictive values have a range of 71.6%-85.2% and negative predictive values have a range of 79.6%-90.4% with the ectocranial set performing best.

Overall, landmark configurations exhibit a longer and narrower base in the Black sample compared to the White sample. The most anterior cranial base landmark, the foramen cecum, is displaced posteriorly in White crania, and the internal occipital protuberance is displaced anteriorly, resulting in a shorter cranium in White compared to Black crania. The paired landmarks, including the stylomastoid foramen, endasterion, and jugular foramen, as well as the sigmoid sulcus point, which is the intersection between the posterior lip of the sigmoid sulcus and the occipitomastoid suture, all are more laterally displaced in White crania relative to Black.

These findings suggest that both midline and paired landmarks in the cranial base are useful in estimating ancestry, as corroborating evidence, or especially in cases in which the more commonly used areas of the cranium are not available for analysis. Although traditional ectocranial landmarks provide the highest classificatory rate, basicranial landmarks from the ectocranial and/or endocranial surfaces can be used to estimate ancestry and contribute to the construction of the biological profile. Forensic anthropologists should consider recording basicranial landmark coordinates when analyzing fragmentary cranial remains.

A63 Craniometric Variation of Modern Asian and Hispanic Individuals Using Multivariate Analysis

Nandar Yukyi, MA, Defense POW/MIA Accounting Agency, 501 Park Avenue, Apt 429, Omaha, NE 68105; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand how cranial morphologies of certain modern Asian and Hispanic individuals compare to each other, and that population histories of different ancestral groups influence their cranial morphologies.

This presentation will impact the forensic science community by providing a deeper understanding of how Asian and Hispanic groups relate based on craniometric analysis.

According to Dudzik and Jantz, there have been a high number of misclassifications between Hispanic and Asian populations in the ancestry estimation software FORDISC®, as reported by forensic anthropologists.[1] In order to avoid mistaking an unknown Asian individual as Hispanic, or vice versa, it is beneficial to conduct further research on cranial morphological comparisons between these two groups with shared ancestry. This study primarily examines how modern Asian and Hispanic groups classify when compared with each other, as well as with other groups. Further, this study investigates any patterns of misclassification observed among and within the population groups used. Finally, this study examines how the samples used classify when ran with reference sample groups currently available on ancestry estimation programs such as FORDISC® 3.1.

The Asian samples included male and female individuals belonging to ten different population groups from East and Southeast Asia (*n*=575). All Asian data were either provided by Dr. Michael Pietrusewsky or obtained from the Howells craniometric database. The Hispanic samples in this study originated exclusively from Mexico (*n*=114) and, thus, are considered one population group. All Hispanic data were provided by Kate Spradley, PhD. Additional samples from the Forensic Anthropology Data Bank (FDB) were included in a second analysis with the initial sample pool to investigate how well Asian and Hispanic samples would classify when other ancestral groups were added for analysis. FDB samples (*n*=524) included American Whites, American Blacks, and Guatemalans. This study utilized 27 cranial Interlandmark Distances (ILDs), some of which are not standard distances used in FORDISC® 3.1; however, they were based on their overall representation of cranial morphology. The ILDs were analyzed using Discriminant Function Analysis (DFA) and canonical variates analysis to assess the similarities and differences in cranial morphologies of the samples, which were separated by sex. Last, 20 male samples were chosen randomly out of the original 11 Asian and Hispanic groups (*n*=588) and ran in FORDISC® 3.1. The purpose was to investigate how the samples from this study would classify when run with the Asian and Hispanic reference groups that are currently available to forensic anthropologists.

Results demonstrated that cranial morphologies of Asian and Hispanic groups are distinguishable. Hispanics represented by individuals originating from Mexico generally exhibit wider faces and nasal apertures compared to most East and Southeast Asians. Some Asian groups, such as North Japan, Ainu, and Philippines, also exhibit similar features to Mexicans. Overall, Mexicans display wider faces and nasal apertures than most Asian groups. Results from the second analysis yielded lower correct classification rates when run with the FDB samples (78.6% without and 71.9% with FDB groups).

Further, Hispanics are generally more similar to American Blacks and Whites than most Asian groups, which contradicts the findings of Dudzik and Jantz.[1] This may be attributed to the utilization of non-standard ILDs in this study, which is consistent with the findings of Spradley and Jantz that non-standard ILDs yield more accurate ancestry estimations, especially for complex groups.[2] Thus, it may be worthwhile to include non-standard ILDs when estimating ancestry for Asians and Hispanics in future research. Differences in cranial features help distinguish Asians and Hispanics from one another. Quantifying the influence that different cranial ILDs have on ancestral group assignment aids in understanding which facial and cranial features are important to differentiate Asians from Hispanics.

Ancestry, Asian, Hispanic

A64 Age Estimation From the Measurement of Open Apices in the Developing Permanent Dentition

Amanda J. Barville, The University of Western Australia, 35 Stirling Highway, Crawley, Perth, Western Australia 6009, AUSTRALIA; Ambika Flavel, MSc, The University of Western Australia, M311, 35 Stirling Highway, Crawley 6009, AUSTRALIA; Rob Hart, PhD, Department of Radiology, Royal Perth Hospital, 197 Wellington Street, Perth 6000, AUSTRALIA; and Daniel Franklin, PhD, University of Western Australia, Centre for Forensic Anatomy and Biological Science, MBDP M311, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA*

After attending this presentation, attendees will better understand a relatively novel method of age estimation involving the measurement of apical width and tooth length of the developing permanent dentition.

This presentation will impact the forensic science community by providing novel Western Australian specific age prediction models.

This study involves establishing age estimation models for juvenile individuals (<18 years of age) from a Western Australian population based on the measurement of open root apices of the developing permanent dentition following the Cameriere method.[1] Current methods of juvenile age estimation primarily involve quantifying the timing of skeletal growth and dental development, which are known to occur in a predictable sequence; the latter is also not as readily affected by malnutrition and other environmental factors as bone growth and development. The specific goals are as follows: (1) statistically quantify intraobserver agreement of apical width measurements in Orthopantomograph (OPG) images; (2) determine the accuracy of the Cameriere method in a sample of Western Australian juveniles; and, (3) develop an age estimation model specific to a Western Australian population based on the Cameriere methodology.

The study sample comprises 187 OPGs of juveniles (97 male and 90 female) aged 3 to 14 years from a contemporary Western Australian population. The OPG scans were acquired from the Western Australia Department of Health Picture Archiving and Communication Systems (PACS) database. The OPG scans were visualized using ImageJ and OsiriX®; apical width and tooth length measurements were acquired from the developing permanent left mandibular teeth (except the third molars) in each OPG scan. These measurements were entered into the Italian Cameriere linear regression formula in order to estimate age.[1]

Prior to primary data collection, accuracy and precision were quantified to ensure all measurement data were repeatable and reliable. Measurement error was quantified using the Technical Error of Measurement (TEM), relative Technical Error of Measurement (rTEM), and coefficient of Reliability (R). The apical width and tooth length measurement data was analyzed with Statistical Package for Social Science (SPSS) and Excel®. The mean differences between actual and estimated age were calculated; paired sample *t*-tests were performed to assess the statistical significance of the differences. Subsequently, a series of stepwise and enter-method regression analyses were performed to establish which variables significantly contribute to accurate age prediction in the Western Australian sample.

Analysis of the accuracy of the Cameriere age prediction model in a Western Australian population revealed that the difference between actual and estimated age was statistically significant in both males and females (p <0.001); the mean difference between actual and estimated age was 0.803 years in males (Standard Error of the Estimate (SEE ±1.295 years) and 0.587 years in females (SEE ±1.312 years). Individual and pooled-sex Western Australian specific age prediction models were developed based on the quantification of apical closure and tooth length measurements. The individual-sex model had an R-value of 0.966 and SEE of ±0.875 years, whereas the pooled-sex model had an R-value of 0.963 and SEE of ±0.909 years. In the analysis of the accuracy of the individual-sex model when applied to the Western Australian holdout sample, the mean difference between actual and estimated age was 0.318 years in males (SEE ±1.458 years) and 0.636 years in females (SEE ±1.347 years). The associated SEE for the pooled-sex model was ±1.548 years. The accuracy of the age prediction models was thus deemed acceptable relative to extant methods for estimating age in the juvenile skeleton. The present study has contributed novel models of age estimation using the developing permanent dentition for Western Australian juvenile individuals and also provides a basis for further research in this area.

A65 Sensitivity Analysis of Craniometric Measurements and Modeling Techniques to Assess Impact of Measurement Error on FORDISC® Results

Michala K. Stock, MA, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610; Katie M. Rubin, MS, University of Florida, CAPHIL, PO Box 103615, Gainesville, FL 32610; and Alexander McGhee, MS, University of Florida, Dept of Mechanical and Aerospace Engineering, Gainesville, FL 32611*

After attending this presentation, attendees will better understand how the magnitude of variation in different craniometric variables affects the results of FORDISC® analyses.

This presentation will impact the forensic science community by challenging the current rule-of-thumb tolerance for measurement error in craniometrics and highlighting the use of mathematical modeling techniques in assessing the sensitivity of metric analyses.

This research uses iterative manipulation of craniometric measurements to assess the impact of measurement error on FORDISC® classification of sex and ancestry.[1]

Metric analysis of skeletal material is an important tool for forensic anthropologists assessing the biological profile of unknown decedents. As measurements constitute the fundamental data for these analyses, recent efforts have focused on standardizing definitions and procedures to produce the highest degree of precision and accuracy when taking measurements. Part of this undertaking has involved investigating which measurements are more problematic for repeatability, as assessed through both interobserver and intraobserver measurement error studies; however, the impact of the magnitude of measurement error on analytical results has not been well captured. Instead, the widely used rule of thumb for skeletal metrics is an arbitrary ±2mm tolerance level for all measurements, even though the size of standardized measurements from an individual can vary by an order of magnitude within both the skull and the postcrania. The discriminant function program FORDISC® 3.1 is routinely used to assess sex and ancestry from the cranium; it remains unclear how measurement error affects the results of these analyses.

Thirteen standard craniometric measurements were taken from 30 skeletal individuals of varying demographics curated at the C.A. Pound Human Identification Laboratory. To establish a baseline FORDISC® classification for each individual, all 13 original measurements for a given individual were entered into the program, and a discriminant function analysis was run without transformations against all groups in the Forensic Anthropology Data Bank. For this project, whether the baseline classification reflected the decedent's true demographic group was unimportant, as the goal was not to assess the accuracy of the program itself. For each individual, each original measurement was then varied in 1mm increments — up to 5mm greater than and less than the original measured value — and the FORDISC® analysis re-run in each iteration. Only one measurement was altered at a time, resulting in 131 FORDISC® runs per individual. The classification, Mahalanobis distance, posterior probability, and type F typicality results of all runs were recorded and compared. Deviations in classification from the baseline classification were recorded as "disparate classifications." To complement this analysis, Latin Hypercube Sampling (LHS), which varies all measurement values orthogonally in an N-dimensional hyperspace within the range permitted by FORDISC® and generates a new FORDISC® analysis for each iteration, was performed on one individual. The LHS method is widely used to test the general sensitivity of measurement variables to variation due to the few number of sample points needed to produce high-quality results.

Average disparate-classification rates by measurement when each measurement is varied by ±2mm (in accordance with the rule of thumb) ranges from 0%–33%, with cranial base length (basion-nasion length) creating the most deviation and the vault chord lengths creating the least deviation in classification. Additionally, the variance of the posterior probabilities and typicalities about the values generated using the original measurements is asymmetrical, but without a general, clearly defined magnitudinal or directional bias. The LHS sampling analysis revealed that midfacial measurements, especially when varied simultaneously, are the most sensitive to variation, even when sensitivity comparisons are scaled by size. Overall, the findings of these analyses suggest that accepting measurement error of 2mm is inappropriate for some craniometric measurements, particularly the relatively smaller breadths and heights measured in the midface. Conversely, the magnitude of within-demographic group variation for other measurements, particularly those in the vault, subsume even large amounts of measurement error, indicating that these are more tolerant measurements. Moving forward, the use of modeling techniques, such as those used above, will allow for the creation of empirically tested error ranges unique to each craniometric measurement, which satisfies *Daubert* criteria. FORDISC® is a powerful tool, and the more that can be understood concerning how different factors influence the outcomes of its analyses, the more successful and reliable forensic practitioners will be.

Metric Analysis, Error Analysis, Latin Hypercube Sampling

A66 The Importance of Sitewide Taphonomic Assessments for Highly Fragmented, Comingled, and Heat-Altered Remains From Mass Graves

Sean Y. Greer, BA, University of Missouri School of Medicine, M263 Medical Sciences Bldg, One Hospital Drive, Columbia, MO 65202; Sarah Baumgarten, MSc*, 6242 North Drive, Apt 2E, University City, MO 63130; Analia G. Simonetto, MS, EAAF, 10 Jay Street, Brooklyn, NY 11201; Mariana Segura, EAAF - Equipo Argentino de Antropologia Forense, Rivadavia 2443, 2ndo Piso, Buenos Aires 1034, ARGENTINA; and Mercedes Doretti, Argentine Forensic Anthropology Team, Equipo Argentino de Antropología Forense, EAAF, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233*

The goal of this presentation is to illustrate the importance of pairing a careful archaeological recovery with a detailed taphonomic analysis in forensic anthropology. Specifically, the case of a mass grave from Mexico where burn patterns of highly fragmented human remains were used to map relative levels of heat alteration across the entire site will be addressed. This analysis allowed for questions of site formation to be addressed, not only through examination of the site itself, but also of the human remains.

This presentation will impact the forensic science community by explaining how this case and method of site analysis are important in that they exemplify the importance of human remains in assessing the formation of a forensic scene. Examination of remains in forensic settings typically takes place at the level of the fragment, skeletal element, or individual; however, when methodically collected and catalogued, human remains can contribute to our understanding of the larger site as a whole.

A detailed taphonomic analysis is critical to any forensic anthropological investigation. Unlike other characteristics typically assessed by the forensic anthropologist, such as the biological profile, the amount of information gleaned from a taphonomic analysis is directly related to the resolution of the preceding archaeological recovery. Cases in which the context and association of each fragment are maintained and proveniences are known offer a unique opportunity to examine site-wide patterns of postmortem alteration.

Taphonomy is a relatively new field of research, its name dating back less than a century.[1] In the time since, some aspects of postmortem skeletal changes have become relatively well understood. In the case of heat modification, clear patterns to alteration have emerged, and the beginnings of standardized characteristics to catalog and interpret are coalescing.[2] Data concerning the level of heat alteration is typically used to identify the pattern of burning on one individual. This cannot always be conducted in highly fragmented and comingled cases; however, the site can be treated as a distinct entity of its own, with different levels of burning based on local hot spots or areas of longer duration heat exposure.

The case presented here involved analysis of thousands of fragments of heat altered human bone from a minimum of 20 individuals. Due to the insurmountable number of specimens, differential ability to identify anatomical location and side of each, and the inability to re-associate remains to individuals, a means for the analysis of site-wide patterns was required. A methodological archaeological recovery had been performed, conserving context of fragments by 1m x 1m square. Fragments were sorted by square and broad anatomical region, when possible. Each collection of specimens was then scored as a group for its level of heat alteration. Scores were based on the overall percentage of fragments that displayed calcination by visual inspection. These scores were mapped across the site to examine any patterns to the burning that may have shed light on the formation of the scene.

Two interesting patterns were clearly visible when considering levels of heat alteration across the site as a whole. First, different anatomical regions revealed different overall levels of heat alteration. The anatomical region demonstrating the most calcination was the cranium, while the pelvic region demonstrated the least. This is interestingly consistent with a normal burning pattern of fleshed remains.[2] A second pattern emerged with the examination of anatomical regions across the site. When mapped, each region displayed a broad U-shaped area of more intense calcination. Inside this area, there appeared an area of relative sparing of remains, containing considerably less calcination.

While the exact cause of these patterns is not determinable based solely on the analysis of the skeletal remains, they add an additional layer of information that can support other indicators of site formation. By combining taphonomic information with other evidence, questions concerning how many areas of burning may have been active, whether or not the remains were altered before, during, or after burning, if multiple distinct burning events have taken place, and why some skeletal elements may be less represented than others can be explored.

A67 The Occurrence of Osteon Banding in Adult Human Cortical Bone

Janna M. Andronowski, PhD, University of Akron, Dept of Biology, Auburn Science and Engineering Complex, Akron, OH 44325-3908; Isaac V. Pratt, MSc, University of Saskatchewan, 107 Wiggins Road, Saskatoon, SK S7N 5C5, CANADA; and David M.L. Cooper, PhD, University of Saskatchewan, Dept of Anatomy and Cell Biology, 107 Wiggins Road, Saskatoon, SK S7N 5E5, CANADA*

After attending this presentation, attendees will have an appreciation for the occurrence of osteon banding in adult human cortical bone.

This presentation will impact the forensic science community by providing key data supporting the presence of multiple osteon bands in single specimens, indicating that this phenomenon should not categorically be taken as evidence of non-human bone. This will result in a higher quality of forensic practice since human species origin should not be ruled out when a significant pattern of osteon banding is encountered in primary and/or secondary lamellar bone.

Differentiating human from non-human fragmented bone is often accomplished using histological methods if the observation of gross morphology proves insufficient. Linearly oriented primary and/or secondary osteonal systems, commonly referred to as osteon bands, are described in the literature as a strong indicator of non-human bone. This phenomenon has been conventionally documented using two-dimensional histology, but such analyses are destructive and typically limited to a single cross-section; however, progressive developments in high-resolution X-ray imaging allow for the non-destructive 3D visualization of bone microarchitecture.

In a previous survey of osteocyte lacunar variation in adult human skeletal elements using Synchrotron Radiation-based micro-Computed Tomography (SR micro-CT), the presence of osteon banding in cortical bone in various bone types was frequently observed.[1] As such, the primary objective of the current research was to visualize and document the occurrence of osteon banding in adult human cortical bone using high-resolution SR micro-CT.

SR micro-CT scanning was conducted at the Canadian Light Source national synchrotron facility. The presence or absence of osteon banding was visualized in human skeletal elements from three adult males with representative samples from all regions of the skeleton (n=129). Visualization of osteon boundaries were enhanced by applying z-projections through 90μm (100 adjacent slices at 0.9μm thickness) and by observation of osteocyte lacunar patterns. Additional projections (standard deviation and minimum intensity) were employed to enhance visualization of air-filled vascular spaces and high-density bone tissue. Subsequently, 3D renders of bone microarchitecture were created. All projections in each image stack were assessed for the presence of osteon banding. An osteon band was defined as a discrete row of five or more primary and/or secondary osteons, as described by Mulhern and Ubelaker.[2] The number of bands in each specimen and the number of osteons per band were documented.

Results indicated that 23 of 129 human cortical bone specimens exhibited osteon banding, representing 18% of the sample. Linear arrangements of primary and/or secondary osteons were observed in the following skeletal elements: temporal, parietal, frontal, occipital, clavicle, mandible, femur, tibia, ulna, second metatarsal, and sacrum. Multiple osteon bands were observed in the temporal, parietal, occipital, and mandible specimens, with three being the maximum number of bands observed. In these elements, osteon bands ranged from 5 to 12 osteons in length and were comprised mainly of primary osteons.

Per research, this work represents the first report of: (1) multiple osteon bands within a single adult human cortical bone specimen; and, (2) inter-element variation in osteon banding from cortical bone from various modern adult human skeletal elements. The frequent occurrence of osteon banding, and the presence of multiple osteon bands within a single specimen, indicate that this histomorphological feature is not solely diagnostic of non-human bone. This characteristic should not be used as a distinguishing feature if alternative non-human characteristics are clearly less visible. Overall, the analyst should not rule out a human species origin when a more significant pattern of osteon banding is encountered in primary and/or secondary lamellar bone.

Cortical Bone, Osteon Banding, Micro-CT

A68 Estimation of the Postmortem Interval (PMI) of Skeletonized Human Remains Using Nile Blue and Indophenol Colorimetrics on Femoral Cortical Thin Sections

Léa M. Lerchundi, MSc, IRCGN, 5, boulevard de l'Hautil, Pontoise 95300, FRANCE; Anne Coulombeix, MSc, IRCGN, 5, boulevard de l'Hautil, Pontoise 95300, FRANCE; and Pierre M.M. Guyomarc'h, PhD, Université de Bordeaux, UMR 5199 PACEA, Allee George St Hilaire, Bat B8, Pessac 33615, FRANCE*

After attending this presentation, attendees will understand the potential of colorimetrics for the estimation of a PMI when applied to femoral bone sections.

This presentation will impact the forensic science community by testing the staining reaction of Nile Blue (NBL) and Indophenol (IND) on thin sections of the femoral cortex and by quantifying the correlation between the coloration and the PMI.

PMI is an essential piece of information for estimation, especially when dealing with skeletonized dry human remains, as it determines whether the case is forensically relevant or historical/archaeological. Although the prescription period varies depending on the country's criminal code, it generally spans between 10 and 30 years (with no limit in homicidal cases for some contexts). PMI estimation is complex after complete skeletonization, and even with a thorough analysis of the taphonomy and surrounding environmental factors, there is no straightforward method available to clearly quantify a PMI. Following Berg and Specht's observations in 1958, the colorants NBL and Indophenol IND tend to reveal differential affinities with cortical bone depending on the PMI.[1] The variations in coloration were visually assessed but not discussed. It was noted that NBL was more sensitive to ancient bones and IND more accurate for coloring recent bones. The protocol was tested later by Knight and Lauder, but judged too unreliable for routine use.[2] As part of the research within the French National Forensic Institute (IRCGN), the PMI estimation through colorimetrics of NBL and IND was further investigated.

A sample of 32 femoral sections from individuals with a known PMI was collected from a Swiss osteological reference collection, a number of French archaeological collections, and a number of recent forensic cases. The coloration protocol followed the procedures described by Berg.[3] Cortical thin sections were sliced at 1.2mm, immersed in 2% NBL or IND for 10 to 20 minutes, rinsed, and differentiated for 12 hours with acetic acid or 70% alcohol (respectively, for NBL and IND). For a more objective assessment of the resulting color, the dried sections were measured using a Konica Minolta CM-2600d/2500d spectrocolorimeter, which quantifies the color using the L=lightness, a=ambiance, b=brightness (Lab) system. The consensus-measured color is the average Lab for 30 measurements of the same section. Some sections were measured on both sides to evaluate potential systematic variations. Additionally, some steps of the protocol for the NBL were tested (i.e., different concentrations of both the NBL solution and acetic acid and different immersion times).

The dispersion of PMI within the tested sample was not homogeneous as there were too few recent individuals (<30 years of age) versus old (30-100 years of age) and archaeological individuals (>100 years of age). Consequently, correlations and regressions did not produce results coherent enough to build estimation models; however, computing the raw Lab data in a principal component analysis allowed for an objective visualization of the distribution of the recent, old, and archaeological individuals. Although this preliminary study did not take into account the taphonomy factors (environmental influence on cortical bone composition and the coloration process), NBL demonstrated a moderate potential to distinguish individuals with a PMI inferior or superior to 100 years, and IND demonstrated a stronger potential to distinguish individuals with a PMI inferior or superior to 30 years. A larger sample that is taphonomically controlled and has a homogenous PMI distribution is required before building a robust estimation model using IND colorimetrics, but this rapid and cost-efficient technique is promising.

Postmortem Interval, Human Remains, Colorimetrics

A69 Volumetric Histological Age Estimation Utilizing a Geographic Information Systems (GIS) -Based Analytical Approach

Suzanna Michener, MSc, Simon Fraser University, 8888 University Drive, Burnaby, BC V3Z 0E3, CANADA; Lynne S. Bell, PhD, Simon Fraser University, Dept of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Nadine Schuurman, PhD, Simon Fraser University, 8888 University Drive, Burnaby, BC V5A1S6, CANADA; and David Swanlund, BA, Simon Fraser University, 8888 University Drive, Burnaby, BC V5A1S6, CANADA*

After attending this presentation, attendees will appreciate the potential of using GIS software to visualize and analyze bone histological structures three-dimensionally.

This presentation will impact the forensic science community by introducing a new method of viewing and quantifying histological remodeling events that are used for age estimation.

If salient macroscopic elements are damaged or missing, adult human age can be estimated through histological examination of the remodeling events in cortical bone. Several techniques have been developed and refined but, to date, all analysis has focused on a single two-dimensional plane. Osteons are 3D structures; they are typically cylindrical in shape, round to ovoid in cross section, 200-250 micrometers (µm) in diameter, one to ten millimeters long, and oriented on average 11°-17° relative to the long-axis of the bone. They are also dynamic structures; they grow, age, and are resorbed. Utilizing the volume of osteons, or incorporating the stage of osteonal development into age estimation regression formulas, may minimize standard error estimates and improve age estimates when building the biological profile in forensic cases.

To date, the only way to view osteons in three dimensions is to use confocal microscopy, which provides a maximum z-axis depth of no more than 100µm, or to use micro-Computed Tomography (micro-CT) or synchrotron-assisted micro-CT, which is better suited for negative spaces, such as the pores or Haversian canals in bone tissue. The current study employed a GIS-based analytical approach to digitally map remodeling events on three serial cross-sections, thereby providing a 3D perspective of bone remodeling. The use of GIS techniques for bone histological analysis is novel, but researchers have previously utilized arcGIS® to manually delineate intracortical remodeling events as polygon feature classes across a single section of femoral midshaft. This study extends this approach in which osteonal systems are measured three-dimensionally, potentially allowing for a more realistic assessment of their features, but it necessitates several additional steps. First, vertical alignment grooves were cut into the cortex of an adult human femoral midshaft in order to maintain multi-planar spatial orientation. Three serial thin-sections of approximately 80µm were subsequently cut using a Leica® SP1600 microtome saw; they were separated by 300µm due to blade thickness, providing an overall height of approximately 840µm. Second, each sample was photographed under circularly polarized light and combined into a seamless image using free photo-stitching software. These entire cross-sections were then imported into arcGIS® v10.1 and aligned to overlay using the vertical grooves as georeferencing points, tying the layers to each other. Third, polygon features tracing the cement line were manually created to overlay each remodeling event.

To accommodate for the off-axis vertical path at which osteons may form, as well as the void created by the saw blade, buffers were produced in arcGIS® around the polygon features, allowing osteons found on multiple cross sections to be connected to each other. Once the osteons on the serial sections were identified as the same remodeling event, they were coded appropriately and excluded from other potential matches. Not all osteons could be followed through all three sections, and some osteons in one layer could potentially connect to multiple others in the next layer. In such cases, the relative size and shape of osteons were used to connect related osteons in different layers. Change detection algorithms to quantify differences in area and shape between remodeling events in the transverse sections provided a volumetric measurement of individual osteons based on the formula for a cylinder.

This study reinforces the value and utility of GIS-based analysis for identifying, comparing, and capturing patterns for histological mapping, as well as introduces the concept of volumetric osteonal measurement for histological age estimation.

Age Estimation, Skeletal Histology, Forensic Anthropology

A70 Validation, Verification, and Performance Checks of Anthropological Equipment and Software: The Importance of Quality Assurance in Forensic Anthropology Laboratories

Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77008; Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; Michal L. Pierce, MS, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will have a better understanding of the recent efforts undertaken at the Harris County Institute of Forensic Sciences (HCIFS) to address the pertinent issue of establishing a validation program and Standard Operating Procedures (SOPs) for anthropological equipment and software, specifically the MicroScribe® 3D digitizer and the 3Skull and FORDISC® software programs used to collect and analyze osteometric data.

This presentation will impact the forensic science community by providing best practices to mitigate potential issues of method and measurement error. The present research will illustrate the significance of validating anthropological equipment in every laboratory as a quality assurance measure, notwithstanding its general acceptance within the forensic anthropological community.

Establishing a quality assurance program and achieving laboratory accreditation has become paramount for forensic anthropology. It is through these processes that the field of forensic anthropology can demonstrate the level of surety associated with anthropological analyses. In August 2015, the HCIFS's Forensic Anthropology Division (FAD) became the first forensic anthropology laboratory to be accredited under the American National Standards Institute-American Society of Quality (ANSI-ASQ) National Accreditation Board's (ANAB's) International Organization for Standardization/ International Electrotechnical Commission (ISO/IEC) 17020 inspection body program. One challenge posed during the accreditation process was answering the question, "Do validation, verification, and performance checks of anthropological methods and activities follow a written procedure?"

Equipment and software programs, including the digitizer, mandibulometer, 3Skull, and FORDISC®, were in use prior to accreditation. Their use and data were assumed to be reliable since members of the forensic anthropology community deem them acceptable and references for their functionality are available in peer-reviewed literature; however, no internal validations were performed when the equipment and software were received. Plans were made to collaborate with the HCIFS's Quality Management Division (QMD) to properly validate the equipment and software in order to meet accreditation standards. All accredited laboratories, per ANAB's Guidance on Uncertainty for Testing Laboratories, must review significant factors that may contribute to the error or variability in measurements. Thus, accreditation standards require in-house validations for analytical equipment to demonstrate the level of surety associated with analyses.

To perform the internal validation of the digitizer, a reference standard was created by selecting an anatomical skull and pre-marking the osteometric landmarks. The elements were measured using calipers and standard collection protocols. Then, the analysts collected the landmarks following the newly-written digitizer SOP, checked that the coordinates were accurately captured in the 3Skull software, and compared the output to the caliper-derived measurements. In the course of establishing this procedure, measurement uncertainty calculations for 35 Interlandmark Distances (IDLs) and one angle were performed using Root Sum Squared (RSS) and following the National Institute of Standards and Technology (NIST) procedure for measurement uncertainty.

For the in-house FORDISC® validation, cranial and postcranial metric data were collected from four known, donated specimens typical of the Black and White groups within the Forensic Databank. These data were processed through FORDISC®, retaining a log of the osteometric measurements used and analytical iterations. The IDLs were then provided to the FAD analysts, who entered them into FORDISC® without viewing the previous results. Validation was considered successful when the FAD FORDISC® classification results were reasonably similar to the previous results when comparable analytical iterations were employed. While the FAD's equipment and software validation SOP is specific to the MicroScribe, 3Skull, and FORDISC®, forensic anthropologists will be able to identify the important elements that should be included in any anthropology software program validation (i.e., 3D-ID, (hu)MANid, Macromorphoscopics) or software update.

Formalizing a process for internal validation to the point where instructions can be documented in SOPs may seem unnecessary to practitioners, especially if anthropologists believe they are already employing validated methods/equipment; however, in-house verification is warranted to guarantee the appropriateness of their use for fulfilling the service needs of the laboratory. The goal is to advance analyses toward uniformity and higher quality. While this may be challenging for laboratories with only one forensic anthropologist, or offices without a QMD, validation, verification, and performance checks for *your* equipment in *your* laboratory is vital in this era of forensic science critique. Therefore, one of the primary deliverables for this project is the availability of the HCIFS's equipment and software validation plans and SOPs, which can be used as a template to meet the needs of any forensic anthropology laboratory.

Validation, Quality Assurance, Accreditation

A71 Accreditation of Forensic Anthropology and Practice in the United Kingdom

Catriona M. Davies, PhD, Centre for Anatomy and Human Identification, MSI/WTB Complex, University of Dundee, Dow Street, Dundee, Tayside DD1 5EH, UNITED KINGDOM; and Lucina Hackman, PhD, University of Dundee, Dow Street, Dundee, Angus DD1 4AH, UNITED KINGDOM*

After attending this presentation, attendees will have gained an understanding of the current state of professional practice in forensic anthropology in the United Kingdom, providing a valuable insight and opportunity for discussion in relation to the development of the discipline.

This presentation will impact the forensic science community by providing an update of the procedures, code of practice and ethics, and the certification of forensic anthropology practitioners in the United Kingdom. With the increasing focus on admissibility of evidence and the weight given to expert evidence, it is imperative that appropriate standards are set and maintained. By providing an update of the status of forensic anthropology in the United Kingdom, this presentation will provide an opportunity for discussion of best practices from an international perspective.

The establishment and maintenance of professional standards and codes of conduct and ethics are fundamental to the practice of forensic anthropology in the modern medicolegal landscape. The process of instigating such practices began in the United Kingdom in 2013, with the positioning of the Royal Anthropological Institute of Great Britain and Ireland as the professional body for forensic anthropology. Since that time, the process of certification of practitioners has completed a full three-year cycle, with practitioners certified at each of the three levels and recertification of practitioners ongoing.

With the increasing attention on standard setting and suitability of evidence and expert witnesses in the court room, the importance of professional certification and development of professional standards has never been higher. Cooperation between government offices, legal practitioners, professional bodies, forensic providers and individual forensic practitioners, and end users is vital if this is to be achieved and maintained. As this process is in its relative infancy in the United Kingdom, the opportunity to discuss these issues with international colleagues will provide wider insight into the process. It is hoped that establishing such dialogue will facilitate cross-fertilization of ideas and best practices in forensic anthropology, leading to a holistic appreciation of the position of certification and professionalization of the discipline, in addition to scientific expert witness evidence in general. This study will present experiences of this process in the United Kingdom, share the difficulties and benefits encountered, and establish knowledge exchanges with international colleagues who may have encountered similar or different challenges.

Forensic Anthropology, Certification, Professionalization

A72 Validation of the Acetabulum as a Skeletal Indicator of Age at Death

Allysha P. Winburn, PhD, University of West Florida, Dept of Anthropology, 11000 University Parkway, Bldg 13, Pensacola, FL 32514*

After attending this presentation, attendees will better understand the biology underlying progressive acetabular changes.

This presentation will impact the forensic science community by demonstrating the utility of the acetabulum for age estimation; the changes occurring in this joint could prove particularly relevant to the development of future multifactorial aging methods.

This research investigated the nature of progressive changes in the acetabulum, with the goal of determining whether they are metamorphic or degenerative and ascertaining whether they are valid indicators of age at death.

The acetabulum has been a focus of age-estimation research during the past decade, and several acetabulum-based aging methods have become available to the forensic anthropological practitioner; however, the nature of the progressive changes that occur in the acetabulum remains poorly understood. These changes may constitute skeletal metamorphoses (akin to the formation of the ventral rampart of the pubic symphysis), which forensic anthropologists generally believe to be tightly linked with age. Alternately, acetabular changes may represent skeletal degeneration (osteoarthritis or OA) — generally viewed as less strongly correlated with age and more influenced by factors such as physical activity and obesity. If the former proves true, this would lend support for the use of acetabular changes in skeletal age-at-death estimation. If the latter proves true, this would suggest that use of the acetabulum for age estimation should be reevaluated.

In order to investigate these problems, acetabular changes and OA were analyzed in a sample of 409 European-American skeletal individuals from the W.M. Bass Donated Skeletal Collection (University of Tennessee, Knoxville). Acetabular changes were observed and scored.[1] In all major appendicular joints, OA was observed and scored.[2] These data were then compared with documented demographic data for the 409 individuals. In addition to age, sex, height, and weight (used to calculate Body Mass Index (BMI)), demographic data also included self-reported habitual and occupational activities, which were assigned values representing their Metabolic Intensity Level (MET) using a system developed for the coding of physical activity survey data.[3] Statistical tests assessed potential associations between acetabular scores and OA scores, ages at death, BMI, and MET values. Non-parametric tests and visualization techniques (e.g., Spearman's rank-order correlation, box-and-whisker plots) were used to assess associations between ordinal data such as acetabular and OA scores. Parametric tests and visualization techniques (e.g., linear regression, scatterplots) were used to assess associations between continuous data such as ages at death, BMI, and MET values. The alpha-level was set at 0.05, and the Bonferroni correction was applied in cases of multiple test iterations.

Acetabular changes were found to correlate statistically significantly positively with OA in all joints and body regions. This indicates that the changes occurring in the acetabulum are degenerative rather than metamorphic; however, these acetabular changes also correlated statistically significantly positively with age, indicating that they are still useful for age estimation. In contrast, acetabular changes showed no associations with BMI or MET values, indicating that these changes are resistant to the effects of obesity and habitual and occupational activities. This finding also supports their use in aging.

In summary, the degenerative changes of the acetabulum are valid skeletal age indicators that are relatively resistant to the effects of lifestyle variables (i.e., obesity, physical activity) in European-Americans. The strong age correlations of degenerative acetabular changes suggest that the metamorphic-degenerative dichotomy of skeletal age change is in need of revision. Further, the lack of association between acetabular degeneration and physical activity indicates that the oft-cited anthropological paradigm of activity-induced joint degeneration is overly simplistic. In a field where *science matters*, it is important not only to test and refine age-estimation methods but also to understand the biology underlying method success or failure. These findings advance an understanding of skeletal aging that can improve both identifications of the dead and health outcomes for the living.

Financial support for this study was provided by the National Institute of Justice Graduate Research Fellowship Program in Science, Technology, Engineering, and Mathematics.

Age Estimation, Osteoarthritis, Skeletal Degeneration

A73 Exploring the Performance of a Global Subadult Age Estimation Model Using Unsupervised Machine Learning Techniques

Kyra E. Stull, PhD, University of Nevada, Reno, Dept of Anthropology, 1664 N Virginia Street, Stop 0096, Reno, NV 89557; and Michael H. Price, PhD, Santa Fe Institute, 1399 Hyde Park Road, Santa Fe, NM 87501*

The goal of this presentation is to inform attendees of the possibility of developing a global multivariable, multi-indicator subadult age estimation model. Numerous variables from the three most frequently applied age indicators were collected from genetically and economically diverse populations and were used to develop and compare the performance of population-specific models and a pooled, global model.

This presentation will impact the forensic science community by providing information regarding the feasibility of a global application of subadult age estimation, which is crucial considering the increased migration events and subsequent admixture resulting in populations with greater levels of genetic variation and complexity.

Most subadult age estimation methods do not account for the variation that exists in the world, as they are tailored for application in a specific location. Unfortunately, there is a possibility of mass and natural disasters in any country around the world, in addition to increased population movements and subsequent increased genetic variation; subadult identification would be facilitated if models were global. Thus, anthropologists need to critically evaluate subadult age estimation and explore the feasibility of global models, specifically, if there are differences in age indicators between geographically diverse groups, how does a global multivariable, multi-indicator model compare to a population-specific multivariable, multi-indicator model?

Epiphyseal fusion, dental formation, and diaphyseal dimensions were collected from a modern sample of children aged between birth and 10 years of age from the United States and South Africa. Two population-specific and one global multivariable, multi-indicator models were constructed using feedforward Artificial Neural Networks (ANN). Unsupervised machine learning techniques make minimal assumptions about the underlying data and thus offer a very flexible prediction framework that can handle different types of data modes, such as continuous and ordinal variables. A test dataset was reserved for all models to independently assess the suitability of each final fit.

The age indicators were compared for each population and scatterplots depicted a complete and consistent overlap in the distributions of the diaphyseal dimensions across the entirety of the age range, though differences in length became apparent in the older ages. In terms of the developmental variables, older South African children expressed the same dental formation and epiphyseal fusion stage as younger children from the United States. The results of the multivariable, multi-indicator models reveal the data trained from the pooled samples provided better age estimations than the population-specific models, based on lower mean squared error. The test data revealed that the United States sample was more predictable than the South African sample, which may be due to the fact that the South African sample was, on average, slightly older than the United States sample.

Unsupervised machine learning techniques use pattern detection to build models. Therefore, if population-specific models are used, and thus account for less variation in the training sample, the error will always be higher. Using a larger sample to train with captures the true range of variation; therefore, the model will always be more precise. The results of this study are very exciting and provide a solid stepping stone to continue the research and address the needs for more rigorous subadult age estimation techniques. Population-specific models may perform just as well as global models, but until larger, more reflective samples of populations with equal age distributions are used, the global model can be applied.

Artificial Neural Networks, Computed Tomography, Juvenile

A74 A Multidisciplinary Protocol to Assess Chronological Age of Unidentified Migrants

Francesco Lupariello, MD, University of Turin - Legal Medicine Section, Corso Galileo Galilei 22, Torino, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Davide Santovito, MD, Department of Public Health and Pediatric Sciences, Corso Galileo Galilei 22, Turin 10126, ITALY; Moreno Bertoni, MD, SC Medicina Legale - AOU Città Salute e Scienza, c.so Bramante 98, Turin 10121, ITALY; and Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will understand the role of forensic sciences in age estimation and the effectiveness of the scientific methods used to correlate biological and chronological age.

This presentation will impact the forensic science community by demonstrating the importance of a multidisciplinary approach in the age estimation of unidentified migrants to minimize errors and complaints.

In Italy, unidentified migrants usually claim to be underage because minors are processed through the juvenile system, where detention is not mandatory. In addition, unaccompanied minors will often have access to educational programs and may be granted a residency permit. In this scenario, the use of age estimation techniques is fundamental. There are several methods that correlate biological and chronological age. They are mostly based on the evaluation of the maturity of hands and wrist bones, teeth and clavicles.[1-5] In the forensic scientific community, there is widely held agreement regarding the use of a combination of these methods to reach the most accurate estimation.[6]

For these reasons, the city of Turin, the local health authority, and the prosecutor's office defined a formal multidisciplinary investigation protocol for age estimation. After the fingerprint pattern is captured as a digital image, a Unique Identification Code (UIC) is assigned; the acquisition of the informed consent is performed, then weight, height, dental formulas, and other clinical findings (secondary sex characteristics, scars, and tattoos) are recorded. Radiographs of the left hand and eventually the Orthopantomogram (OPG) are obtained. The age estimation is performed by the conventional methods for skeletal and dental formulas. The data, associated with the UIC, are reported in the final certification that is delivered to the officers and finally stored in a national database.

This study reports a retrospective analysis of the data collected during the employment of the protocol described above. From July 2014 to July 2017, 458 visits were conducted. Overall, 383 were male and 75 were female. The geographical origins were heterogeneous, mainly from sub-Saharan Africa (Nigeria 17.03%, Senegal 16.81%, Mali 8.3%, Guinea 8.3%, Gabon 7%, and Ivory Coast 6.55%). The mean declared age was 16.94 years (Standard Deviation (SD) ±2.05). The mean Body Mass Index (BMI) was 21.55 (SD±2.42). The languages used to obtain the consent were principally English, Italian, and French. In only one case did the person deny consent to a medical examination. There were 317 adults, and the remaining 141 were underage. In 195 cases, it was necessary to utilize the OPG. In 21 cases, the age estimation obtained with the evaluation of the left-hand X-ray was not consistent with the estimation obtained with methods based on tooth evaluation. In fact, at the same time, these 21 migrants were identified as adult using the evaluation of the left-hand X-ray and as underage considering the methods based on tooth examination. For this reason, in accordance with Italian law, they were considered underage.

The results reported above reveal that this diagnostic process provides accurate results because it is based on the combination of different expert opinions (medical examiner, dentist, and radiologist); however, in order to reach this result, it is necessary to employ well-trained clinicians. They should possess extensive knowledge of the different scientific methods widely used to correlate biological and chronological age in the forensic community. Besides, if the results derived by the application of different methods are not consistent, the clinicians should be capable of understanding and communicating them to the officers and prosecutor.

Finally, this protocol is widely accepted by unidentified migrants, since more than 99% of the subjects agreed to undergo the medical examination. It consists of low-cost procedures that are not harmful to health because the association between fingerprint patterns, the UIC, and the final certification (stored in a national database) determine the reduction of risks associated with exposing the subject to more X-rays and medical examinations, if arrested again. In fact, this presentation should serve as a stimulus to heighten the importance of using standardized procedures in age estimation in order to reduce risks and avoid errors.

Age Estimation, Illegal Migration, Personal Identification

A75 Dental Morphological Ancestry Estimation in a Self-Identified Biracial Sample

Chaunesey Clemmons, BA, Texas State University, 601 University Drive, San Marcos, TX 78666-4684; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will understand the potential for misclassification of Biracial individuals using current dental morphological quantitative methods.

This presentation will impact the forensic science community by showcasing the importance of reference samples and the necessity to understand admixed populations for forensic identification.

The importance of ancestry estimation to the biological profile is well documented in that it can aid medicolegal death investigations by narrowing missing persons lists.[1] Dental non-metric traits have been used successfully to estimate ancestry in American Black and White populations, but no method has examined the effect of mixed ancestry on classification rates. The goal of this study is to understand how a sample of Biracial individuals would ancestrally classify using current quantitative methods for dental morphology.

A sample of 13 (11 female, 2 male) living self-identified Biracial individuals were recruited to complete this study. For this study, the definition of Biracial includes those individuals who are a Black/White racial mix and simultaneously an African/African American and European/European American ancestral mixture. Approval for study on living individuals was granted by the Texas State University Internal Review Board (2016S173). Dental impressions were obtained for each Biracial individual by a licensed dentist. Dental casts were made from the impressions and analyzed using the Arizona State University Dental Anthropology System (ASUDAS) dental morphological traits and the expression count method.[2,3] Root traits were excluded from analysis because they cannot be scored on casts. The scores were used to estimate ancestry for the sample using two methodologies, Edgar and Scott et al. [4,5] The method proposed in Edgar uses discriminant function equations to distinguish between African American (AA), European American (EA), and Hispanic American (HA), while Scott et al. is an online system (http://apps.osteomics.com/rASUDAS/) that processes scores and compares them against sample groups from geographical regions (this study compared between Sub-Saharan Africa and Western Eurasia).[4,5] The system uses a naïve Bayes classifier algorithm to output posterior probabilities for the "Expected bio-geographical origin."

The majority of the 13 individuals classified as European. Using Edgar functions, five of the Biracial individuals classified as EA, seven were not classified as AA/EA and, therefore, HA, and one could not be classified.[4] The web-based rASUDAS system estimated ten of the Biracial individuals as Western Eurasian and three as Sub-Saharan African.[5] The posterior probabilities did not yield results that could indicate a mixture of two ancestries. These results indicate Biracial individuals have a high potential to be misclassified.

Ancestry Estimation, Dental Morphology, Biracial Sample

A76 Improvement to the Estimation of Hispanic Ancestry Through the Combination of Cranial and Dental Traits

Christopher A. Maier, PhD, 2297 Alsace Terrace, St. Petersburg, FL 33714*

After attending this presentation, attendees will understand how the simultaneous analysis of multiple datasets, in this case cranial morphoscopic and dental morphological traits, improves the accuracy of estimating ancestry in the forensic context.

This presentation will impact the forensic science community by highlighting the utility of combining data from different sources when estimating ancestry. Additionally, this presentation demonstrates the power of non-metric ancestry estimation methods in a statistical framework.

With respect to ancestry, "Hispanic" is an umbrella term that fails to account for population histories in different regions of the United States; however, in common usage, "Hispanic" refers to populations with a history of European and Native American admixture, with an added component of African ancestry in southeast and Caribbean populations.[1] The Hispanic population in the United States is growing, and forensic anthropologists increasingly encounter the remains of these individuals in their casework. Several methods have been developed that address the estimation of Hispanic ancestry, but each focuses on a single source of variation.[2-4] This presentation explores whether estimates are improved by combining data.

The present research is based on data from modern Hispanic individuals from a combination of medicolegal and research collections (n=154). It is important to note that many of these individuals are presumed migrants and have yet to be positively identified; however, an ancestry estimate of "Hispanic" has been established using other methods.[5] For each individual, cranial (n=11) and dental (n=23) variables were recorded based on published standards.[6-8] Ancestry estimates were produced using both random forests based on conditional inference trees and naïve Bayes classification on cranial data, dental data, or combined data, resulting in a total of six models for ancestry estimation. The models were tested on each of 30 randomly generated training and test sets to account for variability in correct classification rate. Differences between models were assessed using a paired sample t-test, since classification rates were generated from the same sample across models for each run.

Results reveal that models based on the combined data have higher Positive Predictive Values (PPV) for individuals of Hispanic ancestry ($p < 0.01$). The PPV is a measure of how often the models are correct when giving an estimate of "Hispanic;" because that is the only group considered here, it can be interpreted as a measure of model accuracy. Models based on both types of data have a mean PPV of 0.93 for random forests, and 0.81 for naïve Bayes. In contrast, dental variable-only models performed about 10% worse (0.82, Random Forest Modeling (RFM); 0.72, Bayes) and cranial-only models about 15% worse (0.78, RFM; 0.64, Bayes).

Previous research concluded that the improvement observed when simultaneously analyzing cranial and dental data was of practical, if not statistical, significance, especially in the estimation of Hispanic ancestry. The results presented here demonstrate a statistically significant improvement to ancestry estimation for Hispanic individuals. Future research that combines multiple types of data within a statistical framework will lead to improved estimates of ancestry.

Hispanic Ancestry, Cranial Morphoscopic Traits, Dental Morphology

A77 SkullProfiler: A Simple New Capability for the Quantitative Estimation of Ancestry and Sex From Lateral Skull Photographs

Jodi M. Caple, BS, The University of Queensland, School of Biomedical Sciences, St Lucia, Queensland 4072, AUSTRALIA; John E. Byrd, PhD, DPAA Laboratory, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853-5530; and Carl N. Stephan, PhD, The University of Queensland, School of Biomedical Sciences, St Lucia, Queensland 4072, AUSTRALIA*

The goal of this presentation is to introduce attendees to the R capability SkullProfiler for quantitative estimation of ancestry and sex using outlines of skulls or crania extracted from photographs in norma lateralis.

This presentation will impact the forensic science community by providing a new and freely available computer capability for ancestry and sex estimation that is user-intuitive, field-friendly, accurate, and fast to implement.

SkullProfiler is designed to analyze left lateral skull or cranial photographs of unknown cases, taken with a specifically standardized protocol using a full-frame camera fitted with a 100mm macro lens and subject-to-camera distance of 1.2m. The photograph is imported into R using the SkullProfiler code, which then undertakes a series of semi-automated steps. First, outline coordinates are extracted from the case photograph and Elliptical Fourier Analysis (EFA) is conducted using 40 harmonics.

Group assignment for the unknown case is then achieved using linear discriminant function analysis of a truncated set of Principal Component (PC) scores. Mahalanobis square distances, posterior probabilities, and Chi-square typicality probabilities are reported for the unknown relative to samples selected from an inbuilt reference database. This database comprises skulls (>18 years of age) of known sex from the following collections: the Hamann-Todd Human Osteological Collection, William M. Bass Donated Skeletal Collection, Robert J. Terry Anatomical Skeletal Collection, Khon Kaen Osteological Collection, and Chiba Bone Collection. Groups for analysis are defined as United States Black female (n=87) and male (n=109), Japanese male (n=59), Thai female (n=39) and male (n=47), and United States White female (n=97) and male (n=134).

Five-fold cross validation results are provided in the data outputs to assist users in gauging classification accuracy. Tests using all seven reference samples produced cross-validated accuracies of 73%. This increased to 78% accuracy for reference samples of United States Black and White females and males only.

Tests using an out-of-group sample of nine individuals from the Defense POW/MIA Accounting Agency (DPAA) Laboratory, and all seven reference groups, yielded eight of the nine skulls correctly classifying as White male for both skull and cranial outline data (89%). All nine skulls were correctly classified in a four-way comparison of ancestry when sex was specified ahead of analysis — as would be possible in cases possessing infracranial elements, in which sex could be independently estimated from pelvis.

Both the cross validation and out-of-group validation test results indicated that SkullProfiler can successfully use lateral skull and cranial outlines to correctly estimate an individual's ancestry and sex with high degrees of accuracy, and at rates comparable to other computerized capabilities using linear measurements (namely FORDISC®). The reliance on a single, easy-to-take photograph, portable computer, and semi-automated segmentation program in SkullProfiler increases speed and flexibility of the method. This holds advantages for field use, where robust field assessments of basic bioprofile data can confirm or decline requirements for repatriation of skeletal remains. This becomes paramount in instances with large distances, expenses, and administrative bureaucracy, where unnecessary or incorrect repatriations are better avoided. SkullProfiler and supporting documentation is currently available for free download at CRANIOFACIALidentification.com.

Forensic Anthropology, Elliptical Fourier, Biological Profile

A78 Analyzing Morphometric Methods of Race Differentiation in the Human Pelvic Girdle

Laura Yurka, MA, Mississippi State Medical Examiner's Office, 215 Allen Stuart Drive, Pearl, MS 39208*

After attending this presentation, attendees will understand the importance of replication studies in adequately assessing the reproducibility of scientific methods prior to implementation for casework.

This presentation will impact the forensic science community by providing results from a replication of previously published morphometric methods to differentiate race in the human pelvic girdle. This presentation will highlight the need for comprehensive validation of methods employed by forensic anthropologists and stricter adherence to current statistical standards.

Research has shown that measurements from the pelvic bones and femur can be used for race estimation when the skull is absent or damaged.[1,2] The literature reported up to 95% accuracy when utilizing discriminant function analysis to simultaneously classify race and sex.[1,2] This study attempted to replicate the findings of two previously published methods of race estimation from the pelvic girdle while evaluating them within the guidelines for admissible forensic evidence.[3] It also sought to update the methods where necessary to conform to current statistical standards.[4,5]

This study strove to keep as many variables as possible consistent with the prior research in an attempt to adequately assess the validity of the methods. Both DiBennardo and Taylor, and İşcan utilized the Robert J. Terry Skeletal Collection for the development of their discriminant functions; however, there are concerns that this collection, and collections like it, are no longer representative of populations in the United States and may not be useful for the development of forensic identification methods.[6] To address these concerns, the sample population from the Robert J. Terry Collection was supplemented with individuals from the more contemporary William M. Bass Donated Skeletal Collection, and descriptive statistics from the two skeletal collections were compared. The study sample consisted of 100 individuals each from the Robert J. Terry collection and the William M. Bass collection. A series of 19 metric measurements were recorded across the reassembled pelvic girdle, left innominate, sacrum, and left femur for each individual. The methods for reassembling the pelvis were derived from Bonneau et al. and Peleg et al, and four measurements described by İşcan were recorded.[2,7,8] The bones were then disassembled to record the remaining 15 measurements described by DiBennardo and Taylor.[1]

Statistical analysis was conducted using SPSS and Excel® software and included descriptive statistics, student *t*-tests, multiple discriminant function analysis, and Analysis Of Variance (ANOVA). Statistical significance for metric evaluation is typically set at 95% confidence, meaning there would be a 5% probability ($p < 0.05$) that the difference between groups is caused by chance alone.

Neither method sufficiently separated unknown skeletal remains by race. When the methods were modified to conform to current statistical standards, the overall accuracy fell considerably. The reproductions for DiBennardo's and Taylor's and İşcan's discriminant function analyses yielded accuracy rates of 85.8% and 60.4%, respectively, for the original grouped cases, and 80.7% and 58.9%, respectively, for cross-validated grouped cases.[1,2] These results were substantially lower than those reported in the literature. Thus, the results of the published literature were not reproduced in this study, nor did they adequately meet the standards for admissible evidence in a court of law. Furthermore, descriptive statistics revealed that more variations exist within African American and Caucasian American populations in the United States than among them.

The implications of this research demonstrate the need for more rigorous validation of published morphometric methods, emphasizing replication studies and comprehensive reviews of sample populations and statistical procedures prior to utilization for forensic anthropology casework.

Anthropology, Morphometrics, Validation

A79 Masters of Our Own House: The Planning and Construction of the New Defense POW/MIA Accounting Agency (DPAA) Laboratory in Hawaii

Vincent J. Sava, MA, DPAA Laboratory, 590 Moffet Street., Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; and John E. Byrd, PhD, DPAA Laboratory, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will better understand processes related to planning, designing, and constructing a modern forensic human identification laboratory.

This presentation will impact the forensic science community by providing guidance, experience, and lessons learned from planning, designing, and constructing a modern forensic human identification laboratory. This presentation enables future planners to more easily plan and build similar laboratories.

The mission of the DPAA is to account for United States missing persons. These cases typically involve the identification of what forensic scientists often refer to as "residual remains." In November 2015, the DPAA occupied a new 52Kft^2 human identification laboratory on Joint Base Pearl Harbor-Hickam, HI. It joins the 35Kft^2 laboratory in Omaha, NE, forming the DPAA Laboratory system. The Laboratory, located on the third floor of a larger DPAA facility, supports a multitude of capabilities (e.g., DNA sampling, dental comparisons, and radiographic comparisons) needed to identify human skeletal remains. These capabilities translate into the following laboratory spaces: examination areas for large assemblages of skeletal and dental remains; morgue for decomposition and medical examiner-related cases (DPAA provides medical examiner support); maceration room; evidence transfer and long-term storage areas; radiographic facility including a Computed Tomography (CT) scanner; histology laboratory; DNA sampling facility; material evidence examination area; archeological laboratory; skull-photo superimposition laboratory; Scanning Electron Microscope (SEM) laboratory; synoptic and reference collections storage area; X-ray comparison/superimposition laboratory; photography studio; 3D printer laboratory; evidence cleaning, drying, and conservation areas; case file storage area; administrative areas and offices; visitor, tour, and education center; conference, meeting, and training rooms; family viewing room; and a locker room with showers.

The new Laboratory is the result of 14 years of collaboration of a multidisciplinary project team of forensic scientists, Quality Assurance (QA) experts, architects, and engineers. This improved facility meets the needs of DPAA by allowing rapid throughput of identifications involving the commingled human remains of hundreds of individuals. Already, the new Laboratory is showing dividends in the increased rate of identifications as well as a rise in morale of the Laboratory staff. The new Laboratory was accredited by the American Society of Crime Laboratory Directors/Laboratory Accreditation Board (ASCLD-LAB) in March 2016 on its first assessment and is a powerful asset overall for recruiting quality staff.

There were a multitude of lessons learned during this project. Foremost is the requirement that all users of the Laboratory are involved in all stages of the project and practice innovative and out-of-the-box thinking. In other words, a new laboratory cannot be a clone of the old facility. An architectural/engineering firm, experienced with forensic facilities, must be consulted from project inception to provide subject matter expertise and to keep the customer focused. The firm must have experience with QA standards (in particular the International Organization for Standardization (ISO) 17025) and work with the customer's QA staff to ensure the facility can be accredited. The team must work together, accept compromise, and balance a multitude of competing factors that influence laboratory design. These factors include, but are not limited to: facility layout and adjacencies of functional areas; evidence flow; project costs; energy efficiency; security; environmental impact; available real estate on which to build; long-term Operations and Maintenance (O&M) requirements and cost; public considerations; staff quality of life; future and evolving missions; various legislation and mandates (e.g., Americans with Disabilities Act (ADA)); evolution of QA programs; advances in forensic technology; and advances in building design and construction.

Government construction projects are protracted — in this case, 14 years. As such, the new Laboratory was designed with the future in mind. For example, the Laboratory was flexibly designed for expedient reconfiguration of space over time. Capabilities that were not required in the early 2000s were, in most instances, easily fitted into the design as they became needed.

Finally, maintenance staff must be hired and, as the move-in approaches, a plan formulated to move into the new facility.

In retrospect, there is little in the design that DPAA would change other than program more space for some functions. For example, there is a shortfall of examination space since the need to resolve commingled assemblages increased over time. More storage space and offices for key staff are also needed; however, the design is sound and used with great success in 2011 when planning the DPAA satellite laboratory in Nebraska.

DPAA, Laboratory Concept and Design, Laboratory Construction

A80 Learning From Our Casework: The Society of Forensic Anthropologists (SOFA) Case Database

Cris E. Hughes, PhD, Department of Anthropology, 109 Davenport Hall, 607 S Matthews Avenue, Urbana, IL 61801; Chelsey A. Juarez, PhD, Department of Soc & Anthro NCSU, 1911 Bldg, 10 Current Drive, Campus Box 8107, Raleigh, NC 27695-8107; and Katharine Chapman Pope, MA, Division of Forensic Science, Wilmington, DE 19801*

The goals of this presentation are to: (1) introduce the SOFA Case Database, including a review of the trends in method use for age, sex, ancestry, and stature, as well as biological profile accuracy statistics for the submitted cases; (2) better understand the scope and goals of the database, the user interface, current submitted case statistics, and research potential for users; and, (3) review the submission process, including case eligibility, appropriate case data, and permissions and responsibilities of SOFA Case Database users.

This presentation will impact the forensic science community by introducing a new tool and data resource for research on forensic anthropology case work trends, including method use, biological profile estimation accuracy, and decedent demographics.

SOFA is a United States-based, non-profit organization comprised of practicing forensic anthropologists throughout the country, mostly employed at law enforcement agencies or offices of medical examiners. SOFA's purpose is to promote collaboration of forensic anthropologists, and it seeks to improve the field of practice. In 2013, SOFA began developing the concept and platform for an online forensic anthropology case database tool to serve the broader forensic anthropology community of practitioners and researchers. The purpose for developing the database was to provide a comprehensive and centralized source of information on methods used in forensic anthropology casework. The database is comprised of only identified (positive or presumptive) cases, which then allows researchers to study how forensic anthropological estimations of the biological profile compare to the actual biological profile details of the identified decedent, as well as what methods are being employed in these cases.

The goal of such analyses is to provide insight into avenues for forensic anthropological method development and improvement, as well as decedent demographic trends. To meet this goal, SOFA is engaged in active recruitment of forensic anthropologists with past and present adjudicated cases. With the participation of practitioners and the submission of cases, the SOFA Case Database is the first forensic anthropological community-wide collective resource for case data that can be used to study: (1) the consistency of practitioner-generated estimates of the biological profile with the actual age, sex, stature, and ancestry of the individual, once identified; (2) the trends, accuracy, and precision in method use; and, (3) decedent demographics to address methods gaps. As case data continues to accumulate, interested forensic anthropologists/researchers can access and analyze the anonymous case data (electronically available for download at www.sofadb.com).

SOFA's Case Database fills a data gap in the field of forensic anthropology. At the time of its development, there existed no formal, organized space for the forensic anthropology community to share approaches to casework and casework outcomes. While informal peer interaction is ongoing and useful, a significant source of data was missing — that of casework outcomes (e.g., method-derived *versus* actual biological profile information), a vital aspect for the discipline's ability to self-assess its progress and success.

In the past months, SOFA members have begun actively submitting identified cases to the database, resulting in (as of August 1, 2017) a total of 82 cases representing a wide range of case data, including case year (1993-2017, μ=2012), sex (n_{female}=30, n_{male}=51), age (15-94 years, μ=43), ancestry (n_{White}=34, n_{Black}=23, $n_{Hispanic}$=15, n_{Other}=2), and stature (57-77 inches, μ=67 inches). Additionally, more than 30 forensic anthropological methods were employed by practitioners to assess the biological profile.

Case Report, Methods, Data

A81 Forensic Research Outdoor Station (FROST): The Implementation of a Cold-Climate Forensic Anthropology Research Facility

Jane Wankmiller, PhD, Northern Michigan University, Dept of Sociology and Anthropology, 2400 Jamrich Hall, Marquette, MI 49855; and Scott Demel, PhD, Northern Michigan University, Dept of Sociology and Anthropology, 2400 Jamrich Hall, Marquette, MI 49855*

After attending this presentation, attendees will better understand the importance of collaboration between university, community, law enforcement, and government entities in support of the successful implementation of a forensic anthropology research facility.

This presentation will impact the forensic science community by bringing attention to the processes that were implemented as part of the creation of the FROST at Northern Michigan University (NMU) and by highlighting some of the work that is expected to result from collaborations established between NMU and other research and law enforcement entities.

Casework and research have identified the need for climate-specific research that can inform the forensic community regarding the taphonomic processes associated with the postmortem deposition of human remains. Seven decomposition/taphonomy research facilities already exist in various sub-climates of the continental United States and one in Australia, making FROST the eighth facility of its kind in the world and the only one located in a cold climate. Particularly relevant to research at FROST will be the effects of deep snow and the freeze-thaw cycle on the decomposition of human remains. Additionally, the facility's location in Marquette, MI, with its proximity to Lake Superior and several cold-water inland lakes, has the potential to allow for research that will lead to a greater understanding of the effects of the cold, freshwater lacustrine environments on changes associated with decomposition and other taphonomic effects.

The early successes at FROST and its acceptance by the citizens in the local area, the university, and the law enforcement community can be attributed to extensive outreach, collaboration, and public communication about the facility and its potential benefits to the forensic sciences, law enforcement, and missing persons cases. Prior to conducting any research on the human donors at FROST, several baseline studies are being conducted that have developed collaborative relationships between NMU's Sociology and Anthropology Department and other departments, allowing for faculty and student engagement with the facility and increasing the sense of ownership and community within the university. Interdisciplinary baseline studies at the facility, all of which involve students, include entomological and zoological surveys, a soil chemistry/composition/pH analysis, a Ground Penetrating Radar (GPR) survey, a micro-climate/weather assessment, a Light Detection and Ranging (LIDAR) survey, and archaeological shovel test pits. Results from these baseline studies are included in this presentation.

Stewardship of the 2.5 acres of land that will be occupied by the facility and its parking and outbuildings was transferred to NMU from the Marquette Branch Prison property by the state of Michigan, a process that involved discussion and considerable cooperation on the parts of the university, local law enforcement, the prison wardens, the Michigan State Police (MSP), and the local community, where town hall-style meetings and public forums were held to ensure transparency and education of the various stakeholders. The land allocated to FROST is located approximately four miles from NMU's main campus; it is in an open field, non-residential area, screened from public view. The area (approximately 1.5 acres) includes a security fence with privacy screening and plans are in place to ensure limited access and 24-hour security, including some access oversight by prison personnel — a collaboration that is ideal for maintaining the integrity and security of the facility.

Although the program and the facility are in their infancy, FROST is already well-established as the product of extensive collaboration and communication between NMU and stakeholders of varying interests and backgrounds who have a common goal of advancing forensic science research in a cold climate and contributing to the improvement of methods and techniques used by forensic anthropologists, forensic scientists, and law enforcement

Forensic Anthropology, Taphonomy, Collaboration

A82 The New Revolution of Bone Collection and the Necessity for the International Digital Bone Collection Center (IDBCC)

Yu Ryang Jang, PhD, MAKRI, 65 Hyeonchung-ro Donggak-dong, Donggak-gu, Seoul 156-080, SOUTH KOREA*

After attending this presentation, attendees will better understand the revolution of bone collection and the IDBCC. This presentation will also provide information on challenges faced by the Fourth Industrial Revolution era in the field of forensics.

This presentation will impact the forensic science community by suggesting mid- to long- term solutions for the facilitation of information sharing that can be achieved by the digitization of skeletal collections scattered in different parts of the world through 3D, Computed Tomography (CT), and Magnetic Resonance (MR) images, then sharing them through Memorandum Of Understanding (MOU) with research institutes and countries.

Modern society is evolving into the era of the Fourth Industrial Revolution -— the main theme at the World Economic Forum in 2016. The Fourth Industrial Revolution refers to the new industrial era of Information Technology (IT) convergence and infrastructure in which advanced information and communication technologies, such as Artificial Intelligence (AI), the Internet of Things (IoT), big data, and mobile, are converged into the economy and society as a whole.

With the emergence of the digital era, the field of forensic science has evolved into various areas through the introduction of digital forensics and precision scientific equipment. Bone collection is being pursued by universities and research institutes around the world and is very helpful for researchers in anthropology and forensic science; however, in order to conduct research on the collected bones, researchers have to physically travel around the world. It entails a substantial amount of time, manpower, and costs. Such limitations inevitably prolong the research period and increase the costs, thereby discouraging dynamic research activities.

The digital measurement method is compatible with the current manual measurement method and allows for easier access to the ethnic specification by population group, age, and gender. In addition, the level of reliability and accuracy of the judgments can be enhanced as various analytical methods can be employed through computers due to the development of digital technology.[1] Above all, as the information on bone collections can be accessed freely regardless of time and location, various methods can be developed and shared. In this regard, information sharing is revolutionary as it can eliminate aforementioned problems pertaining to workforce, time, expenses, and residence issues all at once. Also, by doing so, it will provide many young scholars and university students with abundant examples of digital data on the remains found in all different parts of the world.[2] The digital information will allow the analysis of not only human remains, but also others, such as animal bones and crime scenes around the world.

As such, The Ministry of National Defense Agency for KIA Recovery and Identification (MAKRI) of the Republic of Korea is in the process of collecting digital data of remains from around the world to establish the IDBCC. Ultimately, this is to build an environment where labs and organizations around the globe can freely access and contribute to the data collection for further research.

In order to achieve this, a system in which digital data can be donated and shared through cooperation from other nations and organizations is necessary. The center can either digitize collections of remains that are already stored around the world or can gather and centralize medical information such as CT from hospitals or medical institutions with patients' approvals. As the world's widely used medical digital video uses Digital Imaging and Communications in Medicine (DICOM), collections of remains can be managed if stored in the form of Stereolithography (STL), which is compatible worldwide. The data to be stored at the IDBCC will not only facilitate the study of measurement statistics but also characteristics of morphology, culture, era, physical, and biology.[3] A change in the research environment is necessary as we move into the digital era and MAKRI hopes that researchers and scientists around the world will join in the establishment of the IDBCC. This presentation will discuss the effectiveness of the digital bone collection and the necessity for IDBCC.

A83 The Ethics of Conducting Research on Human Subjects in Forensic Anthropology

Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096; and Nicholas V. Passalacqua, PhD, Western Carolina University, 101 McKee, Cullowhee, NC 28723*

After attending this presentation, attendees will understand current legislation surrounding the use of human subjects in research and the ethical implications of conducting research when using deceased human remains.

This presentation will impact the forensic science community by informing practitioners of their obligations in research on human subjects and will establish an ethical means to accomplish this research.

Anthropologists are concerned with the study of humans and must carefully weigh the ethical treatment of human subjects in research. Forensic anthropologists are predominantly focused on the study of deceased individuals who are typically no longer considered human subjects; however, it is not uncommon for research topics or forensic analyses to require the direct involvement of the living or data (including medical records, such as radiographs) from individuals who are still alive. This presentation will outline the current legislation surrounding the use of human subjects in scientific research and its relevance to forensic anthropology. This discussion will also cover the legislation of working with deceased human subjects and ethical concerns surrounding the publication and use of these data for research.

This presentation will highlight the history of the use of living humans as research subjects (e.g., the Universal Declaration of Human Rights, the Nuremberg Trials, and the Declaration of Helsinki) with a focus on legislation within the United States (e.g., the National Research Act of 1974, the Belmont Report, and the "Common Rule"). Discussion will also include the upcoming changes to the Common Rule and the use of the Institutional Review Board (IRB).

This discussion will additionally center on the use of deceased individuals for research to whom the "common rule" does not apply. In the United States, a deceased body is recognized as "quasi-property," which provides the right of sepulcher, and ensures receipt of the decedent in a similar state as in life to the next of kin. This legal concept has ramifications for work conducted in a medicolegal context. Distinctions between forensic cases, donated collections of skeletal remains, and collections in which express consent was not given are also explored. Finally, it is important to consider how research results are presented and the implications for the next of kin, other living acquaintances, or the decedents themselves.

In light of this background, an ethical framework for research on human remains is outlined as relevant to forensic anthropologists. Such a set of guidelines could include obtaining permission from the next of kin or an individual (prior to death) for destructive tests, curation, data collection, and/or publication; however, it is not always possible to locate the next of kin to gain informed consent to conduct research on deceased individuals, and it is not suggested here that research should stop if consent cannot be obtained for such reasons. If permission cannot be obtained, the researcher should ensure the following: (1) the benefit of the research outweighs any harm to the next of kin or the skeletal remains; (2) the right to sepulcher is not hindered; (3) published results are not offensive or inflammatory; and, (4) data are anonymous and cannot be traced back to any living individual.

This proposed set of guidelines is broad in interpretation and scope, as ethical guidelines are typically adjudicated on a case-by-case basis, and what may be appropriate in one context, may not be in another. As such, the future of the discipline may require the adoption of a general ethical code for the practice of forensic anthropology or the implementation of a forensic review board (similar to the IRB process), which could provide oversight to individuals using human skeletal remains in research projects. In today's current scientific climate (e.g., the Native American Graves Protection and Repatriation Act (NAGPRA), the 2009 NSA Report on forensic sciences, the 2011 United States military mortuary scandal, and the 2016 President's Council of Advisors on Science and Technology (PCAST) report on forensic evidence), we cannot afford to appear callous in our treatment of human remains or forensic evidence. As anthropologists at the intersection of biological and social science, we must strike a balance between ethical treatment of human remains and the advancement of our field without alienating ourselves from future research opportunities.

Ethics, Research, Institutional Review Board

A84 Imaging Human Skeletal Remains: Ethical Considerations

David Errickson, Teesside University, Borough Road, Middlesbrough TS1 3BA, UNITED KINGDOM*

The goal of this presentation is to engage with practitioners in forensic anthropology, particularly those who are using 3D imaging, highlighting the recent ethical considerations that have arisen with the implementation of newer 3D imaging technology. After attending this presentation, attendees will better understand the ethical issues and debates that surround imaging human remains and have an opportunity to contribute and implement good practice guidelines in their future work.

This presentation will impact the forensic science community by making practitioners aware of the ethical issues that have recently become prominent due to the use of new imaging technology. This presentation will suggest competent practices when using 3D imaging, while proposing guidelines for good practice for the forensic science community to put into action.

The analysis of human remains via internal and surface documentation has demonstrated valuable benefits that include the digitizing, exposing, comparing, reconstructing, materializing, and sharing of remains. These digitizing techniques include laser, computed tomography, structured light scanning, photogrammetry, and structure from motion. Similarly, standard recording procedures, such as photography, have also been utilized in the same way. Researchers have a responsibility to justify the decision-making process, whether it is a method of presenting an image or manipulating the dataset. In addition, researchers have an ethical responsibility when dealing with the remains of the dead.

Debates and guidelines on ethical considerations with regard to human skeletal remains have previously been discussed and adopted, though, due to newer imaging techniques, some issues have become unaccounted for. It could be argued that many of the newer imaging techniques are respectful of human remains as they are non-invasive, limit handling, and thus reduce further destruction to the individual's remains; however, a key consideration is whether to also treat this digital representation with as much dignity and respect as the body itself. One issue is that the terminology of digitally documenting human skeletal remains is yet to be standardized. Therefore, certain terminology (such as representation, reproduction, and replica) may impact the interpretation of digital human remains, consequently resulting in differential legal status. Thankfully, scientists are becoming more open to discussing these new ethical concerns and practices, but there is a call for more communication due to the varying practices across multiple disciplines. Currently, there are no standard practice guidelines that refer to this technological progression.

Another consideration is that living in a digital age enhances the availability of the internet and the use of social media. Boundaries are constantly being pushed and digital data is becoming increasingly accessible. Not only can academics access this technology, but so too can the public. The impact of this may result in an increase of unnecessary and unethical images that can be accessed and created with one click of a button; however, this "shared data" may not have initially sought the owners' or relatives' permission to do so.

This presentation notes that everyone has an ethical responsibility, but it is up to academics to discuss these responsibilities with the uninformed public. Therefore, this presentation proposes a number of key points to consider prior to publicly sharing images of human skeletal remains. Considerations include whether a form of consent should be gained with regard to display, documentation, and data storage, increasing multidisciplinary discussions on ethical standpoints in the form of workshops and open forums, a standardization of terminology, and that a valid reason should always be sought prior to the undertaking of skeletal documentation.

Skeletal Remains, Ethics, Imaging

A85 The Current State of Forensic Anthropology as a Profession

Nicholas V. Passalacqua, PhD, Western Carolina University, 101 McKee, Cullowhee, NC 28723; and Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096*

The goal of this presentation is to discuss the current state of forensic anthropology in terms of its qualification, certification, accreditation, and ethical processes, all of which are necessary when applying the criteria for a trade to be considered a profession.

This presentation will impact the forensic science community by defining what makes someone a professional, discussing how professional guidelines are, or are not, applied in the field of forensic anthropology, and what the greater implications of this are for the discipline.

Forensic anthropology is a relatively young field, having been formally established in the 1970s. Over the past several decades, the field has continued to evolve in various ways. For example, the definition of forensic anthropology has been expanded to include forensic archaeology, taphonomy, and even socio-cultural approaches to medicolegal issues. Further, the development of methods has shifted toward standardization and validation to meet the *Daubert* challenge. While these changes have served to broaden and standardize the discipline, the education, training, and the practice of forensic anthropology has remained largely static.

Pellegrino argues the practice of a trade can be considered a profession if the trade requires: (1) a body of specialized knowledge; (2) practice within an ethical framework; (3) fulfillment of some societal need; and, (4) some form of social mandate allowing for latitude in a discipline's ability to set standards for education and performance of its practitioners.[1]

To address these requirements within the context of forensic anthropology, this presentation will discuss how forensic anthropologists: (1) possess a unique knowledge base of archaeological methods, skeletal biology, cultural context, and analytical skills; (2) practice within an ethical framework, as long as the forensic anthropologists are certified by the American Board of Forensic Anthropology (ABFA) or are members of the American Academy of Forensic Sciences (AAFS); (3) provide a societal need via the medicolegal nature of the discipline; and, (4) possess a latitude for setting standards for both education and the performance of forensic anthropology, previously through the work of the Scientific Working Group for Forensic Anthropology (SWGAnth) and now of the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) and the AAFS Standards Board (ASB).

While forensic anthropology meets the structural requirements to be considered a profession, the field is lacking in several criteria, as clear standards for ethical behavior, education, and the performance of forensic anthropology have not been expressly delineated or widely accepted. The current processes for ethical practice, certification, and accreditation as stipulations for requirements to act as a forensic anthropologist extend to very few individuals. The reality is that analysts without the current requisite education, training, professional memberships, or Quality Assurance (QA) practices are performing forensic anthropological casework. To address these issues, this presentation further discusses the need: (1) to approach education and training in terms of qualifications and certification; (2) for an enforceable ethical code; and, (3) to approach the practice of forensic anthropology through processes for QA and traceability via accreditation and following published standards and guidelines (e.g., those published by the SWGAnth or NIST OSAC Anthropology Subcommittee).

In the present state of forensic anthropology as a profession, there is little consensus or acceptance of professional practices. As such, the current guidelines are not being widely adhered to and are sometimes completely ignored. The implications of this are that analysts may be acting unethically, either by performing analyses beyond their professional expertise (as determined via certification), misrepresenting their qualifications (i.e., whether or not they are certified to perform the work), or doing harm to the case/investigation (by practicing without QA and traceability protocols). Lacking agreement on ethical practices, qualifications, and accreditations weakens the credibility of forensic anthropology as a profession, and invites non-professionals to practice forensic anthropology without oversight. It cannot be expected that law enforcement agencies, attorneys, or medical examiners be trained in examining the nuances of forensic anthropology as a profession; thus, it is up to forensic anthropologists to collectively generate and follow standards for the practice of their profession. If the discipline is to grow and stay relevant, considerations need to be given to the standardization of ethics, education, training, certification, and accreditation in ways that are inclusive and enforceable.

Professionalism, Ethics, Qualifications

A86 The Suitability of Digital Photographs to Evaluate Decomposition of Pig Carcasses in a Tropical Climate: A Preliminary Investigation

Agathe J.G. Ribereau-Gayon, MSc, University College London, UCL Centre for the Forensic Sciences, 35 Tavistock Square, London WC1E 6BT, UNITED KINGDOM; Carolyn Rando, PhD, University College London, Institute of Archaeology, 31-34 Gordon Square, London WC1H 0PY, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, UCL Centre for the Forensic Sciences, 35 Tavistock Square, London WC1H 9EZ, UNITED KINGDOM; and David O. Carter, PhD, Chaminade University of Honolulu, Forensic Sciences Unit, Division of Natural Sciences and Mathematics, Honolulu, HI 96816*

After attending this presentation, attendees will understand the effects that methodology and the reliance on digital photographs have on the visual assessment of decomposition.

This presentation will impact the forensic science community by demonstrating that decomposition scores generated using photographs tend to overestimate decomposition in the early postmortem period and underestimate decomposition in the extended postmortem period. These scores were also affected by the method used, which did not always accurately reflect real-time decomposition.

The use of color photographs, including digital ones, is often encountered in medicolegal death investigations and retrospective research where the actual remains are not available; however, knowledge as to the suitability of photographs as substitutes for human remains in forensic reconstruction scenarios is currently limited.[1] Some studies demonstrated that the ability to observe and document postmortem changes can be compromised when photographs are relied upon under certain conditions.[2,3] This may hinder the ability to draw reliable postmortem conclusions, including the Postmortem Interval (PMI), from photographs.

To address this gap in the knowledge, the present study investigated the suitability of photographs as a proxy for pig carcasses that are commonly used in empirical research where human corpses are not available, using two published scoring methods to generate a Total Body Score (TBS).[1,4]

As a first step, the decomposition of three exposed pig carcasses (*Sus scrofa domesticus*) was evaluated in real-time at Chaminade University of Honolulu (CUH) in Hawaii (*n* observers=9), using both scoring methods. A month later, 2D digital color photographs of the same carcasses were evaluated by the same group of observers. As a second step, the scoring of the photographs was repeated with a second group of observers of similar composition and size (*n*=9) from University College London (UCL) in the United Kingdom, to investigate the replicability of the results and test the hypothesis that real-time TBS scores will not differ from photograph scores. Differences between real-time and photo-based TBS were identified using a two-way Analysis of Variance (ANOVA) with *post hoc* Tukey Honest Significant Difference (HSD) tests.

Among the CUH group, significant differences between the real-time and photo-based TBS were found with Megyesi et al.'s method ($F_{1,34}$=8.48, p=0.006).[1] Photo-based TBS were consistently greater than real-time TBS before 30 hours postmortem but were then consistently less until the end of the experiment (1,014 hours/42 days postmortem) (p <0.05). In contrast, no significant differences between the real-time and photo-based TBS were found with Keough et al.'s method ($F_{1,34}$=0.104, p=0.749); however, photo-based TBS were consistently greater than real-time TBS before 30 hours postmortem, but were then consistently less until the end of the experiment (p <0.05).[4]

Similar results were observed among the UCL group where significant differences between the real-time and photo-based TBS were found with Megyesi et al.'s method ($F_{1,34}$=13.3, p=0.001).[1] Photo-based TBS were consistently greater than real-time scores before 54 hours postmortem but were then consistently less until the end of the experiment (p <0.05). In contrast, no significant differences between the real-time and photo-based TBS were found with Keough et al.'s method ($F_{1,34}$=2.63, p=0.114) and no significant variations of the TBS according to PMI were observed (p>0.05).[4]

The results lead to the rejection of the research hypothesis because the scoring of real-time and photo-based TBS was found to be highly dependent on the method used and the PMI. Keough et al.'s method appears more suitable for photographs of decomposing pigs in a tropical climate. Overall, consistent overestimation in the early postmortem periods and underestimation in the extended postmortem periods of photo-based TBS demonstrates that the inability to access the remains in real-time can significantly impact the accuracy of TBS. This can have profound consequences on the estimation of PMI, which is a key element in medicolegal death investigations. These initial results indicate the need for further research to address the differences in the applicability of the two scoring methods to photographs and the development of ad hoc practices when photographs are used as substitutes for remains in a forensic setting.

Forensic Taphonomy, Total Body Score, Decomposition

A87 Predicting the Postmortem Submersion Interval (PMSI) From the Microbiome of Bone in a Fresh Water Lake

Claire M. Cartozzo, MSFS, 8207 J David Lane, Mechanicsville, VA 23111; Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will have a greater understanding of the use of microorganisms in estimating the PMSI for skeletal remains recovered from a freshwater lake.

This presentation will impact the forensic science community by providing information concerning a novel area of research, the use of longitudinal succession of microbiomes on skeletal remains submerged in a freshwater lake to predict PMSI.

When individuals die in or are disposed of in aquatic environments, the remains may not be recovered for a period of time, rendering identification difficult. Water turbulence, exposure to aquatic scavengers, as well as accumulated temperatures contribute to tissue decomposition. Once remains are skeletonized, microorganisms endogenous to both the environment and the skeletal remains themselves participate in microbioerosion of bone, increasing the rate of bone diagenesis in water.[1,2] Being able to estimate time since death or, in the case of water-related incidents, the PMSI is pertinent to medicolegal death investigations. Knowing the PMSI assists investigators in identifying remains, validating eye witness statements, and narrowing suspect pools. Because microorganisms are present throughout decomposition, this study proposes the use of longitudinal succession (including aspects of richness, diversity, and indicator taxa) of the microbiome of submerged skeletal remains to estimate PMSI. Advancements in metagenomics approaches (e.g., next-generation sequencing and pipeline analysis software) have demonstrated that bacterial communities can be a useful tool for estimating PMI and PMSI; however, none of these studies have focused on skeletal remains in aquatic environments.[2,3]

In this study, fresh pig (*Sus scrofa)* bones (*N*=100 rib and *N*=100 scapula samples) were purchased from a butcher. Beginning in November 2016 through November 2017, the bones were in cages attached to a flotation device and submerged in Henley's Lake in White Hall, VA (38° 05' 11.7" N, 78° 41' 02.8" W). Water temperature was recorded hourly using waterproof loggers. Every 250 Accumulated Degree Days (ADD), five scapulae, five ribs, and water samples were collected, photographed, and stored at -80°C until processed. Water samples were filtered; meanwhile, bone samples were cut and ground into a powder using liquid nitrogen in a mortar and pestle. DNA was extracted and purified using ChargeSwitch® gDNA Plant Kit. Following parameters set forth by Kozich et al., extracted samples were used to conduct sequencing-by-synthesis of microbial 16S recombinant DNA (rDNA) variable region 4 using the Illumina® MiSeq® 2X300 paired-end sequencing.[4] The resulting data were analyzed via MiSeq® SOP Mothur version 1.36.1.[5]

Preliminary Analysis of Molecular Variance (AMOVA) encompassing collections 0–1,250 ADD indicated a significant difference in the bacterial structure between rib-scapula, (p <0.0002), rib-water (p <0.0002), and scapula-water (p <0.0002). Therefore, samples were analyzed by sample type. Phylum and family level changes were observed for each sample type across ADD. In addition, rib (R^2=0.48) and scapula (R^2=0.64) samples demonstrated a positive relationship between Shannon species diversity and logADD, whereas the water samples showed a negative relationship (R^2=0.48). The decrease in diversity observed in water samples may be related to changes in temperature between the seasons, with bacteria able to survive well on a bone nutrient substrate, but not in colder water.

PMSI, Waterlogged Bone, 16S rRNA Gene

A88 The Faunal Succession of Forensically Important Arthropods and Large Vertebrate Scavengers in Rural Northwest Florida

Kristen M. Grow, BA, 2964 E Olive Road, Pensacola, FL 32514*

After attending this presentation, attendees will better understand the biodiversity of forensically important arthropods and large vertebrate scavengers in rural northwest Florida where little is known about these taxa.

This presentation will impact the forensic science community by providing a survey of arthropods that are associated with decomposing pig carrion and large vertebrate animals that scavenge remains. Even though decomposition stages are the primary component to making Postmortem Interval (PMI) estimations, entomological evidence can provide more precise assessments.[1] Nevertheless, insect activity is dependent on factors such as temperature and habitat, which in turn will affect decomposition rates.[2] Since climactic conditions and insect assemblages vary around the country, and within different habitats, it is important to conduct research in a variety of ecological niches. While Florida is home to one of the most unique and diverse ecosystems, flatwoods and seepage bogs can be found along the Lower Gulf Coastal Plain of Florida and Alabama. Thus, the information garnered from this study may be used to understand arthropod succession and forensically important insect assemblages within Escambia County, FL, and surrounding areas with similar subtropical climates.

This study was conducted using pig carrion (*Sus scrofa* Linnaeus) as models representing human cadavers. One pig carcass was placed in dry flatwoods, while the other was placed in a seepage bog. Adult Calliphorid flies and beetles were collected and some blow fly larvae were reared to the adult stage and identified. Although the pig carcasses were enclosed in cages so large vertebrate animals would not disturb insect activity, game cameras provided evidence for local large vertebrate scavengers that presented themselves in the areas of the pig carcasses.

Based on previous research, it was hypothesized that insect assemblages would be similar but slightly different than those from northcentral Florida.[3] It was also hypothesized that habitat would result in varying insect assemblages, and that large vertebrate animals would be interested in pursuing decomposing remains.

Seven species of Calliphoridae were collected and identified from the carrion, including *Calliphora vicina* (Robineau-Desvoidy), *Chrysomya megacephela* (Fabricius), *Chrysomya rufifacies* (Macquart), *Cochliomyia macellaria* (Fabricius), *Lucilia coeruleiviridis* (Macquart), *Lucilia cuprina* (Wiedemann), and *Phormia regina* (Meigen).

P. regina was the predominant species collected and reared from both pig carcasses. There were also six Coleoptera species collected from the carrion, including *Saprinus pennsylvanicus* (Paykull), *Aphodius rufipes* (Linnaeus), *Trox suberosus* (Fabricius) *Oiceoptoma rugulosum* (Portevin), *Necrodes surinamensis* (Fabricius) *and Creophilus maxillosus* (Linnaeus). *O. rugulosum* and *S. pennsylvanicus* were the most common species collected. These observations reveal that species assemblages in northwest Florida are similar, but slightly different than those in northcentral Florida.[3] Many large vertebrate animals, including vultures (*Cathartes aura and Coragyps atratus)*, opossums (*Didelphis virginiana*), and feral dogs (*Canis familiaris*), showed interest in the carrion. The opossums and feral dogs accessed the carrion and scavenged the remains.

In conclusion, this project provides relevant information to the database of forensic literature regarding medicolegal entomology, decomposition, and postmortem interval. The results can be used to identify potentially forensically important fly and beetle species within Northwest Florida, as well as surrounding areas.

Decomposition, Arthropods, Seepage Bog

A89 Analysis of the Interactions Between Taphonomic and Pathological Processes

Maria L. Cox, BA, 1240 Warner Street, Apt 3, Chico, CA 95926*

After attending this presentation, attendees will better understand how taphonomic events interact with different pathological processes and how these interactions affect overall skeletal preservation.

This presentation will impact the forensic science community by providing information regarding how the taphonomic environment of a burial can affect the preservation and presentation of pathology. As pathological conditions are often used along with the biological profile to create a positive identification and forensic remains are found in a variety of taphonomic circumstances, it is vital to understand how these factors interact.

Variation in pathological processes and damage associated with taphonomic processes can greatly affect observable skeletal material. Research into how these processes interact with each other is therefore important to combat biases that arise from incomplete or damaged skeletal material. Understanding the specific effects of taphonomy on pathology, and their cumulative relationship with preservation, is valuable to forensic practitioners. Pathological conditions are often used to help create a positive identification with a missing persons report. The National Missing and Unidentified Persons System (NamUs) often includes health information that can be used to identify unknown remains. As forensic remains are found in a variety of taphonomic circumstances, it is vital to understand how those factors influence the identification of pathology in skeletal remains.

This study tests the hypothesis that taphonomic events differentially affect bone exhibiting pathologies that increase or decrease bone density. Taking into account density-mediated attrition, taphonomic events are examined separately against pathologies that build or remove bone matrix.

Data were collected from three samples. The first was the Santa Clara Valley Medical Center (VMC) collection, a historic pauper cemetery currently housed at California State University, Chico (CSUC). The second sample was the forensic modern collection at the same location. The final sample included the New York City Office of the Chief Medical Examiner (NYC OCME) forensic anthropology cases. In total, 77 individuals were analyzed. Taphonomic processes were coded as present/absent based on skeletal presentation. Pathological indicators were also coded as present/absent. Attempts at diagnosis were not undertaken; instead, pathological indicators were considered based on the cellular response they elicited. Categories used included osteoblastic, osteoclastic, mixed response, mechanical destruction (e.g., eburnation), and healed trauma. Preservation was recorded in quartiles based on percent present. Chi-square and Cramer's V were conducted using R.

Of the 13 taphonomic events present in the sample, two have significant relationships with bone that exhibited no pathology: scavenging (p<=0.01, V=0.20) and weathering (p=0.04, V=0.08). Osteoblastic response is significantly associated with the same two processes: scavenging (p<=0.01, V=0.14) and weathering (p=0.04, V=0.08). Healed trauma is only significantly associated with overall skeletal preservation (p<=0.01, V= 0.14). Pathological processes that reduce bone density produce a greater number of significant associations. Osteoclastic response is associated with burning (p=0.04, V=0.08). Mixed reaction has significant relationships with staining (p=0.02, V=0.09), Postmortem Damage (PMD) (p=0.01, V=0.10), and acid corrosion (p<=0.01, V=0.11). Mechanical destruction is significantly associated with four taphonomic events: PMD (p=0.02, V=0.09); acid corrosion (p<=0.01, V= 0.12); adhered material (p=0.01, V=0.09); and exfoliation (p<=0.01, V=0.11).

The number of significant interactions demonstrates that taphonomy does differentially interact with pathologies that reduce or increase bone density. Pathological processes that build bone only interacted significantly with two taphonomic events, while pathological processes that remove bone interacted with six, including the more damaging taphonomic processes like acid corrosion and PMD; however, when the direction of the relationships is analyzed, pathological processes that remove bone have lower percentages of taphonomic damage than elements that do not exhibit those pathologies. This may be a byproduct of the extremely poor preservation found in the VMC collection. The high rates of acid corrosion and PMD at this site may have resulted in the removal of elements with reduced structural integrity before excavation, producing a sample with above-average density. While this result is possibly a product of the samples used and further analysis must be undertaken to assess these differences, it may indicate that the interaction between pathology and taphonomy encompasses more than just overall bone density.

Taphonomy, Pathology, Skeletal Preservation

A90 A Comparison of Two Methods for Estimating the Postmortem Interval (PMI) From Decomposed Human Remains

Mary Studebaker-Reed, BA, 845 Beacon Street, Apt 4F, Boston, MA 02215; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Science, 1861 Old Spanish Trail, Houston, TX 77054; and Michelle R. Sanford, PhD, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand how estimating the PMI, also known as the time since death, can differ between methods. Recommendations for future research and validation studies will be provided.

This presentation will impact the forensic science community by providing the results of a comparison of forensic anthropological and entomological methods of PMI estimation from medicolegal cases and reinforce the need for further studies using a multidisciplinary approach.

The goal of this study is not to test the accuracy of the methods, but rather to demonstrate the relationship between them. The two methods that are compared in this study include the Total Body Score (TBS) method used by anthropologists and the Time of Colonization (TOC) method used by entomologists.[1]

In 2005, Megyesi et al. published an anthropological method to estimate PMI by quantifying the stages of decomposition using a standardized scoring system.[1] The system involves scoring the head/neck, trunk, and limbs using four stages of visually assessed decompositional changes. The resulting score, the TBS, is the sum of the scores of all three body regions. TBS is converted into a PMI estimate via the use of Accumulated Degree Days (ADD). ADD is based on local average daily temperatures and provides an estimate of the number of days between the date of death and the date of recovery of the remains.

Entomologists often use the TOC method when estimating PMI based on the presence of insects found in and around the body of a decedent. Using this method, forensic entomologists identify and analyze the age of collected insect specimens to estimate TOC, which may then be used as an indicator of the PMI. Local weather station data is used to estimate the minimum Accumulated Degree Hours (ADH) or ADD for which the insect species present could have reached the maturity level at which they were collected. The relationship of the TOC estimate to the PMI is dependent on various assumptions that may vary depending upon the case.[2]

The present study is a retrospective examination of cases autopsied at the Harris County Institute of Forensic Sciences in Harris County, TX. The study sample was composed of 100 decedents in varying stages of decomposition. The PMI for each of the case had previously been estimated by the staff forensic entomologist using the TOC method. The inclusion criteria for the study sample was based on investigative reports of when the decedent was last known alive. TBS was calculated for each of these cases using autopsy photos and following the Megyesi protocol. The resulting TBS scores for the sample ranged from 4 to 33. Temperature data from a local weather station was used to calculate ADD. A non-parametric Wilcoxon paired-samples test was used to compare the PMI estimates from both methods. The results revealed a statistically significant difference between the PMI estimates derived from the two methods. TBS typically provided a higher PMI than TOC.

This study demonstrates a difference between the two methods for estimating PMI and provides a foundation for future studies. Since accuracy of the methods was not tested, additional research is required to address this issue. Although much research has been conducted on each method independently, there is a paucity of research addressing the comparative efficacy of the anthropology and entomology methods. Therefore, using controlled and context-appropriate validation studies to investigate which methods perform better in different conditions is recommended.

Postmortem Interval, Total Body Score, Time of Colonization

A91 The Differential Effects of Environmental Factors on Immature and Mature Bone Degradation: A Controlled Experiment Using Pig Skeletal Remains

Shera Fisk, BSc, 3888 Point Grey Road, Vancouver, BC V5A 1S6, CANADA; Francesco Berna, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Deborah C. Merrett, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; and Hugo Cardoso, PhD, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will understand the chemical changes in bone composition that occur as a result of the postmortem interval, the degradation environment, and the age at death of the individual.

This presentation will impact the forensic science community by not only advancing the knowledge of the dependency of bone weathering on postmortem environments, but also by providing a direct comparison between the relatively poorly studied chemical decomposition of juvenile bone and the more well-known breakdown of adult skeletal remains. This data provides a means for evaluating the current methods of estimating the time since death of juveniles in the forensic context.

Estimation of postmortem interval is an integral aspect of the forensic identification process. Such estimations provide investigators with a timeline, which can rule out suspects and help to narrow the pool of possible victims. In the case of skeletonized remains, time since death is approximated using trends in bone breakdown. These trends were developed using adult remains and have provided investigators with a relatively predictable timeline for adult skeletal decay; however, juveniles have not been sufficiently studied and, therefore, the applicability of time-since-death estimation methods to their remains is not well known.

This study uses a porcine model to explore the role of bone maturity with regard to: (1) overall susceptibility of the skeleton to chemical degradation; and, (2) the interaction of bone material with different burial environments. The ulnae of immature and mature pigs (*Sus scrofa)* were mechanically defleshed and used as a proxy for human bone of distinct infant and sexually mature age groups. Samples (n=200) from both age groups were left to degrade in a climate-controlled greenhouse, either buried or on the soil surface. These two varying environments provide the comparison of differing environmental impacts. Every month, four bones from each age group and environment were collected. Ash weight analysis was performed on each sample to determine the relative water, collagen, and mineral composition of the bones.

The results of this study indicate that, in the early postmortem interval, the degradation rates of collagen and mineral content of both immature and mature bone are relatively similar. While the collagen content of immature bone was initially higher, and the mineral content initially lower than the mature bone samples, the rate at which these values changed through time appears to be impacted solely by the environment. The buried environment resulted in a rapid destruction of collagen in bones from both age groups, with the values remaining relatively constant throughout the rest of the experimental period. The mineral content was inversely affected by the environment within the first month, then remained constant in both age groups until month six, when there was a noticeable decrease in the values, regardless of the environment. The water content, on the other hand, trended upward for both age groups in the buried environment; however, only the mature samples demonstrated a water content increase in the subaerial environment.

These results indicate that degradation environment plays a major role in the chemical decomposition of bone material, while the maturational stage of the bones only has an affect on the changes in water content throughout the postmortem interval. In particular, this study suggests that, unlike popular belief, immature bone does not seem to degrade faster than more mature bone, at least during the early postmortem period. These results have the potential to inform the forensic community of the behavior of juvenile bone in varying degradation environments, subsequently improving the accuracy of estimating time since death and identifying children in the forensic context.

Postmortem Interval, Juvenile, Degradation

A92 Science as a Human Right: Using DNA to Identify Missing Migrants

Robin C. Reineke, PhD, Colibrí Center for Human Rights, 3849 E Broadway Boulevard, #206, Tucson, AZ 85716; and Mirza M. Monterroso, MA, Colibrí Center for Human Rights, 738 N 5th Avenue, Ste 235, Tucson, AZ 85705*

After attending this presentation, attendees will understand how DNA science and technology can be used to support the identification efforts of undocumented migrants that die attempting to cross the United States-Mexico border.

This presentation will impact the forensic science community by highlighting alternative strategies for the positive identification of unidentified remains.

Since the year 2000, the Colibrí Center for Human Rights, in collaboration with the Pima County Office of the Medical Examiner (PCOME), has collected missing person reports from nearly 3,000 families of those who have disappeared attempting to cross the United States-Mexico border. Also during this time, the remains of more than 2,800 people have been discovered in southern Arizona. Despite the efforts of dedicated forensic professionals, consular officials, and others, 30% to 40% each year are not identified, adding up to a cumulative total of more than 1,000 unidentified human remains cases.

Due to the aridity of the Sonoran Desert and the remote paths migrants take to cross the border, the remains of the dead are difficult to identify without DNA. Even after a strong circumstantial comparison or identification hypothesis is made between an unidentified set of remains and records for a missing person, it is common for DNA to still be required to confirm or refute the match; however, many families of missing migrants cannot utilize the typical mechanism in the United States for investigating missing persons, which depends on reporting to United States law enforcement. Because families of missing migrants live in the United States as undocumented immigrants, or in Mexico or Central America, they are either afraid to contact police, or they are turned away when they attempt to file a report because their case is seen as out of jurisdiction. The more socially marginalized a family is, the more obstacles they face in obtaining information about their missing loved one.[1] The results of a genetic study of human remains examined at the PCOME indicated that those with indigenous backgrounds are less likely to be identified than those with more European ancestry.[2] This indicates that innovative approaches to human identification are needed that focus on macro-level structural conditions of access to the benefits of scientific progress rather than only on micro-level laboratory methods. Families are afraid of or unable to access these systems and wait for news for decades when the remains of their loved ones languish in cemeteries along the border.

The purpose of this presentation is to report the results of a new initiative by the Colibrí Center for Human Rights to bring the science and technology of DNA to the underserved population of Latin American immigrants in the United States. The program is designed to lower the obstacles to care for families of the missing by building sanctuary around the process of submitting DNA. Previous research in public health and medicine has demonstrated that undocumented Americans face challenges to accessing care due to a combination of fear of deportation, poverty, and isolation.[3-6]

The Colibrí Center's DNA Program addresses each of these challenges strategically to make the process of submitting DNA as easy as possible for families. Colibrí hosts DNA collection clinics throughout the United States. These are held in undisclosed sanctuary churches in major cities. Colibrí representatives partner with foreign consulates, a private genetic laboratory, and medicolegal officials, but do not allow United States law enforcement, press, or onlookers into the space during DNA collection clinics.

This presentation will report on two years of results for this initiative. Colibrí has collected Family Reference Samples (FRS) from 315 participants, representing 150 missing person reports. Results to date include 12 positive identifications achieved in collaboration with the PCOME and 26 additional strong genetic matches needing follow-up in the form of further FRS collection. Many of the identifications achieved through this project pertain to cold cases in which the individual died and was examined years ago. This initiative demonstrates the need for approaches to the application of DNA science and technology that are informed by public health literature relevant to the population being served.

Missing Persons, United States-Mexico Border, DNA

A93 The Approach Toward Identification of Deceased Migrants in the United States and European Union: A Comparative Study Between LABANOF (Italy), OpID (Texas) and PCOME (Arizona) Experiences

Annalisa Cappella, PhD, LABANOF - Sezione di Medicina Legale, Dipartmento di Scienze Biomediche Per la Salute, Via Luigi Mangiagalli, n. 37, Milano 20133, ITALY; Timothy P. Gocha, PhD, University of Nevada, Las Vegas, Dept of Anthropology, 4505 S Maryland Parkway, Las Vegas, NV 89154; Jennifer M. Vollner, PhD, Pima County Office of the Medical Examiner, 2825 E District Street, Tucson, AZ 85714; Debora Mazzarelli, BS, LABANOF - Sezione di Medicina Legale, Dipartimento di Scienze Biomediche Per la Salute, Via Luigi Mangiagalli, n. 37, Milan 20133, ITALY; Lara Olivieri, MSc, LABANOF - Sezione di Medicina Legale, Dipartmento di Scienze Biomediche Per la Salute, Via Luigi Mangiagalli, n. 37, Milan 20133, ITALY; Bruce E. Anderson, PhD, PCOME, Forensic Science Center, 2825 E District Street, Tucson, AZ 85714; Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; and Cristina Cattaneo, PhD, LABANOF -Sezione di Medicina Legale, Dipartmento di Scienze Biomediche Per la Salute, Via Luigi Mangiagalli, n. 37, Milan 20133, ITALY*

After attending this presentation, attendees will have acquired an overview of the complex topic of identifying migrants who either die in the United States or the European Union, with special emphasis on the differences and similarities existing in the projects currently conducted in Arizona, Texas, and Italy.

This presentation will impact the forensic science community by illustrating the importance of applying forensic anthropology to the emerging field of humanitarian sciences, which has become increasingly important in recent years and whose potential has yet to be fully recognized in other geographical regions and contexts in the world.

Due to the rise in migrant deaths in Europe, and the continuing crisis of migrant deaths in the United States, an assessment comparing and contrasting the approach of forensic anthropology in these humanitarian crises was conducted. The materials and methods for this research derive from an extensive period of participant observation, namely three years at the Laboratory of Forensic Anthropology and Odontology (LABANOF) in Italy working on the identification of migrants who have perished in the Mediterranean and three months in the United States embedded with anthropologists working at Operation Identification (OpID) at the Forensic Anthropology Center at Texas State University and the Pima County Office of the Medical Examiner (PCOME) in Arizona. Data was derived from systematic surveys of organizational and staffing structures, laboratory protocols and Standard Operating Procedures (SOPs), casework records, and experiences regarding the identification of migrant remains.

Results indicate there are many similarities regarding difficulties in the identification of deceased migrants around the world. The remoteness of migrant deaths often creates challenges in finding or recovering remains, with deaths in Arizona and Texas occurring in desolate, arid lands, while in the Mediterranean, deaths are often the result of a ship sinking and taking hundreds of lives with it at once. Often in the United States and European Union, migrant remains are not found with identification cards or visas that could provide an immediate identification hypothesis. Furthermore, the absence of missing persons reports and/or antemortem data is a universal difficulty.

Similarities and dissimilarities were also found in the way the three different organizations operate within their respective jurisdictions to attempt migrant identifications. Due to the high levels of deaths in Arizona for years, the PCOME is a state-funded agency with two full-time forensic anthropologists to help address the identification of unidentified skeletal remains. Since 2001, their agency has received 2,615 remains of presumed migrants and has helped facilitate the positive identification of 1,676 individuals. As part of a governmental agency, the PCOME also has a staff of death investigators who operate as case managers.

In contrast, the experiences of academic-based LABANOF and OpID have been largely volunteer-based, with OpID gaining a small paid staff only in recent years. This is, in part, due to the higher number of dead in these areas within the past five years, but also to the fragmented nature of migrant death investigations in Texas and the European Union, resulting in a smaller number of remains received by these organizations. Since its inception in 2013, OpID has received 238 sets of unidentified remains and has helped facilitate the positive identification of 24 individuals, while LABANOF has received approximately 1,000 remains/postmortem data coming from three different shipwrecks and has helped facilitate the positive identification of 21 individuals who died in the October 3, 2013, shipwreck that occurred in Lampedusa. The academic-based operations of LABANOF and OpID also lack a staff of death investigators, and therefore anthropologists have taken on the important role of case managers.

Within the United States, there are national databases, such as the National Missing and Unidentified Persons System (NamUs) and the Combined DNA Index System (CODIS), that offer a central repository for case information across jurisdictions, which are utilized by both the PCOME and OpID; however, in the European Union, there are no similar databases, resulting in a more fragmented system than in the United States.

In spite of their unique challenges, anthropologists in all three jurisdictions have implemented strategies and protocols for working with local, regional, and international members of law enforcement and non-governmental organizations to achieve identifications and move cases forward, though approaches differ based on locally available resources and legislative barriers; however, a general model of anthropological involvement has proven successful across the United States and European Union, and could be successfully implemented in other arenas of humanitarian need across the world.

Human Rights, Migrant Identification, Forensic Anthropology

A94 Humanitarian Science in the Texas Borderlands: Incorporating a Sociopolitical Perspective to the Forensic Investigation of Migrant Identification

Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; Alyson O'Daniel, PhD, University of Indianapolis, Anthro Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

The goals of this presentation include an appreciation of the need for: (1) coordination, collaboration, and consistency among various stakeholders during large-scale humanitarian science efforts; (2) knowledge of how the local work of migrant identification connects local issues with global systems and history; and, (3) understanding that forensic science in a humanitarian crisis context requires balancing neutrality and engagement in novel ways.

This presentation will impact the forensic science community by illustrating how sociopolitical conditions and processes shape the work of forensic scientists in this context and how they navigate and transform social relationships and power dynamics circumscribing their work by highlighting identification efforts made by forensic anthropologists since 2013. This presentation proposes these forensic anthropologists are actors in the political economy of forensic science in the Texas Borderlands as they position themselves within a complex set of interactions. This allows them to garner the resources necessary to continue their work, as well as provides them the position to tell the stories of the dead. This presentation pulls from critical reflections of forensic anthropologists working in the Texas Borderlands to illustrate the complexities of operating within the current system, highlights the novelty of this approach, and contemplates how a sociopolitical approach to migrant death can be incorporated into the future of this work.

Forensic anthropologists are often consulted by law enforcement and medical examiners to assist in the recovery of human remains from various contexts and analyze those remains to address questions regarding the death and identity of the individual. While the majority of cases analyzed by forensic anthropologists involve a single individual, practitioners are increasingly becoming involved in mass disaster and mass death situations that unfold in relation to, or as a consequence of, processes of public policy and governance. For example, forensic anthropologists were first formally utilized in politically charged humanitarian efforts in 1984 in Argentina to assist in the identification of individuals “disappeared” during what became known as the Dirty War. The unique skillset of forensic anthropologists to locate and excavate graves as well as analyze skeletal remains positioned them to contribute to the work of identification, as well as the work of witnessing and legitimizing claims of human rights abuses.

In more recent years, forensic anthropologists have utilized their skills in humanitarian efforts in South Texas to exhume and identify migrants who perished crossing the southern United States border. With virtually no resources and deaths at mass disaster proportions, many South Texas counties made the decision to bury unidentified migrants in pauper’s areas of county cemeteries until they obtained the resources for costly forensic investigations. Unfortunately, little documentation survives detailing exactly where the burials are positioned and exactly how many burials are located in each cemetery. Local officials invited forensic anthropologists from several universities to locate, remove, and preserve the context of the burials through proper documentation. Once exhumed, scientific tools were utilized by forensic anthropologists during the investigation into personal identification, including osteological, histological, dental, isotopic, and genetic analyses; however, these scientific practices were implemented in a broader political economic context that formed and was shaped by politics and processes of social justice and human rights.

This presentation, from the view of a visiting volunteer forensic science team, illuminates migrant identification efforts in South Texas as a critical vantage point from which to understand the sociopolitically charged nature of humanitarian forensic science in a contemporary globalized society. Migrant identification requires cooperation, communication, information sharing, and resource coordination between a variety of local, national, and international stakeholders that may each have different missions, motivations, and goals. Thus, many forensic anthropologists working on migrant identification operate as part of a larger, sometimes fragmented and contentious, initiative toward social justice and human rights. As such, forensic investigations in this context are positioned in such a way as to spotlight particular public policies, practices, and social processes that lead to inhumane treatments in life and in death. Forensic scientific practice offers a window into the dynamic and global nature of this crisis and the response mechanisms currently in place and must be viewed through the interconnected lenses of history, power, and scientific practice.

Forensic Anthropology, Humanitarian Science, Migrant Death

A95 Assessing the Spatial Patterns of Undocumented Border Crosser (UBC) Deaths in the Southern Arizona Desert

Caitlin C.M. Vogelsberg, MS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will better understand the application of Geographic Information Systems (GIS) to the field of forensic anthropology through the analysis of spatial patterns of the recovery locations of deceased individuals over a large geographic area.

This presentation will impact the forensic science community by highlighting the utility of geospatial analyses for providing supplemental information to the investigation of UBCs recovered from the southern Arizona desert and potentially leading to more identifications.

Undocumented immigration into the United States via the Mexican border has been a topic of national debate for well over two decades, in part due to the continually high number of deaths as individuals attempt to enter the country via clandestine means. Since 2001, more than 2,600 UBCs have died in the Sonoran Desert and surrounding regions falling under the jurisdiction of the Pima County Office of the Medical Examiner (PCOME) in Tucson, AZ. The PCOME contracts with 11 of 15 Arizona counties, including the four bordering Mexico, averaging roughly 169 UBC deaths a year with an identification rate remaining steady at around 64%.[1]

Migration is an inherently patterned process, including a person's motivation for leaving, the routes they take, and the places they reside; so, presumably, patterns may emerge as to where they die. A directed analysis of the location and distribution of undocumented migrant deaths processed by the PCOME was warranted due to previous studies being only preliminary or limited to the geography of where people are dying in southern Arizona.[2] PCOME case recovery protocol includes the recording of GPS coordinates of the location of the remains, which is stored and mapped at both the PCOME internal database and on the Open GIS (OGIS) platform at www.humaneborders.info. Public data available via OGIS is limited and, therefore, was supplemented using PCOME records of 1,681 identified individuals to include nationality. The majority of identified individuals recovered at the PCOME are of Mexican origin (n=1,403, 84%), followed by the next two largest groups of Guatemalans (n=154, 9%) and Salvadorans (n=45, 3%).[1]

The purpose of this research was to examine the geospatial properties of deceased migrants recovered from southern Arizona to potentially aid in both the investigative and identification processes. Therefore, a combination of exploratory spatial data and GIS analyses was conducted on several demographic variables of identified UBCs (n=1,681). Spatial autocorrelation analyses — including Moran's I and Local Indicator of Spatial Association (LISA) cluster maps — for the variables of recovery year, sex, and nationality or country of origin revealed significant positive spatial relationships for each. As the majority of individuals examined at the PCOME are young, Mexican males, further tests were conducted on nationality, which also resulted in statistically significant positive spatial autocorrelation and areas of spatial clustering. Furthermore, clusters of recoveries from both the beginning and second half of the study period (2001–2016) were visualized using LISA cluster maps and express an east-west movement of case locations. These results may indicate that route choice, as seen through death and recovery location, is also patterned via a person's sex, country of origin, and when they crossed. This supplements other anthropological, sociological, and criminal justice research on the topic and provides further information to the study of international migration along the United States-Mexico border.

Future research will combine these geospatial data with the predictive powers of the biological data (craniometrics and morphometrics) on ancestral affiliation for identified individuals to potentially predict where an unknown individual is from and thus facilitate a more efficient identification.

Undocumented Border Crossers, Geospatial Analysis, International Migration

A96 The Application of Stable Isotopes and Geostatistics to Infer Region of Geographic Residence for Undocumented Migrants

Robyn Theresa Kramer, BA, 1703 N Interstate 35, Apt 11H, San Marcos, TX 78666; Nicholas P. Herrmann, PhD, Texas State University, Dept of Anthropology, 266 ELA, 601 University Drive, San Marcos, TX 78666; Eric J. Bartelink, PhD, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

The goals of this presentation are to: (1) determine how undocumented migrants fit into the established models by constructing coarse-grained baseline strontium and oxygen isoscape models using published data; and, (2) determine if using a probability assignment method for the dual-isotopes can aid in estimating the most likely regions of geographic residence for unidentified deceased migrants recovered along the Texas-Mexico border. Establishing residential history can reduce the potential matches for unknown cases within the National Missing and Unidentified Persons System (NamUs) database and potentially aid in generating positive identifications for deceased migrants.

This presentation will impact the forensic science community by shedding light on the issue occurring at the southern border and promoting interdisciplinary approaches to forensic and human rights problems.

Hypothesis: A dual-isotope isoscape and likelihood assignment method can be used to estimate region of origin for deceased migrants recovered along the Texas-Mexico border and improve the probability of making a positive identification.

Outcomes: This presentation will elucidate the humanitarian crisis occurring at the United States-Mexico border and promote interdisciplinary approaches to forensic identification and human rights issues. Specifically, applying methods from biogeochemistry and geostatistics to answer forensic anthropological questions will advance the field's foothold in the forensic sciences. An additional outcome is closure for the families that have lost loved ones and can finally have them returned home and laid to rest.

Synopsis/Methods: Recently developed bedrock, water catchment, and soil strontium isoscape models for Mexico, Central America, and the Caribbean are adjusted using bioavailable strontium ($^{87}Sr/^{86}Sr$) data collected from a variety of published sources. Oxygen (^{18}O) precipitation data are gathered from the Global Network of Isotopes in Precipitation online database. Digital Elevation Models)DEMs) are factored into the oxygen isoscape to account for isotopic changes in elevation for oxygen precipitation isotopes. Compiling the oxygen and strontium data in arcGIS® produced a multi-layered isoscape depicting isotopic variation in Central America, Mexico, and the Caribbean. Using the Operation Identification collection at Texas State University, dental samples (preference is given to maxillary premolars) are collected from five individuals (n=5) and analyzed for strontium and oxygen. Associated cultural material recovered with the deceased migrants are used as a predictor for region of geographic residence (e.g., an individual carrying quetzals is more likely to originate from Guatemala than Mexico). Strontium and oxygen isotope values extracted from the teeth are run through a likelihood assignment model established in previous publications to produce probability densities for the most probable regions of residence for each individual.

Results/Conclusions: The goal of the research is to map the isotopic variation. The likelihood assignment model in R studio uses probability densities to estimate most likely region of origin. After running the strontium and oxygen ratios through the model, the results consist of multiple heat maps displaying the probability densities for regions of most likely origin for each of the five individuals. Strontium isoscapes tend to be the more accurate model for provenancing migrants, while the oxygen isoscape for the region has a low accuracy rate due to the lack of precipitation data for the regions. Overall, the dual-isotope approach proves successful in narrowing the region of geographic residence for deceased migrants recovered near the Texas-Mexico border. Adding more strontium and oxygen data to each of the isoscapes will improve the method, allowing it to be applied to all migrants recovered along the United States-Mexico border and to be adapted for other regions of the world where deceased unidentified humans are recovered. The implementation of geostatistical and biogeochemical methods to investigations of unidentified human remains will improve existing techniques and increase the efficiency of current identifications.

Spatial Analysis, Forensic Anthropology, Stable Isotopes

A97 Digital Technologies and Forensic Archaeology: Reflections on the Experiences of the Committee of Missing Persons in Cyprus

Caroline L. Sturdy Colls, PhD, Staffordshire University, College Road, Stoke on Trent, Staffordshire ST42DE, UNITED KINGDOM; Dante Abate, PhD, Staffordshire University, College Road, Stoke on Trent ST42DE, UNITED KINGDOM; Noly Moyssi, PhD*, Committee On Missing Persons In Cyprus, 56, Kyriakou Matsi Street, Nicosia 1082, CYPRUS; Demet Karsili, MA*, Committee on Missing Persons in Cyprus, Ledra Palace Hotel, PO Box 21642, Nicosia, Kaymakli 1590, CYPRUS; Marina Faka, MSc, The Cyprus Institute, 20 Konstantinou Kavafi Str, 2121 Aglantzia, Nicosia 2121, CYPRUS; Ahmet Anilir, MSc, Committee on Missing Persons in Cyprus, Ledra Palace Hotel, Nicosia 1590, CYPRUS; Stylianos Manoli, Committee on Missing Persons in Cyprus, Ledra Palace Hotel, Nicosia 1590, CYPRUS; and Sorin Hermon, PhD, The Cyprus Institute, 20 Konstantinou Kavafi Street, 2121, Aglantzia, Nicosia 2121, CYPRUS*

After attending this presentation, attendees will better understand the potential of digital forensic archaeological methods to: (1) improve search efficiency and accuracy; (2) ease access to various environments; (3) inform and create a more accurate record of elements recovered during subsequent excavations; and, (4) provide data outputs suitable for presentation to both experts and non-experts.

This presentation will impact the forensic science community by demonstrating how the combination of traditional investigation and excavation methodologies with digital forensic archaeological methods can affect the outcome of a missing person investigation and how new approaches to searching and documentation of unmarked clandestine burials may be applied around the world.

Using the example of the research undertaken in Cyprus, the objective of this presentation is to demonstrate the application of innovative digital technologies in a forensic archaeological environment and to highlight the pros and cons of interdisciplinary approaches compared with more traditional methods. Because this research was comprised of two distinctive areas of applied digital forensic technologies — those used for the identification of potential excavation sites by means of Non-Destructive Analysis (NDT), and those exploited for the documentation of the excavation process of exhumation sites — both will be included in this presentation. The combination of traditional investigation and excavation methodologies with digital sciences enables the project team to reflect upon the specific forensic needs of the Committee on Missing Persons (CMP) future strategical planning program and to highlight how such approaches may be applied at other unmarked clandestine burials around the world.

Since forensic archaeology became a recognized discipline in the mid-1990s, there have been considerable advances in the search for and recovery of human remains and other trace evidence. An increased appreciation of the role of archaeologists means that, in some countries, they are regularly engaged in forensic cases involving missing persons in the course of legal proceedings. Moreover, in many countries throughout the world, there have been pledges made to locate deceased and missing people for humanitarian purposes, with the main goal of ensuring that they receive the "basic dignity" of a formal burial and of providing answers for their families.

The CMP in Cyprus is a bi-communal body that was established in 1981 by the leaders of the Greek-Cypriot and Turkish-Cypriot communities, with the participation of the United Nations. The objective of the CMP is to determine the fate of 2,000 missing persons who have disappeared since the beginning of the inter-communal fighting of 1963-1964 and the events of 1974. So far, the remains of 1,192 individuals have been exhumed; 740 people have been identified. The locations of the burials of the remainder of these missing persons remains unidentified.

In 2017, a research project was launched between archaeologists, forensic experts, and digital technologists from the CMP, the Cyprus Institute, and the Centre of Archaeology at Staffordshire University (United Kingdom) to explore how tools from a range of disciplines could be utilized to detect and record individual and mass burials from the aforementioned periods of conflict. During this project, a wide range of methods were tested to identify appropriate emerging technologies and scientific applications that could be implemented in forensic scenarios now and in the future. A pyramidal approach was chosen, exploiting different devices mounted on aerial and terrestrial platforms. These included the use of Un-Manned Aerial Vehicles (UAV) coupled with image-based modeling techniques to create Digital Elevation Models (DEM), Digital Surface Models (DSM), and high-resolution ortho-photos. This methodology provided a first assessment of surviving anomalies, both in terms of surface geometry and vegetation growth, that may indicate the presence of burials. This approach was followed by geophysical surveys of selected areas to accurately scan the subsoil and identify and characterize potential underground targets (including potential burial sites). The fusion and visualization of this data was then undertaken alongside more traditional means of witness interviews and excavation.

Forensic Archaeology, Digital Technologies, Missing Persons

A98 Broken Link: The Role of Forensic Anthropology in Cultural Resources Management

Rebekah Loveless, MA, Loveless Linton, Inc, 1421 W Lewis Street, San Diego, CA 92103; and Brandon C. Linton*, Loveless Linton, Inc, 3737 Albatross Street, San Diego, CA 92103*

The goals of this presentation are to: (1) inform the medicolegal community, specifically medical examiners, coroners, and forensic anthropologists, of the lack of standardization and protocol faced by the archaeological and Native American communities when attempting to obtain a legal identification of human remains; (2) share the process developed in San Diego, CA, to attempt to mitigate for the missing link; and, (3) call on the forensic science community to adopt a standard definition for the identification of archaeological bone.

This presentation will impact the forensic science community by bringing awareness to a long-standing problem that has affected many people within the archaeological and Native American communities. After learning the obligations of the forensic community to archaeological human remains and the consequences the lack of a standardized process has on people, the community will want to adopt standardized identification language and try to help fix a broken system.

It is commonly stated that people who work in the medicolegal field "speak for the dead." There are many well-trained individuals who practice forensic anthropology within the defined space of legal jurisdiction; however, there is a place where many people are unspoken for, a place where forensic science, anthropology, the law, and human rights to bury the dead all intersect.

In the Cultural Resources Management (CRM) field, the chain is broken. The pathway from bone being discovered to the identification as human to the determination of Native American (or not) is a gray area that has little to no standardization. As one can imagine, circumstances in which archaeological bone is discovered is often treated as a nuisance and a potential hazard for the project budget. In practice, contractors look to archaeologists to make the identification and preferably identify as non-human. This high-pressure environment, the lack of experts in the field, and the lack of awareness of the medicolegal community may lead to human remains being labeled as other than human.

Archaeological bone is often passed over by the medicolegal community for a number of reasons, primarily because they are busy with forensic cases, understaffed, and/or assume it is not their jurisdiction; however, in many states and in federal policy, the coroner/medical examiner is the person or office that is responsible for the legal identification. Without guidelines, policy, or identification of a legal procedure, bones are not properly identified. Without proper identification by a skilled and legally authorized person, many Native American communities do not have any rights to claim or bury those remains as they see culturally fit.

Osteology, Archaeology, Identification Process

A99 Identifying Vulture Scavenging Locations Through Global Positioning Systems (GPS), Geographic Information Systems (GIS), and Remote Sensing

Lauren R. Pharr, PhD, 6531 Kirby Forest Cove, Memphis, TN 38119; and Michael Leitner, PhD, Louisiana State University, Dept of Geography and Anthropology, E-104 Howe-Russell Geo Complex, Baton Rouge, LA 70803*

After attending this presentation, attendees will be aware of how GPS, GIS, and remote sensing were used to identify when and where vultures scavenge.

This presentation will impact the forensic science community by demonstrating how GPS, GIS, and remote sensing were used to locate 2,104 vulture scavenging locations and to identify their predominant geographic, environmental, and temporal features. The information from this presentation derives from the only study that has tagged and released vultures from a forensic anthropology research facility. This study's findings can aid investigators and forensic anthropologists trying to determine if vultures were at a scene involving human remains.

Vultures have a profound impact on the taphonomic record because these obligate scavengers accelerate decay. As a result, forensic scientists need to account for vulture scavenging when estimating the postmortem interval; however, vultures' scavenging efficiency makes identifying their prior presence at a scene difficult to detect.

To determine the environments where vultures are likely to scavenge and outcompete necrophagous insects and other scavengers in the acquisition of decomposing remains, six vultures were intentionally trapped at the Texas State Forensic Anthropology Research Facility (FARF). Prior to their release on April 10, 2013, the vultures were fitted with 70g solar-powered GPS trackers (transmitters). The tagged vultures included two adult turkey vultures, two adult black vultures, and two sub-adult black vultures (approximately one year old), and they were released in good health and unharmed. The vultures were monitored through satellites for six months, and each transmitter collected hourly spatial point data for 19 hours per day.

More than 15,000 vulture GPS data points obtained between April 2013 and October 2013 revealed the vultures traveled throughout most of Texas and into Oklahoma. Moreover, each data point recorded by the transmitters included the vultures' location in latitude and longitude, altitude above sea level, flight speed, course direction, and a time stamp. The GPS point data had a spatial accuracy of ±18m and a vertical accuracy of ±22m.

To determine where the vultures were scavenging, a digital elevation model was generated for the Texas and Oklahoma study area. Ground elevation was determined for all 15,000 vulture GPS points, then subtracted from the vultures' height above sea level, which resulted in a dataset with the vultures' height above ground. From this new dataset, scavenging locations were defined as daytime points with heights above ground ranging from ±10m; negative values can result from normal variability in the GPS data.

A GIS was used to extract land cover values associated with each scavenging location and to calculate distances between vulture scavenging locations and water and roads.

Results reveal both turkey and black vultures prefer evergreen forests and shrub land for scavenging and normal daily movements. Additionally, vulture scavenging sites on average are located closer to a permanent water source than to a road. Turkey vulture scavenging locations (n=695) averaged 450m from permanent water sources and 609m from roads. Black vulture scavenging sites (n=1,409) averaged 361m from permanent water sources and 547m from roads. The isolation of scavenging locations within the GPS tracking data also revealed that turkey vultures prefer to scavenge in the afternoon, whereas black vultures prefer to scavenge the morning.

GPS tracking of vultures trapped and released from the FARF provided new insight on flight and scavenging behaviors of vultures in Texas and Oklahoma. GIS and remote sensing allowed for the identification and analysis of vulture scavenging locations. The results from this study can help forensic investigators decide which habitats and landscapes are associated with increased vulture scavenging when assessing human remains at crime scenes.

Support for this research was provided by the National Science Foundation (NSF) Doctoral Dissertation Research Improvement Grant (PD 98-1352) and the Louisiana State University (LSU) West-Russell Award. The findings and opinions to be presented are those of the authors and not necessarily those of either the NSF or LSU.

Vulture Scavenging, GPS, GIS

A100 Staged and Altered Homicide Scenes: An Analysis of Secondary Sites

Erin H. Kimmerle, PhD, University of South Florida, FL Institute for Forensic Anthropology, 4202 E Fowler, SOC 107, Tampa, FL 33820*

After attending this presentation, attendees will know how to use a mixed methods approach, including investigative methods, archaeological field methods, and forensic interviews, for locating clandestine burials. Attendees will also learn about homicide patterns involving dumped and buried remains.

This presentation will impact the forensic science community by offering research into an intelligence-based approach with best practice recommendations to provide law enforcement and forensic anthropologists tools and an understanding of the techniques and protocols utilized in each field to find buried bodies.

It is not uncommon that bodies and crime scenes are altered following a homicide, yet the number of cases resulting in dumped or buried remains in a secondary location are less frequent. Many long-term missing person cases are determined to be homicides with secondary sites. Locating human remains in a forensic context is a collaborative effort among law enforcement and forensic anthropologists who each have unique protocols for search and recovery. This presentation discusses an intelligence-based approach to developing search and interview strategies.

To investigate patterns of homicide and the factors that assist with locating clandestine graves and case solvability for cold cases, analyses of homicide cases from 1985 to 2010, in Hillsborough County, FL, were reviewed (n=421 closed criminal homicides). Only cases involving homicidal crimes were included, excluding cases of justifiable, lawful, or vehicular homicides. By analyzing location data and demographic information concerning the victims and offenders, such as whether they are known to each other or are strangers; we can understand modes of body deposition, the spatial patterning of various types of homicide, and the factors that contribute to case solvability through quantified, statistical analyses.

The frequency of bodies moved/tampered with/altered following the homicide represents 38.7% (119/414) of cases. It is expected that domestic killers will go to greater efforts to hide the murder than will strangers in an effort to conceal and distance their involvement with the crime; however, this did not always prove to be the case. Among cases in which bodies were moved/altered/tampered with, 37% were domestic, 27% were robberies, and 12% were associated with rape. It is further expected that bodies will be dumped close to the murder location, in areas of high concealment, more often with use of containers, and generally show highly predictable patterns. The patterns observed in this study generally support these assertions. The victims' bodies were moved to a secondary location or dumped in 40 cases. Among these, slightly more dump sites occurred in rural homicides (county n=51%) compared to city homicides (city n=37%). The victims typically know their killers (77%) and are most commonly friends (30%), followed by boyfriend/girlfriend (25%), and, less frequently, spouses (8%). In 28% of the cases, the homicide was victim-precipitated or robbery-related, whereas, in 25% of the cases, the homicide was sexually motivated. Note that this is a significantly higher concentration given their smaller proportion of cases overall.

Bodies are dumped on the ground surface rather than buried below the surface in a slight majority of cases (53%). Bodies are most often dumped in public spaces, along the road, or in wooded areas (74%). Some type of container was used in only about 10% of the cases; it may have been a blanket, tarp, barrel, trash bin, or other container. Among dumped cases, just over half (58%) were discovered while the remains were fresh or just beginning to decompose, whereas 42% of the victims were found in advanced stages in decomposition or skeletal. Most victims whose bodies were dumped were not killed in the primary residences of their homes or that of the offenders. Interestingly, only about 20% of victims were murdered in their home, then dumped, whereas victims murdered in the offender's home, then dumped, was slightly higher at 33%.

Buried Bodies, Dumped Remains, Staged Homicide

A101 The Application of Photogrammetry for Documenting Scenes With Skeletal Remains: Capabilities and Shortcomings for Use in Central Florida

Kevin Gidusko, BA, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816; John J. Schultz, PhD, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816; and Mason H. Branscome, BA, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816*

After attending this presentation, attendees will have a better understanding of the uses of Close Range Photogrammetry (CRP) for documenting the context of various outdoor forensic scenes. This presentation will focus on the differences in accuracy of 3D models containing faux skeletal material in three simulated outdoor forensic scenes.

This presentation will impact the forensic science community by describing how CRP has advantages over traditional photographic methods, as well as how the context and ground surface composition of outdoor forensic scenes can affect the output texture. The CRP models of the three scenes were created using Agisoft® PhotoScan® Professional.

The documentation of outdoor crime scenes with skeletal remains can pose a challenge to law enforcement professionals and forensic anthropologists because various taphonomic processes normally act upon the crime scene to alter and change context. Recent trends in forensic anthropology highlight the importance of applying more rigorous methodological approaches during forensic recoveries that emphasize proper documentation of context in crime scene scenarios.[1] The purpose of this presentation is to introduce photogrammetry methods, which can be invaluable tools in the preservation of contextual information, that were utilized to document three simulated forensic scenarios within the Central Florida pine flatwoods biome.

Photogrammetry is a data collection technique that relies on photographs and specialized software using a Structure-from-Motion (SfM) visual computing algorithm. The SfM software finds points of intersection among a series of images to compute a 3D model. The use of CRP techniques for the output of 3D models offers a novel approach to the collection and presentation of context at outdoor forensic scenes. While the use of 3D modelling techniques is currently utilized in archaeological settings, little research has focused on the potential use of CRP for comparing different forensic crime scene scenarios. The application of CRP to forensic archaeological settings offers a number of contextual advantages over traditional photographic methods, including documenting the overall context of a scene that may be obscured overhead, making drones and helicopters not a viable method in these instances.

A series of three simulated forensic scenarios utilizing faux human osteological material were constructed at the Deep Foundations Geotechnical Research Site at the University of Central Florida: a simulated, partially excavated burial, a small area scatter (in wooded/scrub), and a wide area scatter (in open field and wooded/scrub). The burial scenario was exposed between 20cmbs to 25cmbs and prepared for standard field documentation. The second scenario depicted an outdoor deposit with only minimal dispersal that was constructed under a pine tree canopy with the ground surface consisting of pine needles. Photographs for the first and second scenarios were collected using both a camera hand-held and attached to a tripod. The third scenario represented a widely scattered surface deposit that extended from under the pine tree canopy out into a grassy area. Photographs for the third scenario were collected using the camera hand-held and attached to an extension pole (camera height 780cm). All scenarios were photographed with and without ground control markers and models were rendered using Agisoft® PhotoScan® Professional.

Photogrammetry results indicate that the simulated burial scenario is the most accurate scene to model, even without ground control points. This is largely due to the flat, uniform surface of the soil in contrast to the faux osteological material in a defined space. Output texture imagery is the clearest, thus providing increased visual precision compared to the other scenarios. The scenarios involving ground scatter are modeled with less accuracy due to the intrusion and complexity of the surrounding surface vegetation and pine needles that decreased the visual precision when zooming in on features. Ground control points improve accuracy results in the final models of these scenarios. Images collected utilizing the extension pole provide models with good overviews of the scene, but at a loss of the vertical accuracy of the faux osteological material. Images captured using hand-held or tripod methods are both more precise visually and accurate to the shape and size of the faux osteological material. Overall, CRP can be a useful addition to forensic archaeological scene documentation protocols. While the scene outdoor surface composition can affect the accuracy of the models created, CRP should be a recommended method for the documentation of context when recovering skeletal remains from outdoor scenes because the output capabilities will be greatly increased over traditional photography.

Photogrammetry, Forensic Archaeology, Scene Documentation

A102 An Examination of the Relationship Between Intrinsic Properties of Bone and Skeletal Element Recovery

Valerie Sgheiza, BS, California State University, Chico, 1240 Warner Street, Apt 3, Chico, CA 95926*

After attending this presentation, attendees will better understand which intrinsic skeletal factors have the greatest influence on the likelihood of skeletal recovery and how the relative importance of such factors varies across different taphonomic environments.

This presentation will impact the forensic science community by contributing to the development of methods for skeletal quantification and by informing field recovery of skeletal remains.

Skeletal assemblage recovery rates are important for estimating the number of individuals present and assessing the amount of skeletal attrition that has occurred, both for individual cases and larger assemblages. This presentation will examine the relationship between intrinsic skeletal properties and variation in skeletal element recovery rates.

A better understanding of the factors that influence recovery rates will assist the forensic science community in continuing to develop methods for skeletal quantification. Furthermore, evaluating the interaction between intrinsic skeletal properties and external taphonomic processes can assist in anticipating challenges in recovering certain elements in the field, as well as aid in selecting appropriate samples in research design.

This project addresses the hypothesis that skeletal attrition is non-random with respect to intrinsic properties of skeletal elements. Furthermore, the relationships between these intrinsic properties and skeletal recovery may be affected by variations in taphonomic processes.

Skeletal inventories were collected from the Forensic Data Bank (University of Tennessee), New York City Office of the Chief Medical Examiner forensic anthropology (NYC OCME) cases, and a subset of carnivore-scavenged cases from the California State University, Chico Human Identification Laboratory (CSUC HIL). Bone mass and length data were collected from the CSUC HIL skeletal teaching and donated cases collections and NYC OCME cases. Bone mineral density data for the six major long bones were obtained from the literature.[1] Inventories and bone mass and length data included 12 major appendicular skeletal elements.

Mass, length, and mineral densities were converted to ratios to account for inter-skeletal differences and to facilitate comparison. In cases in which a single element was bilaterally absent, imputation was performed using regression on the element with the highest correlation to the element missing. Mass and length data were not collected from cases with more than one element bilaterally absent. Counts for each element were converted to recovery rates using Perl; Pearson's correlations between recovery rates and property ratios were computed in R.

Comparison of mineral density, mass, and length for the long bone subset revealed significant correlation (p <0.05) of recovery probability with mineral density and mass for all three datasets. Correlations were higher for mass than mineral density for the CSUC HIL (r^2=0.95 vs. 0.93) and NYC OCME (r^2=0.92 vs. 0.88) datasets, while mineral density revealed the highest correlation for the Forensic Data Bank (r^2=0.95 vs. 0.86). Comparison of mass and length for all 12 elements demonstrated a significant correlation of recovery probability with mass for the NYC OCME dataset (p=0.046, r^2=0.58) and recovery probability with length for the Forensic Data Bank (p=0.0024, r^2=0.79). All other correlations were not significant.

The hypothesis that intrinsic properties of skeletal elements affect skeletal attrition in a non-random fashion was supported. The secondary hypothesis that variations in taphonomic environment will influence the relative impacts of these properties was not well supported. Bone mass was the predominant factor for both the NYC OCME and CSUC HIL datasets, which were affected by very different taphonomic processes. The results of this study suggest that durability may affect element attrition more than size, even when taphonomic processes are widely varied.

Skeletal Quantification, Taphonomy, Commingled Remains

A103 The Use of Geographic Information Systems (GIS) to Identify Relationships Between Victim Dispersal Patterns and Skeletal Trauma After a Blast Event

Alice Fazlollah Gooding, PhD, Kennesaw State University, Dept of Geography and Anthropology, 1000 Chastain Road, MD 2203, Kennesaw, GA 30102; Caroline Johnston, BS, Kennesaw State University, 1000 Chastain Road, MD 2203, Kennesaw, GA 30144; Kendra Thomas, BS, Kennesaw State University, 1000 Chastain Road, MD 2203, Kennesaw, GA 30144; and Michael McClung, BS, Kennesaw State University, 1000 Chastain Road, MD 2203, Kennesaw, GA 30144*

After attending this presentation, attendees will better understand the utility of GIS methods at a post-blast scene and the benefits to anthropological trauma analysis of blast victims.

This presentation will impact the forensic science community by providing the first data out of a series of controlled post-blast trauma experiments from an area with a scant amount of anthropological research to date. This study emphasizes the need for standardization of evidence collection at the scene so anthropological analyses of blast trauma can be effective.

Anthropological study benefits from the inclusion of geographic analysis by connecting observations to specific locations. Forensic anthropologists have recognized the importance of documenting the location of evidence by mapping victim remains found at scenes. The increase of blast-related incidents in areas of conflict worldwide as well as attacks on civilian populations in industrialized regions has necessitated research that simulates blast events to aid in the interpretation of blast trauma. Mapping post-blast evidence is a way to increase base knowledge of what is typical of post-blast scenes and to aid in identifying human remains onsite. As such, there is an immediate need for controlled experiments that test the accuracy of evidence collection methods at blast events and the relationships between victim trauma and geographic location at the post-blast scene. The current study uses GIS as a tool to understand the nature and scope of victim (and associated remains) displacement from their original location after a blast event.

Seventeen non-military grade, outdoor blast events with two porcine proxy victims (*Sus scrofa*) each (N=32) were used to test for the existence of commonality in victim dispersal patterns, fracture type and location on the skeleton, and accuracy of GIS post-blast scene mapping methods. Proxy victims were placed 1.5 meters away from, and facing, each device. Victims were positioned upright to simulate a standing human. After detonation, a Global Navigation Satellite System (GNSS) Receiver was paired with a Bluetooth® connection to a collector app to document all evidence, including victim remains. The GNSS Receiver was paired with a Satellite-Based Augmentation System (SBAS) to compensate for possible inaccuracies due to obstruction, data integrity, point anomalies, and signal availability. Evidence was also mapped using an azimuth board, a hand-mapping technique. Victim remains were decomposed at an outdoor facility, macerated, and analyzed for blast trauma to the skeleton. Seven blunt force trauma fracture types were identified and their frequencies were overlaid on GIS maps developed from scene data.

The remains of all 32 victims were dispersed in a cone-shaped pattern from the seat of the 17 blasts. Remains traveled as far as 57 meters, but the highest concentration of evidence was contained within a 30-meter radius of each blast. Anatomical portion (e.g., lower limb) and fracture type were significantly associated (p=0.036) with distance from the seat of the blast. When assessing accuracy of scene mapping, data points collected using this GIS procedure were not significantly different within 30 centimeters (p=0.081) of the same point collected using the hand-mapping method. Further, the use of the collector app allowed for photographic documentation simultaneously with the collection of geographic location.

The results of this study highlight the importance of collaboration between anthropologists and crime scene investigators at a post-blast scene. Mapping spatial data provides an additional analytical tool for the anthropologist during trauma analysis and scene recreation by investigators. Moreover, digital maps of this nature are often more easily interpreted by the public (i.e., juries) than charts or numerical data tables.

Post-Blast, GIS, Blunt Force Trauma

A104 Variety and Distribution of Orthopedic Devices in the Cyprus Research Reference Collection and Their Relationship to Skeletal Trauma: Preliminary Results

Xenia Paula Kyriakou, Odyssey Fieldschool, 44 Oval Road, Norwich, Norfolk NR5 0DG, UNITED KINGDOM; Amy I. Perez, 1459 E Lassen Avenue, Chico, CA 95973; and Anna Williams, PhD, University of Huddersfield, Applied Sciences, Queensgate, Huddersfield, West Yorkshire HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will better understand the variety, complexity, and distribution of orthopedic skeletal devices in a modern Cypriot skeletal population and appreciate how analysis of the bone associated with the devices can reveal information regarding the likely timescale of the medical intervention. The value of the manufacturer information combined with the skeletal evidence for positive identification will be examined.

This presentation will impact the forensic science community by evaluating the use of orthopedic devices, such as plates, rods, and femoral head replacements, for positive identification in Cyprus in the absence of a national registration database. Despite compliance with the European Medical Device Directive (equivalent to the Food and Drug Administration in the United States) after joining the European Union in 2004, implants are documented as items with all their manufacturing details by the distributor only. As a result, positive identification from medical implants and devices are problematic and reliant on the actions of individual doctors. This is the first detailed study of surgical implants and medical devices conducted on contemporary skeletal remains in Cyprus.

Surgically implanted devices are common in modern skeletal remains and may aid in positive identification, through comparison with antemortem medical records. Currently, positive identification of an individual exhibiting a medical device in Cyprus is dependent on the retention of relevant antemortem medical records by a participating doctor. There is no direct link between the manufacturer of the device and the patient. In the absence of a national registration database, Cyprus needs a platform whereby skeletal medical devices are logged in a way that links the individual with the device.

In a pilot study of contemporary skeletons, an assemblage of 150 individuals was examined from the Cyprus Research Reference Collection (CRRC) (dates of death: 1975-2010) for evidence of medical devices used in the prevention and treatment of trauma in the lower limb.

This study sought to assess and record: (a) the prevalence and distribution of orthopedic medical devices by sex of the individual; (b) to record the type of medical device used in relation to the types of trauma observed; and, (c) to create a catalog of orthopedic devices used in Cyprus between 1975 and 2010 for the purposes of positive human identification. An analysis of the skeletal changes associated with the surgical devices allowed an estimation of the time elapsed since trauma and, therefore, a timescale for the medical intervention.

A total of 49 medical devices were observed in 27% of the population, representing 18 individuals of both sexes (15.0% in males, 12.0% in females). Orthopedic devices such as plates, angled plates, rods, head implants, screws, and wire were recorded. The skeletal healing recorded ranged from <3 days to >1 year. Skeletal changes associated with medical intervention ranged from well-healed trauma to evidence of severe infection associated with the affected area. Peri-mortem injuries indicated mortality relating to post-operative complications. The medical devices were primarily used to stabilize fractures to the proximal femur and tibia and, less often, to the distal tibia. Femoral head implants were the most common of the devices observed.

The sheer number of medical devices observed in the CRRC suggests that their use is common in 20th-century Cyprus. The variety of devices identified offers insights into medical techniques and the evolution of devices over time. Device identifiers have been grouped for the period before and after Cyprus joined the European Union. Skeletal changes associated with the orthopedic device offer a relative chronology between medical intervention and time of death. The information highlights the challenges to forensic investigators in Cyprus attempting to use medical devices for positive identification.

Orthopedic Device, Medical Intervention, Skeletal Trauma

A105 The Application of Consolidation Materials to Burned Bone: A Comparative Approach

Courtney C. Siegert, BA, Texas State University, 7501 Whispering Winds Drive, Austin, TX 78745; Michelle D. Hamilton, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Elizabeth Erhart, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; and Joanne Devlin, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Knoxville, TN 37996*

The goal of this presentation is to provide attendees with a better understanding of the utility of archival-grade consolidants for recovering human remains from a fatal fire scene.

This presentation will impact the forensic science community by quantitatively and qualitatively elaborating on previous research by comparing four consolidants' (e.g., Acryloid™ B-72, Acrysol™ WS-24, Rhoplex™ B-60A, and Butvar® B-98) ability to increase the strength and toughness of thermally altered bone and to identify the most appropriate consolidant and recommend best practices for usage when encountering burned bone.[1,2] It is expected that all materials tested will reduce continued sample fragmentation, mirroring previous researchers' results.

Taphonomic agents and post-depositional factors can significantly influence a bone's ability to withstand the stress of scene removal and analysis. Fire-altered bone presents a particularly unique challenge owing to its inherent friability. The Bridgeville Fatal Fire Recovery Protocols were developed to maximize recovery and mitigate fragmentation of human remains; however, they do not address stabilization methods that could reduce fragmentation resulting from handling at the scene or in laboratory or analytical settings.[3] A possible solution is the standardized use of consolidation materials *in situ* during recovery efforts. Although consolidant materials have been employed on friable bone in numerous contexts, there is little-to-no consensus regarding the most appropriate consolidant for burned bone.

An open fire cell was constructed and subsequently ignited. The sample population, consisting of domestic pig (*Sus scrofa domesticus*) femora (n=58) and skulls (n=5) subdivided into five groups, including a control group, was placed on the structure floor and allowed to extinguish naturally. Consolidant materials were prepared at a 10% concentration and applied to all visible surfaces of the bone samples *in situ* using a polyethylene squeeze bottle for a total of four applications.

Variables investigated in this research include ease of solution preparation and application, dry time, changes to the appearance of the bone surface, and mode of deformation during a loading event, as well as ultimate strength and toughness of the sample after consolidation. Mode of deformation was assessed through load-displacement curves produced by a nanoindentor. Drop weight impact testing and exposure to forced vibration were used to assess strength and toughness. A stratified random sample of relatively smooth and flat fragments was selected for nanoindentation (n=18) and drop weight impact testing (cortical samples: n=176; femoral head: n=43) to ensure accuracy by keeping the sample perpendicular to the applied force. Proximal femora and condylar epiphyses were selected for forced vibration testing. Samples in color stages IV and V were preferentially chosen for mechanical testing as a means of controlling degree of calcination, while anatomical region and bone type were considered to control sample anisotropy.[4]

Results indicated all materials increased the strength and toughness of burned bone compared to the unconsolidated control sample. While Acryloid™ B-72 was not found to be as strong as Rhoplex™ B-60A or Butvar® B-98, the quicker dry time and the lack of alteration to the bone's appearance make Acryloid™ B-72 the most suitable choice for on-scene use. Alternatively, if dry time could be significantly reduced using a more volatile solvent, Rhoplex™ B-60A would be recommended since the alteration to the bone surface after application was minimal. Future analyses should be performed to better understand consolidant influence on modification to bone surfaces and impacts to DNA sampling, as well as the degree to which consolidant increases the ability to establish the biological profile. Results of this research indicate that the dentition, frontal sinus, and other regions displaying biological indicators of sex, age, and ancestry should preferentially be consolidated due to their utility in skeletal analysis toward the identification of the fatal fire victim.

Burned Bone, Consolidant, Forensic Recovery

A106 The Effect of Scanner Performance on Capture Ability and Identification Success on Postmortem Biometric Data

Kelly Sauerwein, MA, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Samantha Upton, BA*, Universtiy of Tennessee, Knoxville, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 36996; Elizabeth Albee, BA, University of Tennessee, Knoxville, 1621 Cumberland Avenue, Strong Hall, Rm 502A, Knoxville, TN 37996; Anielle Duncan, BA, University of Tennessee, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 37996; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 37996; and David Bolme, PhD, Oak Ridge National Laboratory, PO Box 2008, MS-6075, Oak Ridge, TN 37831*

After attending this presentation, attendees will understand the applicability of alternative biometric scanning technologies to obtain postmortem fingerprint, iris, and facial biometrics for positive identification of unknown individuals, including the maximum number of days each biometric type can be successfully used for identification.

This presentation will impact the forensic science community by describing the advantages and limitations of different scanning technologies based upon the points of similarity and match scores for each identifier type.

Biometrics are measurable unique characteristics that are used to classify both living and deceased individuals. This study examines the effects of two different biometric scanners, representing different capture technologies, on the ability to capture fingerprints, facial photographs, and iris scans and successfully identify individuals in the postmortem period. This study examines the number of days in which usable biometric data can be successfully matched to an individual using two different digital technologies and how the image quality and ability to obtain sufficient match scores to make a positive identification differed with each instrument. For the purposes of this study, *usable data* refers to images that are able to correctly identify the individual through a digital biometric program that uses statistical algorithms to match the captured images with those images taken upon the initial receipt of the donated individual. This study was conducted in conjunction with Oak Ridge National Laboratory and the University of Tennessee Anthropological Research Facility between January 2016 and July 2017. Utilizing the SEEK II and the BioSled hand-held digital biometric capture devices, facial photographs (n=200), iris scans (n=172), and fingerprints (n=650) from the donated remains of 16 individuals were obtained daily until usable data could no longer be captured. The individuals were placed supine and uncovered. No interventions were made to the remains prior to data collection; however, specula were placed in the eye in order to enable iris capture during data collection.

Seasonality played a large part in the effectiveness of the instruments to obtain data. With daily high temperatures ranging between 59°F (15°C) and 84°F (28.89°C) during the spring trial (n=5), usable data was obtained for an average of 4.2 days for the SEEK II and 4.1 days for the BioSled; however, the early summer trial (n=6) included high temperatures between 8°F (27.22°C) and 91°F (32.77°C) and the number of days usable data could be captured was reduced to 3.8 for both the SEEK II and the BioSled. The winter trial (n=5) only had high temperatures between 18°F (-7.78°C) and 55°F (12.78°C) and demonstrated that useable data was available, on average, 5.5 days for the SEEK II and 5.9 days for the BioSled. Interestingly, while their overall averages are similar, the SEEK II outperformed the BioSled by an average of one day for fingerprints in the spring (6 days for SEEK II, 5 for BioSled). While both scanners performed similarly with regard to biometric capture longevity, each machine performed differentially in regard to usability. The BioSled excelled at non-contact data collection when capturing facial and iris biometrics on postmortem individuals, whereas the SEEK II required contact with the face for iris capture, which may not be practical in a forensic context. It was noted that both scanners had difficulty recognizing the iris for capture and focused more on objects in the proximity of the eye that resembled the iris (e.g., fly, specula, or dark spots on the face). In regard to scanner reliability, the SEEK II demonstrated a higher consistency than the BioSled in fingerprint capture, especially under inclement weather conditions.

While biometric capture longevity was similar between scanners, they each demonstrated unique advantages and limitations in terms of usability. The results of this study demonstrate that while biometrics do remain viable over time, the ability of scanners to successfully capture biometrics depended upon seasonality and environmental conditions. Temperature, precipitation, and insect activity were the primary factors affecting the retention of biometric information in decomposing human remains. This study builds upon previous work and continues to support the utility of physiological biometric identifiers during the decomposition process. Postmortem biometric research has the potential to make important contributions to forensic anthropology and the law enforcement, military, and medicolegal communities.

Biometrics, Human Decomposition, Positive Identification

A107 In Search of Jane Doe: An Analysis of Solvability Factors in Unidentified Remains

Melissa Ann Pope, MA, University of South Florida, 4202 E Fowler Avenue, Tampa, FL 33620; Kelsee Hentschel-Fey, MA, University of South Florida, Anthropology Dept, 4202 E Fowler Avenue, SOC107, Tampa, FL 33620; and Erin H. Kimmerle, PhD, University of South Florida, FL Institute for Forensic Anthropology, 4202 E Fowler, SOC 107, Tampa, FL 33820*

The goal of this presentation is to investigate solvability factors in long-term unidentified persons cases with specific attention given to the methods employed in the Florida Cold Case Program model. Attendees will be presented with a model for cold case review that has led to seven identifications within the study period.

This presentation will impact the forensic science community by demonstrating the manners in which a comprehensive cold case model using new methods and technologies may provide fresh investigative leads on cases that are decades old.

In Florida, there are more than 10,000 unresolved open homicides, or "cold cases," dating to the 1960s, representing families who have been denied justice. There are also more than 850 individuals recovered in public places who have not been identified to date (including more than 50 juveniles), the majority of whom are homicide victims or who died of unknown circumstances. Many of the long-term unidentified cases remain unsolved because missing persons reports were not issued or not recorded in modern databases such as the National Crime Information Center (NCIC).

The Tampa Bay Cold Case Project started at the University of South Florida Forensic Anthropology Laboratory (USF-FAL) in 2007 and quickly grew in scope to a statewide initiative with cases routinely submitted for review and technical assistance. This project has led to many successful outcomes and positive identifications. As a result, missing persons cases are closed due to identification, and new investigative leads are now available for decades-old cases.

The purpose of this presentation is to conduct a study of the solved and unsolved cases analyzed in the cold case project to assess which methods and factors led to case solvability. To better shape protocols and policies surrounding cold cases, research into the reliability of effective methods is needed.

This study is a systematic assessment using qualitative and quantitative methods to investigate cold cases analyzed by the USF-FAL in the years 2015-2017 (n=58 cases). These cases have dates of discovery that range from the years 1967-2016 and had been previously analyzed at the time of discovery. They are predominately from Florida (n=36) but also represent cold cases from nine additional states. Nineteen individuals died from "homicidal violence" and 26 have an "undetermined" manner of death. The "undetermined" cases include numerous examples of disposal, such as dismemberment, concealment, burning, and the use of sulfuric acid and, in many cases, were reclassified as Homicide following the reanalysis.

The methods utilized in the reanalysis of cold cases are reviewed in the current study to assess their effectiveness and accuracy. These include: collaboration with law enforcement and Medical Examiners Offices (MEOs) to select cases for reanalysis; researching existing primary documents and photographs for leads; resubmission of fingerprints; locating and exhuming human remains; reassessing the biological profile using 3D-ID and other skeletal aging methods; chemical isotopic analysis; facial imaging; resubmission of DNA samples; and the use of the National Missing and Unidentified Persons System (NamUs).

Of the 58 cases investigated, seven were identified. In total, nine had fingerprint cards for resubmission. Eighteen cases were buried in John/Jane Doe graves and had to be exhumed. Although a total of 22 graves were unearthed in the search for the unidentified, three decedents were not located due to the loss of cemetery records. Skeletal analysis included reassessment of the biological profile for 41 cases, isotope sampling and georeferencing of 51 cases, and imaging for 34 cases. As a result, seven have been identified via fingerprint resubmission (n=4) and DNA analysis (n=3). The qualitative assessment of mapping of geochemical referencing and forensic imaging will be presented.

These findings demonstrate the utility for the use of a multidisciplinary approach for solving cold cases. Case reviews, fingerprint and DNA (re)submissions, updated biological profiles, chemical isotopes, and forensic imaging are shown to contribute to case solvability by providing new leads and increasing public interest in an otherwise stale case. In the face of seemingly impossible caseloads, multidisciplinary methods are shown to be of critical importance for addressing the issue of missing and unidentified persons.

Cold Case, Unidentified Persons, Forensic Anthropology

A108 Changes in DNA Quantity and Quality in the Human Tibia After Short-Term Surface or Subsurface Burial

Zachariah A. Landhuis, BA, Michigan State University, East Lansing, MI 48823; McKenzie R. Siewert, BS, Michigan State University, 560 Baker Hall, East Lansing, MI 48824; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will better understand how the quality and quantity of DNA varies along the length of the human tibia and how it is affected by surface and subsurface burial.

This presentation will impact the forensic science community by providing insight into the variation in DNA quantity and quality along the length of the human tibia, aiding forensic biologists in decisions regarding which bone regions to target for DNA-based identification.

Skeletal remains are a commonly recovered form of forensic evidence, and DNA retrieval from them has traditionally focused on dense cortical elements.[1,2] In contrast, Mundorf and Davoren concluded that smaller, primarily trabecular skeletal elements contain more DNA than larger, primarily cortical ones; however, several unexplored factors may contribute to which bones or bone regions contain the most DNA, and whether those regions change after burial.[3] In this regard, researchers in the Michigan State University Forensic Biology Laboratory have shown substantial intra-bone heterogeneity in DNA quality and quantity in bovine and porcine femora.[4] Additionally, Antinick observed some samples with higher DNA recovery following short-term burial.[4] The goal of the current research was to determine whether similar variation exists in human long bones and how it is influenced by short-term surface and subsurface burial.

Four pairs of unpreserved human tibias were obtained from female decedents aged 49–79 years, and soft tissue was manually removed prior to maceration in a 0.5% Terg-a-zyme® solution. Preceding burial, the proximal epiphysis and metaphysis, the distal epiphysis and metaphysis, and the mid-diaphysis were drilled to obtain ~30mg of bone powder. Alternating right and left tibias were buried one foot underground or placed on the surface above the other bone. Tibias were exhumed and drilled after one week and four weeks. Bone powder was digested as per Lorielle et al.[5] Extract volumes were measured, and DNAs were stored at -20°C.

Quantification of mitochondrial DNA (mtDNA) was performed using an in-house TaqMan® quantitative Polymerase Chain Reaction (qPCR) assay. Nuclear DNA was quantified using Quantifiler®. An in-house fluorescence-based quality assay that targets ~100bp, 200bp, 300bp, 400bp, and 500bp amplicons of the human mitochondrial genome was used to assess mtDNA quality. A degradation index was created based on peak height ratio of the 300bp and 400bp amplicons on a 0 to 1 scale in which a degradation index of 1 indicates no degradation.

Quantitative results indicate that the mid-diaphysis region contained the highest median quantity of mtDNA at week 0 and 1, which leveled off with the other locations by week 4. In contrast, all regions had similar quantities of nuclear DNA at week 0 and 1, yet the mid-diaphysis had higher nuclear DNA yields at week 4. Interestingly, approximately 33% of surface exposed and buried samples had higher mtDNA yields after one week, while 25% had higher mtDNA yields in week 4 compared to week 1. Nuclear DNA yields increased in 25% of buried and exposed bone regions in the first week, and approximately 10% increased from week 1 to week 4. No region increased during both timeframes, and no correlation existed between increasing DNA yields and bone region. This indicates that the bone likely softened during environmental exposure, making it easier to drill and releasing more DNA or the DNA sustained less mechanical damage from the drilling process.

The mitochondrial quality assay revealed the 100bp and 200bp amplicons were generated in all locations at all time points tested, while the 500bp amplicon was present in very few samples. The most variation occurred in the quantity of the 300bp and 400bp amplicons. In the distal metaphysis and epiphysis, the degradation index increased as mtDNA quantity decreased, indicating that the small amount of remaining mtDNA was of high quality. Potentially, this means that the remaining DNA was protected, possibly through binding to hydroxyapatite or collagen.

Overall, surface and subsurface burial impacted the quantity and quality of DNA along the length of the human tibia, and different bone regions responded differently to the burial conditions. The mid-diaphysis had the highest median quantity of mitochondrial and nuclear DNA after short-term surface or subsurface burial; however, it is unclear exactly why some DNA yields improve after short-term exposure or burial, which could be a factor in forensic investigations involving skeletal remains.

DNA Degradation, Skeletal Remains, Short-Term Burial

A109 Long-Term Cocaine Use and Its Potential Effect on Bone Morphology

Nicollette S. Appel, MS, 20 Knoll Lane, Glen Head, NY 11545; Donald F. Siwek, PhD, Dept Anatomy and Neurobiology, Program in Forensic Anthropology, 72 E Concord Street, Boston, MA 02118; and Tara L. Moore, PhD, 700 Albany Street, W701, Boston, MA 02118*

After attending this presentation, attendees will understand that long-term cocaine use has effects on bone morphology at the macroscopic and microscopic level.

This presentation will impact the forensic science community by demonstrating that the effect of drugs on bone morphology is an area of study that should be expanded. With the findings of this study, it is apparent that cocaine use and substance abuse can potentially cause age-at-death estimation to be inaccurate. Other works and clinical analyses have proven other drugs to alter bone, but no research has examined the effect of cocaine on bone morphology.

The purpose of this study was to assess the bones of rats exposed to long-term *ad libitum* consumption of cocaine for physical evidence of cocaine use. While it is accepted that many drugs, both prescription and drugs of abuse, do have powerful metabolic effects, those changes have not been examined at the microscopic level.

Eleven male Wistar Rats (*Rattus norvegicus*) from the Laboratory of Behavioral Neuroscience at Boston University in Boston, MA, comprised the experimental group. The rats self-administered cocaine over four weeks at a 0.3mg/kg dosage and the concentration of the IV solution was 1.6mg/ml of cocaine. The control group included five female Sprague Dawley rats (*Rattus norvegicus*) from the Boston University Animal Science Center in Boston, MA. The specimens were exposed to a training protocol but were not given any drugs. All rats went through a dissection and maceration to obtain the femora and humeri. Mass, volume, and length measurements were taken for each element to be used for later analysis. One femur was chosen at random from each rodent to be used for histological analysis. Femora were embedded in a two-part epoxy resin, then cut in half using a diamond band saw. A Buehler® IsoMet™ low-speed saw was used to obtain thinner sections and a Buehler® MetaServ™ 250 grinder was used to achieve a thickness of 100µm-120µm. India ink was used for staining and all stained sections were put onto slides, covered with Permount™ and a cover slip, and labeled.

The outer circumferential lamellar layer of bone diaphyses were measured and compared between the experimental and control groups. Photographs were taken of each cross-section at 1x and 4x magnification through the NIS-Elements™ software. The ImageJ image-processing program was used for analysis. The thickness of the outer circumferential lamellar and the thickness of the total cross section was taken at four random locations of each 4x magnification photograph. The ratio of the thicknesses and the outer circumferential lamellar thickness alone were compared.

A significant difference was found between the density values calculated from the original mass and volume measurements between control and experimental groups. Samples that had been exposed to cocaine had lower density values than those not exposed to any drugs. The control group mean density equaled 1.492g/mL and the experimental group mean density equaled 1.082g/mL. A significant difference was also found between the ratio of the thicknesses and between the outer circumferential lamellar thickness alone. The experimental group had ratio values significantly higher than the control group. The control group's mean ratio equaled 0.2686, while the experimental group's mean ratio equaled 0.4427. This indicates that in the control group, the outer circumferential lamellar thickness, on average, covered approximately 25% of the total cross section, and the experimental groups outer circumferential lamellar thickness, on average, covered nearly 50% of the total cross section. These results were similar when comparing the outer circumferential lamellar thickness alone. The control group's thickness was significantly lower than the experimental group's thickness. The control group's thickness measurements had a mean of 189.7674µm and the experimental group's thickness measurements had a mean of 343.2753µm.

The data reveal that long-term exposure to cocaine has a detectable effect on bone morphology. Further exploration of this phenomenon may show that the changes in bone morphology may be diagnostic for drug abuse. That information could be of use in a medicolegal setting and may alter the accuracy of age-at-death estimations.

Forensic Anthropology, Histology, Substance Abuse

A110 Mismeasurement of theTibia and Femur Reconsidered: How Were Measurements Taken at the Central Identification Unit in Kokura, Japan?

Alexander F. Christensen, PhD, DPAA, 590 Moffet Street, Bldg 1077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will better understand historical changes in osteological measurement definitions and practices and how this impacts the reference samples used in the anthropological calculation of stature.

This presentation will impact the forensic science community by further illuminating change over time in measurement practices within the same forensic anthropological laboratory and how these may have affected reference standards.

In 1952, Trotter and Gleser published one of the baseline references for American forensic anthropology, using measurements from 1,200 World War II United States military casualties and 615 males from the Terry Collection to calculate a series of regression equations for the estimation of living stature from long bone lengths.[1] When Trotter and Gleser completed their 1952 study, the Central Identification Unit (CIU) in Kokura, Japan, conducted a test of how the new formulas compared to those of Krogman and Rollet (which the CIU had been using until that point) by applying both methods to 120 previously identified Korean War casualties. The average deviations between estimated and actual stature for the White males (*n*=100) were 1.24" (Krogman), 1.48" (Rollet), 1.14" (Trotter, averaging all bones), and 1.01" (Trotter, femur and tibia); for the limited sample of Black males (*n*=20), the parallel values were 1.61", 2.03", 1.19", and 1.19".[1-3] Based on these results, the CIU decided to adopt Trotter's formulas. Subsequently, Trotter and Gleser (1958) published a revised study using data from 5,517 United States casualties of the Korean War whose remains were processed at the CIU.[4]

In 1994, Jantz et al. analyzed the original data from Trotter and Gleser (1952) and demonstrated that the tibial lengths omitted the malleolus.[5] In 1995, they compared the mean lengths of the tibia and fibula in Trotter and Gleser (1958) and concluded that the tibiae had not been measured properly in that study either.[4,5] Although the Korean War data used by Trotter and Gleser has not been located, ongoing compilation of measurement data from Korean War casualties whose files are available to the DPAA has yielded a comparable reference set.

Between May and November 1953, the three anthropologists working at the CIU estimated stature in both ways to compare the results. In addition, they recognized that Trotter's measurement definitions differed from their previous ones, and on 35 measurement forms located to date, they recorded two distinct measurements of the femur and tibia. Because the forms only provided a single space for each long bone, whoever entered the data usually added a more specific designation. The first value entered is often unspecified, but several forms label it "KR," while others use "Bicondylar." The second, larger measurement is labeled "maximum" or "Trotter." Comparing the measurements recorded on these forms, the difference between the first and second measures of femoral length averages 4.5mm (*n*=44, Standard Deviation (SD) 2.40, range 1-11); for tibial length, the mean difference is 8.8mm (*n*=51, SD 5.62, range -1-21).

For a broader data set, measurements were compared from 316 skeletons that were analyzed at Kokura using both sets of stature formulas. The initial measurements were taken through May 1953, the second after September 1953. In 410 of 473 femoral length comparisons (87%) and 398 of 461 tibial length comparisons (87%), the later measurement was larger than the earlier one; the mean difference was 3.7mm for the femur (SD 3.17, range -6-15) and 4.5mm for the tibia (SD 3.91, range -6-16). By contrast, the fibula exhibited less change: the average increase in length was only 0.64mm (*n*=390, SD 2.13, range -8-11).

Tibia and fibula lengths were also compared. Until May 1953, the mean difference was 0.26mm (*n*=379, SD 5.09, range -15-14); after September 1953, the mean difference was 3.97mm (*n*=437, SD 5.12, range -13-23). While this increase does indicate that the post-1953 measurement standards were more comparable to those used by modern forensic anthropologists, they do not appear exactly the same.

It is clear that procedures for measuring the femur and tibia at Kokura changed over time. Before 1953, the (apparently unwritten) norm was to record the bicondylar length of the femur and anatomical length of the tibia; after the transition to Trotter and Gleser's formulas, the maximum lengths of both were standard; however, there is noticeable variation in measurements that leaves some uncertainty regarding how any particular bone was measured. In addition, the exact composition of the Korea data set provided to Trotter and Gleser is unknown, so we cannot be sure how many of the individuals within it were measured using each methodology. This introduces clear error into all of Trotter and Gleser's 1958 formulas using both femoral and tibial lengths.[4]

Stature Determination, Skeletal Measurements, War Dead

A111 A Validation Study of the Langley Decision Tree Model for Sex Estimation

Heather M. Garvin, PhD, Des Moines University, Dept of Anatomy, 3200 Grand Avenue, Des Moines, IA 50312-4198; and Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621*

After attending this presentation, attendees will be more knowledgeable regarding the performance of a zygomatic extension scoring method and sex estimation decision tree presented by Langley et. al.[1]

This presentation will impact the forensic science community by demonstrating if and how this method can be incorporated into forensic anthropological casework in light of the *Daubert* and National Academy of Sciences (NAS) Report recommendations.

Walker presented a sex classification method based on the ordinal scoring of five morphoscopic traits of the skull: glabella, mastoid, nuchal, supraorbital margin, and the mental eminence.[2] He provides six logistic regression equations that include combinations of two and three traits for sex estimation. The Walker method has been quickly incorporated into forensic casework both in the United States and internationally; however, studies have indicated high levels of intraobserver and interobserver disagreement for some traits (e.g., mental eminence).[2] Stevenson et al. modified the Walker method by incorporating the same five traits into a decision tree model developed using a chi-square automatic interaction detection.[2,3] Given the many reliability studies that indicate low levels of observer agreement for the mental eminence, the inclusion of this trait into these sex estimation methods is problematic. Seeking to eliminate this issue, among others, Langley et al. developed a decision tree for sex estimation that utilized only the two most reliable of the five cranial traits (glabella and mastoid scores) and included a new trait: zygomatic extension.[1] This study sought to test the reliability of the zygomatic extension scoring method presented in Langley et al. and validate their sex estimation decision tree method.[1]

Ordinal score data were collected from a total of 281 male and female United States White and Black individuals from the Bass Donated, Hamann-Todd, and Terry skeletal collections. Glabella, mastoid, nuchal, supraorbital margin, and mental eminence expressions were scored for each individual from the physical specimens following Walker as part of a previous study.[2] The zygomatic extension was scored from 3D surface models of the specimens following the descriptions, photographs, and diagrams provided by Langley et al.[1] For a subset of 30 individuals, zygomatic extension was scored, then re-scored by this study. Intraobserver agreement was assessed using Intraclass Correlations (ICC) and a weighted Kappa analysis was used to evaluate interobserver agreement. As Langley et al. appear to accidentally present two conflicting decision trees (Figure 2 and Figure 4) in their publication, both trees were tested.[1] These results were compared to results obtained using Walker and Stevenson et al.[2,3]

Intraobserver and interobserver agreement was high for the zygomatic extension (*ICC*=0.839, *wK*=0.716 and *ICC*=0.745, *wK*=0.585, respectively), suggesting that this trait can be reliably scored, although both observers noted some areas of subjectivity in the scoring procedure. The decision tree presented in Figure 2 resulted in only a 55.9% correct sex classification of the pooled sample.[1] If restricted to only the Bass sample (the same collection from which the method was derived), only 50.0% of the individuals were sexed correctly. In contrast, the decision tree presented in Figure 4 resulted in an overall 71.5% correct sex classification (77.4% for the Bass sample).[1] Based on these results and the fact that Langley et al. discuss details about the Figure 4 decision tree in the text, this is assumed to be the correct tree.[1] Still, results obtained were not as high as those reported by Langley et al. and a strong sex bias favoring female classification was observed (94.2% accuracy for pooled females; 49.3% accuracy for pooled males).[1] Male correct classifications ranged from 31.3% to 65.0%, depending on the sample. The method performed only slightly worse on the Black samples compared to the White samples, and similar results were obtained between historic and modern samples. The Walker mastoid/glabella equation and Stevenson et al. European-American decision tree produced higher accuracy rates (80.8% and 82.6%, respectively for the pooled sample), although sex bias remains an issue.[2,3] The results of this study indicate that there is room for further improvement both in cranial trait scoring methods and statistical methods of analysis.

Sex Estimation, Cranial Traits, Decision Tree

A112 Age-Cohort Categorization and Multi-Factorial Age Estimation in Machine Learning Environments

Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824; and Nicholas V. Passalacqua, PhD, Western Carolina University, 101 McKee, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the utility of age-cohort categorization using a multi-factorial approach to the estimation of age at death from adult human skeletal remains. As one part of a larger study into multi-factorial age estimation methods, this presentation addresses a straightforward approach to age estimates based on the combined data of three commonly used adult aging methods.

This presentation will impact the forensic science community by addressing the knowledge gap in multi-factorial age estimate strategies. The method proposed has the added benefits of quantification, verification, and robust statistical classification algorithms necessary for empirically based multi-factorial age estimates.

The traditional approach to producing a final age estimate from multiple skeletal indicators relies, in part, on heuristic cut-off points, minimum-to-maximum estimates, or non-statistical intervals developed using experience and expertise. This traditional approach is generally preferred over other, more robust methods because it is easier to apply during casework than current multi-factorial approaches, such as ADBOU, that provide age-at-death probabilities by means of transition analysis. Motivated by this knowledge gap and recent calls for research into multi-factorial age estimation strategies from the National Institute of Standards and Technology Overseas Security Advisory Council (NIST OSAC), this study tested the efficacy of an age-cohort categorization strategy using three commonly incorporated adult age indicators: the pubic symphysis, the sternal end of the fourth rib, and the auricular surface of the innominate. These age estimation methods were selected because: (1) they are commonly collected during forensic anthropological casework; (2) they constitute verified methods of age estimation; and, (3) as this research seeks to provide proof-of-concept results, these data represent current standards in the field.

Age data were collected following the Suchey-Brooks (pubic symphysis), Iscan et al. (rib), and Osborne et al. (auricular surface) methods. Data were collected for 358 (male, n=240; female, n=118) individuals from the William M. Bass Donated Skeletal Collection in Knoxville, TN, and the Hamann-Todd Collection Cleveland, OH. The sample represents modern American individuals comprising males aged 18 to 97 ($\bar{x}$=55.7, *Standard Deviation (SD)*=16.22) and females aged 20 to 94 ($\bar{x}$=62.4, *SD*=13.1). Age-cohort categorization was achieved using three strategies. First, a broad age class (young adult <39; middle adult 35-59; and old adult >60) was implemented. Next, the data was sub-divided into 10-year (e.g., 18-29, 30-39) and 5-year intervals (e.g., 18-24, 25-29). Male and female data were analyzed both separately and pooled. A two-part data analysis approach measured the ability of three classification algorithms to accurately predict the broad, 10-year, and 5-year age cohorts. To assess how well these data could be combined into a straightforward multi-factorial age estimator, quadratic Discriminant Function Analysis (qDFA) – Leave One Out (LOO) x-validation, Canonical Analysis of Principal coordinates (CAP – 4,999 permutations), and artificial Neural Networks (r-a-NN – hold-out samples for testing and validation) were conducted.

Variable importance measures indicate rib morphology was the single most important variable in every analysis, followed by pubic symphysis, then the auricular surface. This is not surprising given previously documented issues with auricular surfaces as an aging criteria. Classification accuracies for the broad age-cohort categorization were acceptable using qDFA (*F*=64%; *M*=67%; *Pooled*=66%), CAP (*F*=71%; *M*=71%; *Pooled*=68%), and r-a-NN (*F*=77%; *M*=75%; *Pooled*=77%). The qDFA and CAP performed well-below expectation for the 10-year and 5-year interval age-cohort categorizations; however, the regression analysis (with classification) developed using an artificial neural network performed promisingly well, correctly classifying the test samples (hold-out) for the 10-year (73%) and 5-year (74%) age cohorts. To improve network generalization and avoid overfitting, all successful networks were retrained using early stopping and regularization. Retraining generated age-cohort categorization models with mean squared errors lower than the individual performances and, as such, generalized even better to the testing and validation samples while avoiding overfitting.

Developing new multi-factorial approaches to age estimation may require novel applications of data mining and machine learning methods implementing current skeletal age-at-death indicators to predict "reportable" age estimates. The heuristic combination of age-at-death estimates may not properly weigh each indicator, placing emphasis on methods of very little import. In the end, age-cohort categorizations can provide accurate broad, 10-year, and 5-year interval age ranges derived from reliable and verifiable models.

Age Estimation, Machine Learning, Artificial Neural Networks

A113 On the Central Importance of Analysis of Covariance (ANCOVA) in Human Skeletal Research

Stephen P. Nawrocki, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227-3697; Krista E. Latham, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227; and Madeline Parker, BS, 3220 Rue Chanel, Apt 173, Indianapolis, IN 46227*

After attending this presentation, attendees will understand: (1) the power and flexibility of ANCOVA and the important role it can play in interpreting skeletal variability; (2) how basic errors in experimental design severely limit the utility of many forensic osteology studies; and, (3) how the choice of statistical procedures can lead to an over-emphasis on subgroup differences.

This presentation will impact the forensic science community by providing a new "best practice" standard for skeletal research that focuses on completing rigorous multivariate hypothesis testing before generating predictive equations.

The ability to construct a biological profile for the skeleton of an unidentified decedent is predicated on the availability of reliable comparative data, and the accuracy of that profile will vary directly with the quality and depth of prior skeletal research; however, a review of research published in the *Journal of Forensic Sciences* during the last two decades indicates that most studies suffer from one or more major flaws that limit their applicability in forensic settings. These flaws include errors of experimental design and inappropriate or incomplete statistical testing.

The following errors of experimental design were noted: (1) truncating or completely omitting fundamental hypothesis testing procedures. Many studies fail to properly isolate all relevant independent variables (sex, ancestry, body size, age at death) and thus cannot determine which ones actually affect the variance in a skeletal feature; (2) generating predictive regression or discriminant equations for subgroups based on variables that have no proven impact. If an independent variable is not significant in the variance equation, then there is no cause to generate separate equations for those subgroups. For example, stature equations are often provided for sex and ancestry subgroups without demonstrating that they substantively reduce estimation error over mixed-group equations; and, (3) inadequate sampling for the number of variables examined. To thoroughly test hypotheses, large samples are necessary because the addition of each new independent variable splits the sample across an increasing number of cells. For example, 200 specimens used in a typical 28-cell design (two sex groups vs. two ancestry groups spanning seven age decades) results in fewer than eight individuals per subgroup, reducing the power of subsequent statistical testing.

The following problems with statistical testing were noted: (1) over-reliance on simple univariate and bivariate procedures. Chi-squared tests, *t*-tests, and correlation cannot simultaneously control for the effects of multiple independent variables, and so the apparent effects of one variable may be due to the (masked) effects of a second (uncontrolled) variable; (2) ignoring interactions. Simple tests are susceptible to the confounding effects of interactions, which occur when the combination of two variables produces an added effect that cannot be attributed to either variable individually; (3) ignoring unbalanced sampling. Simple tests are influenced by uneven sampling, and since few death assemblages are balanced, most studies must overtly compensate; and, (4) assuming that other complex procedures actually test hypotheses. Principal components analysis and regression, for example, are not adequate for basic hypothesis testing.

A solution to these various problems is to employ ANCOVA as a first step in the experimental process. ANCOVA is a robust and sensitive hypothesis-testing procedure that partitions the variance across all independent variables simultaneously, separating the effects of interactions and controlling for unbalanced samples. The independent variables can be categorical (sex, ancestry) or continuous (body weight, age at death), and varieties of ANCOVA exist for categorical dependent variables (binary logistic regression, ordinal regression). Independent variables that are flagged by ANCOVA as significantly affecting the variance in a skeletal feature can then be explored further to construct predictive models for use in forensic settings.

The historical tendency to eschew thorough hypothesis testing and instead rely on simple statistical tests can explain many contradictory findings between different studies of the same skeletal feature. Furthermore, over time, these errors may have led researchers to emphasize the importance of subgroup differences (and thus the necessity of population-specific methods) at the expense of more robust, non-specific techniques with wider applicability. Until multivariate approaches such as ANCOVA are consistently applied, we will not be able to assess the true importance and relevance of subgroup differences in human skeletal variability and their practical effects on biological profile construction.

Biostatistics, Experimental Design, ANCOVA

A114 Fuzzy Inference System (FIS) as a Novel Statistical Method for Forensic Ancestry Estimation

Donovan M. Adams, MS, University of Nevada, Reno, 1664 N Virginia Street, Reno, NV 89557; and Rebecca L. George, MA, University of Nevada, Reno, 9455 Sky Vista Parkway, Apt 10E, Reno, NV 89506*

After attending this presentation, attendees will understand how fuzzy set theory may assist in ancestry estimation and the advantages of this type of analysis in the field of anthropology.

This presentation will impact the forensic science community by presenting a previously untested statistical technique for the process of forensic ancestry estimation that is built to accommodate such issues as multiple group affiliation and uncertainty in membership classification.

Fuzzy set theory, or fuzzy logic, is a statistical concept developed in the field of engineering.[1] Fuzzy logic is based on the premise that distinct groups are not an accurate reflection of reality due to inherent uncertainty and variation. Individuals may not perfectly belong to any delineated group, or they may identify with multiple groups. Individuals tested are given a membership value, or function, between 0.0 (no membership) to 1.0 (full membership), similar to posterior probabilities that are often presented as part of discriminant function analyses; however, fuzzy logic does not estimate the probability that an individual is part of a group, but rather estimates the degree of membership for each of the groups based on similarities.[2] Previous biological anthropological research has examined its utility in understanding group affiliation of paleoanthropology, primate behavior, and age estimation.[3-5] The accommodation of uncertainty and the analysis of membership to multiple categories makes this statistic an appealing choice for use in estimating the ancestry of individuals with diverse population histories. The objective of the present study is to examine this statistical technique's utility in producing an ancestry estimate for use in the biological profile.

Dental morphological data on eight traits collected by Tsuneiko Hanihara on global populations organized into three major geographic groups (i.e., African, European, Asian) commonly employed in forensic anthropology were used for the present analysis. These traits were not correlated with each other and previous research has shown utility of these traits in distinguishing between populations. This dataset was utilized as a starting point from which to create the system's rules and as a testing sample of the constructed equations. Data collected on Hispanic individuals from New Mexico and Mexico were also used to examine the method's efficacy in estimating individuals of admixed ancestry. A Mamdani FIS analysis in the MATLAB® (R2016a) Fuzzy Logic Designer package was utilized in the present analysis. This FIS uses a system of IF-THEN rules based on *a priori* knowledge to "fuzzify" the data and then "defuzzify" it around the centroid, producing a single membership score. These rules were based on population frequencies of traits gathered from the literature.[6,7] Each individual is then assigned a membership group output that corresponds to a particular ancestral group (e.g., 0.2 would suggest European-derived).

Preliminary results suggest potential utility of this statistic in estimating ancestry; however, the nature of the dataset used in the present analysis precludes a complete picture of its efficacy as the results tend toward a defuzzified membership score of 0.5. Patterns are seen that suggest the FIS is distinguishing between simple and complex dentitions. Any morphological complexity drives membership scores toward African- or Asian-derived estimates. There is also difficulty allocating between African- and Asian-derived populations due to crown complexity. These issues may be due to the use of dichotomized variables and overlapping frequencies of traits in multiple populations. The greatest success occurs when distinguishing between European and African/Asian-derived populations due to European-derived individuals typically having the least complex dentitions.

Breaking down each trait into separate grades, inclusion of more traits, such as enamel extensions and molar crenulations, and refinement of IF-THEN rules may improve the success of this method. Future tests will include a larger, more inclusive dataset to capture the range of variation present in the dentition as well as explore the effects of missing data. While this study represents an early use of fuzzy logic in forensic anthropology, there is great potential to explore this and other statistical methods to improve estimations of ancestry as part of the biological profile.

Fuzzy Logic, Dental Morphology, Ancestry Estimation

A115 Body Mass Estimation: Preliminary Equations for the Undocumented South Texas Migrants Using Bayesian Inference

Elaine Y. Chu, BSc, 225 Craddock Avenue, Apartment D, San Marcos, TX 78666; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand the intricacies of body mass estimation in forensic anthropology and how using Bayesian inference can result in more representative body mass estimations of deceased undocumented migrants from the United States-Mexico border. The goals of this presentation are to generate body mass estimation equations specifically for undocumented migrants found along the United States-Mexico border using Bayesian inference and data from recent national health surveys as an informed prior and to evaluate the accuracy of the equations.

This presentation will impact the forensic science community by providing a new method that results in more accurate body mass estimations for Hispanic individuals.

Forensic anthropologists establish a biological profile for unidentified human remains to help narrow the number of possible missing persons matches. The inclusion of body mass provides additional information to aid in identification since weight (body mass) is often reported in missing persons reports. Previous research reveals there is a need for population-specific formulas for estimating components of the biological profile.[1,2] This conclusion is particularly true of the four currently established equations for body mass estimation from skeletal remains.[3] Operation Identification (OpID) at Texas State University is an initiative to identify migrants that die crossing the South Texas-Mexico border. The inclusion of body mass to the biological profile of the unidentified migrants can assist in the exclusion of many potential matches suggested for each individual in the National Missing and Unidentified Persons System (NamUs).

Reference data come from the National Health and Nutrition Examination Survey (NHANES) and the Encuesta Nacional de Salud y Nutrición (ENSANUT), which are nation-wide surveys that include anthropometric measurements to evaluate the health of the nation. Previous studies have shown that the Waist-to-Height Ratio (WtHR) is a better indicator of health risks associated with weight regardless of sex and ethnic differences.[4,5] This ratio is calculated by dividing waist circumference by height. Evaluation of the relationship between body mass and WtHR from the two health surveys demonstrates a moderately positive correlation (R=0.5757). The informed prior for this study includes the height, waist circumference, and weight of those who identified as United States-born Hispanics (from NHANES) and Mexican-born natives (from ENSANUT). The individuals used for this study (N=36377) include males (n=15,748) and females (n=20,629) between the ages of 20 to 80 years. Linear regression was used to estimate waist circumference from living bi-iliac breadth and again to generate body mass estimation equations for males and females using the WtHR. To test for accuracy of the equations, inverse calibration was conducted on each known body mass to calculate an expected WtHR. A Mann-Whitney Wilcoxon test revealed that there is no statistically significant difference (p=0.3984) between the mean expected WtHR value from the generated equations and mean observed WtHR value of the reference data. This means that WtHR can be used to accurately estimate body mass with a 95% confidence interval.

Skeletal data came from OpID and included an equal number of positively identified males and females (N=6). Fully stature and bi-iliac breadth were obtained for each individual when available. Stature was estimated using FORDISC® 3.1 when the Fully method could not be used. Waist circumference was estimated from bi-iliac breadth, and a WtHR value was calculated. Body mass estimations were generated using the aforementioned equations. The reported weights of the identified individuals from missing persons reports were compared to the estimated body mass ranges. Only one individual from each sex cohort (33.33%) was accurately estimated for body mass. The low accuracy rate may be due to small sample size, self-reporting error, or the individuals falling on the extreme ends of the body weight spectrum.[1,6]

Although the sample size of identified individuals is small, it represents the only remains that are positively identified with full skeletons and an estimated weight on a missing persons report.

Results demonstrate that given the distribution of body mass represented by NHANES and ENSANUT, the resulting equations produce promising body mass estimations when using a WtHR ratio generated from skeletal height and bi-iliac breadth for the unidentified South Texas migrants, but also demonstrates the limitations for cases of largely overweight and underweight individuals.

Bayesian Statistics, Body Mass Estimation, Operation Identification

A116 Decomposition Rates: Autopsied vs. Non-Autopsied Human Remains

Cortnee J. Agan, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501; Christiane Baigent, MSc*, Forensic Investigation Research Station, Colorado Mesa University, 1100 North Avenue, Grand Junction, CO 81501; Melissa A. Connor, PhD, Colorado Mesa University, 406 Lowell Heiny Hall, 1100 North Avenue, Grand Junction, CO 81501-3122; and Eriek S. Hansen, PhD, Colorado Mesa University, Dept Biological Science, 1100 North Avenue, Grand Junction, CO 81501*

After attending this presentation, attendees will better understand the impact of the bloat stage and the effect of penetrating trauma on the trajectory of human decomposition in an arid environment.

This presentation will impact the forensic science community by increasing sample size in future taphonomic studies while highlighting the importance of region-specific testing of the variables assumed to affect rate and timing of decomposition.

Forensic taphonomy research facilities accepting both autopsied and non-autopsied human remains must contend with subsequent sampling concerns. Autopsy incisions approximate penetrating trauma, while evisceration attendant to organ examination and sampling adds an additional layer of insult. Post-autopsy, organs are typically bagged and returned to the thoracic cavity, resulting in the removal of soft tissue structures and the associated necrobiome, both assumed critical impetus to decomposition. While the sum of these postmortem modifications may reflect the circumstances of case trauma, the appropriate use of autopsied remains in controlled research facilities is poorly understood, making assignment to research cohorts challenging and retrospective data difficult to apply.

The potential for differential decomposition between autopsied and non-autopsied human remains was tested at the Forensic Investigation Research Station (FIRS) in Grand Junction, CO.

A sample of 12 individuals, 6 autopsied and 6 non-autopsied, was used to assess the trajectory of decomposition within and between groups. Decomposition was measured using a Total Body Score (TBS), a qualitative measurement of decomposition derived from gross assessment of value-assigned categories of change within three anatomical regions.[1] The indices of time and temperature were combined as Accumulated Degree Days (ADD). ADD was calculated as the average of hourly temperatures within a 24-hour cycle using data collected from an onsite weather station. All data points collected from the time of body placement to the time of analysis were considered in this study. Maximum ADD presented a range of 6,073-11,916 ADD for autopsied donors and a range of 6,178-12,721 for non-autopsied donors.

To ensure there were no significant differences in autopsied and non-autopsied cohorts, *t*-tests were used to compare donor age, height, and weight (α=0.05). A Linear Mixed Model (LMM) using maximum likelihood estimates was used to determine if the rate of decomposition varied between the two groups. The dependent variable was TBS (TBS^2 transformation). The independent fixed variables were ADD ($Log_{10}(ADD+1)$ transformation), an indicator variable for autopsied (*indicator*=1) or non-autopsied (*indicator*=0) remains, and an interaction term ($Log_{10}(ADD+1)$ x Indicator). The random effects for both intercepts and slopes were ADD and donor. The interaction term was used to determine if the slopes were significantly different. The *p*-value for the interaction was determined by a likelihood test comparing the model with and without the interaction term. The analysis was conducted in Program R (version 3.4.0) using the lme4 package.[2,3]

There was no significant difference for age, height, or weight between the two groups. The decomposition rate did not differ between autopsied and non-autopsied donors based on a comparison of slopes $\chi^2_{(1)}$=0.576, p=0.448.

FIRS is located in a semi-arid, high-altitude region, which promotes prolonged periods of tissue retention following desiccation of dermal and visceral tissues. Bates and Wescott observed a similar pattern between autopsied and non-autopsied cohorts in west Texas and concluded that penetrating trauma affects the pattern of decomposition but not the rate.[4] Results at FIRS concur, but also suggest that the bloat stage may not influence the overall trajectory of decomposition as is generally assumed. Bloat is the byproduct of bacterial metabolism within confined organ structures. The removal of the constituent parts necessary for bloat did not have an appreciable effect on the rate of decomposition. This highlights the necessity for regional testing of the biological phenomenon (both direct and auxiliary) traditionally assumed to influence the rate of decomposition and suggests that while dramatic in gross presentation, bloat does not significantly affect decomposition rates in arid regions.

Understanding the variables that affect rate of decomposition is important in the evaluation of prior research studies, future research studies, and for forensic scientists estimating postmortem interval on remains presenting large penetrating wounds.

Taphonomy, Autopsied/Non-Autopsied, Decomposition

A117 Testing the Accuracy of the Correlation Between the Condyles of the Distal Femur and Proximal Tibia: A Validation Study

Erin B. Waxenbaum, PhD, 1810 Hinman Avenue, Evanston, IL 60208; and Lauren Diaz-Albertini, BA, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will have an appreciation for the accuracy of predictive formulas correlating the distal femur and proximal tibia and the potential for this method to be used in mass fatality and/or commingled remains cases.

This presentation will impact the forensic science community by revisiting predictive formulas constructed by Waxenbaum and Linney and tests the accuracy and practicality of this methodology's use in the field on a novel sample.[1]

The knee is one of the most functionally important and largest joints in the body, prompting several researchers to explore sex and ancestral variation in the femur and tibia.[2-5] Assessing the relationship between distal femur and proximal tibia could prove itself useful when attempting to resolve commingled remains scenarios, including mass disasters, human rights violations, and archaeological assemblages, making this relationship both forensically and bioarchaeologically significant.[6,7] Not only do the distal femur and proximal tibia consistently preserve well, but the knee is also one of the last areas to burn when introduced to fire.[8] Due to the consistently strong survival rate of the knee in archaeological, mass disaster, and fatal fire scenarios, the distal femur and proximal tibia are a critical area that requires a more thorough anthropological examination. In 2011, Waxenbaum and Linney constructed predictive formulas, both general and specific to age, sex, and ancestry, on both a modern and archaeological sample through reduced major axis regression.[1] The present research will test the applicability of these equations on a novel sample.

Data were collected on a sex- and population-balanced sample of 103 individuals from the Hamann-Todd Collection housed at the Cleveland Museum of Natural History. Measurements of the left medial and lateral epi/condyles of the distal femur and proximal tibia were taken on all individuals and compared through analysis of variance and covariance as well as reduced major axis regression. The measurements were recorded using a digital sliding caliper and measured to the nearest +/- one millimeter. The effects of interobserver error to determine repeatability was also performed.

All analyses proved the equations to be accurate, yet not very precise. Interobserver error is likely too high for practical use. The medial condyle equations performed best for historic samples, while the potential for the use of the lateral condyle equations on modern samples needs further exploration. In the end, the pooled equations would be the only ones ever used in the field or laboratory. Despite the accuracy, unfortunately, the equations used in commingling situations is unrealistic.

Knee, Condyles, Commingling

A118 Using Microbial Clocks in Human Cadaver Ribs as a Postmortem Tool

Jessica L. Metcalf, PhD, N122 Ramaley Biology, UCB 334, Boulder, CO 80309; Aaron M. Lynne, PhD, 1900 Avenue I, Box 2116, LDB #300, Huntsville, TX 77341; and Jennifer R. Kiely, BS, PO Box 1493, Willis, TX 77378*

After attending this presentation, attendees will have a basic knowledge of the microbiome (study of the genes of microbes) and its application in human decomposition studies. Attendees will be presented with the results of a pilot study, which sought to investigate the bacterial succession in human cadaver ribs during the advanced stages of decomposition.

This presentation will impact the forensic science community by exploring an area with little to no previous research. This pilot study reveals the changes seen in the bacterial communities of cadaver rib marrow, over time, during the later, drier stages of decomposition and its potential usefulness as a Postmortem Interval (PMI) tool.

Determining the PMI is an important aspect of forensic investigations, but accuracy in predicting the interval declines with time. Microbes are important players in the human decomposition process and have been studied on cadaver skin and gravesoil samples during the early, wet decay stages as a potential PMI "clock."[1-5] Bacterial succession on decomposing skin shows promising results, but it becomes less accurate as desiccation occurs and decomposition approaches the skeletonization stage.[1,2] This pilot study investigates the bacterial communities inside the human cadaver rib during the advanced decay stage and into skeletonization.

Twenty-four ribs were excised from three cadavers at the Southeast Texas Applied Forensic Science facility in Huntsville, TX. One rib was sampled from each cadaver every three weeks over a six-month period during the later decay stages (beginning May 2016), representing ~5,000 Accumulated Degree Days (ADD). DNA extracted from the rib samples was sequenced using the MiSeq® Illumina® platform, targeting the 16S recombinant DNA (rRNA) gene region.

Results indicate that bacterial communities shift in community membership with advancing time, with the biggest trend occurring between the first and last sampling periods (advanced decomposition stage and skeletonization stage, respectively). Statistics demonstrate a significant difference in the phylogenetic distance between these samples (first and last). Community composition, more than abundance, may play a role when determining a PMI. Similarly, rarefaction curves trend toward an increase in richness with increasing ADDs, although there were no significant differences found in diversity between samples; however, due to the study's small sample size and unique nature of cadaver research, only generalizations about the microbiome of cadaver bone can be made. A reliable PMI method cannot be formulated from this study at this time, but the results suggest that there is a trend in bacterial succession that could be useful and warrants further investigation.

A119 Toward a Skeletal Atlas of Elder Abuse: A Pilot Study of Fracture Patterns in Documented Cases

Katelyn L. Bolhofner, PhD, Arizona State University, 900 S Cady Mall, Tempe, AZ 85287; Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007; and Jane E. Buikstra, PhD, Arizona State University, PO Box 872402, Tempe, AZ 85287-2402*

After attending this presentation, attendees will be aware there are skeletal fracture patterns associated with the abuse/neglect of elderly individuals distinguishable from those found in accidental falls.

This presentation will impact the forensic science community by introducing skeletal manifestations and patterning of elder abuse, contributing novel data to the ongoing effort to unmask elder abuse at a state and national level.

Increasing rates of elder abuse in the United States have produced an urgent need for improved diagnostic criteria.[1] Physical abuse of elders represents the most severe manifestation of this trend, yet is difficult to prove.[2] Skeletal expressions of elder abuse offer key indications of inflicted injuries, but often are masked by assignation to accidental falls. Currently, there is no standard for the diagnosis of elder abuse in the skeletal system; research in this field is "decades behind."[3-5] Here, results of a pilot project are presented identifying fracture patterns associated with suspected cases of elder abuse/neglect in contrast with those associated with accidental falls.

To establish skeletal patterns of abuse/neglect versus accidental falls, 300 investigative summaries, dating from January 1, 2014 through June 30, 2017, were reviewed. From these, 30 individuals above the age of 60 years were included in the pilot study population based on the following criteria. Decedent must: (1) have been admitted for full exam; (2) be associated with an Adult Protective Services and/or law enforcement investigation; (3) present with skeletal fractures; and, (4) have radiographs/samples available for review. Given these strict criteria, this sample size is known to be an underestimation of cases of abuse/neglect. To establish a comparative baseline of those fractures most likely to occur in accidental falls, 75 cases of witnessed falls from the same pool were reviewed.

A significant difference in the skeletal manifestation of injury was observed between those individuals involved in accidental falls and those for whom abuse/neglect is suspected. For individuals involved in a witnessed fall, fractures occurred most frequently in the hip (n=51; 68%), followed by vertebral compression fractures (n=14; 19%). Five individuals involved in an accidental fall presented with multiple fractured ribs (7%). In contrast, for those individuals identified as possible victims of abuse/neglect, fractures occurred most frequently in ribs 8-11 (n=8; 27%) and the arm (n=9; 30%), followed by fractures in the femur (n=7; 23%) and the tibia/fibula (n=3; 10%).

In cases of suspected abuse/neglect, femoral fractures occurred along the shaft or distal end, while femoral fractures in witnessed falls occurred at the proximal end. Rib fractures occurred in the posterolateral shafts of ribs 8-11 in cases of suspected abuse/neglect, but in varying locations in falls. When an accident involved fractures of the arm, the bones involved consistently displayed fracture types associated with a fall on an outstretched arm.[6-8] In cases of suspected abuse/neglect, arm fractures presented as chronic dislocation of the humeral head and/or healing fractures of the radius and/or ulna shaft. In several cases of suspected abuse/neglect in which the humeral head was involved, fractures of the lateral clavicle and acromion process of the scapula were also noted. This finding complicates reports that falls onto an outstretched hand account for the majority of proximal humeral fractures in the elderly and serves as a warning that cases of abuse/neglect may be masked by a tendency to over-assign arm fractures in the elderly to accidental falls.[8-11]

By exploring these patterns within their contexts, mechanisms that may account for observed differences can be proposed. In several cases of suspected abuse/neglect in this sample, fractures occurring in ribs 8-11 are correlated with reports of a "bear hug" restraint. Where fractures of the distal femur and tibia/fibula are associated with cases of suspected abuse/neglect, individuals were non-ambulatory and had been dropped, resulting in a "crushing" fracture. A rough "jerking" of the arms in the process of moving a non-ambulatory individual resulted in crushing and dislocation of the humeral head.

Fractures are the most common musculoskeletal condition requiring hospitalization among individuals aged 65 and older in the United States, and rigorous diagnostic criteria must be developed to differentiate accidental injury from abuse.[12] Results from this pilot project offer a first stage in the effort to develop and improve diagnostic criteria for a skeletal atlas of elder abuse.

Elder Abuse, Fracture Patterns, Skeletal Atlas

A120 Results of Testing Interobserver/Intraobserver Error for "Planar" Proxy for Upper Facial Breadth and Novel Measurement of Interorbital Distance

Angeline Smith, University of Louisiana at Lafayette, 3201 Kalisite Saloom Lot 258, Lafayette, LA 70508; Jacob L. Cheramie, 3409 Severn Avenue, Apt 327, Metairie, LA 70002; and Maranda A. Kles, PhD, University of Louisiana at Lafayette, PO Box 40198, Lafayette, LA 70504*

After attending this presentation, attendees will better understand the potential benefit of a proxy measurement for upper facial breadth and interorbital distance for analysis of fragmented remains. This study presents the analysis of data collected at the 2016 American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting in Las Vegas, NV, to test for interobserver and intraobserver error in these measurements.

This presentation will impact the forensic science community by testing the accuracy and consistency of alternative methods for collecting cranial measurements. Cranial remains, specifically the facial component, are often fragmented due to the fragile nature of this area. This limits the collections of standard craniometrics, which are used to develop a biological profile necessary for the identification of skeletal remains. This could be rectified by the use of proxy measurements and the development of novel measurements to obtain the necessary information to make an identification. If found accurate and reproducible, these measurements would contribute to the resources and methods available for analyzing fragmented cranial remains when the standard points of reference are damaged. Previous research demonstrated that these measurements can aid in the identification of sex and ancestry of human skeletal remains.[1]

This study is a continuation of the trend in the discipline of forensic anthropology to re-evaluate standard craniometrics and add statistical rigor to the assessment of sex and ancestry. The previous study presented three Upper Facial Breadth (UFB) proxies and one alternative measurement for interorbital breath.[2] This research examined the "planar" UFB proxy and a new measurement, interorbital breadth at nasion, for interobserver and intraobserver error. These measurements are being tested for their utility on fragmentary remains in which the pristine standard craniometrics are unobtainable.

Cheramie and Kles found that "Planar" (a unilateral measurement from nasion to Frontomalartemporalis (FMT) measured in the same plane and multiplied by two) was not significantly different than UFB and produced the same results as UFB in discriminating sex and ancestry, suggesting it could be an effective proxy for UFB in damaged remains.[2] Testing also found the measurement of interorbital breadth at the height of nasion was significantly different than the standard interorbital breadth measurement taken at the height of dacryon, but it was also found to be useful in the assessment of sex and ancestry, suggesting it could be used instead of the standard measurement in damaged remains.

During the 2016 AAFS Annual Scientific Meeting, volunteers were solicitied to measure crania to assess interobserver and intraobserver error. Participants were asked to measure one of three crania with spreading and sliding calipers. They collected nine standard measurements, the Planar proxy for UFB, and the new interorbital distance at nasion measurement. Participants were asked to conduct the measurements twice and were asked a series of questions about their level of education and experience. Fifty-two individuals participated.

Results were inconclusive. The "Planar" measurement was found to be statistically different (p <0.05) in two of the three specimens. No significant difference (p <0.05) was found in interorbital breadth at nasion in two of the three specimens. Although the results were mixed, the findings suggest that these measurements have promise. Future testing will include examining the descriptions of the measurements for clarification, re-testing on larger samples, and collecting data on known samples to test the utility of interorbital distance at nasion.

Craniometrics, Upper Facial Breadth, Interorbital Distance

A121 Challenges in Identifying United States Casualties From Past Conflicts: An Assessment of Lines of Evidence

Heli Maijanen, PhD, DPAA, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853; and Andrea Palmiotto, PhD, DPAA, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will better understand the process of effecting individual identifications of United States service members associated with past conflicts (World War II, Korea, and Vietnam) and recovered by various methods (disinterment, field recovery, unilateral turnover, and a commingled turnover sample) using data from the Defense POW/MIA Accounting Agency (DPAA).

This presentation will impact the forensic science community by highlighting the importance of antemortem records, quality of evidence, and necessity of multiple lines of evidence to effect individual identifications. Differences in the number and/or quality of lines of evidence per identification are evaluated based on conflict and recovery type.

All identifications are guided by historical research and investigations; however, this is not included as a line of evidence in this study. Instead, this study emphasized the five lines of evidence that are analyzed or interpreted in the laboratory. DNA, dental (FOR), and chest radiograph (CXR) comparisons are used for individual identification purposes, as these analyses involve the comparison of skeletal remains against antemortem data. Identifications are supported by anthropological skeletal analyses (FAR), which are completed "in the blind," and analyses of material items (MER), which associate remains with an individual or a conflict.

Ideally, every line of evidence would be at the analysts' disposal; however, due to the effects of time and other taphonomic processes, evidence may be impacted or limited. For example, disinterments generally consist of more complete sets of remains that could not be identified in the past, while field recoveries often consist of incomplete or fragmented remains. Complicating matters, the disinterred remains of many unidentified service members were coated in a formaldehyde powder prior to burial, which presents challenges for DNA analysis. The type of DNA analysis depends on available Family Reference Samples, which may be limited or unavailable despite searches for appropriate relatives. Additionally, antemortem records may be lacking or of poor quality.

This study includes data from 166 recent identifications made by DPAA. Once evidence is received by the laboratory, analyses are completed based on the condition of the evidence. On average, identifications are supported by three different analyses. Only one case was identified with a single analysis, while eight cases were identified with all five types of analyses. Overall, DNA contributed to identification in 70% of the cases, followed by FOR (68%), then CXR (33%). FARs were completed in 98%, and MER in 42% of identified cases. FARs are critical because an "in-the-blind" analysis of skeletal remains provides an unbiased means of supporting other analyses; however, the level of detail possible in any analysis depends on the condition of the remains. Therefore, any analysis may indicate positive association or inability or exclude association with a historical candidate.

When assessed by conflict (World War II, n=67; Korea, n=87; Vietnam, n=12), DNA analyses contribute less to older cases (Vietnam, 83%, vs World War II, 58%); however, FORs corroborate more older cases (Vietnam, 25%, vs. World War II, 88%). CXRs predominantly support Korea cases (42%), which can be explained by the relative absence of antemortem radiographs for other conflicts.

Analyses are also affected by recovery type (disinterment, n=45; field, n=60; turnover, n=11, and turnover/commingled, n=50). Only World War II and Korea cases are represented by disinterments. Less than half of disinterments have DNA results (40%), while DNA is present in at least 65% of other cases. More than 80% of disinterments and field recoveries have FORs, compared to less than 45% of other cases. DNA is most integral for resolution of commingled cases (100%), while material evidence is most commonly used to support identifications from field recoveries (83%, compared to less than 36% of other cases), where identifying media helps confirm loss locations and direct site excavations.

Each case is unique regarding types and conditions of evidence and available records. The elapsed time since the conflict does not appear to limit identifications. Differences exist based on conflict and type of recovery method, which can be explained by antemortem record availability, postmortem processing, and other taphonomic processes. Often records, materials, and/or the remains are incomplete or fragmented, which emphasizes the inadequacy of a single line of evidence.

Individual Identification, Lines of Evidence, Conflicts

A122 The Application of the Megyesi Method and Improved Total Body Scores (TBS) and Accumulated Degree Days (ADD) Equations to Pennsylvania, Ohio, and New York Cases

Dorianis Perez, BS, 407 E Avenue, Erie, PA 16507; Paige A. Lynch, BA, Mercyhurst University, 305 Colonial Drive, Montoursville, PA 17754; Rhian Dunn, BA, 4135 Briggs Avenue, Erie, PA 16504; Audrey E. Constantino, BS*, Mercyhurst University, Erie, PA 16504; and Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will better understand the applicability of the Megyesi method to other regions of the country, including Pennsylvania, Ohio, and New York. Attendees will also gain insight on the practicality and reliability of the Megyesi et al. method (Megyesi method hereafter) and the Moffat et al. method (Moffat method hereafter) for Postmortem Interval (PMI) estimation.[1,2]

This presentation will impact the forensic science community by demonstrating some current limitations of the Megyesi and Moffat methods, stimulating further research to refine and improve PMI estimation methods based on decomposition.

Techniques based on the Megyesi method have been criticized mainly for their allegedly limited applicability to regions different from that of the original sample. In this study, the methods presented in Megyesi et al. and Moffat et al. were applied to a set of forensic cases from the Northeast United States, with known PMIs, processed at Mercyhurst University.[1,2] Seventy-five cases from 1997 to 2016 were examined for this purpose, but only 10 fulfilled the strict criteria of the Megyesi method on context conditions, surroundings, and completeness of the remains. These were all outdoor ground surface deposits with all elements necessary to calculate the TBS according to the Megyesi method.[1] Megyesi TBS were calculated from scene recovery photographs and later recalculated using the Moffat method. Average daily temperatures to calculate the ADD were collected from records of the National Oceanic and Atmospheric Administration (NOAA) for the general area of each scene. Ninety-five percent confidence intervals for the ADDs were calculated based on the equations in each method and compared to establish which of the two methods rendered the closest estimate to the known PMI of each case.

In the areas under study, the Moffat method rendered only a slightly higher accuracy, although more precise (narrower) intervals than the Megyesi method. The Megyesi method incorrectly estimated the PMI in four cases, while the Moffat method estimated PMI incorrectly for three cases. The average error was 16 days for the Megyesi method. For the Moffat method, it increased to 78 days. The much higher error for the latter is mostly derived from a single outlier appearing when the TBS scale was recalculated according to the improved equations; however, after removal of this outlier, the average error of the Moffat method was still 28 days.[2]

These results suggest that, while perhaps providing higher accuracy, the Moffat method may be applicable to a narrower range of PMIs; narrower even than that represented in such a reduced sample as the one examined in this study. Deviations of the confidence intervals from the actual PMI appear to be less frequent in the Moffat method. When they occur, they appear to be potentially much wider than in the Megyesi method, with the narrower confidence intervals of the Moffat method providing only the illusion of precision. This indicates a need for further research, increasing sample sizes and the range of PMIs, and environments considered in future studies to improve TBS/ADD methods.

Megyesi Method, Forensic Taphonomy, Postmortem Interval

A123 The Human Cadaver Decomposition Island (CDI) and the Vegetation Regrowth Interval

Tonya Parnell, BS, Sam Houston State University, 2424 Sam Houston Avenue, Huntsville, TX 77341; Katie Tanner, BS, Sam Houston State University, 2424 Sam Houston Avenue, Huntsville, TX 77341; Stacie G. Gray, BS, 600 Palms Street, Apt 7, Huntsville, TX 77340; Haeli Kennedy, Sam Houston State University, 2424 Sam Houston Avenue, Huntsville, TX 77341; and Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice/Forensic Science Dept, Box 2296, Huntsville, TX 77341-2296*

After attending this presentation, attendees will have a clear understanding of what a surface human cadaver decomposition island looks like with and without scavenging interference and will understand that the CDI is present months after the remains are removed.

This presentation will impact the forensic science community by bringing awareness to those participating in search and rescue efforts to not only focus on looking for the skeletal remains of an individual, but to also look for the CDI, which is an identifiable and useful piece of evidence.

Typically, during the late phase of the Early stage of human decomposition, fluids of the body, formed during autolysis, hydrolysis, and by other chemical and bacterial actions, leach into the soil under and around the body, producing a CDI. The fluid contains high concentrations of organic matter and microorganisms, eradicating any vegetation adjacent to and under the body. When the soil pH and chemicals begin to return to a level similar to the original state, remaining nutrients in the soil cause native vegetation, and flora not indigenous to that area, to flourish. Previous research observing regrowth of vegetation has been conducted using *Sus scrofa*, although no literature to date has recorded the vegetation regrowth of a human CDI.[1]

In 2013, a pilot study was conducted at The Southeast Texas Applied Forensic Science (STAFS) Facility, Huntsville, TX. The pilot study revealed that the CDI is greatest under the trunk, reduced under the head, and further reduced under the limbs. The present study documented the timing of the formation of the CDI as well as the timing of the return of vegetation around and within the CDI. Three subjects were placed in similar environmental conditions; two subjects were inaccessible to scavenging and one was accessible. After the collapse of body cavities and the formation of the CDI, the subjects were removed from their CDI at predetermined intervals of zero and two weeks after leaching. Cages remained over the CDIs and daily observation occurred until regrowth within the CDI formed. For the subject removed at zero weeks (the day after CDI formation appeared complete), regrowth within the CDI occurred after 131 days. For the subject removed at two weeks after CDI formation, the regrowth occurred after 197 days. Most of the CDI for the subject accessible to scavenging had formed under the trunk of the body prior to being moved around by scavengers; however, the CDI of the limbs and head could not be clearly identified after movement of the body by scavenging had smeared the soil. The body was pulled away from the major part of the CDI by scavengers but remained at the periphery throughout the study. After 207 days, vegetation began to appear in the CDI of the scavenged subject. The accessible body that was not removed continued to cover portions of the CDI, thus prolonging the CDI's composition. Results demonstrate that in the piney woods region of Southeast Texas, if a decomposing body can leach the majority of its fluid in an area prior to extensive scavenging, vegetation regrowth may take 100-200 days to appear.

In search and rescue efforts for missing individuals presumed dead, a CDI may be detectable three to six months after death, even if the body has been displaced from its original location. Further studies using a larger sample are currently being conducted.

Cadaver Decomposition Island, Postmortem Interval, Forensic Anthropology

A124 Modern Variation in Vertebral Column Segmentation and Transitions

Janet E. Finlayson, MA, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610; and Amanda N. Friend, MA, C.A. Pound Human Identification Laboratory, 2033 Mowry Road, Gainesville, FL 32608*

The goal of this presentation is to describe the variation observed in individuals accessioned at the University of Florida C.A. Pound Human Identification Laboratory (CAPHIL) from the modal human vertebral formula and discuss potential effects of this variation on forensic analyses. After attending this presentation, attendees will understand the value in assessing variation within the vertebral column.

This presentation will impact the forensic science community by highlighting the importance of understanding modern human biological variation and the potential of anomalous development to affect forensic identification processes.

The modal formula of the human vertebral column consists of 7 cervical, 12 bilaterally rib-bearing thoracic, 5 lumbar, 5 fused sacral, and 4 coccygeal vertebrae. Variation in the number of vertebrae and associated ribs can occur within each vertebral column region. These variations are generally attributed to embryological developmental irregularities, such as an amodal number of somites or abnormal patterns of genetic signaling.[1-3]

This study accessed skeletal inventory and descriptive data of 55 (*F*=14, *M*=41) identified and unidentified individuals analyzed at the CAPHIL between 2007 and 2017. The individuals ranged in age at death from late adolescence to older adult, and the sample varied in ancestry. Sample selection required the presence of at least one developmental vertebral or rib anomaly. Selection of developmental anomalies was limited to differences from the modal vertebral column expression, including: (1) regional segment count; (2) segmental cranialization or caudalization; and, (3) improper segmentation. This criteria allows for identification of variance in vertebra/rib count, transition locations, and segment separation errors. Thoracic and lumbar vertebrae are typically defined morphologically, with the orientation patterns of Superior and Inferior Articular Facets (SAFs/IAFs) or articulation to ribs as defining criteria. For this study, designation of a thoracic vertebra is determined by SAF/IAF orientation patterns and possession of costal facets; designation of a lumbar vertebra is determined by SAF/IAF orientation, regardless of rib-bearing status.

Forty-one of the studied individuals varied in segmental count in at least one region (74.5%). Of these individuals, three had 11 bilaterally rib-bearing thoracic vertebrae (7.3%), 2 had 13 bilaterally rib-bearing thoracic vertebrae (4.9%), 16 had 6 lumbar vertebrae (39.0%), 21 had 6 sacral segments (51.2%), and 4 had 3 coccygeal segments (9.8%).

Thirty-seven individuals exhibited variation in at least one transitional region (67.3%). Of these individuals, four exhibited variation in two regions (10.8%). In one male, C7 articulated unilaterally to a rib (2.7%). One male had a unilateral supernumerary rib of indeterminate anatomical origin in addition to the 24 thoracic ribs (2.7%). Sixteen individuals exhibited bilateral lumbar ribs (43.2%), one of whom exhibited a bilateral set on L1 and a unilateral rib on L2 and two of whom exhibited a unilateral rib on L1. For 13 individuals (35.1%), the thoracolumbar transition occurred at the level of T11; in ten of these cases (76.9%), the vertebra inferior to T11 had lumbarized SAFs/IAFs and was rib-bearing, followed inferiorly by five non-rib-bearing lumbar vertebrae. Thirteen individuals displayed sacralization (35.1%), with seven instances at the level of L5 and six at the level of L6. Of individuals with a sixth lumbar vertebra, 75.0% exhibited sacralization of the element. Four individuals (10.8%) exhibited S1 lumbarization.

Three individuals had segmentation defects (5.4%), of whom there was separation failure of C2/C3 in one female (33.3 %), of C7/T1/T2 in one male (33.3%), and of right ribs 3/4 in one male (33.3%).

In this study, the vast majority of developmental vertebral column anomalies were expressed in the caudal regions. This is likely due to abnormal genetic signaling during embryonic specification of individual vertebral identity in which the signaling code becomes caudally complex. Certain cervical anomalies can be associated with detrimental conditions that may result in perinatal or infantile death; thus, the cervical region has strong developmental constraints.[4,5] This constraint may contribute to the relatively low frequency of cervical anomalies observed in this study.

This study describes relative frequencies of developmental vertebral anomalies observed in a forensic sample. Vertebral anomalies may affect forensic stature estimations, as the vertebral column majority directly contributes to height, and standard stature calculation techniques assume modal vertebral frequencies. Further, deviance from modal expressions can affect the condition of the vertebral column, which may have clinical implications and serve as potentially individualizing pathological features.[6,7]

A125 Spatial Analysis and Animal Activity: A Taphonomic Study Using Geographic Information Systems (GIS) to Document Animal Modification to Human Bone at Outdoor Crime Scenes

Jessica Yopak, BA, Mercyhurst University, 739 E Grandview Boulevard, Erie, PA 16504; Dennis C. Dirkmaat, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; and Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will be familiar with the utility of a standardized approach to document and analyze taphonomy on forensic cases using GIS, including its usefulness in answering questions beyond forensic significance.

This presentation will impact the forensic science community by providing an experimentally derived protocol for documenting and answering taphonomic questions concerning outdoor crime scenes and a test of their applicability in order to broaden the community's understanding of scientifically derived answers to taphonomic questions.

Forensic anthropologists are commonly asked to assist with outdoor crime scenes that involve badly decomposed or skeletonized remains. Remains encountered at these scenes are generally exposed to numerous taphonomic agents, especially if the remains were deposited on the surface. Besides environmental variables, such as climate, wind, water, etc., animals are one of the more commonly encountered taphonomic agents. Carnivores are known to chew on remains, not only leaving signature marks on the bones, but also commonly scattering the bones or removing elements from the immediate scene. Rodents gnaw on the skeletal remains and can also move smaller elements. Although general patterns in carnivore and rodent modification have been described, these patterns have not been objectively analyzed.

In this study, GIS was used to analyze rodent and carnivore modification from a total of 51 Mercyhurst University Forensic Anthropology Laboratory (MFAL) forensic cases. The current practices of documenting taphonomic modification of human tissues is typically conducted through photographs and written notes. When collecting data from these cases, all the notes and photographs were standardized into a diagram format using a homunculus jpeg in Adobe® Photoshop® CC. A separate database was created to identify the case type, bone counts, and any information that was known about the Postmortem Interval (PMI). Individual layers representing carnivore modification and rodent modification were saved as jpegs, entered into GIS, and vectorized. The vectors give exact locations and quantities of taphonomic alteration on the skeleton. Density maps of locations of animal activity on the human skeleton were created. All of this was conducted following a prescribed and detailed protocol. For further analysis of these skeletal maps, four categories of modification based on location and animal type were created: epiphyses, diaphyses, rodent, and carnivore. This allowed the specific areas and timing of animal modification to be identified in order to test established taphonomic interpretations found in the forensic literature.

Using location and animal type categories, basic statistics were run on the data. Chi-square (<0.05) tests revealed there was a significant difference between animal gnathic modification location on the bones. With respect to the long bones, carnivores more frequently chewed on epiphyses, while rodents gnawed on diaphyses. For example, carnivore modification of the epiphysis of the humerus was noted 32.6% of the time and the diaphysis only 2.3% of the time. Rodent activity was noted on the fibula epiphyses 17.6% and the diaphysis 41.1% of the time. This provided a test of the accepted pattern in the forensic literature and illustrated through density maps and statistics that the identified patterns of animal modification on the skeleton are accurate: carnivores tend to modify the long bone epiphyses first while the rodents were more active on the diaphysis.[1-3] Additionally, forensic literature PMI interpretations were compared to the new findings. The average PMI for carnivore gnawing to be exhibited in the MFAL cases was 22 months, while the rodents was 76 months. Performing a *t*-test demonstrated that these means were significantly different. When trying to identify a specific timing of gnawing by animal type using logistic regression, no significant relationships were identified. These results are consistent with the accepted sequence of gnawing found in the forensic literature and indicate that carnivores modify remains while they are in an earlier state of decomposition, as compared to rodents.

This protocol used for mapping the animal modification can be expanded to analyze any taphonomic agent that results in physical alteration of skeletal material. If other variables were analyzed using this method, a larger regional expression of taphonomy could be created to better understand what happens at a crime scene from the time remains are deposited to when they are analyzed in a laboratory. A database of taphonomic human skeletal modification could be created in order to aid forensic archaeological recovery efforts and outdoor scene interpretations.

GIS, Taphonomy, Documentation

A126 The Relative Compositional Changes of Buried Juvenile Porcine Ribs and Ulnae in the Early Postmortem Interval

Luisa Marinho, MSc, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A1S6, CANADA; Shera Fisk, BSc*, 3888 Point Grey Road, Vancouver, BC, CANADA; and Hugo Cardoso, PhD*, Simon Fraser University, Dept of Archaeology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will better understand the compositional changes that different bones of the juvenile skeleton undergo within the early postmortem period in a buried environment, as illustrated by the analysis of ribs and ulnae.

This presentation will impact the forensic science community by demonstrating that bone breakdown and time-since-death estimations from juvenile bone can potentially be influenced by, or vary according to, the skeletal element that is analyzed.

Estimation of postmortem interval is an important aspect of forensic investigations involving human skeletonized remains. Current methods are relatively poorly informed of the process in which juvenile bones degrade. Furthermore, the variation across different skeletal elements of a single individual has not been sufficiently explored. Experimentation with porcine bone as a proxy for humans provides one of the few opportunities to examine these issues.

This study uses a juvenile porcine model to examine the relationship between the length of the postmortem interval in buried environments and the changes in water, collagen, and mineral content of two distinct skeletal elements: ribs and ulnae.

Fifty-four suckling piglets (*Sus scrofa*) aged approximately between two and eight weeks were purchased from a local supplier. Ribcages and ulnae were disarticulated and manually defleshed, then left to decay in a controlled buried environment for 12 months. Each month, nine ribs and four ulnae were excavated, for a total of 108 ribs and 48 ulnae over the duration of the experiment. Each bone was sectioned to obtain a portion that was used for the quantification of water, collagen, and mineral content. This analysis was accomplished through a process of sequential controlled heating, designed specifically for this project. Each sample was weighed four times throughout the process, and the water, collagen, and mineral contents were expressed as a percentage of total weight.

Results indicate that the water, collagen, and mineral contents were approximately the same in both the ribs and ulnae at the beginning of the experiment. Water content diverged between the ribs and ulnae after the second month, with the values for ribs remaining relatively constant and ulnae increasing through time. Collagen appears to remain constant between the two skeletal elements throughout the experimental interval. An overlap in mineral content was observed between ribs and ulnae until month six, when a noticeable decrease in the ulnae values occurred.

These results suggest that the changes in the chemical composition of different skeletal elements may occur at different rates within the early postmortem interval. These varying rates can potentially impact the physical degradation of skeletal elements to differing degrees, thus influencing the reliability of time-since-death estimations from juvenile bone.

Decomposition, Collagen, Mineral

A127 Seasonal and Spatial Variation in Local Weather Station Data From Knoxville, Tennessee

Kathleen Hauther, University of Tennessee, 1621 Cumberland Avenue, 504 Strong Hall, Knoxville, TN 37996; Derek A. Boyd, MA, University of Tennessee, Knoxville, 250 S Stadium Hall, Knoxville, TN 37996; William D. Cawley, BA, University of Tennessee, 1611 Fremont Place, Knoxville, TN 37917; Kelly Sauerwein, MA, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; and Yangseung Jeong, PhD, MTSU, 150 W Thompson Lane, Apt P-103, Murfreesboro, TN 37129*

After attending this presentation, attendees will understand the seasonal and spatial variation in ambient temperatures at the Anthropological Research Facility (ARF) in Knoxville, TN.

This presentation will impact the forensic science community in terms of competency and performance by supporting research that National Weather Service (NWS) weather stations may be an unreliable source of temperature information for use in Postmortem Interval (PMI) estimation.

Estimation of the PMI is crucial to medicolegal death investigation. Some PMI estimation methods rely on the quantification of biological processes driving human decomposition, of which ambient temperature is considered an important factor. Furthermore, anthropological research in human decomposition increasingly utilizes Accumulated Degree Days (ADD) as a way to incorporate ambient temperature into predictive models designed to translate this information into estimates of PMI. An underlying assumption of these models is that the practitioner has access to accurate and reliable temperature data. Dabbs addressed this assumption by examining temperature data from multiple NWS weather stations.[1] She found that differences in recorded temperatures between weather stations translated into potentially meaningful differences in PMI estimation. Additional studies have explored the underlying accuracy and reliability of NWS data through comparisons with localized ambient temperature data loggers.

This study expands upon Dabbs and others by investigating seasonal and spatial variation in temperature data retrieved from NWS weather stations and local data loggers.[1] Specifically, temperature data were collected between 2014-2017 from an NWS weather station located at the University of Tennessee Institute of Agriculture (UTIA), less than 0.5km from the ARF, and were compared to a digital thermometer permanently installed within the ARF. Maximum and minimum temperatures (°C) were compared between both temperature data sources using a Welch's two sample *t*-test in R (version 3.1).[2] Then, daily temperatures were grouped by season (i.e., spring, summer, fall, and winter) and compared between those same two sources. Results were considered statistically significant at the $p < 0.05$ ($\alpha = 0.05$) level.

Overall, the results of this study indicated that maximum and minimum daily temperatures collected across data sources differed by less than one degree. The results of the Welch's two sample *t*-test indicated no statistically significant difference between data sources when all data were pooled. When the data were separated by season, significant differences emerged. Spring (mean ARF 26.6°C, mean UTIA 25.0°C), summer (mean ARF 29.9°C, mean UTIA 31.0°C), and winter (mean ARF 12.9°C, mean UTIA 9.2°C) maximum temperatures were significantly different between sources, as were the minimum temperatures in the summer (mean ARF 20.9°C, mean UTIA 19.7°C). These results clarify earlier studies examining the correspondence between the NWS station data and data collected at specific sites of human decomposition by finding a seasonal link in the variability in temperature data across sources. These results not only have regional implications for decomposition research conducted in East Tennessee, but also have wide-reaching importance for future anthropological and entomological studies of human decomposition. It is strongly recommended that researchers and practitioners independently validate the reliability of their temperature data sources, especially in longitudinal studies encompassing multiple seasons.

Time Since Death, Accumulated Degree Days, Human Decomposition

A128 The Influence of Three-Layered Cranial Architecture Development on Non-Accidental Pediatric Cranial Blunt Force Trauma (BFT) Outcomes

Donna C. Boyd, PhD, Radford University, Forensic Science Institute, PO Box 6939, Radford, VA 24142; Kimber G. Cheek, Radford University, 9800 Gunston Hall Road, Fredericksburg, VA 22408; and Cliff Boyd, PhD, Radford University, Forensic Science Institute, Radford, VA 24142*

The goal of this presentation is to document ontogenetic development of the three-layered (i.e., diploe, inner, and outer table) architecture of the juvenile cranium and investigate the effect of this development on pediatric BFT outcomes.

This presentation will impact the forensic science community by providing forensic anthropologists and pathologists with an enhanced understanding of the spatial and temporal variability in the emergence of a mature cranial architecture and its response to (and, thus, risk associated with) fracture across varying regions and age groups, with important scientific applications for non-accidental BFT trauma prevention.

Approximately 75%-80% of all non-accidental pediatric deaths involve cranial BFT, disproportionately affecting decedents less than the age of one year. These typically involve subdural and retinal hemorrhage and diffuse traumatic axonal injuries, often associated with cranial fracture.[1] A number of extrinsic and intrinsic factors influence pediatric cranial fracture vulnerability, although prior research has focused on biomechanical factors associated with injury, less attention has been paid to the influence of intrinsic features of bone structure on BFT outcomes.

The neonatal cranium is unilaminar — a three-layered cranial architecture does not develop until sometime during the first or second year and a mature structure may not be present until later in childhood; however, the exact timing and mechanism of this process have not been studied on dry bone.[2] Also unknown is the effect of three-layer development on non-accidental (including repetitive) episodes of pediatric BFT.

This study has two goals. First, temporal and spatial development of the three-layered architecture in the juvenile cranium is chronicled. Second, implications of this development for cranial fracture outcomes are explored through testing of the hypothesis that the absence or lesser development of a three-layered architecture in very young subadults leaves their cranial bones thin and vulnerable to the effects of BFT compared to older subadults. Thus, regions of the pediatric cranium manifesting delayed or inadequate development of the three-layer architecture will exhibit greater vulnerability to (and thus, higher risk associated with) the mal-effects of BFT than regions with a developed three-layer structure.

Development of the three-layered cranial architecture is chronicled through macroscopic and microscopic (5x-40x) analysis of a sample of 50 juvenile crania from the Scheuer collection, ranging in age from perinatal to 17 years; 37 of the crania were below the age of 5 years. Variables recorded across the sample included age, bone, bone location, bone maximum, mean and minimum thickness, inner and outer table differentiation, and diploe presence and morphology (including thickness and pattern of diploe distribution, measured with the aid of the digital microscope). These data, including more than 300 micrographs of internal bone structure, were used to illustrate the progression and character of diploe development and generate a topographic map of cranial and diploe thickness and development across age groups. Digital macroscopic and microscopic images of cranial fracture locations from seven Radford University Forensic Science Institute cases involving non-accidental pediatric BFT were compared to the topographic map data to test the above hypothesis.

Results indicate the absence of a three-layered cranial architecture until 4-6 months of age, when initial development of diploe combined with differentiation of inner and outer tables can be noted in the posterior parietal/superior occipital. By 9-12 months, this has expanded to include other buttressed areas of the frontal and occipital crest and pterion. Development of the three-layered structure lags behind at fontanelles and sutures as well as lateral vault walls. A more mature (adult) cranial architecture pattern is not seen until 8 years of age. Although based on a small sample, comparison of forensic case fracture locations with mapped cranial fracture high-risk BFT impact regions across the growing juvenile cranium shows a concordance, supporting the above hypothesis.

These findings illustrate the importance of the growing juvenile cranium's bony architecture on BFT risk and outcome, add to the understanding of intrinsic variables which influence fracture from pediatric BFT, and offer avenues for possible preventive-based education regarding pediatric mortality.

Cranial Architecture, Pediatric, Blunt Force Trauma

A129 Reexamining Differences in the Rate of Decomposition Between Previously Frozen and Never Frozen Human Remains Using the Accumulated Decomposition Score (ADS)

Shelby Garza, BSc, 5506 Christina Path, San Antonio, TX 78247-6611; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will have a greater understanding of how freezing affects the rate of decomposition in human remains in an outdoor setting.

This presentation will impact the forensic science community by adding to the ongoing research being conducted involving the post-thaw effect on human decomposition.

Understanding how the freezing of human remains prior to decomposition affects the rate of decay is important in a forensic setting. Bodies can be frozen due to low outside ambient temperatures or intentionally frozen before being relocated in homicide cases. There are also instances in which taphonomic research facilities need to freeze remains prior to decomposition.

There have been mixed results in studies that examine the differences in decomposition between remains that were previously frozen, then thawed, and remains that had never been frozen. A previous study by Roberts and Dabbs using the Total Body Score (TBS) method found significant differences in the rate of decomposition between previously frozen and never frozen pigs (*Sus scrofa*), with previously frozen subjects decomposing at a slower rate.[1,2] A study recently conducted using human remains and TBS found no significant difference in the rate of decomposition between previously frozen and never frozen subjects.[3] The purpose of this study is to reexamine the difference in decomposition between human remains that had been frozen, then thawed, and human remains that had never been frozen using a newly developed gross morphological method known as the ADS.[4]

For this study, a total of 20 human remains that had been left to decompose in an outdoor setting at the Forensic Anthropology Center at Texas State were used. Ten of the donations had previously been frozen and were pair-matched to remains that had never been frozen using Body Mass Index (BMI) and season of placement. All remains were placed unclothed and on the ground surface under a wire cage to prevent scavenging. An ADS was calculated for each subject at approximately 100, 300, and 500 Accumulated Degree Days (ADD).

An *F*-Test was conducted to explore the homogeneity of variance between groups. Results for both 100 and 300 ADD indicated no statistical difference in variance of ADS between groups ($F(1, 18)$=0.354, p=0.069; $F(1, 18)$=0.567, p=0.205); however, results for 500 ADD indicate there is a statistical difference in variance between groups ($F(1, 18)$=0.295, p=0.042). A two-tailed *t*-test of equal variance was run to test for significance in 100 and 300 ADD, while a two-tailed *t*-test of unequal variance was run for 500 ADD. The P value states that there is no significant difference between groups at 100, 300, and 500 ADD.

This research validates the previously documented results that there is no significant difference in the rate of decomposition between human remains that had previously been frozen, then thawed, and human remains that had never been frozen.

Research reported in this presentation was partially supported by a National Institute of Justice grant. The content is solely the responsibility of the author and does not necessarily represent the official views of the National Institute of Justice.

Decomposition, Frozen, ADS

A130 Assessing the Utility of Total Body Score (TBS) and Accumulated Degree Days (ADD) for Estimating Postmortem Interval (PMI) in Clothed Vulture-Scavenged Human Remains

Krystle Lewis, BS, 601 University Drive, San Marcos, TX 78666; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will have a better understanding of how clothing and vulture scavenging can affect the estimation of PMI.

This presentation will impact the forensic science community by demonstrating the accuracy of employing TBS and ADD to estimate PMI for clothed vulture-scavenged remains.

As taphonomic agents, animal scavengers have the potential to affect the discovery, recovery rate, and estimations of PMI in medicolegal death investigations; however, very little is known about the effects of vulture scavenging on the estimation of PMI when using the TBS to calculate the ADD.[2] The performed study observed clothed human bodies that were exposed to vulture scavenging to examine the effects of vulture scavenging on the estimation of the PMI. It is hypothesized that vulture scavenging of clothed human remains would cause a significant overestimate of the PMI when using TBS.

Five clothed individuals were dressed in white cotton T-shirts, blue denim jeans, white socks, and black tennis shoes. These clothing items are representative of "common" clothing found on deceased individuals from medicolegal investigations, including border crossers.[1] The bodies were placed in an open field for a period of approximately six weeks. Vulture scavenging was verified using motion detector cameras. After completion of the study, data related to estimating the PMI was collected by calculating ADD and determining TBS using the Megyesi et al. method.[2] Local temperature data was gathered from Weather Underground to calculate known ADD from the day of placement to the end of the study period. TBS scores of the head, torso, and limbs were subsequently assessed through photographs. The legs were scored by removing the jeans, if still on the body. The TBS was used to calculate estimated ADD using the Megyesi et al. formula.[2] Both bias and inaccuracy were examined. Bias provided information regarding whether the Megyesi et al. equation systematically under- or over-estimated the ADD/PMI for each individual.[2] The examination of inaccuracy provided information regarding how accurately the Megyesi et al. equation estimates the actual PMI that has elapsed for clothed and vulture-scavenged individuals.[2] A Pearson correlation test and Spearman's rank correlation test were used to evaluate the relationship between estimated and known ADD/PMI.

Results of the Pearson correlation test yielded a correlation coefficient of -0.47, and results of the Spearman's rank correlation test yielded a correlation coefficient of 0.50. Bias was determined to be -1,318.8, while inaccuracy was determined to be 1,318.8 These results suggest that the Megyesi et al. method greatly overestimates ADD, and therefore is not a reliable method for assessing PMI in clothed vulture-scavenged individuals.[2] There was also a low correlation between the estimated and known ADD for these five individuals. Future studies should look at developing a correction in order to properly estimate PMI in clothed, vulture-scavenged remains.

Forensic Sciences, Forensic Anthropology, Taphonomy

A131 A Quantitative Approach to Estimating the Postmortem Interval (PMI) Using Histotaphonomy

Ann H. Ross, PhD, North Carolina State University, Dept of Biological Sciences, Campus Box 7617, Raleigh, NC 27695-7614; and Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695*

After attending this presentation, attendees will be better acquainted with how the specific depositions studied influence histotaphonomy.

This presentation will impact the forensic science community by presenting a model to quantify PMI.

Thirty-one *Sus scrofa* (16 juvenile and 15 fetal) fresh remains were obtained from the North Carolina State University (NCSU) swine farm in the summer, fall, winter, and spring months for two years (2013-2015). The traditional calendar for the start of each season was used as the initial day of placement. Juvenile pigs were used as a proxy for human children up to 9 years of age (35-50 pounds) and fetal pigs were used as a proxy for human neonatal remains (4-6 pounds). Each season, one juvenile pig was placed on the surface and one was buried, and one fetal pig was placed in a plastic bag and one fetal pig was wrapped in a baby blanket. All surface remains were enclosed in cages to prevent scavenging.

Histological thick sections were prepared from a femur midshaft from each of the pigs (n=31). Preparation of the histological samples followed published methods. One-millimeter-thick sections were produced using a Buehler™ IsoMet™ 1000 saw with a 15 HC diamond-edged blade. Each thick-section wafer was ground to a final thickness of 75µm-50µm on a Buehler™ variable-speed grinding unit with a diamond disc. Each thin-section was mounted on a glass slide with cover slip using SECUREMOUNT® mounting media. Histological sections were evaluated using a standard brightfield light as it produced better results than the recommended polarized light in order to assess the degree of diagenetic change and the Histological Index (HI) was employed as described by Hedges and Millard.[1]

Accumulated Degree Days (ADD) were calculated from daily maximum and minimum temperatures with data obtained from the State Climate Office of North Carolina Lake Wheeler Road Field Lab weather station located one-half mile from the open-air site. For the buried remains, ADD was calculated by summing soil temperature as minimum and maximum soil temperatures were not collected.

A destructive degradation model, which is used to model product deterioration over time, was applied using a loglogistic distribution (with the lowest Bayesian Information Criterion or BIC), which is more appropriate for decomposition studies that exhibit logistic patterns, to examine the relationship between the response or degradation measure (HI) and time variable (ADD). Statistical analysis was performed using JMP® Pro 12.1. Results reveal that there is a positive linear relationship between HI and ADD for all depositions. For the bagged fetal remains, there is a 67% probability that the HI score will be 1.5 at 2153.85 ADD, and for the blanketed fetal remains, there is a 70% probability that the HI score will be 2 at 2153.85 ADD. For the buried juvenile remains, there is a 69% probability that the HI score will be 2 at 7153.78 ADD, and for the juvenile surface remains, there is a 47% probability that the HI score will be 2.5 at 2153.85 ADD.

This project was supported by a National Institute of Justice grant.

PMI, Histology, Taphonomy

A132 Microbiome of Forensically Important Flies (Diptera) Associated With Human Cadavers

Sibyl R. Bucheli, PhD, Sam Houston State University, Dept of Biological Sciences, Box 2116, Huntsville, TX 77340; and Aaron M. Lynne, PhD, 1900 Avenue I, Box 2116, LDB #300, Huntsville, TX 77341*

After attending this presentation, attendees will better understand how insects influence the tempo and mode of decomposition by introducing the fly-borne bacteria genera *Ignatzschineria* and *Wohlfahrtiimona* to a cadaver ecosystem.

This presentation will impact the forensic science community by providing information to a very poorly understood microbial ecology. Ultimately, bacterial data such as these can be incorporated to develop a model of microbial succession that can be used to more precisely determine the Postmortem Interval (PMI).

The tempo and mode of human decomposition depends on the conditions of the body at death as well as conditions of the biotic and abiotic environment.[1,2] Decomposition is greatly influenced by microbial interactions, but very little is understood of the bacterial biodiversity of a human cadaver.[3-6]

Flies (Diptera) arrive during the earliest stages of decomposition and have been recorded colonizing the corpse within minutes of death.[2] Therefore, they may be significant in establishing a cadaver-specific microbiome.[5] Understanding the ecology of flies and bacteria may allow for a more precise estimation of the PMI. Flies that colonize cadavers during decomposition may contribute to tempo and mode of decomposition by introducing bacteria to the ecosystem.[5] This study investigates the fly/cadaver microbiome by targeting specific organs of the fly that come in contact with cadavers.

Human cadavers were placed outdoors to decompose under natural conditions at the Southeast Texas Applied Forensic Science (STAFS) facility (a willed body-donation facility) at the Center for Biological Field Studies (CBFS), Sam Houston State University, Huntsville, TX. The first 40 flies visiting each cadaver were collected, identified, and dissected. The tarsi, labellum, and ovipositor were targeted to assess bacterial diversity. Sample processing, 16S recombinant DNA (rRNA) gene amplification, and Illumina® sequencing were performed following protocols benchmarked as part of the Human Microbiome Project.[7] The 16S data were processed and analyzed using the QIIME™ analysis package version 1.9.1.[8] Samples were grouped according to body site, cadaver of origin, and accumulated degree days. Special attention was paid to bacteria that had only been recorded in association with flies previously.

Site samples reveal an abundance of bacteria on the labellum, tarsi, and oocytes. Bacteria community structure seems to be most influenced by season of collection and not by fly organ (site of collection). Bacteria in the genera *Ignatzschineria* and *Wohlfahrtiimonas* were found on all three fly organs. These bacteria have been previously isolated from maggots found infesting live human tissues (myiasis) and recorded during decomposition of humans, particularly during the wet stages. These bacteria may contribute significantly to wet stages of decomposition. Additionally, there is a difference in diversity and abundance for seasons and fly sites sampled, indicating there is a unique microbiome on flies, changing across seasons and addition to years.

Human Decomposition, Forensic Entomology, Microbiome

A133 The Effects of Hydrochloric Acid on Fleshed Porcine Ribs

Amaretta J. Azevedo, MA, University of Califonria, Riverside, 900 University Avenue, Anthropology Dept, Riverside, CA 92521*

The goal of this study was to examine the effects of two concentrations of hydrochloric acid (14.50% and 31.45%) on fleshed porcine ribs and determine if environmental factors such as access to oxygen, agitation, availability of fresh acid, and ambient temperature affect the rate of dissolution.

This presentation will impact the forensic science community by providing a discussion of the importance of understanding the effects of hydrochloric acid and the factors that impact the dissolution of human remains to anticipate how the presence of corrosive chemicals will impact an investigation and to recognize the skeletal changes associated with exposure to hydrochloric acid as a taphonomic agent versus other potential postmortem agents.

Over the years, anthropologists and other forensic experts have been asked to assist with cases in which the perpetrator(s) used corrosive chemicals in an attempt to dissolve a body and other evidence of a crime. Previous studies indicate there are a number of corrosive chemicals capable of dissolving organic tissues, but hydrochloric acid is by far one of the most detrimental chemicals capable of dissolving organic tissue.[1-3] Although it is not a frequently used method, cases in which remains have either been severely damaged or completely destroyed by corrosive chemicals in an attempt to prevent the identification of the victim present unusual challenges for forensic experts.[1,4]

A total of 104 rib samples two to three inches long were placed in 100mL of acid for six days with controls in air and water. Eight samples were placed into an incubator that remained at an average temperature of 85°F throughout the experiment. Ambient and liquid temperatures were monitored and recorded in addition to observations at set intervals throughout the experiment, and the percentage of mass lost was calculated after six days.

The results from this study reveal that hydrochloric acid with a concentration of 31.45% was capable of dissolving macerated remains in less than 24 hours; however, in the case of the lower concentration of 14.50% hydrochloric acid, the acid was not capable of fully dissolving the macerated remains in less than 24 hours. When the remains were fleshed, this delayed bone dissolution by anywhere from 12 (31.45% HCl) to 24 (14.50% HCl) hours. Remains in a sealed container dissolved at a slower rate than those in an open container, indicating that access to oxygen affects the rate of dissolution. Agitating the sample quickened dissolution, and refilling the container with fresh acid delayed dissolution. In addition, it appears that temperature has the potential to impact the degree of dissolution, since samples that were placed in a heated environment were more decimated than those left at room temperature.

One thing is certain: the process of successfully dissolving a body in acid is a very complicated matter. It is important for anthropologists and other forensic experts to understand the effects of hydrochloric acid and the factors that impact the dissolution of human remains to anticipate how the presence of corrosive chemicals will impact their investigations. The effects of specific corrosive chemicals on bone need to be standardized using larger samples over longer durations in order to understand the skeletal changes associated with exposure to hydrochloric acid as a taphonomic agent versus other potential postmortem agents.[3] In addition, studying the differences between agitated and unagitated samples and the differences between refilled and unrefilled samples is important for reconstructing postmortem events and may help investigators understand the amount of effort a perpetrator(s) invested in concealing their crime. Future studies should involve a more thorough examination of the effects of temperature and involve the use of larger, completely fleshed body segments, if not complete pigs.

A134 Sex Estimation Based on Analysis of the Enamel Proteome

Julia Yip, BS, University of California, Davis, One Shieds Avenue, Davis, CA 95616; Michelle Salemi, MS, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Brett Phinney, PhD, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Jelmer Eerkens, PhD, University of California, Davis, One Shieds Avenue, Davis, CA 95616; and Glendon Parker, PhD, University of California, Davis, 4421 Ashwood Common, Fremont, CA 94538*

After attending this presentation, attendees will better understand the use of the tooth enamel proteome in human sex estimation that could be applied to a broad range of samples.

This presentation will impact the forensic science community by offering an alternate approach to estimate sex in a statistically rigorous and scientifically quantifiable manner. This approach can be applied to deciduous teeth and to teeth from degraded skeletal remains.

Sex estimation is necessary to place skeletal remains in forensic context. The current field of forensic anthropology relies on two basic methods to estimate sex in skeletal remains: analysis of sex-specific osteological markers and detection of DNA markers specific to the X- and Y-chromosomes; however, sexually dimorphic osteological markers may be missing when not developed in sub-adult skeletons or degraded by environmental processes. Detection of DNA markers from X- and Y-chromosomes is more direct and predictive; however, the DNA backbone contains phosphodiester bonds and can easily degrade below the point at which it can be amplified. Therefore, this analysis is not often available.

Amelogenin genes on the X- and Y-chromosomes are expressed as protein in teeth and play a major role in the biosynthesis of enamel. Protein is more stable than DNA and can persist in skeletal elements well after DNA degrades. Enamel is also the most robust and archaeologically persistent tissue in the body. Detection of peptides unique to the Y-chromosome form of amelogenin protein (AMELY_ Human) in the enamel proteome is an unambiguous signal for the presence of Y-chromosome in the sample.

In this study, archaeological and modern teeth samples were processed. The enamel was demineralized in 1.2M hydrochloric acid, pH neutralized, alkylated, and treated with trypsin and mass-spectrometry compatible detergent. The resulting data collected from the mass spectrometer was analyzed using PEAKS™ analytical software.

This study measured the peptide ion signals that were specific to the AMELX_HUMAN and AMELY_HUMAN protein. After being normalized for enamel mass, the specific ion signals were plotted onto a Cartesian graph and a calibration curve was established. The curve revealed a clear male cluster, a female cluster, and a cluster of male false negatives. The range of values ranged widely across different samples, up to three orders of magnitude. Nevertheless, the male values for AMELY_HUMAN protein had a linear correlation with AMELX_HUMAN values, the R squared value was 0.88 (p >0.001) and a co-efficient of 0.17. To validate the calibration curve, this study processed 1,000-year-old archaeological deciduous teeth and was able to see clustering with male samples. Detection of the Y-chromosome AMELY_HUMAN is an unambiguous indicator of male sex; however, the lack of detectable AMELY_HUMAN protein could be either a male false negative or due to female sex. The likelihood of false negative assignment will reduce as the AMELX_HUMAN signal increases. This approach has the potential to evaluate sex estimation in a statistically rigorous and a scientifically quantifiable manner. It also has the potential to be applied to skeletons with no osteological markers for sex, such as degraded or juvenile skeletal assemblages.

Sex Estimation, Enamel, Proteomics

A135 Visualizing Commingling in the Korean War Project Assemblage

Caitlyn Estanique, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816; and Sarah M. Richer, PhD, Defense POW/MIA Accounting Agency, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will be able to visualize the distinct form of large-scale commingling represented by the Korean War Project.

This presentation will impact the forensic science community by providing a novel manner to comprehend extensive commingling and discern patterns within data. A greater understanding of the commingling represented by identified individuals will provide important information for future identification efforts.

Commingling is the intermixing of human remains from multiple individuals and is often seen with the mixing of graves and mass fatality incidents.[1] The inherent challenges of commingling are compounded as the number of individuals and the degree of fragmentation increase; additional actions that result in disarticulation of elements further complicate forensic analysis.[2] Current anthropological methods to resolve commingling include the use of DNA and osteometric sorting.[3-6] Additionally, spatial mapping has been used to visualize the relative proximity of remains to determine associated elements.[7] At the Defense POW/MIA Accounting Agency (DPAA), it is critical to accurately resolve commingling to fulfill the mission to provide the fullest possible accounting of service members to their families and the nation.

The Korean War (1950-1953) resulted in 103,284 wounded and 36,574 killed; as of July 2017, there are approximately 7,800 unaccounted-for servicemen.[8] The Korean War Project consists of 208 boxes unilaterally turned over by the North Korean government between 1990 and 1994 and a further 124 boxes from Joint Recovery Operations (JRO) obtained between 1996 to 2005. The North Koreans provided an original location of each of the K208 boxes. The majority of the accessions originated in four areas: two POW camps (Suan, 97 boxes, and Camp 5, 21 boxes) and two battlefield losses (East Chosin, 47 boxes, and Unsan, 23 boxes). The remaining 20 boxes were purported to be from the demilitarized zone (DMZ) and North Korean coastal locations.[4] The JRO boxes originated mainly from Unsan (84 boxes) and East Chosin (28 boxes) locations; 12 boxes were from other locations. Initially, it was believed that each K208 box represented a single serviceman, but early analysis revealed that the majority of the boxes contained multiple individuals. Of the identifications made to date, the most commingled box has a Minimum Number of Individuals (MNI) of 24; the average number of individuals per box is 8.28 for the K208 accessions and 3.05 for the JRO boxes. For the assemblage as a whole, it is estimated MNI is approximately 600.[4]

Although the commingling of the Korean War Project is extensive, it is hypothesized that patterns would be present. It was expected that most of the commingling would be seen within the village/location. Where commingling occurred between K208 boxes and JRO accessions, it was anticipated that this would follow along location lines.

Identified individuals from the Korean War Project were assessed to identify commingling. Accession numbers were noted and tallies were made by purported village. A table was created and input into Circos software package to produce a circular representation of the data.[9] Analysis revealed somewhat unexpected results. For the majority of locations, commingling was higher within the village as expected; however, Suan Mining Camp and Okchi-ri revealed higher levels of commingling with boxes reported as coming from other localities (although still within the general Suan POW camp system). The commingling between the K208 boxes and the JRO accessions was seen across all regions. With the Unsan JRO boxes, anticipated commingling was seen with the Unsan K208 accessions, but also with accessions from Suan POW camp, East Chosin, Camp 5, the DMZ, and coastal regions.

The commingling observed in the Korea War Project directly affects and complicates the DPAA's mission to identify and return United States service members to their families. This presentation reports on the application of Circos software to anthropological research, demonstrating it is a useful tool to visualize large-scale commingling. Gaining a greater understanding of commingling present in the Korea War Project assemblage will aid the DPAA with further identifications.

Chapman Drive, 370 Plant Biotechnology Bldg, Knoxville, TN 37996; Gary Phillips, MS, University of Tennessee, 2505 E.J. Chapman Drive, 370 Plant Biotechnology Bldg, Knoxville, TN 37996; Ernest C. Bernard, PhD, University of Tennessee, 2505 E.J. Chapman Drive, 370 Plant Biotechnology Bldg, Knoxville, TN 37996; and Amy Z. Mundorff, PhD, University of Tennessee - Anthropology, 1621 Cumberland Avenue, 502A Strong Hall, Knoxville, TN 37996-1525*

After attending this presentation, attendees will have learned the differences in soil chemistry resulting from human decomposition. This presentation will increase attendees' knowledge of human decomposition processes, particularly as they pertain to the soil environment. This presentation will allow attendees to understand the differences in soil biology and biogeochemistry at different depth points in a human grave.

This presentation will impact the forensic science community by increasing understanding of variables related to postmortem interval estimation, burial location/site disturbance, and human skeletal DNA degradation. Therefore, this research is expected to inform models or practices relating to such areas.

Soil is a dynamic environment with multiple interacting physiochemical (pH, moisture, ion exchange capacities, redox potentials, and oxygen content) and biological processes (microbial communities).[1] These interacting features constrain cadaver decomposition within a burial environment; however, it is unknown how soil chemistry and biology differ at different depths within a human grave. Results may have significant implications for assessing skeletal degradation (or preservation) within a burial environment.

A burial containing three individuals was interred for four years prior to initiating this research. Soil samples were collected during disinterment at four depths surrounding the bodies within the grave: 0-5cm (surface; above interred individuals); 30-35cm (level with the shallowest bones); 70cm-75cm (base/floor of the grave); and 85-90cm (below the grave). Control samples were collected from undisturbed ground 5m away from the grave as well as from a control grave that had been excavated and backfilled without bodies simultaneous to interment. All soils were analyzed for microbial respiration, pH, conductivity, nitrate (NO_3^-), nitrification potential, NH_4^+, Dissolved Organic Nitrogen (DON) and Dissolved Organic Carbon (DOC), as well as extracellular enzymes (Leucine Aminopeptidase (LAP); N-Acetyl-β-Glucosaminidase (NAG); Phosphodiesterase (PDE); β-D-Cellulobiosidase (CB)). Bacterial (16S recombinant DNA (rRNA) gene) and fungal (ITS gene) abundances were quantified using quantitative Polymerase Chain Reaction (qPCR) and universal primers. Nematodes were also extracted from soil samples to assess population dynamics.

The soil at the base of the grave (70cm-75cm) exhibited significantly elevated microbial respiration rates, elevated DOC, DON, NH_4^+, soil gravimetric moisture, conductivity, and pH compared to surface and 30cm-35cm samples. Nitrification potential and NO_3^- were elevated at 30cm-35cm compared to surface or base-of-grave samples. There was a significant change in NAG enzymatic activity throughout the grave, with the greatest values measured at the base of the grave, indicative of microbial turnover. A mixed soil and adipocere sample collected from within the ribcage of an individual contained the highest activity of LAP and PDE enzymes, indicating that within heterogeneous regions of the grave, protein and cell wall degradation persists after four years.

Mean 16S gene abundances, reflective of bacterial presence, decreased with depth from 5.22×10^9 16S rRNA gene abundances at a depth of 0cm-5cm to 5.78×10^7 16S rRNA gene abundances at a depth of 85m-90cm. The presence of fungi initially increased from an average of 7.14×10^8 ITS gene abundances at 0cm-5cm to 2.56×10^9 ITS gene abundances at 70cm-75cm, then proceeded to decrease to 2.01×10^6 ITS gene abundances at 85cm-90cm. Bacterial and fungal gene abundances were highest in the mixed soil/adipocere sample described above (at ~40cm), consistent with persistent biogenic degradation of interred individuals. In addition to changes in bacterial and fungal communities with depth, nematodes demonstrated changes in community diversity, evenness, and richness with depth. Nematode community richness declined with depth, with no detectable nematodes at a depth of 85cm. Nematode evenness was variable within the grave compared with transect soils, and there was a marked shift in community composition toward bacterial and fungal feeders in the mixed soil/adipocere sample.

This study provides a characterization of soil biology and chemistry at different depths within a multi-person grave. Results provide novel insights into environmental changes within a grave that may inform our understanding of postmortem interval estimation, burial location/site disturbance, and human skeletal DNA degradation.

Funding for this project was provided by the National Institute of Justice.

A137 The Effects of Household Corrosive Acids on Restored and Non-Restored Teeth

Brittany M Trapp, BA, Boston University, 72 E Concord Street, Boston, MA 02119; and Sean D. Tallman, PhD, Boston University, Depts of Anatomy and Neurobiology and Anthropology, 72 E Concord Street, L1004, Boston, MA 02118*

The goals of this presentation are to: (1) better understand how various types of household products affect restored and non-restored human dentition; and, (2) better understand how positive identification utilizing radiography is possible after exposure to certain acids and acid concentrations.

This presentation will impact the forensic science community by identifying the various changes to restored and non-restored teeth after exposure to acids, including changes to mass, crown width and length, color, and overall qualitative features. Additionally, this presentation will provide statistical analyses that identify the significant changes to dentition exposed to different household acidic solutions and concentrations.

A gap in the literature exists regarding the chemical effects of household acids at different concentrations on restored and non-restored dentition. While previous studies have focused primarily on how bone, hair, and teeth are affected by acids through quantitative and qualitative changes over 24-hour time periods, few studies utilize radiographic imaging for identification purposes subsequent to acid exposure or extend the acid exposure beyond 24 hours.[1,2] The paucity of information on acid effects is problematic in forensic contexts, as human remains are frequently exposed to acids for concealment purposes, thereby potentially complicating the identification process.

This study utilizes 105 adult human premolars (n=46) and molars (n=59) consisting of restorations composed of silver amalgam (n=62), porcelain fused-to-metal restorations (n=25), and teeth with no restorative material (n=18). All samples were collected from the Body Donation program cadavers at Boston University's Division of Graduate Medical Sciences. The household corrosive chemical agents consisted of hydrochloric acid (Clorox® Bleach Cleaner and The Works®) and sulfuric acid (Drano® Drain Opener and Watchdog® Battery Acid), in addition to one base (Biz® Detergent) as a control. The teeth were radiographed before and after exposure to the various household products to mimic antemortem and postmortem radiographs. Twenty-one teeth were placed in 20mL of each solution and were removed from the solutions throughout the experimental process after 1, 2, 4, 8, 24, 72, 120, and 264 hours. Documentation included mass, Mesiodistal (MD) and Buccolingual (BL) crown measurements, and photography. Additionally, an ordinal scoring system was developed to assess the visual changes after exposure to the acids.

The results indicate that 86 (82%) of the teeth could be positively identified by radiographs after exposure to the acids. The Works®, which is 20% concentrated hydrochloric acid, resulted in the most destruction and deteriorated 68% of the teeth (mainly the silver amalgam and non-restored dentition). The enamel, dentin, and pulp cavity of these teeth suffered liquefaction. The only dentition that was positively identified after exposure to the Works® were those of porcelain fused-to-metal. Only 28% of this sample were positively identified by radiographs. The Watchdog® Battery Acid, which is 51% concentrated sulfuric acid, was the next most-destructive solution and deteriorated 8% of the teeth (mainly silver amalgam and non-restored dentition). Most of the enamel and parts of the dentin were affected, while the pulp cavity remained intact. Further, 75% of the teeth were positively identified after exposure to the battery acid. The mass, MD, and BL measurements all decreased dramatically for the teeth that were exposed to hydrochloric and sulfuric products. Exposure to Clorox® Bleach Cleaner, which is 8.25% concentrated hydrochloric acid, and Drano® Drain Opener, which is 93.2% sulfuric acid, resulted in minimal damage to the teeth, with 100% of the teeth positively identified by radiographs after exposure. Only the outermost enamel was affected by these two solutions. The mass, MD, and BL lengths slightly decreased in size after exposure to Clorox® and Drano®. Exposure to Biz® Detergent, which is commonly used in maceration, had no effect on the teeth, with 100% positively identified by radiographs, and minimal mass, BL, and MD size decreases.

The results of this study demonstrate that various household corrosive substances can affect the morphology of teeth, and in some cases, destroy teeth, which could mask the identification of an individual; however, the restorations were minimally affected by corrosive agents and can therefore be used for positive identifications. Thus, the quantitative and qualitative data produced from this study can aid forensic cases that display evidence of acidic modification.

Dentition, Household Acid Exposure, Identity Concealment

A138 Differential Recovery Rates of Skeletonized Human Remains

Rhian Dunn, BA, 4135 Briggs Avenue, Erie, PA 16504; Dorianis Perez, BS*, 407 East Avenue, Erie, PA 16507; Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC #218, Topeka, KS 66621; and Dennis C. Dirkmaat, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will better understand the differential recovery rates of human skeletonized remains encountered in outdoor forensic contexts with and without the assistance of forensic anthropologists.

This presentation will impact the forensic science community by demonstrating the utility of incorporating forensic anthropologists into the recovery phase of outdoor forensic scenes.

The field of forensic anthropology has historically been a lab-based discipline, often with law enforcement dropping off a box of bones at the forensic anthropologist's laboratory. The anthropologist's sole role was typically restricted to estimating a biological profile for identification. The field remained largely lab-based until the 1990s, when the rise of forensic archaeology and forensic taphonomy changed the role of forensic anthropologists. Dirkmaat and colleagues suggest that these two developments, along with DNA Polymerase Chain Reaction (PCR), the *Daubert* ruling, forensic trauma analysis, and improvement in quantitative methods, have significantly altered the trajectory of forensic anthropology within the past three decades.[1] Dirkmaat et al. said it best when they noted that "today less than at any point in the past, forensic anthropologists cannot be considered forensic 'sidekicks,' who may be useful advisors when forensic pathologists or law enforcement step into an unusual case or situation, but the most appropriate, and most logical first choice professionals in cases involving all manner of outdoor crime scenes and commingled or severely altered human remains."[1] This study hypothesized that the higher rate of evidence recovery by these experts conducted in a timely fashion surpasses those efforts conducted of law enforcement and coroner/medical examiner officials and, ultimately, significantly benefits the investigation. The primary purpose of this research was to compare recovery rates of skeletonized human remains from outdoor contexts between forensic anthropologists, who are extensively trained in human osteology and in recognizing taphonomically altered bone, versus recovery rates by law enforcement and coroners/medical examiners. The ultimate goal of this research is to demonstrate the value of incorporating forensic anthropologists into the recovery phase, especially in outdoor scenes where remains are often heavily modified by taphonomic agents.

A total of 56 cases were identified from 40 years of forensic casework contained within the Mercyhurst Forensic Case Database and conducted by Dr. Dennis Dirkmaat. Only cases that were completely skeletonized and recovered from outdoor contexts were included in this research. Approximately 60% (n=33) of these cases were recovered by forensic anthropologists, Dr. Dirkmaat and his Mercyhurst Forensic Scene Recovery Team, while the remaining 40% (n=23) of cases were recovered by law enforcement or medical examiner/coroner's offices. The skeletal inventory for each of these cases were charted in homunculi diagrams of the anterior view of the body, then layered to generate density maps using a Geographic Information System (GIS). Each skeletal element was coded as present or absent and bones that were present were further coded into fragmentary versus complete elements to compare recovery rates. For the cases recovered by forensic anthropologists, the recovery rates of burial versus surface-scattered remains were also compared with consideration given to the Postmortem Interval (PMI).

When skeletal elements were analyzed by type or skeletal region (for example, long bones, hands/feet, ribs, vertebrae, skull, upper limb, and lower limb), the forensic anthropology team recovered a higher percentage of total elements than the police/coroner/medical examiner, with the exception of the lower limb and rib fragments. Of note, the forensic anthropology team recovered a higher percentage of the crania, mandible, and pelvis (innominates and sacrum), which is especially important given that these elements are the most informative for estimating ancestry, sex, and age from human skeletal remains. For the forensic anthropology cases, higher recovery rates were found for all regions and bone type in surface-scattered remains, with the exceptions of the small bones of the hands and feet, when compared to recoveries from burial features. The results are not surprising given that the average known PMI for burial cases was 9.3 years, while for surface scatters, the average PMI was only 3.2 years. In conclusion, the incorporation of the forensic anthropologists into the recovery phase of outdoor scenes results in a higher recovery rate of nearly all skeletal elements/regions and especially those areas of the body that are most informative for estimation of the biological profile.

Forensic Archaeology, Recovery, Skeletal Remains

A139 Fracture Pattern Comparison Between Pig and Human Crania Cremated on an Open-Air Pyre

Lisa Monetti, University College London, Institute of Archaeology, 31-34 Gordon Square, London WC1H0PY, UNITED KINGDOM; and Carolyn Rando, PhD, University College London, Institute of Archaeology, 31-34 Gordon Square, London WC1H 0PY, UNITED KINGDOM*

After attending this presentation, attendees will understand the differences in fracture patterns between pig and human cranial cremains. Attendees will understand the need for future research on human analogues before further cremation studies using pigs are undertaken.

This presentation will impact the forensic science community by addressing a current problem in cremation studies using pigs (*sus scrofa domesticus*) as human analogues. It will assist future researchers in establishing suitable proxies for humans in cremation studies and hopefully promote increased usage of human remains in such experimental studies. These future studies will allow forensic scientists to understand the process of cremation to a fuller extent and help with forensic cases involving cremated or partially cremated remains.

While fully cremated remains are not frequently encountered by forensic specialists, it is highly common for burnt/partially cremated remains to be discovered as part of a crime investigation; when these fragmentary remains are discovered, they can be extremely difficult to interpret and analyze. Cremation (even partial cremation) can obscure a great deal of information that the forensic scientist is familiar with using for purposes of identification, such as estimation of Postmortem Interval (PMI) or Minimum Number of Individuals (MNI) present. For primarily ethical reasons, animal analogues are frequently used in cremation experiments wherein researchers attempt to develop methods for better interpreting cremated human remains.[1,2] The literature on cremations has yet to establish whether animals are appropriate proxies for humans, and whether the patterns observed on animals can be accurately and comprehensively applied to humans. To address the absence of research in this area, the present study attempted to identify fracture pattern differences between pig and human crania through a comparison of experimentally created pig cremains and archaeological human cremains.

This study used both archaeological cremains from Roman Britain and pig crania cremated on an open-air pyre, constructed to replicate a Roman pyre.[3,4] Two pig crania were cremated together over a 4-hour period, reaching temperatures exceeding 800ºC, therefore reaching the fusion stage of cremation.[5] The resulting cremains were left to cool and were photographed and weighed.

The archaeological human cremains and pig cremains were analyzed using the same protocol. The photos were uploaded to ImageJ, where the surface area of the fragments was measured along with areas of patina and delamination. Additionally, fractures were counted for each fragment. A total of 248 specimens of pigs and adult humans were analyzed. When measured, each feature (patina, delamination, fracture count) was divided by the total surface area, creating a ratio that allowed fragment size to not affect the results.

Ultimately, it was observed that the pig and human cranial bones were affected differently by the open-air pyre cremation. Pig cranial cremains demonstrated more delamination per mm^2 than the human cranial cremains. Human cranial cremains exhibited more patina than pig cranial cremains. A greater number of fractures were present in human cranial cremains than pig cranial cremains.

The results observed in this small study suggest that pig crania should not be used in experimental cremation studies as a human analogue. Further studies should be conducted to test the similarities of human and pig post-cranial cremains, as well as the usefulness of other animals as human analogues. The researchers suggest that future studies on cremation processes be conducted on human subjects in crematorium or taphonomic facility settings.

A140 Postmortem Interval (PMI) Estimation Using Bone Lipidomics

Beatrix Dudzik, PhD, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Natalie R. Langley, PhD, Mayo Clinic School of Medicine, Dept of Anatomy, 13400 E Shea Boulevard, SC-AB-01-313B, Scottsdale, AZ 85259; Lee Meadows Jantz, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Knoxville, TN 37996-1525; Johnny E. Cebak, PhD, Lincoln Memorial University, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and Paul Wood, PhD, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752*

After attending this presentation, attendees will understand the potential of lipids in marrow cavities and epiphyses for predicting PMI of skeletal remains.

This presentation will impact the forensic science community by providing preliminary data on lipidomic techniques for estimating PMI in skeletonized human remains that are more precise and accurate than gross observations of taphonomic processes.

Common methods for estimating PMI of skeletonized remains are qualitative observations of taphonomic processes, such as bone weathering, staining, sun bleaching, and cortical exfoliation.[1,2] Histological techniques are available but not well validated due to variation caused by microbes.[3,4] Bone degradation garners interest as a means of predicting time since death, yet controlled experimental studies on human remains are limited in the scientific literature.

Successful lipid fraction of bone has been reported in forensic toxicology and archaeology research, but few studies describe the capacity of this methodology for estimating PMI.[5] It has been demonstrated that glycerophospholipids and very long chain fatty acids in the membranes of skeletal muscle tissue accurately predict long-term PMIs up to 30,000 accumulated degree days.[6,7] Lipids are abundant biomolecules with powerful predictive capacity for PMI.

Bone marrow is a rich source of lipid mediators. N-acyl amino acids are one class of lipid mediator monitored in bone, and they also modulate bone metabolism in the case of oleoyl serine. A pilot study was conducted to investigate the diversity of N-acyl amino acids in human bone. Bone marrow was extracted from trabecular bone in a dry human calcaneus with a PMI of approximately seven years. Utilizing a high-resolution electrospray ionization lipidomics analytical platform, 76 potential N-acyl amino acids were identified in the bone marrow sample.[8] The structural identities of these lipids are undergoing validation utilizing tandem mass spectrometry. The structural identities of palmitoyl and oleoyl serine were validated via generation of the MS^2 product ion for serine (<1ppm mass error). The number of lipids identified in the extracted bone marrow support the findings of toxicological studies reporting lipid extraction in skeletonized remains with a PMI of up to five years.[9] The results of this pilot study are being used to evaluate the postmortem metabolism of lipid mediators on an autopsy sample of sternal rib ends and vertebral bodies from cases with known medical histories and PMI.

This study expands previous research on skeletal muscle metabolites to bone, providing a quantitative method for estimating PMI of skeletonized remains. Successful bone lipid extraction after an interval of seven years provides preliminary data that will be used to validate a methodology for predicting PMI of severely decomposed, mummified, and skeletal remains with greater precision and accuracy.

Postmortem Interval, Forensic Anthropology, Lipidomics

A141 A Method for the 3D Restoration of Fragmented Human Crania for Trauma Analysis

Teresa V. Wilson, PhD, Louisiana State University, 227 Howe-Russell Geoscience Complex, Baton Rouge, LA 70803*

After attending this presentation, attendees will better understand how 3D technologies can be used to reconstruct and assess traumatic skull injuries in forensic cases.

This presentation will impact the forensic science community by providing a method for visualizing trauma in skeletal material that is fragile and heavily fragmented. This presentation will demonstrate how 3D scanning and polygon manipulation can be used to assist in skeletal analysis and to communicate anthropological findings in situations ranging from the classroom to the courtroom.

When a forensic anthropologist is confronted with heavily fragmented crania, the task of reconstructing the skull for trauma analysis can be difficult. Skulls that are fragmented due to trauma are weakened and susceptible to further damage when reassembled using traditional methods of reconstruction (i.e., glue). The recent prevalence of 3D scanning technology in forensic anthropology laboratories allows for greater access to digital technology to solve problems related to the condition and fragility of remains. The goal of this project is to develop a method to digitally restore a cranium that can be 3D printed or exported as an interactive digital model.

Two crania were selected that had experienced catastrophic blunt force trauma and were heavily fragmented due to fractures and separated sutures. A FARO® Design ScanArm high-definition laser scanner was used to obtain surface scans of the individual fragments. A point cloud and polygon editing software (Geomagic® Wrap) was used to reassemble the individual fragments of each skull. Individual fragments were merged using points of commonality along suture lines and unique points along fracture lines. Both crania exhibited areas of missing bone that were not reconstructed to maintain the accuracy of the models to the source material. Selected cranial measurements that were not affected by the fragmentation were used to test the accuracy of the restored crania. The skull measurements were obtained with calipers and the models were measured using the measurement tool with the 3D software. Each of the 3D cranial measurements tested were within an acceptable error threshold (<1mm) of the caliper measurements. The results revealed a small amount of variation in measurement; however, this may be due inaccuracies and inconsistencies in measuring the crania within the editing software as opposed to traditional calipers.

Both of the test crania had experienced isolated traumatic events that only became apparent after the original manual reconstructions were completed. If this method of 3D digital restoration had been available at the time these cases were being analyzed, the restorations could have been completed with minimal disturbance to the fragments, and a 3D print could have been made. The 3D scans allowed for viewing of the model in a uniform and neutral color for distraction-free texture visualization. The locations, patterns, and behavior of the fractures were easily seen on the bone and permitted the reconstruction of the traumatic events. This technology is a valuable tool that could be used for teaching future generations of forensic anthropologists about trauma analysis as well as demonstrating complex traumatic events in the courtroom.

3D Scanning, Trauma Analysis, Blunt Force Trauma

A142 Influence of a 1.5 Tesla (1.5T) Magnetic Resonance Imaging (MRI) on Ferromagnetic Microtraces

Rianne Groot, Jacob Boekestraat 175, Nieuw Vennep, Noord Holland 2152AH, NETHERLANDS; Paul Hofman, PhD, Maastricht University Medical Center, Dept of Radiology, Maastricht 6202 AZ, NETHERLANDS; Reza R.R. Gerretsen, MD, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague 2497 GB, NETHERLANDS; Mayonne Van Wijk, MSc, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague 2497 GB, NETHERLANDS; Jeroen Kroll, Maastricht University Medical Center, P Deyelaan 25, Maastricht 6229HX, NETHERLANDS; Erwin Vermeij, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague 2497GB, NETHERLANDS; and Steven B.C.G. Chang, MSc, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague 2497GB, NETHERLANDS*

The goal of this presentation is to determine the influence of the external magnetic field of a 1.5T MRI scanner on the location of ferromagnetic microtraces smaller than 0.5mm in and on bone and in soft tissue.

This presentation will impact the forensic science community by explaining how Postmortem Magnetic Resonance Imaging (PMMR) is increasingly used in forensic medical examinations of crime victims.[1] The findings of this study have important implications for the application of PMMR. During autopsy, perforating injuries are measured and the depth of stab wounds are probed. Injuries extending into the bone are excised and examined for the presence of foreign materials. These microtraces are used to reconstruct a crime event, and microtraces may be linked to a specific (class of) object or weapon.[2] The presence of the external magnetic field in PMMR may disturb evidence when human remains contain ferromagnetic microtraces. Knives consisting of steel or contaminated with steel are known to leave ferromagnetic microtraces smaller than 0.5mm in soft tissue, on bone, or even embedded in bone.[2] Translocation may lead to mistakes in reconstructing a crime event. After attending this presentation, attendees will understand the influence the external magnetic field of a 1.5T MRI can have on microtraces.

Hypothesis: Translocation of microtraces smaller than 0.5mm was not expected. Calculations made before the experiments indicated that the magnitude of forces due to friction and gravity would be greater than the magnetic force on the microtraces.

Methods: Pig feet were used to simulate human remains. The samples were cut with a saw that was contaminated with ferromagnetic steel. The samples contained ferromagnetic particles from 0.2mm to 0.7mm. Computed Tomography (CT) and micro-CT were used to determine the coordinates of the position of the ferromagnetic microtraces before and after exposing the specimens to a 1.5T MRI scanner. Paired *t*-tests were used to statistically assess the translocation. Translocation due to the external magnetic field of MRI and translocation due to transportation were determined separately to preclude the possibility that translocation was caused by transportation instead of the external magnetic field of MRI.

Results: No significant translocation of the ferromagnetic microtraces (with a size of 0.2mm to 0.7mm) due to the external magnetic field of a 1.5T MRI scanner was detected (*p*-values: X 0.31, Y 0.11, Z 0.11). Transport of the pig feet between institutions caused a significant movement in one dimension (X-axis) that was detected (*p*-values: X 0.03, Y 0.41, Z 0.88); however, this movement was not relevant for forensic examination.

Conclusion: The use of 1.5T MRI in forensic medical examinations is applicable in the presence of small ferromagnetic fragments no larger than 0.7mm.

Magnetic Resonance Imaging, Microtraces, Translocation

A143 The Incorporation of 3D Photogrammetry and Geophysics in the Recovery of a Mass Grave: Six Years of Experiential Learning

Stephen J. Yerka, MA, 8505 Baron Drive, Knoxville, TN 37923; and Joanne Devlin, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Knoxville, TN 37996*

The goal of this presentation is to provide crime scene investigators and physical anthropologists exposure to innovative field techniques (incorporating 3D photographic survey and geophysical methods) to increase success in identifying and recovering mass graves. In addition to a review of the methods and processes involved, this presentation will provide tips and tricks for minimizing costs and for working in remote locations.

This presentation will impact the forensic science community by explicating cost-effective and efficient field methods for surveying and documenting mass grave recovery projects. The methods in this presentation have been field tested over several years in an applied setting. 3D survey can be prohibitive in the field for several reasons, but the photogrammetry methods presented here are fast, inexpensive, and simple enough so they do not require specialized field personnel. The geophysical procedures, while still requiring trained personnel, are developed in order to reduce time spent excavating "false positives" and for dealing with difficult subsurface matrices.

The forensic community has seen a steady increase in the use of technology as a means of quickly and accurately documenting crime scenes over the past several decades; however, for the recovery of human remains, timing, conditions, and budgetary constraints often preclude successful use of cutting-edge technology in applied field situations. This research focuses on the application of advanced photographic and geophysical surveys as a practical means to bolster documentation accuracy while still keeping costs to a minimum and reducing the need for specialized personnel onsite. Advances in 3D photogrammetry applications and field methods for geophysics are adapted specifically for the recovery of human remains, and are shown to be particularly useful for mass grave recovery.

This presentation details field- and lab-based processing methodologies that can be implemented for the recovery of human remains in a variety of environments and at various project scales. For this research, experimental graves were surveyed using Ground Penetrating Radar (GPR), soil resistivity, and 3D photogrammetry. Most notably, a planned mass grave was surveyed with geophysical techniques periodically over the course of six and one-half years. Established in May of 2010, the irregular-shaped pit is just under four meters across, and geophysical data were collected beginning two years post-interment, so the usual indicators of clandestine graves on the surface were generally obliterated through natural weathering processes.

The area was additionally surveyed for 3D reconstruction both before and after excavation. 3D reconstruction and photogrammetry methods detailed in this presentation utilize commercial-grade cameras that are inexpensive and do not require specialized photographic skills. Point-and-shoot cameras easily and successfully capture sufficient details for digital measurement of less than 1mm. Even higher levels of precision can be reached with cameras that have macro photography settings. Available commercial software and free and open source software allow quick and easy processing and measuring of digital 3D models. Photorealistic textures are generated that add additional precision and measurable values, such as color and texture. Additionally, the 3D reconstructions provide very compelling digital products that can be explored in Virtual Reality (VR) or Augmented Reality (AR) environments.

The photogrammetry procedures detailed in this presentation can be learned easily, quickly, and, in most cases, do not require any additional equipment or personnel; however, the methods do provide a level of detail and accuracy that is equivalent or surpasses what can be obtained through ground-based laser scanning.

Experimental stations are located at the outdoor Anthropological Research Facility at the University of Tennessee, allowing for the unique examination of human remains in a variety of contexts representative of the natural environment. In addition to providing loci for experimental stations, the facility provides opportunities for student engagement and the training of law enforcement officers, thus providing further insight into how well methodologies can be adopted by these communities and informing pedagogical approaches. This presentation will briefly discuss ways that the aforementioned procedures can be incorporated in an experiential learning environment.

3D Photogrammetry, Geophysics, Excavation

A144 An Analysis of Computerized Tomography (CT) -Derived Bone Density Values and Volumetrics for Age and Sex Estimation From the Proximal Femur

Jonathan M. Ford, PhD, Dept of Radiology, 2 Tampa General Circle, STC 7027, Tampa, FL 33606-3571; Todd R. Kumm, MD, USF Health Dept of Radiology, 2 Tampa General Circle, STC7033, Tampa, FL 33606; and Summer J. Decker, PhD*, USF Dept of Radiology, MCOM, 2 Tampa General Circle, STC 7033, Tampa, FL 33606*

After attending this presentation, attendees will understand how the application of Hounsfield Unit (HU) values and the 3D volume of the proximal femurs can assist in the estimation of age and sex. Attendees will also gain a deeper understanding of how 3D models can contribute to forensic identification, even in fragmentary remains.

This presentation will impact the forensic science community by: (1) providing the results of a methodology that will assist in the forensic analysis of age and sex estimation; (2) enhancing existing research of osteological materials by adding data of a living modern American sample of the proximal femur *in situ*; and, (3) providing insight into the age-related decline of bone density and explaining how the HU values can be used as a predictor for age with an average accuracy of ±10 years. The total volume of the proximal femur can be used with a 94% accuracy in estimating an individual's sex.

The confirmation of identification for an unknown individual is a critical part of forensic practice. The age and sex of an unknown individual are key components in establishing a biological profile. Previous studies utilizing the 2D projections of the proximal femur derived from Dual X-ray Absorptiometry (DXA) estimated sex with a 90%–91.7% accuracy; however, the usefulness of bone density as an age estimate was not examined.[1] The purpose of this study was to determine if the average HU value of the proximal femur derived from CT can be a reliable method to estimate age in an unknown individual. Additionally, this study examined the effectiveness of volumetric quantification of 3D CT-derived proximal femurs to capture sexual dimorphism for the estimation of sex.

The University of South Florida (USF) Health Department of Radiology maintains an anonymized research database of all patient image data collected from 2009 to the present. A series of 200 femurs were acquired from abdominal-pelvic CT scans from living patients. The dataset consisted of 100 males and 100 females. Ages ranged from 18-90 years and were distributed evenly between the sexes. Any individuals with documented pathologies, implants, or clear surgical intervention were excluded from the study. Models of the proximal femur were initially isolated in a modeling software package using a threshold of 226–1,577. The medullary cavity and spongey bone of the femoral head were filled in via hand segmentation. The region of interest was limited from the femoral head to just inferior to the greater trochanter, cut 90° to the long axis of the femur.

For the statistical analysis, a paired *t*-test was run comparing the left and right proximal hip average HU (p=0.2) and volume (mm^3) (p=0.57). No statistical differences between sides were found. A stepwise analysis was used to construct a linear regression model for age estimation. A stepwise analysis was also used to perform discriminant function analysis, which was used to assign sex. All measurements with a $P < 0.05$ were considered statistically significant.

The results of the stepwise linear regression model revealed only the HU average was significant in model creation for age estimation ($p < 0.001$), with an R^2 of 0.63. The resulting model can be used as a predictor for age with an average accuracy of ±10 years. The results for the discriminant function analysis for sex estimation determined the proximal volume was the only relevant predictor with an overall 94% grouping cross-validated accuracy. Females were placed with a 100% accuracy. Males were placed with an 88% accuracy.

With the increasingly widespread use of postmortem CT (PMCT), there is an opportunity to utilize 3D volumetrics and bone density as tools for quick identification. The use of HU values as an age estimator should be limited to freshly deceased or fragmentary remains with soft tissue; however, the use of the proximal femur as a sex estimator can be utilized in any setting from the living to dry bone. The accuracy of the sex estimation found in this study reinforces the distinct dimorphism between sexes while also providing forensic practitioners more tools of analyses. The use of proximal femoral volume as a sex estimator need not be limited to CT scans but can also be used in laser surface scanning or photogrammetry.

CT, Age Estimation, Sex Estimation

A145 Using Fourier Transform Infrared-Attenuated Total Reflection (FTIR-ATR) to Measure Bone Degradation and Crystallinity for Forensic Reconstruction

Kelsa West, BS, 4141 Cowell Boulevard, Apt 3, Aptos, CA 95003; Eric J. Bartelink, PhD, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; Christyann M. Darwent, PhD, UC Davis, 1 Shields Avenue, Davis, CA 95616; and Nicolas Zwyns, PhD, UC Davis, 1 Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will understand: (1) how FTIR-ATR can be applied to determine bone diagenesis; and, (2) how the degree of diagenesis can aid in depositional and taphonomic reconstructions, particularly in a forensic context.

This presentation will impact the forensic science community by offering a new method for weathering estimation and reconstruction of diagenetic processes. This method for assessing the crystallinity of bone may provide a more accurate representation of diagenesis than established methods of weathering, such as the Behrensmeyer weathering estimation, Postmortem Interval (PMI), and Accumulated Degree Days (ADD), and can be used in recent contexts.

Recrystallization is directly correlated to the loss of the organic components of bone.[2-4,7,11] The relationship between bone degradation and recrystallization is important for forensic science because it focuses on the process of degradation and removes chronological time as a variable. Due to the current qualitative methods for assessing the degree of diagenesis, analyzing human remains can only provide a very broad understanding of depositional context. Quantitative approaches must be established to create a system of standardization. The goals are to provide quantitative data to support weathering observations by analyzing diagenesis and to determine if different stresses provide the same or different degrees of crystallinity and diagenesis.

Studies previously addressing the question of bone crystallinity have used the FTIR-Potassium Bromide (KBr) method, but often do not report the relationship between crystallinity and diagenetic stress. The Behrensmeyer technique also does not discern between alterations different depositional and taphonomic environments.[2] Using the degree of recrystallization to assess degree of diagenesis will provide a more detailed and empirical objective scale to be used in conjunction with other methods to reconstruct the full depositional history of any organic bone remains, which is important in forensic science reconstruction.

FTIR-ATR was used to examine the degree of recrystallization and the uptake of specific carbonates from various weathering processes to try to understand bone degradation better. In turn, the goal was to use this information to better categorize degrees of weathering and processing. The use of KBr pellets has been the historical method for FTIR preparation for anthropologists, but the limitations have often been documented in literature.[1,7-10] Benefits of KBr pellets include its ability to use smaller sample sizes, its ability to make quantitative analysis easier, and its ability to not produce interfering wavelength bands; however, serious drawbacks include extensive preparation, changes that may occur during the pressing process, possible water absorption, and possible "solid ion exchange with inorganic compounds."[6]

Preliminary data, analyzed through Multivariate Analysis of Variance (MANOVA) tests, demonstrate that there is no statistically significant relationship between the processing groups and their crystallinity index (Carbon/Phosphate ratio and Splitting Factor ratio). This suggests that the crystallinity index is not a useful measurement or factor for reconstruction, but FTIR-ATR is still a useful tool for measuring the crystallinity index.

After attending this presentation, attendees will better understand how change in the chemical composition of juvenile porcine rib bone correlates with change in the material properties of the same bone over the early postmortem period in a subaerial exposure environment.

This presentation will impact the forensic science community by providing experimental data that informs how changes in bone composition over the postmortem period affect its material properties and the biomechanics of bone response to localized loading, and thus informs regarding the factors that affect fracture timing determination.

When performing trauma analysis, forensic anthropologists are often faced with the challenge of determining fracture timing based on bone characteristics, a critical step in ascertaining the circumstances of death. Bone fracture characteristics used to differentiate between peri-mortem and postmortem fractures are discussed in terms of occurring in "fresh" bone versus "dry" bone, and yet it is still unclear how long into the postmortem period bone can retain its fresh fracture characteristics, particularly in juveniles. Rib fractures represent one of most common occurrences among the pediatric population being involved in a number of fatal circumstances; however, little experimental data have been generated about rib fracturing in juveniles.

This study uses a juvenile porcine model to examine the relationship between the length of the postmortem interval in subaerial exposure environments and the association between changes in: (1) the biomechanical properties of juvenile ribs in response to localized load; and, (2) the chemical composition of juvenile bone.

Twenty-seven suckling piglets (*Sus scrofa*) aged approximately between two and eight weeks were purchased from a local supplier. Their rib cages were manually disarticulated and defleshed, and each rib cage was divided into right and left halves. Three half rib cages (*sub-sample*=45 ribs) were placed on top of a soil-filled container, and a total of 16 soil-filled containers (*total sample*=720 ribs) were studied over a period of 12 months. The first subsample was removed from the container after one week, the subsequent three subsamples were removed one week apart, the following two subsamples two weeks apart, and the remaining ten subsamples four weeks apart, in a total of 16 trials. Sub-samples were randomly assigned to each container. Twenty to 27 ribs were selected from each subsample/trial and fractured experimentally using a three-point bending test. This was performed to quantify mean peak stress and mean tissue modulus for each subsample. Nine of the experimentally fractured ribs in each trial were sectioned to quantify water, collagen, and mineral content through a process of sequential controlled heating. Each sample was weighed four times throughout the process, and the water, collagen, and mineral contents were expressed as a percentage of total weight.

Peak stress and tissue modulus increase up to the fourth month, then level off. Results from the analysis of bone composition revealed a noticeable increase, then a significant decrease ($p \leq 0.01$) in collagen within the first month, and a noticeable decrease, then a significant increase ($p \leq 0.001$) in mineral within the same period of time. Both collagen and mineral were relatively unchanged from week four on. Results did not exhibit a clear trend for changes in water content throughout the postmortem period. No clear relationship was observed between changes in composition and material properties of bone over the postmortem period in this experiment. These results may be affected by residual desiccated soft tissue or environmental factors, such as variation in temperature and humidity.

Fracture Timing, Collagen, Bone Stiffness

A147 Mitochondrial DNA and Stable Isotope Analyses as Molecular and Chemical Signatures of Identity of Victims: A Combined Approach for Provenancing Unknown Skeletal Remains From India

Jagmahender Singh Sehrawat, PhD, Panjab University, Dept of Anthropology, Sector 14, PU Main Campus, Chandigarh 160014, INDIA; and Raj Kamal, PhD, Panjab University, Dept of Anthropology, Sector 14, PU Main Campus, Chandigarh 160014, INDIA*

The goal of this presentation is to scrutinize the combined forensic suitability of molecular and chemical methods of identification for human skeletal remains recovered from an abandoned well situated beneath a religious structure in a North Indian suburb of Ajnala in an attempt to satisfy the major objective of establishing their identity and origin status (local or non-local to the site) from the mitochondrial DNA (mtDNA) and stable isotope analyses of the recovered teeth and bones.

This presentation will impact the forensic science community by illustrating how the combined approach of application of mtDNA and stable isotope analyses has unraveled the scientific truth about these non-scientifically excavated human skeletal remains from a well by amateur archaeologists. The forensic anthropological findings have been corroborated by the molecular and chemical analyses of the remains, which will help in arriving at a number of valid conclusions regarding the forensic identity of these remains.

Unknown human remains have been reported from a number of disaster or multiple burial sites of forensic or bioarchaeological nature, whose identity establishment is of prime concern for a forensic anthropologist. The bones and teeth serve as anthropological, molecular, and chemical signatures of identity of the deceased as their physical structures, molecular signatures, and chemical compositions retain a number of specific individual imprints. Teeth are considered storehouses of invaluable biological, physical, and chemical information, and are crucially required for various forensic anthropological purposes, such as provenance or the establishment of biological identity (age, sex, ethnicity, occupation, migration pattern), exposure to pollutants or taphonomic/traumatic insults, ancient DNA analyses, estimation of dietary practices and subsistence patterns, paleopathology, etc. The small size and mineralized status of human teeth imparts them with a resistance against all types of decompositions and degradations, thus making them suitable for answering a wide range of forensic questions. In addition to certain gender-, race-, and age-dependent variations in human teeth, certain culture- and occupation-specific features also play an important role in the identification process. The disruptive and challenging life events (illness, malnutrition, starvation), especially during childhood, are impregnated in tooth enamel to reveal such severe and stressful life events.

The small size and high copy number of mtDNA ensures a higher probability of intact DNA isolation from severely degraded human remains found in forensic situations, which can be further amplified and studied using DNA markers from nuclear DNA as well. The human molars (mandibular), petrous bone, and femur are comparatively better and thus preferred sources for mtDNA extractions, compared to other traditionally used DNA sources.1 The stable isotope analyses of unknown human skeletal remains have provided novel approaches for their provenancing in forensic or bioarchaeological contexts.2 The isotopic ratios of bones and teeth have proven to be fingerprints of locality, migration patterns, subsistence activities, and dietary habits, such as milk or meat consumption by the victims, infant breast-feeding practices and weaning patterns, prehistoric diets, etc.3-4 Stable isotopes of bone and teeth vary significantly among different geographical regions due to diverse cultural dietary patterns and environmental factors (such as aridity, elevation, and distance from large bodies of water). Thousands of bones and teeth were recovered from an unused well situated beneath a religious structure at Ajnala in April 2014, after being identified in a book.5 These remains were provided to this study in 2015 to establish their biological identity.

Two hundred-fifty-six mandibular molars were randomly selected for mtDNA extraction, quantification, and amplification, and whole genome sequencing was performed for few samples. An equal number of teeth and some bones (femur, humerus, vertebrae, clavicle, metatarsals, and metacarpals) were processed chemically for stable isotope analysis of carbon, hydrogen, oxygen, nitrogen, and strontium. The tooth sample was completely settled in silicone rubber, a dermal cut-off wheel and bids were used to cut the root and make a hole through it, respectively. Approximately 50mg of powder was taken and processed for DNA extraction and analysis at 108 variable positions to genotype the haplogroup-defining motifs of the entire mtDNA. The ancient DNA sequences and haplogroups were compared with individuals of geographical areas to which the victims supposedly belonged. Samples were prepared for stable isotope analysis according to standardized techniques and the isotopic compositions were estimated from different dental and skeletal remains using Isotope Ratio Mass Spectrometer (IRMS), and were then compared with the thresholds available for comparisons for different periods and regions.2

Keeping in mind the enormous diversity of the Indian population, the ethnicity and geographic area of specific mtDNA diagnostic markers (N=104) were used to assign the haplogroups, and it was observed that out of 49 samples, the haplogroup pattern of 35 samples were similar to North Indian populations, whereas 14 samples exhibited more similarity with present-day Pakistani and Iranian populations. The frequency distribution pattern of all haplogroups across Indian, Central Asian, and Middle East populations assigned the affinity of the Ajnala skeletal remains to the Punjab and Uttar Pradesh states of India. These findings were contrary to the written versions and anthropological observations regarding these remains.5,6 The stable isotopic interpretations and the whole genome studies further corroborated these observations, thus unravelling the scientific truth concerning these remains.

A148 Evidence Recorded in Fingernails: Carbon, Oxygen, and Strontium Isotopes Reveal Diet and Travel Histories

Christy J. Mancuso, MS, University of Utah, 257 S 1400 E, Salt Lake City, UT 84112; and James Ehleringer, 423 Wakara Way, Ste 205, Salt Lake City, UT 84108*

After attending this presentation, attendees will understand the basic principles of how carbon ($\delta^{13}C$), hydrogen ($\delta^{2}H$), oxygen ($\delta^{18}O$), and strontium isotope measurements of fingernails can be used in reconstructing recent diets and geographical movements of individuals.

This presentation will impact the forensic science community by increasing the competence of the law enforcement community on an analytical tool that can be used in travel history reconstructions of unidentified decedents or for homeland security-related matters.

Stable isotope analysis of keratin tissues (hair and fingernails) have been used to reconstruct diet and geographic location across multiple disciplines. The foods that humans consume are reflected in the $\delta^{13}C$ and nitrogen ($\delta^{15}N$) isotope signatures and are indicative of the plant and animal protein contributions of their diet. Beverages that are incorporated from tap water and water in foods contributes to the $\delta^{18}O$ and $\delta^{2}H$ signals that reflect particular geographic locations. Strontium isotope ratios (Sr^{87}/Sr^{86}) are incorporated from environmental sources and reflect geologic structures that waters interact with, food is grown in, or are input from environmental dust. These stable isotope combinations form unique signatures that can allow researchers to understand an individual's diet and geographic movement and can play vital roles in forensic and homeland security matters.

This study focuses on the stable isotope patterns of fingernail clippings from volunteer residents of the Salt Lake City (SLC), UT, region who traveled for varying times to locations outside the United States (Central and South America) before returning home. It was hypothesized that the dietary isotopes ($\delta^{13}C$ and $\delta^{15}N$) would not significantly differ as they moved, because both the United States and South and Central America rely heavily on corn inputs of food sources (animal feed, corn sugars, or syrups in processed foods); however, it was hypothesized that the $\delta^{18}O$, $\delta^{2}H$, and Sr^{87}/Sr^{86} would vary with their travels, as precipitation isotope values ($\delta^{18}O$ and $\delta^{2}H$) and the geologic formations (strontium) significantly differ between their region of travel and SLC.

As hypothesized, the $\delta^{13}C$ and $\delta^{15}N$ values did not change over the course of the study, nor did the diets of the volunteers. $\delta^{18}O$ and $\delta^{2}H$ values displayed patterns that were consistent with their reported travel history. It was discovered that $\delta^{18}O$ and $\delta^{2}H$ values were similar to SLC residents when the volunteers resided in the area and, as they moved to their new locations, there was a departure from these values. The incorporation of the new isotope signature happened rapidly, but it took several months before that portion of fingernail was clipped. These findings were consistent with those of $\delta^{18}O$ and $\delta^{2}H$ incorporation patterns in human scalp hair. In contrast, Sr^{87}/Sr^{86} of the fingernail clippings provided surprising results. It was initially hypothesized that the patterns would be consistent with those of $\delta^{18}O$ and $\delta^{2}H$; however, the Sr^{87}/Sr^{86} were indicative of the volunteers' location when they clipped their fingernails. For instance, one volunteer who went to Ecuador initially displayed $\delta^{18}O$ and $\delta^{2}H$ values that were consistent with SLC, but the Sr^{87}/Sr^{86} values did not match those of SLC residents. This difference was attributed to how the isotopes are incorporated into the keratin protein of the fingernail. $\delta^{18}O$ and $\delta^{2}H$ are incorporated during the protein formation and, once the protein is formed, the isotope signature does not change. Thus, as the fingernail grows from the nail plate forward, the signal does not change. $\delta^{18}O$ and $\delta^{2}H$ of clipped fingernails also represent a time from four to five months earlier, based on average human fingernail growth rates. Findings suggest that Sr^{87}/Sr^{86} are incorporated into the fingernail keratin through environmental or bathing waters and reflect an individual's most recent location.

As one of the first multi-isotope studies on human fingernails, this study reports on new travel-related isotope signals that can be obtained from $\delta^{18}O$, $\delta^{2}H$, and Sr^{87}/Sr^{86} measurements. A major conclusion of this study is that human fingernails (as well as other keratin tissues) can provide information on an individual's diet and travel history. This study has also allowed us a more detailed look at isotope incorporation into fingernails and how these values can vary among individuals.

Stable Isotopes, Human Fingernails, Travel History

A149 Taphonomic Effects on Isotope Ratios of Human Hair

Tiffany B. Saul, PhD, Forensic Institute for Research and Education, Middle Tennessee State University, 1301 E Main Street, Box 89, Murfreesboro, TN 37132; Gwyneth W. Gordon, PhD, School of Earth & Space Exploration, Arizona State University, PS-F 686; MC-871404, Tempe, AZ 85287-1404; Brett J. Tipple, PhD, University of Utah, 257 S 1400 E, Salt Lake City, UT 84112; Lesley A. Chesson, MS, IsoForensics, Inc, 421 Wakara Way, Ste 100, Salt Lake City, UT 84108; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 37996; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will understand how isotope ratios of human hair can change throughout decomposition and continued outdoor exposure over a one-year period.

This presentation will impact the forensic science community by providing information regarding the first study conducted on human hair samples to evaluate the effects of taphonomic processes on isotope ratios of postmortem hair. The forensics community uses isotope ratios of postmortem hair for predicting diet and geographic origins of unknown human remains, and this presentation will provide an assessment of geospatial modeling accuracy using isotope ratios from individuals with known residence histories.

Isotope analyses of human remains have been conducted with growing frequency in forensic anthropology. Isotope ratios of elements, such as carbon, nitrogen, hydrogen, oxygen, and strontium from hair have provided information regarding individual diet and geographic origin. The isotope ratios of hair can be projected across landscapes using geospatial models (i.e., isoscapes). As hair grows at a known rate, these data provide a serial recording of diet and travel history for the weeks and months prior to death; however, these isoscapes have been developed using clean modern samples from salons and do not reflect the typical condition of hair found in forensic contexts. A critical knowledge gap has been whether exposure to the outdoor environment and postmortem decompositional fluids have an effect upon isotope ratios in hair. If the isotope ratios of human hair are to be used reliably in forensic casework, it is essential to understand the effects of taphonomy on isotope signatures, and whether these signatures persist and reflect those seen during life.

This research was conducted at the Anthropology Research Facility in Knoxville, TN, an outdoor laboratory for the study of human decomposition. Body donors with known residence histories (n=8) plus two additional donors at the Forensic Anthropology Research Facility in San Marcos, TX, were enrolled in the study, and hair samples were collected over a one-year period of environmental exposure. Two facilities with different climatic and soil environments were used to understand the ways in which temperature, humidity, geographic location, and underlying lithology affect isotope ratios of hair. Donors were placed in both surface and burial conditions to determine the effects of placement condition on isotope ratios of hair. Carbon ($\delta^{13}C$), nitrogen ($\delta^{15}N$), hydrogen ($\delta^{2}H$), oxygen ($\delta^{18}O$), and strontium ($^{87}Sr/^{86}Sr$) isotope ratios from the human hair samples were analyzed. Environmental samples of soil and precipitation were also collected and analyzed. Carbon and nitrogen isotope ratios in human hair underwent little change over time and were more consistent than hydrogen, oxygen, and strontium isotope ratios, all of which were impacted by the depositional environment.

Oxygen and strontium ratios were compared to isoscape models to create geographic predictions for last residence for each of the donors. Oxygen isotope ratios predicted regions within 250 kilometers of the last known residence of the donors 81% of the time, and strontium predicted regions within 250 kilometers of last known residence 100% of the time. Combined, oxygen and strontium predictions fell within 250 kilometers of last known residence 80% of the time. This study revealed that isotope ratios of human hair can change postmortem and are influenced by placement location (i.e., Tennessee or Texas facility), surface or burial placement, and duration of exposure. Isotope ratios of human hair, despite these postmortem changes, still provided valuable information regarding geographic travel history. As these postmortem changes become better understood, they could be incorporated into predictive models to improve model accuracy. Nonetheless, when the isotope ratios of human hair are analyzed postmortem, it is important to consider how taphonomic processes impact isotope ratios.

Isotope Analysis, Human Decomposition, Isotope Ratios of Human Hair

A150 Trace Isotope Analysis of Dental Enamel for Micro Regional Geographic Attribution of Human Remains in Virginia

Nicole J. Palmer, BS, Virginia Commonwealth University, Dept of Forensic Science, 1015 Main Street, Richmond, VA 23220; Robert H. Stein, MS, Pennsylvania State University, Dept of Anthropology, 410 Carpenter Bldg, University Park, PA 16802; Scott Gronert, PhD, Virginia Commonwealth University, 1001 W Main Street, Richmond, VA 23284; Qin Wang, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

The goal of this presentation is to highlight the utility of trace element isotope ratios in bulk and surface dental enamel as a means of enhancing the biological profiles of unidentified remains.

This presentation will impact the forensic science community by providing a method of geographic attribution of birthplace and recent residence of unidentified remains using the presence of certain trace chemical isotope ratios in bulk and surface dental enamel.

Ultimately, this methodology could contribute to the compilation of a database of chemical isotope ratios by locality within Virginia, which could be applied to unidentified remains in long-term storage in the many Offices of the Chief Medical Examiner (OCME) for the Commonwealth of Virginia.

There are currently ca. 165 cases of unidentified human remains in long-term storage in the four Virginia OCME regions. In many of these cases, the remains are severely decomposed or skeletal and do not match any reports of missing persons, and fingerprints, DNA profiles, dental conditions, and facial approximations of these individuals have generated no leads to identification. Dental enamel preserves well despite decomposition and holds promise for the expansion of new forensic identification methods. The bulk enamel composition ceases to change appreciably after a certain age and is thus indicative of an individual's birthplace (or early childhood residence), while the surface enamel composition continues to change due to surface ion exchange and diffusion and is indicative an individual's recent residence.[1]

This study examined the bulk and surface enamel samples of ca. 80 teeth from 44 donors obtained from the Mission of Mercy Project and the Remote Area Medical Project in Wise County and Emporia, VA, respectively, with the Virginia Commonwealth University Institutional Review Board approval. Patients scheduled for an extraction were approached by a researcher and asked for written informed consent; if consent was provided, the patient was asked questions concerning age, sex, city and state of birth, and city and state of residence. Individuals in this study who were born and currently resided in Virginia had a donor age range of 22 to 77 years. The average donor age was 49.5 years with an average donor age of 49.7 years for 24 females and an average donor age of 48.3 years for 20 males. These locations were selected to expand on a pool of 74 samples from 52 donors previously compiled, predominately from central and northern Virginia.[2] After extraction, samples were disinfected in 10% neutral buffered formalin for two weeks. Surface enamel was etched directly using a trace metal-free nitric acid and glycerin solution, while bulk enamel was dissolved in trace metal-free nitric acid after the enamel was ground into a fine powder using a mortar and pestle. Samples were analyzed for the following trace elements via Inductively Coupled Plasma/Mass Spectrometry (ICP/MS): ^{7}Li, ^{11}B, ^{25,26}Mg, ^{27}Al, ^{52}Cr 3^{+}, ^{55}Mn, ^{57}Fe, ^{59}Co, ^{58,60}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{69,71}Ga, ^{78}Se, ^{86,87,88}Sr, ^{204,206,207,208}Pb, and ^{209}Bi. Principal component analysis and discriminant function analysis were performed to examine multivariate relationships among samples and determine which trace elements drive compositional differences among the samples and the locality groups.

The results from a one-way Analysis of Similarities (ANOSIM) yielded significant differences ($p \leq 0.00420$) between bulk and surface enamel ratios of individuals by geographic locality. Tooth characteristics (e.g., restorations, caries, debris, discoloration, chipping, cracking, occlusal wear, etc.) did not significantly affect the isotope ratios of either the surface or the bulk enamel. This suggests that geographic determinations based on the isotope ratios of bulk and surface enamel are most likely neither influenced nor obscured by the tooth type and/or tooth characteristics. Significant correlations were found for bulk enamel ratios with the geographic location of an individual's birthplace and surface enamel ratios with recent residence.

In conclusion, trace isotope ratios are useful in determining where individuals were born and currently reside, adding information to the biological profiles of unidentified remains and generating additional leads to the identification of these individuals.

Human Identification, Trace Isotope Ratios, Dental Enamel

A151 The Application of Isotope Analysis to Aid in the Investigation of Unidentified Remains From a Suspected World War II Mass Grave

Katharine E. Kolpan, PhD, Iowa State University, Dept of World Languages and Cultures, 3102 Pearson Hall, Ames, IA 50011; Ian Hanson, MSc, Bournemouth University, Department of Archaeology, Anthropology and Forens, Fern Barrow, Poole BH12 5BB, UNITED KINGDOM; George D. Kamenov, PhD, University of Florida, Dept of Geological Sciences, 241 Williamson Hall, Gainesville, FL 32611; and John Krigbaum, PhD, 1112 Turlington Hall, Gainesville, FL 32611*

After attending this presentation, attendees will have an understanding of how isotope analysis is employed in efforts to differentiate the origin and context of unidentified remains, specifically suspected combatants from World War II.

This presentation will impact the forensic science community by providing researchers with a greater appreciation of how scientific endeavors may be utilized to both reinforce and undermine prevailing historical and ideological narratives concerning perpetrators and victims in the Balkans and Central Europe. Additionally, this study demonstrates that complex, multidisciplinary investigations collating all data are needed to resolve the origin and identification of such cases and that reliance on single strands of evidence, be it community narratives, associated artifacts, or isotope analysis, does not provide a threshold of evidence to define origins beyond reasonable doubt.

The massive scale of military casualties incurred in World War II made it impossible to recover many of the combatants' material remains, identified and repatriated; however, discovery of graves and remains of combatants and civilians from the conflict has continued, with the lack of information concerning these individuals bringing ambiguity regarding their identity, origin, and fate.

This study concerns a group of suspected World War II combatants (*Minimum Number of Individuals (MNI)*=26) found buried in a mass grave in Bosnia and Herzegovina. The remains were recovered as part of ongoing national investigations into the missing from the 1992-1995 conflict; however, associated artifact evidence suggests the remains are of World War II German Army origin. One objective of the national investigations led by Bosnia and Herzegovina's state prosecutor's office and the Missing Person's Institute is to differentiate remains from previous conflicts to define jurisdictional authority and subsequent activities needed to determine if cases are relevant to prosecutions, as well as identify and/or lay remains to rest.

After Yugoslavia was invaded by the German Army and their allies in 1941, Axis-affiliated military and paramilitary organizations and resistance forces fought for control of the region. Present-day Bosnia and Herzegovina was primarily encompassed within the newly formed Independent State of Croatia, and the Axis military units present were principally composed of German, Austrian, Italian, Croatian, and Bosniak Muslim combatants. That local ethnic groups allied themselves with the different antagonists has been cited as a source of animosity fueling the 1992-1995 conflicts.[1-5] Unidentified remains and unknown combatants leave questions unanswered and may be utilized to reinforce local narratives of victimization inflicted by one's neighbors.[2,3,5] Additionally, records of foreign war dead initiate actions of war graves commissions, such as the German *Volksbund,* which has recovered 40,000 European war dead a year since 1991. Determining the origin of remains may prompt nations of foreign combatants to address their own history and culpability, and, while Germany has spent many years fostering a reconciliatory narrative, other countries, such as Austria and Italy, have been less active in acknowledging the role their combatants played in the World War II Balkan conflict.

The complex history of the conflict, lack of records, limited investigative data, and the potential for unidentified remains to be from a number of armies, nationalities, regions, and conflicts provides scope for scientific investigation to contribute data that may aid in including or excluding remains from active investigations.

To investigate the origins of these individuals, permissions were provided for cases to be examined, and samples of molar teeth (n=24) were subjected to lead, strontium, oxygen, and carbon isotope analysis. Isotopes reflect the local geology and environment of an individual's place of origin. Isotopic analysis indicated there was variation in individual's $^{87}Sr/^{86}Sr$ (0.7080-0.7115) and $^{206}Pb/^{204}Pb$ (17.8-18.4) ratios. There was also variably in the oxygen results (-3.99‰ to -8.16‰), reflecting potential geographical origins from central and southern Europe — though the majority of individuals fall within a range indicative of the southern Mediterranean. It was hoped that the isotope analysis would provide a definitive regional identity for these combatants; however, the results do not provide enough definition to suggest that the remains can be claimed by any nation with a stake in their identity. Some remains can be defined as not of Balkan origin, adding scientific evidence for Bosnia and Herzegovina authorities that the assemblage dates to World War II and is not relevant to investigations of later conflicts. Refining the Balkan isotope baseline data, additional carbon dating and isotope sampling of World War II-era individuals should aid these investigative efforts.

Isotopes, Warfare, The Balkans

A152 Spatial Distributions of Carbon and Nitrogen Isotope Ratios in Human Hair From Central and Southern Mexico — Another Indication of Geographical Origin

Chelsey A. Juarez, PhD, Department of Soc & Anthro NCSU, 1911 Bldg, 10 Current Drive, Campus Box 8107, Raleigh, NC 27695-8107*

The goal of this study is to: (1) explore the relationship between carbon ($\partial^{13}C$) and nitrogen ($\partial^{15}N$) isotopes in human hair from traditionally high immigrant sending areas in central and southern Mexico; and, (2) explore the relationship between carbon and nitrogen values in these hair samples and published values from 14 other countries.[1-3]

This presentation will impact the forensic science community by presenting data on regional dietary differences among Mexican states and between Mexico and other countries and will assess the utility of this relationship to act as a predictor of region of origin.

The use of carbon and nitrogen isotopes in human hair, bone, and fingernails has demonstrated the ability to assist in provenance analysis for modern populations.[1-3] In this study, the influence of regional diet to predict region of origin in modern Mexican populations by analyzing carbon and nitrogen isotopes from hair was tested.

The Mexican hair samples consist of 78 samples collected from 12 contiguous states in Central and Southern Mexico, plus 10 samples collected in southeastern North Carolina. Carbon and nitrogen isotopes were measured in duplicate for samples for all locations using an elemental analyzer connected to a Finnigan–Mat Mass Spectrometer at the University of Utah SIRFER laboratory.

All data for $\partial^{13}C$ values are presented on the Vienna Peedee Belemnite (VPDB) scale, and those for $\partial^{15}N$ are presented on the Atmospheric Air (AIR) scale. Analytical precision for $\partial^{13}C$ and $\partial^{15}N$ was 0.1‰ and 0.2‰, respectively. Stable isotope ratios are reported using the standard ∂ notation. Hair values spanned a range from 8.1‰ to 10.5‰ and -23.5‰ to -19.‰ for $\partial^{15}N$ and $\partial^{13}C$ for Mexican locations, respectively. Hair values from North Carolina spanned a range from 8.4‰ to 8.9‰ for $\partial^{15}N$ and -19.2‰ to -16.6‰ for $\partial^{13}C$. A one-way Analysis of Variance (ANOVA) was conducted to determine if the mean values for $\partial^{13}C$ and $\partial^{15}N$ were different for the 12 regions in Mexico and between the Mexican regions and North Carolina. Means for measured $\partial^{13}C$ and $\partial^{15}N$ were statistically significantly different $F\ (7.87)= 9.040$ ($P < 0.05$); $F\ (7.87)=9.04$ ($P=0.01$). A Tukey Kramer post hoc analysis revealed that $\partial^{15}N$ values between the Mexican samples were not statistically significantly different, but values between Veracruz and North Carolina were statistically significantly different. Carbon data demonstrated the most promising differentiation. A Tukey Kramer post hoc test for carbon demonstrated within country regional differences with means for Chiapas, Mexico, the Federal District, and Oaxaca all statistically significantly different than Morelos, and Chiapas, Mexico, Oaxaca, and the Federal District all significantly different than North Carolina. The mean value for all combined Mexican states was 9.3‰ for $\partial^{15}N$ and -16.1‰ for $\partial^{13}C$. When mean values for $\partial^{13}C$ for Mexico were compared to published mean values for other countries, there was no statistically significant difference with Brazil or Costa Rica, but there were statistically significant differences between Mexico and 12 other countries.

This study demonstrates both the limitations and potential of carbon and nitrogen isotopes in human hair to distinguish provenance. Carbon isotopes clearly demonstrate regional differences both within Mexico and between Mexico and other locations, albeit more broadly than water isotopes; however, the potential demonstrated here for additional indications of region of origin suggest that carbon and nitrogen isotopes in human hair from Mexico are a reasonable investment in the analysis of region of origin.

A153 The Application of Multi-Isotope Analysis to Assist with Georeferencing Unidentified Decedents

Liotta N. Dowdy, MA, University of South Florida, Dept of Anthropology, 4202 E Fowler Avenue, SOC 100, Tampa, FL 33620; Kirsten A. Verostick, MA, University of South Florida, 4202 E Fowler Avenue, Tampa, FL 33620; Erin H. Kimmerle, PhD, University of South Florida, FL Institute for Forensic Anthropology, 4202 E Fowler, SOC 107, Tampa, FL 33820; and George D. Kamenov, PhD, University of Florida, Dept of Geological Sciences, 241 Williamson Hall, Gainesville, FL 32611*

After attending this presentation, attendees will better understand how heavy and stable isotope analysis assists with the estimation of geographic origin and migration of unidentified decedents.

This presentation will impact the forensic science community by providing and highlighting results from several ongoing cold cases, successful identifications, and known Floridian individuals' isotope values for the Tampa Bay region.

Forensic anthropologists employ methods involving skeletal analysis to estimate age, sex, ancestry, trauma, and pathology assessment for the unidentified decedent. By collaborating with other scientists in the field of geochemistry, the biochemistry of human tissue (i.e., bone, enamel, hair, nails) elucidates evidence of geoprofiling for the unidentified decedent. This research has two objectives: (1) to demonstrate how isotope analysis can aid with the solvability of unsolved cases of the unidentified; and, (2) how Florida has a particularly unique demographic situation in terms of a transient population.

An additional goal of this study was to collect more modern enamel and bone samples for known individuals from Florida and throughout the United States to improve reference sample sizes for forensic investigations. Stable oxygen isotopes ($\delta^{18}O$) and carbon ($\delta^{13}C$) were also used to tighten constraints when estimating geographic origins for the unidentified decedent.

Strontium ($^{87/86}Sr$) and lead isotopes ($^{206}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$, $^{208}Pb/^{204}Pb$) were analyzed from the teeth and bone of the unidentified individuals to infer either geographic origins or recent area of residence. Strontium is absorbed into the individual's biology via the food chain. The ultimate source is the local bedrock, soil, and water. Long-distance importation of food and water may affect the individual's strontium isotope ratios and may not be entirely controlled by the local environment. Similarly, the lead isotopic compositions of individuals can be linked back to local environmental sources of lead from the soil or anthropogenic sources, such as leaded gasoline. Over the individual's lifetime, lead is absorbed through dust inhalation at very minimal amounts.

In contrast to strontium, it is believed that lead is more directly absorbed through soil and/or dust ingestion or inhalation and, therefore, is not likely to be affected by importation of foods from other regions. Exposure to lead from lead paint or lead pipes can affect the lead isotopic signal in human teeth and bones. A comparison of the isotope ratios of the enamel and bone can yield a pattern of migration of when the individual moved from one geographic region to another region throughout their lifetime. The tooth enamel formation during early childhood provides a biochemical profile of the individual's early years, while bone will remodel over a course of seven to ten years continually as a person ages. The bone offers a biochemical profile of the individual's last years of life. Human teeth and bone are an archive of long-term strontium and lead exposure.

Analyses of oxygen, carbon, lead, and strontium isotopes were completed on selected current and cold cases, which included a sample of 53 individuals (n=27 males, n=21 females, and n=5 unknown) from 2010 to 2017. Additionally, donated teeth (n=20) with known demographic information were utilized to generate an increased reference sample for Florida. Other known United States samples are included as a comparison for the heavy isotope values.

A trend in the isotope results also reveals that a number of cases in the Tampa Bay region are foreigners or out-of-state individuals. After the isotope analysis was performed for these cases, investigators were able to redirect their investigations and reach out to other agencies with the new information concerning the case. Two interesting non-local cases, which were positively identified, will be highlighted in this presentation. Moving forward, collaborative and multidisciplinary research across the board will enhance the solvability and success in current and cold casework.

Isotope Analysis, Cold Cases, Geoprofiling

A154 Multi-Isotope Approaches for Region of Origin Predictions of Unidentified Border Crossers (UBCs) From South Texas

Eric J. Bartelink, PhD, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; Sarah A. Hall, MA, School of Human Evolution and Social Change, Arizona State University, 900 Cady Mall, Tempe, AZ 85287; Lesley A. Chesson, MS, IsoForensics, Inc, 421 Wakara Way, Ste 100, Salt Lake City, UT 84108; and Melanie M. Beasley, PhD, 2553 Keystone Avenue, Knoxville, TN 37917*

The goal of this presentation is to highlight the value of using a multi-isotope approach for predicting the region of origin of UBCs found deceased in the United States. Attendees will gain a better understanding of how stable isotopes can be used as a geolocation tool for unidentified remains of suspected foreign nationals from Latin America.

This presentation will impact the forensic science community by presenting novel approaches that can assist with unidentified remains cases, especially for foreign nationals.

Since 1999, the remains of more than 6,000 UBCs have been recovered along the United States-Mexico border. While increases in border security during the past two decades have reduced the number of border crossings, this period has been marked by a sharp increase in UBC deaths as migrants are forced to travel through more inhospitable areas, often dying due to heat-related illness. In 2011, the number of deceased UBCs in south Texas exceeded that of Arizona, with the majority of the deceased representing Central American nationals. Most of the deaths in Texas occur near the Falfurrias checkpoint in Brooks County, approximately 80 miles north of the border. This high volume of deaths has resulted in a massive identification challenge. Many barriers to identification exist, including lack of documentation, decomposition of remains, lack of antemortem records, and difficulties obtaining family reference DNA samples. In 2013, forensic anthropologists began exhuming unidentified remains interred in a cemetery in Brooks County for analysis and identification. Several field seasons of exhumations have recovered hundreds of UBC remains, which are currently being analyzed and identified through the efforts of Texas State University and its collaborators.

Stable isotope analysis can aid in identification efforts of unknown decedents, including UBCs from south Texas. Carbon and nitrogen isotope ratios of human tissues reflect cultural dietary practices, which can be used to screen remains as being of likely United States vs. Latin American origin. Oxygen and strontium isotope ratios of bone and tooth enamel reflect the geographic origins of an individual based on the source inputs of water and food, respectively. Further, these isotopes can be used to predict possible regions of origin using geospatial mapping tools (e.g., isoscapes). Although baseline data are incomplete for many regions within Latin America, a multi-isotope approach can provide numerous lines of evidence for predicting region of origin of UBCs.

This study presents isotope results for 30 UBC bone-tooth pair samples from Brooks County, provided by Texas State University. Bones and teeth were prepared for mass spectrometry, including carbon and nitrogen isotope analysis of bone collagen, carbon and oxygen isotope analysis of bone bioapatite and tooth enamel, and strontium isotope analysis of tooth enamel.

The mean bone collagen $\delta^{13}C$ value is –13.3‰ (±2.4‰, 1 Standard Deviation (SD); *range*=10.2‰) and the mean $\delta^{15}N$ value is +9.1‰ (±1.1‰, 1 SD; *range*=4.4‰). The mean bone bioapatite $\delta^{13}C$ value is –7.8‰ (±2.6‰, 1 SD; *range*=9.3‰). Tooth enamel, which reflects childhood diet, exhibits an even greater range of variation, with a mean $\delta^{13}C$ value of –4.9‰ (±3.0‰, 1 SD; *range*=13‰). The mean $\delta^{18}O$ value is –6.7‰ (±1.2‰, 1 SD; *range*=5.0‰) for bone bioapatite and –5.7‰ for tooth enamel bioapatite (±1.3‰, 1SD; *range*=6.0‰). The mean $^{87}Sr/^{86}Sr$ ratio for enamel is 0.70705 (±0.00126, 1SD; *range*=0.00617).

Carbon isotope ratios of bone collagen as well as bone bioapatite and tooth enamel are consistent with previous data on UBCs from south Texas, which reveal a high dietary contribution from C_4 resources such as corn. The high degree of variation in $\delta^{13}C$ values is primarily influenced by three individuals with very low $\delta^{13}C$ values for their bone collagen and bone and tooth bioapatite. Prediction maps based on oxygen and strontium isotope ratios further suggest these individuals may be of United States origin as opposed to Latin American nationals. The other 27 individuals have $\delta^{13}C$ values consistent with a Latin American origin. Measured $\delta^{15}N$ values reveal low variation, consistent with heavy consumption of terrestrial herbivore meat by all individuals. For the majority of the 30 UBC samples, isotope prediction maps based on oxygen and strontium isotopes are consistent with a Latin American origin and often include areas within Mexico as well as portions of Central America. Future research will seek to further narrow possible regions of origin.

Stable Isotope Analysis, Undocumented Border Crosser, Forensic Anthropology

B1 A Comparative Analysis of Globally Used Forensic Semen Detection Methods and Their Differing Applications

Megan Peters, 511 Main Street, Apt G8, West Haven, CT 06516; and Claire Glynn, PhD, Forensic Science Department, University of New Haven, West Haven, CT 06516*

The goal of this presentation is to inform attendees of the effectiveness of differing applications of commonly utilized forensic semen detection methods employed globally.

This presentation will provide the forensic science community with insight into the wide variety of different methods of applying semen identification tests, such as the acid phosphatase test for screening and extraction methods for spermatozoa staining, that are utilized in forensic laboratories worldwide.

The ability to detect and identify the presence of seminal fluid can be crucial to an investigation. Methods used to detect seminal fluid are common across the world; however, the application of these methods varies greatly on a global level. For example, while some laboratories favor the Alternate Light Source (ALS) for locating potential stains, other laboratories favor the Acid Phosphatase (AP) press test, as the ALS has been shown to be unreliable and not specific. The AP press test is common in Europe; however, there is a lack of research into how this method is applied, with varying approaches taken in different laboratories. Further, for the confirmatory identification of semen, the most commonly utilized method is microscopic visualization of spermatozoa; however, it is essential to extract potential stains from substrates, such as fabric, in order to perform microscopic examination. A number of different methods of extraction have been identified but have not been compared to date. Therefore, the goal of this study was to first investigate the differing methods of applying AP for presumptive testing and, second, to compare and contrast the differing extraction methods from a variety of substrates.

Following Institutional Review Board (IRB) approval, semen was collected with informed consent from healthy volunteers. For each experiment, 100µL of semen was deposited onto white cotton fabric in dilutions from neat to 1:1,000. The differing AP application methods examined included: (1) wetting both the substrate and test paper versus just the test paper, including examination of the potential transfer of spermatozoa to the test paper; (2) application of the two AP reagents (sodium α-naphthyl phosphate and Fast Blue B) as a combined formulation versus sequential application; (3) application of the AP reagents directly onto the substrate versus indirect application using test paper; and, finally, (4) evaluation of the reliability of the two-minute cutoff for the AP reaction. The differing extraction methods examined include five methods used globally and were performed on five substrates (cotton, denim, polyester, wool, and cotton swabs) for each of five dilutions, neat to 1:1,000. To evaluate the extracted stains, the extract was seeded on a microscope slide, stained with Christmas tree stain, examined under a microscope, and scored.

The results of this study investigating the differing AP application methods revealed: (1) wetting both the test paper and the substrate greatly enhances the positive AP reactions obtained, particularly through the dilutions, with no observable transfer of spermatozoa to the test papers; (2) the sequential application of the AP reagents provides stronger and faster color reactions; (3) similarly, the direct application of the reagents onto the substrate provides greater sensitivity and faster/stronger reactions, when compared to the indirect application onto the test paper; and, finally, (4) the two-minute cutoff for the AP reaction was insufficient time for positive reactions to be observed with dilutions above 1:5,000. The results of this study investigating the differing extraction methods demonstrated one particular method — utilizing two stacked Eppendorf tubes — to extract the most spermatozoa from four of the five substrates, across all dilutions.

This research highlights the potential impact on results obtained when using differing semen screening and identification tests identified across the globe. These results emphasize the need for more research into the varying application methods used. It is crucial for forensic laboratories to be made aware of the variety of these methods and the potential to improve the effectiveness and sensitivity of their testing.

Acid Phosphatase, Extraction, Christmas Tree Stain

B2 A Powder-Free Approach to Extracting DNA From Environmentally Challenged Bone Samples

LeAnn M. Harrel, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Carrie Mayes, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340*

After attending this presentation, attendees will appreciate some of the advantages and disadvantages of altering bone processing, tissue digestion, and DNA extraction methods in an attempt to increase DNA quantity and quality for more successful Short Tandem Repeat (STR) typing from environmentally challenged bone samples. This presentation proposes a method to efficiently extract DNA from bone samples without the need to pulverize the bone tissue into a fine powder prior to digestion.

This presentation will impact the forensic science community by providing insight into the benefits and limitations of demineralizing bone tissue without the traditional requirement for powdering. This sample-processing approach is coupled with a commercial DNA extraction kit performed with and without automation for downstream STR analysis.

Bone samples are often encountered in missing persons' cases and mass disasters for human identification purposes. In order to generate a high-quality STR profile, it is necessary to extract a sufficient quantity of high-quality DNA (>100pg) while simultaneously eliminating unwanted contaminants and Polymerase Chain Reaction (PCR) inhibitors. Traditional bone DNA extraction methods rely on cutting and crushing bone into a fine powder and a long demineralization step coupled with an organic or silica-based DNA purification method. An alternate approach may be to use a whole bone digestion buffer in combination with a commercial DNA extraction kit to avoid powdering bone samples prior to purification. This study compared the efficacy of both methods with and without automation.

Bone samples (N=6) from human cadavers exposed to various insults (fire, decomposition, sun exposure, burial, and embalming) were prepared, extracted, and STR-typed in triplicate. Compared to each of the other methods, the whole bone digestion buffer paired with the automated extraction consistently resulted in a significantly lower DNA yield per milligram of powdered bone (p<0.05). Regardless of the chemistry used, significantly less DNA (p<0.01) was obtained when the extraction process was automated, compared to performed manually. No statistical difference was observed in the average DNA yields when the commercial kit was performed with or without the whole bone digestion step. Although DNA yields were higher using the complete demineralization protocol, STR success rates and overall profile quality were comparable across all the manual methods tested.

The whole bone system is an alternative method to conventional complete demineralization methods which are more laborious and time consuming (~30hrs versus ~16hrs), require powdering of bone tissue, pose a higher risk of contamination, and consume the entire sample. Another advantage of the whole bone system is the provision for a second DNA extraction from the same sample. These multiple extracts may be used to perform additional analyses or combined and concentrated to increase the amount of input DNA for improved results.

Overall, this research has shown that eliminating the need to powder bone tissue can simplify the DNA extraction process without significantly reducing downstream STR success.

Bone, DNA Extraction, Short Tandem Repeats

B3 Qualitative and Quantitative Analysis of Minute Levels of Saliva in Expirated Blood

Mackenzie E. Whiting, 12 Damask Drive, Clifton Park, NY 12065; and Claire Glynn, PhD, Forensic Science Department, University of New Haven, West Haven, CT 06516*

The goal of this presentation is to inform attendees of the use of the solution SALIgAE®, which has quantitative and qualitative capabilities to detect minute levels of saliva in expirated bloodstains.

This presentation will impact the forensic science community by providing insight into the difficulties of distinguishing between expirated and impact spatter bloodstains and by informing attendees how the use of SALIgAE® can help minimize those difficulties.

A major challenge with Bloodstain Pattern Analysis (BPA) is the differentiation of expirated and impact blood spatter stains. Currently, the only accepted method of classifying an expirated bloodstain pattern is the presence of air bubbles in the stain; however, this is a very subjective approach and leaves the assessment open to much scrutiny. As expirated blood is expelled from the mouth, it is logical to assume there would be trace amounts of saliva mixed with the resultant blood droplets. To date, a method has not yet been identified that is adequately sensitive or specific enough to detect these minute traces of saliva in expirated bloodstains. SALIgAE® is a somewhat new reagent for saliva identification. This is a clear solution that, when mixed with saliva, turns a transparent yellow color, displaying a positive reaction for saliva. It is reportedly more accurate than other saliva detection tests, with a sensitivity of 1:1,000. Additionally, it has both qualitative and quantitative analyses that are rapid and easy to perform. The goal of this research, therefore, is to investigate the ability of SALIgAE® to accurately detect the presence of, and quantity of, trace amounts of saliva within expirated bloodstain patterns.

Following Institutional Review Board (IRB) approval and informed consent, venous blood was collected from a volunteer into sterile EDTA Vacutainer® tubes. Saliva was also collected from the volunteer into a sterile Falcon® tube. The sensitivity of the SALIgAE® solution was first tested with dilutions of saliva:ddH_20 and saliva:venous blood, ranging from 1:1 to 1:1,000,000. Expirated bloodstains were created by placing 1mL of blood into the volunteer's mouth for 30 seconds, followed by the volunteer coughing the blood onto white butcher paper placed approximately 12 inches in front (vertical) and below the volunteer's mouth (horizontal). Two stains were created on separate days when the volunteer had not drunk liquids or consumed any food for at least one hour. Individual blood spots/stains were chosen to be tested from both the vertical and horizontal planes. Each sample to be tested was incubated in ddH_20 for 30 minutes before addition to the SALIgAE® solution. Both a visual color change test and a spectrophotometric reading using the Nanodrop™ OneC Ultraviolet/Visible (UV-Vis) spectrophotometer were used to determine the color change and absorption of salivary amylase. The visual test exhibited a color change from clear to yellow with the presence of saliva, while the UV-Vis test exhibited a change in the absorbance of the saliva and SALIgAE® solution, allowing for the acquisition of quantitative data.

The sensitivity of SALIgAE® with dilutions of saliva:ddH_20 produced the required positive color change up to 1:1,000, as previously reported, with absorbance values ranging from 1.28 to 10.0, and salivary amylase concentrations ranging from 0.12µg/mL to 1.33µg/mL. The sensitivity with dilutions of saliva:venous blood produced the same required positive color change up to 1:1,000; however, the red color of the blood made a distinct color change difficult to observe. The first expirated stain created a large dispersed pattern on the vertical plane, with less abundant but larger drops on the horizontal plane. Forty-two individual stains were selected for testing, each ranging between 1mm and 5mm in diameter. Of the 42 stains, 8 produced a positive color change, with absorbance values ranging from 0.08 to 1.05 and salivary amylase concentrations ranging 0.00µg/mL to 0.09µg/mL. The second expirated stain created a visually similar pattern to the first, and 42 stains were again selected for testing. Of the 42 stains, 9 produced a positive color change, with absorbance values ranging from 0.05 to 1.46 and salivary amylase concentrations ranging from 0.00µg/mL to 0.15µg/mL. While the concentrations obtained from the expirated stains were low, a visible color change did occur.

The results of this study highlight the ability of SALIgAE® to detect the presence of minute quantities of saliva when mixed with blood. This reveals the SALIgAE® method to be an ideal candidate for the differentiation of expirated spatter and impact spatter, thereby overcoming a significant challenge facing bloodstain pattern analysts. This information will ultimately help guide forensic professionals to develop more effective strategies in their processing and analysis techniques.

Saliva, Expirated Blood, SALIgAE®

B4 An Assessment of the PreCR® Repair Mix as a Viable Repair Method for Soil-Degraded DNA

Olivia Negron, BS, 87 Merrimac Street, Danbury, CT 06810; and David San Pietro, PhD, University of New Haven, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand some principles of DNA degradation, how the PreCR® repair mix functions, and the ability to repair DNA samples that have been exposed to degradation by substances in soil, such as humic acid.

This presentation will impact the forensic science community by providing an analysis approach for DNA profiling of buried bloodstained evidence that optimizes the recovery of a DNA profile in order to help provide investigative leads.

The ability to detect a DNA profile from a piece of evidence, such as clothing, can be crucial in a forensic investigation. In many cases, evidence is found outdoors, possibly buried. Buried evidence containing human DNA, such as bloodstains, can pose a challenge for profiling due to accelerated degradation processes in soil by its many components. Humic Acid (HA) in soil has been determined to be a contributor of accelerated DNA degradation, as well as a Polymerase Chain Reaction (PCR) inhibitor. Therefore, the goal of this study was to determine if the PreCR® repair mix can be used for the repair of soil-degraded DNA, potentially aiding with casework by establishing or providing potential suspect and/or victim leads in violent crimes in which evidence containing human blood was buried.

Following informed consent, venous blood was obtained from a single-source volunteer in sterile Vacutainer® EDTA tubes. Then, 50µL and 150µL aliquots of blood were deposited in quadruplicate on 2"x2" polyester swatches, for a total of 30 stained fabric swatches, and dried beneath a hood for 24 hours. Once dried, 18 of the stained swatches and 6 non-stained swatches were buried 1.5" deep in a ten-gallon fish tank containing approximately 3" of soil. Six remaining bloodstained swatches were left in petri dishes on the bench. Over the course of four weeks, four stained samples from each blood amount, in addition to two non-stained swatches that were used as negative controls, and two bloodstained swatches from the table were extracted with the QIAmp DNA Mini® Kit, quantified with the Investigator Quantiplex® Kit, then amplified and profiled using the Powerplex Fusion® Kit with GeneMarker® HID software to assess the level of degradation in the donor's original profile. At the time of each extraction, soil moisture, pH, and room temperature and humidity were monitored in an attempt to keep as many variables as possible to a minimum. Portions of the degraded samples from each blood-stained group that had already been quantified were repaired using the PreCR® repair mix prior to Fusion® amplification. Generated profiles aided in determining the extent of repair. The results of each extraction group were evaluated based on the extent of allelic dropout/recovery and corresponding peak height ratios.

After one week buried in soil, the samples with 50µL of blood showed little (one to two alleles) to no allelic activity. Every PreCR®-treated sample for week one showed a recovery of two or more alleles out of a total of 43 alleles in the known person's profile. Weeks two through four with 50µL of blood did not show any DNA prior to being treated with PreCR® for any sample and zero out of nine bloodstained samples did not show any improvement when treated with PreCR®. Studies are currently being conducted following the above-mentioned protocol with larger quantities of blood to examine repair possibilities when larger amounts of DNA are present, in addition to assessing direct HA inhibition with various amounts of HA to study the direct effect of HA on DNA analysis and repair.

This research has highlighted the challenges that come with severely degraded human DNA, but also brings attention to the possibility of repairing soil-degraded DNA from blood-stained fabric using commercially available methods, such as PreCR®. Additional studies will need to be conducted prior to any laboratory casework application. It is hoped that extensions of this work will enable the forensic science community the ability to explore DNA repair.

DNA Repair, STR Analysis, Humic Acid

B5 An Evaluation of a Novel Massively Parallel Sequencing (MPS) 74-Microhaplotype Panel for Biogeographic Ancestry Prediction

Fabio Oldoni, PhD, The George Washington University, 2100 Foxhall Road, NW, Washington, DC 20007; Rebecca Hart, BS, The George Washington University, 2100 Foxhall Road, Washington, DC 20007; Nyra Rashad, BS, The George Washington University, 2100 Foxhall Road, Washington, DC 20007; Keylie Gibson, 100 N University Drive, Edmond, OK 73034; Sharon C. Wootton, PhD, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Robert Lagacé, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Ryo Hasegawa, BS, 850 Lincoln Centre Drive, Foster City, CA 94404; Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Moses S. Schanfield, PhD, Department of Forensic Sciences - GWU, 2100 Foxhall Road, Somers L08A, Washington, DC 20007; Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the potential of using novel Microhaplotype (MH) markers in addition to Single Nucleotide Polymorphism (SNP) panels for predicting the biogeographic ancestry of individuals.

This presentation will impact the forensic science community by illustrating the usefulness of an MPS MH panel to enhance the prediction of individuals' ancestry and to extrapolate valuable information on the minor contributor's profile in mixed DNA samples.

MHs are loci of two or more SNPs within a short distance of each other (<300 nucleotides) with three or more allelic combinations. The standard Sanger sequencing method does not enable determining the cis/trans relationship between SNP alleles within the same amplicon (i.e., haplotype) whereas MPS methods, which allow specific clonal sequencing of each individual DNA strand, can distinguish the parental haplotypes at a given locus. The key features of MH markers, such as small amplicon size, multi-allelic nature, absence of stutter peaks, and lower mutation rate than conventional autosomal and sexual linked Short Tandem Repeats (STRs), also make them an additional candidate marker for forensic identification, mixture deconvolution, and ancestry prediction purposes.[1] The most common method for ancestry prediction utilized is based on SNPs, which are of little use in mixtures given their bi-allelic nature. The goal of this project was to evaluate whether MPS-based MH analysis could be effective in the prediction of the biogeographic ancestry of individuals in cases of mixed samples where the use of SNPs is more challenging.

A set of 91 European-Americans (EAs), 54 African Americans (AAs), 87 Hispanics (HISs), and 51 Native Americans (NAs) was selected and analyzed on the Ion Chef/Ion S5™ MPS platform using a 74 MH panel specifically developed for improving the accuracy of ancestry prediction. To calculate the Random Match Probability (RMP) of each MH profile from the specific population of interest, allele frequencies from numerous populations, previously inferred with PHASE software, were used.[2] In particular, the RMP calculated for the full population sample sets was observed to be higher in all populations in which individuals self-identified as such. In addition, Likelihood Ratio (LR) values were calculated by dividing the highest RMP obtained among the four populations by the second highest. The resulting LR value expresses how much more likely it is to observe the given profile if it originated from an individual belonging to the population at the numerator than if it originated from an individual belonging to the population at the denominator. The biogeographic ancestry of representative EA, AA, HIS, and NA population samples was correctly predicted and the related LR values were found to be at their highest in the corresponding population of origin. These results support the hypothesis that the novel MPS 74 MH panel is a useful forensic assay that enables effective biogeographic ancestry prediction complementing the accuracy of current binary and non-binary marker-based ancestry prediction tools.

B6 Assessing Alternative Polymerases for Amplifying Mitochondrial DNA From Shed Hairs

Natalie Damaso, PhD, ORISE/FBI Laboratory, 2334 Brookmoor Lane, Woodbridge, VA 22191; Emily Ashe, BS, 16460 Stedham Circle, #203, Dumfries, VA 22025; Kelly A. Meiklejohn, PhD, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22204; Mark F. Kavlick, MPhil, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, CFSRU, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand that the choice of DNA polymerase used in Polymerase Chain Reaction (PCR) can influence the yield of products substantially. Additionally, attendees should be able to identify the importance of selecting an efficient and robust polymerase for use in the PCR, so that yields necessary for downstream sequencing are routinely obtained from hairs representing a range of treatments and biogeographic ancestries.

This presentation will impact the forensic science community by identifying efficient and robust DNA polymerases that can be used to amplify DNA from forensic-type samples.

Forensic DNA analysis of hair evidence typically involves the amplification and sequencing of the Whole Control Region (WCR) of the mitochondrial (mt) genome. In compromised hair samples, such as shed hairs, the number of mt genome copies could be low; thus, it is imperative that the polymerase used in PCR is efficient to ensure the maximum recovery of information. Considering this, the first phase of this study compared the yields obtained from 12 polymerases (sourced from a range of commercial companies) when amplifying the WCR, Hypervariable Region II (HV2), and Hypervariable Region II-B (HV2B). This initial assessment was performed using total genomic DNA extracted from 2cm of hair adjacent to the root from three donors. Two polymerases were identified that consistently resulted in significantly higher yields ($p<0.05$) for all three regions, when compared to the currently used polymerase (6- and 4-fold increase in yield). The second phase of this project was focused on assessing the broad utility of these top two performing polymerases for amplifying the WCR and HV2B from hair samples representing diverse biogeographic ancestries (i.e., Caucasian, Hispanic, African American, Asian, and Native American), treatments (i.e., bleached, dyed, and chemically straightened), and anatomical locations (e.g., head and genitalia hairs) (n=41). The results indicated that regardless of sample type, the top two polymerases still significantly ($p<0.05$) outperformed the currently used polymerase (13- and 7-fold increase in yield). The results from this study highlight that novel commercially available polymerases could greatly assist with the analysis of mitochondrial DNA, especially from the challenging hair samples encountered in evidence.

Mitochondrial DNA, Polymerases, Shed Hairs

B7 Direct Amplification of Sperm Using Laser Microdissection (LMD) and Promega's® PowerPlex® Fusion 6C Amplification Kit

Kelli B. Raley, MSFS, Arizona Dept of Public Safety, 2323 N 22nd Avenue, MD1150, PO Box 6638, Phoenix, AZ 85005-6638; and Michelle M. Baker, BS*, 2102 W Encanto Boulevard, Phoenix, AZ 85009*

After attending this presentation, attendees will be able to adapt this method to help streamline Short Tandem Repeat (STR) analysis of sperm from sexual assault casework samples when equipped with a laser microscope.

This presentation will impact the forensic science community by illustrating that sperm can be directly amplified using a Polymerase Chain Reaction (PCR) kit that captures the 20 Combined DNA Index System (CODIS) -core STR loci now accepted for use at National DNA Index System (NDIS).

Sexual assault cases comprise approximately 45% of all DNA casework and account for a significant amount of casework DNA extractions. The major problem encountered with traditional differential extraction is incomplete separation of male and female DNA, especially when epithelial cells greatly exceed the number of sperm, resulting in a mixture. This can produce difficult DNA profile interpretations, statistical calculations, and ultimately, explanations of the results to a jury. Additionally, the traditional differential extraction method is laborious and time consuming. To overcome these problems, the Arizona Department of Public Safety (AZDPS) developed a direct amplification protocol for sperm isolated via LMD.

LMD microscopy replaces the challenges of traditional sexual assault casework methodologies. It provides the ability to simultaneously identify, physically separate, count, and collect cells from a microscope slide for further DNA analysis. Using LMD with a direct amplification expedites DNA analysis of sex assault evidence by offering the following advantages: (1) efficient physical separation of sperm and epithelial cells; (2) greater precision in locating and collecting small amounts of sperm cells in the presence of large epithelial cell populations; (3) elimination of the traditional differential extraction technique; (4) elimination of traditional quantification; (5) reduction in analyst handling and sample manipulation; and, (6) reduction in time spent on analytical interpretations, all while maintaining the ability to obtain full DNA profiles.

LMD with the Leica™ LMD6500 Microsystem integrates microscope and laser functions. In a user-friendly fashion, images are captured by a camera and combined with image analysis software to allow a large sample image to be displayed on a computer screen. This simplifies the ability to locate and dissect cells into separate tubes. Slides are mounted upside down onto the microscope stage for capture of dissected cells via gravity into PCR tubes located in a substage tube holder.

The AZDPS current direct amplification protocol for sperm isolated via LMD was optimized for use with PowerPlex® Fusion 6C STR amplification kit. This evaluation included testing of the previously validated LMD protocol, as well as experimental variations in the pre-amplification lysis solution, amplification buffer, and sperm lysate input volume. Because of LMD implementation, the laboratory workflow was streamlined and the processing time for producing CODIS-eligible DNA profiles for sperm positive sexual assault casework was significantly decreased.

Laser Microdissection (LMD), Direct Amplification, Sperm

B8 The Evaluation and Implementation of the Promega® Casework Direct Kit for Y-Screening on Sexual Assault Samples

Carmen Young, 1328 Neel Street, Huntington, WV 25701; Amy McGuckian, MSFS, Palm Beach County SO, Crime Laboratory, 3228 Gun Club Road, West Palm Beach, FL 33406-3001; Julie Conover Sikorsky, MS, Palm Beach County SO, Forensic Biology Unit, 3228 Gun Club Road, West Palm Beach, FL 33406; and Kelly Beatty, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand how to implement the Promega® Casework Direct Kit to screen for the presence of male DNA and the kit's use as an alternative to conducting differential extractions as the primary extraction method on sexual assault samples.

This presentation will impact the forensic science community by informing attendees, especially those in the field of DNA analysis, on the ability to screen for the presence of male DNA using a new extraction method.

Current serological screening of sexual assault samples is time consuming and provides the analyst with little predicative power as to the DNA profile that may be obtained. Recent legislation across the country has increased the number of sexual assault samples that are submitted to forensic laboratories for testing. With this new demand on laboratories, there is a need for the rapid detection of male DNA in a sample and a faster and more efficient DNA process to generate DNA typing results. Prior to the introduction of new robust Short Tandem Repeat (STR) megaplexes and the advent of probabilistic genotyping software, differential extractions and DNA purification methods were developed to separate epithelial and sperm cells in an attempt to produce single-source DNA profiles. With more laboratories turning to probabilistic genotyping software, laboratory personnel may consider using a fast and efficient extraction method that results in DNA mixtures. The Promega® Casework Direct Kit enables the rapid generation of lysates from casework samples and can be used directly in an STR amplification to generate DNA typing results.

Evaluation of the Promega® Casework Direct Kit was conducted by the Palm Beach County Sheriff's Office (PBSO) Forensic Biology Unit. Samples were extracted with the Casework Direct Kit and PBSO's in-house differential extraction method using the QIAGEN® EZ1® XL Advanced® Robot and quantified with the Promega® PowerQuant® System on the Applied Biosystems® 7500 Real-Time Polymerase Chain Reaction System. PCR amplification was achieved using the Promega® PowerPlex® Fusion 5-dye System with 30 PCR cycles and Promega® PowerPlex® Y23 System with 30 PCR cycles on the Applied Biosystems® GeneAmp® 9700 thermal cycler. Capillary electrophoresis was conducted on the Applied Biosystems® 3500xL Genetic Analyzer with a 24-second 15kV injection and data was analyzed using Applied Biosystems® GeneMapper® ID-X v 1.5.

The data generated was evaluated to determine if the Casework Direct Kit could be used to detect the presence of male DNA and as an alternative to differential extraction. Quantification results were evaluated to determine if the autosomal-to-Y ratio could be used as an indicator for downstream process decisions, such as taking the lysate directly to autosomal amplification, Y-chromosomal Short Tandem Repeat (Y-STR) amplification, or for re-extraction of a sample using a differential extraction method to optimize male DNA recovery.

Quantification results obtained for the male target show that the amount of a male DNA recovered from the Casework Direct Kit extraction was comparable to the differential extraction method. Lysates from the Casework Direct Kit with an autosomal to Y ratio of less than 200 were taken direct to STR amplification and produced male DNA profiles in the presence of high female DNA. A full Y-STR haplotype was obtained in a 96-hour post-coital sample. The presence of male DNA was detected and a full Y-STR haplotype was obtained from non-probative samples where sperm cells were not observed during microscopic examination.

The results indicate that the Casework Direct Kit can extract DNA from typical sexual assault evidence and, based on the quantification results, may assist the analyst in making decisions regarding downstream processing or re-extracting with a differential extraction method. Implementation of the Casework Direct Kit would replace conventional serology screening for sexual assault evidence as it would provide a more sensitive method to determine the presence of male DNA.

Y-Screening, Non-Differential Extraction, Sexual Assault Samples

B9 The Development of a Multianalyte Paper-Based Device for Serological Measurements

Rosa L. Cromartie, BS, 16800 SW 137th Avenue, Apt 1124, Miami, FL 33177; George T. Duncan, PhD, Broward County Crime Lab, 201 SE 6th Street, Rm 1799, Fort Lauderdale, FL 33301; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand how the development of a paper-based device can be used to obtain serological measurements from various biological samples. This multianalyte device permits a simultaneous analysis of various body fluids obtained from a variety of substrates. This device is rapid, simple, and permits a quick presumptive screening of body fluids collected at crime scenes.

This presentation will impact the forensic science community by demonstrating that multiplexed serological measurements can be made using a microfluidic device developed from paper and wax with colorimetric sensing pads. The design and developmental validation of the system will be discussed, including stability, interference testing, and reproducibility studies. Fieldable test kits are important in evidence screening as they aid in the collection of samples and improve efficiency. Properly designed, they permit simple, fast, and presumptive testing to occur at a lower cost. Unfortunately, many of these tests generally run one body fluid at a time, which can be lengthy in time and potentially destructive to critical samples. This presentation proposes a multianalyte serological screening procedure based on a paper microfluidic platform.

Multianalyte paper-based devices utilize sheets of chromatographic paper and thermal wax to create hydrophilic channels that direct a liquid sample to multiple test wells, each with a different colorimetric sensor. This multianalyte paper-based device can be used to detect various body fluids for field-presumptive testing. The device produces quick and easily distinguishable results without the need for external instrumentation.

In this project, the developmental validation of this multianalyte device will be discussed. Sensitivity studies, interference testing, and experiments involving aged and degraded samples were all performed as part of these validation studies. Colorimetric tests used in this device include modifications of the Kastle-Meyer test for blood, the Urease-Nessler's test for urine, the amylase test for saliva, and the acid phosphatase test for semen. All four tests were implemented on a single paper-based analytical device. Key issues in design included adjusting reagent concentrations for visibility and long-term stability. Tests of single and mixed analytes were performed.

For the determination of blood, a Kastle-Meyer test was used; however, hydrogen peroxide was not an appropriate reagent for this test due to problems with evaporation. Therefore, sodium perborate was used in this test to oxidize phenolphthalein. Although this test is not blood specific, it did provide a generalized test method for the presence of blood. Dilution factors as high as 1:750 still produced results. Interferences included certain acidic foods and bleach. For the determination of urine, urease-based decomposition of urea to ammonia was utilized. The release of ammonia was then detected using the Nessler's reagent. Dilutions of urine up to 1:100 provided a response and urine samples up to 30 days in age still produced results. Interferences included other substances containing urea. For the determination of saliva, the ability of amylase to hydrolyzed starch/iodine mixtures was used. This reaction produces color change from a black-purple color to a clear color. Sample dilutions up to 1:100 were still detectable, as were samples aged up to 30 days. Lastly for determination of semen, the acid phosphatase reaction was used. Sample dilutions up to 1:400 were detectable on the chip. Interferences included herbal drinking tea and vaginal secretion fluids.

Experimental results with mixtures and single-source samples demonstrate clear, distinct signals for each serological sample that was present. Results discussed will include the sensitivity of each test, the range of interferences, and how age affects the results. Overall, this presumptive testing method is rapid, reproducible, and easily used in the field for screening unknown fluids during a forensic investigation.

Multianalyte, Serological, Validation

B10 Botanical Evidence in a Case of Environmental Crime: The Application of Short Tandem Repeat (STR) DNA Markers and Tree Ring Analysis of *Eucalyptus Globulus* Disks

Jaime H. Solano, PhD, Universidad Católica De Temuco, Avenida Rudecindo Ortega 02950, Temuco 4813302, CHILE; Leonardo Anabalon, Universidad Catolica, Odas Elementales 0828, Temuco, CHILE; and Alejandra Figueroa, BSc, Policia de Investigaciones de Chile, odas elementales 0828, Temuco, CHILE*

After attending this presentation, attendees will understand the importance of using botanical evidence in casework.

This presentation will impact the forensic science community by increasing the fundamental understanding of the application of STR DNA markers and tree ring dating analysis as it applies to the discrimination of illegally cut forest timber.

Forensic botany is an emerging discipline that uses plant evidence in matters of law. Botanical evidence is usually found at crime scenes and is sometimes the only available element for criminal investigations. Currently, as supporting evidence, DNA analysis is nearly the only element that can be used as a reliable identification tool, due to the high variability of DNA across all species. One way to identify a distinctive DNA fragment for a species is to study the Polymerase Chain Reaction (PCR) products for microsatellite markers (Simple Sequence Repeats (SSRs), STRs, Simple Sequence Length Polymorphisms (SSLPs), and Variable Number of Tandem Repeats (VNTRs)). DNA regions with short repeat units (usually 2bp-6bp in length) are called STRs. In this case, the application of STR markers enabled the demonstration of the molecular traceability of *Eucalyptus globulus* seizures. On the other hand, dendrochronological techniques require the presence of annual growth rings; new growth in trees occurs in a layer of cells near the bark. A simple method for determining the periodic nature of growth in trees of unknown origin is counting its rings with computer assistance. An Image Analysis System has been specifically designed to look for a precise and efficient way to measure annual tree-ring widths from wood disks, providing an independent tool to confirm the accuracy of dating.

A robbery case in a timber forest was investigated using STR markers and dendrochronological analysis. A truck driver was accused of stealing several *Eucalyptus globulus* logs and transporting them in a truck. The truck was found by the police in a nearby forest that had been illegally logged, and wood disks were collected from the vehicle. Genetic and dendrochronological analyses of wood samples collected from the truck (evidence) were performed and results were compared to those obtained from *Eucalyptus globulus* tree disks collected at the forest (crime scene). Briefly, *Eucalyptus globulus* DNA was extracted from the wood using a commercial kit and quantified with a fluorometer; the genetic profile was obtained using EMCR 9, EMCR 10, and EMCR 11 microsatellite markers. Genetic analysis revealed different profiles for wood collected in the truck and for wood obtained at the forest. At the same time, *Eucalyptus globulus* disks were dried, sanded, and placed face down on the scanner for image acquisition, and software measured the rings in the image by making straight lines with a single mouse click from the center to the bark. A graphic of ring-widths identified by year was displayed during the analysis. Dendrochronology techniques determined a non-match of tree rings when the wood evidence was compared against the wood disks collected at the crime scene. Consequently, *Eucalyptus globulus* logs found in the truck did not come from the illegally logged forest.

This investigation demonstrates the potential for plant microsatellite markers and dendrochronology dating analysis for linking botanical evidence and plants growing at the crime scene. Following this analysis, the arrested truck driver was declared innocent.

DNA Typing of *Eucalyptus globulus*, Dendrochronology Dating, Botany Forensic

B11 An Evaluation of the Illumina® ForenSeq™ DNA Signature Prep Kit and Promega® PowerPlex® Fusion System in the Evaluation of Degraded Identical Twin Samples

Aminna M. McGee, MS, Virginia Commonwealth University, 130 Stonegate Terrace, Apt 204, Zion Crossroads, VA 22942-7048; Abigail S. Bathrick, MFS, Bode Cellmark Forensics, 10430 Furnace Road, Lorton, VA 22079; and Sarah Cavanaugh, MSFS, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will better understand the Illumina® ForenSeq™ DNA Signature Prep kit and Promega® PowerPlex® Fusion systems' abilities to analyze naturally degraded samples.

This presentation will impact the forensic science community by providing an understanding of both kits' limitations in evaluating degraded samples when degradation levels are considered.

A comparison of Short Tandem Repeat (STR) profile quality generated by both Massively Parallel Sequencing (MPS) and traditional Polymerase Chain Reaction-Capillary Electrophoresis (PCR-CE) will be presented. The analysis of phenotypic, ancestry-informative, and identity-informative Single Nucleotide Polymorphisms (SNPs) from degraded samples will also be discussed.

MPS enables an increased amount of forensically beneficial genetic information to be obtained over traditional CE. The ForenSeq™ DNA kit simultaneously amplifies up to 231 genetic markers, namely 27 autosomal STRs (aSTRs), 24 Y-chromosomal Short Tandem Repeats (Y-STRs), 7 X-chromosomal Short Tandem Repeats (X-STRs), 95 identity-informative SNPs (iiSNPs), 22 phenotypic-informative SNPs (pSNPs), and 56 ancestry-informative SNPs (aSNPs). MPS amplicon sequencing allows for small amplicon sizes, hypothetically making MPS technologies more beneficial when evaluating degraded samples; however, minimal research has been conducted on the efficiency of the ForenSeq™ DNA kit in conjunction with environmentally degraded samples to test this hypothesis. This research sought to explore this hypothesis by comparing the ForenSeq™ kit with that of a traditional forensic chemistry, Promega® PowerPlex® Fusion, in the evaluation of naturally degraded samples.

Seventy-six degraded buccal samples were quantified using Applied Biosystem's® Quantifiler® Trio DNA Quantification Kit to obtain information on the samples' degradation levels. The samples' Degradation Index (DI) values ranged between 2.93 and 110.12, with values greater than 10 indicating severe degradation. The samples were then processed using the PowerPlex® Fusion and ForenSeq™ kits with DNA inputs ranging between 0.250ng and 1ng. Comparative analysis of the PowerPlex® Fusion and ForenSeq™ DNA kits were performed for the overlapping loci, while the additional ForenSeq™ loci were assessed to evaluate the kit's ability to provide additional individualizing information.

As expected, the quality of the profiles decreased with increased DI values. With some exceptions, MPS generated higher average percent profiles, exhibited less allelic drop-out, and produced better heterozygous balance, while PCR-CE produced better inter-locus balance. There was no significant difference observed for profile uniqueness between the systems when average Probabilities Of Identity (POI) values were calculated. All samples generated biogeographical ancestry estimations with three observed discordances from donor self-reported ancestry. Hair color estimations were only possible for the least degraded sample. Several previously unreported STR sequence variants were observed in aSTRs, Y-STRs, and X-STRs when samples were processed with MPS; however, no genetic differentiation between identical twin siblings was observed in either system.

Overall, the ForenSeq™ kit produced more forensically beneficial information for the degraded samples in this study, demonstrating that it is highly valuable for the analysis of degraded samples; however, the kit is limited in its ability to produce investigative leads from degraded samples due to the number of pi-SNPs required to generate phenotypic estimations and the ForenSeq™ Universal Analysis Software's incorrect estimations of donor biogeographic ancestry groups.

Massively Parallel Sequencing, Degraded DNA, STR

B12 Oxidative Mitochondrial DNA (mtDNA) Damage and Repair: A Modeling Approach Compared to DNA Recovered From Bullet Cartridge Cases

Rachel M. Bonds, BS, 015 Thomas Bldg, Shortlidge Road, University Park, PA 16802; Charity A. Holland, MPH, Penn State University, 015 Thomas Bldg, University Park, PA 16802; and Mitchell M. Holland, PhD, Penn State University, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will understand the practice in identifying, characterizing, and repairing oxidative DNA damage lesions and will be able to observe oxidative mtDNA damage in both modeled samples and forensic-type samples.

This presentation will impact the forensic science community by helping in the development of best practices for collection of DNA evidence from cartridge case evidence, as well as accurately identifying, characterizing, and repairing oxidative damage lesions when performing mtDNA sequence analysis in forensic casework.

DNA damage involves a change in the chemical structure of DNA through the introduction of strand breaks and lesions and is a well-known characteristic of forensic evidence and ancient samples. The type of damage observed will depend on the conditions under which the evidence is exposed, the length of exposure, and the type of evidence that is collected. There are several categories of DNA damage; for example, hydrolytic and oxidative. Damage can result in deamination, depurination, and oxidation of nitrogenous bases.

The first part of this study compared the modeling of oxidative damage in the Control Region (CR) of the mtDNA genome to the pattern of damage observed when pristine DNA was exposed to the surface of different types of metallic bullet cartridge cases. Previous studies have explored the ability to recover DNA from fired cartridge cases using Short Tandem Repeat (STR) analysis. A challenge has been the ability to effectively recover enough DNA for a partial or complete STR profile. In particular, there has been little success when attempting to recover DNA from copper and brass cartridge cases. One hypothesis is that the DNA is highly damaged due to the oxidative properties of copper. In the laboratory, three types of cartridge cases composed of different metals were analyzed: copper, brass (copper and zinc), and aluminum. Buccal DNA was deposited on the casings through liquid extracts and touch DNA through handling, was recovered with swabs moistened in molecular grade water or 0.5 M EDTA, and DNA extraction was performed using a low copy number approach. Damage to pristine DNA was accomplished through a Fenton reaction (an iron catalyst reacting with hydrogen peroxide to create hydroxyl radicals that inflict damage lesions on the DNA to effectively model oxidative damage). The second part of the study utilized NEBNext® Formalin-Fixed, Paraffin-Embedded (FFPE) DNA Repair Mix to repair the damaged DNA. Following Polymerase Chain Reaction (PCR) amplification and library preparation with the Promega® PowerSeq™ Mito Control Region Nested Kit, Massively Parallel Sequencing (MPS) on the Illumina® MiSeq® FGx benchtop sequencer was used to assess the damage, characterize the lesions, and observe the effects of the DNA repair mix. Donor haplotypes and heteroplasmy status were previously determined for comparison purposes.

A preferred approach was identified for lifting DNA from cartridge cases containing copper. Oxidative damage was characterized through active damage, compared to results for DNA samples recovered from bullet casings and repaired using FFPE DNA Repair Mix. The findings presented should aid the practitioner in developing best practices for collecting DNA evidence from cartridge case evidence, accurately identifying, characterizing, and repairing oxidative damage lesions, and applying the findings when performing mtDNA sequence analysis in forensic casework.

Mitochondrial DNA (mtDNA), DNA Damage/Repair, Massively Parallel Sequencing

B13 The Development and Optimization of a Direct Polymerase Chain Reaction (PCR) System of Mixtures of Sperm and Epithelial Lysates From Cotton Swabs

Meghan Roig, BS, Florida International University, 11200 SW 8th Street, OE 294A, Miami, FL 33199; Vanessa Martinez, 1245 NW 35 Avenue, Miami, FL 33125; Deepthi V. Nori, PhD, 1185 W Mountain View Road, Apt 3411, Johnson City, TN 37604; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand a novel method for differentiating, extracting, and amplifying epithelial and sperm mixture samples.

This presentation will impact the forensic science community by providing results for a method that can decrease the analysis time for mixture samples of sperm and epithelial cells. Attendees will observe the results of an experimental design-based method that aids in direct PCR for amplification of post-coital lysates. These results provide a method to minimize the long cell lysis and purification process by quickly extracting and directly amplifying cell lysates.

At present, there is increasing concern regarding case backlogs involving Sexual Assault Kits (SAK). The goal of this project is to improve the speed of extraction and to provide a method for quickly separating and screening mixed samples. It is common for epithelial and sperm cell mixtures to require labor-intensive processes and time to achieve differential extraction. The goal is to develop a rapid Short Tandem Repeat (STR) -based screening method that minimizes the DNA extraction, purification, and quantitation steps for a faster analysis.

In this study, alkaline lysis and direct PCR were used to extract and amplify epithelial and sperm DNA from simulated SAK samples, with various concentrations of epithelial and sperm cells. The direct PCR method was developed and optimized using an experimental design software program using mixture design methods. Cotton swabs were treated with 0.05N sodium hydroxide (NaOH) under ten cycles of 15 seconds at 20kpsi and 15 seconds at ambient pressure. This removed and lysed epithelial cells from the cotton swab. The swab then underwent incubation in 0.4N NaOH at 95°C for five minutes to remove and lyse sperm cells. After neutralization, the lysate was incubated at 50°C for ten minutes with 125mM dithiothreitol (DTT) to remove the protamines, isolating the male DNA. The samples underwent drop dialysis and were amplified using an inhibition-resistant polymerase. The PCR reaction mixture was optimized using experimental mixture designs. The experimental design considered salt concentration, buffer addition, deoxynucleotide triphosphate (dNTP) addition, primer addition, and PCR enhancers to develop experiments to maximize amplification of sperm and epithelial DNA. Output was measured by peak height of Amelogenin, D5, D13, D7, D16, CSF, and Penta D. The STR multiplex was analyzed using capillary electrophoresis and peak height was evaluated to determine the most effective reaction mix.

Results demonstrate the most effective amplification of sperm and epithelial DNA lysates without isolation and purification. The alkaline and pressure lysis effectively separate the epithelial fraction from the sperm, with the sperm being further lysed with heat, alkali, and reduction. The experimental runs demonstrate the enhancement of direct PCR using combinations of the reaction components. The analysis of the experimental runs is accomplished using mixture design analysis with experimental design software. This uses the results to model a contour plot demonstrating the expected ideal reaction mix to maximize peak heights. The model is tested with more experimental runs based off the components that lead to increased peak heights to determine the ideal conditions for maximized peak heights.

Direct PCR, Experimental Design Methods, Pressure Cycling

B14 WITHDRAWN

B15 Protein-Based Human Identification Using Hair Shafts From Different Body Sites

Jennifer A. Milan, BS, University of California, Davis, One Shields Avenue, Davis, CA 95616; Pei Wen Wu, MS, 7355 Fountain Avenue, Los Angeles, CA 90046; Michelle Salemi, MS, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Brett Phinney, PhD, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Robert Rice, PhD, University of California, Davis, Dept of Environmental Toxicology, 4138 Meyer Hall, One Shields Avenue, Davis, CA 95616; and Glendon Parker, PhD, University of California, Davis, 4421 Ashwood Common, Fremont, CA 94538*

After attending this presentation, attendees will better understand a new protein-based approach for analyzing human hair evidence that allows inference of Single Nucleotide Polymorphism (SNP) variation in DNA and is both statistically and scientifically rigorous.

This presentation will impact the forensic science community by informing attendees of a method of analyzing human hair proteins to infer non-synonymous SNP (nsSNP) alleles using hair shaft protein. This expands what can forensically and scientifically be achieved with hair trace evidence.

Nuclear DNA typing is not always an option due to degradation or low quantity of starting material. For example, sufficient nuclear DNA is difficult to obtain from hair shafts due to low copy number. Instead, mitochondrial DNA (mtDNA) is commonly used for analysis as it is present in higher copy numbers in the hair shaft; however, mtDNA cannot be used for individualization because it is maternally inherited and there is no recombination. Consequently, all maternally related individuals have the same mtDNA haplotype. In such cases, it would be helpful for the forensic science community to have an alternative, quantitative method for analyzing hair for identification purposes.

With advances in mass spectrometry technology, it has become possible to use proteomic approaches since proteins are more chemically stable than DNA and are found in greater abundance. Recent studies have demonstrated that is it possible to use protein expression profiling to distinguish hair shafts from different body sites and to differentiate between unrelated individuals.[1,2] Additionally, proteins contain genetic variation in the form of Single Amino acid Polymorphisms (SAPs) that are the result of nsSNPs in the genome. These SAPs can be detected as Genetically Variant Peptides (GVPs) in proteomic datasets. From these GVPs, it is possible to impute the nsSNPs and calculate frequency estimates of profiles. This approach has been demonstrated in recent studies in which GVPs from scalp hair shafts were used to differentiate between unrelated individuals; however, whether this approach can be used for hair shafts from other body sites has not yet been determined.[2,3]

This study tests the hypothesis that individuals are distinguishable by GVP analysis of hair shafts from any of four body sites: scalp, beard, axillary, or pubic. It is further hypothesized that the GVP profile will not significantly vary between body sites and that hair between different body sites of an individual will have more in common than hair from another individual. To test these hypotheses, hair samples from the four body sites were collected from five volunteer subjects. The hairs were processed using a sodium dodecanoate-based method, then digested with trypsin. The digested peptides were analyzed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), and the resulting proteomic datasets were analyzed using the Global Proteome Machine (http://www.thegpm.org/). The datasets were then screened for previously characterized and validated GVPs. Preliminary GVP analysis of type I keratins from these proteomic datasets exhibits evidence of clustering such that hair shafts derived from any of the four body sites of a single individual are more correlated to each other than to those of another unrelated individual. Future work will focus on analyzing additional keratin, keratin-associated, and other proteins, as well as exploiting new sample processing methods to increase detection of characterized GVPs.

B16 Argon Direct Analysis in Real-Time Mass Spectrometry (Ar DART®-MS) for Forensic Analysis of Illicit Drugs

Liguo Song, PhD, Western Illinois University, Dept of Chemistry, 324B Currens Hall, 1 University Drive, Macomb, IL 61455; Wei Chean Chuah, Western Illinois University, 214 Currens Hall, 1 University Circle, Macomb, IL 61455; Xinyi Lu, PhD, University of Tennessee, 552 Buehler Hall, 1420 Circle Drive, Knoxville, TN 37996-1600; and John E. Bartmess, PhD, University of Tennessee, 552 Buehler Hall, 1420 Circle Drive, Knoxville, TN 37996-1600*

After attending this presentation, attendees will understand a new mode of DART®/MS using Ar instead of the popularly used Helium (He) as the DART® ionization gas, its ionization mechanism toward polar compounds, its capability in positively identifying commonly abused drugs, and its application in successfully analyzing drug tablets.

This presentation will impact the forensic science community by introducing a novel Ar DART®/MS technique as an alternative to He DART®/MS for forensic analysis of illicit drugs, especially in consideration of the looming worldwide helium shortage.

Helium was originally selected as the DART® gas because its long-lived $^2S_3$ state has an Internal Energy (IE) of 19.8eV, which is the highest among inert gases; however, a helium shortage has been looming over the past ten years. Argon is the most abundant noble gas in the air at 9,340ppmv, third only to nitrogen and oxygen. To this point, dopant-assisted Ar DART®/MS has been investigated for the analysis of melamine, labile compounds, polycyclic aromatic hydrocarbons, diesel fuels, etc. In this study, Ar DART®/MS is explored as an alternative to He DART®/MS for the forensic analysis of illicit drugs, without the assistance of any dopant.

The ionization capability of Ar DART®/MS was first tested with polar solvents, including water, acetonitrile, methanol, ethanol, isopropanol, ethyl acetate, acetone, and tetrahydrofuran with respective ionization energy of 12.62eV, 12.20eV, 10.84eV, 10.50eV, 10.17eV, 10.01eV, 9.70eV and 9.40eV. It was found that Ar DART®/MS was unable to efficiently ionize water, acetonitrile, and methanol, but was able to ionize ethanol moderately and the rest of the polar solvents efficiently. Therefore, it was concluded that Ar DART®/MS was able to ionize all the organic compounds, including illicit drugs as they are molecularly larger and should have IE lower than ethanol.

Subsequently, ten commonly abused drugs (i.e., (±)-amphetamine, cocaine, diazepam, heroin, Lysergic Acid Diethylamide (LSD), (±)-3,4-Methylenedioxymethamphetamine (MDMA), Phencyclidine (PCP), psilocin, testosterone, and Δ^9-Tetrahydrocannabinol (THC)) were analyzed by Ar DART®/MS to test the ionizing capability of Ar DART® toward compounds with diverse functional groups, optimize the instrumental conditions for the analysis of illicit drugs, estimate the Limit Of Detection (LOD) of the analysis, and develop a general analytical protocol for the analysis. Under optimum conditions, the LOD of Ar DART®/MS was determined to be approximately 100μg/mL. Because the sampling volume was approximately 1μL, the LOD of Ar DART®/MS was approximately 100pg in quantities. The general analytical protocol took approximately three minutes in the analysis of each commonly abused drugs. All the commonly abused drugs were positively identified at 100μg/mL because the experimentally measured monoisotopic mass of the predominate $[M+H]^+$ ion, sometimes with the additional molecular ion, from each drug were within ±5mDa of the theoretically calculated monoisotopic mass. No time-consuming and labor-intensive sample preparation steps were required during the analysis.

Finally, the general analytical protocol was applied to tablet analysis of six prescriptions drugs (i.e., clonazepam 1mg, cyclobenzaprine 10mg, metaxalone 800mg, oxycodone/acetaminophen 5/325mg, tramadol/APAP 37.5/325mg, and zolpidem10 mg). It was found that while Ar DART® was able to efficiently ionize and subsequently identify the active ingredients, it practically omitted the inactive ingredients in the tablets.

The ionization mechanism of Ar DART® was likely the generation of protonated molecular ions through direct Penning ionization of polar compounds by metastable Ar followed by self-protonation of the analytes, which was also confirmed by the observation of molecular ions of some commonly abused drugs. In comparison with He DART®, Ar DART® generated much cleaner background mass spectrum and simpler mass spectra of tested drugs due to the lower IE of metastable Ar species, which was an advantage in data analysis; however, Ar DART® had an LOD approximately two orders of magnitude higher, though it should be still sensitive enough for the analysis of seized drug evidence.

Illicit Drugs, Ar DART®/MS, Tablet Analysis

B17 Forensic Analysis of Illicit Drugs by Nitrogen Direct Analysis in Real-Time Mass Spectrometry (N_2 DART®-MS)

Liguo Song, PhD, Western Illinois University, Dept of Chemistry, 324B Currens Hall, 1 University Drive, Macomb, IL 61455; Wei Chean Chuah, Western Illinois University, 214 Currens Hall, 1 University Circle, Macomb, IL 61455; Jeffrey D. Quick, Western Illinois University, 214 Currens Hall, 1 University Circle, Macomb, IL 61455; Sheher Mohsin, PhD, Agilent Technologies, Inc, 201 Hansen Court, Ste 108, Wood Dale, IL 60191; Benjamin Owen, PhD, Agilent Technologies, Inc, 201 Hansen Court, Ste 108, Wood Dale, IL 60191; Edward Remsen, PhD, Bradley University, 1501 W Bradley Avenue, Peoria, IL 61625; and John E. Bartmess, PhD, University of Tennessee, 552 Buehler Hall, 1420 Circle Drive, Knoxville, TN 37996-1600*

After attending this presentation, attendees will appreciate a new mode of DART®/MS using cheaper and more easily accessible N_2 instead of the popularly used Helium (He) as the DART® ionization gas, its great ionization capabilities for illicit drugs, and a general analytical protocol to use N_2 DART®/MS for the forensic analysis of illicit drugs with either a JEOL AccuTOF™ orthogonal Time-Of-Flight (TOF) MS or an Agilent® 6550 quadrupole TOF (qTOF) MS.

This presentation will impact the forensic science community by introducing a novel N_2 DART®/MS technique to effectively ionize seized drug evidence, which has the potential to be used with a miniature mass spectrometer in the future for the forensic analysis of illicit drugs at crime scenes.

Currently, helium gas is popularly used in DART®/MS. Theoretically, He DART®/MS should have the best sensitivity because He is an inert gas that occupies a front position in the periodic table, therefore producing metastable species with the highest internal energy (i.e., long-lived He 2^3S electronic excited state atoms with an internal energy of 19.8eV); however, when He gas is not readily available (e.g., during space missions or the forensic analysis of illicit drugs at the crime scene), nitrogen gas is the best option because it is the next inert gas behind He in the periodic table.

In this study, N_2 DART®/TOF/MS with a JEOL AccuTOF™ mass spectrometer was first used to analyze ten commonly abused drugs (i.e., (±)-amphetamine, cocaine, diazepam, heroin, Lysergic Acid Diethylamide (LSD), (±)-3,4-Methylenedioxymethamphetamine (MDMA), Phencyclidine (PCP), psilocin, testosterone, and Δ^9-Tetrahydrocannabinol (THC)) to test the ionizing capability of N_2 DART® toward compounds with diverse functional groups, optimize the instrumental conditions for forensic analysis of illicit drugs, estimate the Limit Of Detection (LOD) of the analysis, and develop a general analytical protocol for the analysis. Under optimum conditions, the LOD of N_2 DART®/TOF/MS was determined to be approximately 10μg/mL. Because the sampling volume was approximately 1μL, the LOD of N_2 DART®/TOF/MS was approximately 10pg in quantities. The general analytical protocol took approximately three minutes in the analysis of each commonly abused drug. All the commonly abused drugs were positively identified at 10μg/mL as the experimentally measured monoisotopic mass of multiple ions, predominately the $[M+H]^+$ ion, from each drug were within ±5mDa of the theoretically calculated monoisotopic mass. No time-consuming and labor-intensive sample preparation steps were required during the analysis. The general analytical protocol was then applied to the tablet analysis of six prescriptions drugs (i.e., clonazepam 1mg, cyclobenzaprine 10mg, metaxalone 800mg, oxycodone/acetaminophen 5/325mg, tramadol/APAP 37.5/325mg, and zolpidem 10mg). It was found that while N_2 DART® was able to efficiently ionize and subsequently identify the active ingredients in the tablets, it practically omitted the inactive ingredients. Therefore, it was concluded that the general analytical protocol can be utilized in the analysis of seized drugs because they are mixtures with similar complexity as the tablets.

N_2 DART®/qTOF/MS with an Agilent® 6550 mass spectrometer was further used to analyze ten commonly abused drugs at 10μg/mL in order to test the applicability of N_2 DART® on different MS platforms. First, all of the commonly abused drugs were positively identified by TOF/MS of the $[M+H]^+$ ions with their monoisotopic mass and isotopic pattern. Then, they were further positively identified by qTOF/MS/MS of the $[M+H]^+$ ions at Collision-Inducted Dissociation (CID) at 10.0V and 20.0V. The obtained mass spectra were automatically matched with the Agilent® Forensic Toxicology Personal Compound Database and Library (PCDL).

Illicit Drugs, N_2 DART®/MS, Seized Drug Analysis

B18 Structural Elucidation of Synthetic Opioids

Julie R. Pallister, MSc, Canada Border Services Agency, 79 Bentley Avenue, Ottawa, ON K2E6T7, CANADA; and Cathy Copeland, MSc, 79 Bentley Avenue, Nepean, ON K1A 0L8, CANADA*

After attending this presentation, attendees will better understand the analytical strategy employed by the Contraband Drug Analysis Section of the Canada Border Services Agency for identifying new substances.

This presentation will impact the forensic science community by providing an overview of analytical challenges encountered during casework involving fentanyl analogues and related drugs. The impact of salt forms and mixtures on the analytical approach as well as the use of Nuclear Magnetic Resonance (NMR) methods for structural elucidation will be discussed. These challenges will be communicated with the drug analysis community in the hopes of spreading awareness and providing others with the ability to apply caution when presented with analysis of these substances and gaining confidence in structural determination.

With the emergence of powerful new opioid agonists (such as W-18 and U-47700) and a resurgence of fentanyl and its analogues, it is increasingly important for drug chemists to share analytical data and strategies for the identification of these compounds. The number of sites on the fentanyl structure that are easily substituted has led to a vast number of potential analogues. Identifying where substitutions have occurred on the molecule by structure elucidation can be challenging. As a result, NMR techniques are often required.

There has been a steady increase in both the number and diversity of synthetic opioid shipments intercepted by the Canada Border Services Agency (both importations and exportations). As of the beginning of 2017, the Contraband Drug Analysis Section has identified an average of one new fentanyl analogue per month. According to a recent United Nations Report, Canada consumes more prescription opioids per capita than any other country in the world. As a consequence, many users look to the illicit market to support their addictions. The emergence of fentanyl, its analogues, and other low-dose drugs in the illicit market has developed new concerns for public safety professionals and new challenges for forensic drug analysis.

When encountering a new drug substance, database references are not always available and literature references can be difficult to find. In these cases, full structural elucidation allows for the identification of the compound. The Contraband Drug Analysis Section is fortunate to have a number of instruments to assist in substance identification: Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR), FT-Raman, Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), Gas Chromatography/ Infrared Spectroscopy (GC/IR), and Nuclear Magnetic Resonance (NMR), among others. Upon analysis of fentanyl analogues, there have been circumstances in which typical analysis methods were not enough to confidently identify the compound. As an example, NMR methods beyond the routine ^{1}H, ^{13}C, ^{1}H-^{1}H COSY, ^{1}H-^{13}C HSQC, ^{1}H-^{13}C HBMC, and Distortionless Enhancement by Polarization Transfer (DEPT) experiments were employed, including ^{1}H-^{15}N HMBC and Two-Dimensional Incredible Natural-Abundance Double-Quantum Transfer Experiment (2D INADEQUATE) in order to identify 2-methoxy-furanylfentanyl and rule out 3-methoxy-furanylfentanyl. Details of this case as well as structural elucidation of other compounds will be discussed.

Fentanyl, NMR, Elucidation

B19 The Detection of Gamma-Hydroxybutyric Acid (GHB) in Water and Mixed Drinks Without Sample Preparation Using Total Vaporization-Solid Phase Microextraction (TV-SPME) With On-Fiber Derivatization

Logan D. Hickey, BSc, 723 Lockefield Court, Apt I, Indianapolis, IN 46202; Jordan Ash, MS, 1435 Stadium Way, Apt 2101, Indianapolis, IN 46202; Vicky Pai, Indiana University Purdue University Indianapolis, 420 N Blackford Street, Indianapolis, IN 46202; and John V. Goodpaster, PhD, FIS Program, IUPUI, 402 N Blackford Street, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will be aware of a new technique by which GHB can be effectively identified by Gas Chromatography/Mass Spectrometry (GC/MS) in aqueous or mixed drink samples with no sample preparation required.

This presentation will impact the forensic science community by introducing a new procedure for the detection and identification of GHB in drink samples using GC/MS without extensive sample preparation. The method is simple and effective and could be used to acquire evidence of drug-facilitated sexual assault involving the use of GHB.

GHB is often used in drug-facilitated sexual assaults because it incapacitates victims, induces memory loss, and does not persist in the human body.[1] The drug can be surreptitiously administered to a victim's drink, in which case a forensic scientist would receive a beverage suspected of containing GHB. The "workhorse" technique of forensic science laboratories is GC/MS. GHB is difficult to analyze by GC/MS due in part to its acidity (pKa 4.7), high polarity, and high solubility in aqueous solution. It is also well known that GHB readily dehydrates to Gamma-Butyrolactone (GBL) in the high heat of the GC inlet, further complicating its analysis.[2] One method used to make compounds more amenable to GC/MS analysis is derivatization, in which labile hydrogens are replaced with more stable groups, resulting in a product that has increased volatility and stability.[3] Derivatization in solutions followed by liquid injection GC/MS is already in use in forensic science laboratories, but this practice requires separate steps for solvent extraction, derivatization, and analysis.

Solid Phase Microextraction (SPME) is a technique in which the analytes are pre-concentrated onto a thin fiber coated in absorptive or adsorptive material. In TV-SPME, a small aliquot of analyte in solution is placed in a vial and heated until the sample completely vaporizes, resulting in a two-phase system. An SPME fiber is then introduced and the sample is absorbed onto the fiber coating. The maximum volume for total vaporization of a given solvent can be easily calculated given the solvent vapor pressure, molecular weight, vial volume, and temperature.[4] For example, the calculated maximum volume of methanol for total vaporization in a 20mL vial at 60°C is 24µL. The use of TV-SPME for sampling can streamline the derivatization process by allowing the derivatization to be done on-fiber. In this process, an SPME fiber is exposed to the headspace of a vial containing derivatization agent, then exposed to the heated headspace of a vial containing the sample. The reaction between the analyte and the derivatization agent then takes place directly on the SPME fiber. After sufficient time for reaction, the fiber is moved to the inlet of the GC for desorption. The use of a robotic autosampler can make this a fully automated process for which no sample preparation is necessary.

This method is ideal for the analysis of GHB in drink samples. GHB has been successfully identified in aqueous solution and in simulated mixed drinks by TV-SPME with on-fiber derivatization using N, O-Bis trifluoroacetamide with 1% trimethylchlorosilane (BSTFA + 1% TMCS).

Solid Phase Microextraction, Derivatization, GHB

B20 The Detection of Phytocannabinoids From Buccal Swabs Using One Vial Headspace Vaporization Derivatization Coupled With Solid-Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS)

Lauren M. Perry, BS, 2902 Whispering Winds Drive, Apt 802, Pearland, TX 77581; Sun Yi Li, BSc, Sam Houston State University, Chemistry and Forensic Science, Bldg 221A, 1003 Bowers, Box 2525, Huntsville, TX 77341; and Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand the application of Heated Headspace/Solid Phase Microextraction (HHS/SPME) for the extraction of phytocannabinoids from the headspace of air-dried buccal swabs.

This presentation will impact the forensic science community by providing a novel methodology for the detection of phytocannabinoids from buccal swabs. This HHS/SPME-GC/MS analytical platform potentially can be used to non-destructively extract phytocannabinoids from buccal swabs. Further chemical or biological testing of the HHS/SPME processed buccal swab evidence can still be conducted when needed.

Headspace derivatization of phytocannabinoids will also be discussed for the qualitative and quantitative phytocannabinoids analysis using GC/MS.

Marijuana is classified federally as a Schedule I controlled substance and is becoming a prevalent controlled substance reported in motor vehicle accidents. In order to screen for target drugs in evidence, samples undergo preparation to concentrate the drug of interest and remove interferences before instrumental analysis. SPME is a versatile alternative to Liquid-Liquid Extraction (LLE) and Solid Phase Extraction (SPE). This study combined the Total Vaporization Technique (TVT), high-temperature technique, and in-vial derivatization with SPME in one single step to facilitate the extraction and detection of phytocannabinoids from buccal swabs.

One vial headspace vaporization derivatization of phytocannabinoids was achieved by placing a 250uL glass insert containing a derivatization reagent inside a 20mL headspace sample vial. In order to determine the interferences level from buccal swabs using HHS/SPME, five different swab sources were tested. Each swab had 0.4µg of Δ9-THC added onto it for the test. Approximately 5mg of each swab material was placed into a 20mL headspace vial and sealed with a silicone septum and a magnetic cap for automated HHS/SPME-GC/MS. To determine the optimal headspace derivatization and extraction in one HHS/SPME step, varying amounts of derivatization reagent were evaluated. First, 4µL aliquots of Δ9-THC standard solution (100µg/mL) were placed in eight separate 20mL headspace vials. After drying the solvent, 1µL, 2.5µL, 5µL, 7.5µL, 12.5µL, 15µL, 20µL, and 25µL of N-Methyl-N-(trimethylsilyl)trifluoroacetamide (MSTFA) were added to the inserts inside headspace vials. HHS/SPME-SPME conditions had been optimized for the separation and detection of phytocannabinoids and their derivatized products.

This technique allowed for the detection of seven phytocannabinoids on buccal swabs, including Cannabichromene (CBC), Cannabidiol (CBD), Cannabigerol (CBG), Cannabinol (CBN), delta-8-Tetrahydrocannabinol (Δ-8-THC), delta-9-Tetrahydrocannabinol (Δ-9-THC), and Tetrahydrocannabivarin (THCV), at sub-microgram levels. This new approach not only improved sensitivity and selectivity through the successful derivatization of phytocannabinoids from sample headspace but also facilitated automation of HHS/SPME-GC/MS. This methodology has the potential for the forensic application to detect phytocannabinoids from swab samples.

Marijuana, Buccal Swab, HS/SPME

B21 The Determination of the Source of Origin for Methomyl in a Fatal Poisoning Case by Gas Chromatography/Isotope Ratio Mass Spectrometry (GC/IRMS)

Nam Yee Kim, National Forensic Service, 10 Ipchun-ro, Wonju-si, Seoul 26460, SOUTH KOREA; Hye-Jin Choi, National Forensic Service, 10, Ipchun-ro, Wonju-si, Gangwon-do 26460, SOUTH KOREA; Byeong-Yeol Song, PhD, National Forensic Service, 10, Ipchun-ro, Wonju-si 26460, SOUTH KOREA; Seongshin Gwak, PhD, National Forensic Service, 10 Ipchoon-ro, Wonju, Gangwon 26460, SOUTH KOREA; Geummun Nam, PhD, 10, Ipchun-ro, Wonju-si, Gangwon-do, 26460 , SOUTH KOREA; Young-Shik Choi, PhD, Division of Forensic Medicine, Seoul 158-707, SOUTH KOREA*

After attending this presentation, attendees will better understand how stable isotope analysis by GC/IRMS can apply for determining the source of origin for methomyl, a carbamate insecticide, from a fatal poisoning case.

This presentation will impact the forensic science community by demonstrating the application of GC/IRMS in a methomyl poisoning case. With the application of GC/IRMS, it was possible to correlate a potential perpetrator to a methomyl poisoning case.

On the night of March 9, 2016, six people who live in a small town were playing a Korean card game in a town community center. While playing cards, two men opened two bottles of Soju (one of the most popular alcoholic beverages in South Korea). While the two men were drinking the Soju, they felt nauseated, began vomiting, and were admitted to an emergency room. During medical treatment at the hospital, the 62-year-old man was pronounced dead due to fatal poisoning from methomyl and the 67-year-old man was hospitalized for further medical treatment.

The two bottles of Soju were seized at the crime scene and biological samples from the two victims were also submitted to the laboratory for analysis to determine their source. To determine who blended methomyl into the bottles of Soju, seven different methomyl products were seized from suspects who played a card game together and lived in the same town; however, it was found that ^{13}C isotope ratio values of seven methomyl products ($\delta^{13}C \approx -28‰ \sim -32‰$) were different from the values of methomyl contained in the two bottles of Soju ($\delta^{13}C \approx -22‰$).

Three weeks after the initial incident, the husband of one of the suspects committed suicide in his barn and an energy drink bottle containing methomyl was found next to his body. It was discovered that the cause of death was also methomyl poisoning. The empty energy drink bottle and biological samples of this third person were submitted for isotope analysis. It was determined that the stable isotope ratios of carbon and nitrogen ($\delta\,^{13}C$, $\delta\,^{15}N$, $\delta\,^{2}H$) for methomyl components from the Soju bottles found at the town community center were similar to the $\delta\,^{13}C$, $\delta\,^{15}N$ values of the bottle of energy drink, indicating that methomyl from the Soju bottles originated from the same source as the energy drink bottle. In order to identify a manufacturer of methomyl products, the stable isotope ratio ($\delta\,^{13}C$, $\delta\,^{15}N$, $\delta\,^{2}H$) of 11 types of methomyl products with different expiration dates were collected from suspects and were analyzed by GC/IRMS. As a result, it was determined that a Samgong methomyl product with an expiration date of October 31, 2011, had a similar stable isotope ratio.

This study illustrates that GC/IRMS can be readily applied to the determination of a source when it is not possible to identify a perpetrator due to lack of information.

GC/IRMS, Methomyl, Forensic Provenancing

B22 A Comparison of Portable Infrared (IR) Spectrometers and the Narcotic Identification Kit (NIK) Field Test for the On-Scene Analysis of Cocaine Hydrochloride (HCl)

Dory K. Lieblein, 150 Daytona Street, West Haven, CT 06516; Meghann McMahon, MS, Wisconsin DOJ, Milwaukee, WI 53204; Pauline E. Leary, MS, PhD, SmithsDetection, 1934 Bulls Head Road, Stanfordville, NY 12581; Peter Massey, MS, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; and Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand the benefits and limitations of both portable IR spectrometry and the NIK field tests for the on-scene analysis of cocaine HCl.

This presentation will impact the forensic science and law enforcement community by determining whether portable IR spectrometers or NIK field tests are more advantageous for the analysis of cocaine HCl at crime scenes.

The majority of inmates across the United States are incarcerated for drug-related offenses. It is important that the technology used to test for controlled substances is accurate and reliable. For on-scene presumptive testing, the NIK test is most often utilized to test for the presence of a controlled substance. The NIK tests use colorimetric reactions, which rely on a specific moiety of the drug molecule to react with the provided reagents to produce characteristic color changes. In the NIK test used to detect and identify cocaine, there are three chemical ampoules within a plastic pouch closed with a safety clip. To test a substance, a loading device is used to deliver the correct amount of sample to the pouch. A positive result for cocaine is indicated by blue or pink with blue speckles after the reaction in the first ampoule, pink after the reaction in the second ampoule, and a pink top layer with a blue bottom layer after the reaction in the third ampoule. Recently, it has been discovered that there have been numerous cases where false positive NIK tests at the scene were later disproven via confirmatory lab testing. As a result, there have been hundreds of wrongful convictions.[1] This has resulted in press coverage condemning the NIK tests, followed by significant public outrage. In addition, as of July 2017, the Houston, TX, police department has stopped using these tests at the scene, eliminating all on-scene drug testing. The possible dangerous exposure of officers to potentially lethal drugs such as fentanyl was also cited as a reason for stopping on-scene drug testing; however, this abandonment of on scene presumptive drug testing could be premature given the availability of portable IR spectrometers that can be used to provide accurate and reliable identifications at the scene, with minimal risk of exposure to law-enforcement personnel when appropriate levels of personal protective equipment are employed.[1] IR spectroscopy measures the absorption of IR radiation, specifically the vibrations of the bonds between atoms, to determine the structure of a molecule. This research compares the use of portable IR technology with NIK tests to determine which method is better suited for the on-scene analysis of illicit drugs, specifically cocaine HCl.

This research assessed important performance characteristics for each method, including a short- and long-term cost analysis, whether the method is destructive or non-destructive, the ease of use, knowledge and skill required of the operator, speed of analysis, limit of detection, susceptibility to false positives and false negatives, and the effect of common diluents on the ability to identify cocaine. The experimental determination of the limit of detection and the effect of common diluents on the recognition of cocaine HCl used common chemical diluents (e.g., lidocaine, mannitol, and caffeine) as well as common household diluents (e.g., artificial sweetener and baby formula). A positive result for cocaine HCl with the NIK test was indicated by the appropriate color changes and was documented with photographs. A positive result with the portable IR spectrometer was a "hit" for cocaine using the library search function for the instrument. Manual spectral analysis was conducted as well to identify any instrument false positive and false negative results that could be due to the search algorithm used for library matching. Replicates of each analysis were conducted to ensure reproducible results.

This research concluded that although portable IR spectrometers require a large initial financial investment, their high-performance characteristics (e.g., ease of use, rapid analysis, non-destructive, acceptable limit of detection, minimal false positives and negatives) makes them a more superior tool than the NIK tests for the on-scene presumptive analysis of cocaine HCl.

Infrared Spectroscopy, Controlled Substance, NIK Tests

B23 An Assessment of Drugs in Syringes From New York City Syringe Exchange Programs

Taís R. Fiorentin, PhD, 210 Krewson Terrace, Willow Grove, PA 19090; Jaclyn Blachman-Forshay, NYC Department of Health and Mental Hygiene, 42-09 28th Street, Queens, New York City, NY 11101; Alexandra Harocopos, NYC Department of Health and Mental Hygiene, 42-09 28th Street, Queens, New York City, NY 11101; Denise Paone, EdD, NYC Department of Health and Mental Hygiene, 42-09 28th Street, Queens, New York City, NY 11101; Zeland Schwartz, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the number and variety of substances in syringes collected from 11 Syringe Exchange Programs (SEPs) in New York, NY.

This presentation will impact the forensic science community by providing data on the use of syringe testing as a surrogate for evaluating the cutting agents and toxic adulterants present in injected drugs through the analysis of methanolic rinses and acid/basic extracts from syringes collected from intravenous drug users between May 2017 and July 2017.

Fentanyl is driving an increase in fatal overdose in New York City, and this study was conducted to estimate the prevalence of fentanyl in the drugs used by SEP participants. An SEP is a service that provides hypodermic syringes and associated injection equipment to injecting drug users at no cost. The goal of the program is a reduction in potential harms to the users, including risks of infection from non-sterile drug injection equipment and the transmission of blood-borne pathogens, such as HIV and HCV.

In addition to their pharmacoepidemiological value as an index of patterns of drug use, drug paraphernalia is frequently submitted to forensic science laboratories for analysis. These exhibits may contain important information regarding the presence of controlled substances, helping in the investigation of crime scenes, drug deaths, and drug possession or trafficking cases in addition to helping characterize the drug abuse scenario and the cutting agents in a specific population.

Three hundred and fifty-six syringes were submitted by the New York City Department of Health and Mental Hygiene for analysis of residue or drug content. Samples were submitted to NMS Labs for an initial screening for the presence of controlled substances. The internal surfaces of the syringes were washed with methanol, and a portion of the methanol wash was used to perform an acid/base extraction to clean up and concentrate the samples. The acid/base extracts were tested by Gas Chromatography/Mass Spectrometry (GC/MS) at NMS Labs. The instrument was operated in the electron impact mode and full scan acquisition (range 40-550m/z), using a ZB35HT column, injection volume of 1µL, splitless mode, injection and detection temperature of 265°C and 300°C, respectively. Total run time was 15 minutes.

The methanol rinses and the remaining acid/base extracts were transferred to the Center for Forensic Science Research and Education (CFSRE) for further analysis by Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS). A reverse phase gradient was performed using ammonium formate (10mM, pH 3) and methanol/acetonitrile (50:50) for chromatographic separation on a Phenomenex® Kinetex C18 analytical column at a flow rate of 0.4mL/min for a total run time of 15.5 minutes. Precursor ions were acquired by TOF/MS scan (100-510m/z) via positive electrospray ionization. Precursor isolation was performed using SWATH™ acquisition, consisting of 27 overlapping isolation windows. Fragmentation was achieved using a rolling collision energy of 35±15eV. The acquisition total cycle time was 0.77 seconds. Data processing was performed using PeakView® with an extracted ion chromatogram (XIC) list containing 1,463 compounds, of which 382 had fragment and retention-time data, and accurate mass library containing 1,790 compounds.

Of the 356 syringes analyzed, 270 (75.8%) were positive for any substance. The most common drug identified was heroin (47%), followed by cocaine (40%), fentanyl (22%), methamphetamine (10%) and furanyl fentanyl (3.9%). Caffeine (34%) was the most common cutting agent detected, followed by quinine/quinidine (28%), lidocaine (21%), levamisole (16%), and phenacetin (12%).

The cutting agents used are constantly changing over time and may contribute to the toxic effects of the drugs on users. Levamisole and phenacetin are among the most-used cutting agents and are associated with neutropenia, agranulocytosis, skin necrosis, and nephrotoxicity. Some studies have already reported deaths as a result of complications secondary to levamisole-tainted cocaine.

Knowledge about the drugs used and cutting agents found in paraphernalia from a select drug using population can help to inform patterns of drug use and associated health risks to users, including the rates of exposure to toxic adulterants or highly risky substances, such as fentanyl. The presence of drug combinations, cutting agents, and adulterants may assist in determining common origin from drugs in the possession of different users. The analysis of drug residue in syringes from this population can contribute to a better informed public policy that helps reduce risk for people who inject drugs.

Syringe, GC/MS, LC/qTOF

B24 Narcotic Age and Working Dog Performance: Instrumental Perspectives on Training Aid Lifespan

Lauren Alejandro, BSc, 4510 Ironton Avenue, Apt 12107, Lubbock, TX 79407; and Paola A. Prada, PhD, Texas Tech University, Institute for Forensic Science, 4434 S Loop 289, Lubbock, TX 79414*

After attending this presentation, attendees will better understand the chemicals emitted from both pseudo and real narcotic K-9 training aids evaluated over periods of time and how these aids perform in routine canine training.

This presentation will impact the forensic science community by providing strong, scientific perspectives, implementing both chemical and behavioral studies, concerning the odor concentration levels of K-9 narcotic training aids over time. Canines are the front line of defense in detecting narcotics by police and military working units worldwide. Therefore, this study will further enhance optimum canine detection procedures for national security purposes. The optimal implementation of canine narcotic detection impacts the forensic field by providing a valuable, highly deployable tool in the war against drugs.

There has been little scientific research into the use of narcotic training aids in relation to K-9 performance, even though they are a pivotal part of the training regimen. Many different associations that certify canines as narcotic detector dogs have very few standards as to the optimal lifespan of their training aids. Emerging research is beginning to look into canine detection, but none is specifically looking at the age or lifespan of narcotic canine training aids and their subsequent impact on canine performance.

The goals of this study were to monitor and provide a calibration standard of the target odor vapors emanating from real and pseudo K-9 training aids based on age and to document their training aid alert performance during K-9 field testing. The odor evaluation process consisted of collaboration with the Lubbock Police Department (LPD) Canine Unit and the use of their narcotic training aids that range up to 10 years of age compared to fresh training aids. The study used nine certified narcotic detection K-9 teams for field testing purposes. Instrumental evaluation utilized Divinylbenzene/Carbon/Polydimethylsiloxane (DVB/CAR/PDMS) -coated Solid-Phase Microextraction (SPME) fibers that were injected into a Gas Chromatography/Mass Spectrometry (GC/MS) system for the identification of extracted narcotic headspace odor profiles of heroin, methamphetamine, and cocaine. The LPD narcotic training aids were sampled in individual mason jars for time increments of 15 minutes, 30 minutes, and 1 hour to allow for headspace extraction time optimization. The pseudo narcotic formulations were evaluated in a controlled laboratory setting of storage time ranges of 2 weeks, 4 weeks, 6 weeks, and up to 12 weeks. Evaluation of both abundance and type of target volatiles was performed at each extraction time to measure training aid condition for both real and pseudo narcotics. This was performed in order to document the emission of odor vapors at different time ranges. Field testing of both the real and the pseudo narcotic training aids were then run through routine K-9 detection narcotic training by a double-blind line-up test. The findings include an assortment of chemical compounds emitted from each narcotic exhibiting distinctive odor profiles as a factor of age.

Conclusion and Significance: The benefit this study provides is enhanced knowledge in the realm of optimal canine detection procedures for national security purposes and K-9 detection performance. This research will ultimately bridge a gap in knowledge regarding the odor concentration levels for canine narcotic training aids at various ages and how this age or lifespan impacts practical canine field work, an aspect which has not previously been evaluated.

Canine Detection, Narcotic Odor, SPME-GC/MS

B25 The Classification of Synthetic Phenethylamines According to Structural Subclass Using Multivariate Statistical Procedures

Amanda L. Setser, BS, Michigan State University, 578 S Shaw Lane, Rm 205, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

The goal of this presentation is to demonstrate the application of multivariate statistical procedures for the classification of synthetic phenethylamines according to structural subclass.

This presentation will impact the forensic science community by increasing familiarity with the use of Principal Components Analysis (PCA) to identify ions characteristic of the phenethylamine subclasses and the subsequent use of Discriminant Analysis (DA) to develop classification models based on mass spectral data.

Recently, synthetic designer drugs have become a major concern in the United States. These drugs are synthesized with a slightly different molecular structure than already scheduled compounds to mimic the effects while avoiding legal ramifications; however, definitive identification of these rapidly emerging analogs is often challenging as no reference standard is immediately available to aid in identification.

The study presented describes the development of statistical models that can be used to classify a new analog to a known designer drug class or subclass. The initial work focused on three phenethylamine subclasses: Aminopropylbenzofuran (APB); 2,5-dimethoxy- (2C); and 2,5-dimethoxy-N-2-methoxybenzyl- (NBOMe) phenethylamines. A number of compounds from each subclass were selected to represent the variety of substitutions on the core structure.

Each phenethylamine was analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) and the resulting mass spectra were first subjected to PCA to identify ions that were most characteristic of each subclass. In the PCA scores plot, members of each subclass were grouped together, with clear distinction among the three phenethylamine subclasses. The loadings plot for each PC was then assessed to identify the ions contributing most to the variance described in the scores plot. For example, *m/z* 91, 121, and 150, which are dominant ions in the NBOMe-phenethylamines, were weighted positively on PC1 whereas, *m/z* 44, which is the base peak in the APB-phenethylamines, was weighted negatively. As a result, the NBOMe- and APB-phenethylamines were distinguished on the first PC. The same *m/z* values were weighted positively on PC2 while *m/z* 165, 180, and 197 were weighted negatively. These latter ions are present in many of the 2C-phenethylamines with the result that this subclass was distinguished from the other two subclasses on PC2. Additional PCs were investigated in a similar manner to identify additional characteristic ions.

The ions identified in the PC loadings were used as the variables to develop classification models using DA. To do this, a training set was defined that included phenethylamines representative of the three subclasses. Models were tested using an external test set that consisted of phenethylamines representative of the three subclasses that were analyzed on a different day.

The first model included the nine characteristic ions identified in the first two PCs, which accounted for 46% of the variance in the data set. With this model, the classification success was 79%, with two of the 2C-phenethylamines and two of the NBOMe-phenethylamines misclassified. The second model included 14 characteristic ions that were identified in the first three PCs, which accounted for 56% of the variance in the data set. With this model, classification success increased to 89%, although two of the NBOMe-phenethylamines were still incorrectly classified as 2C-phenethylamines. A third model was developed that included the 18 characteristic ions identified in the first four PCs, which accounted for 64.6% of the total variance; however, despite the increased number of variables, there was no improvement in the rate of successful classification.

This presentation will demonstrate the utility of multivariate statistical procedures for the classification of synthetic phenethylamines. While this research focuses on phenethylamines, the statistical methods can be applied to develop classification models for different classes of drugs to combat the growing problem of new emerging designer drugs.

Synthetic Phenethylamines, Classification, GC/MS

B26 The Development of a Multichannel Paper Microfluidic Device for the Detection of Drugs of Abuse Using Gold Nanoparticle/Aptamer Complexes

Ling Wang, MS, Florida International University, CP-304 11200 SW 8th Street, Miami, FL 33139; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to describe a design of a multichannel paper microfluidic device that provides colorimetric detection based on the formation of a complex of gold nanoparticles and aptamers. Information provided will include the design of the multichannel paper microfluidic device, the multiplexed detection of different controlled substances, and the validation of the multichannel paper chip.

This presentation will impact the forensic science community by demonstrating an application of presumptive detection using a novel paper-based detection method. This new procedure is rapid, inexpensive, and applicable for the detection of multiple seized drugs, including cocaine, codeine, and methamphetamine.

Recently, new types of aptamers have been developed to bind specific drugs of abuse. Aptamers are oligonucleotides or peptide sequences that bind other molecules. This binding can be exploited for detection using various techniques such as colorimetry, amperometry, or surface plasmon resonance. An alternative platform for gold nanoparticle/ aptamer detection based on paper microfluidic devices has been investigated. To accomplish this, a paper microfluidic chip with a multiple-channel design has been created that combines gold nanoparticles and special aptamers into a ready-to-use format. To operate the procedure, samples are dissolved in a carrier solvent in vials, then applied to the paper just before analysis. The high specificity of aptamer binding can result in a useful presumptive test with minimal interferences. These devices are easy to prepare and inexpensive to operate.

Paper microfluidic devices were prepared with a wax-ink printer, thermal laminator, chromatography paper, gold nanoparticles, and aptamers. The melted wax ink creates hydrophilic channels on paper chips. Gold nanoparticles and the developed aptamers are then placed sequentially in each channel. Drug samples dissolved in ionic moving solutions migrate up the channel via capillary action, whereupon they reach a zone containing free aptamers followed by a zone containing gold nanoparticles. If the target drug is not present, the aptamers bind the nanoparticles in a non-specific fashion, and no color change occurs; however, if the target drug is present, the aptamers bind the drug and a salt-induced color change occurs since there are no aptamers left to prevent nanoparticle aggregation. The resultant color change from red to black indicates a positive response. The entire process takes five to ten minutes.

This new microfluidic device permits the development of rapid, inexpensive, and easily operated tests for drugs of abuse. The multi-channel design provides a safe and convenient presumptive tool for the detection of several drugs at once.

Presumptive Drug Testing, Aptamer, Gold Nanoparticles

B27 The Prevention of Occupational Exposure to Fentanyl and Fentanyl-Like Compounds: Elbow Grease and OxiClean™

Travis J. Worst, PhD, Bowling Green State University, 43 College Park Office Bldg, Bowling Green, OH 43403; Noah M. Froelich, Department of Chemistry, Bowling Green State University, Bowling Green, OH 43403; and Jon E. Sprague, PhD, Center for the Future of Forensic Sci at BGSU, 39 College Park, Bowling Green State University, Bowling Green, OH 43403*

The goal of this presentation is to provide information on safely and effectively preventing occupational exposure to fentanyl through a decontamination procedure.

This presentation will impact the forensic science community by providing a method of preventing occupational exposures to fentanyl, which has not been addressed to date.

The current opiate epidemic not only affects the lives of those using the illicit substances; the lives of first responders and evidence custodians are also at risk. There have been multiple occupational exposures in the state of Ohio in the first seven months of 2017. Although the Centers for Disease Control and Prevention has provided useful information regarding personal protective equipment, there is very little information regarding appropriate and effective methods to clean a potential fentanyl spill. While there is one publication regarding the best oxidizers to degrade fentanyl, that study was not practical for various reasons.[1] The present study was designed to account for a working environment and supplies that can be purchased easily. This study also addresses the physical act of scrubbing the area with a standard paper towel in addition to chemical detergents.

Consistent amounts of fentanyl or acetylfentanyl were measured and placed in tape-defined squares on a laboratory benchtop surface. The powdered drugs were then subject to either tap water or a solution of tap water and OxiClean™ Versatile Stain Remover powdered detergent using 5mg in 500mL. This specific type of OxiClean™ uses oxidizers from the Qi study, where other versions may not.[1] Using time points of 0, 15, 30, and 60 minutes, samples were collected after allowing the water or solution to "soak" the drug or after "scrubbing" the area after soaking. The swabs were then soaked and agitated in methanol for 15 seconds and analyzed using a Gas Chromatograph coupled to a Mass Spectrometer (GC/MS). The maximum amount of drug detected by the instrument was calculated to be 200ng based on the amount seeded on the table, the volume injected into the instrument, and the volume split off during method acquisition. This nanogram level of fentanyl is less than the microgram levels that constitute a pharmaceutical dose of the prescription-only opiate. The evaluated spectra demonstrate that scrubbing the area is more effective than soaking at all time points evaluated. Further, OxiClean™ combined with scrubbing the area has more beneficial results compared to water, but both soaking and scrubbing conditions fail when evaporation occurs. For this reason, the area should be cleaned with scrubbing action within 15 minutes of spraying the OxiClean™ solution and the paper towel should be discarded in a biohazardous waste container along with personal protective equipment (e.g., double gloves, disposable laboratory coat, particulate mask) used for decontamination.

Fentanyl, Decontamination, Occupational Exposure

B28 Touch DNA in Forensic Science

Ashley Hall, PhD, University of Illinois at Chicago, 833 S Wood Street, 456A PHARM (MC 865), Chicago, IL 60612*

The goal of this presentation is to inform attendees about the use of touch DNA.

This presentation will impact the forensic science community by advancing the proposal that touch DNA should be accepted as routine evidence.

The relationship between fingerprint component topography and touch DNA retrieval will have an impact on the forensic science community by increasing the efficiency of touch DNA retrieval from fingerprints. Optimized touch DNA collection methods based on this knowledge will be presented in order to expand their application across the forensic science community.

Touch DNA is a trace amount of DNA left on a surface by a donor who touches said surface and can be found on everyday objects as well as on evidence left at a crime scene. Fingerprints may lead to the identification of a donor through their uniqueness in ridge detail, but they may also be used to identify the donor as touch DNA evidence. Skin cells, eccrine sweat, and sebum comprise fingerprint residue. Though a touched surface may retain cells from the donor individual, cell-free DNA can also contribute to the retrieval of human touch DNA. Microorganisms on the skin also transfer to surfaces. DNA analysts, with improvements in technology and techniques, have the potential to extract a full or partial DNA profile from a single fingerprint from a touched surface; however, several confounding factors can inhibit this potential, such as shedder status of the donor and degradation of the DNA present due to environmental factors.

A thorough survey of the location in which cell-free DNA, whole human cells, and microorganisms reside within a fingerprint was conducted to fully assess the impact of these topographical differences on touch DNA retrieval. To meet this goal, three research objectives were developed and executed: (1) develop a technique for fluorescent and bright field visualization of palmar keratinocytes, cell-free DNA, nuclear DNA, and microorganisms in true fingerprints; (2) assess fingerprint topography before and after DNA collection methods to determine where any lack of collection may be occurring; and, (3) optimize DNA collection techniques on various surfaces and with various collection media based on these results to minimize sample loss.

Due to the complex composition and unique donation of DNA from fingerprint to fingerprint, mock fingerprints containing a known quantity of DNA were developed from buccal epithelial cells to generate standard curves for quantification purposes. Standardizing these mock fingerprints as a positive control for collection alongside true fingerprints allowed for further examination into loss of DNA during collection and extraction. By determining the quantity of DNA retrieved from these mock fingerprints, estimations of extraction efficiencies as well as initial DNA deposited in a true fingerprint can be made.

Both true and mock fingerprints were visualized through staining of various biological components: whole cells, cell-free DNA, nuclear DNA, and microorganisms. The distribution of these components in true and mock fingerprints was gauged before and after collection of touch DNA from glass slides using a variety of collection methods and devices. Once the optimal collection method from glass was determined from these results, mock and true fingerprints were deposited onto/collected from various surfaces, such as wood and paper, and various objects one might receive as evidence, such as a steering wheel or piece of tile. The most successful retrieval methods and collection devices for each respective surface will be presented in order to encourage their use by other forensic analysts and, ultimately, lead to enhanced performance and efficiency in forensic DNA collection.

Touch DNA, Fingerprint, Low Template

B29 Mathematics Takes a Holiday — The Scientific Working Group on DNA Analysis Methods' (SWGDAM's) Imaginative Y Haplotype Guidelines

Charles H. Brenner, PhD, 6801 Thornhill Drive, Oakland, CA 94611-1336*

After attending this presentation, attendees will understand that the formulas recommended by SWGDAM for Y haplotype evidence are not based on mathematics or on population genetic models, but rather represent confused analogies and cookbook statistics.[1]

This presentation will impact the forensic science community by raising the level of scepticism about trusting expert or committee authority rather than insisting on logic and data.

Mathematical treatment of forensic DNA evidence has some weak spots, the worst being Y haplotypes. SWGDAM's recommendations for computation rest on several confused ideas about mathematics and genetics.

Start with genetics. SWGDAM offers the claim, "It is recognized that population substructure exists for Y-STR haplotypes" to justify an "Eq 3," $Pr(A \mid A) = \theta + (1 - \theta)\, p_A$, adapted from a similar formula in autosomal practice. In the autosomal world θ comes into play to cater to the idea of population substructure from preferential mating — sexual reproduction. But Y haplotypes reproduce clonally, not sexually. There cannot be Y haplotype "population substructure," not in anything like the sense of the autosomal forerunner to Eq 3. The conclusion is that Eq 3 comes about not from clear thinking, but by a careless false analogy that confuses two different senses of "population substructure" — one based on sexual mating, the other on geography or on tribal identity.

What does the guideline mean by θ? The guidelines are vague on that, but reverse-engineering from tables of numbers in an appendix in the guideline reveals that θ is quite close to the average matching chance of two randomly selected haplotypes. The left-hand side, $Pr(A \mid A)$, of Eq 3 must also be on average close to the average matching chance. It would follow that p_A, which purports to be a probability, is negative about half the time!

The guidelines avoid confronting the embarrassment of negative probabilities by bad mathematics: though p_A is meant to be a probability — which is an inference from *data* ("the degree of expectation of its occurrence, which we are warranted in entertaining by our present *evidence*" as the 19th-century thinker JS Mill put it) — the guidelines insist on confusing it with population frequency and on estimating that frequency by a clumsy cookbook statistical procedure which is intended — both misguidedly and unreliably — to be generous.[1]

Hence, the entire process is founded on confusion. Nobody can possibly understand it because there is nothing there to understand. But the above-average analyst, who mistakenly trusts the expertise of the committee, is likely to imagine that the recommendations are fair, useful, and meaningful. The analyst thus gulled testifies in court, unfairly in a Native American context, that the involvement of θ means that the formula takes into account tribal structure. In another case, the pointless generosity means a big break to an offender for no principled reason. Confusion is awkward and expensive — and careless reasoning is bad precedent.

B30 Using Computers to Overcome Forensic DNA Testing Bottlenecks and Improve Recovery From Complex Samples

John Donahue, Beaufort County Sheriff's Office, 111 Industrial Village Road, Beaufort, SC 29906; and Mark W. Perlin, PhD, MD, Cybergenetics, 160 N Craig Street, Ste 210, Pittsburgh, PA 15213*

After attending this presentation, attendees will better understand the potential for automation of DNA mixture interpretation and genotype comparison.

This presentation will impact the forensic science community by demonstrating the advantages of automating DNA mixture interpretation with computer technology.

DNA testing has been utilized in criminal investigations for more than 30 years. In that time, technological advances have improved the ability of laboratories to provide information to investigators and the courts. These gains in technology have primarily come through an improved ability to recover and detect alleles present in the DNA sample, but additional gains have come through automation.

A recent survey of the National DNA Index System (NDIS) -participating laboratories demonstrated that nearly all respondents have implemented automation to some degree. In practice, automation tends to be limited to DNA extraction and setup of DNA quantification, amplification, and sequencing plates. While automation has reduced the time required for completions of these steps, the unintended effect is often a backlog in profile interpretation.

Technological improvements have also increased both the number of samples submitted to laboratories and the complexity of the DNA profiles obtained from these samples. Laboratories are now testing many more sample types than when forensic DNA testing was first implemented. While initial DNA testing was restricted to identifiable body fluids, such as semen, blood, and saliva, improvements have led to testing of various substrates, such as articles of clothing or items that have been handled or manipulated. Such items are often referred to as trace or touch DNA evidence. These samples tend to present mixed profiles showing varying numbers of contributors and mixture ratios.

Mixture interpretation in general can be time consuming, and interpretation of mixtures from trace DNA samples may be very difficult and, at times, too complex for accurate interpretation by human analysts. This complexity has in the past led to many results being reported as inconclusive. Those mixtures that can be interpreted by the human analyst may require a significant amount of time for the analyst to capture all the possible genotype combinations for each contributor and even more time for technical review. This bottleneck leads to an overall increase in case turnaround time.

Contamination assessment is another problem. While some software (e.g., Genemapper® ID-X, the Combined DNA Index System (CODIS)) allows for comparison to reference profiles such as laboratory staff or crime scene investigators, these searches are typically restricted to simple allele-to-allele comparisons. Depending on the number of alleles at each locus, the size of the comparison database, and the search parameters, a simple allele-to-allele comparison can lead to a large number of candidate matches, which must all be reviewed by the human analyst. Conversely, if the search is restricted to reduce the number of adventitious matches, then a contamination event may not be detected.

Problems with mixture complexity, interpretation, and contamination assessment can be alleviated through the use of computer technology to automate DNA mixture interpretation and comparison to reference samples. This presentation will detail the methods that a small laboratory has used to automate DNA profile interpretation with the TrueAllele® computer system.

By using TrueAllele® to automate DNA profile interpretation, a human analyst can upload an entire 96-well plate to the TrueAllele® Investigative Database at the end of the workday, return the next morning, and examine the results. Potential matches and exclusions are identified immediately. In addition, the TrueAllele® Investigative Database can identify matches to every evidence profile and reference sample previously tested, and generate investigative leads to cases already worked.

Automated interpretation may also assist the examiner in the inference of genotypes suitable for export to CODIS. The TrueAllele® software will also automatically compare all mixture data to crime scene investigators and laboratory staff, thus giving the analyst the ability to easily identify contamination. By automating DNA mixture interpretation, the analyst's hands-on time can be reduced, more investigative leads may be identified, more CODIS-eligible profiles may be generated, and all DNA mixtures may be assessed for potential contamination.

DNA Bottlenecks, Computer Automation, Investigative Database

B31 A Comparison of Open-Source Software for Assessing the Weight of Evidence in Forensic DNA Profiles

Keith Inman, MCrim, Dept of Criminal Justice Admin, Rm 412 Student Faculty Services, 25800 Carlos Bee Boulevard, Hayward, CA 94542; Norah Rudin, PhD, 650 Castro Street, Ste 120-404, Mountain View, CA 94041; Clare Marsden, PhD, University of California, Los Angeles, Dept of Ecology and Evolutionary Biology, c/o Dr K.E. Lohmueller, Los Angeles, CA 90095-1606; and Kirk E. Lohmueller, PhD, UCLA, 621 Charles E Young Drive, S, Los Angeles, CA 90095-1606*

After attending this presentation, attendees will better understand how known complex mixture samples are treated by different probabilistic genotyping models as implemented in various software tools.

This presentation will impact the forensic science community by providing information concerning how different probabilistic genotyping models treat the same profile.

It has been a challenge, historically, to compare different software approaches and implementations for assessing the weight of evidence. The various approaches use different models, which make different assumptions and are implemented in different ways. This makes it difficult to compare the results between approaches. An additional quagmire is that no true answer exists, so it is not possible to compare results from any model to a static neutral standard. Furthermore, for some time, software that automatically modeled variables such as peak height and stutter was only available as expensive proprietary programs. Finally, training is key to using any of these programs in an optimal way, and the expertise to execute a variety of programs does not exist in one individual or even one group.

Recently, the number and type of open source free-of-charge software programs has expanded to include options for more sophisticated modeling of multiple parameters. Thus, it became possible to perform a reasonable comparison between different models. Part of this study was the recent opportunity to spend time at the special forensic statistics program sponsored by the Isaac Newton Institute for Mathematics at Cambridge University. This time was spent learning and organizing four different software programs for the purpose of comparison. The programs were: Lab Retriever, LRmix Studio, European Forensic Mixtures (EuroForMix) and likeLTD v. 6.1. Lab Retriever and LRmix Studio use discrete models in that the programs only consider nominal alleles, but do not automatically model other parameters, such as peak height and stutter. EuroForMix and likeLTD v. 6.1 model multiple parameters and also use an iterative process to find the best-fit answer.

Another advantage that has recently become available is a set of 164 complex mixture samples created from known contributors, each amplified five times, for a total of 820 samples. This sample set was created as part of a National Institute of Justice (NIJ) and will be made publicly available. The profiles from these mixture samples provide a rich source of material with which to perform informative comparisons between the different software programs. A subset of these samples will be compared to determine how profile complexity affects the Likelihood Ratio (LR) under different approaches. Results from these comparisons will be presented.

Open-Source, Probabilistic Genotyping, Model Comparison

B32 The Development of Polymorphic Combined DNA Index System (CODIS) Short Tandem Repeat (STR) Primers for Unbalanced DNA Mixture Analyses

Katie Kranz, BS, 3500 Beaumont Park Drive, #118, East Lansing, MI 48823; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the advantages of using polymorphic STR primers for unbalanced DNA mixture analyses.

This presentation will impact the forensic science community by detailing the development of polymorphic CODIS STR primers and how these primers can be utilized to detect a minor contributor in a DNA mixture.

Currently, there are several methods available to help analysts assess mixed DNA profiles, including comparison of relative peak heights of STRs, Y-chromosomal Short Tandem Repeat (Y-STR) analysis, or the use of expert software systems; however, these methods have several limitations. For instance, it is often difficult to detect minor contributors in extremely unbalanced mixtures due to Polymerase Chain Reaction (PCR) amplification bias, Y-STR haplotypes being shared by paternal relatives, and the question of whether expert software system analysis violates defendants' rights (e.g., the Confrontation Clause).[1-3]

In the research presented, an alternative method for analyzing DNA mixtures that exploits polymorphic PCR primer sites was explored. Combining a Single Nucleotide Polymorphism (SNP) or an Insertion/Deletion (INDEL) polymorphism with an STR can create a tool suitable for analyzing mixtures when one component is in much lower quantity than the other. In this case, a conserved primer flanks one side of the STR, while the other primer is designed to anneal to a specific SNP or indel allele on the opposite side of the STR. This allows an analyst to specifically target one DNA component in a mixture depending on the polymorphism present. For example, if a major contributor is homozygous for a deletion at one locus, the primer set designed for the insertion would be used to target the minor contributor. Specifically targeting SNP or INDEL alleles absent in the major contributor overcomes the PCR amplification bias that otherwise occurs.[4]

Polymorphic primer sites near the expanded set of CODIS STR loci were identified using the University of California, Santa Cruz database genome browser and allele-specific primer pairs were designed using Primer3 web version 4.0.0.[5-7] PCR conditions were optimized for each primer set by varying cycle number, primer concentration, and annealing temperature using a thermal gradient thermocycler. DNA collected from volunteers was then isolated from buccal swabs, quantified, and amplified in singleplex reactions. When amplification was successful with just one allele-specific primer set for a given locus, the individual was classified as homozygous; successful amplification with both allele-specific primer sets for the same locus was classified as heterozygous. Results were confirmed by sequencing the SNP or INDEL locus.

After the DNAs were quantified and genotyped, mixtures at ratios ranging from 1:10 to 1:1000 were created. DNA from an individual homozygous for an SNP or INDEL associated with a marker was used as the major contributor with input quantities ranging from 1ng to 100ng, and DNA from an individual heterozygous or homozygous for the other SNP or INDEL allele was used as the minor contributor with input quantities as low as 20pg. Using this method resulted in detection of minor contributor alleles via gel electrophoresis at DNA mixture ratios of up to 1:1000. Primers were then labeled with fluorescent dyes for fragment analysis via capillary electrophoresis. Mixtures genotyped with the labeled primers were consistent with known minor contributor alleles.

In conclusion, the availability of polymorphic CODIS STR primers provides a valuable tool for forensic biologists. Successful amplification of the minor contributor will allow the STR genotype to be compared to a reference sample or database, and established allele frequencies for the STR loci can be used to calculate random match probabilities. The development of polymorphic primes will allow analysts to deconvolute and easily apply statistics to unbalanced DNA mixtures that may otherwise be uninformative.

DNA Mixtures, Polymorphic Primer Sites, CODIS Short Tandem Repeats

B33 An Evaluation of DNA·VIEW® Mixture Solutions Beta Software with Two-, Three-, and Four-Person Mixtures for Forensic Applications

Timothy J. Graham, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Drew Badder, BS, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Fabio Oldoni, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Selena Cisana, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Charles H. Brenner, PhD, 6801 Thornhill Drive, Oakland, CA 94611-1336; and Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will have a basic understanding of how DNA·VIEW® Mixture Solutions can be utilized for forensic applications such as mixture analysis. Attendees will also understand the impact of this software on DNA mixture interpretation.

This presentation will impact the forensic science community by demonstrating the power, speed, and accuracy of DNA·VIEW® Mixture Solution as a possible tool for forensic mixtures interpretation.

DNA mixture interpretation is a rising issue in the field of forensic science and can be very challenging. Most current software used for forensic mixture interpretation are continuous models that use the Markov Chain Monte Carlo (MCMC) method to analyze mixtures and produce likelihood ratios. These also often require the user to input the number of assumed contributors prior to initiating the analysis of a mixture; a new analysis is required to test a different number of contributors. DNA·VIEW® Mixture Solution is new software that uses mathematical algorithms, rather than MCMC, to determine the probabilities of the evidence under various scenarios. The software calculates the probabilities for multiple prosecution hypotheses (Hp); for example, the probabilities of the evidence given that it includes the Person Of Interests (POI), perhaps a known victim, plus one, two, three, etc., unknown individuals. Similarly, it calculates the probabilities for multiple defense hypotheses (Hd). The probabilities of the most desirable Hp and Hd are then divided to obtain a fair likelihood ratio. The systematic exploration takes the place of guesswork regarding contributors and numbers of contributors.

Previously extracted DNA from four individuals from a Hispanic population was supplied by The George Washington University, Department of Forensic Science. The samples were quantified using the Quantifiler® Duo DNA Quantification Kit. Different volumes of these reference samples were then used to create two-, three-, and four-person mixtures with multiple ratios and diluted down to different DNA amounts for Polymerase Chain Reaction (PCR) reactions (2ng, 1ng, 500pg, 250pg, and 100pg). A total of 75 mixtures were created. The mixtures created ranged from simple to more complex with clear major contributors and the minor contributor remaining the same in all mixed samples. DNA samples, including single-source samples, were then amplified using AmpF*l*STR® Identifiler® PCR Amplification Kit and detected on the 3130 Genetic Analyzer. Short Tandem Repeat (STR) profile analyses were performed with the Genemapper® ID-X version 1.4; a text file was created from each electropherogram data and imported into the latest DNA·VIEW® Mixture Solutions beta software version and interpreted. The software was analyzed on its ability to produce consistent likelihood ratios over several runs, its run time in the analysis of different mixtures, and its accuracy in determining the likelihood of a minor contributor being present in a mixture.

From the data, DNA·VIEW® Mixture Solutions provides consistent and repeatable results for all mixtures. DNA·VIEW® Mixture Solutions was also able to rapidly calculate and (if desired) deconvolve mixtures with times as low as a few seconds for simple two-person mixtures and ranging up to about one and one-half hours for more complex mixtures at low DNA concentrations, though such time may be affected by computational power of the instrument. Finally, the software seemed to accurately represent the compositions of the mixed samples for the most part as complex four-person mixtures with low DNA and would result in very little of the minor contributor being detected.

In conclusion, DNA·VIEW® Mixture Solution is an efficient, fast, consistent, repeatable, and intuitive program that has many potential applications in the field of forensic science and can assist in the efficiency of processing DNA mixtures.

DNA·VIEW®, Mixtures, DNA Contributors

B34 An Evaluation of DNA Results With Propositions at the Activity Level: How to Identify the Features That Influence the Bayes Factor — An Example With a Stabbing Scenario

Lydie Samie, School of Criminal Justice of Lausanne, Ecole des Sciences Criminelles-UNIL-Batochim, Lausanne, Vaud 1015, SWITZERLAND; Franco Taroni, PhD, Batochine Quartier UNIL-Sorge, Lausanne 1015, SWITZERLAND; and Christophe Champod, PhD, ESC / University of Lausanne, Batochime, Quartier Sorge, Lausanne-Dorigny, Vaud 1015, SWITZERLAND*

The goal of this presentation is to demonstrate how to identify the features that influence the Bayes factor using a Bayesian Network, allowing the evaluation of DNA cases at the activity level. This allows the identification of the type of experimental studies that are needed in a specific case and will help the scientist focus on a limited number of variables of interest. This presentation illustrates the variable of interest for a specific stabbing scenario.

This presentation will impact the forensic science community by assisting attendees in evaluating DNA cases at the activity level.

Traces with low levels of DNA can be the result of a secondary transfer or even a tertiary transfer. Consequently, factors such as transfer, persistence, recovery, and background need to be considered. Scientists should consider their biological results given activity-level propositions. The issue here is that many experts do not feel they can do so. One of the reasons is that each case has its own features. Can numerical values from experimental studies performed under controlled conditions be used for evaluation in real-life cases? Experiments allowing a wide variety of options for any unknown specific feature should be conducted, but it is difficult to design an experiment that takes into account all possible variations of all factors; however, the most significant fact is not that the feature varies but whether the variation of the feature has an impact on the value of the results (i.e., Bayes factor).

The goal of this review is to illustrate how to identify the features that influence the Bayes factor using a Bayesian Network. This permits identification of the type of experimental studies needed in the case at hand. It helps scientists focus on a limited number of variables of interest, helping them to evaluate DNA results at the activity level. Cases presented as demonstrations are cases in which the main proposition is that the person of interest stabbed the victim and the alternative propositions are either that the person of interest shook the hand of the real offender or that the person of interest has nothing to do with the stabbing or the offender (i.e., an unknown person stabbed the victim).

Results demonstrate that in both situations the greatest impact on the value of the results were extraction efficiency, sampling efficiency, proportion of contact between hand and target surface, transfer proportion, type of surface, and type of contact. The background, the environmental conditions, the quantity of DNA on the person of interest's hand and on the alternative offender's hand have the least impact.

Considering the alternative proposition, "The person of interest has nothing to do with the stabbing, an unknown person stabbed the victim," the most impactful feature is the conditional match probability. This feature has no impact on the value of the results under the other alternative proposition (i.e., the person of interest shook hands with the actual offender).

For a case, once extraction efficiency and sampling efficiency have been established and the type of surface and of contact are known and instantiated, the features of interest remain proportion to contact and transfer proportion.

Activity, Bayesian Network, DNA

B35 A Cost-Benefit Analysis of Kinship Testing Involving Siblings and Half Siblings

Brandi L. Iorio, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Timothy J. Graham, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Riya Thekdi, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington DC, DC 20007; Rachael Holderle, BS, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Washington, DC 20007; Brieanne T. Knight, MSc, SNA International, 525 Wythe Street, Alexandria, VA 22305; Amanda C. Sozer, PhD, SNA International, 525 Wythe Street, Alexandria, VA 22314; Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Moses S. Schanfield, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Somers L08A, Washington, DC 20007*

After attending this presentation, attendees will understand the current status of kinship testing in forensic science, the costs and benefits associated with testing an increasing number of siblings in order to more accurately establish a biological relationship, and the effect of substituting half siblings for full siblings for the identification of a biological relationship in question.

This presentation will impact the forensic science community by improving knowledge regarding kinship testing involving siblings and by informing a variety of agencies of the most cost-effective approach for kinship testing involving full siblings and half siblings. The results from this study will be utilized to inform the Department of Homeland Security of the costs and benefits of testing multiple members of a family and will indicate if this practice can offer greater success in the identification of a biological relationship. Depending on the results of this research project, some agencies and organizations may alter their current practices to attain a higher success rate for the identification of biological relationships in question.

A DNA kinship test assesses the relatedness between two or more individuals. A kinship test is used as a method for confirming the presence of a biological relationship between two individuals for immigration purposes, parentage testing, forensic casework, and the identification of victims of mass disasters; however, the testing of siblings in kinship testing can become complicated, since siblings can share between 0% and 100% of their DNA. Since there is a high level of variation among the amount of DNA shared between two siblings, this research investigates whether kinship testing should be performed on more than two siblings when possible. Additionally, the effect of substituting half siblings for full siblings is examined in order to assess if less information is obtained using half siblings in a kinship test. With this information, the cost-benefit relationship of utilizing an increased number of siblings in kinship testing was examined. Many factors, such as the cost of the DNA testing, the access to more than two family members for kinship testing, and the variation in the amount of DNA shared between siblings, are discussed in the examination of this cost-benefit relationship.

In order to study this cost-benefit relationship, 415 known DNA samples sourced from the Applied Genetics Technology Corporation (AGTC) in Denver, CO, were provided by the Department of Forensic Science at The George Washington University. The samples were collected from 96 total families from Caucasian, Hispanic, African American, and Asian populations, with 24 families belonging to each ethnic group. The previously extracted DNA samples were quantified using the Quantifiler® Duo DNA Quantification Kit and amplified using the GlobalFiler™ and VeriFiler™ Direct Polymerase Chain Reaction (PCR) amplification kits. The samples were analyzed using an Applied Biosystems® 3130 Genetic Analyzer and GeneMapper® ID-X software version 1.4. Using the likelihood ratios obtained from statistical calculations between the biological full siblings and half siblings, the strength of the biological relationship in question was determined. By comparing the likelihood ratio calculations between siblings, it was determined whether the biological relationship is strengthened when using an increasing number of siblings in the kinship test, and if there is a significant difference in the strength of a biological relationship when substituting half siblings for full siblings.

This presentation will provide a cost-benefit assessment of kinship testing using multiple siblings, will examine if using a greater number of siblings in kinship testing yields a more accurate identification of a biological relationship, and will determine the effect of substituting half siblings for full siblings. With this knowledge, more cost-effective approaches for kinship testing involving siblings can be adopted and practiced.

This research was funded by the Department of Homeland Security.

Kinship Analysis, Sibship Testing, Siblings

B36 Science Matters: Using DNA to Solve Missing Persons Cases in New York City

Andrew J. Schweighardt, PhD, 108 Sandy Hollow Road, Northport, NY 11768*

After attending this presentation, attendees will better understand that many of the human remains for which a DNA profile is successfully obtained would still remain unidentified without the awareness of families and their willingness to provide reference samples for comparison. Attendees will hear success stories from a Missing Persons Day and gain insight into the ability of this event to provide resolution to missing persons cases.

This presentation will impact the forensic science community by providing vivid examples of success when the power of a DNA database is fully exploited. Many DNA profiles in the database belonging to unknown individuals would remain unidentified without families of the missing being made aware of the need to submit reference samples. Identifying a missing person not only provides resolution to the family but also creates leads in cases in which foul play or violence is suspected in the disappearance of the missing person.

There are nearly 100,000 active missing persons cases in the United States. Potential success in connecting these cases to Unidentified Human Remains (UHRs) is often dependent on the awareness of families and their willingness to provide DNA reference samples for comparison. The collection of family samples may sometimes be the only way to identify unknown remains that pass through the nation's mortuaries with nothing more than a DNA profile as a possible pathway to identification. Attendees of this presentation will gain insight into the ability of a special event, Missing Persons Day, to provide resolution to missing persons cases.

New York City maintains a massive 100-acre cemetery on Hart Island that is used for burying the indigent, unclaimed, or unidentified. The impetus for conducting DNA testing on the city's UHRs came from the success of DNA methods developed in response to the terrorist attacks of September 11, 2001. State-of-the-art techniques for testing bone were used to obtain DNA profiles from samples that would have otherwise been difficult to recover. This novel protocol has since been applied to thousands of bones from UHRs.

Many of the UHRs for which a DNA profile is successfully obtained would still remain unidentified without the willingness of families to provide samples for comparison. In 1975, a teenage male disappeared. Although a police report was filed, no DNA reference samples were collected because the case preceded DNA testing. The next year, a trash bag with human remains was recovered from a highway shoulder in a neighboring state. When bones from the trash bag were tested for DNA years later, the profile was uploaded to the national DNA database. In 2014, New York City initiated an annual event called Missing Persons Day, designed to connect families of the missing with resources and to provide an opportunity to submit DNA samples. One of the attendees at this event was a relative of the missing teenage male. When the relative's sample was collected and the profile uploaded to the database, it revealed kinship to the profile obtained from the bones in the trash bag.

There are many instances in which identifications have been made that would have otherwise been impossible without the ability of the Missing Persons Day event to raise awareness of the need for families of the missing to submit reference samples. In 2003, a man from one of New York City's outer boroughs went missing. Shortly thereafter, skeletonized remains were found in a suburban area approximately 30 miles away. There was no investigative progress and both cases remained unsolved for years. In 2014, the children of the missing man attended the Missing Persons Day event and submitted reference samples. The DNA profile from the children showed kinship to the profile developed from the skeletonized bone whose source was determined to be their father.

The Missing Persons Day event is billed as a humanitarian effort in which attendees are given the opportunity to visit a laboratory that is managed by the city's Department of Health and be connected to police detectives, chaplaincy services, mental health counselors, and forensic scientists. Conducting the event at a venue not associated with law enforcement is particularly important in urban areas, where potential attendees could have skepticism of the police or fear of repercussions regarding their own criminal history or immigration status. In 2013, a male in his 30s was crossing the United States-Mexico border illegally when he lost contact with family. The next year, his family attended the Missing Persons Day event and submitted reference samples. The DNA profiles obtained from these samples revealed kinship to a bone that was recovered in the desert near the border.

Since its inception in 2014, the New York City Missing Persons Day has aided in eight identifications. These are cases that would have remained unsolved without the willingness of families to submit DNA samples as part of the search for their loved ones. The full potential of the national DNA database is realized only when events such as Missing Persons Day make families aware of the need to provide samples for comparison. Identification of a missing person may also provide valuable leads in cases in which death of a UHR is ruled as homicide.

Missing, DNA, Bone

B37 The Evaluation of the Effects of Linked Markers on Kinship Testing

Timothy J. Graham, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Riya Thekdi, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington DC, DC 20007; Brandi L. Iorio, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Rachael Holderle, BS, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Washington, DC 20007; Brieanne T. Knight, MSc, SNA International, 525 Wythe Street, Alexandria, VA 22305; Amanda C. Sozer, PhD, SNA International, 525 Wythe Street, Alexandria, VA 22314; Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Moses S. Schanfield, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Somers L08A, Washington, DC 20007*

After attending this presentation, attendees will better understand the implications of linked loci in kinship calculations and how best to approach such loci in familial relationship testing.

This presentation will impact the forensic science community by demonstrating to what degree three sets of linked loci (vWA and D12S391, CSF1PO and D5S818, and SE33 and D6S1043) are linked and by illuminating the potential impact of treating these as independent instead of linked. The results of this research may impact the processes involved in familial kinship testing for both domestic and foreign immigration cases by more accurately depicting pedigrees.

Kinship testing cases are common practice and important in many immigration cases globally. The kits used to analyze the DNA in such cases vary, but very often will contain linked markers. Linked markers are used occasionally in forensic DNA analyses, including kinship calculations, often with little regard for their potential impact on the calculations. The simple product rule should not be used with linked markers that are shown to not segregate independently. What should be considered is the diplotype frequency with its own frequency for recombination based on a diplotype database.

DNA from previously extracted samples from 96 families with multiple children (both full and half sibling children) from four ancestry populations (European, Asian, Hispanic, and African) from past paternity cases were supplied by The George Washington University, Department of Forensic Science, sourced from the Applied Genetics Technology Corporation (AGTC) in Denver, CO. These samples were quantified using Quantifiler® Duo, amplified using GlobalFiler™ and VeriFiler™ Direct PCR amplification kits, run on an Applied Biosystems® 3130 Genetic Analyzer, and typed using GeneMapper IDX® software version 1.4.

The results of the genetic typing were exported into Excel® where allele and diplotype frequencies were calculated for each population of n=24 families per population. Additionally, recombination frequencies were calculated at each linked diplotype that were further utilized to determine if they exhibited linkage disequilibrium.

To demonstrate the impact of using these loci in conjunction with the product rule for kinship cases, familial relationships likelihoods were calculated assuming independent assortment of the genes. These relationship likelihoods were then compared to relationships calculated by accounting for linkage to show the true impact of not accounting for linked loci.

This presentation will discuss the level of linkage between vWA and D12S391, CSF1PO and D5S818, and SE33 and D6S1043, demonstrate the impact of ignoring the linkage disequilibrium between the loci pairs, and discuss more efficient ways of approaching the use of linked loci in familial testing.

Research Funded by The Department of Homeland Security.

Kinship, Linked Markers, Diplotypes

B38 Short Tandem Repeat (STR) Profiles and Ethnic Affiliation — Chemometric Evaluation

Patryk Wlasiuk, MSc, Dept of Analytical Chemistry, Jagellonian Univers, ul.Golebia 24, Krakow 31007, POLAND; Eugenio Alladio, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano (Turin) 10043, ITALY; Monica Omedei, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano 10043, ITALY; Giuseppina D'amico, Regione Gonzole 10/1, Orbassano, ITALY; Denise Caneparo, MS, Regione Gonzole 10/1, Orbassano, ITALY; Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY; Roberto Testi, MD, PhD, ASL Torino, Via Lessona 54/12, Torino 10145, ITALY; Paolo Garofano, MD, PhD, Laboratorio Genetica Forense - CAD, Regione Gonzole 10/1, Orbassano (TO) 10043, ITALY; and Grzegorz Zadora, Institute of Forensic Research, Westerplatte 9, Krakow 31033, POLAND*

After attending this presentation, attendees will better understand an alternative approach for the interpretation of ethnic affiliation from unknown DNA trace evidence.

This presentation will impact the forensic science community by providing an alternative method for the estimation of ethnic affiliation with a proposition stemming from the chemometric evaluation of the data.

The issue of ethnic affiliation may arise in a forensic context. For instance, the determination of the race of a donor of a stain, left at the crime scene, may be thought to ease the investigation by contrasting such evidence with an eyewitness account. The DNA typing is a powerful tool in the determination of the identity since the majority of genetic variation is ascribed to inter-individual differences. Although the contribution of population differences is quite small to the overall variability, the genetic profiles have been used to infer the population of origin.[1,2] As the Short Tandem Repeat (STR) microsatellites are still intrinsic to the forensic domain, the present study focuses on the use of STR profiles as the basis for inferring ethnic affiliation. In the course of the past two decades, a few approaches have been presented. The methods implemented in the population genetics software usually follow the profile frequency approach, procedures based on the genetic distance, or the approaches that use tools derived from the multivariate data analysis methods. The latter two are said to be free of considering the Hardy-Weinberg (HW) and Linkage (L) equilibriums.

The goal of this study is to contrast those ethnic affiliation approaches with the proposition stemming from the chemometric evaluation of the data. For the purposes of the present study, the STR profiles were generated from the allele frequency tables available for different populations. As the derivation of the STR profile depends on the set of markers, this study inspects the usefulness of different, used-in-daily-practice sets (e.g., the Combined DNA Index System (CODIS), the European Standard Set (ESS), and the International Society for the Study of the Origin of Life (ISSOL)). For a fair comparison of models, the test set of profiles was held out for testing models developed on the training data. The ethnic affiliation methodology for each approach was to be set in the Bayesian framework to enable the forensic weight of the evidence assessment. Different chemometric approaches were inspected and evaluated.

Ethnic Affiliation, Chemometrics, Unknown DNA Trace Evidence

B39 A Statistical and Allele Frequency Evaluation on the Methods of Kinship Calculations

Riya Thekdi, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington DC, DC 20007; Timothy J. Graham, BA, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Brandi L. Iorio, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Rachael Holderle, BS, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Washington, DC 20007; Brieanne T. Knight, MSc, SNA International, 525 Wythe Street, Alexandria, VA 22305; Amanda C. Sozer, PhD, SNA International, 525 Wythe Street, Alexandria, VA 22314; Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Moses S. Schanfield, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road, Somers L08A, Washington, DC 20007*

After attending this presentation, attendees will be better informed regarding the variations found in the statistical calculations used by commonly utilized DNA kinship analysis programs.

This presentation will impact the forensic science community by demonstrating that the variability present in statistical calculations of kinship analysis programs can have effects on kinship determination.

Kinship analysis of Short Tandem Repeat (STR) profiles is often used in cases of parentage testing. Kinship analysis programs calculate the likelihood ratios of paternity, maternity, and sibship using allele frequency databases. It is important to determine the extent of variation between numerical precision within these programs since small variances in value can yield different analyses and conclusions. The first portion of this presentation reports on the differences in numerical precision of these programs.

The choice of race-specific allele frequency databases brings additional variation in statistical calculations of kinship. Race-specific allele frequency databases provide for the genetic similarities and differences found within racial groups and become important for kinship analysis due to the expected genetic similarities of individuals within a biological family. Accuracy in kinship analysis is especially relevant in cases involving half siblings due to the increase of genetic dissimilarity. The second half of this presentation focuses on how the use of a race-specific allelic frequency database can affect accuracy in determining sibship between related individuals.

To identify the effects of using race-specific allele frequency databases for sibship determination, an analysis was conducted on the Short Tandem Repeat (STR) profiles collected from 96 families comprised of 415 individuals. The samples were sourced from the Applied Genetics Technology Corporation (AGTC) in Denver, CO, and were provided by the Department of Forensic Science at The George Washington University. The profiles were obtained from DNA samples collected from prior paternity and immigration testing and were self-defined as belonging to Asian, African American, Hispanic, or Caucasian backgrounds. Twenty-four families were chosen from each racial group to ensure equal representation within the data. The samples were quantified with Quantifiler® Duo DNA Quantification Kit, amplified with GlobalFiler™ and VeriFiler™, and analyzed using an Applied Biosystems® 3130 Genetic Analyzer and GeneMapper® ID-X software. Kinship analyses for the families were conducted on the software DNA•VIEW®. Sibship calculations yielded likelihood ratios that compared the likelihood of sibship with the likelihood of no biological relationship between the individuals. Four sibship likelihood ratios were calculated from four race-specific allelic frequency databases (Asian, African American, Caucasian, and Hispanic databases) for each sibship case, regardless of the individuals' reported backgrounds.

Preliminary analysis of the results conducted with DNA•VIEW® reported accurate determination of sibship for all cases involving full siblings and half siblings. In the cases determining full sibship, 94% demonstrated likelihood ratios as expected by race, with the true racial background of the family members showing the least discrimination. In cases determining half sibship, 50% demonstrated likelihood ratios expected by racial background. A chi-squared analysis of each case was conducted, and all cases showed no independence ($p \leq 2*10^{\wedge -18}$) between the likelihood ratios reported from the four race-specific allelic databases, thus demonstrating a significant difference in allele frequency values between the databases.

The results from the sibship analyses suggest that race-specific allelic frequencies have a diminishing effect on discriminating less related individuals versus more related individuals and supports prior research that half sibling analysis require highly discriminatory loci for accurate sibship determination.

Overall, this two-part evaluation of statistical calculation and allele frequencies seeks to inform the public of numerical variations involved within kinship programs and reaffirms the importance of race-based data for accuracy, allowing for the development of a more standard approach to kinship analysis.

Kinship Analysis, Statistics, Race

B40 The Development of a Biogeographic Ancestry and Phenotype Single Nucleotide Polymorpism (SNP) Panel Using Ion Torrent™ Chef System

Ozlem Bullbul, PhD, Istanbul Universitesi, Adli Tip Enstitusu, Istanbul, TURKEY; Gonul Filoglu, Institute of Forensic Science, Istanbul University, Istanbul, TURKEY; and Faruk Asicioglu, MD, PhD, Poligon Mah Sariyer Cad, Lara sok Seba Home Sitesi, Daire 18, Istinye-Saryyer, Istanbul 34460, TURKEY*

After attending this presentation, attendees will have a better understanding of the performance of the Ion Torrent™ Chef Next Generation Sequencing (NGS) system and development process of an NGS panel for SNP.

This presentation will impact the forensic science community by providing results from a novel development of an NGS panel for SNP in order to predict biogeographic ancestry and phenotype of an individual. This presentation will also increase understanding of the practical utility and benefits of the NGS technology.

It is essential to perform fast and accurate identification of all types of traces that belong to mass disaster victims or unknown biological evidence collected from crime scenes. Only gender identification can be achieved by using standard STR kits. Additional physical characteristics could provide important information regarding suspects/individuals. Recently, SNP markers have been used for identification, determination of phenotype, and prediction of ancestry. "Molecular eyewitness" is defined as the determination of the suspect's or individual's population origin by using Ancestry Informative SNPs (AISNPs) and the determination of the suspect's or individual's physical characters by using Phenotype Informative SNPs (PISNPs). Since there are a few studies related to geographic region that includes the interest region of Southwest Asia, it is essential to study novel and informative markers for accurate ancestry assignment for this region. Hence, the objective of this study was to develop an SNP panel on Next Generation Sequencing (NGS) devices for use in predicting biogeographic ancestry and phenotype (i.e., eye, hair, and skin color) of an individual.

In this developed panel, this study sought to determine a set of AISNP markers that could be used to differentiate Southwest Asia and Mediterranean regions from Europe and other continental regions; therefore, SNPs were selected from previous research.[1-3] The set of PISNP markers was integrated into the set of AISNP markers in order to develop one reaction system on the NGS instrument. PISNPs were used to determine physical characteristics such as eye, hair, and skin colors and were chosen from previously published papers.[4-6] As a result of this study, a biogeographic ancestry and phenotype panel, including 160 SNP markers, was developed by using the Ion Torrent™ Chef instrument. The optimization and validation of the system was performed by using commercially available reference samples (e.g., 9947a, 007). Sensitivity and reproducibility parameters were determined for the optimization and the validation of the Ion Torrent™ Chef panel.

In conclusion, the developed NGS SNP panel, which can be used for predicting the biogeographic ancestry and physical characteristics of an unknown, will contribute to the direction of the investigation and to clarify the incident quickly for unknown contributors, cold cases, or the identification of missing persons and disaster victims. In this presentation, results from the NGS panel will be presented in addition to additional evaluations of individual prediction results using statistical regression and Bayesian methods for the forensic use of this panel.

B41 The Utility of the Precision ID Ancestry Panel for Predicting Ancestry From High-Quality and Forensic-Type Samples

Ashley M. Cooley, MS, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Kelly A. Meiklejohn, PhD, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22204; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; and James M. Robertson, PhD, CFSRU, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand that a commercially available panel of Single Nucleotide Polymorphism (SNP) markers can be used to effectively predict the ancestry of known samples. Attendees will learn that genotype accuracy can be examined by testing congruence between the manufacturer's software and a third-party, well-accepted software. Attendees will also learn the impact of DNA degradation on ancestry predictions using this panel and the manufacturer's software.

This presentation will impact the forensic science community by providing the results of an initial assessment of the novel Precision ID Ancestry Panel for determining genotypes from samples of differing ancestry. This presentation will provide valuable information as to the applicability of the panel for forensic-type samples and the potential limitations of using this panel as tool for investigative leads.

Human individualization is typically accomplished by analyzing Short Tandem Repeats (STRs); however, in cases in which only a partial or incomplete STR profile is obtained, SNPs could provide valuable information to aid the investigation by providing information on biogeographic ancestry. Thermo Fisher Scientific, which developed the high-throughput Ion Torrent™ PGM™ sequencer, released the Precision ID Ancestry Panel, a 165-SNP panel for forensic ancestry prediction.

This study was directed at assessing the accuracy, reproducibility, and sensitivity of this novel panel and with the ability to provide accurate ancestry predictions for: (1) seven high-quality DNA samples that represent the three major ancestries of forensic interest in the United States (Hispanic, Caucasian, and African American); and, (2) forensic type samples, such as a toothbrush, bone, hair, shaving razor, cigarette butt, and nail clippings (*n*, 9). Libraries were prepared in triplicate using 0.2ng, 0.5ng, and 1.0 g DNA as input for the high-quality DNA samples (*n*, 63), and in duplicate where possible for the forensically relevant samples using 0.05ng–1.0ng of DNA (*n*, 39). Data was analyzed using the manufacturer's Human Identification (HID) SNP Genotyper plug-in (v.4.3.1) as well as CLC Genomics Workbench. Only 2% of all possible Quality Control (QC) flags were raised for the high-quality samples by the plug-in QC filter; 59% of these flags were due to the major allele frequency being outside the manufacturer's defined thresholds. A total of 9.8% of all possible flags were raised for the forensic type samples by the plug-in QC filter; 45% of the flags were due to locus drop-out.

A simulated degradation study was also conducted using the data generated from the seven high-quality samples prepared using 1.0ng of DNA. Data was divided into SNP subsets based on known amplicon lengths and commonly observed degradation lengths (i.e., SNPs with amplicon lengths <50bp, <75bp, <100bp, and <200bp), and ancestries subsequently predicted for each subset using the FROG-kb database (http://frog.med.yale.edu/FrogKB/). Incorrect ancestry predictions did occur in approximately 20% of the samples, primarily when Ancestry Informative Single Nucleotide Polymorphisms (AISNPs) with amplicon lengths <75bp were used in analyses. Even though the forensic type samples had more flagged SNPs than the high-quality DNAs, 72% of samples still had concordant ancestry predictions between replicates, demonstrating that this panel has the potential to be used in forensic casework with further testing.

SNP Typing, Ancestry, NGS

B42 Enhance the Power of Discrimination of Semen Identification by a Combination of Microfluidic Chips and Erase Kits

Fang-Chun Chung, MS, Institute of Forensic Medicine, Ministry of Justice, No 123, Min'an Street, Zhonghe District, New Taipei City 235, TAIWAN, REPUBLIC OF CHINA; Chu-Chun Hsu, MS, Institute of Forensic Medicine,Ministry of Justice, No 123, Min'an St., Zhonghe Dist, New Taipei City, Taiwan 235, TAIWAN, REPUBLIC OF CHINA; Hua-Sheng Tsai, MS, Institute of Forensic Medicine, Ministry of Justice, No 123, Min'an Street, Zhonghe District, New Taipei City 235, TAIWAN, REPUBLIC OF CHINA; Kuan-Miao Yen, MS, Institute of Forensic Medicine, Ministry of Justice, No 123, Min'an Street, Zhonghe District, New Taipei City 235, TAIWAN, REPUBLIC OF CHINA; Yu-En Chen, MS, Institute of Forensic Medicine, Ministry of Justice, No 123, Min'an Street, Zhonghe District, New Taipei City 235, TAIWAN, REPUBLIC OF CHINA; and Chun-Yen Lin, 123 Min-An Street, Zhonghe District, New Taipei City, TAIWAN, REPUBLIC OF CHINA*

The goal of this presentation is to overcome the problems of the differential extraction method by using the microfluidic chip technique combined with the Erase Sperm Isolation Kit (combination method).

This presentation will impact the forensic science community by reducing the interference of female DNA in the isolated sperm DNA and enhancing the power of discrimination in the semen identification.

A key point of forensic examination is how to effectively locate sperm in sexual assault case evidence. Practically, the differential extraction method was applied to isolate male DNA from the mixtures of sperm and epithelial cells; however, this is a time-consuming and less effective process. Currently, the Erase Sperm Isolation kit, a commercially available reagent, hydrolyzes cell-free female DNA before extraction of sperm DNA to reduce contamination of female DNA in isolated sperm DNA. Additionally, the microfluidic chip technique can separate sperm from the mixtures of sperm and epithelial cells according to the differences of density, size, and settling rate between sperms and epithelial cells.

The goal of this study was to overcome the problems of the differential extraction method by using the microfluidic chip technique combined with the Erase Sperm Isolation kit (combination method). Five semen samples and two buccal swabs were collected from adult men and women, respectively, as were two mixtures prepared with the ratios of sperm and epithelial cells of 1:1 and 1:3, respectively. These mixtures were stored at room temperature for 1, 3, 7, and 14 days, then their DNA profiles were analyzed. The combination method presented excellent results — the ratios of complete Short Tandem Repeat (STR) DNA profiles (15 loci, without female DNA interference) of sperm DNA were approximately 80% and 60% in the 3 and 14 days, respectively, whereas the results using the differential extraction method were less than 30%, accompanying more than 60% of interference of female DNA, in all time periods. These data indicated that the combination method can greatly decrease the female DNA interference in STR DNA profiles. The effectiveness of the combination method with nine forensic specimens that were positive for semen stains was also examined. The data of STR DNA profiles revealed that interference of female DNA was observed in only one case; however, only two cases were obtained in the complete STR DNA profiles. The possible reasons may that the amounts of isolated sperm DNA were too small to obtain the complete STR DNA profiles. In contrast, sperm DNA isolated by the differential extraction method presented high interference of female DNA (seven cases), and only one case of STR DNA profile was complete (15 loci, without female DNA interference). Taken together, these results suggested that the combination method can greatly reduce the interference of female DNA in the isolated sperm DNA and enhance the power of discrimination in semen identification.

Semen Identification, Microfluidic Chip, Differential Extraction

B43 Investigating the Impact of Protein and Peroxidase Blood Enhancement Reagents on DNA Recovery From Laundered Clothing

Gabrielle A. Hartley, 64 Indian River Road, Milford, CT 06460; and Claire Glynn, PhD, Forensic Science Department, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will better understand the use of protein and peroxidase reagents for blood detection and their potential effect on DNA recovered from laundered clothing. Additionally, attendees will gain insight into the potential transfer of DNA evidence from one article of clothing to another during the laundering process.

This presentation will impact the forensic science community by providing a comprehensive analysis of the effects of six blood enhancement reagents on DNA recovery from laundered clothing, allowing forensic examiners to make more informed decisions when analyzing this difficult type of evidence. This research will serve as an advantageous resource for forensic science professionals to use when deciding the type of enhancement reagent to use given various fabric compositions.

Blood is a commonly encountered biological fluid in criminal investigations concerning a violent incident, and visual traces of the fluid on a suspect's clothing can be diminished through laundering. Despite the potential to arouse suspicion and help reconstruct a crime, the mere presence of blood on laundered clothing is not often sufficient enough to make conclusive inferences about the nature and circumstances of a specific person's involvement in a crime. Because of this, it is essential that a method exists that both enhances a forensic examiner's ability to visualize a dilute bloodstain on a piece of laundered fabric while maintaining and preserving the quality of the DNA evidence that may be present. This study proposes to analyze the effects of laundering and the application of commercially available blood enhancement reagents commonly used to improve visualization of dilute bloodstains on DNA recovery.

Following Institutional Review Board (IRB) approval and informed consent from volunteers, venous blood was collected in sterile vacutainer EDTA vials. Six commonly used and commercially available enhancement reagents were chosen: Hungarian Red, Coomassie Blue, Amido Black, luminol, Bluestar® Forensic Magnum, and aqueous Leuco Crystal Violet (LCV). Then 100µL of human blood was deposited onto cotton, polyester, denim, and wool in triplicate, and these samples were laundered under standard washing conditions with blank controls. Following laundering, a selection of samples from each fabric type was enhanced with each of the six reagents. DNA was extracted from these samples using a QIAamp® DNA Investigator Mini Kit and quantified using a NanoDrop™ OneC Ultraviolet/Visible (UV/Vis) spectrophotometer.

Following laundering and enhancement, quantifiable amounts of DNA originating from bloodstains were obtained from all fabric types. Although washed blood samples often had a lower DNA recovery than unwashed blood samples, all untreated washed samples had a suitable DNA recovery, ranging from 0.9ng/mL to 38.2ng/mL. Similarly, samples treated with all enhancement reagents except Amido Black had DNA yields higher than the washed blank samples that ranged from 1.1ng/mL to 23.0 ng/mL. Despite this, measurements indicated that the application of some blood enhancement reagents, particularly Amido Black, may affect DNA recovery. Across all fabric types, samples treated with Amido Black had a low DNA recovery comparable to blank samples, returning yields as low as 0.7ng/mL on cotton samples. Across the board, washed blank fabric samples had a higher amount of recovered DNA than the unwashed blank samples; however, these samples were treated exactly the same with the exception of laundering. While unwashed blank samples had an average DNA yield of 3.57ng/mL, washed blank samples had an average DNA yield of 8.59ng/mL. Because of this, it is suggested that cross transfer of DNA between samples during the laundering process is possible.

Despite these results, the NanoDrop™ OneC UV/Vis spectrophotometer does not provide differentiation between human-specific DNA and DNA from other sources. Although unlikely that other DNA sources are largely contributing to the quantities of DNA present within the sample, it remains a possibility that not all of the quantified DNA yield is representative of human-specific DNA that would be probative during a criminal investigation.

This study highlights the importance and value in choosing enhancement reagents that enhance bloodstains while maintaining the integrity of critical DNA evidence on laundered clothing. The results provide a crucial resource for forensic investigators and future researchers to aid in the utilization of laundered fabric evidence.

DNA, Laundered, Enhancement Reagents

B44 Investigating Novel Methods for Estimating Time Since Deposition (TSD) of Bloodstains in Forensic Samples

Amanda L.J. Adams, University of New Haven Connecticut, Forensic Science Department, 300 Boston Post Road, West Haven, CT 06516; and Claire Glynn, PhD, University of New Haven Connecticut, Forensic Science Department, 300 Boston Post Road, West Haven, CT 06516*

The goal of this presentation is to inform attendees of three techniques for estimating the TSD of blood in relation to forensic cases.

This presentation will provide the forensic science community with insight into multiple methods that exhibit potential to estimate the age of bloodstains. These include the measurement of enzymatic activity, protein concentration, and the degradation ratio of two ubiquitously expressed RNAs.

Blood is the most commonly encountered biological fluid found at violent crimes and can provide probative evidence in terms of DNA profiles and pattern analysis; however, these stains can also reveal previously untapped potential in determining the time of deposition of a bloodstain resulting from a trauma or event. The ability to estimate TSD of bloodstains has been researched in the past utilizing many different methods, yet results varied with no complete agreement on one method for implementation into real casework. The goal of this study was to investigate a variety of methods which exhibit potential for TSD estimation. These include investigating over time, enzyme activity, the quantification and spectrophotometric observation of total protein, and the degradation of two RNA species.

Following Institutional Review Board (IRB) approval, venous blood was collected from volunteers with informed consent into sterile EDTA vacutainer tubes. Then 100µL of blood was deposited on white cotton cloth, in triplicate, and allowed to age in a cool, dark environment for 24 hours, 48 hours, 1 week, 2 weeks, 1 month, 3 months, and 6 months. Enzyme activity of Alkaline Phosphatase (ALP) was determined using a colorimetric reaction that was measured using a Nanodrop® OneC Ultraviolet/Visible (UV/Vis) spectrophotometer. Total protein was extracted, quantified, and viewed spectrophotometrically using the UV/Vis spectrophotometer. Total RNA was extracted using the RNeasy Mini Kit, quantified, and expression analysis was performed using Real Time-Polymerase Chain Reaction (RT-PCR) targeting beta-actin and 18 S RNA.

After spectrophotometrically observing the enzymatic activity of ALP, the concentration was determined using a standard curve. It was found that from fresh blood to six-month blood the concentration dropped from 178.9U to 32.36U. When examining the amount of quantified total protein, it was found to have not decreased as drastically, ranging from 5.912mg/mL to 4.981mg/mL in the same six-month period. When each sample is spectrophotometrically observed, three specific peaks are seen at 412nm designated λ, 541nm designated β, and 576nm designated α. These peaks have historically shown correspondence to the derivatives of hemoglobin and decrease in parallel with the conformational changes that correspond to hemoglobin's degradation. The most specific change is found between 541nm and 576nm. These two separate peaks begin to fuse into one smaller peak, relating the eventual conformational change of hemoglobin into hemichrome. The most pronounced peak, found at 412nm, remains present over time; however, it diminishes from an absorbance of 1.52 to 0.50 over the six-month period. Quantifiable amounts of total RNA were extracted from all samples ranging from 22.159ng/µL to 7.000ng/µL, with no real trend of an increase or decrease over time observed. Both Beta-actin and 18S RNA were detected in all samples and have shown a general trend to decrease in expression over time.

This study has shown, using several different methods, the great potential present in the ability to estimate the TSD of bloodstains. Further research is yet to be conducted; however, the results obtained thus far show great promise for the future. It is believed that not one single method will provide the answer; rather, the utilization of multiple methods in concert with each other will ultimately provide the investigator with greater accuracy.

Aging, Blood, Degradation

B45 Isoalleles Revealed by Massively Parallel Sequencing (MPS) Provide Increased Resolution and Discrimination in Forensic Casework

Adam M. Garver, MFS, BCI - London Office, PO Box 365, London, OH 43140; Jocelyn M. Bush, MS, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201; Max M. Larijani, MSFS, Ohio Attorney General, CODIS Unit, PO Box 365, London, OH 43140; Steven M. Wiechman, BS, Ohio BCI, 1560 State Route 56, SW, London, OH 43140-8623; and Esley M. Heizer, Jr., PhD, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201*

After attending this presentation, attendees will understand what isoalleles are and how they can be used in forensic casework.

This presentation will impact the forensic science community by demonstrating the power MPS holds for increased discrimination in forensic casework.

Short Tandem Repeat (STR) typing by Capillary Electrophoresis (CE) is the standard for DNA processing in forensic laboratories; however, this method is limited in the amount of information that it yields for analysis by only providing length-based information from STRs. In contrast, STR typing by MPS yields both size- and sequence-based information. This ability makes it possible to detect isoalleles (alleles that are homozygous by length but heterozygous by sequence). Because these are sequence-based differences, they are not observable in CE-based STR assays. Not only can sequence variation between individuals at the same loci be revealed, but this kind of diversity is often observed at one or more alleles in a DNA profile.

Battelle and the Ohio Bureau of Criminal Investigation (BCI) have collaborated to evaluate a customized MPS workflow utilizing the Promega® PowerSeq™ Auto/Y prototype amplification kit and the Illumina® TruSeq® DNA PCR-Free library preparation kits for sequencing on the Illumina® MiSeq® instrument. Sixteen buccal swabs (extracted and quantified) and 49 database samples (directly amped) were processed with this workflow and analyzed for the presence of isoalleles. In this study, 17 of 65 samples displayed at least one isoallele. The most common locus displaying isoalleles was D3S1358, a locus with a compound repeat, where it was observed in five individuals. Isoalleles were also observed in four samples for locus D21S11, which is a complex locus. The sample with the highest number of isoalleles contained three at different loci within the profile.

Due to the relatively common appearance of this characteristic during this study, isoalleles present a unique potential for resolving contributors of mixed samples. Several mixtures at different ratios were prepared and sequenced. Analysis of these mixtures revealed that isoalleles are able to yield valuable information when attempting deconvolution of MPS mixture data. In one mixed sample, there were three loci where the contributors to the mixture showed isoalleles. There was an additional locus where the sequence data allowed the allele type of the minor contributor to be differentiated from the stutter of the major contributor's allele. These preliminary studies suggest MPS will be a valuable tool for analyzing mixed samples in forensic casework.

As one part of a larger validation study, genetic transmission was studied to ensure that the markers included in the PowerSeq™ Auto/Y prototype amplification kit are consistent with the expected Mendelian inheritance pattern. The pattern of transmission from mother and father to offspring allowed an evaluation of the inheritance pattern as well as the stability of genetic transmission events. Isoalleles were observed in this study and were traceable from parents to their offspring. In one family, a male child had a heterozygous genotype at locus D1S1656 with isoalleles of two different sequence variants that were traced back to the mother and father. In another family, the father exhibited isoalleles at D2S441 (10a and 10b). Upon sequencing the amplified products in the offspring, it was observed that the daughter had inherited the 10a allele while the son inherited the 10b allele.

The studies performed as part of this evaluation highlight the prevalence of isoalleles and their high value to forensic casework. Whether in mixture cases, paternity cases, missing persons cases, or familial searches, MPS can provide valuable information that extends beyond those of traditional CE-based methods.

MPS, Isoalleles, Casework

B46 The Development of a Mitochondrial DNA (mtDNA) Assay for Forensic Human Inclusion/Exclusion Screening Using Real-Time Polymerase Chain Reaction High-Resolution Melt (PCR HRM) Analysis

Ashley F. Cowan, Towson University, Chemistry Dept/Smith Hall, 8000 York Road, Towson, MD 21252; and Kelly M. Elkins, PhD*, Towson University, Chemistry Dept/Smith Hall, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will understand how PCR coupled with HRM can be used as a presumptive mtDNA screening tool for degraded DNA samples in forensic casework.

This presentation will impact the forensic science community by demonstrating a new method of screening mtDNA evidence and comparing it to reference samples to determine if further testing is required or to sort preliminary groupings. It is the intention that this process could be used as a presumptive step prior to standard DNA sequencing in forensic laboratories. In addition, equipment required for this additional screening is readily available to forensic DNA scientists in major crime laboratories.

Forensic scientists currently use mtDNA to identify missing persons and remains recovered from mass disaster cases. It is often valuable in these situations due to its higher copy number compared to nuclear DNA, which can become highly degraded and thus compromised. By comparing the recovered mtDNA to maternal lines, a potential identification can be made. While less discriminating than nuclear DNA, mtDNA is an excellent tool for screening and has been shown to differentiate human populations. It is highly advantageous for crime scene laboratories to be able to exclude or include a possible suspect(s) before focusing additional time and resources into further investigation.

Within the mitochondrial genome, there have been reported to be hypervariable regions known as one, two, and, more recently, a third has been discussed (HVI, HVII, and HVIII). Mutation rates in these areas are known to be five to ten times higher than nuclear genes due to low fidelity of mtDNA polymerase and the lack of repair mechanisms within the mtDNA overall. These regions are located within the control region of the mtDNA and code for no known medically or phenotypically significant genes. Additionally, other highly variable polymorphisms are located within and around these three hypervariable regions. Through the culmination of data from mtDNA sequencing over multiple populations throughout the world, databases such as MITOMAP have compiled known areas of variation designated as Single Nucleotide Polymorphisms (SNPs).

Many current techniques for SNP assays involve utilizing complex primer set-ups like SnaPShot® or fluorescently labeled Dideoxynucleotide triphosphates (ddNTPs), which ultimately conclude with capillary electrophoresis for visualization of the amplicons. As an alternative to costly sequencing or Short Tandem Repeat (STR) -like methods, real-time PCR HRM has been proposed as a more cost effective and faster approach to differentiate between mtDNA SNPs. In addition to forensics, research using HRM has also been applied to coding regions of mtDNA related to mutation-causing human diseases, such as MELAS and LHON, and evaluating polymorphisms within the control region of common carp.

In this study, primers have been constructed to amplify the variable regions of interest in the human mitochondrial genome (HVI, HVII, and HVIII), as well as SNPs of interest specifically modified with GC-tail primers to increase melt temperatures of specific polymorphisms and thus better differentiate identifying peak heights resulting from HRM. DNA Standards including 9947A, 2800M, and K562, as well as IRB-approved volunteer buccal samples were evaluated via real-time PCR-HRM and agarose gel electrophoresis. A known T477C transition within the HVIII of 2800M showed a distinguishable temperature shift in comparison to 9947A and K562. More specific primers were designed to highlight SNPs of interest, such as the mtDNA 16519 (A/G) variant which was probed with three sets of primers. The addition of the GC-tail to the G variant allowed for a visibly increased melt temperature in comparison to the A variant on the resulting melt curve and thus facilitated differentiation.

Mitochondrial DNA, Real-Time PCR, High-Resolution Melt

B47 Differentiation of Henna-Based Hair Dyes Using Attenuated Total Reflectance/ Fourier Transform Infrared (ATR/FTIR) Spectroscopy

Morgan Vesco, 33 Dowling Circle, Parkville, MD 21234; and Kelly M. Elkins, PhD*, Towson University, Chemistry Dept/Smith Hall, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will better understand how ATR/FTIR spectroscopy and a valid statistical classification method can be used to analyze spectra of henna-based hair powders of varying colors and from several manufacturers.

This presentation will impact the forensic science community by describing a new application of ATR/FTIR, a rapid, non-destructive spectroscopic technique, to discriminate henna-based hair dye powders in the analysis of forensic evidence.

Hair is frequently encountered at crime scenes, especially those in which a struggle has taken place between the victim and the perpetrator, but also from daily hair shedding. Microscopy is used to evaluate hair evidence. Henna (*Lawsonia inermis* L.) is a plant that has been used for centuries for hair dyeing and applying body decoration, such as body painting and palm coloring, primarily in Asia/the Middle East. Henna is increasing in popularity in the United States because of the desire of people to use a more natural method for cosmetics. Henna-based hair dyes are available in a variety of colors that are different due to the varying combinations of plant powders that include henna, cassia, and indigo. Henna is pulverized into a powder for purchase, which is then made into a paste for application. To make the paste, the powder is mixed with water. When the henna dye is applied, the henna only coats the outside of the strand instead of permeating it, making this a safe and natural alternative to synthetic dyes. As the interaction of the molecules on the diamond surface are probed in ATR/FTIR spectroscopy, the chemical features of the henna and other dyes in henna-dyed hair are recorded when it is applied to the hair. The data results were gathered from the spectra and Principle Component Analysis (PCA) was performed to create classification models, which statistically classified the powders into distinct groups based on color. ATR/FTIR analysis is a powerful tool for trace examiners because it is a quick and non-destructive technique and requires a minimal amount of sample with little-to-no sample preparation. Although the trace analyst could strip the hair of the chemical, the henna can serve as an additional tool to differentiate hair evidence.

This study evaluated the ATR/FTIR absorbance spectra for 49 different henna-based hair dye powders from 4,000-500cm^{-1} with a spectral resolution of 1.929cm^{-1} using a Thermo Fisher Scientific Nicolet™ iS™10 spectrometer running the Omnic™ software and equipped with the Smart iTR™ ATR attachment. Background spectra of air were recorded at ambient temperature. The samples were purchased from eleven different suppliers. Thirteen colors were chosen due to their availability from the individual suppliers. Thirty-two scans were recorded for each replicate; each henna sample was recorded multiple times and was used to build an FTIR henna spectral library. The average ATR/FTIR absorbance was averaged over all scans by saving the data as .CSV text files that were imported into Microsoft® Excel® for spectral analysis. Predominantly variations were observed in the fingerprint region. Absorbance ratios were analyzed at selected frequencies to produce a table of ATR/FTIR results that emphasized the variations and could be clustered using PCA statistical analysis. Statistics were used to differentiate the henna samples from one another. The Unscrambler Multivariate Analysis Software PCA will be employed for statistical analysis. ATR/FTIR spectroscopy combined with chemometrics increases the selectivity of the method.

To compare to the ATR/FTIR results, the powders and pastes were also analyzed using a smartphone application called ColorAssist. ColorAssist uses the iPhone® camera with or without the flash to capture RGB values of colored materials. The dry powders and wet paste could not be differentiated by color or manufacturer using an Excel® scatter plot of RGB data results. This research supports the use of ATR/FTIR spectroscopy to differentiate henna-containing evidence. The ATR/FTIR database will provide another tool to help solve forensics cases and can be applied in most laboratories as they are widely equipped with this instrument.

Henna, ATR/FTIR Spectroscopy, Hair

B48 A Dietary Supplement of Choline and Seminal Choline Crystals: A Consideration for Seminal Fluid Identification by Florence Iodine Reagent

Khudooma Saeed Alnuaimi, MSc, Abu Dhabi Police GHQ, Forensic Bio Sect, Forensic Evidence Dept, PO Box 66722, Al Ain City - Abu Dhabi, UNITED ARAB EMIRATES*

After attending this presentation, attendees will understand the morphological differences and similarities between crystals produced by the dietary supplement choline and seminal fluid using the Florence Iodine (FI) test. This study considers an important area of seminal fluid identification as false positive in the presence of a choline dietary supplement and other sources that can be encountered during an evidence examination for seminal fluid.

This presentation will impact the forensic science community by reviewing and comparing the crystal formation of choline from seminal fluid and from a dietary supplement using light and polarized light microscopy.

Choline is a non-protein component of semen that can be found in high concentration in seminal stains. The choline test is used as a presumptive or an initial test for the presence of seminal fluid in many laboratories around the world.[1] As a presumptive test, it can be very important forensically from a different perspective. It can reduce the time spent searching and screening an item by focusing on a certain area that provides an indication of the searched-for stain. This test will also reduce the cost of operation by using less of the expensive confirmation testing. The test can also be less destructive on suspected semen stains as it uses less sample.

Generally, the need for tests for seminal fluid is vital in forensic sexual case examinations if there is no sperm found in the microscopic examination. The possibility of confronting no-sperm samples is increasing in forensic work due to vasectomy and azoospermia conditions in men worldwide. Another condition that can cause an of absence of sperm includes penetration without ejaculation.

Worldwide, vasectomy is increasing; in the United Kingdom, more than 45,000 operations are performed each year in National Healthcare System (NHS) hospitals and an unknown number in private clinics.[2] The trend for vasectomies worldwide is 30 million, 43 million, 44 million, 28 million, and 30 million in 1982, 1991, 2001, 2009, and 2015, respectively.[3] On the other hand, azoospermia can be defined as the absence of sperm in the ejaculate. This condition can be found approximately in 1% of all men and in 10% to 15% of infertile males.[4]

The need to identify seminal stains that have no sperm has produced several tests, such as the choline test, the Acid Phosphatase (AP) test, the Prostate Specific Antigen (PSA) test, and the Rapid Stain Identification (RSI) test for Semenogelins (Sg).[1] The AP and PSA tests are considered to be presumptive tests that were found to be less specific than the FI test for choline.[5] The Sg gene is also present in primates, which can indicate that it can also be found in non-human sources.[6]

In this research, an attempt was initiated using light and polarized light microscopy to characterize the morphology of choline crystals from seminal fluid and from dietary supplements, which were studied microscopically after using FI. The results can be used in choline source evaluation. The use of choline in addition to other presumptive tests can increase clarification of the case.[7] There is a need for more research on the subject of choline crystal formation tests and the chemical differences between various sources of choline in addition to other modern testing.[8]

B49 The Effect of Body Mass and Cadaveric Bloat on DNA Quantity and Downstream Short Tandem Repeat (STR) Success

Madeline G. Roman, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Amy E. Sorensen, MS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340*

The goal of this presentation is to provide attendees with information regarding the effect of decomposition on the quantity and quality of DNA extracted from the muscle tissue of human cadavers for identification purposes. Attendees will become familiar with how the processes of DNA degradation and damage occurring throughout the early stages of the human decomposition process affect downstream STR typing success.

This presentation will impact the forensic science community by emphasizing the importance of sample collection before a body enters the bloat stage to ensure the highest chance of successful genotyping using STRs for human identification purposes.

Human remains may be recovered for identification during forensic casework, missing persons cases, or after a mass disaster. These bodies may be found in various stages of decomposition, including fresh, early decomposition, bloat, advanced decomposition, and skeletonization. In such cases, DNA profiling using STRs is routinely applied to identify the remains; however, DNA is known to degrade after death, and harsh environmental conditions such as heat, humidity, and exposure to sunlight speed up decomposition and lead to increased DNA damage and degradation. In addition, body mass is also known to affect the rate of decay. This project assessed the amount and integrity of DNA recovered from low (average 53kg) and high (average 84kg) body mass cadavers through the early stages of decomposition and determined the success of STR profiling throughout each stage.

This study investigated the quantity and quality of DNA extracted from the quadriceps muscles of six cadavers during the first 12 days of decomposition where soft tissue persisted. The cadavers were placed in an outdoor environment in either April or October in southeast Texas. DNA from the quadriceps muscle was extracted and assessed to determine DNA quantity and quality via real-time Polymerase Chain Reaction (PCR) (DNA concentration and degradation ratio), and genotyping was performed using a commercial STR amplification kit.

As expected, the quantity and quality of DNA decreased as decomposition progressed, accompanied by a decrease in the number of reportable alleles and peak heights across the STR profiles. Complete STR profiles were obtained from all bodies until day four of decomposition. Although variation between the cadavers was evident, an interesting trend was observed between low and high body mass cadavers. The DNA quantity and STR profile quality decreased rapidly at the onset of bloat (around day six) in the low body mass cadavers, whereas in the high body mass cadavers, a similar decrease occurred several days later (day ten), near the end of the bloat stage. This phenomenon resulted in complete (or near complete) STR profiles being obtained from the larger cadavers for up to four days longer than the smaller bodies. On average, the number of STR alleles recovered from all cadavers decreased during bloat, indicating the importance of collecting tissues for DNA analysis as early as possible from all decomposing bodies, with the bloat stage marking the most rapid decrease in DNA quantity and STR success during the initial stages of decomposition for both high and low body mass cadavers.

Human Decomposition, STR Typing, Human Identification

B50 The Collection of DNA From Fingerprints on Weathered Trash Bags

Ellen M. Cassidy, BS, Arcadia University, 65 School House Road, Shushan, NY 12873; Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038; Jillian C. Fesolovich, Keystone College, One College Green, PO Box 50, La Plume, PA 18440; and Allen F. Stewart, MS, Swede and Airy Streets, Norristown, PA 19401*

After attending this presentation, attendees will recognize the importance of the cyanoacrylate fuming technique for the development of fingerprints left on garbage bags after being subjected to weathered conditions. Attendees will also understand the importance of obtaining touch DNA from the developed fingerprints.

This presentation will impact the forensic science community by demonstrating that touch DNA can be obtained from the developed fingerprints on weathered garbage bags.

At crime scenes, any evidence found can be considered probative. Research is being conducted to discover new techniques for the development of fingerprints, the impact of weather conditions on the development of the fingerprint, and/or if the substrate the fingerprint was left on affects the collection. Each of these aspects may affect how fingerprints are collected. Fingerprints are left behind on surfaces by transferring three main products from the secretory glands — sebaceous, eccrine, and apocrine glands — on the human skin. These products include a mixture of organic, inorganic, and environmental contaminants. Every latent fingerprint left behind has different ratios of each component, which can affect the durability, resistivity, and quality of the fingerprint.

The Cyanoacrylate (superglue) Fuming Method (CFM) has been found to be effective for the development of latent fingerprints on non-porous surfaces.[1] This analytical tool involves subjecting a latent fingerprint to cyanoacrylate vapors in an enclosed chamber that polymerizes with the fingerprint residues to form a polycyanoacrylate polymer along the ridges.[2] Stated in the *Portland Press Herald*, approximately 30% of latent fingerprints collected from crime scenes are usable for fingerprint comparison; this illustrates the importance of being able to collect DNA from the developed fingerprints to analyze and obtain a DNA profile.[3] Cyanoacrylate fuming is a non-destructive process, which means DNA transferred from the individual in the latent fingerprint can be extracted and analyzed, which allows for the source of the fingerprint(s) to be determined.[4]

The goal of this research was to collect and develop fingerprints from weathered trash bags through the process of cyanoacrylate fuming, subject each sample to an automated extraction, quantify each sample through quantitative Polymerase Chain Reaction (qPCR), Short Tandem Repeat (STR) profiling, then complete a comparison between the known and unknown samples.

During the research, a series of experiments were conducted to determine if the weather (hot, cold, and light versus dark) affects the quality of latent fingerprints when developed with cyanoacrylate. Each fingerprint was analyzed to determine if a fingerprint comparison could be completed after fuming, then a DNA sample was taken. A control was placed in a room with sunlight and ambient temperature. The effect of sunlight on developed fingerprints was also tested to determine if the quality of the fingerprint changes. This was completed by placing a garbage bag in a dark cabinet that was not opened. Each variable had multiple bags present that contained a total of 20 fingerprints per bag to test if fingerprint quality and DNA analysis is affected by time. A second variable of time was looked at that included leaving the garbage bags outside for a period of 24 hours, 2 weeks, 1 month, and 3 months. After the development of each latent fingerprint, a second method was developed to look at the collection and extraction of DNA from the visible fingerprint. Chosen individuals were given multiple garbage bags and were asked to place their thumbprints on the side of each garbage bag. Each bag was then subjected to a different variable and the fingerprint quality and DNA analysis was tracked and analyzed. For consistency between the amounts of touch DNA, a protocol was determined, which included the time since washing of their hands and the objects each person touched before placement. The focus of future research is the development of a method to test whether the cyanoacrylate fuming technique can develop latent fingerprints on garbage bags, more specifically on the side of garbage bags.

Cyanoacrylate Fuming, DNA, Fingerprints

B51 Blast Suppression Foam Does Not Inhibit DNA Recovery and Analysis

Calvin R. Justus, PhD, Federal Bureau of Investigation/ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Kelsey Kyllonen, MA, 1200 Green Tree Road, #202, Fredericksburg, VA 22406; Keith L. Monson, PhD, 2501 Investigation Parkway, Quantico, VA 22135; and Mark F. Kavlick, MPhil, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the effects Aqueous Foam Concentrate-380 (AFC-380) blast suppression foam has on DNA recovery and analysis.

This presentation will impact the forensic science community by verifying that the use of AFC-380 does not obstruct DNA evidence collection or deter its subsequent analysis by Polymerase Chain Reaction (PCR).

To develop investigative leads in response to an Improvised Explosive Device (IED) explosion, biological evidence is collected from the exploding apparatus or surrounding material post-blast and analyzed. DNA collected from IED-blasted material can provide decisive evidence for ensuing criminal investigations or intelligence operations; however, recovery of high-quality DNA from exploded IEDs is infrequent and is met with considerable obstacles. The explosive force and heat produced by a blast can destroy or degrade DNA. PCR inhibitors may also be co-extracted, impeding amplification of target fragments and preventing identification of possible suspects. Aqueous blast suppression foam is commonly used in military and anti-terrorism applications to contain blasts associated with IEDs by suppressing the shock wave associated with detonation. The use of blast suppression foam in response to IED threats requires an understanding of any potential detrimental effect on DNA recovery, quality, and succeeding forensic analysis.

In this study, the effects of blast suppression foam on DNA recovery and analysis by two different quantitative Polymerase Chain Reaction (qPCR) methods were investigated. Human blood was spotted onto various sample materials, (e.g., PVC pipes, metal pipes, paper, and cloth). Samples were exposed to AFC-380, both with and without detonation, and compared to unexposed/undetonated controls. All samples were collected and swabbed, and DNA was extracted using the EZ1™ DNA Investigator Kit. DNA extracts were evaluated for nuclear DNA quantity and quality using the Quantifiler® Human Plus DNA Quantification Kit and for mitochondrial DNA quantity and quality using a custom qPCR method.

Overall, following analysis of nuclear and mitochondrial DNA by PCR, 86.2% of the samples were within the standards range of the assays (>0.005ng/µl nuclear DNA or >10 copies mitochondrial DNA). Out of the 13.8% that were not within standards range, 10.4% were blasted, indicating detonation-damaged biological evidence isolated from those particular samples. In addition, internal PCR controls of recovered samples that were treated with AFC-380 amplified similarly as untreated samples. Importantly, treatment with AFC-380 did not cause DNA degradation.

The results of this investigation provided no evidence that AFC-380 reduces DNA quantity (aside from potential DNA dilution effects), degrades DNA, or results in PCR inhibition. This study validates that use of AFC-380 should not obstruct the recovery and subsequent analysis of DNA collected from critical explosive device evidence.

DNA Analysis, Blast Suppression Foam, PCR

B52 Preliminary Experiments on Human Bloodstain Age Estimation by ^{1}H,^{13}C Nuclear Magnetic Resonance (NMR) Spectroscopy

Roberto Rosa, PhD, University of Modena and Reggio Emilia, Via Pietro Vivarelli 10, Modena 41125, ITALY; Erika Ferrari, PhD, Università degli Studi di Modena e Reggio Emilia, Dipartimento di Scienze Chimiche e Geologiche, via Campi 103, Modena 41125, ITALY; Consuelo Mugoni, PhD, Università degli Studi di Modena e Reggio Emilia, Dipartimento di Ingegneria Enzo Ferrari, via Pietro Vivarelli 10, Modena 41125, ITALY; Paolo Veronesi, Dept of Engineering "Enzo Ferrari," via Vivarelli 10, Modena, Italia 41125, ITALY; and Cristina Leonelli, PhD, Dept Materials and Environmental Engineering, via Vignolese 905, Modena 41125, ITALY*

After attending this presentation, attendees will understand the advantages and the possibilities offered by high-resolution ^{1}H and ^{13}C NMR in studying the aging of bloodstains found at a crime scene. Indeed, the possibility of dating blood still represents a challenge of paramount importance in the forensic sciences research field and, although numerous techniques have been proposed in recent years, an accurate estimation of the time elapsed since the crime was committed by using bloodstains is still not possible.[1]

This presentation will impact the forensic science community by presenting the preliminary results on the use of NMR spectroscopy in monitoring the changes of bloodstain spectra as a function of time.

Despite the typical lower sensitivity and higher cost of this technique with respect to other techniques which are more commonly found in forensic laboratories, mainly Mass Spectrometry (MS) and Raman spectroscopy, this techniques' main advantage relies on the possibility of acquiring spectra that directly represents the molecular composition of the whole sample, thus realizing an "-omics" approach, similar to what has recently been proposed for food matrices.[2-4]

Since blood constitutes a complex biological matrix, the possibility of monitoring the modifications of the different classes of molecules present in the whole blood over time is extremely appealing in a forensic framework.

Fresh peripheral blood was collected from different healthy adult volunteers. The obtained simple bloodstains were aged without the addition of any anticoagulants.

NMR spectra were recorded on a Bruker FT-NMR AVANCE III HD 600 MHz spectrometer with a CryoProbe™ BBO H&F 5mm probe and ^{1}H NMR data were acquired using standard Bruker pulse sequences: zg (1D sequence), zgcppr (1D sequence with pre-saturation, using composite pulse for selection), ledbpgp2s1d (Bipolar Longitudinal Eddy Current Delay (BPPLED) pulse sequence), and cpmgpr1d (Carr-Purcell-Meiboom-Gill (CPMG)).

Multivariate data analysis was applied to the collected NMR spectra in order to condense redundant information, to examine overall differences, trends in variation, and relationships between samples and variables, therefore identifying the pools of compounds able to discriminate the age of a particular bloodstain found at the crime scene.

Bloodstain Aging, Nuclear Magnetic Resonance, Multivariate Analysis

B53 The Influence of Ceramic Tiles' Surface Characteristics on the Analysis of Bloodstain Patterns

Roberto Rosa, PhD, University of Modena and Reggio Emilia, Via Pietro Vivarelli 10, Modena 41125, ITALY; Alessio Ferrara, MSc, Reparto Carabinieri Investigazioni Scientifiche, Sezione di Biologia, via Parco Ducale 3, Parma 43125, ITALY; Consuelo Mugoni, PhD, Università degli Studi di Modena e Reggio Emilia, Dipartimento di Ingegneria Enzo Ferrari, via Pietro Vivarelli 10, Modena 41125, ITALY; Paolo Veronesi, Dept of Engineering "Enzo Ferrari," via Vivarelli 10, Modena, Italia 41125, ITALY; and Cristina Leonelli, PhD, Dept Materials and Environmental Engineering, via Vignolese 905, Modena 41125, ITALY*

After attending this presentation, attendees will be more aware of the many differences existing in the surface characteristics of traditional as well as modern ceramic tiles, currently employed worldwide both for floor and wall covering applications, and the consequent implications on the analysis of bloodstain pattern characteristics associated with a bloody criminal event. Although recent research on Bloodstain Pattern Analysis (BPA) was also necessarily directed toward the study of the effect of surface characteristics of different types of substrates, similar studies on ceramic tiles are completely missing in the scientific literature.[1-3] Indeed, a wide range of ceramic tiles is available on the market with different technical characteristics, such as porosity and surface roughness, which will inevitably affect the morphology of the patterns arising from blood impact on that specific tile. Moreover, in the last decade, digital decoration of ceramic tiles by inkjet printing technologies began replacing conventional decoration techniques, smoothing the way toward many new possibilities, including the decoration of structured surfaces with ever-more-complex textural characteristics, for example, those reproducing natural wood and stone.[4,5]

This presentation will impact the forensic science community by, for the first time, presenting and discussing results of BPA experiments performed on traditional as well as innovative and digitally decorated ceramic tiles. The importance of this study also relies on its global character, as Italy and particularly the ceramic district of Sassuolo (Province of Modena, Emilia Romagna region) covers approximately 38% of the international trade of ceramic tiles.[6]

Therefore, in this study, ceramic tiles with different surface finishing and textures (from the ceramic district of Sassuolo) were considered as the substrates for simple BPA experiments; for example, drop patterns reproduction. In particular, ceramic tiles with structured, smooth, matte, and glossy surfaces were selected and accurately characterized in terms of surface roughness, mineralogical (X-ray diffraction), and microstructural analysis (Scanning Electron Microscopy (SEM)) in order to correlate the surface properties with the morphological characteristics of the obtained bloodstains.

Blood from healthy swine was utilized according to the studies by Christman, and the experiments were performed according to Laber and Epstein.[7,8] The resulting bloodstain patterns were recorded by means of a Nikon® D5100 reflex digital camera.

B54 Method Validation for DNA Recovery From Cartridge Casings

Mackenzie Matney, BS, 236 9th Avenue, Huntington, WV 25701; Mark Powell, 1245 3rd Street, Crime Lab, San Francisco, CA 94158; Eleanor J. Salmon, MSFS, San Francisco PD, 850 Bryant Street, Bldg 606, San Francisco, CA 94103; and Kelly Beatty, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

The goal of this presentation is to inform attendees regarding the efficacy of two DNA extraction methods for cartridge casings, soaking and swabbing, with comparisons also made between cartridges and casings, ammunition brands, and treatment (loading) methods.

This presentation will impact the forensic science community by enhancing the small group of recent studies that have involved DNA recovery from casings and may influence attendees to take these findings back to their labs and begin the process for changing their extraction methods.

Touch DNA is gaining popularity in the forensic science community. Increased kit sensitivities and better methodologies have contributed to obtaining DNA evidence from steering wheels, firearms, and, as with the focus of this study, cartridge casings.[1,2] Skin cells have the potential to be left behind on anything a person encounters.[3] Most ammunition is loaded into a magazine by hand, so there is a chance that DNA could be left behind on the ejected casings often left at crime scenes. The main goal of this study was to validate the best method for case use by the San Francisco Police Department (SFPD) Crime Lab. Swabbing involved using a swab moistened with sterile water, followed by a dry swab. The soaking method required placing the casing itself in a tube and surrounding it with the extraction components as well as swabbing the cartridge when removed from the liquid portion.

Overall, 96 swabbed casings and 96 soaked casings were tested. The profile of the loading analyst was the only one observed, with the exception of three samples. These were treated as blank samples when calculating results. The swabbed casings returned an average of 0.788pg/µL of DNA, while soaked casings averaged 1.46pg/µL, a significant difference. The majority of profiles produced by both methods had less than five alleles with 26.04% of swabbed and 43.75% of soaked casings generating profiles. The average percentage of alleles recovered by swabbed casings was 8.93% with an increase to 14.12% for soaked casings. With the help of STRmix™ software, soaked casings also produced a greater quantity of likelihood ratios exceeding one sextillion.

Additionally, 48 cartridges were tested and proved less successful than casings with an average percent allele recovery of 3.1% in comparison to 11.5%, which was a significant difference. There was also varied success across brands and treatments. The brands tested were .40-caliber Winchester®, Remington®, Blazer®, and Speer® ammunition with normal, handled, and saliva-transferred treatment methods. The treatment methods involved grabbing cartridges directly from the storage envelope and loading (normal), licking the thumb before grabbing each cartridge and then loading (saliva transferred), and carrying the ammunition in pockets for three hours and loading (handled). The Blazer® casings and saliva-transferred treatment had the highest percent allele recoveries with 30% and 29%, respectively. Blazer® was significantly higher than all other brands. The saliva-transferred method was significantly higher than the normal and handled treatments. The lowest recovery was the Remington® brand with 1.3% and the normal treatment with 2.6%. The ejection port was also swabbed after each emptying of the magazine with the target profile observed in 41.7% of samples.

SFPD will be adopting the soaking method in their lab due to the general trend of higher success within each variable. Even though every comparison did not return a significant difference, it would be their best attempt to recover DNA. In the future, this study could be conducted with multiple loaders to see if results improve, and with more samples to increase data normality.

Cartridge Casings, Soaking Method, Touch DNA

B55 New Strategies and Recommendations for Front-End Separation of Compromised Biological Mixtures Using Cellular Fluorescence Profiling and Flow Cytometry

Emily Brocato, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Briana Ratchford, BS, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Kate Philpott, JD, 11509 Drop Forge Lane, Reston, VA 20191; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will better understand how cellular properties such as fluorescence, optical scattering, and diversity of surface antigens can be used to analyze and ultimately separate contributor cell populations in aged or degraded biological mixture samples.

This presentation will impact the forensic science community by introducing new methods and technical guidelines for separating biological mixture contributors prior to DNA extraction using flow cytometry. This can improve the efficacy of mixture interpretation in DNA caseworking units.

Previous studies have demonstrated that hybridizing cell mixtures with fluorescently labeled antibody probes, and then isolating fluorescent cells using flow cytometry, can be an effective technique for separating certain types of cell mixtures; however, mixture samples that have been compromised and/or degraded demonstrate a significant decrease in the efficiency of antibody probe binding as well as an overall loss of intact cell targets. This presents an ongoing obstacle for adopting a cell separation workflow for forensic applications. Therefore, the goal of this study was to investigate the molecular dynamics of cellular decomposition in simulated forensic samples and develop new strategies for mitigating biochemical processes that can lead to non-specific probe interactions and subsequent inefficiencies in cell sorting.

To accomplish this, a series of two-person blood mixtures that varied in drying time (between 24 hours and 128 hours), contributor ratio (10:1, 5:1, 3:1, 1:1), and total starting volume of blood (between 20µl and 500µl) was analyzed. This study found that non-specific interactions with the antibody probe were a significant factor in blood mixtures that had been dried for more than 24 hours, such that target cell populations were difficult to identify against non-target populations. This could be mitigated by reducing the antibody-to-cell ratio in the hybridization to <0.1µg per 20,000 cells. Subsequent sorting experiments performed on two-person mixtures with varying contributor ratios demonstrated that the Short Tandem Repeat (STR) profile of the minor contributor was successfully enriched in each sorted cell fraction when compared to the STR profile of the unsorted mixture. For example, in the 10:1, 5:1, and 3:1 mixtures, the ratio of minor contributor increased to ~1:2, ~1:1, and ~1:1 (major:minor), respectively. Although there was no systematic relationship between the degree of profile enrichment and the original contributor ratio, it was observed that the position of the sorting gate had a significant effect on the quality of the resulting STR profile, such that gates designed to capture cells at the tail ends of the fluorescence distribution of the mixture demonstrated the highest enrichment for the target cell population. To test the robustness of this sorting criteria, three different dried blood mixtures were created with 100µl total volume each with a 1:1 contributor ratio and the tails of the fluorescence distribution were sorted in a blind fashion (i.e., without measuring the fluorescence histograms of single source cell populations). The resulting sorted cell fractions showed enrichments of 2:1 and 3:1 for the A02 positive and A02 negative contributor respectively. This was consistent across multiple mixture replicates.

Last, this study conducted a limit of detection test using the above sorting workflow by drying blood mixture samples with 100µl, 50µl, and 20µl total starting volumes and 1:1 contributor ratios for each. Results demonstrated enrichments of the target population of 2:1 to 23:1, suggesting that clear separation can be obtained for blood mixtures that originally contained as little as 20µl of total volume.

Overall, these results suggest that antibody probes coupled to front-end separation with flow cytometry can be used to enrich target cell populations in whole blood mixtures that have been dried and/or compromised. Protocol changes to a traditional cell separation workflow, such as reducing the concentration of antibody probe, targeting cells with different optical properties, and sorting cells representing the "tail ends" of the distribution of fluorescence values for the mixture samples, can be effective strategies for minimizing the effects of cellular decomposition during front-end probe labeling and separation.

Biological Mixtures, Mixture Interpretation, Flow Cytometry

B56 Probing Potential Interferences in DNA Extraction of Semen Collected on Surface-Enhanced Raman Spectroscopy (SERS) -Active Forensic Evidence Swabs

Katarina G. Ruehl, WCU, 90 Merlite Court, Cullowhee, NC 28723; Brittania J. Bintz, MSc*, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Geraldine Monjardez, PhD, Western Carolina University, 327 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723; and David D. Evanoff, Jr., PhD*, Western Carolina University, 231 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the effects of synthesis reaction temperatures on silver characterization of SERS-active forensic evidence swabs. Attendees will also know how the fabrication of the swabs relates to the silver recovered in the extraction solution.

This presentation will impact the forensic science community by introducing a method using silver-coated forensic evidence swabs to successfully identify semen and subsequently extract and genotype DNA, following the insertion of a centrifuge step in the extraction protocol. The following technique has advantages over current approaches because it is sensitive, time efficient, and non-destructive. This could result in the potential identification of a variety of human bodily fluids to be used for DNA analysis.

SERS-active forensic evidence swabs are coated in silver to achieve a technique known as SERS. SERS was developed because Raman spectroscopy is an unfavorable occurrence that can be amplified by placing a metal extremely close to the sample. It was chosen for this research because of its distinctive ability to outline specific biological molecules and do so with minute amounts of sample. This technique would allow for a more convenient method to identify human bodily fluids in the forensic field.

Plain nylon swabs were placed in a synthesis reaction with silver oxide and hydrogen gas via the hydrogen reduction method.[1] This reaction produces silver nanoparticles that grow on the individual fibers of the swabs, thus making them silver-coated. A $[Ru(bpy)_3]^{+2}$ solution was swabbed and used to measure the Raman signal because of its easily identifiable Raman spectrum.

A trial was performed to see how the variation of reaction temperatures affected the efficiency of the swabs. $[Ru(bpy)_3]^{+2}$ solution was swabbed using five swabs of each temperature, which were dried to be tested with a Horiba LabRAM HR Raman microscope. All five data sets were averaged for each swab temperature and compared to observe the best signal. This procedure was similarly used for swabs containing seminal fluid samples. Atomic absorption spectroscopy was also used to obtain the quantity of silver on the swabs before the extraction process. Dissolving the swabs in nitric acid and filtering the solution extracted the silver present on the coated swabs. The solutions were then measured with a Perkin Elmer® Atomic Absorption spectrometer.

To ensure that measureable DNA could be recovered from the silver swabs, an extraction protocol was performed. The DNA recovery results showed no interference with silver nanoparticles, although there was a sizeable amount left in solution during extraction. To resolve a potential issue with silver leaching into the buffer solution, a centrifuge step was added to remove the nanoparticles from suspension, hence allowing for the extraction of the silver-free supernatant. An Applied Biosystems™ PrepFiler™ Forensic DNA Extraction Kit was used on plain silver-coated swabs to obtain solutions just before and after the centrifuge step. To show that the silver was not interfering with results, Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES) was performed on both buffer solutions. Electron microscopy imaging was also conducted on the post-extraction swabs to better characterize how the silver left on the swabs was changing. Data analysis was conducted to determine if a correlation was present between the reaction temperatures and the efficacy of the swabs.

B57 The Optimization of Human Hair Proteomic Processing for Single Hair and Ancestral Analysis

Zachary Carl Goecker, MPS, 1505 S Spruce Street, Visalia, CA; Michelle Salemi, MS, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Brett Phinney, PhD, UC Davis Proteomics Core, 4138 Meyer Hall, Davis, CA 95616; Glendon Parker, PhD, University of California, Davis, 4421 Ashwood Common, Fremont, CA 94538; and Robert Rice, PhD, University of California, Davis, Dept of Environmental Toxicology, 4138 Meyer Hall, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will understand the impact of using genetic information from hair peptides to aid in human identification. Attendees will also realize why proteomic processing is important in generating meaningful proteomic datasets.

This presentation will impact the forensic science community by shifting human identification into a dual DNA-proteomics perspective. Further implications will also be made in making identifications and ancestral classifications based on genetic information found in protein from a single human hair.

Forensic hair evidence obtained by microscopic morphological comparison has been criticized as being subjective, unreliable, and not reproducible. Mitochondrial DNA analysis has been able to remedy the reliability of hair analysis, but DNA can degrade substantially under environmental insults, particularly with greater distance from the scalp. Unlike DNA, protein has peptide bonds that are more resistant to cleavage. This research explores a proteomic approach to hair analysis. Variations in protein expression level reflect variations in transcription factor levels, their affinities for response elements, and possibly epigenetic and genetic variation. Another form of variation is the presence of Genetically Variant Peptides (GVPs) that offer the prospect of even more discriminating analysis.[1]

GVPs are the result of non-synonymous Single Nucleotide Polymorphisms (SNPs); therefore, genetic information such as SNPs can be predicted via the protein sequence and confirmed with parallel DNA sequencing. With high-resolution mass spectrometric instrumentation, single amino acid polymorphisms can be detected in the amino acid sequences of keratin, keratin-associated, and other proteins. As a result, GVPs can be used to help identify an individual or even classify ancestral origin.

This research focuses on increasing peptide yield from hair protein by optimizing its chemical processing. Further goals include comparing European and African hair GVPs and assigning the differences in population frequency found therein, as well as decreasing the working hair length to 20mm (~100µg). Data have been obtained to optimize conditions for disulfide reduction, alkylation, and peptide digestion. Temperature, time, agitation types, and concentrations of the reagents have been tested. The four metrics used to determine the best parameters for processing are yield of the insoluble fraction, yield of the soluble fraction, unique peptide number, and the number of GVPs. Results indicate that lower temperatures were better than higher temperatures. Agitation by stirring resulted in higher solubilization than swirling or remaining static. A time course quantifying the insoluble fraction has shown that trypsinization for six hours solubilizes most of the hair by mass and results in detection of the most unique and total peptides. The optimized hair processing procedure, with shorter times for both reduction and digestion, has yielded improvements in detectable GVPs, and yields similar numbers of GVPs compared to other approaches that rely on urea and a mass spectrometry compatible detergent; however, the increase in peptide and GVP generation is more pronounced in European hair as opposed to African hair. This is mainly due to the lower quantity of keratin-associated proteins detected in African hair. Overall, the data show optimized proteomic processing of human hair results from shorter reduction and digestion at room temperature with gentle stirring.

Proteomics, Hair, Genetically Variant Peptides

B58 Quantifiler® Trio or PowerQuant® System? Is One Kit Better at Predicting the Success of Short Tandem Repeat (STR) Typing of the Male Component of Sexual Assault Evidence?

Danielle K. Gibbes, BS, 7 N 8th Street, Apt 816, Richmond, VA 23219; Susan Greenspoon, PhD, Department of Forensic Science, 700 N 5th Street, Richmond, VA 23219; Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079; and Bonnie Brown, PhD, 1000 W Cary Street, Richmond, VA 23284-2012*

After attending this presentation, attendees will better understand the relationship between the quantitation data for the male component of a complex mixture and the success of developing a meaningful male autosomal STR or Y-chromosomal Short Tandem Repeat (Y-STR) profile.

This presentation will impact the forensic science community by providing information about quantitation and prediction of STR genotyping success that can help streamline the DNA analysis process and decrease the sexual assault kit backlog.

The sexual assault kit backlog in forensic casework remains a prominent issue across the nation, despite additional funding from government programs such as the DNA Backlog Reduction Program.[1] The nationwide backlog problem has been attributed to factors including the timely submission of the sexual assault kits to the laboratories, the time required to analyze the complex samples in conjunction with the shortage of resources, shortage of qualified forensic scientists, and overall increased demand for forensic services.[2] A recent study, conducted in 2009, disclosed approximately 406,000 forensic biology requests estimated to be backlogged for DNA casework by the year's end nationwide.[3] DNA quantitation data using multi-target quantitation kits can help streamline the analysis process by identifying the total autosomal and male DNA concentrations, while also assessing the quality. Analysts can use this data to predict STR genotyping success, triage the samples for autosomal or Y-STR profiling or both, and determine if it is worthwhile to continue with DNA testing.

In this study, male and female buccal swabs were extracted organically and quantitated. A lower limit sensitivity study was conducted for both the Applied Biosystem® QuantifilerTrio® kit and the Promega® PowerQuant® System to determine the lower limit of DNA detection and percent Coefficient of Variation (CV). A dilution series was created ranging from 1ng to 0.0015ng for the male and female samples and run in triplicate with each quantitation kit. Next, a dilution male and female mixture series was prepared by increasing the female-to-male ratio of DNA template in a dilution series ranging from 1:1 to 163,840-fold while holding the male DNA template quantity constant at 0.010ng. The dilution mixtures were run in duplicate using both the QuantifilerTrio® kit and the PowerQuant® System and the performance differences were assessed.

When the sensitivity was assessed, the PowerQuant® and QuantifilerTrio® kits showed similar results with reproducible data. A low percent CV was observed down to 10pg of template DNA; thus, 10pg was the quantity of male DNA chosen to hold constant for the male:female ratio study. Dilution male:female mixtures were prepared in duplicate with each quantification kit. Using the quantitation data obtained for both kits, an average quantity value for each dilution was calculated for PowerQuant® and QuantifilerTrio® for both the autosomal data and the Y-chromosome data. There was little difference observed between the quantity averages for the autosomal data for each kit. Further statistical analysis will determine whether the difference is significant or not. Both kits were able to detect the male contributor when the female contributor was many thousand times greater in concentration. The data obtained thus far is promising; however, more work is necessary to establish which quantification kit is superior at detecting male DNA in an excess of female at extreme ratios.

Overall, this study will provide information to the forensic science community about using DNA quantitation to predict STR genotyping success to further streamline DNA analysis of sexual assault kits. Further work on this project will include analysis of degraded tissues from a variety of sources utilized to construct complex male:female mixtures. The ability to utilize the quantitation and degradation data in order to predict STR outcomes will be provided since all mixtures will be analyzed using the Promega® PowerPlex® Fusion and Applied Biosystem® Y Filer® STR kits.

DNA Quantitation, Sexual Assault Kits, STR Genotyping

B59 Ion Mobility Mass Spectrometer (IMMS) — A Useful Confirmatory Tool for Analyzing Drugs and Explosives

A. Bakarr Kanu, PhD, Winston-Salem University, Rm 311, Dept of Chem, WB Atkinson, 601 S Martin Luther King Jr Way, Winston-Salem, NC 27110*

After attending this presentation, attendees will have developed an understanding for the practical analytical capability the interface between an Ion Mobility Spectrometry (IMS) and Mass Spectrometry (MS), often referred to as IMMS, can offer the forensic chemist. In forensic instrumental analysis, separation techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Mass Spectrometry (LC/MS), and Capillary Electrophoresis/Mass Spectrometry (CE/MS) are considered confirmatory test instruments. On the other hand, the IMMS technique, not yet fully implemented as a routine instrumental analytical technique in crime laboratories, can be classified as a confirmatory test instrument with advantages not well understood within the forensic community. IMMS offers value-added data not possible from these other interfaces. Separation of isomers, isobars, and conformers, reduction of chemical noise, and measurement of ion size are possible with the addition of ion mobility cells to mass spectrometers. In addition, structurally similar ions and ions of the same charge state can be separated into families of ions, which appear along a unique mass-mobility correlation line.

This presentation will impact the forensic science community by broadening knowledge about IMMS. Such knowledge may prove useful and be applied to confirmatory test analysis in forensic investigations. This presentation will add to research already conducted in forensic instrumental analysis by broadening understanding of yet-to-be fully implemented instrumental techniques in the crime laboratory. Such knowledge may well speed the implementation of IMMS as a routine analysis in the crime laboratory.

Any instrumental method used for confirmatory tests must be capable of producing reproducible, reliable, and accurate data. The IMMS technique can play a major role in achieving this goal. Data generated from IMMS can be used to evaluate the quality, reliability, and consistency of analytical results, which is an important part of any good analytical laboratory practice.

In conclusion, IMMS has the following advantages: simultaneous separation and identification of isomeric, isobaric, and conformer type drugs and explosives; charge state and trend line separations; isotope separation of complexed mixtures; short separation time; reduction of false positive rates; and random MS noise can be separated from real signal in IM space.[1-5] With all these advantages, why not employ the technology as a routine analytical tool for generating confirmatory data with forensic samples? The technology holds great promise for routine analysis in crime laboratories.

Ion Mobility Mass Spectrometry, Drugs and Explosives, Confirmatory Tests

B60 A Preliminary Characterization of Sexual Assault Lubricants: A Comparison Between Direct Analysis in Real-Time Time-Of-Flight/Mass Spectrometry (DART®-TOF/MS), Gas Chromatography/Mass Spectrometry (GC/MS), and Fourier Transform Infrared (FTIR) Spectrometry

Caterina Vadell-Orsini, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; Mark Maric, PhD, PO Box 162367, Orlando, FL 32816; Candice Bridge, PhD, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; and Brooke Baumgarten, BS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand the utility of the classification of lubricants as a novel technique for the analysis of sexual assault trace evidence using DART®-TOF/MS, in comparison to GC/MS and FTIR spectrometry.

This presentation will impact the forensic science community by aiding in the classification of unknown sexual lubricant samples based on components that are indicative of a type or class, thus providing investigative leads and innovative techniques in the analysis of trace evidence.

Unfortunately, sexual assaults are a reality in today's society. Due to the increasing use of condoms, there may be a reduced potential of finding DNA evidence in sexual assault cases. This requires a novel approach to the analysis of other trace evidence. The classification and characterization of lubricants is a relatively new approach in providing a method to analyze unknown trace evidence in such instances. In this study, approximately 20 samples from different sexual lubricant manufacturing types were tested, including water-based, silicone-based, oil-based, organic/edible, and others, which may include Personal Hygiene Products (PHPs) and lotions. The tested lubricant samples may be sub-classified as regular, sensation, flavored, spermicidal, and anesthetic based on additives in the formulation designed to impart a specific functionality (i.e., lidocaine or capsaicin).

This research sought to analyze lubricants and PHPs using DART®-TOF/MS, GC/MS, and FTIR methods that could aid in the identification of components in sexual lubricants. The goal of this study was to create a classification and characterization scheme to provide investigative leads from unknown lubricant samples. Neat lubricants as well as extracts were analyzed in both positive and negative ionization modes using DART®-TOF/MS in replicates of five. Neat lubricants and extracts (i.e., chloroform and hexane) were also analyzed via FTIR in triplicate. The neat lubricant samples were not analyzed directly by GC/MS; in turn, only the extracts were analyzed in triplicate. This information provided the necessary data to identify unique markers that define each individual lubricant class. Multivariate statistical techniques were used to create a classification scheme for the lubricants from the DART®-TOF/MS, GC/MS, and FTIR results. The outcomes of the classification schemes are expected to separate the different manufacturing types into different groups, as well as sub-classes within each manufacturing type. Unknowns were classified based on each Linear Discriminant Analysis (LDA) model from each instrument and were used to determine which instrument provides the best classification.

To provide a real-world example, cotton swabs from sexual assault kits were utilized as the collection media. Small amounts of lubricant and PHP samples were deposited onto the cotton swab and allowed to sit for one hour. Subsequently, a portion of the cotton swab was extracted in a 1:1 dichloromethane and methanol mixture for DART®-TOF/MS and GC/MS analysis. The remaining portion was extracted with either chloroform or hexane for FTIR. The extract results were compared to the classification scheme developed from the neat samples to determine how accurate the classification of real-world samples would be. The classification scheme developed from this preliminary study may ultimately enable future identification of questioned lubricant samples collected from crime scenes.

Sexual Lubricants, DART®-TOF/MS, Characterization

B61 An Analysis of Standard Glass Reference Materials Via Advanced Chemical Techniques for Forensic Applications

Kelsey E. Seyfang, BSc, Flinders University, College of Science and Engineering, Physical Sciences Road, Bedford Park, South Australia 5042, AUSTRALIA; Paul Kirkbride, PhD, Flinders University, GPO Box 2100, Adelaide 5001, AUSTRALIA; Rachel S. Popelka-Filcoff, PhD, Flinders University, Sturt Road, Bedford Park 5042, AUSTRALIA; and Hilton Kobus, PhD, Flinders University, Bedford Park, Adelaide 5001, AUSTRALIA*

After attending this presentation, attendees will understand how various techniques, including Glass Refractive Index Measurement (GRIM), Neutron Activation Analysis (NAA), Time-Of-Flight/Secondary Ionization Mass Spectrometry (TOF/SIMS), and Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) have been used to characterize several internationally available glass reference materials. The goal of this research was to measure elemental concentrations and stable isotope ratios in several glass reference materials, some of which have not been previously characterized, and thus enhance their value as reference materials.

This presentation will impact the forensic science community by illustrating that the main research outcomes presented in this study are stable isotope ratios and trace element concentrations in a range of soda lime and borosilicate glass reference materials. These values can be used for matrix-matched calibration of instruments used for the elemental analysis of glass, and thus have impact in regard to improving the quality of trace evidence examination. Furthermore, this presentation describes the scope and limitation of TOF/SIMS for the semi-quantitative analysis of trace elements in glass for forensic purposes.

All the reference materials (soda-lime glasses National Institute of Standards and Technology (NIST) 612, Float Glass Standards (FGS) 1, FGS 2, and borosilicate glasses NCS DC61104 and NIST 93a) were analyzed to determine if they had refractive indices relevant to forensic casework. This was accomplished via the oil-immersion temperature variation method using a Foster + Freeman GRIM® 3 instrument.

The soda lime glass reference materials were quantitatively analyzed by NAA at the Australian Open Pool Australian Light water (OPAL) nuclear reactor. Compositional data were generated by NAA for more than 20 elements in FGS1 and FGS2, including at least nine that were not measured in the previous research by Latkoczy et al., or the American Society for Testing and Materials (ASTM) inter-laboratory study.[1,2] NAA analysis of NIST 612 gave concentrations for 29 elements, including 10 for which no data are given on the certificate of analysis, and these values agree with the average values from other literature sources.[3,4] Trace element concentrations were also measured using LA-ICP/MS and semi-quantitatively determined using TOF/SIMS. The precision of the measurements using each of the techniques was used to determine the relative suitability for each technique for forensic microanalysis of glass.

The borosilicate glass reference materials NCS DC61104 and NIST 93a were analyzed using multi-collector ICP/MS to measure boron and lithium concentrations and stable isotope ratios and TOF/SIMS was used for the semi-quantitative analysis of trace element concentrations. Currently, these standards only have published concentration values for major elements and not for trace element analysis or any isotopic ratios.[5,6] Sensitive High-Resolution Ion Microprobe (SHRIMP) is a multi-collector mass spectrometric technique that can be used for the direct analysis of very small particles with high mass and spatial resolution. This technique was used to conduct replicate measurements of boron and lithium isotope ratios of several chips taken from different regions of the glass standards to check for compositional homogeneity. NAA and LA-ICP/MS analyses of these materials were not possible due to the high boron content of the samples.

The main research outcomes given in this presentation are stable isotope ratios and trace element concentrations in a range of soda lime and borosilicate glass reference materials. These values can be used for matrix-matched calibration of instruments used for the elemental analysis of glass, and thus have impact in regard to improving the quality of trace evidence examination. Furthermore, this presentation describes the scope and limitation of TOF/SIMS for the semi-quantitative analysis of trace elements in glass for forensic purposes.

Glass Reference Materials, Micro-Chemical Analysis, Neutron Activation Analysis

B62 Quantifying the Uncertainty of Measurement for Gas Chromatography/Mass Spectrometry (GC/MS) Acceptance Criteria

J. Tyler Davidson, MS, West Virginia University, 21 Marion Street, Apt 101, Morgantown, WV 26505; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will better understand the current acceptance criteria used for the identification of chemical substances with GC/MS. Attendees will also understand how the variability measured over more than six months in three different laboratories on five different instruments compares with recommended acceptance criteria provided by different governing bodies.

This presentation will impact the forensic science community by providing a numerical basis for the acceptance criteria generated with respect to GC/MS instrumentation. Additionally, the demonstration of a simple technique to determine the analytical uncertainty of measurement with the use of a 2 sigma (2s) criterion will assist practitioners with determining the uncertainty of measurement for their own analytical instrumentation. Finally, a demonstration of the analytical uncertainty of measurement in comparison to the published values will assist with the development of standardized language for the assessment and presentation of analytical uncertainty of measurement in court.

This research is not hypothesis driven; however, the experimental results are important and novel in the sense that the reproducibility of GC/MS results are rarely evaluated in such a detailed manner. The results provide practitioners with an appreciation for how realistic uncertainty compares with the acceptance windows recommended by different organizations.

The selectivity and confidence of compound identification by GC/MS is affected by the uncertainty in measuring the retention times and fragment ion abundances. Forensic chemists need to understand the factors that influence retention time and mass spectral measurements so that they can better present and defend the results in court.

Data analysis was conducted on GS/MS measurements collected using 13 different drug standards from three different laboratories using five different instrumental setups. An expanded uncertainty of two times the standard deviation from the mean (2σ) was used to identify the uncertainty of measurement for the retention time and relative ion abundance measurements made within these laboratories. The rationale for the use of a 2σ criterion is that this corresponds with an estimate of the 95% confidence interval, assuming normally distributed data.

Based on the numerical results, the retention time acceptance criteria currently recommended by different agencies are considerably wider than the average 2σ per week or per month determined through this study. Similarly, differences exist between recommended acceptance criteria for the uncertainty of measurement of relative ion abundances and this data set; however, when the uncertainty of measured relative ion abundances was averaged across all substances and all laboratories, the measured uncertainties agree quite well with the recommended acceptance criteria. The numerical analysis based on this data set indicates that the acceptance criteria within an instrument within a laboratory should be considerably tighter for the retention time. Also, depending on the tune frequency of the mass spectrometer, the relative ion abundance measurements should have narrower acceptance criteria than typically recommenced. The application of tighter acceptance criteria would provide more selective identification than the currently used broad-applicable recommendations.

Variability, Acceptance Criteria, GC/MS

B63 The Characterization of Nylon Fiber Color by Ultra High-Performance Liquid Chromatography-Mass Spectrometry (UHPLC-MS)

Vanessa M. Cardona, BS, 5465 N Morgan Street, Apt 404, Alexandria, VA 22312; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will recognize the merits of using UHPLC coupled with Time-Of-Flight/Mass Spectrometry (TOF/MS) in the analysis of nylon fiber dyes.

This presentation will impact the forensic science community by demonstrating that UHPLC-TOF/MS is suitable for the analysis of dyes in nylon fibers.

Nylon is a synthetic polyamide with repeating units made of hydrocarbons linked by highly polar amide groups. Acidic dyes are commonly used to color nylon fibers, where the dye molecules interact with the amide groups via hydrogen bonding. Current techniques for analyzing dyes in nylon fibers include microspectrophotometry, thin-layer chromatography, high-performance liquid chromatography, and capillary electrophoresis.

There are advantages to using UHPLC-MS to analyze nylon fiber dyes. The results provide chemical-level information about the dyes that would not be available via analysis by microspectrophotometry or thin-layer chromatography. Besides molecular mass information, partial structural information may be accessible if a fragmentation technique is available. On the downside, the method is destructive and other analyses, such as microspectrophotometry, would need to precede it.

Depending on the type of dye used to color the fiber, extraction can be difficult. A solvent for extracting the dye from the nylon fiber must be capable of solvating the dye molecules by reducing their affinity for the nylon fiber. Equal parts deionized water, pyridine, and ammonium hydroxide were mixed and used as extraction solvent. The fiber and solvent were heated at 100°C for one hour to achieve optimum dye extraction. Then various nylon fibers of different colors from several manufacturers were subjected to this dye extraction protocol followed by analysis of the extracted dyes via UHPLC-MS. Each sample was run under both positive and negative ion modes. The UHPLC column used was a Brownlee SPP by Perkin Elmer® (2.7µm:C18 2.1x30mm) with a method run time of four minutes.

The method yielded signals in both positive and negative ion modes for the dyes extracted from samples of different colors. Manufacturers typically use a proprietary blend to obtain different dye colors by mixing dyes in different ratios. Consequently, different colors from the same manufacturer display signals corresponding to the same dye components, in different ratios. Some dyes were present in all colors, while others were only present in certain colors. The data generated from UHPLC-MS analysis yielded a fingerprint for each sample that could be used to improve the confidence in the forensic examination of nylon fibers.

Nylon Fiber, Dye, UHPLC-MS

B64 A Sticky Situation: How Adhesive Collection of Fibers Affects Analysis

Lauren Todd, Virginia Commonwealth University, 3211 W Franklin Street, Apt 1, Richmond, VA 23221; and Eric J. Hazelrigg, MS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will understand how the use of tapes as a collection method could negatively impact the comparison of fibers.

This presentation will impact the forensic science community by explaining the effect of adhesive tape collection on common fiber analytical techniques. The outcome of this study will be the creation of a standardized methodology for forensic fiber collection using tape.

This study focuses on three techniques commonly employed in the analysis of fibers: fluorescence microscopy, Microspectrophotometry (MSP), and Fourier Transform Infrared (FTIR) spectroscopy, along with stereomicroscopy and polarized light microscopy. These techniques were utilized to examine contamination issues by the adhesive on fibers exposed to a variety of collection tapes.

In this study, four adhesive types were chosen: water-soluble trace evidence tape, Post-it® adhesive, fingerprint tape, and duct tape. These are commonly available products to crime scene investigators or tapes commonly found in crime scenes. Both natural and man-made fibers were selected for testing to provide a wide diversity of different morphological and chemical matrices for exposures to the adhesives. The fibers tested against each adhesive included cotton, wool, polyester, and nylon.

For fluorescence microscopy, four filter cubes were used with an Olympus® BX51. A scale of brightness was created to compare the fluorescence of each sample. The MSP data was gathered by a CRAIC™ MSP AX10 and analyzed by comparing the spectra in the Ultraviolet (UV) and visible region. A Nicolet™ FTIR with a Continuum Microscope was used to collect the FTIR spectra through the infrared to near visible wavelengths. A baseline analysis was made for each of the fibers and each of the adhesives (the controls). Then, the fiber was placed on the adhesive and removed again and the combination of fiber and adhesive was analyzed (combination fibers).

The fibers taken from the adhesives revealed contamination for most of the combinations. Results disclose changes in fluorescence, both enhancing and quenching, especially in the fingerprint adhesive and the trace evidence tape. For MSP, there were distorted peaks on the combination fibers compared to the control fiber. These peaks matched with the adhesive control, demonstrating that the contamination on the combination fibers comes from the adhesive from which the fiber is collected. The FTIR spectra for some contamination fibers revealed a mixture of peaks from the fiber control and the adhesive control.

These results establish the need for caution when using tape to collect fibers and when retrieving fibers from adhesives found in a crime scene. When comparing two fibers, the possibility of adhesive contamination must be recognized and, if possible, an analysis of the adhesive conducted to compare the spectra. Using the least-contaminating adhesive for collection is the most effective way to compare two fibers in these analyses.

Fibers, Tape Collection, Trace Evidence

B65 The Identification of Fine Plastic Materials by Thermal Desorption and Pyrolysis Combined With Direct Analysis in Real Time-Mass Spectrometry (TDP/DART®-MS)

Chikako Takei, BioChromato Inc, 1 12 19, Honcho, Fujisawa-shi, Kanagawa-ken 251-0053, JAPAN; and Kenichi Yoshizawa, MPharm, BioChromato, Inc, 1-12-19, Honcho, Fujisawa-shi, Kanagawa-ken 251-0053, JAPAN*

After attending this presentation, attendees will understand the value of TDP/DART®-MS for the rapid identification of minute plastic materials. This analysis method does not require any sample pre-treatment, such as solvent extraction.

This presentation will impact the forensic science community by explaining how TDP/DART®-MS can be effectively applied as an identification of minute plastic materials, such as synthetic fibers.

Drugs present in biological and autopsy specimens cannot be detected without first selecting the pretreatment and analytical conditions appropriate for the drugs. Thus, it is extremely important to investigate the analytical conditions suitable for specific compounds and samples; however, in recent years, due to the situation in which new substances appear one after another, including New Psychoactive Substances (NPS) that threaten society, it is very difficult to examine individually the analytical conditions that are appropriate for each new substance. Thus, a comprehensive analysis system for drugs that requires minimal investigation of pretreatment and analytical conditions is greatly desired. This study is investigating an analytical method for directly analyzing drugs in blood that does not require any pretreatment. In a previous study, by using TDP/DART®-MS for drugs in urine, each drug was separated and detected through thermal gradient heating for all drugs.[1] The detected ions were correctly identified according to their measured accurate mass and product ion spectra. Moreover, for the quantitative analysis, the calibration curves were prepared with urine-added drugs at concentrations ranging from 0.01μg/ml to 1μg/ml, and the curves were linear in that range; however, the detection sensitivity was not satisfactory, and this study sought higher sensitivity. In this presentation, the results of the investigation to improve the detection intensity of drugs will be described.

The samples were standard drug-mixture solutions and drug-mixtures loaded blood and urine (i.e., blank blood and urine samples with several types drug mixtures added). Mass spectra were obtained by using a quadrupole Time-Of-Flight (qTOF) MS equipped with a DART® ion source and a TDP unit. The TDP unit was mounted between the DART® ion source and the MS. Mass spectra were measured in positive-ion mode as the samples were heated from ambient temperature to 300ºC. Additionally, in order to improve the detection intensity, the solvent extraction for deproteinization treat and the analysis systems were investigated. For the investigation of solvent extraction for deproteinization treat, Ethanol (EtOH), Methanol (MeOH), and Acetonitrile (ACN) were used. For the investigation of the analysis system, the glass tee-tube (the HOOD) between an ion source and a qTOF was attached. This glass tee-tube can work to prevent the diffusion of volatilized drugs from the blood samples.

As a result of the investigation of solvent extraction for deproteinization treat, the highest sensitivity was attained using ACN. In addition, when using the HOOD, the peak areas of the extracted ion current gram of each drug were increased. It is concluded that the volatilized drugs had been ionized more efficiently by attaching the HOOD. Also, it is concluded that the sensitivity is further increased by increasing the heating rate of the samples.

B66 The Evidentiary Significance of Automotive Paints From the Northeast: A Study of Red Paint

Kaitlin Kruglak, 491 Washington Avenue, Apt 4W, West Haven, CT 06516; John A. Reffner, PhD, John Jay College of Criminal Justice, 524 W 59th Street, New York, NY 10019; Virginia M. Maxwell, DPhil, Department of Forensic Science, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand the significance of population studies specifically pertaining to automotive paints.

This presentation will impact the forensic science community by providing physical and chemical population data on automotive paints in the Northeast, thus informing criminalists about the significance of automotive paint characteristics.

This research was completed to provide data relating to the significance of automotive paint chips found in a specific population. Research has previously been conducted regarding Midwestern automotive paint populations as well as populations regarding the layer chemistry of the paints.[1,2] But to date, no research has been conducted on automotive paints from the Northeast. This research looked at paint samples from the Northeastern portion of the United States and uses common techniques in addition to emerging techniques for automotive paint analysis.

The populations of automotive paints are constantly changing and, thus, need to be thoroughly monitored. By investigating these populations, forensic scientists can begin to understand what significance each individual automotive paint may hold. In order to do this, the physical appearance, layer structure, and layer chemistry can be analyzed to provide a forensic examiner with more detail that can be used to give strength to a conclusion made during an automotive paint examination.

This population study involved the discrimination of red automotive paints using a comparative analysis approach and data analysis. The red samples were chosen as a target group from a larger automotive paint population based on popularity among consumers and manufacturers. The first portion of the analysis used stereomicroscopy, brightfield, and polarized light microscopy to analyze all samples collected in the population. This study analyzed the paint samples from approximately 200 automobiles ranging from 1989 to 2017. The macroscopic and microscopic characteristics of each sample analyzed included: relative surface color, presence of effect pigments, relative size of effect pigments, number of different pigments, number of layers, layer color, layer texture, and relative thickness of the layers. The population data obtained varied from the previously released reports from a Midwestern and North American automotive paint populations.[1,3] The Midwestern study analyzed 300 samples and the North American study was conducted on a much larger scale, but each demonstrates the importance of doing this type of study. For example, the present research had a 20% gray-colored frequency which differed from the less then 10% obtained in the Midwestern study and 16% in the North American study. The target color of red had a 13% frequency in the current study, as compared to the 15% in the Midwestern and 10% in North American studies.

Next, only the red automotive paints were further analyzed using a comprehensive sequence. This helped to determine the differentiating power of the analytical sequence as well as analyze the chemical properties of similarly colored paints. Current laboratory methods were used to analyze the red automotive paints, and included Ultraviolet/Visible Microspectrophotometry (UV/Vis MSP), Scanning Electron Microscopy with Electron Dispersive X-ray Spectroscopy (SEM/EDX), and Fourier Transform Infrared (FTIR) microspectroscopy. In addition, this research used Raman microspectroscopy, an emerging technique for automotive paint analysis that has been demonstrated to provide valuable pigment information.[1]

This study was conducted to highlight the significance of automotive paint comparisons and the characteristics each sample possesses. The frequency data and the degree of differentiation is important information as it can provide a foundation for determining the significance of indistinguishable samples.

Paint, Population Study, Analytical Sequence

B67 Assessing the Capability of Combining Elemental and Phase Mapping in Automotive Paint Systems Analysis Using Scanning Electron Microscope/Energy Dispersive Spectroscopy (SEM/EDS)

Sun Yi Li, BSc, Sam Houston State University, Chemistry and Forensic Science, Bldg 221A, 1003 Bowers, Box 2525, Huntsville, TX 77341; William M. Davis, PhD, 1861 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1861 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to familiarize attendees with new methods that are potentially useful in the analysis of automotive paint systems.

This presentation will impact the forensic science community by demonstrating how the combination of elemental analysis and phase mapping using SEM/EDS can provide useful information during forensic analysis of automotive paint systems. The use of this new method may also help confirm elemental compositions among the layers of paint systems, where overlaying of the principal X-ray lines of some elements occurs.

The analysis of automotive paint systems is of utter importance in forensic investigations of hit-and-run accidents to help to identify possible involved vehicle(s) and/or accident dynamics. During the manufacturing process of automobiles, a number of layers of coatings are applied sequentially to the car body to fulfill visual and functional demands. Each layer can be composed of different ratios of organic and inorganic binders, pigments, and additives, which in combination create characteristic automotive paint systems that could be highly distinguishable. When coupled with Fourier Transform Infrared Spectroscopy (FTIR) in forensic paint analysis, SEM/EDS provides comprehensive information regarding the inorganic and organic components of each coating layer. Standard elemental mapping using SEM/EDS provides detailed elemental information, but the indication of possible chemical compounds is limited. In this work, the capability of phase mapping to identify possible constituents and provide supplementary information in addition to elemental mapping is investigated.

The analytical method was developed and tested on 13 automotive paint systems. The paint systems were embedded in epoxy and the surface was thoroughly polished to expose the cross sections of the coating layers. Elemental data were collected in replicates on the Backscatter Electron (BSE) images of the cross sections. Based on the X-ray elemental maps and the quantitative information, such as weight percentage of each element, areas of distinctive composition of elements were identified as phase maps using commercially available software. The distribution, spectra, and major contributing elements of the phases were analyzed in each sample and their corresponding chemical compounds were identified based on mole fractions calculated using weight percentages.

Results demonstrate that phase analysis can be a useful tool in identifying possible inorganic compounds present in automotive paint systems. Elemental and phase maps collected in replicates are repeatable. A slight difference was observed between the experimental and empirical mole fractions, which will lead to further investigation in the range of experimental values for accurate and precise identification of the compounds. In addition, phase mapping may also be used to determine the presence of elements in cases where overlaying of the principal X-ray lines was found. More specifically, Barium (Ba) and Titanium (Ti) were co-detected across two coating layers in three samples, and elemental maps were not sufficient in confirming whether the elements were only present in one coating or in both layers due to the overlaying of K_α line of Ti, and the L_α line of Ba. Phase maps obtained from two of the samples allowed the exclusion of Ba from the E-coats of both samples and produced more resolved spectra for analysis.

The results from this work may provide a tool to identify inorganic compounds in complex automotive paint layers that cannot be accomplished by FTIR and elemental SEM/EDS analyses alone. The application also reveals a promising potential in assisting the interpretation of X-ray lines overlay in standard SEM/EDS analysis.

Automotive Paint Analysis, Phase Mapping, SEM/EDS

B68 The Enhancement of Human Scent Profiles as Forensic Evidence

Alice B. Boone, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Howard Holness, MBA, 11200 SW 8th Street, CP330, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand how human odor profiles can be collected and evaluated, why human scent can be utilized as an individual or class characteristic, and why there is a need for profile enhancement of odor profiles for all ethnicities.

This presentation will impact the forensic science community by portraying the reproducibility of findings in previous Caucasian and Hispanic human scent analyses as well as the novel incorporation of African American odor profiles.

Human scent has been previously defined as a complex mixture of Volatile Organic Compounds (VOCs) detected in the headspace above a scent sample.[1] Humans generate odor from several areas of the body, including scalp, hair, mouth, hand, axillae, and feet. The analysis of the chemical composition of human scent has enabled scientists to portray variations within these factors (age, gender, and ethnicity) to distinguish between individuals. Due to the novelty of human scent research, human scent evidence has been undervalued in the court of law; however, this type of evidence has significant value when physical evidence is not available at crime scenes. In order to increase the individualization and differentiation power of human scent evidence, this study sought to further investigate the identification of chemical signatures within the hands and axilla of specific ethnicities and genders.

During the study, the axilla odor of 60 participants was sampled. Upon collection, samples were extracted using both Headspace/Solid Phase Micro extraction (HS/SPME) and Liquid Extraction (LE) and analyzed using Gas Chromatography/Mass Spectrometry (GC/MS). The utilization of SPME immediately followed by LE complements the extraction of semi-volatile and non-volatile compounds, hence filling in the gaps of the compounds that could not be recovered using HS/SPME alone. This ensured that a full VOC profile was obtained, allowing for improved statistical analysis without requiring any additional sample collection. The samples were evaluated statistically to extrapolate data unique to specific individuals and groups.

Scientific advances have enabled the forensic science community to use scent as a feature for individual or class characteristic determination. The several analyses of body odors using the VOCs emitted have proven that, if enhanced, human scent can be just as useful as fingerprints and DNA in the attempt to identify individuals. In future work, the VOCS emitted from the underarm of human subjects can potentially correlate to specific Human Leukocyte Antigen (HLA) alleles. Additionally, once the unique odor profiles of each ethnicity can be identified and reproduced efficiently, the development of live human scent training aids for canines can commence.

Human Scent, Volatile Organic Compounds, Solid Phase Microextraction

B69 Phase Equilibria of Complex Fluid Mixtures: Modeling and Measurements With the Advanced Distillation Curve With Reflux (ADC-R)

Megan Harries, National Institute of Standards and Technology, 325 Broadway MS 647, Boulder, CO 80301; Marcia Huber, PhD, National Institute of Standards and Technology, 325 Broadway MS 647, Boulder, CO 80305; and Thomas J. Bruno, PhD, National Institute of Standards and Technology, 325 Broadway, Boulder, CO 80305*

After attending this presentation, attendees will better understand how the vapor-liquid equilibrium of complex fluids (such as ignitable liquids) can be measured using a modified distillation apparatus and how such measurements may be used to interpret results of forensic headspace analysis.

This presentation will impact the forensic science community by providing a metrology to improve understanding of the complex, real-world fluids that those in this community encounter daily. The experimental approach presented may support forensic analysis conducted by headspace methods, including arson fire debris analysis, by providing quantitative, low uncertainty data describing the relationships between the vapor and condensed phases of a sample of interest.

Building on the successful development and widespread implementation of the ADC approach to measuring the volatility of complex fluids like fuels, the ADC-R metrology was developed to address the gap in our ability to experimentally determine the vapor-liquid equilibrium of fluids containing more than two components.[1] High-quality measurements of the volatility of pure components and binary mixtures are readily available, but the fluids encountered by a criminalist, like fuels, contain many more components.[2] For such complex mixtures, the ADC-R collects data about the chemical composition of both liquid and vapor phases across a variety of temperatures, elucidating the entire two-phase region at atmospheric pressure.

Two simple mixtures were used to demonstrate the ADC-R method: a decane + tetradecane binary mixture and the Huber-Bruno surrogate, a ternary mixture developed to represent the volatility of an aviation turbine kerosene.[1,3] These simple mixtures used to develop and test the approach were chosen because they are well understood, having been extensively measured in previous work. The experimental T-P-x-y data were compared to existing mixture models. For both test fluids, the measurements of vapor-liquid equilibrium were in very good agreement with model predictions. The data were also used to improve the binary interaction parameters used in modeling.

This study concludes that the ADC-R is an appropriate method for measuring the T-P-x-y behavior of the complex and polydisperse fluids used in the real world. Gasoline and other ignitable liquids relevant to the forensic community may be measured using ADC-R. This approach and the data it may make available in the future are relevant to the interpretation of forensic headspace analyses, for example, the carbon strip method conventionally used to analyze arson fire debris.[4]

B70 The Development of the Precision ID GlobalFiler™ Next Generation Sequencing (NGS) Short Tandem Repeat (STR) Panel

Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Chien-Wei Chang, PhD, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Ryo Hasegawa, BS, 850 Lincoln Centre Drive, Foster City, CA 94404; Sharon C. Wootton, PhD, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; and Robert Lagacé, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080*

After attending this presentation, attendees will be aware of the development of sequencing STRs on an NGS platform and better understand visualizing and analyzing data with a new software platform.

This presentation will impact the forensic science community by presenting an NGS system developed and optimized for STR sequencing and data analysis. The resulting STR NGS profiles can be used in adjunct with partial Capillary Electrophoresis (CE) STR profiles from difficult casework samples.

Not unlike CE STR kit development, extensive studies were performed for new primer and master mix designs. Since these designs are made for NGS, they were developed to be compatible with library and template preparation techniques. Additionally, novel bioinformatics algorithms and software were invented to visualize and analyze data and allow analysts to transition from CE and NGS data and vice versa.

The Precision™ ID GlobalFiler™ NGS STR Panel targets 31 autosomal STRs and 4 sex-determining markers. The Precision™ ID DL8 Kit for Library Preparation on Ion Chef™, the Ion S5™ Precision™ ID Chef & Sequencing Kit for Template Preparation, and Ion S5™ Sequencing Systems for sequencing were developed to sequence STRs. Additionally, there are 53 Single Nucleotide Polymorphisms (SNPs) In Flanking (SIFs) regions surrounding the repeat. These SIFs allow for further discrimination of mixtures between major and minor contributors, as well as what may look like a stutter with CE versus a minor contributor allele.

In concert, the new Converge 2.0 Software provides an optimized pipeline for STR panel sequence analysis and reporting. Developed with a GMID-X-like interface, with browser-based navigation, Converge can be directly or indirectly connected to the Ion Torrent™ server. This allows secondary analysis data to be automatically transferred to Converge after sequencing runs are complete.

A study utilizing 34 known samples were sequenced with the Precision™ ID system workflow and concordance with previously generated CE genotyping assessed. In addition, 32 of the samples were used to create 1:10 and 1:20 mock mixture sample sets of both genders (male:female, male:male, and female:female). The mixture samples were a stress test for both the STR bioinformatic algorithms and detection of a low-level male contributor(s). High levels of concordance between the CE genotype and Massively Parallel Sequencing (MPS) genotype were observed and resulted in accurate results displayed in simplified STR and International Society of Forensic Genetics (ISFG) long-sequence nomenclature. Stutter ratios in the MPS system are elevated in comparison to those in a CE fragment length-based system due to the multiple rounds of PCR performed; however, even with higher stutter, the more complex and compound STRs allow for determining between stutter and minor contributor when the repeat motif of the minor contributor differs significantly from the stutter allele of the major contributor.

Next Generation Sequencing, Massively Parallel Sequencing, Mixture Analysis

B71 A Novel Workflow for Identifying Phenotypic Polymorphisms in Detoxification Enzymes Associated With Drug Metabolism

Kari A. Graham, BA, 2445 Montgomery Road, Apt 426, Huntsville, TX 77340; Ryan Gutierrez, BS*, 1805 Spring Meadow Court, Alvin, TX 77511; Kyleen Elizabeth Elwick, BA, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; and Bobby Larue, Jr., PhD, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77341*

After attending this presentation, attendees will have an alternative workflow to proprietary enrichment and library preparation pipelines provided by the major manufacturers of Massively Parallel Sequencing (MPS) platforms for the identification of Single Nucleotide Polymorphisms (SNPs), small Insertions and Deletions (INDELs), and Copy Number Variants (CNVs) in detoxification enzymes related to drug metabolism.

This presentation will impact the forensic science community by presenting an alternative workflow for identifying genetic polymorphisms associated with drug metabolism that forgo the proprietary workflows developed by manufacturers of next generation sequencing platforms. Alternative approaches have potential cost-saving implications as phenotypic polymorphisms are considered in molecular autopsies.

The capabilities and affordability of MPS are bringing personalized medicine into the realm of possibility for many patients. As costs continue to fall for MPS analysis, pharmacogenomic approaches offer an opportunity to provide insight into personalized drug metabolism rates. Most current efforts in this area have focused on opiate metabolism by members of the cytochrome P450 family of enzymes, typically in regard to accidental overdoses.

Polymorphisms associated with metabolism function are largely classified into the type of genetic lesion and the phenotypic effect associated with each particular mutation. The types of lesions are broken down into SNPs, small INDELs of nucleotide sequence, and additional CNVs from gene duplication events. (Due to being the most prevalent and similar to INDELs, both SNPs and INDELs will be referred to as SNPs for the remainder of the discussion.) As mentioned previously, the mutations are then further classified based on the phenotypic effect they have on enzyme function. These are broken down into silent mutations (in which no effect on metabolism is observed), gain of function mutations (in which an increased rate of metabolism is observed), and reduction/loss of function (in which an ablated or reduced rate of metabolism is observed).

As mentioned above, the expanding capabilities and reduced costs of MPS platforms allow an expansion of this technique to not only provide information for molecular autopsies associated with cardiac arrest or opiate overdoses but could provide insight into the levels of intoxication an individual has based on personalized drug metabolism rates. This information could be pertinent in establishing levels of impairment for culpability associated with drug-induced accidents.

One limitation to wider implementation of such technologies is that the costs are still slightly more than would be feasible for routine testing. To remedy this, a series of iterative price reductions are likely necessary to bring the costs down enough to make this type of testing routine. One area in which large cost savings are possible is the area of target enrichment and library preparation. Currently, manufacturers of MPS platforms have proprietary custom target enrichment/library preparation workflows that ease the design of the assay by taking the work load from the practitioner and exporting it to their production facilities. Without budgetary restraints, this scenario is favorable and desirable.

In situations in which budgetary constraints don't allow the higher price associated with proprietary custom target enrichment/library design, an alternative method that is only slightly more labor intensive is proposed.

Utilizing Primer-BLAST, primers were designed for long Polymerase Chain Reaction (lPCR) around the gene for the human carboxylase enzyme (CES1), which is known from literature to affect methylphenidate metabolism. The gene is encoded over an approximately 31kb region on the q-arm of chromosome 16 in humans. This study designed lPCR primers that broke the gene into two overlapping amplicons of approximately 17kb each. These amplicons were then pooled at equimolar concentrations and served as the enriched target for MPS library preparation. A third party enzymatic library fragmentation kit was used to cleave the lPCR amplicons into fragments of 200bp for MPS suitability. Another enzyme from the same kit was used to repair the cleaved ends and a third enzyme was utilized to ligate adaptors for barcoding/indexing of fragments prior to clonal amplification on an automated library preparation platform. Once the samples were placed onto the automated library preparation platforms, the recommended workflow of the manufacturer was followed through sequencing. SNPs were identified via both the manufacturer's bioinformatics software package as well as independently via generated fastq files and freely available software (IGV).

Analytical thresholds for identified SNPs were established based on depth of coverage in a region and percentage of reads observed for individual SNPs. This was based on an initial training set of 32 individuals sequenced twice for concordance between runs. Additionally, the nature of the mutations was determined based on 172 individual samples that were classified based on their sensitivity to methylphenidate and clustered via principle component analysis.

The method described could be adapted to other targets and purposes, such as molecular autopsy and other detoxification enzymes. Additionally, sonic fragmentation of amplicons could be used in a similar fashion.

Phenotypic SNPs, Detoxification Enzymes, Pharmacogenomics

B72 From the Ashes: Genetic Identification of Burned or Cremated Human Skeletal Remains

Kelly Grisedale, PhD, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Brittania J. Bintz, MSc, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Maureen Hickman, MS, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the potential and limitations of genetic investigations of burned and cremated human remains using traditional forensic DNA analysis techniques and next generation sequencing.

This presentation will impact the forensic science community by providing an avenue to gain maximum information from fire-damaged and cremated human remains that have historically been very difficult to identify.

Identification of human skeletal remains is a routine task for forensic DNA analysts; however, this task can be more challenging when the recovered bone fragments have been badly burned or charred, as occurs in cases such as mass disasters, house fires, or car accidents. Additionally, after commercial cremation, there may be a need to confirm the identity of the remains, for reasons including civil or criminal cases, paternity or kinship analysis, or identification of missing or deceased individuals.

Examination of skeletal remains typically begins with anthropologists who can employ various metric analyses to assess whether the remains are human or animal and assist in determining a biological profile including sex, stature, and weight; however, diagnostic bone fragments may not be available in remains damaged by fire or cremation. Furthermore, the accuracy of metric analyses of cremated samples is typically dependent on having the entire cremated remains, which is not always the case.[1] As such, DNA analysis may be the only option for identification.

Genetic identification of severely burned or cremated remains using traditional short tandem repeat analysis or mitochondrial DNA (mtDNA) sequencing has historically been limited due to low quantity and extreme degradation of remaining DNA and, in the case of cremated remains, concerns regarding contamination; however, advances in DNA analysis chemistries and technologies present an opportunity to re-assess these processes.[2]

Presented here are the results from five case studies involving aged, severely burned, or cremated human remains. DNA was extracted using an in-house-developed method modified from a commercial silica-based extraction kit. All extracts were quantified using real-time Polymerase Chain Reaction (PCR) to determine nuclear or mtDNA recovery. Nuclear DNA was assessed using the InnoTyper® 21 Kit. This kit targets small amplicons (60bp-125bp) and is intended for use with samples containing low quantity and highly degraded DNA. Mitochondrial DNA was assessed using an in-house-developed, whole-mtDNA genome probe-capture assay for sequencing on the Illumina® MiSeq®. Multiple samples from individual sets of remains were examined to assess consistency across results.

Results indicate that low levels of nuclear and mtDNA can be recovered from burned and cremated bone. Degradation indices obtained via quantitative PCR (qPCR) showed the recovered DNA was highly degraded. Partial InnoTyper® 21 profiles were obtained from concentrated extracts; however, exaggerated stochastic effects, such as allele drop out and peak-height imbalance, were observed in some profiles due to the low amount of starting template, complicating the profile interpretation. Results also revealed that sufficient mtDNA could be recovered from some remains for whole mtDNA genome sequencing using the probe capture approach and massively parallel sequencing. Overall, results determined that genetic information can be obtained from burned or cremated skeletal remains using emerging chemistries and technologies, providing an option for identification when traditional methods fail.

Cremated Remains, DNA Identification, Next Generation Sequencing

B73 An Analysis of Challenging Forensic Samples Using Probe Capture Next Generation Sequencing (NGS)

Symone Watson, 49 Ingleside Drive, Hamden, CT 06514; Maria G. Almada, MS, Poder Judicial, Destacamento Morgue Judicial Tuc, Av. Indepenencia s/n esq. La Rioja, Muñecas 469- 6to A, S. M. de Tucuman, Tucuman 4000, ARGENTINA; Cassandra Calloway, PhD, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Junior Way, Oakland, CA 94609; and Shelly Y. Shih, MS, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Junior Way, Oakland, CA 94609*

After attending this presentation, attendees will understand the advantages and application of a customized probe capture NGS system designed for forensically challenging samples.

This presentation will impact the forensic science community by illustrating how the custom probe capture NGS method is useful for the recovery and sequencing of the whole mitochondrial genome of forensically challenging samples (e.g., telogen hairs and touch DNA).

Forensic biological samples that are highly degraded, limited, and mixed (such as telogen hair and touch DNA) can be challenging for conventional Short Tandem Repeat (STR) genotyping. An alternative strategy for analyzing forensically challenging samples is analysis of mitochondrial DNA (mtDNA); however, conventional mtDNA sequencing methods such as Sanger Sequencing are limiting in discrimination power because they often fail to detect low level heteroplasmy or mixtures that are common in forensic samples. NGS methods have the potential to overcome many of the limitations of conventional methods used for analyzing mtDNA markers due to the high-throughput massively parallel clonal sequencing nature. In conjunction with using NGS, this study developed a custom probe capture enrichment system targeting the entire mitochondrial genome and 451 nuclear Single Nucleotide Polymorphism (SNP) markers for highly degraded and mixed samples. This approach uses DNA probes to enrich targeted regions from randomly fragmented DNA libraries for clonal, massively parallel sequencing, thereby maximizing recovery of short DNA fragments characteristic of forensic samples.

This custom probe capture NGS assay was successful in recovery and sequencing of the entire mitochondrial genome from forensically challenging samples, including 33 telogen hair roots, 22 telogen hair shafts, and 19 touch DNA samples recovered from spent cartridges using the double-swab method with cotton and flocked swabs. Thirty of 33 telogen hair roots yielded 100% coverage of the mitochondrial genome while 3 telogen hair roots had >80% coverage of the mitochondrial genome at >100x read depth. Seventeen of the 22 telogen hair shafts yielded 100% coverage of the mitochondrial genome while 5 showed >80% coverage of the mitochondrial genome at >100x read depth. Of these 5 telogen hair shafts, 4 failed conventional PCR-based amplification while 1 showed weak results. Furthermore, a subset of the DNA libraries of these telogen hair roots were captured and sequenced using a customized SNP probe capture assay, yielding 65.1% to near 100% coverage of the 451 nuclear SNPs. In addition to telogen hairs, touch DNA collected using cotton swabs exhibited an average of 93.7% coverage of the mitochondrial genome while touch DNA collected using flocked swabs exhibited 100% coverage of the mitochondrial genome at >100x read depth. A subset of these touch DNA samples collected using flocked swabs exhibited 100% coverage of the mitochondrial genome at >500x read depth. The major mtDNA variant sequences were consistent for all touch DNA samples and with the subject's profile. The mtDNA haplogroup was determined to be H7 for all four of the touch DNA samples and the reference.

In conclusion, this probe capture NGS system is shown to be useful for recovery and sequencing of the entire mitochondrial genome for forensically challenging samples, including telogen hair roots, telogen hair shafts, and touch DNA recovered from spent cartridge casings. Furthermore, both nuclear SNP and mtDNA markers can be analyzed from a single DNA library prepared from challenging samples that are limited in quantities and compromised in qualities. Therefore, when a sample with degraded or a low amount of DNA is encountered, this probe capture NGS method will allow for both SNP and mtDNA analyses without consuming more DNA extract.

Probe Capture, Next Generation Sequencing, Touch DNA

B74 An Innovative Massively Parallel Sequencing (MPS) 74-Microhaplotypeplex Forensic Assay for Improved Deconvolution of Mixed DNA Samples

Fabio Oldoni, PhD, The George Washington University, 2100 Foxhall Road, NW, Washington, DC 20007; Sharon C. Wootton, PhD, Thermo Fisher Scientific,180 Oyster Point Boulevard, South San Francisco, CA 94080; Robert Lagacé, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Ryo Hasegawa, BS, 850 Lincoln Centre Drive, Foster City, CA 94404; Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will appreciate the potential of using MPS for short DNA regions containing multiple Single Nucleotide Polymorphisms (SNPs), called Microhaplotypes (MHs), to deconvolute DNA mixtures.

This presentation will impact the forensic science community by proposing a novel analytical approach on an MPS platform to improve the forensic analysis of mixed DNA samples.

Microhaplotypes are novel genetic markers with two or more SNPs within a short distance of each other (≺300 nucleotides), which jointly define a multi-allelic locus. MHs are useful for identification purposes and prediction of biogeographic ancestry, but also demonstrate great potential for mixture deconvolution as they are characterized by having important differences from conventional Short Tandem Repeat (STR) markers, such as same size alleles, lower mutation rate, and the absence of stutter peaks.[1] As the mainstay Sanger sequencing does not allow determining the cis/trans relationship between individual SNP alleles (i.e., the haplotype), the MPS technology overcomes such limitations by clonal sequencing of individual strands and the detection of the haplotype of interest within a specific locus.[2]

In this study, an innovative MPS multiplex panel of 74 MH loci, with optimum characteristics for improved deconvolution of DNA mixtures, was developed and tested on the Ion Chef/Ion S5™ MPS platform. To simulate a range of scenarios typically encountered in casework samples, a series of unbalanced two- to four-person DNA mixtures characterized by different ratios between contributors was prepared. The performance of the assay in targeting one or more minor contributors in the presence of up to 160-fold excess of major contributor(s) was tested using different amounts (1ng-10 ng) of input of genomic DNA (gDNA).

For data analysis of the Ion AmpliSeq™ sequencing results, the latest released beta version of Microhaplotyper Plugin was used for genotyping the DNA contributors. The MPS 74-MHplex forensic assay was shown to detect the minor contributor at higher mixture ratio than conventional autosomal STR markers, regardless of the sex of the individual. For two-person mixtures, a full MH profile of the minor contributor was reported at 1:10 and 1:20 ratios, whereas an increased number of allele/locus drop-out events was observed proportionally at 1:40, 1:80, 1:100, and 1:160 ratios; fewer were also reported at lower mixture ratios for three- and four-person DNA mixtures. Albeit allele drop-outs reduced the total number of exploitable MH loci, the Random Match Probability (RMP) calculated for the minor contributor(s) was higher or within the range of values typically obtained from full/partial autosomal STR profiles at low and high mixture ratios, respectively. In addition, MH mixture profiles of two to six persons were statistically simulated to determine the global distribution of alleles detected for 74 MH loci. Interestingly, promising results suggest the possibility of estimating the potential number of contributors based on the total allele count observed for each specific two-, three-, four-, five-, and six-person mixture-group.

These findings indicate that the MPS 74-MHplex assay is an insightful forensic DNA tool for improving the deconvolution of mixed samples and simultaneously extrapolating useful biogeographic ancestry information of the detected contributors.

B75 Massively Parallel DNA Sequencing Applications for Forensic Mixture Analysis

Christine H. Baker, MS, Battelle Memorial Institute, 1001 Research Park Boulevard, Town Center Two, Ste 400, Charlottesville, VA 22911; Jocelyn M. Bush, MS, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201; Lindsay Catlin, MS, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201; Esley M. Heizer, Jr., PhD, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201; Adriana N. Swatzell, 1400 Lascassass Pike, Apt H45, Murfreesboro, TN 37132; Richard A. Guerrieri, MS, Battelle, 1 Corduroy Court, Stafford, VA 22554; Mark Wilson, PhD, Battelle, 2001 Jefferson Davis Highway, Ste 1203, Arlington, VA 22202; and Michael L. Dickens, PhD, Battelle, 505 King Avenue, Columbus, OH 43201*

The goal of this presentation is to characterize massively parallel DNA sequencing data for the analysis of mixture samples.

This presentation will impact the forensic science community by making a powerful case for the promise of Massively Parallel Sequencing (MPS) technology to enhance current capabilities for mixture deconvolution.

The introduction of MPS technology for forensic DNA analysis offers many advantages over legacy Capillary Electrophoresis (CE) typing due to the elucidation of sequence information in addition to fragment size, as well as the ability to multiplex many forensically relevant markers. The information gleaned from DNA sequence data relative to CE fragment size may provide increased discriminatory power among individuals, which could prove valuable for the deconvolution of mixture samples. Despite the clear theoretical advantages of MPS data for mixture analysis, mixture deconvolution software tools have not been developed to utilize the added information obtained from sequence data.

To characterize MPS data for mixtures samples, more than 100 artificial mixture samples were established, ranging from two to five contributors (male and female) in varying ratios to include minor contributor input at 3% of the total mixture quantity. Samples were generated using eight single-source contributors (four males and four females) previously characterized using CE and MPS technologies and selected for size- and sequence-based allele diversity. A dilution series of all single-source samples was created to establish profiles at various input levels from 500pg to 15pg. These samples were processed using the Promega® PowerSeq™ Auto/Y System (targeting 22 autosomal Short Tandem Repeats (STRs), 23 Y-chromosomal Short Tandem Repeats (Y-STRs), and amelogenin) across five sequencing runs on the Illumina® MiSeq®. Data were analyzed with Battelle ExactID® software. Results were further characterized using custom software applications to identify allele and stutter sequences and to recognize contributor profiles among the mixture data.

Data from the single-source samples were evaluated for genotype accuracy and patterns in stutter and drop out across the dilution series. Single-source samples generated with full DNA input (500pg) were accurate and complete relative to data generated with CE and other MPS platforms. Across the 8 contributors, 8 out of 46 loci exhibited at least one isoallele, which are identical by length but differ in sequence. Loci D2S1338 and D12S391 displayed the largest gains in resolution due to sequence differences among same-size alleles. Patterns in sample- and locus-specific drop out were characterized across the dilution series. Stutter patterns were largely consistent across dilution series and reflected similar patterns to those observed in CE data.

Mixture samples were queried for each contributor profile and were compared with expectations based on single-source sample performance. Minor contributors were detected even when providing as little 3% (approximately 15pg) of the template DNA in the mixture. The relative representation of each contributor in the MPS data was evaluated by comparing read counts for alleles present only in a single contributor, as well as by comparing read counts attributed to Y-chromosome versus autosomal STRs to compare male versus female contributions. By all measures, the relative read counts attributed to each contributor were highly consistent with the true proportions of each sample contributing to the mixtures.

The current data set provides novel insight into the value of MPS data for mixture analysis. The results support a growing body of evidence suggesting that MPS technology provides accurate and reliable data for forensic STR markers, with an improved power of discrimination for loci exhibiting isoalleles. Moreover, the current demonstration of the sensitivity of MPS data to capture minor contributors, together with the strong reflection of the true contributor ratios in the relative read counts, makes a powerful case for the promise of MPS technology to enhance current capabilities for mixture deconvolution.

Massively Parallel Sequencing, Mixture Deconvolution, Forensic DNA Analysis

B76 Enzymatic Cascades for Biochemical Identification From Sweat

Mindy Hair, 103 Guilder Lane, Apt 10, Guilderland, NY 12084; Adrianna Mathis, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222; Erica K. Brunelle, BSc*, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222; Lenka Halamkova, PhD, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222; and Jan Halámek, PhD*, State University of New York, University at Albany, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will better understand that sweat is a complex, non-invasive, biological fluid capable of discriminating between multiple individuals based on the respective concentrations of biochemical content in the sweat of each individual.

This presentation will impact the forensic science community by providing a new method and purpose for sweat analysis that is capable of differentiating metabolic compounds inherent in each individual's sweat. This presentation will demonstrate the potential of sweat analysis for biochemical identification purposes to increase security measures by serving as a locking mechanism for electronic devices. Future research into sweat analysis will also create an alternative to the time-expensive DNA identification processes via the bio-affinity detection of small molecules in sweat.

Sweat is a non-invasive, biological fluid that is continuing to attract attention by the scientific community as it contains various amino acids and other low molecular-weight compounds. The concentrations of the biochemical content within an individual's sweat are controlled by hormone metabolism processes that are variable and fluctuate daily based on factors such as age, gender, diet, and activity levels. Therefore, no two individuals will have the same hormone levels at a given time and the concentrations of these sweat components should be specific to each individual; however, the limitation of instrumental detection limits prevents the determination of an individual based on a single analyte. By monitoring multiple analytes, the probability of correctly identifying a person based on these metabolic analyte concentrations increases. The combination of these levels has the potential to increase security measures by serving as a locking mechanism for electronic devices containing personal information, such as smartphones and tablets, and are much more difficult to duplicate than current security measures.

Three compounds commonly found in sweat and fingerprints were studied using three separate and respective single-analyte enzymatic assays for the analysis of sweat by ultraviolet-visible spectrophotometry. The separate use of all three methods has the ability to determine the concentrations of each compound within the sweat of the sample originator. Analysis was first performed on 50 mimicked sweat samples that were created and tested based on the physiological concentrations of amino acids and small molecules known to be present in sweat. Additionally, a collection and extraction method was successfully developed in order to collect and test authentic sweat samples from volunteers. The use of similar enzymatic assays has been previously demonstrated when analyzing fingerprints. Since the amino acid content was sufficient for authentic fingerprint detection, the amino acid content in authentic sweat should be the same, if not greater. The application of sweat collection was designed to decrease the sampling error, as compared to fingerprint collection, and increase the amount of sweat collected to aid in the analysis of small molecules at low concentrations.

Biomarker analysis is a well-established discipline in forensic science that involves the analysis of biological samples for the presence of various substances indicative of personal attributes, such as the identification of an individual through DNA in blood. Although the forensic science field has developed rapidly over the years, the investigation processes are lengthy and the majority of the routinely used forensic science techniques require proper sample collection at the crime scene, followed by transportation to a laboratory facility before any informative analyses. This has led to a backlog in the analysis of serology samples. The research presented here addresses this situation by introducing the use of bio-affinity-based assays for quick and straightforward analyses of sweat. Because only miniscule amounts of enzymes and substrates are necessary, this method only requires very small amounts of samples and can be developed into a field kit for on-site testing. Furthermore, the bio-affinity-based cascades are remarkably versatile and can be adjusted for the analysis of a wide range of substrates. By utilizing re-programmable bio-affinity-based cascades, this approach has the potential to create a new method for identification, which can decrease crimes through increased security measures and move the strictly laboratory-based analyses to rapid on-site analyses that do not require specialized laboratory training. This could lead to the revolution of the field of forensic science and result in the acceleration of many criminal investigations.

Identification, Sweat, Cascades

B77 A Comparison Study of a Mass Spectrometry (MS) -Based Serological Assay With Existing Casework Models

Catherine O. Brown, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Phillip Danielson, PhD*, University of Denver, Dept of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210; and Kevin M. Legg, PhD*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand the advancements achieved with protein MS for the identification of five human body fluids and their impact on existing casework models.

This presentation will impact the forensic science community by assessing the performance of a validated MS-based serological assay in an operational environment. The results of this study demonstrate an increase in sensitivity and specificity over existing workflows.

Protein MS has emerged as a technique to supplant traditional enzyme- and antibody-based tests for the identification of body fluids. As part of a multi-year initiative, a robotic, fully automated sample preparation workflow coupled with protein MS has been developed and validated for the confirmatory identification of five biological fluids (saliva, blood, seminal fluids, vaginal fluids, and menstrual fluids). Sample preparation is conducted in 96-well plate format using the Agilent® AssayMAP Bravo automation platform with protein identification on an Agilent® 6495 triple quadrupole mass spectrometer coupled to an Agilent® 1290 series Ultra High-Performance Liquid Chromatography (UHPLC). Combining these two pieces of hardware, up to 100 samples can be prepared and analyzed in one day. A fit-for-purpose developmental validation has been completed by integrating appropriate studies according to guidelines set by the Scientific Working Group for Forensic Toxicology (SWGTOX) and the Scientific Working Group on DNA Analysis Methods (SWGDAM). Developmental validation studies assessed reproducibility/repeatability, sensitivity, stability, mixture analysis, specificity, carryover, ion suppression, and limit of detection.

In addition to the developmental validation studies, the workflow was assessed to demonstrate that the technology is "fit-for-implementation" in relation to existing casework models (e.g., immunochromatographic/antibody screening, and DNA/Short Tandem Repeat (STR) typing protocols) and the overall operational workflow of a forensic laboratory. A series of appropriate mock casework samples that assessed recovery of substrates, overall assay sensitivity, impact of potential contaminants, multi-fluid mixtures, sample degradation, and mock sexual assault kits were prepared and processed in tandem by MS, currently employed serological tests, and by standard DNA profiling methods.

Commercially available serological tests included antibody- and enzyme-based platforms targeting blood (RSID™ Blood, ABAcard® HemaTrace), seminal fluid (RSID™ Semen, ABAcard® p30), and saliva (RSID™ Saliva, SALIgAE®). DNA extracts were processed via organic/organic differential extraction, Quantifiler™ Trio DNA Quantification Kit, GlobalFiler™ Polymerase Chain Reaction (PCR) Amplification Kit/Y Filer® Plus PCR Amplification Kit, and analyzed using Applied Biosystems® 3500 Genetic Analyzer. Two hundred fifty samples were assayed across the three approaches. For serological analysis, the MS approach offered superior detection limits (e.g., human blood detection from less than 10nL of whole blood recovered from a swab) while also providing true confirmatory results. Furthermore, the MS method can reliably detect vaginal and menstrual fluids, for which commercial assays do not exist. While genetic testing of STRs has historically proven to be much more sensitive than traditional serological methodologies, MS and DNA analysis are more comparable in terms of sensitivity limits. For low-level samples (e.g., picoliter quantities of body fluid), a relationship between the number of protein targets identified and corresponding peak height intensities with the number of alleles detected from the known donor was observed. For example, a low-level seminal fluid sample produced two out of five target seminal fluid markers and generated 67% of an STR profile. Overall, the MS method allowed for clear, unambiguous, serological identification of body fluids to the point where the technology can be called "comparable" to STR testing.

In conclusion, the implementation of the MS approach offers comparable sensitivity to current genetic testing methodologies, providing an advantageous relationship between a positive body fluid identification and the likely success of downstream DNA analysis. This provides a greater tool to forensic examiners seeking to perform sample prioritization and deliver confirmatory contextual information in a criminal investigation.

Serology, Proteomics, DNA Testing

B78 Confirmatory Identification and Genotyping of Human Seminal Fluid Collected on Surface-Enhanced Raman Scattering (SERS) -Active Forensic Evidence Swabs

Brittania J. Bintz, MSc, Western Carolina University, 231 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723; Katarina G. Ruehl, WCU, 90 Merlite Court, Cullowhee, NC 28723; Geraldine Monjardez, PhD, Western Carolina University, 327 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723; and David D. Evanoff, Jr., PhD*, Western Carolina University, 231 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand a novel method for serological screening of forensic evidence for confirmatory identification of human seminal fluid.

This presentation will impact the forensic science community by providing results for a method that enables rapid, highly sensitive, non-destructive identification of semen. These data will ultimately be used to expand the utility of the method to other human biological fluids.

Forensic evidence is often screened to determine whether biological fluids are present prior to attempting DNA analysis. Fluid-specific serological tests employing immunological and biochemical indicators are typically used to make these determinations. Initially, a presumptive test establishes the possibility that a particular fluid is present. Next, a confirmatory test is used to identify the material and species of origin; however, these methodologies lack sensitivity and specificity. Additionally, because these tests are performed sequentially, biological fluid identification can be expensive, labor intensive, and require consumption of precious samples.

Raman spectroscopy is an optical technique that characterizes the inelastic scattering of light that is indicative of the composition of a particular molecular species. Due to the low probability of the Raman scattering event, Raman analysis of small amounts or concentrations of analyte can be problematic. SERS is an extension of the Raman spectroscopic technique in which analyte signals can be enhanced by several orders of magnitude when on or near a nanostructured metallic surface. Interaction of the electronic structures of the analyte and SERS substrate increases the analyte's Raman cross-section (i.e., the likelihood of inelastic scattering) through a chemical and/or electromagnetic enhancement mechanism. Some studies have shown that Raman spectroscopy is well suited for the analysis of biological fluids because it is rapid, highly selective, and non-destructive.[1] In the forensic laboratory, Raman spectroscopic analysis could enable a reduction in the number of serological tests performed on an evidentiary item since it can be used for simultaneous identification of all relevant biological fluids; however, Raman spectroscopy alone may not provide the level of sensitivity required for forensic samples, especially in cases in which low laser excitation powers are preferred and/or fast analysis times are required. As a result, SERS may be a more appropriate approach. This presentation describes a novel method to identify human seminal fluid on nylon-flocked swabs coated with silver nanoparticles.

For this study, sample collection swabs were prepared by synthesizing silver nanoparticles on the surface of COPAN® 4N6FLOQSwabs™ using the hydrogen reduction method.[2] Distribution and size of nanoparticles were characterized using a scanning electron microscope. Efficacy of SERS enhancement was tested by swabbing a dried sample of $[Ru(bpy)_3]^{+2}$ with a prepared collection swab, followed by detection with a Horiba LabRam HR Raman microscope. A 3X serial dilution of sole-source human seminal fluid was performed to create a total of seven samples with concentrations ranging from 15ng/µL to 21pg/µL of genomic DNA. Diluted semen (10µL) was pipetted onto the surface of swabs with and without SERS nanoparticles. Raman data of analyte adhered to the SERS-active swabs were collected using 632.8nm laser excitation and various collection geometries and integration parameters and analyzed to determine a limit of detection of the method. Following spectroscopic analysis, DNA was extracted from each swab using the Applied Biosystems® PrepFiler® Forensic DNA Extraction Kit. Several controls were also integrated during extraction. Extracts were quantified using the Applied Biosystems® Quantifiler® Trio kit. Quantifiable DNA was detected in all extracts except those obtained from swabs with low initial concentrations. Recovery was not affected by SERS particles or exposure to the Raman laser, as no difference was observed in DNA recovered from semen on naked swabs, SERS swabs, and positive controls. Additionally, quantification values were compared to Raman results to determine whether a correlation exists between SERS signal intensity and DNA recovery. DNA from a subset of samples was amplified using the Applied Biosystems® Quantifiler® kit. Full STR profiles were obtained for all samples with high starting concentrations. As expected, stochastic effects were observed in data obtained from samples with the lowest starting concentrations; however, no differences were observed in DNA profiles from SERS extracts versus non-SERS extracts. These results demonstrate that confirmatory identification of human seminal fluid using SERS is robust, sensitive, and does not affect downstream analyses.

Serology, Semen, SERS

B79 Identification of Body Fluid Using Multiplex Polymerase Chain Reaction (PCR)

Quentin T. Gauthier, MSFS, 16 Longacre Court, Hockessin, DE 19707; Joana Antunes, MS, Florida International University, 11200 SW 8th Street, Lab OE294A, Miami, FL 33714; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand the development of a novel trace method for the determination of body fluids based on epigenetic markers and sequencing techniques. The procedure involves a multiplex amplification of tissue-specific methylation sites followed by pyrosequencing and/or massively parallel sequencing to determine the identity of the tissue.

This presentation will impact the forensic science community by providing results from an optimization study and evaluation of a multiplex reaction that combines previously developed singleplex reactions determined in prior studies. This presentation will contribute to efforts being made worldwide to expand the information that can be gleaned from an individual's DNA for use in a forensic investigation.

When investigating a crime, it can sometimes be more important to determine the origin of a DNA extract in order to prove criminal intent. For example, in situations such as child abuse, it is the type of body fluid present that is important and not the presence of the suspect. In recent years, multiple DNA methylation markers have been developed for use in the prediction of whether a DNA sample originated from blood, saliva, vaginal epithelia, or semen.[1,2] These loci, known as tissue-specific Differentially Methylated Regions (tDMRs) can exhibit hypomethylation in one body fluid type while exhibiting relatively high methylation levels in other body fluids. Additionally, methylation markers have been found for the prediction of biological age, but demonstrate that the body fluid can influence the results.[3,4] Therefore, it is necessary to first determine from which body fluid the DNA originated. The goal of this project is the development of a multplexed amplification that would permit the analysis of a single sample of genomic DNA for all body fluid types. Such a procedure can save valuable evidence and time, as well as permitting a quicker and more comprehensive result.

In this experiment, a multiplex of previously published tDMRs, found in BCAS4, CG06379435, PFN3A, and ZC3H12D, was created and the amplification process was optimized for further analysis. This optimization was achieved by careful design of the primers to minimize mispriming events, as well as altering the concentrations of primers and Magnesium Chloride ($MgCl_2$) in order to attain roughly equal representation of each amplicon in the final PCR product. Next, a set of 16 samples of extracted DNA — consisting of saliva, blood, vaginal epithelia, and semen — were treated with bisulfite in order to convert unmethylated cytosines to uracil.[5] Methylated cytosines are not converted, permitting determination of relative levels of methylation based on sequence analysis. A multiplex amplification of the above tissue's specific methylation sites was then performed and the resultant DNA sequenced using a pyrosequencer. The results of pyrosequencing were performed using four separate pyrosequencing runs of the amplified samples. An additional subset of samples was also analyzed simultaneously using massively parallel sequencing. The results of the pyrosequencing and massively parallel sequencing were compared to ensure that the same results were being attained in either method.

The 16 DNA samples were correctly identified as belonging to one specific body fluid type. In either sequencing method, the percent methylation at each of the amplified regions was found to be consistent with the results of these methylated regions when amplified individually.[6] Going forward, it would be advantageous to build upon this multiplex by adding in age-specific methylation markers. These markers would rely on the identification of the body fluid in order to increase the accuracy of the age prediction model.

Body Fluid Identification, tDMR, Massively Parallel Sequencing

B80 The Effect of Organic Acid Influenced by Sample pH on False Positive Test Results Using Immunochromatographic Assays

Megan M. Foley, MSFS, NMS Labs, 2300 Stratford Avenue, Willow Grove, PA 19090; Catherine O. Brown, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Christian G. Westring, PhD, 2300 Stratford Avenue, Willow Grove, PA 19090; Phillip Danielson, PhD, University of Denver, Dept of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210; and Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand how the presence of organic acids at various pH levels can affect the accuracy and reliability of results obtained using immunochromatographic assays for multiple biological fluids from a number of manufacturers.

This presentation will impact the forensic science community by emphasizing the importance of using immunochromatographic tests as a presumptive indication of biological fluids and will illustrate how results from these assays should not be overstated. Instances of non-specific binding events utilizing various immunochromatographic assays as influenced by sample pH and the presence of organic acids will be evaluated.

A majority of forensic biological evidence requires detection of bodily fluids as a means to identify and prioritize items that should be processed for genetic analysis. The screening and confirmatory identification of these bodily fluids can greatly aid an investigation; however, it is important to understand the limits of the test employed. The current methodology most routinely applied to forensic casework for the detection of biological fluids is immunochromatographic assays. Manufacturers of these tests, including Seratec®, Abacus Diagnostics®, and Independent Forensics, market such assays for blood, semen, saliva, and urine detection. Regardless of manufacturer or target analyte, these tests function in a similar manner and therefore suffer from the same limitations. Target biomarkers present in lower concentrations in other biological fluids have demonstrated the potential to produce positive reactions.[1-3] Additionally, false positive reactions due to cross-reactivity with non-target molecules with similar conformational epitopes are possible as are non-specific binding events.[4] This latter category of false positives was further investigated in this study.

Common immunoassay tests utilized in forensic casework, including ABAcard® p30 and ABAcard® HemTrace® by Abacus Diagnostics®; RSID™-Urine, RSID™-Semen, RSID™-Blood, and RSID™-Saliva by Independent Forensics; and PSA Semiquant, HemDirect, and Amylase Test by Seratec®, were evaluated. A 300mM solution of citric acid was prepared across a pH range from 1.78 to 12. Citric acid solution was added according to the manufacturers' recommendations for each test with regard to sample incubation times, volumes, and run times for analysis. Invalid test results, negative results, and false positive results were recorded over the indicated pH range. Repeatability was evaluated by testing the lowest and highest pH citric acid solution to produce a false positive result in triplicate for each test. Deionized water solutions over the pH ranges that produced false positive results for citric acid solutions were also analyzed.

False positive results were observed for each assay evaluated and were seen between a pH of 2 to 12 on various tests. Repeatability was observed for all tests evaluated. All deionized water solutions produced negative test results as expected, indicating the role of organic acids in generating non-specific binding events. It should be emphasized that based on the findings exhibited in this study, immunochromatographic tests display presumptive findings due to lack of specificity. Additional organic acids were also evaluated at multiple concentrations as were possible mechanisms leading to false positive test results.

After attending this presentation, attendees will better know and understand the unprecedented spread of synthetic opioids, the trends that most law enforcement agencies face as a direct result of widespread opioid use and illicit sales, and what is currently being accomplished to better understand and combat this unceasing epidemic.

This presentation will impact the forensic science community by raising awareness of the spread of synthetic opioids and by examining perspectives from a variety of forensic science areas, including field investigations, criminalistics, forensic pathology, toxicology, and pharmacology.

In the past year, there have been more known fentanyl-related overdose deaths in the United States than in the past 60 years. The current crisis is multi-faceted and involves a global supply of the substances being smuggled into the United States. The increase of drug fatalities over the past few years demonstrates that more potent and more sophisticated designer drugs are not only available on the streets but are also finding their way into the population following internet purchases and receipt through the mail.

This session intends to address this epidemic from multiple perspectives. In March of 2017, the American Academy of Forensic Sciences, seeing a need to gather its diverse resources to evaluate the current synthetic opioid crisis, established an *ad hoc* committee. Four task groups (Analytical Chemistry, Education and Outreach, Medicolegal Issues, and Health and Safety) were created to approach this challenge from a targeted perspective. A summary of these efforts will be provided through a discussion of lessons learned and opportunities gained. Experts of various disciplines will intervene and share their experience and expertise on this topic from various perspectives.

Discussion will include how the Prohibited Mail Narcotics program with the United States Postal Inspection Service is committed to protecting its employees, customers, and the public from the dangers of handling mail pieces containing illegal narcotics and the violence associated with drug trafficking.

The facets of a medicolegal death investigation paradigm shift in Cuyahoga County, OH, will be described. A new paradigm was adopted involving consideration of the use of internet and electronic media communication, purchase and distribution of product, and new safety concerns in the investigation of drug overdose deaths. The approach to telephone interviews on death reports, scene investigation and safety considerations, and interactions with law enforcement personnel, family members, witnesses, Emergency Medical Teams (EMTs), and medical personnel has evolved.

Recently developed methodologies for signature profiling of illicit fentanyl and fentanyl-related seizures at the Drug Enforcement Administration (DEA) Special Testing and Research Laboratory will be discussed. These methodologies include the quantitative determination of fentanyl, adulterants, and diluents, the quantitative determination of occluded processing solvents, and the identification of trace synthetic impurities from clandestine synthesis. The use of profiles of fentanyl isotopes, trace components, occluded solvents, and cutting agents to chemically link fentanyl seizures in which relationships were previously unknown or only suspected will also be discussed.

Detection, identification, and reporting of these novel and emerging illicit opioids is technically challenging, mainly due to their structure similarity and their mixture with other drugs. A Real-Time Communication Network has been created by the DEA Southeast Laboratory to provide technical assistance to forensic scientists and to facilitate the rapid dissemination of information regarding the analysis of synthetic opioids in real time. The use of this communication tool to share information of emerging synthetic opioids as they are being identified will be reviewed.

From a medicolegal perspective, the development and implementation of an online website that provides public access to a wide array of drug-related death surveillance resources and tools will be described. This database is populated by medical examiners and coroners' agencies and can be accessed by the public with no intermediary. This resource gives users access to detailed information regarding specific drugs, demographic information pertaining to the decedent, and to investigational findings related to the circumstances of the death.

An overview of the role of pharmacology and toxicology of opioids will be provided and the resources and analytical methodologies used to identify and quantify new drugs in driving under the influence cases and postmortem toxicology will be examined. The challenges of interpreting the role of these drugs in human performance and fatalities will be presented. In addition, data collected by a large reference laboratory that performs testing for municipalities and counties across the United States will be presented.

Synthetic Opioids, Fentanyl Analogs, Pharmacology

B82 The Data Needed to Realize the Value of Forensic Science

Sheila Willis, PhD, Forensic Science Ireland, Garda HQ, Phoenix Park, Dublin, IRELAND*

After attending this presentation, attendees will better understand the dangers associated with reporting test results in isolation and the effect of addressing activity-level propositions rather than source-level propositions.

The presentation will impact the forensic science community by highlighting the broader role that forensic scientists must play to ensure their information and findings do not contribute to miscarriages of justice.

The concept of forensic scientists addressing propositions at different levels of the hierarchy is well documented in the scientific literature.[1] The higher up the hierarchy, the greater is the value provided by the forensic scientist.

This presentation will outline the impact of addressing activity propositions rather than source propositions and highlight the type of data forensic scientists need to ensure their information is not misleading or used by others in a misleading manner.[2,3] Source propositions are those in which the scientists seek to establish whether two materials share the same origin or not, while activity propositions address what materials are expected to be found given a specific activity. Activity propositions need data on the probability of materials transferring in given scenarios and provide much more useful information to forensic questions. Following this logic, it is seen that the scientist may address whether two groups of glass fragments share the same source. This demands information on the discriminating power of the techniques used and the frequency of occurrence of specific parameters. This may be useful in court but will not be as helpful as considering whether the findings support the suspect being the man who broke the window rather than some other man. To address the latter, the scientist needs information for the court on the likelihood of glass transferring given the details of the breaking glass and the time since the incident to address the prosecution proposition and will need to know the probability of specific populations having glass on their clothing to address the defense proposition. The weight of evidence or likelihood ratio is the ratio of these two probabilities. This type of information is less well documented and sometimes less explicit than the data on techniques and frequency of occurrence.

Confining reports to source propositions can be misleading. Consider a situation in which a rare fiber is recovered from a garment and found to be indistinguishable from a reference sample. In isolation, the court is likely to consider this information to be helpful, but consider again if, given the contextual information, the scientist expects that multiple fibers should be transferred and recovered. It is advanced that the court needs this information and that the scientist has a duty to supply it.

The logic applies to all trace evidence and is, according to this presentation, also the case for low levels of DNA in which the discriminating power of the technique may overwhelm the other relevant factors.

The basis of this presentation will be the three principles learned from Evett: (1) that forensic science findings need to be interpreted in a context; (2) that at least two propositions should be addressed; and (3) that the scientist is well placed to address the probability of the findings rather than the probability of the propositions.[1]

This presentation will include examples from personal experience in which source rather than activity propositions were misleading and examples to illustrate why the context is important.

Data, Principles, Activity

B83 Criminalists' Ethics in the Era of Social Media

Jennifer S. Mihalovich, MPH, Oakland Police Department, Criminalistics Division, 455 7th Street, Rm 608, Oakland, CA 94607; and Gregory B. Matheson, BS, Los Angeles Police Department, Crime Laboratory, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032*

After attending this presentation, attendees will better understand the impact and additional pitfalls the expanding everyday use of social media has on the ethical behavior of criminalists.

This presentation will impact the forensic science community by providing a forum for the discussion on how social media can inadvertently draw an ethical criminalist to participate in actions that are counter to professional ethical codes of conduct.

Social media such as Facebook®, Twitter®, LinkedIn®, YouTube®, and Instagram™ have revolutionized the distribution and "life span" of information. The ability to instantly share our lives and activities with potentially millions of people by providing truncated bits of data without taking the time for thoughtful editing has changed the way society interacts. Social media is a valuable tool but can also be dangerous.

All professions have some form of code of conduct to provide guidance for ethical behavior. Forensic science is no different; there are codes such as the American Academy of Forensic Sciences (AAFS) Code of Ethics and Conduct and the American Board of Criminalistics (ABC) Rules of Professional Conduct. Forensic science codes of ethical or professional conduct can be found in many professional associations. As forensic science professionals, we strive to adhere to these codes and perform our work ethically, with honor and integrity. Unbeknownst to us, many of us have used social media without first evaluating the link between our ethics and social media outlets. Without recognizing and understanding the pitfalls, social media has made it more difficult to adhere to the codes of conduct. Actions that used to be a personal communication between two individuals have become public knowledge and available on line, forever.

Other professions, such as attorneys and health care professionals, are actively studying the impact of social media and providing their practitioners with additional ethical guidance. The federal government has prepared a guidance document for federal employees. Forensic scientists need to enter the conversation soon as too much time has already passed and damage may have already happened. Examples of social media damage in the criminal justice system include cases resulting in mistrials due to witnesses, jurors, and judges inappropriately commenting on cases through their social media accounts.

Ethics Code sections will be examined and discussed to help identify pitfalls. In addition, other concerns such as *Brady*, reputation management, and employment impacts will be considered. Can postings on Facebook®, YouTube®, or Instagram™ keep you from being hired by a government agency? Can defense attorneys or prosecutors use postings to show *Brady* violations? What impact can your on-line life have on your professional life?

Social Media, Ethics, Conduct

B84 A Report on the Forensic Science Research and Evaluation Workshop: A Discussion on the Fundamentals of Research Design and an Evaluation of Available Literature

Edward G. Bartick, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007*

The goal of this presentation is to make attendees aware of the information contained in the published report.

This presentation will impact the forensic science community by serving as a guide to improve research design and literature evaluation.

This report is based on a "Forensic Science Research Evaluation Workshop" sponsored by the National Science Foundation and the National Institute of Justice and was held at the American Association for the Advancement of Science headquarters in Washington, DC. The impetus for the workshop was recent criticisms of the forensic sciences from public, legal, and scientific sources. One of the more important critical reports was the 2009 National Research Council Report, *Strengthening Forensic Science in the United States: A Path Forward.*[1] It was highly critical of the scientific foundations for several of the forensic disciplines, declaring that "Little rigorous systematic research has been done to validate the basic premises and techniques in a number of forensic science disciplines." and "… a statistical framework that allows quantitation … is greatly needed."[1]

Since the early 1990s, DNA analysis testimony began stating the probability of identified matches. Researchers have only recently begun to look at a mathematical and statistical basis for pattern comparison analysis, such as latent fingerprints, fired bullets, and toolmarks.[2-4] Materials such as paints, fibers, and tapes that are often found as physical evidence at crime scenes could be of greater value should we establish a statistical significance of an association with a suspect or victim. Knowing the abundance and variation in composition of these materials could be used to establish probability estimates of these materials randomly being found at the scene. Historically, there has been resistance to this approach because information on manufactured materials has been considered to be too difficult to maintain due to production changes; however, the establishment of well-maintained centralized databases are possible and should be developed.[5]

The workshop was formed to discuss the fundamentals of research design and the evaluation of the literature in order to conform to higher scientific standards in critical thinking and laboratory performance. The publication from the workshop is intended to provide some grist for evaluating and elevating the research efforts in the forensic sciences and it may be of value for the Organization of Scientific Area Committees (OSAC) members advanced practitioners, peer reviewers, and students of forensic science.[6,7]

The workshop was organized by a planning committee. Three subject areas were chosen, each consisting of a half-day session as follows: (1) experimental design and statistics; (2) interpretation and assessment; and, (3) policy implications. The goal was to bring together a range of 17 experts in the experimental and behavioral sciences, law, policy, and government funding to address the need for a higher standard of forensic science research. Each session consisted of one plenary speaker and four to five additional speakers. Each speaker had one-half hour to present their topic.

Each participant submitted a short essay of the topic they presented at the workshop, and they are included in the publication.[6] Additional observations and conclusions were made during panel discussions and these are included after the write-ups of each section.

In the summary of the report publication, there is an outline of topics to design research and evaluate forensic science literature.[6] The outline provides important considerations when planning a research project, reviewing submitted papers for publication, or simply determining the scientific quality of forensic literature. The report is intended to be a guide to assess forensic science research and its literature. The topics are not all-inclusive and are meant as a starting point. Each write-up has significant references to assist in a greater depth of background on the subject. For each specific discipline within the forensic sciences, evaluators will need a thorough knowledge base of the specific discipline to properly evaluate writings. If the evaluator is not strong in statistics, it is recommended that they confer with a statistician. A close look will be required to determine if the statistics used are appropriate. With this, it is hoped that a greater level of forensic science research is attained in the future.

B85 FORESIGHT 2020 Project: Connecting Labs, Laboratory Information Management Systems (LIMS), and FORESIGHT for Benchmarking Performance

Max M. Houck, PhD, 140 7th Avenue, S, Davis Hall, St Petersburg, FL 33701*

After attending this presentation, attendees will understand a project connecting forensic LIMS to a forensic industry benchmarking process named FORESIGHT that provides labs with data for process improvement, efficiency, and quality control.

This presentation will impact the forensic science community by providing information regarding how the FORESIGHT 2020 project will make data submission to FORESIGHT and the National Institute of Justice (NIJ) grant compliance reporting easier, how analytics can improve laboratory performance and efficiency, and how using metrics increases accountability and cost effectiveness in both governmental and for-profit labs.

FORESIGHT 2020 is an information technology project that has developed software connecting forensic science LIMS to a forensic industry benchmarking process named FORESIGHT. Benchmarking is the comparison of an organization's processes and performance metrics to industry best practices from other organizations. Metrics can be descriptive (cases submitted or items tested, for example) or ratio based (reports per employee or tests per item, for example). Ratios allow for robust comparisons between laboratories providing a foundation for communication about better practices. FORESIGHT is the result of an NIJ award to improve the quality and quantity of industry information to forensic labs for process and quality improvement. FORESIGHT has been active for a decade in the forensic and public health industries, with hundreds of participating agencies worldwide. Forensic laboratories have used FORESIGHT data to improve efficiency, cut costs, reduce backlogs, and increase wages and compensation for employees.

The FORESIGHT 2020 software allows labs to submit data to the FORESIGHT process with a few clicks of the mouse, thereby easing data submission, improving the quality of the data, and increasing participation in FORESIGHT, resulting in broader representation of the nation's forensic laboratories' performances. The laboratories will have data to help with process improvement, efficiency, and quality control. In addition, the software helps achieve compliance with NIJ granting requirements and reports, and an analytical dashboard will assist the lab's self-awareness of real-time statistics, caseloads, and productivity.

The FORESIGHT 2020 software is currently in beta testing at laboratories around the country. Once beta testing is completed, the software will be made available for laboratories to download and install for use with JusticeTrax, STaCS, Porter Lee, or StarLIMS systems. The software is free under a grant to the American Society of Crime Laboratory Directors (ASCLD) from the Laura and John Arnold Foundation.

FORESIGHT, Benchmarking, Quality Assurance

B86 Rates of Loss and Replacement of Very Small Particles (VSP) on the Contact Surfaces of Footwear During Successive Exposures

David A. Stoney, PhD, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20151; Andrew M. Bowen, MS, United States Postal Inspection Service, 22433 Randolph Drive, Dulles, VA 20104-1000; Madeline Ausdemore, MS, South Dakota State University, Dept of Mathematics and Statistics, Brookings, SD 57007; Paul L. Stoney, MBA, 14101-G Willard Road, Chantilly, VA 20124; and Cedric Neumann, PhD, South Dakota State University, Mathematics & Statistics Dept, Brookings, SD 57007*

After attending this presentation, attendees will better understand the rate of loss and replacement of VSP from the contact surfaces of footwear, methods to measure this rate, and the potential contribution to the evaluation of trace evidence on footwear.

This presentation will impact the forensic scientific community by providing information necessary to properly appreciate and interpret VSP on the contact surfaces of footwear.

The separation of particle signals arising from different sources is one of the enabling operations for Particle Combination Analysis (PCA).[1] Although it is well-recognized that criminals track dust to and from every crime scene, dust particles on a suspect's shoes are very seldom used as evidence linking the accused to the crime. The major obstacle preventing the use of this type of evidence is that the shoes have mixtures of particles arising from activity before, during, and after the crime itself.[2] Methods separating the evidentiary particle "signal" from background noise would enable a powerful new and widely applicable forensic capability. This capability would augment traditional footwear pattern evidence with objective quantitative associations, addressing one of the specific issues raised in the 2009 National Academy of Sciences (NAS) Report. To help pursue this possibility, methods are being developed and tested that will lead to better understanding of the loss and replacement of VSP on the contact surfaces of footwear.

Prior work established that a 250m walk (approximately 175 steps per shoe) removes and replaces particles on the outermost contact surfaces of footwear.[3] It is important to achieve a better understanding about how quickly this replacement occurs. This understanding will: (1) help interpret the significance of the trace evidence found on the contact surfaces (representing the most recent environment(s) to which the footwear was exposed — how recent?); and, (2) provide a foundation for the differential analysis of these traces and those found on other areas of the footwear.

Two distinctly different and commonly encountered types of shoe soles were used in this study: athletic shoes (with flexible rubber soles) and work boots (with hard rubber soles). Three well-characterized environmental sites with characteristic VSP profiles (distinguishable by defined qualitative and quantitative particle characteristics) were used for footwear exposures under dry, dusty conditions.

Thirty-six pairs of shoes (18 pairs of each type) were exposed to a "loading site" by walking distances of 175 steps/shoe: six pairs (12 shoes) of each type in each of the test site environments. For each set of 12, two shoes (one pair) was set aside as a control (0 steps in the second environment). Each of the remaining 5 pairs of shoes were exposed for a different number of steps to a second of the three environmental sites: 5, 10, 25, 50, and 100 steps/shoe.

VSP were recovered from the contact surfaces of all shoes by swabbing, analyzed by polarized light microscopy, and interpreted using: (1) a chi-square measure of distance; and, (2) a Latent Dirichlet Allocation model developed at South Dakota State University.

Substantial loss and replacement of VSP occurs on contact surfaces of footwear in as little as five steps/shoe. By 25 steps/shoe, the replacement is substantially complete. Knowledge of the rapid loss and replacement on contact surfaces provides a basis to explore differential analysis of: (1) VSP signals from the contact areas of footwear; and, (2) those from more recessed areas of the footwear sole.

This project was supported in part by awards from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Trace Evidence, Footwear, Particle Signals

B87 The Determination of Key Factors in Particle Combination Analysis to Enable Systematic Improvement, Optimization, and Transition to Practice

David A. Stoney, PhD, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20151; and Paul L. Stoney, MBA, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20124*

After attending this presentation, attendees will better understand the current state of development of a particle combination analysis capability, results from recent and ongoing research, important next steps for development, opportunities for collaboration, and expected impact — both near and long term.

This presentation will impact the forensic science community by providing the information and perspective necessary to systematically improve particle combination analysis.

Particle combination analysis using Very Small Particles (VSP) is a new approach, highly significant for its potential to expand the number of cases to which trace evidence can meaningfully contribute and for its ability to include a quantitative statistical approach to data interpretation.[1,2] Research has demonstrated this approach has exceptional promise to expand the number of cases in which trace evidence can be used and to provide quantitative measures of evidential value. The laboratory analyses are highly efficient, utilizing existing crime laboratory personnel and equipment.

The current state of development of particle combination analysis will be briefly reviewed: what has been demonstrated, what has been suggested, and what remains to be accomplished. Prior research, employing *reasonable choices* of analytical and statistical parameters, has: (1) demonstrated the presence of highly discriminating VSP profiles on the surfaces of common items of physical evidence; (2) characterized VSP combinations using analytical instrumentation and expertise commonly available in forensic laboratories; (3) developed statistically rigorous measurements of correspondence between VSP profiles; and, (4) produced objective measures for the resulting probative value.[2-4]

The reasonable choices of analytical and statistical parameters employed in prior research were sufficient to demonstrate feasibility and potential. Systematic development and validation of these methods require that the analytical and statistical parameters be more critically examined, and that the key factors influencing the performance of the methods be identified.

The optimization of a VSP analysis protocol requires that factors influencing the reliability, costs, and selectivity be identified. Separating factors (a quantity or quality that does have an influence upon the system) from variables (a quantity or quality that might have an influence upon the system), requires a screening stage of experimental design. The result will be identification of a few important, controlling factors that must be addressed in order to meaningfully optimize the protocol. It will also provide information, such as the variability and magnitude of effects that will be needed for the next stage of process improvement.

Determination of the key factors and the magnitude of their effects will result in a significantly improved capability. Analytical and computational parameters, previously selected as *reasonable choices*, can be revised and replaced, with a combined effect that will have a material impact. Second, these results will provide necessary input to experimental designs that will permit systematic improvement and optimization. Identification of key factors will enable these critical steps and further the transition of particle combination analysis to practice. Third, and most importantly, the results will contribute directly to the fundamental advancement of a new quantitative and broadly applicable approach to trace evidence. Well-documented factors and effects for one VSP analysis protocol will allow parallel, collaborative assessments of alternative options for high efficiency analysis of VSP (such as micro Raman methods, micro X-Ray Fluorescence (microXRF), genetic analysis, or alternative Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) protocols).

This project was supported in part by awards from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Trace Evidence, Particle Combination Analysis, Very Small Particles

B88 A Forensic Comparison of Sandy Soils Using Raman Spectroscopy, X-Ray Diffraction, and Synchrotron Powder Diffraction (PD)

Kari M. Pitts, PhD, ChemCentre, Bldg 500, Curtin University, Manning Road, Bentley, Perth, West Australia 6147, AUSTRALIA; Richard M. Clarke, BSc, ChemCentre, PO Box 1250, Bentley Delivery Centre, Perth 6983, AUSTRALIA; Mehrooz Aspandiar, PhD, Curtin University, Manning Road, Bentley, Perth 6983, AUSTRALIA; and John Coumbaros, PhD, ChemCentre, South Wing, Bldg 500, Curtin University of Technology, Bentley 6112, AUSTRALIA*

After attending this presentation, attendees will better understand an additional technique for the analysis of sandy soils, the ability to replicate that technique, and an understanding of the place of the technique in a forensic soil analysis approach.

This presentation will impact the forensic science community by raising the ability of practitioners to analyze sometimes-problematic sandy soils. This in turn may increase the profile of forensic soil analysis as a whole, leading to further developments and optimal use of a valuable evidence type. In addition, this presentation is a demonstration of opportunities for synchrotron research, an emerging field with funding available.

The examination and comparison of soil and related materials transferred in situations of contact is a powerful method for linking persons, vehicles, equipment, and locations. The evidential value of soil comparison derives from its widespread distribution, highly variable composition, relative ease of transfer, persistence, and resistance to degradation.[1] Ideally, sufficient soil is recovered to perform a range of tests allowing meaningful comparisons with samples from known locations. These tests include the comparison of the inorganic and/or organic fractions, with multiple techniques utilized.[2-4] Possible associations can be established in which the difference in characteristics lie within the expected limits of natural variation and measurement uncertainty.

Nonetheless, forensic soil comparisons employing bulk methods of analysis provide only limited discrimination where the soils have similar geological origin, or where insufficient sample is available to measure bulk properties reproducibly. Sandy soils present an additional challenge, with minimal organic material and heavy minerals resulting in limited material for comparisons, regardless of the bulk amounts present. One such area of forensic importance is the Swan Coastal Plain in Western Australia, covering much of the Perth metropolitan region and dominated by strongly leached sandy soils. While urbanization has resulted in an enrichment in the soil by organic and clay materials, areas of predominantly quartz sands remain.[5]

Primary and secondary minerals recovered from quartz grains within sandy soils allow additional scope for the differentiation of soils dominated by siliceous grains. A method for their recovery and analysis has been developed at ChemCentre and has been successful in analyzing trace mineral coatings on quartz sands from the Swan Coastal Plain in Perth, Western Australia. It is proposed that the approach is applicable to a broader range of sandy soils in general.

This study outlines efforts undertaken to characterize the primary and secondary minerals using Raman Spectroscopy, X-Ray Powder Diffraction (XRPD), and Synchrotron Powder Diffraction (PD). More than 40 samples of sites from within the Perth Metropolitan region have been examined, with the goal of further validating and expanding the technique previously undertaken using laboratory-based X-Ray Diffraction (XRD) on more than 350 samples. The chemometric analysis of PD beamline data obtained at the Australian Synchrotron from these samples exhibits differentiation and associations even within areas of minimal geological differences. Preliminary experiments attempting to analyze single sand grains using PD at the Australian Synchrotron were also undertaken.

This presentation will detail the approach, interpretation, and its place within a standard soil analysis framework. Examples of the use of the approach in casework will be provided. It is envisaged that the approach and associated database can be expanded and allow for the increased differentiation of highly leached, sandy soils from locations outside of Western Australia.

Portions of this research were undertaken on the powder diffraction beamline of the Australian Synchrotron, Victoria, Australia.

B89 The Use of Scanning Electron Microscopy With Energy-Dispersive X-Ray Spectroscopy (SEM/EDS) for Quantitative Forensic Comparisons of Blue Glass

Thomas Kubic, JD, PhD, 8 Pine Hill Court, Northport, NY 11768; Tiffany J. Millett, MS, 467 Ridgewood Avenue, Staten Island, NY 10312; Mircea Comanescu, MPhil, John Jay College of Criminal Justice, NY, 524 W 59th Street, New York, NY 10019-1007*

After attending this presentation, attendees will understand the problems encountered during the quantitative analysis of SEM/EDS spectra of blue glass samples and how to overcome them.

This presentation will impact the forensic science community by instructing attendees on how to overcome problems of black-box software while using SEM/EDS for the quantitative analysis of blue glass samples.

EDS, especially when employing an SEM as an excitation source, is a core elemental characterization technique for micro and ultra-micro samples. This technique has long been used to add to the evidential value of micro-transfer trace evidence by microscopical forensic examinations. Glass chips are one specific class of transfer evidence for which this technique has been employed. As a strategy for comparing glass samples by EDS, criminalists often normalize the data and compare ratios of peak heights or peak areas to one common major element, such as silicon. Courts today often require data regarding the frequency of occurrence of similar spectra to assist the trier of fact concerning the weight of this comparative evidence. This research hopes to add insight into this matter.

In this presentation, X-ray spectra obtained from 46 blue glass samples will be compared. Previous work has been completed that looked at the Ultraviolet/Visible (UV/VIS) spectra of these blue glass samples using a fiber optic micro-spectrophotometer in which few spectral differences led to possible differentiation among certain samples in this set. As color is the first logical step in comparing glass samples for analysis, it could sometimes be subjective to the observer. This research allowed for the comparisons to be instrumentally supported. The UV/VIS spectra will be compared with the SEM/EDS spectra to determine if differentiation among these glass samples is possible using these two techniques alone or in conjunction with one another. Sample preparation will be discussed as often how the sample is prepared for analysis will define any further analysis.

Being mindful of the caveat given by Dr. Peter Zoon of the Netherlands Forensic Institute (to be careful about how we generate and use data obtained with computerized black box software), the quantitative data generated from the blue glass samples and a pair of standard reference materials (620 and 621) from the National Bureau of Standards (NBS) were evaluated by a commercial software package utilizing both standardless and with-standard algorithms. In addition, the raw data was processed using the National Institute of Standards and Technology's (NIST's) Desk Top Spectrum Analyzer II (DTSA II). By use of the NBS standard reference materials, the advantages of both DTSA II and the commercial software package can be assessed. Statistical treatment of the data in the form of principal component analysis allows determination of the discrete characteristics of elemental composition to classify and discriminate between these glass samples. The results of these investigations, as well as some topics to be mindful of, will be presented.

SEM/EDS, Glass, Quantitative

B90 Chemical Pattern Recognition in Glasses: What Can Be Extracted From Spectroscopic Data Sets?

Sergey Mamedov, PhD, 3880 Park Avenue, Edison, NJ 08820*

After attending this presentation, attendees will understand X-Ray Fluorescence (XRF) microscopy in applications to glass analysis, which is an important element in forensic identification of these materials.

This presentation will impact the forensic science community by providing key aspects of glass analysis and an example of a practical application of XRF spectroscopy to materials identification.

XRF spectroscopy is a useful tool in the identification of substances and in confirming their identity with little or no sample preparation. New capabilities of the energy-dispersive XRF analytical microscope (micro-XRF) enable recording not only spectra of small glass particles (as small as 50-100 microns) but also hyper-spectral images of any object with high spatial resolution (<10 micrometers). Hyper-spectral image is a set of the data which contain information about position of the point along with a full XRF spectrum at this point. This means the data can be mined for unsuspected elements after the measurements have been made, and that statistical methods can produce chemical distributions of the elements and/or material classification based on Principal Component Analysis (PCA), in particular, with association between elements that can aid in the identification of bonded phases. For example, statistical analysis of micro-XRF data for glass can be used to locate the make, model, and year of cars by analyzing a glass chip. This presentation will provide practical insights into the application of the micro-XRF to the analysis of glass and soil.

The XRF analytical microscope was used in this study. XRF spectra of the glass were collected using 30keV acceleration voltage and with an X-ray spot size of 50 microns. XRF spectra of the glass strongly depend on X-ray optics, sensitivity of the detector, and accelerating voltage. In addition, background from the substrate will contribute to the spectrum of the small glass pieces because excitation X-ray penetrates through the glass and interacts with the substrate. This effect becomes very importance for the particle size of 300 microns (or less) or powder. The change in the spectrum due to the shape or size will lead to the different quantification of the sample (different composition). A method that allows one to minimize this effect or take it into consideration was developed. In this presentation, examples of the spectra from bulk material, small glass pieces, and powder will be shown.

The spectra of glass from several car manufactures and commercial glass (microscope slides, window glass, fuse glass) in the range of 1.00keV–40.96keV (<400 spectra) were collected. The spectra were truncated and analyzed in the spectral range of 1.00keV–15keV because major X-ray lines are in this range. A standard Fixed Point Multiplication (FPM) algorithm without any correction and/or calibration was used to calculate concentration of Na_2O, MgO, Al_2O_3, SiO_2, K_2O, CaO, TiO_2, MnO_2, Fe_2O_3, As_2O_5, and CeO_2 in all samples. All spectra and concentration data sets were scaled before PCA was applied. The correlation between classification based on spectral analysis and concentration analysis was found.

Glasses, XRF, PCA

B91 A Forensic Analysis of Automotive Paint Evidence Using Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Mark Maric, PhD, PO Box 162367, Orlando, FL 32816; Robert B. Cody, PhD, JEOL USA, Inc, 11 Dearborn Road, Peabody, MA 01960; and Candice Bridge, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will have a fundamental understanding of the significance of automotive paint evidence as it pertains to automobile crashes, hit-and-run accidents, and vehicular homicides. Furthermore, attendees will be familiar with a novel rapid analytical protocol involving DART®-MS for the chemical interrogation of automotive paint evidence.

This presentation will impact the forensic science community by demonstrating a unique analytical methodology for the forensic analysis of automotive paint evidence. The following research seeks to highlight the potential of this technique for the analysis of paint and polymer evidence in an effort to add another instrumental method to the current suite of analytical techniques available to the forensic examiner.

While no current universal methodology exists for forensic paint examination, general frameworks for the analysis of paint evidence can be obtained through guidelines developed by the Scientific Working Group on Materials Analysis (SWGMAT) and the American Society for Testing and Materials (ASTM).[1,2] These guidelines advise that forensic examiners use a combination of microscopic and instrumental techniques to characterize both the organic and inorganic components of the paint samples. Most forensic paint examinations begin with optical microscopy, followed by Infrared (IR) spectroscopy and, if necessary, pyrolysis-Gas Chromatography (py-GC), often interfaced to a Mass Spectrometer (MS). Py-GC/MS is the most discriminating technique available to the forensic paint examiner for differentiating between samples with similar binder compositions. Although the discriminating capability of this technique is high, it is a destructive technique and sample analysis is extremely time intensive.

As a result, DART®-MS was employed to investigate if this technique can pyrolyze and characterize automotive paint coatings. DART®-MS is an ambient ionization technique capable of rapidly analyzing samples in any physical state with high resolution and accurate mass detection, while requiring minimal sample preparation. An optimized protocol has been developed and used to pyrolyze a small subset of automotive clear coats obtained from black vehicles. The mass spectral data were compared to results obtained from a standard py-GC/MS protocol developed by the Florida Department of Law Enforcement. Preliminary data indicate that DART®-MS with a gas heater temperature of 550°C is able to pyrolyze and analyze automotive coatings within five minutes, a significant improvement on current py-GC/MS methodologies. Interpretation of the data obtained from both instrumental techniques revealed that the information was complementary in nature. Additional analysis of the paint samples was conducted using the ionRocket DART®-MS system, which enables more precise temperature control and a greater temperature gradient. Approximately 10 to 20 automotive clear coats were then characterized using the DART®-MS protocol and multivariate statistics (cluster analysis, principal component analysis, and linear discriminant analysis) were utilized to assess the chemical diversity of the clear-coat population (intra- vs. inter-sample variability).

Automotive Paint, DART®-MS, Py-GC/MS

B92 Comparing X-Ray Diffractometry (XRD) and Fourier Transform Infrared (FTIR) Spectrometry for the Analysis of Forensic Evidence

Ke'La Kimble, 511 E Bolivar Drive, Baton Rouge, LA 70819; and Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the value of XRD as a method of analysis applicable to a wide variety of forensic evidence, including soil, drugs, plastics, and papers. Attendees will become aware of instances in which XRD is superior to FTIR, particularly in providing compositional information about samples. Attendees will also become aware of the replacement of large XRD facilities with benchtop XRD units and the availability of new solid-state detectors that obviate the need for liquid nitrogen cooling.

This presentation will impact the forensic science community by increasing awareness of the value of XRD as a replacement for or supplement to FTIR in the analysis of certain types of forensic evidence.

Most forensic science laboratories tend to use FTIR as their go-to analytical method for the identification of unknown samples. The FTIR spectra of unknowns may be searched for in a variety of spectral libraries (e.g., drugs and polymers); even if no spectral match for the unknown is found, structural information about the unknown can be obtained. FTIR instruments are relatively inexpensive and well within the budgets of most forensic science laboratories. XRD has long been recognized as being similar to FTIR in the richness of the data it provides. For example, the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) places XRD in the same category of analytical techniques as FTIR, Raman scattering, and mass spectrometry. In the past, XRD instrumentation was large (often requiring its own laboratory with attendant cooling units) and the detectors required liquid nitrogen cooling to function. New benchtop XRD instruments have reached the market; these have a small footprint and their new solid-state detectors eliminate the need for liquid nitrogen cooling. Forensic science laboratories should consider adding XRD to their repertory of analytical techniques. XRD can be particularly useful for the identification of minor crystalline constituents of samples where the infrared absorptions of these constituents are weak due to their low concentrations or where their absorptions are obscured by those of more abundant components of the samples.

To compare XRD and FTIR, two types of forensic samples were analyzed by both techniques. Sixteen different brands of trash bags and 28 different brands of black electrical tape were analyzed by both methods. These are two frequently encountered types of forensic evidence. The FTIR spectra of both the trash bags and the electrical tapes were dominated by absorptions of the polymers comprising the samples, with minor contributions from inorganic additives. In some cases, the infrared absorptions of the minor constituents were masked by the infrared absorptions of the polymer. The XRD patterns provided more information and better discrimination among samples than FTIR. For trash bags (composed primarily of polyethylene), the XRD patterns exhibited a clear distinction between Low-Density Polyethylene (LDPE) and Linear Low-Density Polyethylene (LLDPE). The trash bags were found to contain crystalline additives in varying concentrations (talc, calcite, or a combination of talc and calcite), while the electrical tapes contained a variety of additives whose XRD patterns were readily distinguished from one another. The differentiation of forensic samples is particularly important when questioned and known samples are compared in order to identify possible sources of the questioned samples.

This research demonstrates the value of XRD in analyzing forensic evidence, particularly when it is important to identify minor constituents whose infrared absorptions are very weak.

X-Ray Diffraction, FTIR, Analysis

B93 The Persistence and Environmental Degradation Patterns of Sexual Lubricants and Personal Hygiene Products (PHPs) Using Direct Analysis in Real-Time Time-Of-Flight/Mass Spectrometry (DART®-TOF/MS) and Gas Chromatography/Mass Spectrometry (GC/MS)

Yasmine Moustafa, MS, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816; and Candice Bridge, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will be able to visualize the degradation profiles of lubricants and PHPs under various environmental conditions and time periods. The discriminating capabilities of DART®-TOF/MS and GC/MS will also be demonstrated. Each technique will be evaluated through statistical treatments such as Hierarchal Cluster Analysis (HCA), Principal Component Analysis (PCA), and Linear Discriminant Analysis (LDA).

This presentation will impact the forensic scientific community by introducing a framework in which sexual assault evidence can be analyzed given trace amounts and degraded samples on fabric matrices.

Recently, condoms have been used to conceal DNA evidence gathered from seminal fluid, thereby bypassing conviction of the perpetrator. As a result, sexual lubricants have been considered as trace evidence in sexual assault crimes; however, the residuals from lubricants tend to resemble that of personal hygiene products, which may give rise to false positives in analysis. In a recent study in which the neat form of lubricants and PHPs were analyzed using DART®-TOF/MS, a statistical distinction between lubricants and PHPs was demonstrated.[1] With this research, a protocol in which both sample groups are distinguished can be utilized in sexual assault cases. Furthermore, a way to be able to trace a degraded profile back to the neat lubricant profile is required as the delayed reports of the assault are likely, thus resulting in degraded or trace amounts of residuals collected from the victim versus the neat, unaltered profile. The purpose of this study was to analyze the degradation profiles of lubricants and personal hygiene products over time.

The samples were analyzed using two techniques, DART-®TOF/MS and GC/MS. GC/MS will be utilized in the analysis of samples to illustrate how degraded samples change over time; however, co-elution issues and the inability to analyze silicone-based samples without prior sample extraction or pyrolysis makes it difficult to develop a single simplistic method for the analysis of sexual lubricants. Conversely, DART®-TOF/MS is an ionization technique that employs a heated, excited gas stream to ionize the sample in an ambient atmosphere in either positive or negative modes. The lack of chromatographic separation allows for the analysis of silicone-based lubricants in addition to the other marketing types. Additionally, no sample preparation is generally required for analysis and real-time, high-resolution mass spectra are produced.

Thirty-two samples consisting of 12 bottled lubricants, 10 PHPs, and 10 condoms were analyzed and subsequently degraded. For this study, both persistence over specified time intervals, (0, 3, 6, 9, 12, 16, 24, 48, and 72 hours) and induced environmental conditions were evaluated. To determine the environmental and persistence effects on the degradation of the lubricants, .25g of each lubricant was deposited and rubbed into common fabrics (e.g., underwear and bedding). Samples were exposed to different environmental conditions, then analyzed to determine how the chemical composition of major and minor components changed over a three-day period, thereby identifying the persistence of the specific components after use. Each lubricant sample was exposed to the following situations in an indoor environment: cold temperature (5°C), room temperature (22°C), and hot temperature (39°C) under the specified exposure times with and without direct Ultraviolet (UV) exposure.

Following sample analysis, chemometric methods were applied to the dataset and compared against the neat dataset of both lubricants and PHPs. Using HCA and PCA, a clear distinction between lubricants and PHP samples was observed, with correlation decreasing with prolonged exposure to degradation conditions. The degraded profiles of lubricants and PHPs were found to be statistically different using significant peak classifiers as discriminating factors. LDA was used to compare the degraded samples against the neat dataset to evaluate if the classifications from degraded profiles would provide similar groupings, displaying the relationship of neat and degraded samples alike.

The goal of this study was to evaluate the degraded profiles of lubricants and personal hygiene products over time under induced environmental conditions. Additionally, a method in differentiating the neat and degraded profiles of both lubricants and PHPs was developed. The ultimate goal is to create a protocol in which lubricants and PHPs (in their neat and degraded forms) can be examined as common pieces of evidence in sexual assault cases.

DART®-TOF/MS, Lubricant Degradation, Extraction Process

B94 Using Eye Tracking to Understand Decisions Made by Forensic Latent Print Examiners

Bradford Ulery, MS, 2002 Edmund Halley Drive, Reston, VA 20191; R. Austin Hicklin, MS, 3150 Fairview Park, Falls Church, VA 22042; Tom Busey, PhD, 1101 E 10th Street, Bloomington, IN 47405; Maria A. Roberts, 2501 Investigation Parkway, Quantico, VA 22135; and JoAnn Buscaglia, PhD*, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

The goal of this presentation is to assist attendees in understanding how the eye-tracking behavior of professional latent print examiners is associated with their decisions.

This presentation will impact the forensic science community by describing the underlying bases of forensic latent print examiners' conclusions.

A variety of studies have been conducted evaluating the latent print examination process, but there has been relatively little research regarding the fundamental basis of this visual task: how examiners use their eyes to accomplish these tasks, and what visual information guides the examination process.[1-13] This presentation will discuss the results of a study conducted to gain a greater understanding of how latent print examiners perform analysis and comparison tasks and to gain a greater understanding of why examiners make different determinations. By asking examiners to annotate or mark up their work, some understanding of the information those examiners relied upon in making their determinations has been gained, but this is limited to the information they felt was worthy of annotating. Eye gaze can assist to better understand the factors that lead to differences in examiners' interpretations and, ultimately, their conclusions. The eye behavior of forensic examiners provides insight into how examiners make their decisions.

Eye-tracking technology was used to monitor examiners as they performed their tasks to learn what visual information they used and how they worked with that information. Eye tracking allows the determination of not only how examiners differ in the features they look at in the images, but also how they aggregate information from those images; that is, using spatial as well as temporal aspects of eye tracking. Analyses of why some examiners make inconclusive conclusions when others exclude or individualize will provide information that can be used to improve the reliability of the latent print comparison process, particularly for the more challenging comparisons.

In this study, more than 130 hours of eye-gaze information was collected from 121 practicing latent print examiners as they performed more than 2,000 fingerprint comparisons and more than 1,200 other tasks that were designed to isolate specific behaviors that arise during comparisons. The latter tasks included ridge counting, ridge following, and searching for a designated feature group in a comparison print. Eye gaze was sampled at a rate of 1KHz using a camera and infrared illumination. The raw data was calibrated, partitioned into saccades (rapid movements) and fixations (median duration of 0.27 seconds), and mapped onto image coordinates for subsequent analysis. Examiner annotations from previous studies were available for the majority of the comparisons.

This presentation will discuss how eye behavior is associated with examiners' determinations, including the extent to which eye behavior can explain erroneous determinations (false positive and false negative conclusions) and non-consensus determinations (conclusions that differ from the majority of examiners). This presentation will also discuss how eye behavior is affected by the difficulty of comparisons, and how the presence or absence of visual context affects eye behavior. The results of this study reveal explanations for how some errors occur. This presentation will describe how examiners use information in the latent print and how that relates to comparison efficiency and risks of misinterpretations. Variability in the eye-tracking data and issues in the interpretation of this data that will be important to future research will be discussed.

Latent Prints, Eye Tracking, Examiner Behavior

B95 A Case Impact and Operational Cost Analysis of Blind Verifications in Latent Print Examinations

Thomas Wortman, BS, USACIL, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will better understand the case impact (as defined by conflict or non-consensus conclusions) as well as impact on operational costs (as defined by time spent verifying) of blind verification procedures.

This presentation will impact the forensic science community by presenting data and general observations accumulated during blind verifications of all latent print comparison conclusions at the United States Army Criminal Investigation Laboratory's (USACIL) Latent Print Branch.

Blind verifications have been advocated as a panacea for many of the concerns related to latent print examinations. Error rate studies demonstrate the potential for blind verifications to both uncover non-consensus conclusions as well as limit examiner errors. Other stakeholders believe blind verifications would mitigate contextual bias that standard verifications (non-blind) would not. Although both ideas hold merit, there has been a surprising lack of research data to understand the impact of blind verification procedures on actual casework operations and in which scenarios the procedures would yield the most impact.

For six months, USACIL's Latent Print Branch completed blind verifications of all comparison conclusions in live casework. Typical latent print examinations comprise three main phases: Analysis, Comparison, and Evaluation (or ACE). The fourth phase, referred to as Verification, is typically a repeat of the previous phases of ACE. In most laboratories, the verifying examiner will have access to all the work previously completed by the original examiner, including resulting conclusions from a comparison between an unknown impression (a latent print) and a known impression (or a set of known standards). In blinded situations, the verifying examiner will only be supplied with the compared latent print(s) and the known standard(s) these were compared to. Task irrelevant information, such as the original examiner's annotations or conclusions, the source of the known standards (e.g., an Automated Fingerprint Identification System (AFIS) "hit"), and the relationship between the known standards and the case (e.g., "victim") are not available to the blind verifier; however, task relevant information, such as substrate or matrix, may be requested by the blind verifier. At the completion of the blind verification, the two examiners compared conclusions. Differences in opinion were noted and resolved in accordance with laboratory conflict-resolution procedures and documented for purposes of this evaluation.

This presentation will discuss the data and general observations accumulated when comparing blind verification procedures to non-blind verification procedures in terms of case impact (rates of conflicting conclusions) and operational costs (time required to conduct verifications) as well as incidental observations related to interpersonal dynamics that were displayed during the evaluation period.

Blind, Verification, Impact

B96 Statistical Interpretation and Reporting of Fingerprint Evidence at the United States Army Criminal Investigation Laboratory (USACIL)

Henry J. Swofford, MSFS, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have a greater understanding of how fingerprint evidence may be quantified, policies and procedures guiding the use of such methods in practice, and next steps to ensure the method is accessible by the broader forensic community.

This presentation will impact the forensic science community by discussing the progress and challenges of implementing a method for statistical interpretation and reporting of fingerprint evidence at the USACIL.

The results of forensic fingerprint examinations are traditionally based on the visual comparison and subjective opinions of forensic examiners and reported as categorical statements of inclusion or exclusion of a particular individual as the source of a latent print. In 2009, the National Research Council (NRC) encouraged the forensic science community to develop tools to evaluate and report the strength of forensic evidence using validated statistical methods rather than relying solely on the subjective opinion of forensic examiners. The recommendations of the NRC are consistent with those of the President's Council of Advisors on Science and Technology Report (PCAST) in 2016. The primary concern of the NRC and PCAST is the legal field's inability to assess the reliability of fingerprint comparison results for a given case at hand without validated statistical data concerning the strength of the findings, thus bringing into question the scientific validity of fingerprint evidence and its admissibility in criminal courts.

Over the past couple of years, the USACIL has been taking incremental steps forward to facilitate the transition from solely subjective, experience-based practices to integrating more robust, scientifically demonstrable, and data-driven practices for latent print examinations. As a part of this effort, the USACIL has developed, validated, and implemented a method that facilitates the evaluation and reporting of the statistical strength of fingerprint evidence. In March 2017, the USACIL began reporting the statistical strength of fingerprint evidence within the military criminal justice system and is navigating a way forward for the broader forensic fingerprint discipline toward stronger scientific foundations and improved practices. This presentation will provide a general explanation of the statistical methods employed, discuss policies and procedures governing its use in casework, observations related to its operational and technical impact and challenges following implementation, and discuss how other federal, state, and local forensic service providers can implement similar reforms within their laboratories.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Fingerprints, Statistics, Likelihood Ratio

B97 An Update on the Academy Standards Board (ASB) Firearms and Tool Marks Consensus Body

Gregory E. Laskowski, MPA, Criminalistics Services International, LLC, 8021 Dottie Court, Bakersfield, CA 93308*

The goals of this presentation are to describe the purpose of the ASB Firearms and Tool Marks (FATM) Consensus Body and to present updates as to the Body's work on developing and approving standards in the disciplines of firearms and tool marks analysis.

This presentation will impact the forensic science community by providing attendees with information on the progress the FATM Consensus Body has made and is making in the areas of firearms and tool mark examinations.

The American Academy of Forensic Sciences created the ASB as a response to the need for standardization from the forensic community. This was in line with recommendations in the 2009 National Academy of Sciences (NAS) Report. It is now working in cooperation with the Forensic Science Board of the Organization of Scientific Areas (OSACS). The purpose of the FATM Consensus Body is to focus on standards and guidelines related to the examination of firearm and tool mark evidence. This includes the comparison of microscopic tool marks on bullets, cartridge cases, and other ammunition components and may also include firearm function testing, serial number restoration, muzzle-to-object distance determination, tools, and tool marks.

This presentation will discuss the inception of the ASB, its legal status as an entity, its membership, its mission, and a discussion on its consensus bodies with particular emphasis on the discipline of firearms and tool marks. Created in 2016, and under ASB Secretariat Brad Wing, the FATM Consensus Body is comprised of 33 members representing a number of disciplines that include subject matter experts, general interest, consumer groups, user/government (federal, state, and local), academia, producers, and user/industry. In addition to members, there are observers as well as managers from the ASB. Observers and other non-members are encouraged to participate by reviewing documents and offering comments. Standards can be developed by the Consensus Body or offered by other bodies such as the OSACs. Once documents containing recommended standards and guidelines are submitted to the Consensus Body, the documents will be reviewed by members of that body, and changes to those documents may be made to meet the American National Standards Institute (ANSI) publishing guidelines. Once the documents have been reviewed, they will be offered up for public comment. All public comments must be reviewed and addressed by the Consensus Body. After final review, the documents will be published as guidelines or standards.

It is imperative that all members participate, and that those individuals and bodies that are affected by proposed standards and guidelines participate by subscribing to the FATM Consensus Body and listen to meetings which are broadcast on Join Me™, read the documents, and offer constructive comments.

ASB, Consensus Body, FATM

B98 An Objective Comparison of Striated Tool Marks Produced From Ten Consecutively Manufactured Cold Chisels Measured by Contact and Optical Surface Profilometry and Comparison Microscopy

Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; Junfeng J. Song, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; and Wei Chu, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899*

The goals of this presentation are: (1) to inform attendees of the developments in quantitative measurement comparison of striated toolmarks; (2) to introduce recent developments in tool mark profile measurement using 2D and 3D surface profile instruments; and, (3) to demonstrate the robustness of proposed mathematical-based comparison scoring methods on a challenging tool mark test set.

This presentation will impact the forensic science community by informing and maintaining currency in the development, testing, and validation of the emerging technology of tool mark comparisons using 3D profilometry and objective mathematical comparison methods.

In the forensic science specialty of tool mark identification (which includes firearm identification), "tool marks" are the result of a harder surface acting upon a softer surface, usually but not exclusively metal alloys. The method for tool mark comparison relies on an objective side-by-side evaluation of the agreement by comparison microscopy; however, the opinion of "sufficient agreement" for conclusion to identify a tool source is subjective in nature, relying on the education, training, and experience of the examiner.

The first extensive study focusing on quantifying matching patterns of tool mark stria was performed by Biasotti in 1959.[1] His work demonstrated that consecutive matching stria groups were diagnostic for a quantitative measurement of similarity when two striated tool marks are microscopically compared, now termed Quantitative Consecutive Matching Stria (QCMS). Known Matching (KM) and Known Non-Matching (KNM) rifling land impressions on fired bullets were compared and the consecutive matching stria were counted. In non-matching comparisons, small QCMS numbers were observed, demonstrating the quantity of agreement observed by chance, understanding that agreement sufficient for identification must exceed that quantity. The minimum number of QCMS that was necessary for an accurate conclusion of the firearm source was empirically determined. The QCMS method is currently used by many examiners to quantify the agreement in striated tool mark comparisons.[2-7]

Optical 3D systems are emerging as objective methods in forensic tool mark measurement and comparison. These adapted instruments are useful due to the increasing computational power of modern computers and control systems tasked with handling high-definition 3D data.[8-17]

This is the first scientific investigation to employ consecutively manufactured tools (chisels) to produce striated tool marks whose contour profiles were measured by: (1) contact stylus profilometry; (2) non-contact 3D optical profilometry employing focus variation instrumentation; and, (3) the QCMS method. Striated tool marks were created pairwise in a controlled manner from ten consecutively manufactured cold chisel blades. Comparison tests between tool marks created in this manner have the best potential for producing microscopic agreement between two or more different tool sources, resulting in false positive identification. The striated tool mark profiles were measured using contact stylus 2D profilometry and non-contact optical 3D profilometry. Profile similarity and differences of KM and KNM tool marks were compared using two mathematical methods: Cross-Correlation Function Maximum (CCF_{MAX}) and the recently developed Congruent Matching Profile Segments (CMPS).

Both 2D- and 3D-acquired profile comparisons exhibit a wide separation between KM and KNM CCF score distributions when the full-length profile comparisons were made. Similarly, large separations of KM and KNM score distributions were also the result of segmented profile comparisons performed by CMPS. Replicas of the KM and KNM chisel tool marks were also compared using comparison microscopy, and the similarity and differences were measured by the QCMS method. Results of these comparisons also demonstrate a wide separation of distributions between the QCMS "runs" in KM and KNM tool mark comparisons, and no KNM comparisons exceeded three consecutive matching stria. The score distributions were also examined in a subjective statistical manner for their theoretical estimations of matching probability and demonstrate an exceedingly rare probability of sufficient agreement that would result in false positive identifications.

Conclusions: The results support the use of quantitative methods of profile comparisons for the discrimination of matching and non-matching striated tool marks. Both contact and non-contact methods of profilometry are useful in later mathematical comparison and score methods; however, in actual casework, the non-contact methods would be more acceptable because the contact stylus method may introduce stylus marks onto the evidence tool marks and, therefore, change the original evidence features. Additionally, the full profile comparison method in the CCF_{MAX} method is not as applicable to casework because the vast majority of striated tool marks on evidence items or collected at crime scenes exhibit partial tool marks from the full tool-working surface. The CMPS method exhibits the best promise for an objective comparison method and is better designed to compare much smaller profile segments of the striated tool mark profile to typically larger reference profiles. The evaluation of the tool mark peak frequency could also be employed to select optimum profile segment widths for the tool marks to be compared.

Tool Mark, Objective Comparison, Profilometry

B99 The Critical Angle of Bullet Impacts in Common Materials Seen in Forensic Casework

Richard T. Wyant, MS, Washington State Patrol CLD, 2203 Airport Way, S, Ste 250, Seattle, WA 98134*

The goal of this presentation is to demonstrate the angles of bullet impacts into materials that will penetrate, ricochet, or fragment.

This presentation will impact the forensic science community by informing attendees that the approximate angles to which bullets will penetrate or ricochet a material can be crucial to the reconstruction of a shooting event.

A case was investigated that involved the death of a young woman who was killed from a rifle bullet at long range.[1] There was debate as to whether the bullet that struck the victim was a direct shot or had ricocheted off a river between the shooter and the victim. Data from previous research related to bullet ricochet characteristics served as a basis to perform independent testing.[2] An AK-style rifle similar to the one used in the incident was fired into water at various angles and the departure angles from ricocheted bullets were documented through witness panels. During this experiment, the impact angle at which the bullet ricocheted off the water was evaluated. The impact angle that yielded penetration into the water was approximately seven degrees and greater. Although consistent with previous literature, the question was raised as to whether this angle would vary across other substrates encountered in forensic casework.

It is known that a bullet will ricochet off the surface of a substrate, such as wood, at one angle and penetrate the surface at steeper angle.[3] The angle at which a bullet will penetrate/perforate versus ricochet off a substrate is referred to as the critical angle.[4] An experiment was devised to measure critical angles from 25 shots using two common law enforcement pistol and rifle calibers with standard bullet types. Substrates utilized for this experiment included wallboard, automotive steel, wood, and two different types of glass.

Critical angle results from this experiment varied from five to nine degrees, depending on the surface composition. Attendees will be presented with the specific critical angle determinations from these tests as well as the detailed interaction of the bullet and surface that was captured with high-speed videography.

Critical Angle, Bullet Impact, Ricochet

B100 Battelle's Final Report on the National Institute of Justice (NIJ) -Sponsored Initiative: A Feasibility and Guidance Study of Massively Parallel Sequencing (MPS) for Forensic DNA Applications

Richard A. Guerrieri, MS, Battelle, 1 Corduroy Court, Stafford, VA 22554; Mark Wilson, PhD, Battelle, 2001 Jefferson Davis Highway, Ste 1203, Arlington, VA 22202; Jocelyn M. Bush, MS, Battelle Memorial Institute, 505 King Avenue, Columbus, OH 43201; Angela Minard-Smith, MS, Battelle, 505 King Avenue, Columbus, OH 43201; and Michael L. Dickens, PhD, Battelle, 505 King Avenue, Columbus, OH 43201*

After attending this presentation, attendees will better understand the MPS technology, its potential viability for forensic applications, and the identified gaps and considerations for implementation perspectives.

This presentation will impact the forensic science community by providing an awareness of MPS technology advancements in the field of forensic DNA analysis, the potential strengths and limitations of the specific technology application, and critical information relevant to the laboratory-specific decision process for potential investment in such a technology.

Forensic DNA analysis through Capillary Electrophoresis (CE) -based typing of Short Tandem Repeat (STR) is a well-established and successful technology with widespread legal and technical acceptance and is integral for the generation of more than 16 million DNA profiles registered within the Federal Bureau of Investigation's (FBI's) National DNA Index System (NDIS). The emergence of MPS presents opportunities for potential success beyond conventional CE-based techniques, specifically with respect to degraded specimens (missing persons) and possibly complex samples (mixtures). More significantly, MPS provides a broader scope of informative and discriminating data through Single Nucleotide Polymorphisms (SNPs) for identity, physical appearance, ancestry, and kindred relationships. Consistent with newer technologies, MPS also introduces levels of change, some of which are disruptive to the present approaches routinely applied by forensic DNA laboratories, ranging from nomenclature, workflow, and instrumentation, to data interpretation and reporting.

In 2014, Battelle first reported the receipt of a National Institute of Justice (NIJ) grant for initiating a two-year study (2015-17) to assess the technical readiness and feasibility of the MPS technology for forensic applications. The study consisted of both Performance Testing (Phase 1) to assess system capabilities and optimization of commercially available MPS products, and Inter-Laboratory Testing (Phase 2) for conducting a series of carefully designed studies to address key validation criteria. The Phase 2 effort specifically included the integral testing participation of technical leads from the Armed Forces DNA Identification Laboratory (AFDIL); the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATFE); the California Department of Justice (CAL DOJ); the FBI; Harris County Institute of Forensic Sciences (HCIFS); the National Institute of Standards and Technology (NIST), the New York City Office of the Chief Medical Examiner (NYC OCME), and the North Carolina State University. The validation study included assessment of the technology with respect to reproducibility, precision, concordance, sensitivity, mixtures, and non-probative casework. For the latter, each participating laboratory selected up to 14 samples, varying in types and often reflective of the respective missions for each laboratory. This presentation will convey the final results of this comprehensive study, including strengths, gaps, and considerations of strategic roadmaps for the MPS technology acceptance and transition. In total, a contemporary assessment of the technical readiness of the MPS technology will be provided, including examples of actual casework processed across two of the commercially available analysis workflows.

Massively Parallel Sequencing, Abundance, Iso-Allele

B101 Massively Parallel Sequencing (MPS) of Short Tandem Repeats (STRs) and Microhaplotypes for Mixtures

Sharon C. Wootton, PhD, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Joseph P. Chang, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Ryo Hasegawa, BS, 850 Lincoln Centre Drive, Foster City, CA 94404; Chien-Wei Chang, PhD, Thermofisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Sheri J. Olson, MS, Thermo Fisher Scientific, 409 Roosevelt Boulevard, Half Moon Bay, CA 94019; Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; and Robert Lagacé, BS, Thermo Fisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080*

After attending this presentation, attendees will understand how to utilize microhaplotypes and STR data generated by MPS.

This presentation will impact the forensic science community by presenting a novel method using microhaplotypes to determine the number of contributors in a mixture sample as well as infer biogeographical ancestral information.

Primers, library and template preparation chemistries, and algorithms were designed to analyze these markers. The AmpliSeq™ library preparation chemistry was developed to handle up to 100ng of input DNA, along with using a high-multiplex panel, which is important to increase the probability of recovering the minor contributor.

Microhaplotypes are multi-allelic genomic markers that contain more than one SNP residing in genetic proximity, whereby each haplotype is represented as statistically phased SNP genotypes.[1] These markers provide an ideal tool for mixture analysis, with a lower baseline and better intralocus balance over STRs in an MPS context. Furthermore, microhaplotypes are surrounded by conserved sequences, which can be sequenced with high accuracy, so therefore lack the complexity and interpretation issues of stutter. On the other hand, MPS exposes the additional diversity in compound and complex STR loci when repeat and flanking sequence is compared.[2-4] To investigate the sensitivity of the two marker types for mixture detection, a range of major to minor donor ratios and number of individuals was sequenced.

Seventy-eight microhaplotypes that have been previously typed on 83 populations showing high numbers of alleles and ancestry informativeness were targeted for design in multiplex with 31 autosomal STRs and 4 Y-markers.[5] DNA was extracted from samples taken from individuals of different biogeographic ancestries. Mixtures were created at ratios of 1:1, 1:3, 1:10, 1:20, and 1:50, along with mixtures containing up to four donors. Libraries for MPS were barcoded with both manual and automated Ion Chef™ library preparation methods. The libraries were then quantified and subsequently run through template preparation on the Ion Chef™, then sequenced on the Ion S5™. Using GlobalFiler™, fragment analyses were also performed on the same mock mixture samples to gather STR concordance and performance data. Reads were aligned to target regions of the reference human genome and haplotypes, biogeographic ancestry, number of contributors, mixture ratios, and minor and major contributors were determined. Converge™ 2.0 software was used to visualize sequence, STR profiles, strand bias, and number of contributors.

With the capacity to sequence many markers in parallel, MPS underscores the power of microhaplotypes and STR sequence as powerful forensic markers for handling mixture samples when Capillary Electrophoresis (CE) systems are not capable of generating conclusive results.

Microhaplotypes, Massively Parallel Sequencing, Mixtures

B102 Investigating Rates of Mitochondrial DNA (mtDNA) Heteroplasmy in Different Haplogroups Using Massively Parallel Sequencing (MPS)

Emmy L. Demchak, Penn State, 15 Thomas Boulevard, University Park, PA 16802; Jennifer A. McElhoe, DPhil, Pennsylvania State University, 13 Thomas Boulevard, University Park, PA 16802; and Mitchell M. Holland, PhD, Penn State University, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will understand MPS analysis of mtDNA haplotype and heteroplasmy and whether rates of heteroplasmy are linked to populations of different haplogroups.

This presentation will impact the forensic science community by introducing a robust MPS approach to sequencing mtDNA and enhancing the discrimination potential of mtDNA typing by evaluating rates of heteroplasmy across haplogroups.

MPS, a high-throughput form of next generation sequencing, allows increased resolution of mtDNA heteroplasmy and is at the forefront of efforts to expand the utility of forensic mtDNA typing. Maternally inherited mtDNA is present in hundreds to thousands of copies within one cell, has a high mutation rate, and passes through multiple bottlenecks, which allows for a range of variant percentages in the mtDNA sequence. Heteroplasmy is a heterogeneous collection of sequence variants in the cytoplasm of the cell. Heteroplamic rates from a population of European haplogroups (for example, H, J, K, T, and U) have provided evidence that heteroplasmy is common in the Control Region (CR) of the mitochondrial genome (mtgenome). A maternal lineage of mtDNA will share the same collection of major variant Single Nucleotide Polymorphisms (SNPs) and insertions/deletions (indels) called the haplotype. Certain haplotypes are common in population groups and may be shared among unrelated individuals.[1] In line with this, a haplogroup consists of similar haplotypes that have risen from related ancestral lineages. It is hypothesized that there is potential for differences in rates of heteroplasmy linked to population haplogroups, based on assumption and empirical observation that the position and rate of heteroplasmy may be linked to the haplotype sequence.

This current project has used a robust MPS approach to measure, analyze, and report rates of heteroplasmy on a per sample and per nucleotide basis for 750 samples in population groups reporting to be non-European (NIJ-2016-DN-BX-0171). Buccal cells were collected from 750 unrelated non-European individuals and MPS analysis conducted on the CR using Nextera® XT library preparation and 300X300 paired-end reads on an Illumina® MiSeq®. Secondary analysis was performed using GeneMarker® High-Throughput Sequencing (HTS) software to evaluate haplotype and heteroplasmy, and HaploGrep to determine haplogroups.

The forensic science community requires further validation of MPS analysis of mtDNA to encourage adoption of this technology into working laboratories and investigations. This project utilized a reliable MPS workflow developed in a laboratory, along with proper software for evaluation of MPS mtDNA data. Implementation of this optimized procedure combined with establishment of rates of heteroplasmy across the CR in different haplogroups will significantly enhance the accessibility to, and discrimination potential of, mtDNA typing. This highly resolved reporting will encourage the forensic science community to increase implementation of mtDNA analysis as a whole.

Mitochondrial DNA, Massively Parallel Sequencing, Heteroplasmy

B103 Is That Peak Real or Is It a Mis-Type? Only the Profile Donor Knows for Sure

Keith Inman, MCrim, Dept of Criminal Justice Admin, Rm 412 Student Faculty Services, 25800 Carlos Bee Boulevard, Hayward, CA 94542; and Norah Rudin, PhD, 650 Castro Street, Ste 120-404, Mountain View, CA 94041*

After attending this presentation, attendees will gain an appreciation for the possibility of frank mis-types in forensic DNA profiles, specifically with regard to peaks in stutter positions of a contributing profile.

This presentation will impact the forensic science community by raising awareness of the possibility for frank mis-types in forensic DNA profiles, especially in low-template samples and in particular, in stutter positions of alleles from a true contributor.

Samples containing low levels of DNA and/or mixtures of DNA from multiple individuals are routinely encountered in forensic DNA casework. These samples can be considered inclusively as "complex" samples. Such samples are challenging to interpret because of the inherent uncertainty in determining the genotypes of the contributors to the evidence profile. To further investigate the challenges involved in interpreting complex samples, a specific sample set was created. This sample set comprised two-, three-, and four-person mixtures. The template amounts were 30pg, 50pg, 100pg, and 500pg. The mixture ratios were 1:1, 2:1, 4:1, and 9:1. The various mixtures resulted in a total of 164 complex samples, each of which was amplified five times for a total of 820 profiles. The sample set provides a rich source of data than can be queried in numerous ways. Because these samples derive from known sources, ground truth is known, and the alleles expected in each of the profiles can be determined.

The Polymerase Chain Reaction (PCR) amplification typing artifact known as stutter introduces an element of ambiguity into the interpretation of forensic DNA profiles. Most analysts are aware of issues that arise from a stutter peak deriving from a relatively high-quantity contributor. These peaks can sometime be higher than expected, introducing the possibility of calling a false allele; they can also potentially mask a real allele in a low-quantity minor component of a mixture; however, there has been little discussion of the behavior of stutter in low-template mixtures and of the potential for the generation of a false profile that does not represent the true profile of the input sample.

In reviewing the aforementioned dataset, it became apparent that a non-trivial proportion of profiles would result in frank mis-types if read blind. Most, but not all, of these instances occurred in low-template samples, and the vast majority of these mis-types were attributed to peaks in either the N-1 or N+1 stutter positions of known input alleles. This phenomenon will be discussed and examples will be shown.

DNA, Mis-Type, Low Template

B104 Genotyping Challenging DNA by the Isolation of Polymerase Chain Reaction Products (IPCRp)

Pero Dimsoski, PhD, Ultra Detection, 3445 Seminole Trail, Ste 141, Charlottesville, VA 22911; Dragan Primorac, MD, PhD, 471 Wolcott Lane, Orange, CT 06477; and Gordan Lauc, PhD, Genos doo, Hondlova 2, Zagreb, CROATIA*

The goal of this presentation is to demonstrate the application of the IPCRp method for genotyping challenging DNA samples, in particular, touch and low copy DNA samples.

This presentation will impact the forensic science community by increasing competence when genotyping challenging DNA samples, such as touch and low copy DNA.

Genotyping field-collected samples of low quantity amplifiable copies or Low Copy Number (LCN) DNA has been a considerable challenge primarily due to the constraints of the PCR reaction itself in which the amount of the amplified targeted DNA at the end of the PCR cycle process is directly proportional to the amount of the template DNA at the start of the reaction. Increasing the number of cycles or going through another cycling process, as in the case of the nested PCR method, would increase the amount of a PCR product. Optimizing the PCR reaction for increased cycle number requires advanced technical skills and specialized reagents; however, even when done properly, high PCR cycle reaction creates additional problems due to increased stutter and background noise, the most important factors that have an adverse effect on the genotyping of LCN DNA. The IPCRp genotyping method reportedly can increase the detection levels more than 10-fold compared to classical PCR, does not require increased cycle number, and eliminates background noise in the process of genotyping.

The IPCRp method was used for genotyping touch DNA samples. Fingerprints from a stainless steel bar were swabbed and DNA was extracted by QIAGEN® Micro Kit, followed by IPCRp amplification and genotyping on a Capillary Electrophoresis (CE) genotyper platform. The 6-Plex PCR kit was designed according to the IPCRp method protocol with both forward and reverse primers labeled with fluorescent dye and biotin, respectively. The kit simultaneously amplified THO1, FGA, CSF, D21, TPOX, and D7 loci. Following the PCR, the double-stranded PCR product was captured on a streptavidine plate, washed, and only dye-labeled targeted DNA in single-stranded configuration was released and loaded to the genotyping platform. The loading quantities of the PCR product into streptavidin plates and the CE instrument were optimized. With the IPCRp amplification/genotyping method, a full genotype was obtained out of 10pg of template DNA when 12µl of captured targeted DNA was loaded to a 310 Genotyper®.

The full profile was obtained from all touched DNA samples, the stutter levels were not increased, and there was considerable reduction in background noise. Results from genotyping touch DNA samples and low copy number DNA will be presented. It is recommended that the IPCRp method be used in every case with genotyping challenging samples.

Touch DNA, Low Copy DNA, IPCRp

B105 Forensic Biology Under the Microscope

James Anstead, PhD, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Kelsy Lowther, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Erica Reynaga, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Elizabeth O'Bannon, MS, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Sherri Deaton, MS, DNA Solutions, 840 Research Parkway, Oklahoma City, OK 73104; and Brandt G. Cassidy, PhD, DNA Solutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104*

The goal of this presentation is to help forensic analysts identify and recover minute quantities of biological material from evidence with the aid of a dissecting microscope when necessary.

This presentation will impact the forensic science community by demonstrating the successful production of screening results and DNA profiles from biological evidence collected with the aid of a dissecting microscope that may otherwise have gone untested.

Attendees will learn about techniques that have been developed for recovering DNA from tiny amounts of evidence. The recovery of biological material, with samples merely millimeters in size, presents unique challenges in DNA processing. Without the proper techniques, many laboratories may overlook the value of testing minute amounts of biological evidence. Biological material from physical evidence may be difficult to access, potentially wedged in the cracks of the piece of evidence or trapped in the weave of a fabric. Somewhere between the analysis of DNA from a single cell and large quantities of blood, bone, or tissue is the realm of biological evidence that can be visualized and recovered using a dissecting microscope.

Over the past 17 years, DNA Solutions® has developed tools and techniques that allow enough biological material to be recovered from these types of difficult samples for screening and DNA analysis. Manual DNA isolation techniques have been coupled with sensitive Short Tandem Repeat (STR) kits to produce unique DNA profiles from some evidence that might have gone untested. Casework examples will be presented, ranging from the processing and recovery of residual biological evidence from medical trocars that were used in surgery to the successful production of a DNA profile from a tiny speck of blood identified on a pill from a large chain pharmacy. The processes used to successfully perform DNA analysis from traces of dried mucus on a handkerchief that had been recovered from within a commercial food product will be outlined, as well as the determination of the wearer of a set of clothes covered in the victim's blood following a brutal murder. Finally, the development of a DNA profile from hollow point bullets after the bullets had been cleaned for ballistics matching and stored for more than four years will be described. The DNA profiles were able to be matched to the victim, confirming their origin. Each of these cases highlights the tools (micromanipulators) and techniques (vacuum systems) developed at DNA Solutions® and used to successfully recover minute amounts of biological evidence and produce data critical to the investigations surrounding each case.

Forensic Biology, Dissecting Microscope, Minute Evidence

B106 High Resolution Melt (HRM) Curve Analysis for Preliminary Screening of Short Tandem Repeat (STR) Loci at Quantification — Obtaining More Information Earlier in the DNA Workflow

Darianne Cloudy, BS, 1205 Hale Drive, Hampton, VA 23663; Hannah Wines, BS, Virginia Commonwealth University, 223 S Cherry Street, Richmond, VA 23220; Kristiana M. Kuehnert, MS, 144 Wellington Circle, Williamsburg, VA 23185; Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079; Jordan Cox, MS, 1823 Floyd Avenue, Richmond, VA 23220; Edward Boone, PhD, 1020 W Main Street, Richmond, VA 23284; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will better understand how HRM curve analysis may be used with various statistical tools to screen forensic DNA samples for determination of specific genotypes or geno-groupings.

This presentation will impact the forensic science community by providing a method to detect exclusionary data as well as potentially detect the presence of a mixture prior to multiplex STR amplification and analysis.

Currently, the DNA laboratory workflow does not allow the possibility of quickly identifying exclusionary contributors or determining whether a sample is a mixture until end-point DNA profile interpretation and identification. This presents a problem for low template DNA samples, particularly those from touch DNA samples where numerous small areas of a touched item are individually swabbed to avoid inadvertently creating mixtures. Thus, those samples with low DNA yields may not produce full or even partial STR profiles and since this is determined at the end-stage of the DNA workflow, the possibility of combining multiple single-source extracts may be lost. A screening assay at an earlier step could be a beneficial tool, allowing an analyst to determine if consumption of the sample is warranted or if swabs from different areas of the evidence item should be combined prior to STR amplification. The quantification step is the most logical place to add this screening assay, due to the multifaceted capabilities of quantitative Polymerase Chain Reaction (qPCR) instruments and human DNA quantification kits. Previous work demonstrated that commercially available quantification assays did not themselves produce melt curve products nor was their quantitative accuracy altered by the presence of an additional HRM dye. These data also indicated that genotyping or geno-grouping single-source samples and identification of mixture samples is possible using HRM curve analysis of the D5S818 and D18S51 STR locus using EvaGreen® intercalating dye and a QIAGEN® Rotor-Gene® Q. The current data focuses on a statistical approach for examining duplexed HRM data from two STR amplicons (D5S818 & D18S51) using two different qPCR platforms.

Buccal swab DNA was obtained from individuals who expressed one of seven desired D5S818 and D18S51 genotypes (n=20 for each genotype at each locus). An optimized amplification reaction was used to amplify both STR targets followed by HRM analysis on the QIAGEN® Rotor-Gene® Q and the ABI® 7500 qPCR platforms. Quantitative examination of all peaks identified in the melt curve (including shoulder peaks) revealed that while temperature shifts alone were not significant enough to determine genotypes, the additional differences in the number of peaks present and the primary peak:shoulder peak height ratios were significant enough to allow statistical assessment. Statistical modeling of the resulting data was accomplished using the Principle Component Analysis (PCA) -based Rotor-Gene® Q ScreenClust HRM® software, ABI® 7500 instrument Sequence Detection Systems (SDS) software, and Linear Discriminate Analysis (LDA) approach using R statistical software. Each statistical model evaluates a set of known samples to create training groups for each genotype, which are then used for comparison against each unknown for identification of the most closely related and/or least dissimilar genotype or genotype grouping. From those groupings, the accuracy of this prediction was calculated for each approach. At the D5S818 locus, the ScreenClust HRM® software provided an accuracy of 23.9% when classifying the data between seven genotypes. To improve the predictive power using the PCA-based model, geno-groupings were created from the seven genotypes by combining genotypes with similar melt patterns together into groups. The accuracy was re-evaluated and demonstrated improvement to 46.6% with three geno-groups. The same set of samples was re-evaluated using LDA in R. This resulted in an accuracy of 58.9%. Geno-groups were created again to improve predictive value and the resulting three groups yielded an accuracy of 81%.

These data support the use of an LDA-based statistical model of HRM data from highly polymorphic STR amplicons for identification of a geno-group. Incorporation of this amplification and melt analysis into a commercially available quantitation kit could provide early exclusionary information and potentially provide detail about the number of contributors to a DNA sample *prior* to STR multiplex amplification and CE analysis. Future experiments will include integration of this HRM duplex into commonly used human DNA quantification chemistries and evaluation of both single-source and mixture samples.

High Resolution Melt Curve, qPCR, STRs

B107 Maximizing the Amount of DNA Recovered: A Study of Mawi DNA Technologies' iSWAB™-ID Collection Device for Forensic Science Application

Michelle K. Gordon, MS, Boston University Biomedical Forensic Sciences, 25 Hawthorne Drive, Sudbury, MA 01776; and Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118*

After attending this presentation, attendees will understand the utility of a new device for the collection and stabilization of cells and Deoxyribonucleic Acid (DNA). Attendees will also learn about: (1) problems that may exist with the current collection and recovery of cells and DNA; and, (2) the benefits and limitations of implementing the new collection technology into the field of forensic sciences.

This presentation will impact the forensic science community by introducing a device that enhances the collection and recovery of cellular material for subsequent DNA testing. The mechanism of the device allows for an increase in specimen release into proprietary direct lysis buffer that is compatible with commonly used forensic amplification kits and produces robust and reliable Short Tandem Repeat (STR) profiling.

DNA evidence often contains low amounts of cells; therefore, the importance of proper collection and storage to protect the DNA and ensure that maximum recovery of cells is achieved cannot be overemphasized. New techniques and inventions have made the collection of DNA evidence more efficient and consistent through the development of different types of swabs, lysing buffers, and various other improvements; however, DNA specimen release can be impeded by the structural properties of the swabs and the chemistries of buffers used for collection. Relatively substantial portions of the biological material, ranging from 20%-76%, can be lost through retention on the swab or loss during the extraction process.

The purpose of this study was to define conditions and limitations of the use of Mawi DNA Technologies' iSWAB™-ID collection device for the collection of forensic samples and subsequent DNA testing. Originally, the iSWAB™-ID collection device was designed to improve bio-sampling in the medical field in underprivileged areas where refrigeration is unavailable. Its unique room-temperature-stable chemistry and device design for optimal bio-sampling can potentially be adapted for forensic purposes. Experiments were designed to answer questions about the efficiency and effectiveness of the iSWAB™-ID collection device for forensic purposes. The following parameters of the iSWAB™ buffer and collection device were tested: (1) ability to collect dried stains; (2) ability to recover cellular material from different types and conditions of swabs; (3) ability to lyse different cell types; (4) ability to stabilize DNA over an extended period of time; and, (5) ability to perform in downstream Polymerase Chain Reaction (PCR) testing and produce quality STR profiles.

The Quantifiler® Duo DNA Quantification Kit on an Applied Biosystems® 7500 Real-Time PCR instrument was used to estimate the quantity of human DNA present in each sample. For comparison with samples extracted with currently used methodologies, STR typing was performed, following DNA quantification, on all samples of DNA extracted with the iSWAB™-ID collection device using the GlobalFiler™ PCR Amplification Kit and Identifiler® Plus PCR Amplification Kit and analyzed using the GeneMapper™ ID-X software.

Cumulatively, the data indicates that the iSWAB™-ID collection device is efficient and convenient while providing enhanced DNA recovery and full, high-quality STR profiles when targeting as little as 0.5ng of DNA; however, some limits exist, which include the potential of making low-input samples too dilute for subsequent analysis. The results of this study illustrate the potential benefits and limitations of implementing the iSWAB™-ID collection device in the forensic field.

This study was partially supported by Mawi DNA Technologies. The opinions, findings, and conclusions or recommendations expressed are those of the author(s) and do not reflect those of Mawi DNA Technologies.

Biological Specimen Collection, DNA Recovery, Direct Lysis

B108 An Evaluation of QIAGEN® Investigator® 24plex GO! Using Crime Scene Substrates and Direct Amplification

Marcel Burton, BS, The Pennsylvania State University, 325 B Whitmore Laboratory, Eberly College of Science, University Park, PA 16802; and Reena Roy, PhD, Pennsylvania State University, Forensic Science Program, 325 Whitmore Lab, University Park, PA 16802*

The goal of this presentation is to educate attendees in direct amplification of body fluids without the time-consuming and labor-intensive extraction and quantification steps. After attending this presentation, DNA analysts will be able to generate DNA profiles from body fluids when commonly found crime scene substrates containing inhibitors remain in the amplification reaction during the thermal cycling procedure.

This presentation will impact the forensic science community by generating DNA profiles quickly. The results can be obtained within a very short time period. This in turn can help to quickly locate a perpetrator or exonerate the innocent. No new instrument is needed and the method can be easily implemented in the forensic laboratory.

Short Tandem Repeat (STR) analysis is a technique performed routinely in forensic laboratories. Markers in these regions are amplified by Polymerase Chain Reaction (PCR) technology using specific primers, which have made them valuable in the forensic community. In violent personal crime cases, blood, saliva, semen, and nasal secretions are routinely encountered on various substrates. Direct amplification of these body fluid stains without time-consuming, labor-intensive extraction and quantitation steps has proven useful in forensic science laboratories.

Direct amplification entails amplifying the DNA present in a body fluid stain without extraction or quantitation steps and injecting the amplified product in a capillary electrophoresis system. The QIAGEN® 6-dye amplification system, Investigator® 24plex GO! allows the identification of 22 polymorphic STR loci and includes two innovative internal PCR controls (quality sensors). The quality sensors, QS1 and QS2, provide information regarding whether there is degradation and/or inhibition. These also indicate the absence of DNA or a failed PCR reaction. The current research utilizes this amplification kit to directly amplify minute amounts of blood, saliva, semen, and nasal secretions placed on various simulated crime scene substrates while the substrates remained in the reaction during amplification. Substrates chosen for deposition of these body fluids included various types of fabric ranging from white cotton to blue denim jeans and leather as well as cigarette butts, chewing gum, woodchips, straw, grass, and other objects.

Blood from four deceased donors was obtained from a forensic pathologist. Four semen samples were purchased from commercial vendors. Saliva and nasal secretions were collected from four individuals following the guidelines of the Office of Research Protection (ORP). Each body fluid was diluted in a 1:1 ratio. For blood, semen, and nasal secretions, 0.2µL of each diluted sample was deposited on a 1.2mm punch or cutting of each substrate. For saliva samples, 0.5µL of the body fluid was deposited on each substrate. After drying overnight, the stains were transferred to individual tubes. Next, 5µL of Investigator® GO! Lysis Buffer was added to each punched substrate containing blood, saliva, and nasal secretions and left at room temperature for 20 minutes with occasional mixing.

For semen samples, after drying overnight, 0.2µL of 1M DTT solution was added to each substrate containing semen samples. Each semen-stained substrate was then incubated at 56°C for 30 minutes. In the next step, each sample was shaken at 600rpm for another 30 minutes using a thermal mixer.

Each substrate containing only one type of body fluid was then subjected to amplification. For this step, 20µL of the reaction mixture was added to all tubes and amplification was performed following recommended protocol. During the amplification step, each substrate containing one of the four body fluids remained in the reaction mixture. Amplified products were injected into the 3130xl Capillary Electrophoresis (CE) system. GeneMarker® HID analysis software v 2.9 from SoftGenetics® was used for fragment analysis.

All stains created from the four body fluids using simulated crime scene substrates were amplified successfully, even when the substrates remained in the reaction mixture during amplification steps. All stains were created as single-source samples to generate DNA profile from one single donor. Thus, no mixture analysis was necessary in this project.

Consistent and concordant profiles were obtained from all body fluid-stained substrates. The S peak on QS2 locus occasionally dropped out, indicating inhibition in the sample, even when a complete profile was obtained. Known inhibitors such as soil or dye were present in some of the substrates. Therefore, this observation was not unexpected. Despite the substrates being present during the thermal cycling steps, the reagents were able to overcome inhibition and amplify DNA from challenging samples.

This study suggests that the Investigator® 24plex GO! is a valuable tool that can be easily incorporated in the analysis of body fluids such as blood, saliva, semen, and nasal secretions in forensic laboratories. Since there is no extraction and quantitation involved in the described procedure, the results can be obtained within a very short period of time. This can quickly help find a perpetrator or exonerate the innocent.

Direct Amplification, Investigator® 24plex GO!, Inhibitors

B109 An Evaluation of the Quality of Short Tandem Repeat (STR) Profiles Generated by Rapid DNA Instruments

Tetsushi Kitayama, PhD, National Research Institute of Police Science, #6-3-1, Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Takashi Fukagawa, PhD, National Research Institute of Police Science, 6-3-1, Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Haruhiko Watahiki, MS, National Research Institute of Police Science, 6-3-1, Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Yusuke Mita, PhD, National Research Institute of Police Science, 6-3-1, Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Koji Fujii, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; and Natsuko Mizuno, PhD, 6-3-1 Kashiwanoha, Kashiwa 277-0882, JAPAN*

After attending this presentation, attendees will understand the performance of the Rapid DNA instruments and whether the Rapid DNA instruments can be applied for casework samples.

This presentation will impact the forensic science community by reporting on the quality and characteristics of STR profiles produced by two different Rapid DNA instruments.

The Rapid DNA instruments are optimized to produce STR profiles from reference buccal swabs without human review. The applicability of the Rapid DNA instruments to disaster victim identification and casework samples is also of great interest to the forensic community.

In this study, the quality and the characteristics of STR profiles produced by the DNAscan™ 6C Rapid DNA Analysis System using the High DNA Content (HDC) Flexplex™ chemistry and the Low DNA Content (LDC) Flexplex™ chemistry, and the RapidHIT™ System using the GlobalFiler® Express chemistry were evaluated. High DNA content samples, such as reference buccal swabs, mock casework, bloodstain, and saliva stain samples were analyzed. Buccal swab samples were collected from volunteers. Blood dried on the glass slide and saliva on water bottles were collected by wiping using the swabs moistened with sterile distilled water. Cotton swabs manufactured for the DNAscan™ 6C Rapid DNA Analysis System were used. A full DNA profile without an incorrect allele calling and low-quality flag issued by the Rapid DNA expert systems was counted as a success. A profile with an allelic dropout at any loci caused by consumables or instrument defective was counted as a failure. A profile with a labeled non-allelic peak, such as a dye blob and spectral pull-up as an allele, was also counted as failure. The .fsa files were exported from both systems. Human review data analysis using the GeneMapper® ID-X Software was performed after the peak detection threshold for each system had been established using an electropherogram obtained from clean blank swabs.

The success rates for buccal samples for both Rapid DNA systems were approximately 80%, as reported by other publications. It was found that the success rate for mock casework samples was less than 50% due to low-quality flags that indicate the presence of non-allelic peak and/or the substantial variability in peak height and/or inter-loci balance, was more frequently issued by the Rapid DNA expert systems than buccal samples. No indications of carryover and cross contamination were observed in any of the blank samples by the Rapid DNA expert system and the GeneMapper® ID-X Software analysis. It was shown that the success rate can be improved significantly when .fsa files were analyzed by GeneMapper® ID-X Software.

An allelic ladder is run concomitantly with samples in each cassette. When the allelic ladder fails to meet the quality parameters of the Rapid DNA expert systems, the pre-loaded virtual allelic ladder implemented in each of the Rapid DNA instruments is employed to designate the sample alleles; however, it was found that some incorrect alleles were called by the Rapid DNA instruments in such cases. Therefore, it was considered that the success of the allelic ladder run was important for the correct allele calling.

Rapid DNA, Data Analysis, Allelic Ladder

B110 The Recovery of the Mitochondrial Genome From Cremated Human Remains

Maureen Hickman, MS, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Mark Wilson, PhD, Battelle, 2001 Jefferson Davis Highway, Ste 1203, Arlington, VA 22202; and Kelly Grisedale, PhD, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand how mitochondrial DNA (mtDNA) may be recovered from highly degraded samples, such as cremated remains, and analyzed using Massively Parallel Sequencing (MPS).

This presentation will impact the forensic science community by introducing a protocol that provides the means for DNA identification from severely burned human remains when other methods for identification have been exhausted or are not feasible.

The combination of a DNA extraction method designed for calcified tissues combined with a whole mitochondrial Genome (mtGenome) multiplex Polymerase Chain Reaction (PCR) assay and MPS will yield sufficient sequence information necessary for DNA identification of cremated human remains.

In cases of fires or explosions, forensic identification by traditional methods such as fingerprinting or anthropological analysis is often not possible. DNA identification of charred or incinerated remains may be the last resort for family members wishing to identify their loved ones. The recovery of DNA from burned human remains has been notoriously difficult. Some studies have been successful in typing DNA from charred remains and dental pulp; however, concerns exist regarding the quality and purity of DNA that is recovered.[1,2] Nuclear DNA in bone is often limited and PCR inhibitors can impede amplification of Short Tandem Repeats (STRs). The circular structure and subcellular sequestration of mtDNA may provide some protection from degradation, and high copy number of mtDNA per cell increases sensitivity of DNA typing assays, making it better suited for DNA identification of severely degraded samples such as burned remains.[3]

In this study, mtDNA was sequenced from an individual whose remains had been incinerated in a commercial crematorium. Ashes and small bone fragments were recovered from the cremated remains of the deceased. Bone fragments were externally cleaned with bleach and pulverized. DNA was extracted from ash and pulverized bone using a kit optimized for calcified tissues.[4] MtGenome copies from each extract were quantified, and Hypervariable region 1 (HV1) was amplified and sequenced via Sanger sequencing. Whole mtGenome was amplified using a multiplex PCR assay, and libraries were prepared and sequenced via MPS. HV1 and whole mtGenome sequences were compared to one another for concordance. All sequences were also compared to a maternally related reference to establish identity.

Results indicate that mtDNA can be successfully extracted from cremated remains. The combination of a calcified tissue-specific DNA extraction method with multiplex PCR and MPS is a useful technique to maximize recovery of genetic information from such severely compromised sample types.

Mitochondrial DNA, Massively Parallel Sequencing, Cremated Remains

B111 The Development of an X-Chromosome Insertion-Deletion (InDel) Multiplex for Forensic Applications

Gonul Filoglu, Institute of Forensic Science, Istanbul University, Istanbul, TURKEY; Selen Ozyer, BSc, Institute of Forensic Science, Istanbul University, Istanbul 34098, TURKEY; Zulal Uslu, MSc, Institute of Forensic Science, Istanbul University, Istanbul 34098, TURKEY; Tugba Ünsal, PhD, Üsküdar University/ Department of Forensic Science, Altunizade Mah. Haluk Türksoy Sok. no:14, Üsküdar, Istanbul, Üsküdar/Istanbul 34662, TURKEY; and Ozlem Bullbul, PhD, Istanbul Universitesi, Adli Tip Enstitusu, Istanbul, TURKEY*

After attending this presentation, attendees will have a better understanding of the development and application of the X-chromosome InDel marker system for use with forensic DNA samples.

This presentation will impact the forensic science community by providing results from a developed novel X-chromosome InDel as a key aspect for the analysis of special forensic investigations as it can contribute to traditional DNA testing systems in cases in which those systems do not produce results due to the presence of degraded DNA.

Short Tandem Repeats (STR) loci are commonly used genetic markers for the purpose of forensic identification; however, there are many situations in which a full DNA profile cannot be achieved from a crime scene due to degradation of the biological samples over time. Recently, there is a tendency toward Single Nucleotide Polymorphism (SNP) and InDel among forensic scientists since these markers have smaller DNA sequences; therefore, a successful DNA profile can be achieved from even a small amount or degraded biological samples. InDel polymorphism is a type of genetic variation that is formed by the addition or loss of one or several bases in the human genome. InDel loci have small (60bp to 200bp) amplicon length (Polymerase Chain Reaction (PCR) products) and have begun to be used in forensic identification. X-chromosome InDel polymorphism can be used in specific kinship investigations (incest cases, etc.).[1-5] The goal of this study is to develop a multiplex InDel panel, consisting of 18 X-chromosome loci with a short amplicon size, for forensic purposes.

Eighteen X-chromosome InDel markers were chosen based on the following criteria: (1) mean heterozygosity of more than 30% in Europeans; (2) a minimum of 250Kb differences between each InDel loci; and, (3) the amplicon length was less than 300bp. InDel primers were designed using the PRIMER3 software and tested for hairpin and primer-dimer secondary structures with the AutoDimer software. Singleplex PCR was applied to the InDel loci, then multiplex PCR was performed containing PCR master mix, optimized primer concentrations, and 1ng-10ng of genomic DNA. InDel loci fragments were separated using an ABI® PRISM® 310 Genetic Analyzer and analyzed with GeneMapper® v3 software. The validation study of these 18 InDel loci was performed with the following parameters and aspects: analytical threshold, sensitivity and stochastic threshold, heterozygous balance, precision and accuracy, repeatability and reproducibility, genotype concordance (9947a), DNA mixtures, and case samples.

Eighteen InDel loci were successfully amplified using a single multiplex reaction. Optimization and validation parameters of the 18 InDel Multiplex was successfully applied. The high performance of this 18 InDel multiplex fluorescent PCR system makes it a valuable additional system to the current STR systems and can be used for forensic purposes.

X-Chromosome, InDel, Panel Development

B112 The Impact of Antioxidant Beverages on the Chemiluminescent Detection of Bloodstains at Crime Scenes

Kelsey D. Bettex, University of New Haven, 137 Meroke Lane, East Islip, NY 11730; and Claire Glynn, PhD, Forensic Science Department, University of New Haven, West Haven, CT 06516*

The goal of this presentation is to inform attendees of the recent findings related to the antioxidant inhibition of the chemiluminescent detection of bloodstains.

This presentation will impact the forensic science community by improving insight into the inhibition of the reaction between chemiluminescent reagents, specifically luminol and Bluestar Forensic®, and blood found at crime scenes. The possibility of this inhibition has been suggested in several published articles but has yet to be studied.

The identification of blood deposited at a crime scene is crucial to the reconstruction of events leading to and following a crime, as well as corroborating or rejecting statements and alibis. Many biochemical reagents are at the crime scene investigators disposal to both screen for, and confirm, the presence of visible and non-visible bloodstains. One such reagent for the detection of non-visible, or latent, bloodstains is a chemiluminescent reagent known as luminol, which comes in multiple formulations, the most widely utilized being Bluestar Forensic®. It was recently reported, but not further studied, that the presence of antioxidants in contact with a blood stain may hinder the reaction of such chemiluminescent reagents, giving way to a false negative reaction.[1,2] Conceivably, blood is the most commonly encountered bodily fluid at crime scenes. Therefore, further investigation of the possibility of antioxidants within the environment potentially masking bloodstains is necessary to address the opportunity for hindered investigations.

This study investigated the potentially negative effects of seven different antioxidant sources on the reaction between chemiluminescent reagents and blood. Methods involved staining both absorbent and non-absorbent surfaces, carpet and tile, respectively, with 2mL of four dilutions of blood: neat, 1:10, 1:100, and 1:1000. Each bloodstain, after a 24-hour drying period, was then treated with 5mL of one of seven antioxidant sources: orange juice (100%, not from concentrate); green tea (one processed Pure Leaf® cold green tea beverage and one unprocessed organic hot green tea leaf beverage); a supplement drink (Bai® Antioxidant Infusion); red wine (Pinot Noir); coffee (premium roast); or black English breakfast tea. Bloodstains were also treated with Coca-Cola®, which contains no antioxidants, acting as a control. Following a 24-hour drying period, each sample was then treated with one of two chemiluminescent reagents, luminol or Bluestar Forensic®, and documented for chemiluminescent intensity. A Canon® EOS Rebel T3i digital SLR camera was used to document each reaction to later compare to control samples and better approximate the chemiluminescent intensity.

The results of this study revealed red wine and coffee to negatively impact the chemiluminescent reaction of both luminol and Bluestar®, creating false negatives on both surfaces, with all dilutions. Samples tested with Coca-Cola® all produced moderate-strong positive chemiluminescence, showing the application of beverages to not act as a barrier for the reaction, rather potentially the antioxidants present in red wine and coffee inhibiting the reaction. The other five antioxidant drinks produced positive chemiluminescent reactions; however, these reactions were impacted and could lead to misinterpretation. Orange juice, both green teas, the supplemental drink, and black tea produced weak-moderate reactions on both surfaces, with Bluestar® fading very quickly compared to typical reactions, which could be misinterpreted as a false positive.

This research has highlighted the importance of the choice of method and considerations to be taken when screening evidence items/crime scenes for blood and of the possibility of antioxidants in the environment having a negative impact. The results of this study provide a valuable and novel contribution to the forensic science field as the impact of antioxidants has largely been unexplored, yet warrants investigation.

Blood, Antioxidants, Chemiluminescence

B113 The Development and Evaluation of Reverse Transcription Loop-Mediated Isothermal Amplification (RT-LAMP) Assay for Forensic Saliva Identification

Chih-Wen Su, No 5 Lane, 553 Sec 4 Zhongxiao E Road, Taipei, TAIWAN, REPUBLIC OF CHINA; Kuo-Lan Liu, No 5 Lane 553, Sec 4, Zhongxiao E Road, Xinyi District, Taipei City, TAIWAN, REPUBLIC OF CHINA; and Hsing-Mei Hsieh, PhD, 56 Shu-Jen Road, Taoyuan , TAIWAN, REPUBLIC OF CHINA*

After attending this presentation, attendees will better understand a novel combined approach for the detection of saliva as a model for body fluid identification using real-time RT-LAMP.

This presentation will impact the forensic science community by demonstrating that real-time RT-LAMP is an ideal tool to identify saliva. It shows great potential in forensic casework by presenting the possibility of identifying body fluids via messenger RNA (mRNA) and is capable of identifying body fluid stains at crime scenes by combining with Direct LAMP and multiplex LAMP technology.

LAMP employs a DNA polymerase which contains the 5' to 3' polymerase activity, but lacks 5' to 3' exonuclease activity. It replaces and releases the complementary strands instead of hydrolyzing them. The previously released strands can be used as a template and amplified with proper primers. Via auto-cycling mediated by the DNA polymerase, it keeps displacing target strand DNA and creates new targets as it amplifies. Thus, LAMP reaction can take place at a constant temperature.[1] LAMP has been proven to be a rapid, sensitive, accurate, and economical technique for DNA amplification widely used in detection of various kinds of pathogens, microorganisms, fungi, and parasites.[2,3]

RT-LAMP with the saliva-specific marker, Statherin (STATH), was used to identify the presence of saliva in this study. The 18S rRNA gene was used as the internal control. Seven body fluids, including venous blood, saliva, semen, menstrual blood, sweat, urine, and vaginal secretions, were collected from volunteers using procedures approved by the Institutional Review Board (IRB) of the Central Police University in Taiwan. Total RNA was extracted from each body fluid with the RNeasy® Mini Kit and then quantified using NanoDrop® ND-1000 UV spectrophotometer. One-step RT-LAMP was performed using Loopamp RNA Amplification Kit. For Direct LAMP, body fluid samples were simply boiled before RT-LAMP without RNA extraction.[4] The LAMP product was confirmed by electrophoresis and restriction enzyme digestion. The real-time turbidimeter was used to monitor the change of turbidity, which indicated the real-time accumulation of LAMP products. Calcein was used for fluorescence detection. Additionally, Polyethylenimine (PEI) was also used for multiplex LAMP.[5]

Saliva samples were successfully identified using LAMP with STATH primer sets without false positive and negative (at least 12 samples for each body fluid and negative controls were tested). The Threshold time (Tt) for saliva was 39.4±2.9min. LAMP products with 18S rRNA primer sets were detected from all body fluids samples (Tt: 26.8±2.2mins for venous blood, 44.2±2.3mins for saliva, 33.2±2.2mins for semen, 44.7±5.6mins for menstrual blood, 44.7±2.5mins for sweat, 32.9±0.4mins for urine, and 38.2±2.8mins for vagina secretions). Evaluation for LAMP products of all samples by fluorescence and electrophoresis is consistent with the results. It also revealed that less than 1µl of saliva could still be detected, which is equal to or slightly better than identifying body fluids by mRNA profiling (1µl of saliva).[6] STATH and 18S rRNA could be successfully identified simultaneously using multiplex RT-LAMP with PEI. Saliva samples without RNA extraction were also successfully identified by Direct LAMP.

Results demonstrate that LAMP exhibited high potential for providing an ideal tool in saliva identification for its simplicity, efficiency, specificity, and sensitivity. One-step RT-LAMP takes less than one hour to complete the entire reaction. Traditional two-step procedures including reverse transcription and PCR comparatively cost more money, time, and labor and raise a higher risk of contamination. Also, traditional PCR-based methods require a heavy and expensive thermal cycler for reaction, making it difficult to perform at the crime scene. RT-LAMP could be performed using one piece of laboratory equipment instead of a dedicated machine. It was also shown that Direct LAMP without RNA extraction and fluorescence detection with the presence of calcein could be performed simply and is applicable to test remotely from the laboratory, such as at a crime scene. The assay was also applied successfully to the putative identification of saliva from non-probative forensic samples, demonstrating that LAMP is capable of identifying body fluid stains at the crime scene. This is the first application of RT-LAMP for the identification of saliva.

B114 Identification of Kratom (*Mitragyna Speciosa*) DNA Using a Real-Time Polymerase Chain Reaction High-Resolution Melt (PCR HRM) Assay

Ashley F. Cowan, Towson University, Chemistry Dept/Smith Hall, 8000 York Road, Towson, MD 21252; and Kelly M. Elkins, PhD*, Towson University, Chemistry Dept/Smith Hall, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will be able to evaluate how a newly developed real-time PCR assay coupled with post-PCR HRM can be used for kratom identification when dealing with degraded or mixture plant samples in forensic casework.

This presentation will impact the forensic science community by demonstrating a new method to identify kratom from other illegal and "legal high" plants that may be in forms indistinguishable by eye and through microscopic techniques. This process could be used as a cost-saving alternative to chemical analysis currently in use, such as Fourier Transform Infrared (FTIR) or Gas Chromatography/Mass Spectrometry (GC/MS). In addition, equipment required for this screening is readily available to forensic DNA scientists in major crime labs.

Kratom (*Mitragyna speciosa)* is a plant that is a member of the family Rubiaceae, or coffee family, and is commonly used for the analgesic, opiate-like, and stimulant properties from the alkaloids it produces. The most famous and widely cited of these alkaloids is mitragynine as it is the most abundant metabolite, although there are more than 40 alkaloids produced by the plant, including 7-hydroxymitragynine. While it is widely referred to as kratom worldwide and in its native Southeast Asia, it is also referred to by other names in various countries, including biak-biak or ketum in Malaysia, krathom, kakuam, ithang, or thom in Thailand, and mambog in the Philippines. Its popularity among users primarily relies on its stimulant and pain-relieving properties, which have been reported to be 17 times more potent than morphine.

The first country to formally control the use of kratom was Thailand in 1943. In recent years, its use as a recreational drug has increased worldwide and numerous case studies have been reported in the literature documenting various effects on users and in the extreme instances, including its presence in cases of death in which the drug was taken in combination with other legal and illegal substances. Western nations have responded to this recent increase of prevalence by all-out banning, controlling, and/or imposing restrictions to only be used with a medical prescription. The United States Drug Enforcement Administration (DEA) currently includes kratom on the list of Drugs and Chemicals of Concern. As of September 2016, the DEA reopened the comment period to consider labeling kratom as a Schedule I substance; thus, its legality currently defers to a state-by-state basis.

Current methods of identification seen in the literature include visualization techniques such as colorimetric tests and microscopy and quantitation through alkaloid chemical analysis such as Hydrogen-1 Nuclear Magnetic Resonance (^{1}H NMR), GC/MS, FTIR, High-Performance Liquid Chromatography (HPLC), and Direct Analysis in Real-Time Mass Spectrometry (DART®-MS), to name a few. Recent DNA techniques have relied on Restriction Digest Length Polymorphism (RFLP) assays.

In this study, primers designed for the PCR-HRM assay targeted the Secologanin Synthase 2 (SLS2) and Strictosidine Beta-D-Glucosidase (SGD) genes within the *M. speciosa* genome. Amplification of SLS2 and SGD genes produced amplicons of 168bp and 66bp, respectively. The SLS2 primer set was specific for *M. speciosa* against other "legal high" plant species such as *Cannabis sativa*, *Datura wrightii,* and *Papaver orientale* with a melt curve of 77.09°C. Further sensitivity testing indicated continued detection of SLS2 amplicon at concentrations as low as 0.05µg/mL.

Kratom, Real-Time PCR, High-Resolution Melt

B115 Internal Validation of a Quantifiler® Trio Setup Method on the Hamilton® Microlab® Sequential Transfer and Aliquotting Robot (STAR)

Kelsey J. Peloso, 32 Lohse Road Extension, Willington, CT 06279; David R. Fisher, MS, NYC OCME, Dept of Forensic Biology, 421 E 26th Street, #11-50, New York, NY 10016; Kyra McKay, MA, 421 E 26th Street, New York, NY 10016; and Kelly Beatty, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will have a better understanding of the importance of increased automation in the forensic DNA laboratory workflow, specifically as it relates to Quantifiler® Trio set up on the Hamilton® STAR.

This presentation will impact the forensic science community by demonstrating that the Hamilton® STAR has the capability to set up a 96-well plate for quantitation and achieve reliable results that are comparable to those obtained manually and perhaps even more precisely than a manual setup. This presentation will also highlight the benefits of combining different automated methods on the STAR in order to create a more seamless process with less analyst intervention, leading to fewer opportunities for contamination or human error.

The Hamilton® Microlab® STAR is an automated liquid-handling robot that can be programmed to perform a variety of tasks, such as extraction, quantitation set up, normalization, amplification set up, and capillary electrophoresis set up, in the forensic DNA workflow. Robots such as the Hamilton® STAR are useful in forensic DNA laboratories because they reduce the risk of contamination between samples and increase the precision of pipetting. The use of air-displacement pipetting reduces the risk of contamination presented by liquid-displacement pipetting used in some other robots. The Hamilton® STAR also reduces the amount of bench work time for analysts, allowing more time for analyzing data and technical review, which are the major bottlenecks in most forensic DNA laboratories. The use of a worksheet that establishes each sample's destination allows flexibility of sample processing, and a barcode reader for samples adds a second check that prevents sample mix-up. The Hamilton® STAR is able to process up to 96 samples at once, which allows for more samples to be processed in less time than with manual preparation. With increased automation in their workflow, forensic DNA laboratories can increase their efficiency, thereby reducing case turnaround time.

In this presentation, the quantitation set up method developed by Sorenson Forensics® was validated for use on the Hamilton® STARs currently used by the New York City Office of Chief Medical Examiner's Department of Forensic Biology. The internal validation study was conducted in accordance with the Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines, including cross contamination, volume verification, and precision studies as well as manual and robot-to-robot comparison studies. In addition, automation workflow strategies for large metropolitan forensic DNA laboratories will be discussed.

Hamilton® STAR, Automation, Quantitation

B116 The Identification of Forensically Relevant Body Fluids Using Methylation-Specific Polymerase Chain Reaction (PCR) and High-Resolution Melt (HRM) Analysis

Rebecca Levine, Towson University, 8000 York Road, Towson, MD 21252; and Cynthia B. Zeller, PhD, Towson University, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will be informed of the benefits of using Methylation-Specific PCR (MSP) and HRM analysis to differentiate between different body fluids.

This presentation will impact the forensic science community by informing attendees of the ability to quickly and easily determine the presence of a specific body fluid prior to completing DNA analysis.

The combination of MSP with HRM analysis is a method that can demonstrate the difference between various forensically relevant body fluids. This type of body fluid identification involves targeting expressed genes and comparing their methylation status to other cell types.[1] DNA extracted from different body fluids undergoes a bisulfite conversion process that converts any unmethylated cytosines to uracil, which ultimately becomes thymines during PCR amplification. Forward and reverse primers are designed to amplify a target region of DNA that contains multiple CpG sites. The methylation status of the cytosines results in an alteration to the Melting Temperature (T_M); methylated cytosines produce a higher T_M than unmethylated cytosines. The primers can then be designed to bind specifically to methylated or unmethylated template strands.

Several studies have previously identified gene sequences that are differentially methylated in several relevant body fluids. The majority of these studies used pyrosequencing to identify changes in the methylation status of semen, blood, and saliva. The goal of this study is to use MSP and HRM analyses to visualize these differences and identify each body fluid. Using those results, two or more primers will be multiplexed to ensure a greater specificity in determining the presence of a forensically relevant body fluid.

Throughout this study, ten known primer sets and several primer sets of new design were studied to enhance body fluid identification. The forward and reverse primers were analyzed during their methylated and unmethylated forms to display the various T_Ms. ZC3H12D and DACT1_F have already been identified and analyzed using HRM analysis.[1,2] The eight remaining primer sets were obtained from studies involving sequencing to determine the differentiation likely to occur among body fluids. These include FGF7, cg06379435_W, BCAS4, cg06379435_S, DACT1_B, USP49, DDX4_B, and B_SPTB_03.[3-6] This study has proven the ability to differentiate semen from other body fluids. Further analysis is being performed to differentiate between blood and saliva, as these body fluids tend to display a similar T_M for many primer sets. The next step for this study is to combine two or more of the primer sets into a multiplex assay which will increase the specificity of the distinct body fluid identification.

Body Fluid Identification, Methylation-Specific PCR, High-Resolution Melt Analysis

B117 A Comparison of Extraction Methods for Amplification of Nuclear DNA From Hair Shafts Using the InnoTyper 21® DNA Typing Kit

Anna L. Kelleher, BS, Armed Forces DNA Identification Laboratory, 201 Washington Street, Berlin, MD 21811; Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118; and Sudhir K. Sinha, PhD, InnoGenomics Technologies, LLC, 1441 Canal Street, Ste 307, New Orleans, LA 70112*

The goal of this presentation is to share data from studies comparing multiple methods for nuclear DNA extractions from hair shafts, demonstrating that full nuclear DNA profiles can be obtained from hair shafts with as little as 30 picograms of DNA using the InnoTyper 21® DNA amplification kit.

This presentation will impact the forensic science community by assessing and demonstrating methods that can obtain full nuclear DNA profiles from highly degraded DNA from evidence samples, such as hair shafts.

Forensic crime laboratories receive hair shafts as evidentiary samples and process them for DNA evidence as a means of identification of individuals. Nuclear DNA is often too scarce and degraded to enable sufficient profile recovery from hair shafts using standard methods. There are many more copies of mitochondrial DNA in a cell than nuclear DNA. Therefore, it is common practice to target mitochondrial DNA instead of nuclear DNA when processing a hair shaft for DNA evidence.

Researchers at InnoGenomics® Technologies have developed a nuclear DNA quantification system, InnoQuant®, which targets 80-basepair and 207-basepair fragments and a novel amplification kit, InnoTyper 21®, which targets ~60bp-125bp fragments. Targeting short DNA fragments creates the potential to obtain sufficient nuclear DNA data from samples containing highly degraded DNA or low template DNA. Rather than targeting loci that contain Short Tandem Repeats (STRs), these kits target retrotransposable nuclear elements, which are non-coding genomic DNA repeat sequences, or "mobile insertion elements," comprising approximately 40% of the human genome.

This study compares nuclear DNA extraction methods from hair shafts such as the QIAamp® Fast DNA Tissue kit, direct lysis procedures using ZyGEM® prepGEM™ enzyme, and direct lysis procedures using pronase. Pronase is a mixture of proteases isolated from the bacteria *Streptomyces griseus.* It is reported that pronase will cleave peptide bonds into single amino acids. A common challenge with extracting DNA from hair shafts is the breakdown of keratin proteins in the hair shaft to release the DNA. Therefore, it was hypothesized that direct lysis extraction methods utilizing pronase will result in sufficient keratin degradation and therefore release enough nuclear DNA from hair shafts to be quantified with the InnoQuant® quantification kit and typed using InnoTyper 21® DNA typing kit.

This study exhibited mixed results with direct lysis using pronase at concentrations of 0.05mg/mL and 0.01mg/mL, generating a range of full, partial, and null InnoTyper 21® profiles. Higher pronase concentrations of 0.25mg/mL produced significant PCR inhibition, causing amplification failure. The QIAamp® Fast DNA Tissue kit extraction method resulted in the highest average concentration of DNA (0.0495ng/µl) extracted from hair shaft samples and the most complete profiles using the InnoTyper 21® kit. Full profiles of nuclear DNA from hair shafts were obtained using the InnoTyper 21® amplification kit from samples with as low as 0.0021ng/µl of DNA; however, not all samples at this concentration resulted in successful amplification. There was a large discrepancy between partial profiles which ranged from 2 to 18 loci. The success of DNA typing appeared to be dependent on the donor source as well as the extraction method.

Hair Shafts, DNA Extraction, Degradation

B118 The Limits of Detection (LODs) of Surface-Enhanced Raman Spectroscopy (SERS) -Active Swabs Used to Screen for Human Bodily Fluids (HBFs)

Geraldine Monjardez, PhD, Western Carolina University, 327 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723; Brittania J. Bintz, MSc*, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; Katarina G. Ruehl*, WCU, 90 Merlite Court, Cullowhee, NC 28723; and David D. Evanoff, Jr., PhD*, Western Carolina University, 231 Natural Sciences Bldg, 111 Memorial Drive, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the sensitivity associated with a novel technique for the screening of HBFs for confirmatory identification of semen, saliva, and their mixtures.

This presentation will impact the forensic science community by providing the LODs of a technique that enables rapid, highly sensitive, non-destructive identification of semen, saliva, and their mixtures. The sufficient concentration of each HBF and mixture analyzed that are needed to produce an analytical signal that can be reliably discriminated from the signal produced without the pure HBFs or mixtures will be determined. The methodology will ultimately be extended to acquire the LODs of other pure HBFs (blood and vaginal fluid) and other mixtures.

The screening of HBFs is routinely conducted in crime laboratories prior to DNA analysis. First, a presumptive test is conducted to determine whether a specific bodily fluid can be present, followed by a confirmatory test, which establishes the identity of the material; however, the existing methods are prone to false positives and false negatives and therefore lack sensitivity and specificity. Furthermore, these tests require extensive sample pre-treatment, expensive chemicals, and are time consuming and destructive for the sample.

Raman spectroscopy is an analytical technique that provides information about molecular vibrations that can be used for sample identification and quantitation. The suitability of Raman spectroscopy for the analysis of bodily fluids has been reported as this technique allows for the rapid, highly selective, and non-destructive analysis of the samples.[1] Raman may also offer the possibility of performing one type of measurement for all HBFs, while also preserving the DNA evidence contained in such samples; however, the high sensitivity required for forensic samples may not be obtainable with Raman spectroscopy alone. Therefore, SERS may be more suitable for the analysis of HBFs as it enables the enhancement of analyte signals by several orders of magnitude. This increases the sensitivity of the Raman and therefore its ability to detect small amounts, dilute samples, and mixtures, which can be found at a crime scene.

Silver nanoparticles were attached to nylon Copan 4N6FLOQSwabs™ using the hydrogen reduction method.[2] Seminal fluid from was obtained from Lee Biosolutions™, Inc. Mixtures were prepared with different semen/saliva ratios. A range of concentrations of the semen and saliva, as well as their mixtures, were produced to measure their LODs. Different swabbing techniques were explored and Raman data of analyte adhered to the SERS-active swabs was measured using a 632.8nm laser excitation. Distinctive SERS bands of semen and saliva were used to identify their contributions in the mixtures. Based on the signal-to-noise approach, the LODs were then determined. The measured signals from the bodily fluids of known low concentrations were compared with those from blank samples using a signal-to-noise ratio of three. The minimum concentration at which the bodily fluids and mixtures could be reliably detected was then established.

B119 The Extraction of Touch DNA From Chemically Developed, Aged Fingerprints

Amber J. Smith, BA, Arcadia University, 450 S Easton Road, Glenside, PA 19038; and Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will better understand how latent fingerprints deposited onto a paper substrate are developed with various chemical reagents, what touch DNA is and how it can be extracted from paper, and how touch DNA can still be recovered several days to weeks after a fingerprint has been chemically developed.

This presentation will impact the forensic science community by demonstrating that fingerprint evidence can be tested for touch DNA even after being chemically developed. This is important in cases such as cold case files or exoneration cases in which fingerprint evidence has been in storage over time after being chemically developed, but DNA testing was either not available or not requested.

Fingerprints recovered from crime scenes are rarely perfect and often require enhancement. For latent fingerprints deposited onto porous surfaces such as paper, developing reagents like ninhydrin can be applied to make the print visible by staining it dark purple.[1] If after development a latent print cannot be used for comparison, the next step may be to test the print for touch DNA. Touch DNA is left behind by a person upon touching a surface and leaving behind DNA-containing skin cells.[2] The development of touch DNA has provided forensic scientists with a tool for extracting DNA from fingerprints when traditional developing methods cannot produce a usable print.

If a fingerprint is not usable for comparison purposes, it can then be tested for touch DNA; however, laboratory backlogs can sometimes leave developed fingerprint evidence sitting in storage for several days, weeks, months, and even years before it can be tested. Several studies have been conducted to examine the effect that developing reagents, such as 1,2-indanedione, have on the recovery of touch DNA from developed fingerprints deposited onto porous surfaces over time.[3,4] It has been shown that DNA can be recovered up to 21 days post-development after treatment with 1,2-indanedione, but research is lacking as to how other reagents for porous surfaces, such as ninhydrin, 5-methoxy ninhydrin, 5-methylthio ninhydrin, genipin, and lawsone, affect future DNA analysis.[3]

To examine the effect of chemical reagents, fingerprints from four participants (two males, two females) were deposited onto personal checks, developed with the reagents listed above, then allowed to age for various time intervals (1-180 days). Reference buccal swabs from the participants were collected for subsequent DNA analysis. A set of control fingerprints were also collected from each participant and were not treated with a reagent. After aging, the samples were swabbed, quantified, amplified, and then analyzed using capillary electrophoresis to determine if a DNA profile could be generated. Results determined that even after treatment with chemical reagents, a genetic profile can be generated for the aged samples. This demonstrates that even in cases in which treated fingerprint evidence is left to sit in evidence for extended periods of time, DNA can still be extracted and used to help identify a suspect.

Touch DNA, Aged Fingerprints, Ninhydrin

B120 The Impact of the Length of Time of Personal Contact on Secondary DNA Transfer

Cynthia Cale, BS, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241; Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; and Gay L. Bush, PhD, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241*

After attending this presentation, attendees will appreciate how much contact may be necessary for secondary DNA transfer to occur and the potential impact on forensic investigations. The learning objectives are to evaluate the detection of secondary DNA transfer using next generation amplification kits, to investigate the length of contact time that might result in secondary DNA transfer, and to assess the impact of secondary DNA transfer on determining how evidence relates to a crime scene. The hypotheses are that secondary DNA transfer: (1) can occur during brief periods of contact; and, (2) can complicate interpretation of DNA evidence.

This presentation will impact the forensic science community by demonstrating that secondary DNA transfer can occur during brief encounters and that it can have a significant impact on understanding evidence in relation to a crime scene.

The analysis of trace amounts of DNA from items possibly handled by a suspect during the commission of a crime often plays a crucial role in criminal investigations. In some cases, DNA left on a touched object can be the only link to the perpetrator. The increased capability to detect minute traces of DNA from a perpetrator at a crime scene has been a continuous goal of the forensic community. While enhancing the sensitivity of Short Tandem Repeat (STR) kits to increase the likelihood of obtaining results from trace DNA samples, there also appears to be a simultaneous increase in the detection of extraneous DNA, the presence of which can complicate the identification of a suspect.

Empirical research has not only demonstrated the primary transfer of DNA via direct contact with an object, but also the secondary transfer of DNA whereby an individual's DNA is transferred to an object or another individual via an intermediary. The indirect transfer of DNA as an explanation for the presence of trace DNA samples at a crime scene appears to be becoming more prevalent in forensic investigations and during the subsequent court proceedings. In Europe, the focus of forensic investigation appears to be moving toward not only identifying the source of a DNA profile, but identifying how the DNA was deposited on an evidentiary item — directly or indirectly.[1,2]

Expanding upon the Cale et al. study by introducing additional variables, this project used handshaking to simulate contact that could lead to secondary DNA transfer.[3] Participants shook hands for varying lengths of time: 10, 30, and 60 seconds. Plastic knives were handled immediately following contact. The knife handles were subsequently sampled for DNA using a wet swabbing technique. The samples were amplified with the GlobalFiler® Polymerase Chain Reaction (PCR) Amplification Kit and analyzed on an ABI® 3130xl genetic analyzer. The Mixture Analysis Tool within GeneMapper® ID-X version 1.5 was utilized to facilitate data interpretation.

Data was obtained from all samples (n=72). Interpretable DNA profiles were obtained from 38 samples. The DNA yields for samples that resulted in interpretable profiles ranged from 50pg to 3ng. In 26 of the 38 interpretable profiles, single-source profiles or mixed DNA profiles with the major component matching the primary contributor were obtained. Five contributor inversions were observed, where the secondary contributor matched the major component of a mixed DNA profile. Indistinguishable mixtures of both contributors were obtained from seven samples, making it difficult to identify the primary handler of the knife. In the remaining 34 samples, the presence of alleles from the secondary contributor and/or extraneous DNA rendered the profiles inconclusive. Consequently, secondarily transferred DNA complicated the interpretation of DNA typing results in those samples.

Mixed DNA profiles are often obtained from trace DNA samples in which multiple handlers of an object can be detected. Typically, the greatest proportion of the DNA comes from the most recent handlers, but not necessarily the last handler.[4] In some instances, an individual who did not directly handle the object can be detected. The results of this study demonstrate that under certain conditions, secondary DNA transfer can occur during brief interactions. The presence of DNA transferred through an intermediary to an object can make the identification of the primary handler of an object difficult. Forensic DNA analysts need to be cautious when assessing the likelihood of one mode of transfer over another as an explanation for the presence of an individual's DNA at a crime scene.

B121 Statistical Modeling of the Case Information From Ohio's Sexual Assault Kit (SAK) Testing Initiative

Jaimie E. Kerka, 31307 Fairwin Drive, Bay Village, OH 44140; D.J. Heckman, BS, BGSU, Math Dept, Bowling Green, OH 43404; James Albert, PhD, BGSU, Math Dept, Bowling Green, OH 43404; Jon E. Sprague, PhD*, Center for the Future of Forensic Sci at BGSU, 39 College Park, Bowling Green State University, Bowling Green, OH 43403; and Lewis O. Maddox, PhD, Ohio BCI&I, 4055 Highlander Parkway, Richfield, OH 44286*

After attending this presentation, attendees will be informed concerning: (1) the application of logistic regression model to forensic science; and, (2) lessons learned from the Ohio SAK Initiative.

This presentation will impact the forensic science community by demonstrating that the application of logic regression modeling to SAK processing can be used to provide insight into whether a sample might yield a Combined DNA Index System (CODIS) -eligible DNA profile.

There is limited comprehensive data documenting the progression and results of statewide SAK forensic testing. The state of Ohio has now analyzed SAKs that did not initially undergo DNA testing, and a wealth of information now exists regarding the DNA test results from nearly 14,000 kits processed because of Ohio's SAK Initiative. Case information from a sample of 2,500 completed SAKs was collected in order to investigate a number of relationships regarding SAK data. Data collected from the SAK case files included: (1) pertinent information from the nurse notes taken at the time of the kit collection; (2) whether or not a particular forensic sample was collected; (3) whether or not a sample yielded foreign DNA; (4) whether the sample produced a CODIS-eligible DNA profile; (5) whether the sample resulted in a CODIS hit; and, (6) the total number of samples run in the first round of testing.

The majority of the focus of the study involved analyzing the results of DNA testing by swab or sample location (vaginal, anal, oral, hair, clothing, etc.). A logistic regression model was fit to the data to predict whether or not a kit contained CODIS-eligible DNA profiles. The individual effects of variables identified early in the study on the response were observed. The number of days a victim waited between the date of the sexual assault and SAK collection significantly impacted the probability of obtaining a CODIS-eligible DNA profile. As the wait time increased, the probability of obtaining a CODIS-eligible DNA profile decreased. The probability of obtaining at least one CODIS-eligible sample from a kit varies as a function of victim age and days to kit collection. The impact of years to kit submission to the laboratory for testing is being further investigated. Days to submission were more significant than years until testing. This study demonstrates that application of logic regression modeling to SAK processing can be used to provide some insight into whether a sample might yield a CODIS-eligible DNA profile.

CODIS, SAK, Statistics

B122 The Development of Epigenetic DNA Methylation Markers to Predict Tobacco Smoking of Unknown Suspects

Hussain J.H. Alghanim, MS, Florida International University, 6833 SW 106th Court, Miami, FL 33173; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to demonstrate to attendees a new method to predict tobacco smoking behavior based on DNA samples recovered from crime scenes.

This presentation will impact the forensic science community by proposing a novel and effective pyrosequencing-based technique able to determine smoking habits of a suspect based on the blood or saliva samples left behind at a crime scene. This presentation will illustrate the model used to distinguish tobacco smokers from non-smokers.

Recent developments in the analysis of epigenetic DNA methylation patterns have demonstrated that certain genetic loci show correlation with the tobacco smoking.[1,2] It is the goal of this study to identify a set of epigenetic methylation markers that exhibit variations in DNA methylation with tobacco smoking and can be used in forensic laboratories. In forensics, finding a suitable biomarker for tobacco smoking could be a very useful tool for predicting the individual's lifestyle. These results may prove beneficial in determining the potential identity of a suspect by narrowing the range of those who could have been the source of the recovered samples.

Different epigenome association studies have reported various genetic loci in which methylation levels were associated with tobacco smoking. From those previous studies, five genetic loci (AHRR, ALPP, IER3, GFI, and F2RL3) that contained smoking-related CpG sites have been identified; however, those results were based on chip arrays that only provide information on single CpG sites.[1,2] Initially, a total of 52 novel CpG sites located on the five genetic loci were examined to check their correlation with tobacco smoking. Among those tested, CpG sites at the AHRR gene were found to have the strongest correlation with tobacco smoking. Biological samples of blood and saliva were collected from volunteers based on smoking status: current smoker and non-smoker. DNA samples were extracted and bisulfite was modified in order to convert the unmethylated cytosines to uracil while maintaining the methylated ones as cytosine. Next, the DNA was Polymerase Chain Reaction (PCR) amplified, and the methylation level at each CpG site was quantified by pyrosequencing.

A prediction model for tobacco smoking was constructed using a set of CpG sites at the AHRR gene. This DNA methylation-based model was very effective in predicting a history of smoking habits using blood samples and was less informative when tested using saliva. Methylation patterns for all CpG sites used in the model exhibited a statistically significant decrease in average methylation levels for smokers when compared to non-smokers. The results indicate that specific CpG sites in AHRR could be used as potential epigenetic markers to predict specific individual lifestyle (tobacco smoking) using blood and saliva specimens. As a result, these epigenetic markers could be used to provide investigative leads in cases with unknown perpetrators.

Tobacco Smoking, DNA Methylation, Pyrosequencing

B123 The Development of a Paper Microfluidic Device for the Detection of Organic Smokeless Powder Residue

Kathryn R. Chabaud, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199; and Ilaria Pirazzini, MS, University of Bologna, Via Zamboni 33, Bologna 40126, ITALY*

After attending this presentation, attendees will better understand current research relating to the development of microfluidic Paper-based Analytical Devices (μPADs) as an easy and cheap alternative to current presumptive field-testing of low explosives, particularly smokeless powders. Minimal training is required to operate these devices and they are ideal for use in the field by the military and law enforcement. Attendees will also gain a basic understanding of the organic compounds contained in smokeless powders.

This presentation will impact the forensic science community by providing insight into the possibility of cheap, user-friendly, presumptive testing devices for smokeless powder residues.

In this project, colorimetric tests are implemented on paper microfluidic devices, permitting organic residues from smokeless powders to be detected in the field. Paper microfluidic devices are usually prepared from chromatographic paper. For these particular devices, wax printing was followed by lamination at elevated temperatures to create hydrophobic wax barriers and hydrophilic channels. Capillary action is then used to mobilize liquids containing dissolved analytes through the channels of the device. Colorimetric reagents are placed at the end of each channel for detection of the individual compounds, which are, in this case, organic additives. Paper-based microfluidic devices were initially designed for application in medicinal and disease testing in remote areas where the lack of refrigeration limited the ability to store expensive reagents. Because reagents are dried on the device prior to use, shelf lives are prolonged when compared to these liquid reagents. μPADs now have a wide variety of applications. This research been exploring forensic applications of this technology. In this project, a paper microfluidic chip has been developed that involves presumptive, colorimetric tests for multiple different organic compounds contained in smokeless powder residues.

Residue from smokeless powder-based explosive devices mainly consists of nitrocellulose and other organic compounds. Contained within the powder are additive packages that consist of energetic materials such as nitroglycerine, deterrents such as dibutyl phthalate, plasticizers such as ethyl centralite, and stabilizers such as diphenylamine. For this project, a paper microfluidic device for the detection of various organic smokeless powder additives is currently being developed. For example, potassium hydroxide has been used for the colorimetric detection of dinitrotoluenes producing a green color and the Greiss reagent can be used for the detection of nitroglycerine producing an orange/brown color. These tests, among others, were first prepared in solution and then optimized for use on paper.

These devices are currently undergoing developmental validation to measure the reproducibility, stability, and sensitivity of the analysis. These paper-based devices should prove useful to the analysis of smokeless powder residue, as the chips are compact and minimal time is needed to produce results. The ultimate goal of this project is to design and test a series of these devices for the presumptive detection of a variety of explosives residues in the field.

Smokeless Powder, Paper Microfluidics, Low Explosives

B124 Determining the Threshold of Identification Via Gas Chromatography/Mass Spectrometry (GC/MS) of Weathered Gasoline Extracted From Nylon Carpet

Charlotte Allison Newton, 1884 Edgewood Road, Parkville, MD 21286; and Ellen Hondrogiannis, Towson University, Dept of Chemistry, 8000 York Road, Towson, MD 21252*

After attending this presentation, attendees will understand how the amount of weathering a gasoline sample undergoes can impact the threshold of identification for GC/MS for ignitable liquid analysis.

This presentation will impact the forensic science community by establishing a method for determining the threshold of identification for ignitable liquids. This method may be used to optimize GC/MS instrument analysis, allow for comparison of data between instruments, and eventually let a minimum threshold of identification be set and become part of quality assurance programs.

The Organization of Scientific Area Committees (OSAC) defines the threshold of identification as the minimum concentration of ignitable liquid that can be identified from GC/MS spectra using accepted pattern identification criteria. A method for determining this threshold for ignitable liquids has not been established. Variation in the ion ratios of weathered gasoline samples has also not been investigated.

Due to its frequent use as an accelerant, gasoline was used as the ignitable liquid in this study. Weathered gasoline samples were used because they are more representative of what is recovered from arson scenes.

Neat gasoline samples were weathered to varying percents (50%, 75%, 90%, and 99%) by volume. All samples were prepared in duplicate. A system blank and a positive control were also prepared alongside the samples. The nylon carpet matrix was prepared by burning the substrate for ten seconds with a blow torch. The burned carpet samples were spiked with gasoline and an internal standard. The spiked carpet was then extracted using passive headspace according to the American Society for Testing and Materials (ASTM) 1412. The carbon strips were desorbed using carbon disulfide.

GC/MS analysis, using an Agilent® 7890a GC with a 5975C MS, was performed in this study. A temperature program consistent with ASTM 1618 was used to analyze the samples.

Data was interpreted by examining the ratio of the base peak area counts to the qualifier ion area counts for ten target compounds. The area counts for the internal standard were used to correct for instrument variation. Target compounds were chosen based on ASTM 1618 guidelines and compounds that would still be present in a largely weathered sample. The chosen compounds were dodecane, 1,2,3,-trimethylbenzene, 2-ethyl-1, 4-dimethylbenzene, 1-ethyl-2,4-dimethylbenzene, 1,2,3,4-tetramethylbenzene, 1-methyl-indane, 3-phenylbut-1-ene, naphthalene, and 2-methyl-napthalene. Neat gasoline peak ratios were used to establish an acceptable range for the peak ratios of the weathered samples. The acceptable range was considered to be within ±20% of the neat gasoline peak ratio.

GC/MS, Arson, Threshold of Identification

B125 The Characterization of Propellants in Shotgun Cartridges by Isotope Ratio Mass Spectrometry (IRMS) and X-Ray Fluorescence (XRF) Spectroscopy

Nam Yee Kim, National Forensic Service, 10 Ipchun-ro, Wonju-si, Seoul 26460, SOUTH KOREA; and Hye-Jin Choi, National Forensic Service, 10, Ipchun-ro, Wonju-si, Gangwon-do 26460, SOUTH KOREA*

After attending this presentation, attendees will better understand the application of Gas Chromatography (GC) IRMS and XRF to the characterization of propellants in shotgun cartridges.

This presentation will impact the forensic science community by demonstrating how isotope ratio analysis by GC/IRMS and elemental analysis by XRF can differentiate propellants in shotgun cartridges from various brands and countries.

Although firearm-related deaths are not as common as in the United States and other countries, a shotgun is occasionally encountered in violent cases in South Korea. In this research, nine shotgun cartridges (shotgun shells) of seven different brands that were produced in four different countries were purchased to characterize the propellants and differentiate between various brands and countries. First, organic components of propellants in the pre-shot cartridges were analyzed by Thin Layer Chromatography (TLC), color test, and Gas Chromatography/Mass Spectrometry (GC/MS). In order to be able to differentiate the shotgun cartridges, the stable isotope ratios of carbon and nitrogen ($\delta^{13}C$, $\delta^{15}N$) were obtained by GC/IRMS, targeting Nitroglycerin (NG) in the propellant from each cartridge. For shotgun shells in which NG was not detected, bulk samples were analyzed by Elemental Analysis/IRMS (EA/IRMS) to obtain stable isotope ratios of carbon and nitrogen ($\delta^{13}C$, $\delta^{15}N$) for nitrocellulose and additives of the propellants. This is because most explosives (including propellants in shotgun shells) are mixtures with additives at low levels.

The results of the stable isotope analysis revealed that NG is a major component of the propellant in the five shotgun shells from four different brands out of nine cartridges. Although it was not possible to detect NG in four shotgun shells of three different brands, nitrocellulose and additives were identified in four cartridges. In addition, it was possible to differentiate shotgun cartridges based on their brands and countries by means of their characteristic stable isotope ratios of carbon and nitrogen. Elemental analysis of propellants from nine cartridges was also performed by X-Ray Fluorescence (XRF)spectroscopy. It was found that each shotgun shell displayed characteristic compositions of multiple elements. As a result, they could be differentiated based on their relative amounts of potassium (K), iron (Fe), cupper (Cu), and lead (Pb), categorizing them into five groups.

This study demonstrated that XRF and IRMS are useful techniques to differentiate propellants in shotgun shells as screening and confirmatory methods, respectively. With the combination of two methodologies, it is expected that the differentiation of propellants in shotgun shells is readily possible in forensic firearm analysis.

Shotgun Cartridges, IRMS, XRF

B126 An Explosives Analysis With Portable Ion-Trap Gas Chromatography/Mass Spectrometry (GC/MS) for Battlefield Forensics

Kayla M. Moquin, 35 Sunnyslope Avenue, Agawam, MA 01001; Pauline E. Leary, PhD, Smiths Detection, 1934 Bulls Head Road, Stanfordville, NY 12581; and Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will better understand how portable ion-trap GC/MS with Solid-Phase Microextraction (SPME) sampling is used to detect explosive residue for applications in the area of battlefield forensics.

This presentation will impact the forensic science community by evaluating the method parameters used by the portable GC/MS to determine the most efficient mode of explosives testing in the field.

Recent advancements in portable GC/MS instrumentation have enabled the field analyses of explosives and explosive residues by emergency responders, the military and law-enforcement organizations. For battlefield forensics, portable GC/MS instruments are used for the detection and confirmatory identification of threats pre- and post-explosion to provide intelligence, investigation, and adjudication information. Traditional analysis for explosives involves sample selection, collection, packaging, transport, laboratory analysis, and data interpretation; however, there are many challenges to this type of analysis, and if there are any errors in the process, such as incorrect sampling or packaging, the results may be meaningless. Time is also important. The ability of a commander to make decisions in near real-time with data collected and interpreted at the scene can be critical. Additionally, because many explosives readily decompose or evaporate, it is imperative that analysis be completed in a short time frame, which is not always possible due to remote military locations or laboratory backlogs. Although the on-scene detection and analysis of explosives by portable Ion Mobility Spectrometry (IMS) has been used for years, this is a presumptive test that suffers from both false positive and false negative results. Using modern, portable GC/MS instruments in the area of battlefield forensics is crucial as it provides an easy user interface that provides clear confirmatory results in a short time frame, which is important when the chemical being searched for may endanger lives.

The portable GC/MS system used in this research uses a Low Thermal Mass (LTM) resistively heated capillary column directly linked with a miniaturized toroidal ion trap mass spectrometer. The LTM capillary GC column enables fast separation and thermal recovery, resulting in rapid consecutive runs of approximately five minutes. Sample collection was performed using Solid-Phase Microextraction (SPME) with direct injection via thermal desorption from the SPME into the GC/MS inlet. SPME is especially useful in field-portable settings because it provides an easy, small, lightweight, and solvent-free method for sample collection. Using SPME for explosives analysis removes the need to perform extensive extraction procedures that significantly complicate the analysis and is thus difficult to perform in the field.

In this research, 12 different explosives covering both military (e.g., PETN, RDX) and homemade (e.g., TATP, HMTD) explosives were deposited onto the SPME fiber and separately injected into the GC/MS. Various parameters (e.g., injection port temperature, column temperature, and ramp rate) were adjusted to determine an optimal method for detection and identification of the explosive. This method development is important because there is a need for a cooler-temperature method than the standard test method employed to test for dangerous toxic industrial chemicals and chemical warfare agents. Many explosives degrade at higher temperatures, which can make their analysis challenging. The current standard method for the portable GC/MS employs an inlet temperature of 270°C, a column start temperature of 50°C with a hold time of ten seconds, and a ramp rate of 2°C/second, resulting in a total run time of 180 seconds. Eleven of the 12 explosives were detected and identified at amounts of 200ng. Explosive compounds that have traditionally been difficult to identify, such as TATP, were readily detected using all methods tested. RDX was the only non-identified explosive, which was not surprising given that it is notoriously difficult to detect by GC/MS due to its rapid thermal decomposition. It was concluded that a lower temperature method than what is currently implemented is a superior alternative for the detection of explosives in the field by portable GC/MS because it yields less degraded results.

Portable GC/MS, Explosives, Battlefield Forensics

B127 An Examination of Striations on Bullets Discharged From 3D-Printed Metallic Gun Barrels

Jennifer Turner, MS, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; Robert Baldwin, JD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Scott Golightly, BS, Sam Houston State University, Management & Marketing Dept, 1821 Avenue I, Huntsville, TX 77341; Pamela Zelbst, PhD, Sam Houston State University, Management & Marketing Dept, Huntsville, TX 77341; and Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will better understand the 3D printing process to design and manufacture firearms. Direct Metal Laser Sintering (DMLS) will be used as an example to discuss the new manufacturing process and its potential influences in firearms examination.

This presentation will impact the forensic science community by providing new data in firearms examination of 3D-printed metallic gun barrels and tool marks left on bullets associated with them. Two identical metallic gun barrels 3D printed from the same digital file were used to test the impact of 3D manufacturing in firearms examinations.

3D printing is a manufacturing process that potentially can transform a virtual digital model into a real-world 3D solid object. This process has been a popular technique to produce a phototype of any design. Because this manufacturing process is becoming affordable and available, 3D printing is becoming a method of choice to manufacture functional product in many industry, including firearms.

In this work, two identical metallic gun barrels were 3D-printed from the same digital file from the same printing chamber. The model was built based on the physical dimensions of a 1911 pistol using a computer software without the use of 3D scanners. Because the roughness of the 3D-printed gun barrel surface, some exterior surface of the barrels required some hand-fitting in order to fit into a 1911 pistol. The surface of the interior part of the gun barrel was left untreated in this study. After fitting the barrels, 100 cartridges were discharged from each of these two identical barrels to examine and compare striations left on the bullets.

The first 50 rounds, from both barrels, discharged without incident. The only issue noted was that a substantial number of test fires did not properly extract and resulted in a stove-piped cartridge case. At approximately the 65th test fire, from each barrel, the slide started to lock up and would not cycle back to allow the cartridge cases to extract. Due to the locked slide, it became necessary to tap the slide back with a ball-peen hammer to remove the fired cartridge case. Multiple attempts were made to clean, dremel, and oil the chambers in hopes of improving extraction, none of which proved successful, and the locking up continued through the end of the 100 test fire cycles. Post-printing surface treatment of the barrel may be needed to eliminate this issue. Examination of the 100 fired bullets from either barrel revealed that all 100 bullets could easily be identified to each other. The striations maintained their consistency in individual characteristics over the course of the test firing. When comparing the test fires from two identical 3D printed barrels, the bullets were easily eliminated as having been fired from the same barrel.

Firearms Examination, 3D Printing, Direct Metal Laser Sintering

B128 Bridging the Gap Between Categorical and Probabilistic Statements in Fire Debris Analysis

Mary R. Williams, MS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367; and Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will better understand Receiver Operating Characteristic (ROC) curves and how they depict the relationships between categorical decisions and evidentiary value.

This presentation will impact the forensic science community by exploring these and other relationships between categorical decision thresholds and likelihood ratios as applied to fire debris evidence.

The paradigm shift from categorical statements to statements of evidentiary value are facilitated by ROC curves and the visual representation they provide of the relationships between the strength of the evidence, decision risk and cost, and other related parameters.

A categorical statement implies that a decision has been made regarding some aspects of a forensic examination. For example, it may be categorically stated that a fire debris sample contains residue of an ignitable liquid from one of the American Society for Testing and Materials (ASTM) E1618 classes.[1] When a categorical statement is made, it is also implicit that the analyst has set some threshold upon which the decision is based. Unfortunately, the current system of fire debris analysis does not define and implement a numerical scale for setting a decision threshold, and consequently analyst bias is possible. In addition, a categorical decision coupled with a variable decision threshold provides no information regarding the strength of the evidence. It is possible to understand the relationship between decision thresholds and evidentiary value with the assistance of the ROC curve.[2]

Generating a ROC curve requires assigning a score to each sample in a data set. The ground truth (positive or negative for ignitable liquid) must be known for each sample. Samples of known ground truth can be generated in the laboratory; however, the samples must be realistic and representative of casework samples. Assigning a score to each sample is the more complicated task. The score should be a single value and should reflect the probability that a sample belongs to the positive class (i.e., those samples containing ignitable liquid residue). Samples containing a more prominent ignitable liquid profile should receive a higher score. The scores can come from numerical calculations, the application of rules lists, decision trees, or other methods.[3] Once a scoring method has been determined, it is applied to all the samples in the known ground truth data set and each sample is assigned a score. Since the ground truth is known for each sample, along with an assigned score, it is easy to generate a ROC curve by using each score as a threshold and assigning each sample with a score greater than or equal to the threshold as belonging to the positive class. Once the class assignment is made, calculate the true positive and false positive rates and plot these values on an x, y coordinate system. After stepping through all of the possible thresholds, the points are connected to generate the ROC curve. The tangent to the ROC curve at any score gives the likelihood ratio for samples with that score. The slope of a line from the origin (0, 0) through a point on the curve that has been defined as a decision threshold corresponds to the likelihood ratio for all decisions based on that thresholding score.[4]

These and other relationships between categorical decision thresholds and likelihood ratios will be explored for fire debris evidence.

Fire Debris, Likelihood Ratios, ROC Analysis

B129 Useful Characteristics to Assist With Identifying Hornady® Bullets and Their Potential Caliber

Renee Hudson, BSc, Washington State Patrol Crime Laboratory, 2203 Airport Way, S, Ste250, Seattle, WA 98134*

After attending this presentation, attendees will be aware of the various features that can be used to identify Hornady® polymer-tipped bullets. Furthermore, attendees will understand the potential use of cannelure height as a means to determine the specific caliber of .38 caliber-class Hornady® Critical Defense® bullets.

This presentation will impact the forensic science community by increasing awareness of the various features of Hornady® polymer-tipped bullets and the many ways they can be identified. In addition, this presentation will provide insight regarding the potential for cannelure height to be used to determine the specific caliber of .38 caliber-class Hornady® Critical Defense® bullets.

Bullet examinations are a pivotal aspect of firearm/tool mark examinations, especially for cases in which a suspect firearm is not recovered. Information, such as caliber, ammunition manufacturer, and the potential type of firearm, are valuable details that help guide detectives' investigations. For this reason, it is important for examiners to be knowledgeable about the various characteristics that can be used to identify specific ammunition brands and bullet calibers.

Hornady® is an ammunition manufacturer whose signature polymer-tipped bullets (specifically, Critical Defense®, Zombie Max™, and Critical Duty®) have begun to appear more often in casework. There are a few important characteristics that examiners should be aware of to assist in identifying these bullets. Initially, the bullets can be recognized by their polymer tips. The majority of the polymer tips are red; however, pink and green have also been used. Additional features, such as the number of cannelures and the characteristics of the expanded hollow point, can be useful for identifying Hornady® polymer-tipped bullets.

Furthermore, the potential to differentiate 38 caliber-class Hornady® Critical Defense® bullets based on cannelure height, in combination with bullet weight, was explored. In casework, firearm examiners often receive damaged bullets, which can make caliber determination challenging. The ability to utilize cannelure height, along with bullet weight, as a means to determine caliber could further assist in providing specific, useful, investigational information to detectives.

An assortment of 38 caliber-class Hornady® Critical Defense® ammunition was obtained. A bullet was pulled from each specific caliber. The cannelure height was measured from the base of the bullet to the base of the cannelure using calipers and a stage micrometer. From the measurements, it was determined that cannelure height does differ with respect to specific caliber; however, some of the cannelures were fairly close in height. Therefore, it would be difficult to narrow down to one specific caliber. In general, the cannelure height increased as bullet weight increased.

Hornady®, Cannelure, Caliber

B130 The Effects of Varying Decomposition Settings on Powder Stippling Patterns on Skin

Meaghan C. Dougher, BA, Penn State University, Forensic Science Program, 329 Whitmore Lab, University Park, PA 16801; Ralph R. Ristenbatt III, MS, Penn State University, Forensic Science Program, 329 Whitmore Laboratory, University Park, PA 16801; Jason W. Brooks, VMD, PhD, Penn State University, Animal Diagnostic Laboratory, Wiley Lane, University Park, PA 16802; and Peter J. Diaczuk, Penn State University, Forensic Science Program, 329 Whitmore Lab, State College, PA 16802*

After attending this presentation, attendees will better understand the persistence of Gunshot Residue (GSR) patterns over time under varying decomposition variables and be aware of methods to best identify GSR on decomposed skin.

This presentation will impact the forensic science community by illustrating the effect of decomposition on GSR patterns and indicating optimal methods to identify such patterns when visual identification is no longer possible. The chemical methods discussed in this presentation, adapted from traditional form, may assist investigators in the field in identifying firearm evidence on decomposed bodies.

The purpose of this study was to examine the effect of varying decomposition exposure settings on GSR powder patterns, particularly powder stippling patterns, on skin using animals as a model for human skin. The GSR patterns were examined using photography, stereo-light microscopy, and chemical methods.

GSR is of particular forensic importance in firearm-related incidents as it can be used in forensic reconstruction in regard to distinguishing range-of-fire since GSR patterns are defining features of an intermediate range-of-fire.[1] Powder stippling is a specific type of GSR pattern that results from the impact of unconsumed and partially consumed gunpowder kernels with live skin that leads to small, hemorrhagic injuries in live tissue; however, the preservation and condition of these patterns throughout decomposition are dependent on a variety of factors, as even human activity can impact exposure.[2,3] Some case reports have even indicated attempts to conceal the smell of putrefaction via the application of insect repellant.[4]

In this study, 11 anesthetized bull calves were shot with a handgun at a distance of approximately two inches and immediately euthanized. They were then subjected to decomposition in an open field fully exposed and under three altered decomposition settings: buried, covered in vegetation, and covered in insect repellant. Bull calves were chosen since studies have shown that bovine tissue is similar in structure to human skin and exhibits similar decomposition activities to human cadavers.[5] For comparison, the experiment with bull calves was coupled with a series of trials in which fresh pig skin was shot to create GSR patterns and subjected to decomposition fully exposed. The pig skin GSR patterns and bull calves' powder stippling patterns were photographed throughout all stages of decomposition and examined with a stereo-light microscope. When GSR patterns became difficult to identify visually, the patterns were swabbed and subjected to modified Griess and Sodium Rhodizonate tests to test for chemical components of GSR, including nitrites and lead, respectively. Tissue specimens were collected from select bull calves for histology as an additional method of visualization for the presence of GSR.

It is hypothesized that decomposition will progressively alter the physical appearance of the gunshot lesion and GSR pattern, but that visual identification of the patterns will persist up until the stage of advanced decay. Furthermore, purposeful efforts to limit exposure (burial, vegetative covering, or chemical masking) will increase the persistence of patterns that permit visual identification. Finally, it is hypothesized that chemical analyses and histology may be able to identify the GSR pattern in an advanced state of decomposition. Preliminary results of this study have shown that Sodium Rhodizonate tests are the more sensitive chemical method for identifying the presence of GSR in advanced states of decay. The pig skin trials have illustrated that the visual persistence of GSR is impacted by the firearm and ammunition used. Stereo-light microscopy has also identified the presence of unburnt GSR kernels on skin approximately two months decomposed.

Gunshot Residue, Decomposition, Shooting Reconstruction

B131 "Free Range" Gunshot Primer Residue: A Study on Multiple Transfers of Gunshot Primer Residue

Thomas R. White, BS, Texas Dept of Public Safety, Austin Crime Lab, 5800 Guadalupe Street, Austin, TX 78752; Stephanie A. Freiwald, BS, Texas Department of Public Safety, 5800 Guadaupe Street, Austin, TX 78752; and Christopher P. Chany, MS, Texas Department of Public Safety, Austin HQ Crime Laboratory, Trace Section, 5800 Guadalupe Street, Bldg U, Austin, TX 78752*

After attending this presentation, attendees will better understand the number of times gunshot primer residue can transfer from one surface to the next.

This presentation will impact the forensic science community by providing attendees with insight into the dynamics of gunshot primer residue particle transfers from one surface to a second surface to a third surface. This presentation describes the methods used to test this theory of transfer of gunshot primer residue.

Gunshot primer residue is produced by a firearm when it is discharged. The primer for centerfire cartridges is mainly composed of lead styphnate, barium nitrate, and antimony sulfide. The residue from the primer explosion escapes from openings in the gun and can be deposited on a person's hands and clothing. These particles can be collected and analyzed using automated scanning electron microscopy energy dispersive X-ray. Characteristic gunshot residue primer particles have a molten appearance and are composed of barium, antimony, and lead. There have been several studies that examine the transfer of gunshot primer residue to the interior of police cars from a person who has gunshot residue on their person. There have not been studies conducted that try to determine the number of times gunshot primer residue particles could transfer from one surface to another.

This presentation will detail the results of a study on the transfer of gunshot primer residue from a gunshot primer residue-contaminated area to a clean subject who enters the area and subsequently transfers the gunshot residue particles to other surfaces outside the contaminated area.

The firearms section of the laboratory was conducting firearm familiarization training. One of the analysts of the Trace Evidence section of the laboratory attended the training. This analyst does not handle firearms at all. At the end of the training, the analyst was asked to stub her clothing, her cubicle chair, the driver seat of her car, and any chairs that she may have sat in at her home in the same clothing she had worn to the training. These stubs were analyzed using scanning electron microscopy energy dispersing X-ray spectroscopy instrumentation using standard laboratory procedures for the analysis of gunshot primer residue.

This research takes a novel approach by investigating the likelihood of multiple transfers of gunshot primer residue particles between surfaces.

Gunshot Residue, Scanning Electron Microscopy, Contamination

B132 The Sub-Particle Composition and Morphology of Gunshot Residues (GSR)

Nick J. Lucas, MSc, Flinders University, College of Science and Engineering, Flinders Drive, Bedford Park, South Australia 5042, AUSTRALIA; Kelsey E. Seyfang, BSc, Flinders University, College of Science and Engineering, Physical Sciences Road, Bedford Park, South Australia 5042, AUSTRALIA; Paul Kirkbride, PhD, Flinders University, GPO Box 2100, Adelaide 5001, AUSTRALIA; and Hilton Kobus, PhD, Flinders University, Bedford Park, Adelaide 5001, AUSTRALIA*

After attending this presentation, attendees will have a more developed understanding of the variation in sub-particle composition and morphology of different types of GSR and its significance to GSR evidence evaluation.

This presentation will impact the forensic science community by reporting on work that has been conducted in the sectioning and sub-particle analysis of GSR from different types of ammunition and firearms, allowing for a more thorough understanding of the variation in and differentiation of GSR particles that can be demonstrated at this level.

This presentation explores the key hypothesis that GSR particles are not homogeneous and their sub-structure carries valuable information that can be exploited in GSR examination.

Complex interactions in the moments after firing result in the formation of GSR particles.[1] Incorporation of key elements is thought to come principally from the ammunition's primer; however, inclusions from the projectile, casing, and barrel of the firearm are not uncommon.[2] When it comes to the assessment of GSR evidence, the usual standard technique, Scanning Electron Microscopy with Energy-Dispersive X-Ray Microanalysis (SEM/EDS), operates on a whole particle analysis level. While this has been useful in providing a qualitative assessment of the presence of particles characteristic of GSR, detailed characterization and differentiation of particles originating from different ammunition types has been elusive.

Recently, there has been research to suggest that the complexity of GSR formation results in distinct differences in both the sub-particle composition and morphology. Prior studies have indicated that beyond the external morphology and composition, sub-surface morphological differences can be used as a means of identifying particles from different ammunition types.[3] More recent work has suggested the use of a Focused Ion Beam (FIB) to examine the internal composition and morphology of GSR particles as a means of obtaining more in-depth information about a particle's composition and origin.[4,5] Practically, the casework experience has shown that in some situations three component particles are observed in situations where one component – antimony – is absent from the primer mix but is present in the projectile.[6,7] This is most often the case with .22 caliber ammunition, which is common in Australia. The prospect of being able to assess the origin of different particles, or specific components within them, would provide useful information in forensic investigations and GSR research.

This study applies FIB techniques supported by SEM/EDS and X-ray mapping, as well as Auger Electron Spectroscopy (AES) and Time-of-Flight/Secondary Ion Mass Spectroscopy (TOF/SIMS), to GSR particles originating from different ammunition calibers and types, with a view to demonstrating their sub-surface features and heterogeneity. Specific morphological and compositional features were then evaluated as to their relationship to the origin of the particles, with a view to determining if they originate purely from elements in the primer or of a mixed primer and projectile origin. GSR samples were collected from the hands of shooters, following the discharge of a number of different ammunitions. Characteristic particles were then selected and elemental X-ray maps collected using an SEM/EDS system. These particles were then cross-sectioned or had slices collected from them using a gallium ion FIB. The cross-sectioned face of these particles was re-mapped with SEM/EDS to assess internal morphology, composition, and discrete phases. Slices collected from these particles were analyzed using AES and TOF/SIMS in order to provide further compositional information.

Ultimately, this study has demonstrated that in many cases there are distinct sub-particle compositional and morphological features that clearly demonstrate the non-homogeneous nature of GSR particles. GSR examiners could use these features to improve the probative value of GSR examinations.

Gunshot Residue, Criminalistics, Focused Ion Beam

B133 The Refinement of a Mathematical Model to Predict Evaporation of Gasoline

Natasha K. Eklund, BA, Michigan State University, 578 S Shaw Lane, Rm 204, East Lansing, MI 48824; Victoria L. McGuffin, PhD, Michigan State University, Dept of Chemistry, East Lansing, MI 48824-1322; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with the application of a mathematical model that can be used to generate chromatograms of evaporated ignitable liquids. More specifically, this presentation will discuss the refinement of the model to generate chromatograms corresponding to evaporated gasoline in a more accurate manner.

This presentation will impact the forensic science community by providing a method by which chromatograms corresponding to evaporated gasoline can be generated mathematically, thus eliminating the need for experimental evaporation. The modeled chromatograms can be used as a reference collection that can aid in the identification of gasoline present at any evaporation level in fire debris samples.

During an intentional fire, ignitable liquids used as accelerants undergo evaporation, among other processes. To aid in identification, chromatograms of the ignitable liquid residue are compared to a database containing chromatograms of ignitable liquid reference standards. Databases typically contain chromatograms corresponding to the unevaporated liquid, as well as the liquid evaporated to different levels to account for chemical changes as a result of evaporation; however, experimentally evaporating a liquid to different levels can be a time-intensive process with many variables to take into account, for example, agitating or heating the reference liquid.

A mathematical model was developed that predicts the evaporation rate constant of compounds as a function of retention index (I^T). The model was developed using diesel, a heavy petroleum distillate that contains compounds that elute over the I^T range 800–2,200. The predicted evaporation rate constants are used to determine the fraction remaining of each compound which can then be used to generate the modeled chromatogram.

In the initial assessment of model performance, Pearson Product-Moment Correlation (PPMC) coefficients were used to compare modeled chromatograms to those obtained from the corresponding, experimentally evaporated liquid. For the petroleum distillates tested, PPMC coefficients greater than 0.9 indicated strong correlation between the modeled and experimentally derived chromatograms; however, performance was diminished when the model was applied to gasoline, with a mean PPMC coefficient of 0.806±0.004 indicating only a moderate correlation for comparison of the modeled chromatogram and the corresponding chromatogram for a 50% experimentally evaporated gasoline.

This presentation will focus on refinement of the model to improve performance in generating chromatograms corresponding to evaporated gasoline. As a more volatile liquid, gasoline contains compounds that elute in the I^T range 400–1,500; a majority of these compounds were not included in the original model. Thus, the model was refined to broaden the I^T range and, hence, include these more volatile compounds.

To accomplish this, gasoline was experimentally evaporated from 10%–90% (by mass) in 10% increments. Each evaporated gasoline was analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) initially using a 100% polydimethylsiloxane column (100m x 0.25mm i.d. x 0.50µm d.f.). The longer column and thicker stationary phase film were necessary to identify the highly volatile compounds present in gasoline. Using the more conventional 30-m column, these compounds eluted with the solvent front and were not observed.

The performance of the model improved with the more representative chemical profile for gasoline in the experimentally evaporated samples. For example, for comparison of predicted and gasoline experimentally evaporated to 50% by mass, the PPMC coefficient increased from 0.8 to greater than 0.97, which indicated strong, rather than moderate, correlation. To investigate the potential for further improvement, the model was refined to span the wider I^T range 400–2,200. To refine the model, the abundance of the early eluting compounds (e.g., butane, pentane, hexane, and branched isomers of these alkanes) was plotted as a function of evaporation time. The resulting decay curves were fit to the first-order kinetic rate equation to determine evaporation rate constants, which were then plotted as a function of I^T. These data were combined with corresponding data from the original model and linear regression was applied to redefine the model.

This presentation will describe refinement of the model in more detail and will further discuss the improvements in model performance to predict chromatograms corresponding to gasoline evaporated to any level.

Mathematical Model, Gasoline, Evaporation

B134 Assessing Microheterogeneity of Surrogate Post-Detonation Urban Debris (SPUD) Standard Reference Material (SRM) 4600 Using Microbeam X-Ray Fluorescence (µ-XRF)

Barbara L. Fallon, MS, FBI/ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Kevin Pfeuffer, PhD, ORISE/FBI, 2501 Investigation Parkway, Quantico, VA 22135; John L. Malloy, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Mark A. Tyra, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Jacqueline L. Mann, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; and JoAnn Buscaglia, PhD*, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the importance of developing a well-characterized, homogeneous SRM to aid in the development of methods needed to characterize the debris expected from the aftermath of a nuclear attack.

This presentation will impact the forensic science community by discussing how the development of this SRM will facilitate the ability to analyze debris from an improvised nuclear device detonation in a city, aiding intelligence efforts in identifying the responsible parties.

Concerns over the use of nuclear or radiological materials in terrorist attacks have led to the emergence of the nuclear forensics field. This discipline focuses on best practices to evaluate such material both before and after the detonation of a nuclear device. A thorough characterization of pre- and post-detonation materials may aid intelligence efforts to attribute responsibility for an attack by identifying the fuel type, weapon design, production process, production date, and other features of the device.[1] Well-characterized SRMs and Certified Reference Materials (CRMs) are needed to ensure that nuclear forensic measurements will be sufficiently accurate and precise to be legally defensible.

Currently, there is a shortage of SRMs/CRMs needed to develop methods for analyzing pre- and post-detonation nuclear material.[1] In some cases, cost, scarcity, or quality of existing materials is problematic, whereas in other cases, a suitable material simply does not exist. Given the likelihood that a large city would be the target of an attack, efforts have been undertaken to prepare to analyze the debris expected from the detonation of an improvised nuclear device in an urban environment. The National Institute of Science and Technology has led a collaboration to develop two vitrified SPUD SRMs: SRM 4600 and SRM 4601.[2] A glass-like material was selected for its durability, control over what can be added to the mixture, straight-forward mass balance, and relative ease of homogenization. The matrix of the SRMs is a composite of materials and metals present in concrete (cement, crushed stone, and sand) and steel, two of the most common urban building materials. SRM 4600 was doped with natural depleted uranium to serve as a blank; SRM 4601 was doped with Uranium-235 (approximately 22% highly enriched uranium) to serve as a test sample.

As part of the process to certify the major and minor components of the SRMs, non-destructive µXRF measurement with Principal Component Analysis (PCA) on the resulting data was used.[3,4] Sixteen 1.5-gram samples of loose solid SRM 4600, each representing a replicate of the production lot, were prepared in XRF sample cups sandwiched between two sheets of X-ray-transparent film. To assess the homogeneity of the sample, 10,000 spectra were collected at both a single, fixed location and random locations from each of the sixteen "sandwiches." Collecting 5,000 spectra from the same location provided measurements of variability due to the instrument and systemic sources of error. The 5,000 spectra collected from random locations across the "sandwich" represent variability due to both the instrument and sample heterogeneity.

Quantifying the homogeneity of a sample is necessary to identify the effects of "nuggets," small subsamples of the bulk material enriched in certain elements.[3,4] These nuggets, which can vary in size and composition, cause the XRF data to stray from a normal distribution, precluding the use of common statistical measures of variability. PCA is able to take multiple statistical factors from the X-ray map and single location data in order to establish a detection limit for nuggets. The nominal beam diameter of the instrument used is 400µm, and a larger spot size can be simulated by averaging adjacent data points. This process will average out any imperfections present, and the averaging can be repeated iteratively until the PCA treatment indicates no detectable nuggets. From these analyses, a Minimum Sample Mass (MSM) can be calculated, which defines the smallest mass of sample needed for all elements to be homogenous. Preliminary calculations for SRM 4600 suggest an MSM of 3mg is required for reproducible measurements of element concentrations to not be susceptible to sample heterogeneity. This presentation will discuss the analysis of the 16 replicates of SRM 4600, which were analyzed by the above methodology to verify the accuracy of the preliminary MSM calculations and determine if the MSM can be decreased.

Nuclear Forensics, Post-Detonation, Standard Reference Material

B135 Statistical Characterization of Aluminum (Al) Powders in Explosives Using Automated Particle Micromorphometry

JenaMarie Baldaino, MS, 14701 River Walk Way, Apt 389, Woodbridge, VA 22191; Danica Ommen, MS, South Dakota State University, Department of Mathematics & Statistics, Box 2220, Brookings, SD 57007; Cami Fuglsby, South Dakota State University, Department of Mathematics & Statistics, Box 2220, Brookings, SD 57007; Christopher P. Saunders, PhD, 272 Indian Hills Road, Brookings, SD 57006; Jack Hietpas, PhD, Penn State University, 329 Whitmore Lab, University Park, PA 16802; and JoAnn Buscaglia, PhD*, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the forensic potential of automated particle micromorphometry and statistical analysis to aid in making comparisons between questioned and known Al powders.

This presentation will impact the forensic science community by demonstrating the application of Al particle micromorphometry as a quantitative method for the characterization and comparison of explosive evidence, which may also provide valuable lead identification for forensic investigations.

Starting materials for an Improvised Explosive Device (IED) are readily obtainable from local commercial sources. Al powder, a common metallic fuel, has a wide variety of legitimate uses and is widely available without significant regulatory constraints.[1] Al powders can be obtained from industrial manufacturers or can be produced inexpensively using basic instructional manuals and videos. Due to the online sharing of instructional manuals and published books on how to construct IEDs, bomb makers are now informed on the easily accessible household materials that can be used to make explosive chemical mixtures.[2]

Previous results using S Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) showed morphology and surface characteristics can differentiate some methods of Al powder manufacturing (i.e., industrial vs. homemade). Particle micromorphometry may be used as a complementary method to gain additional information to differentiate Al powder sources. This presentation addresses fundamental factors of Al particle metrology, including sample slide preparation, imaging parameters, and potential methods to minimize sampling biases; the statistical methods used to analyze these large multidimensional datasets will be discussed.

Al powder samples were obtained from legitimate industrial manufacturers, various "in-house" production methods, and seized IEDs. The amateur methods were replicated to produce Al powder from easily available sources, including 25 brands of Al foil, 7 brands of metallic spray paints (40 cans), 24 Al ingots melted from Al cans and filed or lathed, 23 pyrotechnics, and 40 catalyst packets from two brands of binary exploding targets. To prepare microscope slides for imaging, a subsample containing ~1,000µg from bulk Al powder was placed into a microtube containing Permount® mounting medium. The solution was mixed until evenly dispersed, then an aliquot of the subsample was placed dropwise onto a microscope slide and a coverslip added. Preliminary statistical analysis on these microscope slide preparations that contained only four subsamples and one aliquot from each subsample determined there were large within-sample variations; therefore, more subsamples are needed for a representative sample of the bulk Al powder. A subset of 17 Al powder samples were prepared using ten subsamples and three aliquots for each subsample. Leave-One-Out Cross-Validation (LOOCV) was performed on this subset of samples and it was statistically determined that seven subsamples of the bulk Al powder and three aliquots for each subsample were sufficient to obtain a representative sample of the bulk Al powder.

Transmitted light microscope images ($n \approx 4{,}200$ fields of view/sample) of the Al samples were acquired using an automated stage and automated Z-focus. Dimensional analysis was calibrated using a National Institute of Standards and Technology (NIST) -traceable stage micrometer; polystyrene spheres of 100µm, 50µm, and 10µm were used as secondary standards to assess linear calibration. Images were batch processed using commercial image analysis software and customized code. Each image was converted to a binary image to enhance edge detection and the particles were counted and measured. Seventeen parameters were measured for each particle within the image field of view, including area, aspect ratio, perimeter, roundness, mean diameter, mean feret, radii (maximum and minimum distance from particle centroid to edge), radius ratio, box height, box width, and fractal dimension. The large multidimensional datasets ($n \approx 90{,}000$-$500{,}000$ particles/sample) were analyzed using an open source statistical package.

The datasets are too large and complex to analyze at this point without some dimensionality reduction. Preliminary work focused on the use of a weighted summary of 17 morphometric measurements on the subsamples. This was achieved by first taking weighted averages of the particles per Fields Of View (FOV) yielding a 17-dimensional vector for each FOV (i.e., average particle for each FOV). Then, the average of the average vectors for each FOV per aliquot was calculated, giving a 17-dimensional vector per aliquot. Likewise, the average vector across the aliquots corresponding to a given subsample was calculated, resulting in one 17-dimensional vector for the entire subsample for each sample. The classification accuracy between sources of Al powders using this weighted approach and results from the various multivariate statistical methods tested will be presented.

Improvised Explosive Devices, Metal Fuel, Image Analysis

B136 A Case Study: Rubber Buckshot Tissue Penetration Capability

Dijana Coric, Washington State Patrol Crime Lab, 2203 Airport Way S, Seattle, WA 98134*

After attending this presentation, attendees will better understand the penetration capabilities of rubber buckshot pellets fired at various distances and at different media.

This presentation will impact the forensic science community by demonstrating the inability of rubber buckshot to penetrate ballistic gelatin, a tissue simulant, from approximately eight yards. The experiments in this presentation were conducted due to a question posed in a case by the submitting agency; therefore, the methodology and results/conclusions can impact the forensic science community by exposing fellow colleagues to an unusual case and the approach that was taken to answer the posed question.

A determination was requested as to whether 12-gauge RIO™ brand rubber buckshot was able to penetrate ballistic gelatin, a tissue simulant, at a muzzle-to-target distance of approximately 40 yards (the approximate distance between the suspect and victim at the time of the shooting). According to the detective and multiple police statements, on November 14, 2015, the suspect indicated that the victim and his friends were trespassing on his property on their All-Terrain Vehicles (ATVs). The suspect proceeded to retrieve his 12-gauge Mossberg® model 500A shotgun and fired two warning shots using RIO™ brand rubber buckshot (marketed as less lethal ammunition). One pellet penetrated the victim's thigh; however, the pellet could not be removed for medical reasons. The victim was wearing four layers of clothing — none of the clothing was collected. The fired shotgun shells could not be located at the crime scene to verify what type of ammunition was fired. The detective had reason to presume that the suspect was not firing less lethal ammunition (i.e., rubber buck shot) but was instead firing lethal ammunition, such as lead buckshot.

Testing was conducted at the Seattle Police Department shooting range and high-speed videos were taken. The Mossberg® 500A shotgun was used to fire 12-gauge RIO™ brand rubber buckshot at cardboard and denim-covered ballistic gelatin at various distances to determine the penetration/perforation ability of the rubber buckshot. The 10% ballistic ordinance gelatin was mixed using standard practices and calibrated using a BB. During testing, the gelatin was not temperature controlled. Ballistic gelatin is intended to simulate soft tissue and does not account for skin, bone, additional layers of clothing, or other intervening materials. At approximately eight yards, all 15 rubber pellets perforated cardboard with an approximate pattern diameter of 24 inches. At approximately 40 yards, four rubber pellets impacted the cardboard, none of the four perforated the cardboard (only 4 of the 30 rubber pellets impacted the cardboard target). At approximately eight yards, two rubber pellets perforated the layer of denim, but there was no penetration of the gelatin (only 6 of the 15 rubber pellets impacted the denim-covered gelatin). Obtaining data for rubber buckshot into gelatin from 40 yards away was not feasible due to the wider pattern distribution of the rubber pellets. That being said, as a projectile travels downrange, it will gradually decelerate; therefore, if the rubber pellets could not penetrate the gelatin at approximately eight yards, it was concluded that they would not penetrate gelatin at approximately 40 yards. In conclusion, the 12-gauge RIO™ brand rubber buckshot pellets did not penetrate/perforate the cardboard at approximately 40 yards or the denim-covered ballistic gelatin at approximately eight yards.

Rubber Buckshot, Ballistic Gelatin, Case Study

B137 Multiple Factors Influencing Probabilistic DNA Mixture Interpretation of Highly Challenging Samples: The Relevance of Deep Validation Studies to Ensure Quality Assurance Requirements in Actual Casework

Paolo Garofano, MD, PhD, Laboratorio Genetica Forense - CAD, Regione Gonzole 10/1, Orbassano (TO) 10043, ITALY; Monica Omedei, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano 10043, ITALY; Giuseppina D'amico, Regione Gonzole 10/1, Orbassano, ITALY; Denise Caneparo, MS, Regione Gonzole 10/1, Orbassano, ITALY; Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY; Roberto Testi, MD, PhD, ASL Torino, Via Lessona 54/12, Torino 10145, ITALY; and Eugenio Alladio, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano (Turin) 10043, ITALY*

After attending this presentation, attendees will better understand how important deep validation studies and Quality Assurance (QA) are in order to establish the limits and the capabilities of laboratories and experts, and how protocols, kits, instruments, and probabilistic software choices may influence the statistical results.

This presentation will impact the forensic science community by providing the ability to establish robust and reliable lab protocols useful when approaching actual casework samples.

DNA mixture probabilistic interpretation is undoubtedly one of the most challenging tasks in forensic genetics.[1,2] In the past ten years, new statistical models and software have been developed in this field to perform more sophisticated calculations to include or exclude a suspect from a complex DNA profile; but can we ever determine that we have enough information, and the right information, to accomplish this?

Multiple factors may affect DNA mixture interpretation and this is obviously due to one-by-one contributor template concentration and integrity, but also to systematic protocols chosen during sample processing. For these reasons, DNA extraction and quantitation methods, typing kits, and Capillary Electrophoresis (CE) instruments play a fundamental role in information used for probabilistic interpretation; results will only be as close to reality as the data used for calculation is reliable.[3,4] Semi-continuous and fully continuous methods play a key role as they take into account different aspects of DNA mixture profiles in qualitative terms, such as quantitative data used for statistics.[5] Therefore, QA processes, for both analysis and probabilistic calculations, can guarantee results' robustness and permit understanding laboratory performances when approaching complex DNA profile interpretation such as Low Template DNA (LT DNA) mixtures derived from trace evidence collected at the crime scene.

The detailed knowledge of each step of the entire validated method from trace evidence to interpreting a DNA mixture profile is certainly the crux to solving the most complicated problems in forensic genetics and, even more importantly, to understanding if laboratories and experts have all the puzzle pieces to accomplish this.

Multiple quantitation kits, typing kits, instruments, and probabilistic software results will be presented in order to underline their characteristics and differences, revealing what expectations experts may have for each of them during the interpretation of actual casework.

DNA Mixture Interpretation, Validation, QA

B138 Probabilistic Prediction of the Number of Contributors in DNA Mixtures Using a Machine Learning-Based Approach

Michael Marciano, MS, Forensic and National Security Sciences Institute, Syracuse University, 1-014 Center for Science and Technology, Syracuse, NY 13244-4100; and Jonathan Adelman, MS*, Syracuse University, CST 1-014, 100 College Place, Syracuse, NY 13244*

The goal of this presentation is to present the state-of-the-art approach to the prediction of the number of contributors in DNA mixtures, an area of significant need in the forensic science community.

The prediction of the number of contributors remains a significant gap in the available suite of forensic software tools. This is an approach that is believed could be seamlessly implemented into the standard workflow. This presentation will impact the forensic science community by informing attendees of possible methods to combat this issue. Attendees will be equipped with the information necessary to bring this information back to their labs to discuss the positives and negatives of this approach.

DNA mixture interpretation remains one of the most significant areas of need in the forensic community. The success of many current mixture interpretation approaches relies on the assumption that the number of contributors is correctly predicted. When this presumption is incorrect, it may lead to decreased likelihood ratios or incorrect exclusions or inclusions, particularly when faced with increasingly complex mixtures of three or more contributors. The use of machine learning to probabilistically estimate the number of contributors in a DNA mixture is proposed in this presentation. A machine learning algorithm is a statistical tool that can, after exposure to an initial set of data, be used to classify previously unseen data. Machine learning approaches excel when faced with complex problems involving implicit patterns (such as the problem of successfully classifying three- and four-person DNA mixtures). These algorithms are specifically capable of learning probabilistic models that can be subsequently used for prediction. Such a predictive model was created using a support vector machine, and the model's performance was compared against currently used methods for predicting the number of contributors.

The model had an accuracy of greater than 98% in identifying the number of contributors in a DNA mixture of up to four contributors. A comparison to approaches utilizing Maximum Allele Count (MAC) and Markov Chain Monte Carlo (MCMC) methods exhibited a greater than 6% improvement in classifying three-contributor samples and an improvement of more than 20% when assessing four-contributor samples. The Probabilistic Assessment for Contributor Estimation (PACE) also accomplishes classification of the number of contributors for mixtures of up to four contributors in less than one second using a standard laptop or desktop computer. The initial assessment of classification via machine learning relied on samples amplified using the AmpFℓSTR® Identifiler® Polymerase Chain Reaction (PCR) Amplification Kit, primarily due to the availability of large data sets. The functionality of the system has been broadened to address the new expanded-locus Combined DNA Index System (CODIS) kits, such as the PowerPlex® Fusion PCR amplification kit, with data analysis currently nearing completion.

Considering the high classification accuracy rates of PACE, the inherent complexity of standard methods to classify three or more contributors, and the lack of rapid alternatives, this approach provides a promising means of estimating the number of contributors and, subsequently, will lead to improved DNA mixture interpretation.

Number of Contributors, Mixture, Machine-Learning

B139 Validating TrueAllele® Interpretation of DNA Mixtures Containing up to Ten Unknown Contributors

Nasir A. Butt, PhD, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106; David W. Bauer, PhD*, Cybergenetics, Pittsburgh, PA 15213; and Mark W. Perlin, PhD, MD, Cybergenetics, 160 N Craig Street, Ste 210, Pittsburgh, PA 15213*

After attending this presentation, attendees will understand the reliable interpretation of low-level DNA mixtures containing many people. Fully Bayesian computer methods can accurately extract identification information from complex DNA evidence.

This presentation will impact the forensic science community by providing empirical support for sophisticated scientific interpretation of DNA evidence often found in criminal justice applications.

Mixed samples of known genotype composition were prepared following a randomized experimental design that included very low contributor amounts. The mixture samples contained from two to ten contributors. The Cuyahoga County Regional Forensic Science Laboratory (Cuyahoga) amplified the samples using a PowerPlex® Fusion Short Tandem Repeat (STR) kit. Cybergenetics and Cuyahoga independently conducted TrueAllele® casework testing to interpret the DNA mixture data.

TrueAllele® provides fully Bayesian analysis. The system examines all STR data without human intervention, without knowing the comparison genotype; data objectivity eliminates contextual bias. The computer extracts all information from the evidence data, inferring genotypes and other parameters; the model completely eliminates unneeded calibration. Inferred evidence genotypes are compared with references only after genotypes have been separated from DNA mixture data; the two-phase Likelihood Ratio (LR) approach enforces objectivity.

The study examined sensitivity, specificity, and reproducibility of TrueAllele® match information. Fewer contributors in a mixture generally improved these metrics. With more contributors, longer Markov Chain Monte Carlo (MCMC) statistical sampling increased accuracy. Assuming excess contributors did not affect match information for true contributors, but added superfluous genotypes containing little information.

Sensitivity: As contributor number increased from two to six, average match strength decreased from 24 to 5 LR log units ("ban"). With up to four contributors, only positive log (LR) values were observed.

Specificity: As contributor number increased from two to six, average specificity decreased from -33 to -13 ban. When comparing with non-contributors, a match statistic of more than a thousand had a false positive probability of under 0.0001. With LR more than a hundred thousand, the probability decreased to less than 0.000001.

Reproducibility: Fewer contributors conferred greater reproducibility. The within-group standard deviation for two contributors was 0.17 ban, and for six contributors was 1.00 ban.

DNA Amount: Match information depended on a contributor's DNA amount, regardless of how many contributors were in the mixture. (More contributors mean less DNA per contributor.) Contributors comprising less than 10% of the mixture exhibited an average log (LR) of 3 ban; however, with fewer contributors, the match statistics were higher. Major contributors (more than 50%) averaged 28 ban. Contributors over 20% gave positive log (LR) values, regardless of how many contributors were present.

Contributor Number: When given the number of contributors a user observed in the data, the computer's mixture solutions were better than when given the expected number known from the study design. This result demonstrated application robustness, as practiced by forensic analysts on DNA mixtures.

Assumed Genotypes: With low-level minor contributors, providing the computer with known (i.e., previously matched) references reduced uncertainty in genotype inference. For a 15% minor in a ten-person mixture, the log (LR) value increased from 3 to 8 ban when assuming previously matched references as known genotypes. The log (LR) value for a 2% minor in a ten-person mixture increased from 1 to 4 ban. When assuming known genotypes, specificity improved — the non-contributor log (LR) average shifted from -3 to -6 ban.

MCMC Sampling: More MCMC sampling increased sensitivity. With six contributors, MCMC sampling at five thousand cycles gave an average log (LR) of 2.4 ban for true contributors; this increased at one hundred thousand cycles to 5.2 ban. Specificity was essentially unchanged by further MCMC sampling, so faster run times did not increase false positives. Regardless of contributor number, reproducibility at one hundred thousand cycles revealed a between-run variability of less than 1 ban.

Independent Testing: Cybergenetics average match statistic for true contributors was 8.52 ban, while Cuyahoga's average was 8.24 ban. On average, the log (LR) values for independent comparisons conducted at the two sites were within 1.15 ban.

A validation study showing reliable interpretation of complex DNA evidence will be presented.

DNA Evidence, Mixture Validation, Bayesian Computing

B140 Autosomal, Chloroplast, and Mitochondrial Data of a United States Cannabis DNA Database

Rachel M. Houston, BS, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340; and David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will understand the basic principles behind employing both autosomal and lineage (mitochondrial and chloroplast) markers for individualizing and sourcing marijuana samples.

This presentation will impact the forensic science community by demonstrating the applicability of an autosomal and lineage panel that could not only assist law enforcement agencies in verifying legal marijuana products but also aid in the linkage of illegal cases. These methods could also serve as additional tools to previously established marijuana profiling programs used in federal agencies such as the United States Customs and Border Protection (CBP) and the Drug Enforcement Administration (DEA).

Since *Cannabis sativa* (marijuana) is a controlled substance in many parts of the world, the ability to track biogeographical origin of cannabis could provide law enforcement with investigative leads regarding its trade and distribution. Population substructure and inbreeding cause individual marijuana plants to become more genetically related. This genetic relatedness can be helpful for intelligence purposes. Using autosomal, chloroplast, and mitochondrial DNA allows not only for prediction of biogeographical origin of a plant, but also allows its genetic identification.

A previously validated 13-autosomal Short Tandem Repeat (STR) multiplex was used to genotype 496 samples. Samples were analyzed from four different sites: 21 seizures at the United States-Mexico border, Northeastern Brazil, hemp seeds purchased in the United States, and the Araucarian area of Chile. In addition, a previously reported multi-loci system was modified and optimized to genotype five chloroplast and two mitochondrial markers. For this purpose, two methods were designed: a homopolymer STR pentaplex and a Single Nucleotide Polymorphism (SNP) triplex with one chloroplast (cscp001) marker shared by both methods for quality control. For successful mitochondrial and chloroplast typing, a novel real-time Polymerase Chain Reaction (PCR) quantitation method was developed and validated to accurately estimate the quantity of the chloroplast DNA (cpDNA) using a synthetic DNA standard. In addition, a sequenced allelic ladder was designed for the homopolymer STR pentaplex.

For autosomal typing, distinguishable profiles generated from 381 samples that yielded full STR profiles and 44 duplicate genotypes within seizures were observed. Phylogenetic analysis and case-to-case pairwise comparisons of 21 seizures at the United States-Mexico border, using F_{ST} as genetic distance, revealed the genetic association of nine seizures that formed a reference population.

For mitochondrial and chloroplast typing, subsampling was performed and 141 samples were genotyped. Complete haplotypes (STRs and SNPs) were observed for 134 samples. As expected, extensive haplotype sharing was observed; five distinguishable haplotypes were detected. In the reference population, one haplotype was observed 39 times in addition to two other unique haplotypes. Haplotype sharing was observed between the United States border seizures, Brazil, and Chile, while the hemp samples generated a distinct haplotype.

Results revealed that both autosomal and lineage markers could discern population sub-structure. Phylogenetic analysis of the four populations using the neighbor joining method and F_{ST} as genetic distance were estimated with the GDA software. Parsimony analysis was then performed with the PAUP* software. The STRUCTURE software was employed to investigate the population structure among groups. And finally, the R package, adegenet, was used to visualize the genetic distance of the populations using Principal Component Analysis (PCA).

In conclusion, the results of this research demonstrate the utility of both autosomal and lineage genotyping methods for characterizing marijuana samples.

Forensic Botany, *Cannabis sativa*, DNA Database

B141 The RoarPlex – A Novel Tetranucleotide Microsatellite and Sex Identification Panel

Colton L. Ames, 1084 Maple Avenue, DuBois, PA 15801; Jan E. Janecka, PhD, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15282; Nickolas P. Walker, 6370 Woodland Court, East Amherst, NY 14051; and Lisa R. Ludvico, PhD, Duquesne University, Biology Dept, 238 Mellon Hall, Pittsburgh, PA 15282*

After attending this presentation, attendees will recognize the natural research barriers wildlife genetic studies pose and how to successfully overcome them to learn more about the species of focus. A better understanding of the benefits tetranucleotide microsatellite markers provide in comparison to their dinucleotide counterparts will also be accomplished through the analysis of the designed RoarPlex.

Due to the constantly evolving and largely emerging nature of wildlife forensics, the RoarPlex could have a tremendous influence on future studies involving large felid species. This presentation will impact the forensic science community by providing exposure to the wildlife forensics field and illustrating what can be accomplished using a forensic skill set to aid in wildlife conservation efforts.

The snow leopard (*Panthera uncia*) is an elusive species native to the mountainous regions of Central and South Asia. Targeted for its fur and bones or to protect the livestock upon which they prey, the snow leopard is an endangered species that requires immediate conservation action. Due to the snow leopard's cryptic nature, research based on direct observations required for effective conservation is problematic and can be supplemented by non-invasive surveys and genetic analysis.

A multiplex containing eight tetranucleotide microsatellite markers and a sex-determining region Y marker was developed to aid in the investigation of illegal killings of snow leopards and to assist with population abundance and distribution studies on a larger geographic scale. Previously, studies relied on dinucleotide repeats that were complicated to score and difficult to combine across data sets. Dinucleotide microsatellite markers are vulnerable to errors associated with high stutter percentages and misinterpretation of adenylylation stutter. The previous panel also included only four microsatellite markers in one reaction. Tetranucleotide repeats drastically reduce the errors caused by slippage and decrease the visual impact of adenylylation stutter, making for unambiguous allele interpretation. The addition of more microsatellite markers in one reaction exponentially increases the individual identification information available, a component comparable to the Combined DNA Index System (CODIS) increasing the number of core loci accepted. An allelic ladder was developed to ensure accurate allele designation across laboratories, with validation according to the Scientific Working Group on DNA Analysis Methods (SWGDAM) and the International Society of Forensic Genetics (ISFG) recommendations. To accomplish the multiplex design, 16 tetranucleotide microsatellite markers originating in the domestic cat (*Felis catus*) were screened. Results indicated that 15 markers could be successfully amplified using the available primer sets due to common ancestry and similar genome structure. Using M13 labeling, the 15 amplified microsatellites were fluorescently tagged and genotyped. Resulting peaks of the successful microsatellites were more distinct and allele calling was simplified. An informative multiplex containing eight of the most optimal microsatellite markers was constructed through selective data analysis, primer redesign, and compatibility determination. A sex-determining region Y marker was inserted into the reaction mix to simultaneously accomplish sex identification. The tetranucleotide panel provided more information, including sex, in one reaction, reducing the cost, error, and time required to perform the assay.

The enhanced panel and allelic ladder simultaneously improved research methods, assisted with transboundary initiatives, and enabled data sharing, thereby increasing the impact of population studies. Despite multiplex design being focused on the snow leopard, initial studies indicate that the RoarPlex could be successful in obtaining the individual identification of other large felids, including the bobcat (*Lynx rufus*), lion (*Panthera leo*), and cheetah (*Acinonyx jubatus*), expanding its utility. Due to the constantly evolving and largely emerging nature of wildlife forensics, the RoarPlex could have a tremendous influence on future studies involving large felid species.

STR, Tetranucleotide, Multiplex

B142 The Development of the Field Isolation and Amplification of DNA Assay (FIA-DNA) Kit: A Revolutionary Method for Species Identification of Unknown Samples

Nickolas P. Walker, 6370 Woodland Court, East Amherst, NY 14051; Matthew J. Jevit, MSc, Texas A&M University, 400 Bizzell Street, College Station, TX 77843; Colton L. Ames, 1084 Maple Avenue, DuBois, PA 15801; Jan E. Janecka, PhD, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15282; Lisa R. Ludvico, PhD, Duquesne University, Biology Dept, 238 Mellon Hall, Pittsburgh, PA 15282; and Mary Janecka, MSc, Texas A&M University, 400 Bizzell Street, College Station, TX 77843*

After attending this presentation, attendees will better understand the impact of wildlife forensics and genetic analysis on conservation and wildlife management plans for threatened and endangered species.

This presentation will impact the forensic science community by presenting a novel technique for genetic species identification of biological samples in the field for both international conservation and law enforcement efforts.

A major challenge in biodiversity conservation is the identification of unknown samples collected in the field. Most endangered species are elusive; therefore, many monitoring programs rely on non-invasive sampling using scat or hair. One difficult hurdle is identifying unknown biological samples in the field due to the reliance on genetic analysis in a laboratory. The use of specialized software and equipment is generally tied to labs located in developed countries such as North America, Europe, India, and Japan; however, sample collection and management are often conducted in rural and developing countries in Africa, South America, Asia, and remote areas of North America where most large animal populations remain.

This can cause delays in obtaining important information and is often infeasible for many on-the-ground conservation efforts with limited resources. Because there is no method of on-site species identification for these samples, money and time are wasted sending non-target samples to labs for expensive and time-consuming analyses. The goal was therefore to develop an FIA-DNA Kit for genetic field identification of species for both international conservation efforts and management of Pennsylvania wildlife without the need for Polymerase Chain Reaction (PCR) and agarose gel electrophoreses.

Once successfully implemented, the FIA-DNA Kit will allow field researchers and wildlife managers to perform a simple genetic analysis for species identification without requiring samples to be sent to a laboratory. The FIA-DNA Kit makes use of Loop-Mediated Isothermal Amplification (LAMP) and visual product detection using calcein, a novel technique which eliminates the need for a thermal cycler for DNA amplification and detection. This technique was coupled with a modified extraction protocol using Whatman® Non-Indicating Fast Technology for Analysis (FTA) Elute Micro Cards, allowing for portability and ease of use outside of the laboratory setting.

Preliminary results tested efficacy on snow leopard *(Panthera uncia*), bobcat (*Lynx rufus*), and coyote (*Canis latrans*) samples for species-specific identification. This method using LAMP amplification of DNA has exhibited 100% specificity for more than 30 previously extracted snow leopard scat samples. Coupling LAMP amplification with the modified FTA extraction protocol has yielded successful, repeatable detection in more than 50% of tested scat samples to date. This method can be completed in less than one hour with minimal equipment, using Ultraviolet (UV) fluorescence within the reaction tube to confirm species identification.

Results from initial field deployment tests of the FIA-DNA Kit at the Powdermill Nature Reserve in Rector, PA, will be discussed. The FIA-DNA Kit was tested for precision in identifying a wide range of scat samples, eliminating the time and cost of lengthy lab-based analyses. Due to LAMP amplification's ease of use, rapid reaction time, and isothermal conditions, which do not require a thermal cycler, this kit will be able to be used in the field to effectively identify samples to a species level.

The ability to pre-screen samples will also increase the efficiency and turnaround time for the genetics laboratory. Because the FIA-DNA Kit is easily modified to test for other species by developing primers, it will prove invaluable for other time-sensitive applications, including population surveys of game species, poaching cases, and outdoor crime scenes involving unidentified biological samples. Due to the expanding field of wildlife forensics, the FIA-DNA Kit holds endless potential for wide applicability across genetic and forensic disciplines.

LAMP, Species Identifiction, Wildlife Forensics

B143 The Development and Validation of a Dual-Genus, Multiplex Polymerase Chain Reaction (PCR) Assay for African and Asian Elephants for Forensic Purposes

Jillian C. Fesolovich, Keystone College, One College Green, PO Box 50, La Plume, PA 18440; Margret J. Potoczniak, MSFS, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Lawrence Quarino, PhD, Cedar Crest College, Dept of Chemistry & Physical Science, 100 College Drive, Allentown, PA 18104; and Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will understand how a multiplex PCR genotyping assay has been developed that will detect African and Asian elephant DNA simultaneously. Attendees will also understand how to efficiently create PCR assays for wildlife identification.

This presentation will impact the forensic science community by providing a standardized PCR assay that detects elephant DNA for use in wildlife investigations. The development of this assay fills a research gap in wildlife forensic science.

African (*Loxodonta africana)* and Asian (*Elephas maximus*) elephant populations are categorized under Appendix I or II of the Convention on the International Trade in Endangered Species (CITES), respectively.[1] CITES is an agreement that regulates plant and animal species throughout the world to ensure that international trade of their products does not impact their survival.[1] An Appendix I listing includes species that are threatened with extinction, thus trade of these plants and animals is highly restricted.[1] Species not facing extinction that require extra attention and regulations so they don't become exploited and over-utilized are listed in Appendix II.[1] The primary reason for the decline of these two animals is the illegal trade of their ivory. Other reasons for the decline in the elephant population are deforestation and human conflict.

Working toward conserving endangered and threatened species takes many forms throughout the world. Conservation efforts can include educating people of all ages, *in vitro* fertilization of healthy females, or surveying populations in the field. Wildlife forensic science can be defined as a field that promotes conservation efforts and the investigation of wildlife crimes through the use of scientific techniques that can be applied to the law.[2] Crimes against animals can be deterred and/or further prosecution sought through testing with forensic genetic techniques. The creation of novel genetic assays can greatly impact wildlife forensic science, not only in identifying the species, but also the individual from which the evidence originated. This information can also be used to track illegal trade routes throughout the world. Few publications describe the development and subsequent validation of tools and assays that can generate data of evidentiary quality.[2] Molecular genetics techniques can help enforce conservation efforts; however, they must be properly developed and validated in order to be of evidentiary quality for court systems.

In wildlife crime laboratories, species of origin can often be determined by morphology. This method is limited by the expertise of the taxonomist and the condition of the animal product. Ivory is commonly carved into small figurines and trinkets. Elephant meat, hair, and hide are traded, which can make it difficult to identify the species. These limitations have led to the development of genetic tests to identify species of origin in wildlife investigations. The targeting of Short Tandem Repeats (STRs) is used in this novel assay. African and Asian elephants do have highly similar genomes; however, in portions of these highly polymorphic regions, variation exists.

In this study a dual-genus, multiplex PCR genotyping assay to identify elephant DNA for forensic purposes was developed. By eliciting information from the variable areas of the elephant genomes, both genera of animals can be identified. Following the assay development, a rigorous developmental validation was conducted according to current community recommendations set forth by the Scientific Working Group for DNA Analysis and Methods (SWGDAM). The completion of this work provides an assay that can generate data of evidentiary quality for wildlife crime laboratories.

Multiplex Development, Elephant, STRs

B144 Public Sequence Databases: An Assessment of Their Reliability for Identifying Non-Human Biological Material

Kelly A. Meiklejohn, PhD, ORISE/FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22204; Natalie Damaso, PhD, ORISE/FBI Laboratory, 2334 Brookmoor Lane, Woodbridge, VA 22191; and James M. Robertson, PhD, CFSRU, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand: (1) the differences between the two main public databases of DNA barcode data (GenBank and Barcode Of Life Data Systems (BOLD)) with regard to the number of sequences, curation, and quality checks; (2) the success of both databases for obtaining the correct taxonomic assignment for insects, plants; and fungal taxa; and, (3) the precautions necessary when using public sequence databases in a forensic setting.

This presentation will impact the forensic science community by identifying varied challenges of using public sequence databases for the identification of unknown biological material encountered in casework.

Crime laboratories routinely receive evidence which contains non-human biological material. If identified, such material could help reduce the search area in provenance cases or identify the best method for isolating a plant toxin. DNA barcoding permits species-level identification of biological materials through the comparison of the unknown barcode sequence to a reference database.

There are two main public sequence databases containing barcode data, BOLD and GenBank, the latter for which the data is not curated. This study performed an initial assessment of both the quality and reliability of the DNA barcode data contained in these databases, a prerequisite for their use in a forensic setting. To achieve this, curated reference material was sourced from national collections, with taxa chosen based on their inclusion in BOLD but also to represent the main lineages of plants, macro-fungi, and insects (total *n*, ~150). The relevant barcode sequences from these reference samples (rbcL, matK, trnH-psbA, ITS, and COI) were generated and used for searching against both databases. The ability of each database was assessed to obtain the correct taxonomic assignment (genus and species), when using the default search parameters; GenBank outperformed BOLD for insect taxa (86% and 50%, respectively) whereas for plant and fungal taxa, both databases performed comparably (~78% and ~64%, respectively). Considering that the correct match was often not discernible among the top matches, modified searches against each database were performed to assess whether resolution improvements were possible. Given that the underlying algorithm and associated parameters for searching BOLD are fixed, modified searches were limited to changing the subset of barcode sequences against which an unknown is compared (i.e., all records, only records with species level identifications, only full-length sequences). For a blast search against GenBank, the impact of altering parameters, including word-size and the penalties/rewards for mismatches and gaps, was systematically assessed.

This presentation will outline the optimal search parameters needed to consistently obtain the correct identification of an unknown when using either the BOLD or GenBank database. Additionally, some precautions needed when using public sequence databases in a forensic setting will be identified.

Public Sequence Databases, GenBank, BOLD

B145 Optimized Recovery of DNA and Protein Components From Contact Traces on Fired and Unfired Cartridge Casings

Mechthild K. Prinz, PhD, John Jay College of Criminal Justice, Dept of Sciences, 524 W 59th Street, NB 05.66.20, New York, NY 10019; Steven Kranes, 2 Kristoffer Court, New City, NY 10956; Stacey-Ann Sterling, BS, John Jay College of Criminal Justice, Dept of Sciences, 524 W 59th Street, New York, NY 10019; Glendon Parker, PhD, University of California, Davis, 4421 Ashwood Common, Fremont, CA 94538; Katelyn Mason, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Deon Anex, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; and Bradley Hart, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550*

After attending this presentation, attendees will be aware of potential proteomic applications in forensic biology and realize that it is possible to extract DNA and protein from touch evidence without compromising yields for either type of biological material.

This presentation will impact the forensic science community by alerting crime laboratory scientists to a new tool for touch evidence analysis. This approach may ultimately improve source identification for contact traces on cartridge casings.

Current DNA typing success rates for spent cartridge casings have been reported as less than 10%, and recent studies have shown that metal surfaces, specifically brass, can be detrimental to DNA.[1-3] These types of probative but low-level samples would benefit from supplemental testing of protein polymorphisms, also known as Genetically Variable Proteins (GVPs), as has been described for keratin in hair samples.[4] Proteins are expected to be more abundant than DNA and may be less affected by heat and mechanical pressure. This data reveal that it is possible to extract DNA using a mass spectrometry-compatible lysis buffer and sequencing grade trypsin as the protease. The incubation buffer consists of 0.01% ProteaseMAX™ and 5mM DTT in 50mM NH_4CO_3. Extraction proceeds with 20 minutes of denaturation at 56ºC, three hours at 37ºC for trypsin digestion, and EMD Millipore™ MW100 membrane filtration. The concentrated DNA fraction will be above the membrane and mass spectrometry-ready peptides are in the flow through. Protein sequencing was performed by reversed-phase liquid chromatography using Easy-nLC™ 1000 High-Performance Liquid Chromatography (HPLC) and Q Exactive™ Orbitrap™ mass spectrometer. Polymerase Chain Reaction Short Tandem Repeat (PCR STR) testing utilized the Identifiler® Plus multiplex and a 3500 Genetic Analyzer. The method was first established using sebaceous-rich fingerprints on glass slides, then tested for fired and unfired 9mm nickel, aluminum, steel, and brass cartridges.

Trypsin digest DNA yields were similar to a standard proteinase K method and DNA was suitable for STR typing. Peptide fractions could be injected on the HPLC without further modification. Data revealed significant differences for protein and DNA recovery before and after firing and between the larger steel cartridges and the other three metals. Even samples with no detectable DNA still yielded peptide peaks, with the average of identified proteins ranging from 27-74 for unfired and 12-30 for fired casings. Extraction negatives were generally negative, but sampling uncleaned cartridges straight out of the box, without deliberate touching, showed high levels of protein background. This needs further investigation. Parallel sets of ten unfired touched brass cartridges were tested using dry collection with tape versus wet swabbing. While tape lifts on average did not recover more DNA, STR typing rates were slightly improved with six full or good partial profiles for tape-lifted samples compared to five for the swabbed samples. Supplemental peptide testing has the potential to increase the power of discrimination for low-level samples. The same proteomic data can also be used to infer body fluid and/or species attributions.

B146 Alternate Proteases and Direct Cell Lysis Methods for the Recovery of Exogenous DNA From Fingernails

Caitlin Izzo, 467 Louisa Avenue, Wyckoff, NJ 07481; and Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118*

The goal of this presentation is to present data from an evaluation of the efficiency of alternative proteases and direct cell lysis methods in extracting foreign DNA from fingernails.

This presentation will impact the forensic science community by suggesting alternative extraction methods for fingernail samples beyond the use of Proteinase K (PK).

When extracting a fingernail sample, it is possible to recover endogenous Deoxyribonucleic Acid (DNA) of the nail donor from within the nail and from the surface of the nail; similarly, foreign DNA may also be present on and recovered from the nail surface.[1,2] When attempting to recover the latter, fingernail samples present particular problems. Often, the foreign component is masked by the greater mass of nail donor DNA present in and on the nail sample.[3] This masking effect is exacerbated by the use of PK in the DNA extractions, as PK, with an average of 200 cut sites per keratin molecule, is capable of breaking open the keratin matrix of the nail and exposing the nail DNA intercalated in the matrix. Directly extracting nail clippings, in contrast to swabbing or scraping, would further introduce nail DNA when using PK.[4] This present study attempts to compare alternative proteases (ZyGEM® and Acrosolv®) with fewer cut sites than PK and two direct cell lysis methods (IGEPAL® CA-630 and Mawi iSWAB™-ID) with the intent of minimizing recovery of nail DNA from within the nail and thus mitigate the masking effect often seen with fingernail samples.

The endogenous DNA extraction efficiency of each suggested method was compared with QIAGEN® QIAamp® DNA Investigator extraction of hand-washed and/or cleaned nails. In contrast to previously published literature, a comparison of the results between hand-washed and cleaned nails suggests that much of the endogenous DNA recovered from fingernail samples is derived from DNA on the surface rather than from within the nail. QIAamp® extraction with the inclusion of Dithiothreitol (DTT) recovered significantly more DNA (p=0.0088) than the sample protocol without DTT. The IGEPAL® method recovered the least DNA from the nail, whereas the Acrosolv® method recovered more DNA than the QIAamp® protocol without DTT. Recovery was observed with the Mawi iSWAB™-ID buffer, but additional experiments are needed.

Fingernails were also spiked individually with blood, saliva, and semen to assess the recovery of foreign DNA. The extractions of the spiked nail samples demonstrate variability across all samples, owing, to some degree, to inconsistencies of sample preparation. IGEPAL®'s inability to recover complete foreign profiles suggests that the method is not viable for extraction of fingernail samples. Conversely, the ZyGEM®, Acrosolv®, and MAWI extraction methods demonstrate potential as alternative extraction methods for fingernail samples and would benefit from additional experimentation.

B147 Increasing DNA Typing Success With Improved Front-End Processing and Alternate Workflow Strategies

Allison J. Sherier, TX, 1208 Mirike Drive, White Settlement, TX 76108; Angie Ambers, PhD, Center for Human Identification, 3500 Camp Bowie Boulevard, University of North Texas Health Science Center, Fort Worth, TX 76107; Rachel E. Wiley, MFS, University of North Texas Health Science Center, Center for Human Identification, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; Nicole M. Novroski, MS, UNT Health Science Center, 3500 Camp Bowie Boulevard, Fort Worth, TX 76108-3893; and Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107*

After attending this presentation, attendees will understand that there are a number of alternatives from swab selection to designed workflow to consider in order to improve sample recovery and extracted DNA yield, as well as to minimize sample consumption. The outcome can be increased success, improved processes, and maintaining as much sample as possible for additional testing.

This presentation will impact the forensic science community by stressing the importance of collection and extraction and how these processes, if considered in a systems approach, can benefit developing investigative leads in a cost-beneficial manner. Indeed, it is these processes that contribute substantially to the success of DNA typing, especially for low-quantity samples. This presentation will describe the important features to consider to affect an efficient process of DNA recovery and reduced consumption of biological evidence.

Consumption of evidence is a critical concern in forensic DNA analyses, especially for challenged samples that contain low quantity and/or degraded DNA. Success of DNA typing is related to the amount of target material recovered from an evidentiary item. Collecting as much sample as possible, maintaining the integrity of the sample after collection, and recovering as much DNA as possible should be sought. In addition, there have been arguments in legal proceedings that samples should be split, regardless of whether there is potentially ample material or if there are only minute quantities. Sample splitting for low-quantity samples can translate into no or inconclusive results in some cases in which consuming the entire sample may have generated an interpretable result.

A better way to address increasing typing success and concomitantly minimize sample consumption is to consider novel methodologies or tools and alternate workflows. These approaches should improve sample collection by using effective collection devices (such as nylon flocked devices), by utilizing tools that release DNA well during extraction to obtain the highest yield possible (such as specialized extraction baskets), and can subsample evidence to minimize sample consumption (such as micro-sized collection systems). The issues surrounding legal arguments on sample consumption and workflows using newly developed swabs and extraction baskets will be described. The subsampling method consumes such a small portion of the stain that essentially the entire sample is preserved for additional testing or re-analysis. After collection, the sample is amplified directly. Under the amplification conditions, there appears to be an enhanced sensitivity of detection likely due to a localized Polymerase Chain Reaction (PCR) effect even at 1:99 dilutions of blood and saliva based on higher Short Tandem Repeat (STR) peak heights than standard procedures with 1ng input DNA from the same samples. Touch samples from common items and textiles yielded results consistent with the types of the donors and items. The results of this study may potentially have important implications for analysis of low quantity and/or degraded samples that plague forensic casework.

Swab, Extraction, Sampling Strategy

B148 The Evaluation and Optimization of DNA Recovery and Amplification From Bullet Cartridge Cases

Heather V. Milnthorp, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Phillip Danielson, PhD, University of Denver, Dept of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210*

After attending this presentation, attendees will better understand the complexities and challenges associated with the collection, extraction, amplification, and analysis of touch-type DNA samples commonly encountered with ballistics evidence. Attendees will also learn techniques for improving the probability of recovering sufficient DNA to generate interpretable Short Tandem Repeat (STR) profiles.

This presentation will impact the forensic science community by providing information on the optimization of commonly employed DNA collection methods and extraction techniques in an effort to improve the ability to successfully obtain interpretable DNA profiles from both fired and unfired cartridge cases without resorting to Low-Copy Number (LCN) DNA profiling methodologies.

Cartridge cases, both fired and unfired, are commonly encountered at crime scenes. According to the Federal Bureau of Investigation (FBI) crime statistics for 2015, 71.5% of homicides, 40.8% of robberies, and 24.2% of aggravated assaults involved the use of a firearm. Despite the high frequency and latent value of cartridge case evidence, these samples are not routinely submitted for DNA analysis, as it is a commonly held belief that it is difficult or impossible to recover DNA from this type of evidence. Underlying this belief is a preponderance of published studies on generating STR profiles from cartridge cases that indicate low success rates and/or minimal profiles that are unsuitable for comparative purposes.

To optimize DNA recovery from cartridge cases, numerous collection and extraction techniques were paired and evaluated. Five collection techniques (a tape-lift method, a double-swabbing wet:dry method, a double-swabbing wet:wet method, a soaking method accompanied by sonication and lyophilization, and a soaking method accompanied by vortexing and lyophilization) were paired with each of three extraction techniques, including phenol:chloroform organic extraction, PrepFiler™ Forensic DNA Extraction Kit, and the QIAamp® DNA Investigator Kit. First, 1,800 unfired 9mm cartridge cases of various metal compositions (450 each of brass, nickel-plated, aluminum, and steel) were tested with all pairings of techniques to assess possible impact of cartridge metal-type. Next, an additional 450 fired brass 9mm rounds were tested with all pairings of methodologies to assess the effects gunshot residue can have on profile quality. Finally, 230 unfired and 230 fired brass 45 Automatic Colt® Pistol (ACP) rounds were tested to assess the impact larger surface areas would have on optimum collection methods. All samples were quantified using the Life Technologies™ Quantifiler® Trio quantification kit and subjected to post-amplification concentration using an Eppendorf™ Vacufuge® plus vacuum concentrator. Samples were then amplified with the Life Technologies™ GlobalFiler® amplification kit and analyzed using Capillary Electrophoresis (CE) or analyzed using Massively Parallel Sequencing (MPS) methods.

For unfired samples of all metal types, extraction technique had the greatest effect on DNA recovery ($\bar{x}$ *Fs*=5.775; *df*=2,8; *p*=0.0103) with organic (phenol:chloroform) extraction producing optimum results. Recovery technique optimization was dependent on caliber size/surface area of the sample. For 9mm rounds, the tape-lift collection method consistently provided higher yields of DNA than other collection methods; however, for larger caliber ammunition the tape-lift method was inferior when compared to the two soaking methods. Analysis of fired samples indicates even greater differences in the success of profile generation when using optimized methodologies resulting in full and partial genetic profiles as compared to alternative combinations of recovery and extraction methods, which generated a total loss of genetic information. Comparison of these CE data to MPS data is underway.

This study demonstrates that by optimizing the methods employed for DNA collection and extraction, it is possible to increase the likelihood of obtaining good-quality STR profiles from cartridge cases without resorting to LCN DNA profiling methodologies. The presence of Gun Shot Residue (GSR) as well as the caliber of the cartridge case may impact the choice of optimal methodology and workflow. Further studies are targeted at identifying and mitigating the impact of possible co-eluting components of GSR or reactive metallic species from the casings themselves that compromise DNA profiling success through inhibition and/or augmented DNA degradation.

Touch DNA, Cartridge Casings, DNA Extraction

B149 Crime Scene Culture: How Inadvertent Collection of Bacteria Affects DNA Profiling Success

Robert A. Bever, PhD, Bode Cellmark Forensics, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Sayed Mohammad R. Mosavi, MSc, Bode Cellmark Forensics, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Allie Flores, BS, Bode Cellmark Forensics, 10430 Furnace Road, Ste 107, Lorton, VA 22079; Jangbir Sangha, MA, Bode Cellmark Forensics, 10430 Furnace Road, Ste 107, Lorton, VA 22079; and Daniel Watsula, MS, Bode Cellmark Forensics, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will better understand the external factors impacting DNA evidence stability and its impact on DNA profiling success. Attendees will also learn how microbiological organisms, collected with the sample, at crime scenes can significantly impact the results.

This presentation will impact the forensic science community by increasing knowledge of the need to preserve or process DNA evidence, especially from touch or compromised samples, in a timely manner. Increasing casework analysts' knowledge of the biological factors impacting their results will allow them to take necessary precautions to ensure that the sample collected at the crime scene has not degraded prior to analysis.

In recent years, a combination of new technologies being introduced into the market and the increasing impact of the use of DNA to solve crimes has led to both increased reliance on DNA and more collections. One often-overlooked area is the impact that biological materials, collected with the samples at the crime scene, can have on the resulting DNA profile. Bacteria, fungi, and enzymes such as DNases can have a dramatic impact on the stability of a DNA sample, possibly breaking it down before it ever reaches an analyst's bench for extraction and amplification.

This presentation will describe the studies performed on mock crime scene samples to study the specific effects of microbes and enzymes on the collected sample. Blood, saliva, and touch samples were deposited on various surfaces from picnic tables and bricks to plastic knives and shoe soles. After deposition, the samples were placed outside in the environment for a few days to simulate and stimulate normal bacterial, fungal, and enzymatic activity that can occur at a crime scene. After a few days in the environment, the samples were collected using the wet/dry swab method with a cotton swab and placed in a swab box. Accelerated aging experiments were performed on the samples by placing them in various temperature (room temperature, 37°C, and 56°C) and humidity (ambient ~20%-40% RH and >60% RH) conditions.

At selected time intervals, samples were removed and analyzed for DNA profiling success and for enzymatic activity and microbial growth. Bacterial activity was evaluated by incubating the mock evidence swabs in nutrient broth to observe turbidity in addition to inoculating nutrient agar plates to obtain single colony isolates. To evaluate DNase activity from the collected mock crime scene samples, DNase Test agar plates with methyl green were streaked with the collected swabs. DNase Test agar contains embedded DNA polymers that form a complex with the methyl green. In the presence of DNase activity, the embedded DNA depolymerizes and the methyl green/DNA complex fades into clear zones of agar surrounding the DNase positive bacteria. Some of the single colony isolates demonstrated DNase activity that may have a significant impact on obtaining a DNA profile from low-level or touch samples.

By combining the data obtained from the bacterial and enzymatic assays with the data from the DNA profiling, interesting observations and correlations were determined. Not only was microbial and enzymatic activity dependent on the surface of deposition, but it also affected the stability of the DNA collected. The results presented from this study will highlight bacterial and enzymatic activity and how it correlates to the resulting DNA profile.

Collecting a sample from an individual or from a crime scene is only one aspect of obtaining a DNA profile. Depending on the surface and suspected biological stain, analysts may need to take additional steps to ensure sample integrity. True success is when that profile can be used to identify a missing person, solve a crime, or exonerate a wrongfully convicted individual.

DNase, Bacteria, Evidence Collection

B150 An Improved Method for the Analysis of Fiber Evidence Using Polarized Light Microscopy (PLM)

John A. Reffner, PhD, John Jay College of Criminal Justice, 524 W 59th Street, New York, NY 10019; and Samuel Kaplan, BS, John Jay College, 524 W 59th Street, New York, NY 10019*

After attending this presentation, attendees will better understand a unique, useful, and rapid method using a traditional PLM to classify and identify the composition of fiber evidence.

This presentation will impact the forensic science community by introducing a new approach based on mounting fibers in a fluid medium that has a Refractive Index (RI) value that is intermediate between the fiber's principal RIs. When fibers are mounted in such a fluid medium and observed with a microscope equipped with a single linear polarizer, the fiber's RI will match the mounting fluid's RI at some specific angle of rotation. This angle of match is easily measured and provides a quantitative value for classification.

Multiple fiber types may be present in a single mount and be classified individually without the need to prepare multiple mounts. Implementing this method requires a polarized light microscope with a graduated rotating stage and is most efficient when either a graduated rotating polarizer or analyzer is available.

The classic PLM method of fiber identification is to measure the principal refractive indices using the Becke line method to determine the relative RI between the fiber and its surrounding mounting fluid.[1] The classic method requires mounting of fibers in a series of fluids of differing RIs until both principal RIs are matched. Synthetic fibers and some natural fibers behave optically as uniaxial crystals. As such, fibers have a continuous gradient of refractive index. This gradient ranges from the high to low values of the principal RI. Fibers have their principal RI values aligned parallel and perpendicular to the fiber axis. In this method, a fiber is mounted in a fluid with an RI value that is between the two principal RI values. It is observed using only linear polarized light. As the orientation of the polarized light vector is changed relative to the fiber axis, the Becke line will vanish. The angle between the fiber axis and the position at which the Becke line is indistinct is readily measured using a PLM. The PLM must have a rotating stage and either a graduated rotational analyzer or substage polarizer. A rotating stage is used to align the fiber so that the initial polarization direction is parallel to the fiber axis, then the analyzer (or polarizer) is rotated until a match point is reached. This angle of matching RI is only a function of the fiber composition and refractive index of the fluid.

The angle of rotation for matching refractive index (θ) can be calculated when the refractive index of the mounting media and the principal values of the fiber are known. Using the equation of an ellipse in spherical coordinates, a spread sheet was developed to generate tables of data that aid in textile fiber analysis. For example, fibers mounted in refractive index fluid RI=1.570 have angles of matching refractive index (θ) as follows: nylon (vivrelle), 0.0°; olefin (PE), Q=22.4°; nylon 6, Q=19.4°; nylon 6, 6 Q=24.5°; polyester (PCDT) Q=55.8°; polyester (PET) Q=65.7°; polyester (PTT) Q=75.2°. These data demonstrate the ability of this method to identify several common fibers in a single preparation. The efficiency of fiber identification is greatly improved over the classical PLM method.

Fiber, Evidence, PLM

B151 Microscopical Discrimination of Human Head Hairs Sharing a Mitochondrial Haplogroup

Sandra Koch, MS, Penn State University, Dept of Anthropology, Carpenter Bldg, Rm 403C, University Park, PA 16802; Corey Liebowitz, BS, Penn State University, Dept of Anthropology, Carpenter Bldg, Rm 403C, University Park, PA 16802; Nina G. Jablonski, PhD, Penn State University, Dept of Anthropology, Carpenter Bldg, Rm 403C, University Park, PA 16802; and Mark D. Shriver, PhD, Penn State University, Dept of Anthropology, Carpenter Bldg, Rm 403C, PA 16802*

After attending this presentation, attendees will better understand the current state of forensic hair analysis and the benefits a combined microscopic and genetic approach can offer for discrimination of human hair samples. Attendees will appreciate the different forms of information available from microscopy and mitochondrial DNA (mtDNA) analysis and how these can complement each other in a forensic analysis.

This presentation will impact the forensic science community by introducing data from a current inter-laboratory study on the level of discrimination possible by microscopic hair analysis, adding to understanding of the strengths and limitations of microscopic comparisons of hairs and demonstrating the importance of combining microscopic and genetic analyses when evaluating evidential hairs. Previous studies have looked at the degree to which mtDNA can be used to differentiate microscopically similar hairs. This study focuses on hair samples that may not otherwise be discriminated by mtDNA to assess how well microscopy can differentiate hairs that share a mitochondrial haplogroup. This analysis illustrates that microscopy can provide distinguishing information not contained in forensic mtDNA DNA examinations.

Interpreting microscopic assessments of hair necessitates an understanding of the human factors that are involved in these examinations, such as visual perception, experience, and training. The accuracy and reliability of microscopic hair analysis was tested using 20 sets of hair samples from participants who share mtDNA haplogroups. The test sets were created using participants who had been genotyped and the hair samples for each test were then selected based on shared mtDNA haplogroup, ancestry, macroscopic similarity, and length. The tests were assigned random alphanumeric designators and mailed to hair examiners in forensic laboratories across the United States. Additional data was collected regarding the amount of training a forensic hair examiner had, how often hair proficiency tests were taken, years of experience, the types of casework typically received, degree of specialization in trace evidence subfields, and how the examiner characterized ancestry from the hair samples. The level of consensus was assessed between examiners for each test and how "rare" or "common" it was to not be able to differentiate hairs of mtDNA-defined groups by microscopic comparison. This study addresses some of the criticisms by the President's Council of Advisors on Science and Technology (PCAST) of forensic hair analysis and provides data regarding the strengths and limitations of microscopic hair analysis.

It is generally accepted that microscopic analysis of hairs will not provide a level of individualization that allows for identification of a hair to a single person to the exclusion of all others. By choosing sets of hairs from people who share the same mtDNA haplogroup, this study sought to determine how microscopically similar hair samples from these individuals may be and the degree to which microscopy can provide reliable differentiation of these hairs. While nuclear DNA analysis can lead to an individual identification, most evidential hairs are shed without sufficient follicular tissue for such testing, therefore limiting genetic testing of the majority of the hairs found in casework to mtDNA. Furthermore, identification through a destructive DNA analysis without first assessing a hair microscopically can hinder an investigation through the loss of valuable information. This study summarizes the current understanding of the utility of microscopic hair analysis in forensic casework, demonstrates the strengths and limitations of microscopic hair comparisons, and highlights the importance of combining non-destructive and destructive tests, such as microscopy and genetic analyses, to obtain the most information from a piece of evidence.

This study rigorously tested the accuracy and reliability of microscopic hair analysis with the conclusion that microscopy can discriminate greater than 85% of the hairs that mtDNA cannot. Accordingly, microscopic analysis of hairs should be maintained in forensic laboratories because it offers a cost-effective and non-destructive test that serves as the first level of sample discrimination and provides complementary information not available from mtDNA analysis.

Hair, Microscopy, Mitochondrial DNA

B152 Determining the Effects of Storage Conditions on the Preservation of Ignitable Liquid Residues

Clare Fried, MSFS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899; Marcela Najarro, MFS, NIST, 100 Bureau Drive, MS 8371, Gaithersburg, MD 20899; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will understand to what extent different factors influence the preservation of stored ignitable liquid residue samples.

This presentation will impact the forensic science community by providing fire debris analysts with data to support which storage factors are important to consider when the preservation of samples is desired.

Preservation of ignitable liquid residue extracts is necessary for possible re-examination of suspected fire debris samples. Preliminary research investigating the effects of storage has been completed previously, although many aspects of storage have not yet been addressed.[1-3] The work completed by Sandercock provided foundational preservation research; however, this research will examine a wider range of factors.[2] In this study, Gas Chromatography/Flame Ionization Detection (GC/FID) was used to evaluate the extent to which select storage factors influence the preservation of fire debris samples over a 30-day period. A test mixture was created containing approximately 20 compounds commonly found in ignitable liquid residues. An aliquot of the test mixture was deposited into a metal can and adsorbed onto charcoal strips through active headspace. Chromatograms between the initial time-point and 30 days after analysis were compared to understand the relative effects of the storage conditions.

A partial factorial Design of Experiments (DOE) was used to evaluate the effects of different storage factors on the ability to preserve the sample. The six factors considered were: vial type (screw cap vs. crimp cap), storage temperature (23°C vs. -4°C), method of sample concentration (ambient evaporation vs. dry nitrogen stream), extraction solvent (carbon disulfide vs. pentane), whether the sample vial was stored in a vapor-tight fire debris bag, and whether the vial was covered with Parafilm®. This partial factorial design was replicated across the different methods of preservation suggested in the American Society for Testing and Materials (ASTM) E2451 *Standard Practice for Preserving Ignitable Liquids and Ignitable Liquid Residue Extracts from Fire Debris Samples* (i.e., reconstitution of the sample onto a charcoal strip vs. cutting the strip in half).[4]

The results of this study will be used to understand the relative effects storage factors have on the preservation of ignitable liquid residue extracts and will provide a platform to both continue future work on preservation and allow analysts to make informed decisions on archiving and preserving casework. Sample preservation can be an important step in a suspected fire debris case and this research will provide analysts with insight into critical preservation factors and the effect the factors have on the data.

Fire Debris, Ignitable Liquid Residues, Preservation

B153 The Identification of Representative Compounds in Ignitable Liquids and Substrates: Classification of Fire Debris Using a Naïve Bayes Approach

Anuradha Akmeemana, MS, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; Mary R. Williams, MS, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; and Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will better understand the classification of fire debris as positive or negative for the presence of ignitable liquid residue using a Naïve Bayes approach.

This presentation will impact the forensic science community by utilizing a method for the identification of representative compounds in fire debris and the determination of the presence or absence of ignitable liquid residue in fire debris using likelihood ratios. The purpose of the presentation is to propose a classification system for fire debris.

In this study, 700 burned and 100 unburned substrates and 646 neat ignitable liquids were used. The burned substrate samples were prepared using Modified Destructive Distillation Method (MDDM), Direct Heat (DH), and Indirect Heat (IH) methods. Identification of the compounds in the chromatograms of the substrate and ignitable liquid samples were analyzed by Automated Mass Spectrometry Deconvolution and Identification System (AMDIS) software, using a library containing 282 compounds, including the retention times, retention indices, and mass spectra of each compound.[1]

Logistic regression and Receiver Operating Characteristic (ROC) analysis were applied to evaluate the probability of the presence of the library compounds in substrates and ignitable liquids. For these calculations, the delRT ($1/[1+|\Delta r.t.|]$) parameter was introduced. This parameter uses the absolute value of the retention time difference ($|\Delta r.t.|$) between the compound in the library and the sample. The data used to generate the logistic regression model was comprised of multiple compounds from each of 42 ignitable liquids taken from the Ignitable Liquid Reference Collection (ILRC) database.[2] Liquids were selected from all American Society for Testing and Materials (ASTM) E1618-14 classes.[3] ROC analysis was used to determine the best logistic regression model. Compounds having a probability ≥ 0.75 were designated as being present in the sample.

Based on their estimated presence or absence, the frequencies of occurrence of the compounds in substrates and ignitable liquids were calculated as the number of occurrences divided by the total number of ignitable liquid or substrate samples. For example, methanol was identified 13 times in 624 substrate samples. Therefore, the frequency of occurrence of methanol in substrates is 2.1×10^{-2}. Some compounds were found to have a zero frequency of occurrence in substrates or ignitable liquids. For instance, acrolein was found to have a zero frequency of occurrence in ignitable liquids. Failure to observe a compound in ignitable liquids or substrates is the result of the statistical sample and not a true estimate of the frequency of occurrence in the population. The Good-Turing smoothing technique was used to estimate the probabilities of occurrence for the compounds that were not seen in the substrates and ignitable liquids.

The frequency of occurrences obtained for the 282 library compounds in substrates and ignitable liquids were used to calculate likelihood ratios for the presence of ignitable liquid in a fire debris sample using a Naïve Bayes approach. The likelihood ratio is calculated by Naïve Bayes as the ratio of the product of the probabilities of occurrence in ignitable liquids (numerator) and substrate (denominator) for each of the 282 compounds found in a fire debris sample. Results will be presented for the cross validation of the method and testing on fire debris data.

This research was supported by the National Institute of Justice, Office of Justice Programs. The findings and opinions expressed in this work are those of the authors and do not reflect those of the United States Department of Justice.

Fire Debris, Logistic Regression, Naive Bayes

B154 The Calculation of Likelihood Ratios in Fire Debris Analysis: Model Effects

Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; and Mary R. Williams, MS, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will better understand modern methods of fire debris analysis, the calculation of Likelihood Ratios (LLRs) and how model effects on the LLR can be taken into account. Model effects on the LLRs calculated for fire debris samples can arise through distributional changes, which may have an impact on the class means, variances, and covariances of the model.

This presentation will impact the forensic science community by helping analysts understand how to implement models based on a relevant population and statistical sampling of a database.

A simple method is presented for the calculation of LLRs for fire debris samples. The method involves statistically sampling a database of ignitable liquids and substrate pyrolysis data in proportion to the estimated class distribution in a relevant population. The sample of ignitable liquid and substrate pyrolysis data will form the basis for calculating class means, variances, and covariances to be use in a kernel density estimate of the LLR for a fire debris sample. The multivariate kernel density is calculated from a limited feature set comprised of the scores for the first four principal components, which are derived from principal component analysis of the statistically sampled data. Multiple models are prepared by repeated sampling of the database. Bootstrap validation was calculated for each model and the average area under the Receiver Operating Characteristic (ROC) curve was taken as a measure of model performance.

Ten models were prepared for each of three population distributions. Each of the models had an average area under the ROC curve of greater than 0.9. The models were used to estimate the evidentiary value for a set of laboratory burns. One set of burns involved polyester carpet and padding with added gasoline. Samples were burned for time periods of 0.5 minute, 1 minute, 2 minutes, 3 minutes, and 5 minutes. A set of samples containing polyester carpet and padding with added medium petroleum distillate were burned for the same time periods. A set of polyester carpet and padding samples without added ignitable liquid were also burned for the same time periods. The base 10 log of the LLRs for all samples were in the range of 2 to -2, which are considered reasonable. The LLR values for the samples containing ignitable liquid were observed to be positive at early burn times and proceeded to become negative at longer burn times as the solvent was weathered and pyrolysis products were produced in the burn.

The method discussed is considered suitable for casework samples. The method allows the analyst to report the evidentiary value of fire debris samples as numerical (LLR) values.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this manuscript are those of the authors and do not necessarily reflect those of the Department of Justice.

Fire Debris, Likelihood Ratio, Database

B155 The Utilization of Receiver Operator Curves (ROCs) for the Evaluation of Fire Debris: The Influence of Population Distributions on Classifier Performance

Alysaa Allen, National Center for Forensic Science, 12354 Research Parkway, #225, Orlando, FL 32826; Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; Mary R. Williams, MS, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand how diverse populations can alter the covariance matrices that affect the performance of classification modeling in fire debris analysis. An introduction to the use of subpopulation distributions and their influence on Likelihood Ratio (LR) calculations will also be explored.

This presentation will impact the forensic science community by discussing the development of "relevant" populations and their impact on the evaluation of fire debris evidence.

An important aspect in fire debris analysis is determining whether a sample contains an ignitable liquid residue. In this work, fire debris samples are assigned to two classes, those containing Ignitable Liquid (IL) residue and those containing only Substrate (SUB). One consideration in the development of classification models for fire debris is defining a population. A population is comprised of SUB and a subpopulation of IL classes drawn from the eight American Society for Testing and Materials (ASTM) E1618-14 IL classes in a defined distribution.[1] The challenge of defining a relevant population is attributed to the lack of known ground-truth ASTM E1618-14 IL class distributions in casework samples. This work examines the effect of diverse population distributions on LRs calculated from a one-level multivariate normal classification model.[2] The one-level classification model only takes into account between-sample variances. Diverse population distributions were generated computationally, as previously reported.[3]

Receiver Operating Characteristic (ROC) curves for model performance were generated based upon the results of LR calculations. Models were built based on each distribution and were tested on data from all other distributions. An Area Under the Curve (AUC) was calculated to evaluate classifier performance from the ROC curves. The change in the population distribution altered the mean and covariance of SUB and IL classes. Changing the covariance matrices modifies the LRs used to generate the ROC curves and assigns a different ordering of ground-truth labels. The population models that demonstrated the best performance consisted of significant SUB contribution and subpopulation comprised of representatives of each ASTM E1618-14 IL class. Population distribution models that contained a minimum SUB contribution and lacked representations from an ASTM E1618-14 IL class resulted in poorer performance.

Fire Debris, Likelihood Ratio, Population Distribution

B156 A Combined Approach of Gas Chromatography/Mass Spectrometry (GC/MS) and Chemometric Strategies for Fire Debris Investigation Purposes

Eugenio Alladio, PhD, Centro Regionale Antidoping "A. Bertinaria," Regione Gonzole 10/1, Orbassano (Turin) 10043, ITALY; Marco Pazzi, PhD, University of Turin, Dept of Chemistry, Via P. Giuria n.5, Torino, ITALY; Laura Pacifici, MSc, Dipartimento di Chimica, Università di Torino, VIa P Giuria 7, Torino 10125, ITALY; Fabrizio Malaspina, MSc, Corpo Nazionale Vigili del Fuoco - Torino, Corso Regina Margherita 330, Torino 10143, ITALY; Paolo Garofano, MD, PhD, Laboratorio Genetica Forense - CAD, Regione Gonzole 10/1, Orbassano (TO) 10043, ITALY; and Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY*

After attending this presentation, attendees will better understand how to combine GC/MS data with multivariate data analysis strategies for fire debris investigations.

This presentation will impact the forensic science community by illustrating that, even though in a preliminary stage, this study seems to emphasize the employment of multivariate strategies targeted at potentially helping the interpretative process of fire debris investigations.

In fire debris investigations, a largely debated issue deals with the possibility of recognizing whether or not the collected evidence is related to the occurrence of an arson.[1] In practice, data from GC/MS analyses performed on collected fire debris may be compared to those from ignitable liquids (e.g., that found in possession of a suspected arsonist). With the goal of evaluating the use of gasoline as a fire accelerant, several gasolines sampled from different gas stations located within the area of Turin, Italy, were analyzed by Solid-Phase Microextraction (SPME) -GC/MS.[2] Fresh and weathered samples were analyzed and compared to standard mixtures and protocols, namely American Society for Testing and Materials (ASTM) 1618.

The collected mass chromatograms were subsequently interpreted using a variety of targeted and untargeted approaches of multivariate data analysis, using both raw and semi-quantitative data. A data set including 150 GC/MS analyses relative to 30 gas stations was used for multivariate analysis. Gasoline samples were analyzed both as pure liquids and as mixtures of fresh and weathered mixtures at different percentages (i.e., 25%, 50%, 75%, and 95%). Several multivariate data analysis procedures were tested and their results were compared. The use of chemometric strategies allowed the building of explorative, classification, and likelihood ratio models, indicating the probabilities that fire accelerants have actually been employed. Once the chromatograms had been collected, different chemometric approaches were tested on both raw and semi-quantitative data. Principal component analysis located the fresh gasoline samples within a scores plot according to their origin (i.e., the different gas stations). *N*-way strategies were tested to determine how multivariate strategies were able to assess the occurrence of fire accelerant in an arson scene. To this purpose, whole tridimensional GC/MS data collected in scan mode were compared with those obtained from different gas station gasoline samples. Similar investigative approaches have been used with the integration of Bayesian's logic. Further development of multivariate feature-based and score-based likelihood ratio models built on the collected GC/MS spectra are in progress. In particular, principal component analysis, Self-Organizing Maps (SOM), and partial least squares – discriminant analysis, as well as *N*-way models, proved successful with the goal of identifying the usage of fire accelerant.[3,4]

Even if in a preliminary stage, this study seems to emphasize the employment of multivariate strategies aimed at potentially helping the interpretative process of fire debris investigations.

Fire Debris Investigation, GC/MS, Multivariate Data Analysis

B157 The Detection of Toxic Adulterants in Seized Drug Exhibits in Kentucky and Vermont

Taís R. Fiorentin, PhD, 210 Krewson Terrace, Willow Grove, PA 19090; David M. Martin, PhD, Drug Enforcement Administration, Educational Found, 2020 Pennsylvania Avenue, Washington, DC 20006; Thom Browne, Jr., Rubicon Global Enterprises, 790 E Valley View Trail, Huachuca City, AZ 85616; Jeremy S. Triplett, MS, Kentucky State Police Forensic Laboratories, 100 Sower Boulevard, Ste 102, Frankfort, KY 40601; Trisha L. Conti, PhD, Vermont Forensic Laboratory, 45 State Drive, Waterbury, VT 05671; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the number and variety of adulterants encountered in seized drugs in Kentucky and Vermont in the United States.

This presentation will impact the forensic science community by providing data on the prevalence of toxic and non-toxic adulterants in drug evidence seized from March 2015 through May 2017.

Cutting agents are constantly changing over time, increasing the risks to the user's health caused by the compound's interactions. Many laboratories in the United States perform seized drug analysis by an acid/base extraction of drug evidence. This may result in toxic adulterants being removed before the analytical phase. Also, most laboratories will report on only controlled substances in the Drug Enforcement Administration (DEA) list (Schedules I to IV) or per their state regulations. Both factors lead to under-reporting of other substances that may contribute to the adverse effect profile of illicit drug use.

Two hundred aliquots from seized drug exhibits from Kentucky and 315 samples from Vermont were received dissolved in methanol or ethanol and were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS), followed by Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS) after dilution (1:100) of the neat sample in mobile phase. The samples were received deidentified, but were assigned an in-house identifying number, linked to the date of receipt for analysis by the originating lab and the zip code or county of origin.

Overall, the most prevalent toxic adulterant found was caffeine (31.0%), followed by quinine/quinidine (24.7%), levamisole (11.6%), acetaminophen (8.2%), and procaine (8.2%). In Kentucky, levamisole (18.0%) was the most prevalent toxic adulterant detected, followed by caffeine (15.0%), diphenhydramine (14.0%), quinine/quinidine (11.0%), and lidocaine (8.0%), while in Vermont, the most prevalent was caffeine (46.2%), followed by quinine/quinidine (37.7%), procaine (16.0%), carisoprodol (15.0%), and diltiazem (10.3%).

The seized drugs of abuse identified overall were as follows: heroin (117 samples), cocaine (85 samples), methamphetamine (61 samples), fentanyl and analogs (40 samples), MDA/MDMA (4 samples), and U-47700 (4 samples). Heroin was primarily adulterated with caffeine (50.4%) and quinine/quinidine (41.8%), as well as fentanyl and analogs (caffeine in 74.0% of the samples, quinine/quinidine in 51.6% of the samples). Cocaine was primarily adulterated with caffeine (35.2%) and levamisole (28.2%). Caffeine was also the main adulterant identified in U-47700 samples (75.0% of the samples). The methamphetamine samples were less adulterated in general; the most prevalent adulterants identified in those samples were diphenhydramine and caffeine in 6.5% and 4.9% of the samples, respectively. The four MDA/MDMA samples identified in this batch were not adulterated.

In Kentucky, the majority of the samples were methamphetamine, of which some were adulterated with diphenhydramine (6.5%) or caffeine (4.9%), and cocaine mostly adulterated with levamisole (33.3%), caffeine and diphenhydramine (22.2%). By contrast, in Vermont, most of the samples were heroin adulterated with caffeine (48.9%) and quinine/quinidine (41.6%), and cocaine adulterated with caffeine (58.0%), quinine/quinidine (29.0%), and procaine (25.8%).

Knowledge concerning the toxic adulterants is important for the management of acute intoxications and also in criminal investigations, helping in the identification of routes of trafficking; however, common reporting practices frequently do not provide information regarding the prevalence of these toxic adulterants.

Seized Drug, Cutting Agents, Toxicity

B158 An Investigation into Darknet Markets: Their Use in Predicting Emerging Drug Trends and the Correlation With Discussion on Surface Web Drug Forums

Robert Paul Hessler, Jr., BS, 2429 E Orvilla Road, Hatfield, PA 19440; Kathy Macropol, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038; David Klein, BA, GuardiCore, 650 California Street, 7th Fl, San Francisco, CA 94109; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will understand the information that darknet drug markets and surface web drug forums can provide in predicting ever-changing trends in drug use.

This presentation will impact the forensic science community by highlighting the role vendors, buyers, and forum users on darknet markets and drug forums play in driving developing drug trends. This research seeks to bring to light the changes in drug trends over time through the discussions found on both drug forums and darknet markets.

Darknet markets, also known as cryptomarkets, are online marketplaces that are hidden from normal web browsing and can only be accessed through the use of privacy software such as The Onion Router (Tor). Surface web drug forums are found through normal search engines and are communities in which drug users and enthusiasts can discuss their drug habits as well as their experiences with various illicit substances. Both locations offer their members a place to openly converse on the new substances they are ingesting to create a euphoric effect; however, darknet markets allow for the open selling of the illicit substances, while the drug forums are restricted to discussion only. Despite the added anonymity Tor software provides, most darknet market drug forum discussions are focused on vendor reviews rather than discussion of the euphoric experiences.

The correlation between the drug trends and the discussion contained within the forums and markets was analyzed via different means. The information contained on the surface web forums was collected using a forum crawler, while statistics were generated for the drug listings on the darknet markets. In addition to total listings for the major drug classifications, vendor and buyer information was browsed to look for location-based differences in drug popularity. An open source forum crawler was modified for this research to collect the data found on popular drug forums. The data was then analyzed using data mining techniques to search for popular keywords that were previously unknown. A lexical repository was created to store the information found.

Due to the constant flux of popular drug use and the increased law enforcement activity targeting darknet markets, the up-to-date results will be reported during the presentation. Multiple darknet markets have been investigated throughout the course of this research to provide a broader collection of the illegal drug trade. The well-established prevalent opioid use on the East Coast flowing in from European vendors and the fact that the West Coast suffers from a high influx of amphetamine derivatives supplied by Asian vendors was verified through this research, allowing for the validation of the methodology.

Darknet Markets, Drug Forum, Drug Trends

B159 Predicting the Origin of Heroin by Analysis of Inorganic Elements and Isotope Ratios of Strontium (Sr)

Joshua S. DeBord, MSc, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Ali Pourmand, PhD, University of Miami, Rosenstiel School, Dept of Marine Geosciences, 4600 Rickenbacker Causeway, Miami, FL 33149; Sarah C. Jantzi, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Rm OE116, Miami, FL 33199; Sini Panicker, 22624 Dulles Summit Court, Dulles, VA 20166; and Jose R. Almirall, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to inform attendees regarding the efforts to profile heroin by means of inorganic trace element compositions as well as Sr isotope ratios 87Sr/86Sr.

This presentation will impact the forensic science community by demonstrating the potential for heroin sample matching and origin determination by examination of radiogenic Sr isotope ratios and trace elemental composition and the potential for this application to other forensic matrices.

The effort to understand the dynamic nature of drug production and distribution has lead intelligence and forensic experts to increasingly rely on analytical chemistry for solutions. In an attempt to aid assignment of origin to seized shipments, heroin samples of known provenance have been dissolved by microwave-assisted acid digestion and studied by three varieties of Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) for elemental composition and isotopic ratios $^{87}Sr/^{86}Sr$ whenever possible. For the elemental analysis of heroin, inorganic composition was quantitatively determined by quadrupole ICP/MS and high-resolution ICP/MS. For the precise measurement isotope ratios of strontium, samples were prepared by affinity resin chromatography and analyzed by multi-collector ICP/MS. To predict a provenance assignment, the results of the analysis have been analyzed by single-variable and multivariate statistical analysis. This is the first large-scale study with 40+ samples from each of the major source regions to investigate provenance determination through inorganic trace element composition and radiogenic strontium isotope ratio analysis.

The utility of light-element, stable isotopic ratio values has been investigated in heroin for provenance studies.[1-3] Geochemical studies have demonstrated that $^{87}Sr/^{86}Sr$ values found in plants and animals can be directly correlated to those found in the geological material upon which the organisms live (and feed). The natural variation in $^{87}Sr/^{86}Sr$, which is primarily resultant from spatial and temporal differences in geological formation, forms the basis of the hypothesis for this study. One of the few forensic studies into strontium isotope ratios reveals that natural-product drugs (marijuana, in this example) can be used for origin determination.[4] In the case of semi-synthetic drugs, such as heroin in this study, it is believed that batches of heroin that are cultivated and processed in a particular location will share similar radiogenic Sr ratio values. It is assumed that strontium contamination is possible during the processing of opium (morphine) into heroin as well as subsequent packaging and handling; therefore, it is expected that there may be some bias to the heroin $^{87}Sr/^{86}Sr$ values.

Despite this anticipated uncertainty, it has been estimated that ≥70% of unknown samples can be correctly assigned based upon the described methods.[5] As expected, inorganic methods of analysis do not currently possess the discriminating certainty of published methods for organic analysis; however, this research was conducted in order to provide an orthogonal means of analysis to support existing, successful heroin-profiling techniques.[6-8] This has been the first known study to profile heroin by a fusion of inorganic element composition and heavy-element isotopic ratio data.

Heroin, Trace Elements, $^{87}Sr/^{86}Sr$ Ratios

B160 The Material Effects of Commercial Swabs on the Extraction of Multiple Drugs Using Microfluidics and Mass Spectrometry

Emily Lynn Lichtenberger, BS, 207 Orchard Park Drive, Cary, NC 27513; Michael Roberts, BS, Shimadzu Scientific Instruments, 4022 Stirrup Creek Drive, Durham, NC 27703; and Nelson R. Vinueza, PhD, North Carolina Sate University, 1020 Main Campus Drive, Campus Box 8301, Raleigh, NC 27695*

After attending this presentation, attendees will understand how different materials of commercially sold swabs can affect extraction and analysis of multiple New Psychoactive Substances (NPS) using a microfluidic extraction device in combination with High-Performance Liquid Chromatography (HPLC) and low-resolution Mass Spectrometry (MS).

This presentation will impact the forensic science community by providing material effects of commercially sold swabs for decisions on better trace evidence collection of NPS and drugs of abuse.

This specific Microfluidic Device (MFD) was developed for the extraction of dyes from fibers and is now being fully tested for other areas of forensic science.[1] This research is a continuation of a presentation given at the 2017 AAFS annual meeting on the comparison of three instrumentation methods for the identification of 70+ drugs. The method developed of collecting the extraction in a micro-vial is used because it extracted, separated, and identified the most compounds, efficiently allowing a valid comparison of material effects.

How materials of commercially sold swabs affect the extraction of certain compounds is the primary goal of this study. This enables forensic specialists to understand what swabs are better for specific NPS for evidence collection. A variety of swabs with tips of materials such as polyurethane foam, cotton, polyester, rayon, and nylon were procured from Puritan Medical Products®. These included a variety of tip types such as flocked or pre-wetted, as well as Popule swabs, which are swabs that contain a small amount of solvent or water in their shafts to saturate the tip for cleaning. To determine material effects, swabs of each material were saturated in a standard solution of 70+ compounds that contain various Differential Optical Absorptions (DOAs) such as amphetamines, cannabinoids, opiates, and barbiturates. To determine trace effects, 10µL of the solution were pipetted onto the swab tips and sampled. Sample preparation for the MFD involved removing a small piece of the swab tip doped with the solution, placing it in the cavity of the microfluidic chip, placing a glass slide on top, and inserting it into the MFD. Extraction commences via the user-friendly interface that controls the parameters and is collected in a micro-vial for HPLC-Triple quadrupole (QqQ) analysis using a method previously developed with Shimadzu Scientific Instruments®, a collaborator on this project. All electronic conditions were the same for ionization and detection parameters, and the QqQ was operated in Multiple Reaction Monitoring (MRM) where multiple product ions are detected for precursor ion identification. An NPS was accurately identified if at least two product ions were detected for the precursor, the signal-to-noise ratio for these ions in the mass spectrum is three or more, and the area of the mass-to-charge ratio signal increases when compared to a blank spectrum collected from the MFD and analyzed.

Results indicate that polyester and polyurethane foam are the most effective at releasing a larger variety of NPS when the tips are fully saturated. Ionization bias caused by electrospray ionization is decreased with this method because the extraction is first separated via HPLC. The lesser amount of NPS identified is simply due to the material effects. For the second method for trace analysis, smaller sized, flocked tips were better since the swab had less depth to absorb the 10µL of solution. This kept the NPS in the same location; thus, the piece removed for extraction and analysis contained most of the drugs. Samples taken from larger swabs rarely contained even half of the compounds as the solution had too much area to spread. This can be improved by sampling multiple areas of one swab. Wetted versus dry Popule swabs revealed that more drugs were released when the Popule contained a solution of 91% Isopropyl Alcohol (IPA) and 9% Deionized (DI) water. Limited variation occurred between dry and wetted swabs when the Popule contained sterile water.

Overall, this work provides forensic analysts with new knowledge for determining swabs to use for evidence collection of trace samples. The MFD adds a simplified extraction step with reduced human error and bias since no analyst interaction is needed during the extraction process. It shows versatility for extraction of drugs from a variety of materials, where only the effects of the materials cause different NPS to be identified. This work benefits the forensic community by fast, automated extraction, simple transfer into the HPLC/MS system, facilitated identification with a low-resolution MS instrument by MRM, and simplified confirmation of identification via comparison with the blank spectrum of the MFD.

Multiple Drug Analysis, Material Effects, Microfluidic Mass Spectrometry

B161 Low-Field Nuclear Magnetic Resonance (NMR) Applications in Forensic Drug Analysis

Jonathan J. Duffy, BS, 1525 28th Street, S, Apt 6, Arlington, VA 22206; Aaron Urbas, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Katrice Lippa, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Luke Short, PhD, DC Department of Forensic Sciences, 401 E Street, SW, Washington, DC 20024; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will understand the potential utility of low-field NMR spectroscopy in the qualitative and quantitative analysis of drugs. This presentation will focus on the use of low-field NMR as a substitute for high-field NMR for differentiating structural isomers of New Psychoactive Substances (NPS) that can be difficult to distinguish with other methods. The use of low-field NMR to provide accurate quantitation will also be discussed.

This presentation will impact the forensic science community by suggesting an alternative to current methods employed by forensic laboratories that have limitations for confirming specific positional isomers. This presentation will demonstrate that low-field NMR can be a suitable technique by using examples from several drug classes. Limitations of the technique will also be discussed.

Forensic laboratories commonly receive new synthetic cannabinoids, cathinones, and opioids that are difficult to report. Slight changes to chemical structures (e.g., shifting the position of functional groups, such as methyl groups or halogens, around an aromatic ring) can cause problems with identification using traditional methods. Classic gas chromatography/mass spectrometry cannot easily distinguish between certain positional isomers.

NMR is a powerful tool used to elucidate the structure of these isomers using 1D and 2D spectra from ^{1}H, ^{13}C, ^{19}F, and ^{15}N nuclei probes to assign elements to their specific position on the molecule. High-field NMR is typically used for these determinations but is not practical in many forensic laboratories due to the cost of the instrumentation as well as cryogen, facility, and staff requirements. In contrast, low-field NMR is less costly, has a smaller footprint, does not need cryogens, and requires little maintenance; however, this comes at the cost of spectral resolution and sensitivity.

This study evaluated the use of ^{1}H NMR on low-field benchtop NMR (60 MHz) and 600 MHz systems to differentiate positional isomers of several classes of NPS. The positional isomers were readily differentiated on both instruments, as expected. The use of quantum mechanic spin system modeling of ^{1}H spectra on the high-field system for portability of experimentally observed spectra to other magnet field strengths was also investigated and successfully demonstrated by transforming 600 MHz spectra to 60 MHz. This capability suggests that the generation of field-strength independent spectral libraries may be feasible and would facilitate data dissemination across instruments without the need to acquire a large collection of reference spectra.

Quantitation based on NMR is unique in that it can be performed relative to a distinct reference compound without requiring a calibration curve derived from the analyte of interest as utilized commonly in chromatographic methods. Purity determination for certain drugs (e.g., methamphetamine) can affect sentencing guidelines and can also be used by law enforcement for intelligence purposes. This study also explored the use of low-field NMR for quantifying methamphetamine in commonly encountered sample mixtures to mimic casework.

Low-Field NMR, New Psychoactive Substances, Methamphetamine

B162 Separation and Identification of Drugs of Abuse by nano-Liquid Chromatography/Electron Ionization/ Mass Spectrometry (nLC/EI/MS)

Jocelyn V. Abonamah, BS, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; and Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the merits of nLC/EI/MS for the analysis of drugs of abuse when compared to Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/ Electrospray Ionization/Tandem Mass Spectrometry (LC/ESI/MS/MS) methods.

This presentation will impact the forensic science community by introducing a viable method for the separation and identification of thermally labile drugs of abuse, as well as the advantages of nLC/EI/MS when compared to GC/MS and LC/MS/MS.

GC/EI/MS and LC/ESI/MS/MS are two commonly used analytical techniques in the forensic analyses of drugs and explosives. The primary advantage of GC/MS is its extensive library-searching capability, which allows identification of unknown compounds; however, many compounds used in forensic sciences are thermally labile and decompose in the GC injector, which typically operates at high temperatures. LC/MS has been useful in addressing the issue of thermal degradation by utilizing an atmospheric pressure ionization source, such as ESI, eliminating the need for a high-temperature injector and, therefore, vastly decreasing or eliminating fragmentation.[1] By using an MS/MS, compounds can be fragmented; however, no good library for LC/MS/MS currently exists.

LC/EI/MS is an ideal analytical technique for the analysis of thermally labile drugs because it combines the advantages of the LC for sample introduction at low temperatures with the EI/MS ionization, fragmentation, and library-searching capability.[2] Many Novel Psychoactive Substances (NPS), including synthetic cathinones and synthetic cannabinoids, are thermally labile and, therefore, are difficult to detect and identify using GC/MS. Moreover, analysis of these compounds by LC/MS/MS is hindered by the lack of a universal library searching of the MS/MS spectra. There is also a need to develop a field-portable analytical technique for on-site real-time confirmatory analysis of illicit drugs, especially the synthetic drugs that are flooding the illegal markets. To address these issues, a field-portable nLC/EI/MS is being developed by using a field-portable Easy 1000 nanoLC™ in conjunction with a field-portable Viking 573 mass spectrometer, on loan from the Federal Bureau of Investigation (FBI). Development of the nLC/EI/MS also allows the analysis of thermally labile compounds or compounds that are difficult to analyze by GC/MS. NanoLC flow rates are in the range of 100nL-500nL/min, allowing the sample to be introduced directly into the MS ion source. Analytes are then ionized and fragmented using electron ionization, producing fragmentation patterns similar to the conventional GC/MS. An nLC flow rate of 300nL/min was used with a mobile phase of H_2O and acetonitrile each containing 0.1% formic acid. First, the method parameters such as flow rate, column length and inner diameter, mobile phase composition, and injection volume were optimized for maximum sensitivity using caffeine, methamphetamine, and morphine. After determining the optimum parameters, a nano C18 column was attached to the nLC for separation of drug mixtures. Good separation was achieved for a methamphetamine and caffeine mixture, as well as for a morphine and cocaine mixture. These compounds were identified using the Viking National Institute of Standards and Technology (NIST) EI library. Application of this new technique to the separation and identification of novel psychoactive drugs, such as synthetic cathinones and synthetic cannabinoids, will be discussed. Once method development is completed, it is planned that the nLC/EI/MS will be tested in the field.

Portable Nano-LC, LC/EI/MS, Drug Analysis

B163 A Collaboration for Forensic Student Success: Bridging the High School-to-College Transition

Jillian C. Fesolovich, Keystone College, One College Green, PO Box 50, La Plume, PA 18440; Ashley Hudgins, MS*, Phoenixville Area High School, 1200 Gay Street, Phoenixville, PA 19460; and Vicki A. Stanavitch, PhD, Keystone College, One College Green, Capwell Hall of Science, La Plume, PA 18440*

After attending this presentation, attendees will be knowledgeable regarding a new approach to forensic science students transitioning from K-12 studies into undergraduate programs. Attendees will learn about this transitionary program through a pilot research-focused internship conducted between a high school and a primarily undergraduate institution.

This presentation will impact the forensic science community by providing a model of how to prepare high school seniors for undergraduate forensic science programs on two different aspects: forensic science educational expectations and campus life expectations. Research has shown that a gap exists between secondary and post-secondary education due to a lack of consensus between K-12 graduation requirements and higher education curriculum requirements.[1] Although a tight collaboration between a high school and college forensic science program cannot endeavor to change requirements, the pilot internship provides a first glance at the skills and critical thinking needed to succeed in a forensic science undergraduate program. With the increase of interest in forensic science, universities and high schools have responded by developing summer programs, outreach programs, and college-level classes for students.[2] While these programs provide opportunities to promote the many sciences rooted in the forensic discipline, the transitionary program offers an advantage. Students have the ability to work on original forensic research, analyze samples via instrumentation, present their results, and explain how their studies impact real-world situations. The pilot program's hands-on experience with forensic research prepares students for the skills and critical thinking expected in forensic science.[3]

Any life transition is difficult, and the first year of college transition is oftentimes considered the hardest a young person's experiences. During this time, students may experience personal and emotional problems while struggling to be successful in the classroom. Many colleges and universities have created programs and courses to help ease the stressors encountered during this transition (e.g., first-year experience groups, orientation sessions, and individual counseling). Faculty and administrators also continually work toward addressing deficiencies in the classroom with tutoring, small class sizes, and individualized student support. The approach presented in the pilot internship addresses the deficiencies of college-bound young adults by creating an opportunity for students to begin this transition during their senior year of high school. The program allows the students to experience campus life through dorm housing, social activities, off-campus trips and field work. These experiences help to ease the transition of high school students to campus life.

The pilot program partnered a Philadelphia, PA, suburban high school with a rural Pennsylvania college. In the early summer of 2017, Keystone College hosted seven high school seniors with varied interests in the biological and physical sciences. Three students were interested in the forensic sciences and are the focus of this program assessment. The goal of the program was to immerse high school seniors in original forensic science research through a week-long internship program in which they live and learn on campus as college students. At the completion of the week, students gained laboratory, critical thinking, presentation, and research skills to carry into college. These newly acquired or enhanced skills will help them be successful in their high school-to-college transition. Original research focused on trace evidence analysis and the postmortem submersion interval was conducted and results will be presented. Data and evaluation through surveys of the students during the program and during their first term as college students will also be presented.

Education, K-12, College Transition

B164 Using Forensic Cases to Improve Ethical Reasoning Skills

Lyndsie N. Ferrara, MS, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15219; and James B. Schreiber, PhD, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15282*

After attending this presentation, attendees will understand how and why an ethical reasoning curriculum was created for forensic science students.

This presentation will impact the forensic science community by highlighting the importance of improving the ethical reasoning skills of forensic science students. This presentation will explore the ethical reasoning modules created and the classroom results. Particular focus will examine the way real-life cases are incorporated in the problem-based learning format.

The misconduct of Fred Zain, Annie Dookhan, Phillip Mills, and Sonja Farak still haunt the forensic science community. The misconduct performed by these individuals highlights the need for improved education focused on ethical reasoning and decision making. A pro-active educational approach provides students with the skills necessary to navigate ethical challenges in the workplace.

A national higher education organization, the Association of American Colleges and Universities (AAC&U), lists ethical reasoning and action as an essential learning outcome. Ethical reasoning skills are imperative for the successful navigation of career challenges. Ethics education is beyond right and wrong. Traditional ethics education is often recall-based. Students study theories and professional codes, but skill development is missing. Students need to be equipped with the skills to make ethical decisions.

A curriculum was designed to improve ethical reasoning skills for forensic science majors. Examples from pop culture along with real-life criminal cases highlight ethical reasoning in forensic science. The reasoning process and ethical dilemmas presented in the curriculum simulate real-life work. The curriculum is built as a developmental trajectory from understanding reasoning to activities that simulate decision making in real-life cases. This is a problem-based learning focus. Developing a problem-based learning curriculum in a module format engages students in an active learning process. Additionally, creating the modules in an online system allows for more detailed data analysis and expansion to a broader audience beyond a single classroom.

Multiple modules exist in the current ethical reasoning curriculum. First, the student is exposed to a brief philosophical background that provides a basic understanding of an individual's belief system and how new beliefs are created when confronted with genuine doubt. The next module explores the different types of reasoning methods. Students identify the three forms of reasoning in a variety of circumstances (i.e., text, video, and case descriptions). The next module further delineates the types of reasoning into multiple modes. Another module specifically focuses on the ethical theories and principles surrounding justice, privacy, and the common good. The role of these ethical principles as they relate to forensic science are explored. The modules use pop culture examples, from shows such as Monty Python and Sherlock Holmes, to introduce concepts before real-life examples are incorporated into the modules. The modules progress from simple to complex case examples. The use of real-life case examples is imperative for students to understand the impact of the forensic practitioner's actions. The module integrates the previous materials into full case studies that are completed by individuals or groups. These full cases present information at different times in the analysis in order to simulate how information is obtained in a case.

Results specifically from the module focused on reasoning types demonstrate students' abilities to understand and identify the three reasoning types. Detailed data analysis further illustrates questions in which students struggle. Additionally, specific skills tied to each assessment question indicate the level of student learning. The data analysis tools associated with the online system allow for detailed evaluation of student learning and provide constructive feedback for improved iterations of the modules.

Ethics, Reasoning, Education

B165 Teaching Ethics in Forensic Science: A Laboratory Approach

Douglas A. Ridolfi, MS, Buffalo State College, Chemistry Dept, Rm 451, 1300 Elmwood Avenue, Buffalo, NY 14222*

After attending this presentation, attendees will be informed of other methods by which a traditional lecture-based and discussion-based subject may be presented in an alternate format that emphasizes creativity and laboratory skills that may be applied to novel applications. Suggestions for laboratory practicals involving a variety of true-to-life ethical dilemmas that one may face in a laboratory environment will be presented, in addition to suggestions for active learning.

This presentation will impact the forensic science community by examining real-world ethical dilemmas and constructing a case scenario around them that would lead to guided discussion, creative problem solving, and laboratory-based principles to help resolve some of the issues addressed. Such an approach will involve looking at underlying motivation, methods for accomplishing deceptive practices in forensic practice, and utilizing methods to uncover them.

This proposed class is designed to integrate the teaching of ethics into a forensic chemistry major at the undergraduate or graduate level. Expanding on an existing one-unit special-topics class dealing with ethics in a forensic science setting to a three-unit semester class will involve laboratory and case study sessions along the lines of: (1) production, examination, and detection of forged fingerprints and footwear lifts; (2) detection of altered and fraudulent photographs in scientific journals; (3) detection of misrepresentation in photographs; (4) questioned document examination of altered laboratory notes, such as examination of interlineations, examination and decipherment of obliterations, altered ink entries (Infrared (IR) luminescence and fluorescence), and Electrostatic Detection Apparatus (ESDA) methods for the examination of indented writing); (5) development of protocols for the detection of planted crime scene evidence; (6) preparation of simulated historical documents accompanied by artificial aging methods; (7) evaluation of court displays and other demonstrative evidence; (8) obtaining background information on opposing expert witnesses — evaluation of resumes; (9) critical examination of court transcripts; (10) dry labbing — work flow, time management, supervision issues, and quality assurance methods to aid in its detection; and, (11) ethics tool kits — establishing guidelines for ethical decision making, personal and general, and the development of decision-making processes for different ethical dilemmas.

In addition to the lab practical's, the course will incorporate homework and discussion topics centering around ethical case studies and common ethical situations that may occur in a laboratory setting. Using creative problem-solving methods, students will brainstorm and develop methods to falsify evidence, detect various types of altered evidence, and develop methods to challenge questionable evidence.[1]

Education, Ethics, Applied Learning

B166 Supplementing Forensic Science Services With Research, Training, and Mentoring: Employing Quality Management Personnel to Meet an Organization's Continuous Education Program Goals

Jasmine M. Jefferson, MS, Harris County Institute of Forensic Sciences, Quality Management/Training Manager, 1861 Old Spanish Trail, Houston, TX 77054; Michal L. Pierce, MS, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have a reference model of quality management staff employed to manage continuous education programs in a forensic science organization.

This presentation will impact the forensic science community by providing knowledge of a system to meet the continuous education and scientific research needs of a combined medical examiner and crime laboratory institute.

With a focus on casework, backlogs, and turnaround times, many forensic science laboratories are unable to commit to the development of research projects or programs to mentor future forensic scientists. Time is a limiting factor to consider if an organization strives to fulfill an objective of maintaining a connection between forensic science practitioners and the broader scientific community.

The Harris County Institute of Forensic Sciences (HCIFS) is an integrated medical examiner office and crime laboratory located in Houston, TX. The HCIFS organizational structure includes an independent Quality Management Division, which oversees the multiple quality systems throughout the entire organization. Based on a strategic goal to establish an academic environment for training in forensic science, HCIFS created a full-time Training and Development Manager position that reports directly to the Quality Director. HCIFS demonstrates dedication to diversity in the education of current practitioners, future forensic scientists, and forensic pathologists, while fostering a research culture through a variety of programs and also maintaining seven accreditations, including two dedicated to the education and training of forensic pathologists. The Training and Development Manager coordinates the activities in each of these programs and assesses training needs, organizes and administers professional development opportunities, coordinates training and research programs, and creates training programs to support the continuing education of the large percentage of staff who hold a certification in each of the diverse forensic disciplines.

Accredited by the Texas Medical Association for Continuing Medical Education (TMA-CME), HCIFS offers continuing medical education opportunities year-round, specifically designed to meet the unique knowledge, competence, and performance needs of forensic pathologists. HCIFS trains up to two forensic pathologists per year through their comprehensive and rigorous forensic pathology fellowship program, which is accredited by the Accreditation Council for Graduate Medical Education (ACGME). Post-doctoral fellowship programs designed for advanced research and method development are maintained in three additional disciplines at the Institute — forensic anthropology, forensic genetics, and forensic toxicology. Additionally, medical students and medical residents can participate in a rotation through the forensic pathology division for education and training.

HCIFS offers an annual summer internship program through which students from United States academic institutions can apply to be an intern in a variety of different disciplines. Internship opportunities are offered with each of the forensic disciplines in the Institute, including: forensic anthropology, forensic entomology, forensic toxicology, drug chemistry, forensic genetics, trace evidence, firearms identification, forensic investigations, forensic emergency management, forensic imaging, and histology. The Institute also offers internship opportunities in the administrative branch, such as systems support and finance. The summer internship program offers a structured program where students apply their scientific knowledge to a structured research project, provide presentations of the results of those projects to HCIFS management and staff, and participate in professional development. Year-round internship opportunities are maintained through partnerships with local universities in the victim's assistance section and the histology laboratory.

A unique opportunity for international medical examiners and forensic science practitioners is also available at HCIFS. Practitioners in the field of forensic science affiliated with academic or governmental institutions outside of the United States can apply to observe HCIFS methods and procedures as an information-sharing partnership.

The HCIFS hosts an annual "Topics in Forensic Sciences" (TIFS) conference. The TIFS conference is a multidisciplinary forum for information sharing with the medical, forensic science, legal, and law enforcement communities. During the TIFS conference, research is presented, procedures are illustrated, and best practices in methods are discussed.

The HCIFS supplements forensic science services with comprehensive training and maintains connection with the broader scientific community. By employing a Training and Development Manager in the Quality Management Division, the organization is able to maintain and coordinate training programs, research projects, and mentoring programs while complying with the standards set forth by multiple accreditation bodies.

Continuous Education, Quality Management, Training Programs

B167 Validation of a Portable Direct Analysis in Real-Time Mass Spectrometry (DART®-MS) System for Trace Explosives Detection in the Laboratory or in the Field

Marcela Najarro, MFS, NIST, 100 Bureau Drive, MS 8371, Gaithersburg, MD 20899; Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899; and Elizabeth Robinson, MS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899*

The goal of this presentation is to provide performance characteristics of a portable DART®-MS system for the rapid analysis of trace explosives.

This presentation will impact the forensic science community by providing a validation framework for the use of a portable DART®-MS system in the detection of trace explosives and smokeless powders.

The detection and identification of trace explosives is critical to counterterrorism efforts as well as the forensic analysis of post-blast residues. While techniques such as Ion Mobility Spectrometry (IMS) are capable of rapidly screening for explosives with high sensitivity, benchtop instruments with a mass spectrometer detector are preferred due to their increased specificity. Forensic science practitioners are hopeful that the recent advances in the field of Ambient Ionization Mass Spectrometry (AIMS) will provide analysts with a robust analytical solution to meet the demands of both the laboratory and the field. AIMS techniques allow for the direct analysis of samples, or surfaces containing residues, without the need for sample preparation, extraction, and/or separation, thereby increasing sample throughput and reducing backlogs issues. The most popular and promising ambient MS technique for forensic applications is DART®-MS. Forensic laboratories around the country have already applied DART®-MS to the analysis of forensic evidence such as illicit drugs, pharmaceuticals, lotions and lubricants, and chemical warfare agents. Ionsense® (in collaboration with Waters Corporation) has recently released the DART® QDa, a mobile miniaturized mass spectrometer with a DART® source. This type of instrument has the potential to improve routine forensic analyses in the laboratory as well as be a reliable tool for first responders in the field by providing rapid and accurate detection.

Before a novel analytical technique can be fully adopted by forensic laboratories for casework, a thorough validation study must be completed to establish performance characteristics. This work was completed to address many of the components required for a thorough validation study. Initial studies utilized a Design Of Experiments (DOE) to identify the parameters most influential to method optimization for the analysis of mixtures, real-world samples, and unknowns. To accomplish this, two separate studies were completed, one examining source/desorption effects and one examining mass spectrometer effects. In both instances, a two-level full factorial DOE was implemented. Results identified the relative impact that instrument parameters, such as thermal desorber temperature, DART® ionization gas, and DART® grid voltage, have on explosive response.

After completion of the DOE studies, analytical figures of merit such as Limit Of Detection (LOD), linear dynamic range, repeatability, and reproducibility were determined. In order to accurately obtain these figures, inkjet printed standards were used. Inkjet printing technology allows for the precise deposition of traces of material on a surface with great reproducibility (<1% Relative Standard Deviation (RSD)).

Explosives studied included military explosives (RDX, TNT, PETN), peroxide-based (TATP, HMTD), inorganic explosives (AN, PC), and smokeless powder components (ethyl centralite, diphenylamine, dibutyl phthalate, nitroglycerin, and n-nitrosodiphenylamine). These compounds were analyzed both as pure compounds and in complex mixtures to better understand competitive ionization effects. For most explosives, performance was comparable to laboratory-based DART®-MS systems, with LODs in the sub-nanogram range, and minimal interferences from complex matrices.

Explosives, DART®-MS, Smokeless Powders

B168 Chemical Imaging of Cyanoacrylate-Fumed Fingerprints Using Mass Spectrometry Imaging

Kelly C. O'Neill, Iowa State University, 1111 WOI Road, 0027A Roy J Carver Co-Lab, Ames, IA 50011; Paige L. Hinners, MS, 1521 North Dakota, #2, Ames, IA 50014; and Young-Jin Lee, Iowa State University, 35A Roy J Carver Co-Lab, Ames, IA 50011*

After attending this presentation, attendees will understand how mass spectrometry imaging is compatible with some current forensic practices, such as cyanoacrylate fuming, and could therefore be a valuable technique in the forensic field.

This presentation will impact the forensic science community by drawing attention to compatibility issues that are inhibiting the adoption of new technologies. In addition, new insight into the polymerization mechanism of cyanoacrylate fuming is presented.

Introduction: Chemical analysis of fingerprints using mass spectrometry is a method for gaining valuable information about potential suspects. In order for the technique to be realistically integrated into an investigative procedure, it must be compatible with current forensic techniques. As much of current practices are focused on visualization of fingerprint ridges for a database match, procedures to enhance the quality of the fingerprint are common. Cyanoacrylate fuming is one such technique in which latent fingerprints are exposed to gaseous cyanoacrylate, forming a visible polymer on the surface of fingerprint ridges. In this work, the compatibility of cyanoacrylate fuming and Matrix-Assisted Laser Desorption/Ionization-Mass Spectrometry (MALDI-MS) is investigated as well as the cyanoacrylate polymerization mechanism.

Methods: Several fingerprint samples were prepared both with and without development by cyanoacrylate fuming and with different matrices for MALDI-MS. They were analyzed using a MALDI-linear ion trap-Orbitrap™ MS coupled to an Nd:YAG laser. Unique background peaks present in only the negative mode spectra of cyanoacrylate-fumed samples were further analyzed and structural information was obtained with Tandem Mass Spectrometry (MS/MS). Standard solutions of several common fingerprint compounds were used to study the polymerization reaction, including a triacylglycerol (glyceryl tripalmitate), several fatty acids (oleic, stearic, and palmitic acids), cholesterol, squalene, and an amino acid (isoleucine). The solutions were pipetted onto two slides, one of which was fumed with cyanoacrylate, while the other was not. The level of polymer formation was compared between different analytes.

Results: Dihydroxybenzoic Acid (DHB), α-Cyano-4-Hydroxycinnamic Acid (CHCA), iron oxide nanoparticles, and silver nanoparticles were tested as matrices, which are necessary to absorb the laser energy and desorb/ionize analytes. All endogenous compounds were still present at their expected masses with no significant change in their signals. The images of endogenous compounds in the fumed fingerprints were of equal quality to the images from the non-fumed fingerprints. Likewise, exogenous compounds appeared at their expected mass; however, one class of ionic compounds had suppressed signal in fumed fingerprints. Other groups have attempted similar analyses of fumed fingerprints on MALDI-Time Of Flight (TOF) without much success. It is proposed that the instrument used in this study, MALDI-linear ion trap-Orbitrap™, is superior to MALDI-TOF for MS imaging of cyanoacryalte-fumed fingerprints because there is minimal influence from electric field inhomogeneity on the MALDI plate surface.

Several peaks were observed in fumed fingerprints in negative mode that were not present in non-fumed fingerprints. These peaks were thought to be related to the cyanoacrylate polymer and were further analyzed by MS/MS. Based on the MS/MS as well as elemental composition from accurate mass, these peaks were determined to be cyanoacrylate dimer and trimer derivatives. A mechanism for their formation and polymerization is proposed based on their structure.

Varying amounts of polymer formed on the surface of different standard compounds. For example, some, such as triacylglycerols and squalene, had little-to-no polymer formation, while others, especially fatty acids, had significant polymer formation. This result indicates that fatty acids may play a more important role than other endogenous compounds in the polymerization process. In addition to the visual increase in cyanoacrylate polymer formation, signal intensities for the cyanoacrylate compounds also increased.

Conclusion: Cyanoacrylate fuming and MALDI-MSI of latent fingerprints are very compatible techniques. Important chemical information can be gained from fingerprints that have been cyanoacrylate fumed without sacrificing signal intensity. No compounds studied so far have been chemically modified by the fuming process, so data analysis is straight forward. In addition to the compatibility study, valuable insight into the mechanism for polymerization of cyanoacrylate on fingerprints was also achieved. Cyanoacrylate dimers and a trimer were identified in the mass spectra and the importance of fatty acids in the polymerization process was revealed.

Polymerization, Cyanoacrylate Fuming, Mass Spectrometry Imaging

B169 Lifestyle Determination From Chemical Identification in Fingerprints

Paige L. Hinners, MS, 1521 North Dakota, #2, Ames, IA 50014; Kelly C. O'Neill, Iowa State University, 1111 WOI Road, 0027A Roy J Carver Co-Lab, Ames, IA 50011; and Young-Jin Lee, Iowa State University, 35A Roy J Carver Co-Lab, Ames, IA 50011*

After attending this presentation, attendees will better understand Mass Spectral Imaging (MSI) applications to latent fingerprint analysis. Specifically, this presentation will focus on the importance of all exogenous compounds present in latent fingerprints.

This presentation will impact the forensic science community by improving understanding of the usefulness of MSI for the identification of chemical compounds in latent fingerprints. Most importantly, the exploitation of all exogenous compounds will allow the forensic science community to compile the lifestyle of an unknown fingerprint donor.

We are surrounded by chemicals, many of which are influenced by the lifestyle of an individual, and can be studied by metabolomics tools.[1,2] This lifestyle characterization approach can be extended to latent fingerprints. MSI has been applied to chemical imaging of fingerprints and visualizing endogenous and exogenous compounds. Previous work for exogenous compounds has focused on drugs and explosives, but little has been done to exploit other compounds that can be used as lifestyle markers.[3,4] The focus of this work was to compile potential lifestyle markers of a fingerprint and develop a method that can efficiently analyze a broad range of exogenous compounds.

Consumer products were applied per product instructions, and a fingerprint was then deposited on a glass slide pre-cleaned with methanol. Citrus fruits, alcohol, and food oil samples were touched to mimic consumption, a spill, or the handling of foodware before making a fingerprint. Gold and silver targets were sputter coated for matrix deposition at 20mA for ten and five seconds, respectively. A linear ion trap-Orbitrap™ mass spectrometer with a Matrix-Assisted Laser Desorption/Ionization (MALDI) ion source was coupled with a 355nm Nd:YAG laser. Imaging and profiling of fingerprint samples was conducted with a 100µm raster step, ten laser shots per raster step, and a 30µm laser spot size over the m/z range of 50-1,000. For multiplex imaging, a spiral raster step was employed for fragmentation of known precursor masses.[5] Positive and negative ion modes were employed for profiling, imaging, and multiplex imaging.

In the analysis of latent fingerprints containing bug spray and sunscreen, the variations in active ingredients allowed brand differentiation. The differences in the spectra of three bug spray brands were easily correlated to the active ingredient in each. While most sunscreens can be differentiated based on the active ingredient list, two brands containing the same active ingredients were isolated based on the relative abundances of each compound. The spectra of Coppertone® and Neutrogena® sunscreens were dominated by octocrylene, but avobenzone was only abundant in Neutrogena®. Octocrylene, avobenzone, and octinoxate proved to be key compounds in distinguishing sunscreen brands.

Human fingerprints naturally contain Triacylglycerols (TGs), secreted from sweat glands, but those from plants have distinct patterns of saturation on fatty acyl chains. As expected, three cooking oils and a vegetable spray revealed distinct TG patterns distinguishable from human TGs. The most abundant TG species in olive and canola oil is TG 54:3 as a sodiated adduct at *m/z* 907, and TG 54:4 at *m/z* 905 in sesame oil, which are present only in minimal abundance in natural fingerprints. Olive oil had a narrow unsaturation pattern, whereas sesame and canola oil exhibited very broad unsaturation patterns. Vegetable spray is easily identified in fingerprints due to multiple unique TGs and the presence of phosphatidylcholines.

Fingerprints contaminated with alcohol were commonly identified based on the presence of sugars, ethyl palmitate, ethyl myristate, and glycerol. The analysis of wine proved to be the most informative in negative mode, based on the presence of gallic, tartaric, succinic, malic, and galacturonic acids. Fingerprint spectra containing beer were dominated by various sugars, including a unique malt starch, from the malting and brewing process.

The chemical compounds in mandarins, lemons, and limes were explored. Citric acid was present in all three, but consistently present at higher relative abundance in the lemons and limes. Mandarin fingerprints also contained malic acid, naringenin, tangeretin, and nobiletin, which were not present at detectable levels in the lemons and limes.

This study proves that a broad range of exogenous compounds can be detected and confirmed in latent fingerprints using MSI. A multiplex imaging method was applied to the analysis of exogenous compounds in latent fingerprints. Each compound in the latent fingerprints was identified by accurate mass and Tandem Mass Spectrometry (MS/MS). The compilation of the detected exogenous compounds could lead to a lifestyle determination of the unknown fingerprints source.

B170 The Identification of Prohibited Treatments on Racing Tires by Solid Phase Microextraction (SPME)

Zackery Roberson, 710 Sunset Boulevard, Greenwood, IN 46142; and John V. Goodpaster, PhD, FIS Program, IUPUI, 402 N Blackford Street, LD 326, Indianapolis, IN 46202*

The goal of this presentation is to provide attendees with an understanding of SPME as applied to the detection of racing tire treatments.

This presentation will impact the forensic science community by highlighting the area of trace tire treatment analysis in automotive racing.

In the realm of automotive racing, many competitors will do whatever it takes to win a race. In several racing leagues, it is prohibited to alter tires in an attempt to increase the "grip" or ability of the tire to maintain contact with the track. The most common way that competitors will attempt to alter tires is by applying "tire treatments," mixtures of chemicals that either swell or soften the rubber to increase the surface area in contact with the track. Tire treatments are commercially available and are allowed in some racing leagues. The commercial treatments fall into two categories — "plasticized" and "petroleum distillate." Many of the products used in leagues that prohibit them are labeled as "undetectable," implying that they would not be found by testing post-race. Some competitors will use their own mixtures that are typically based on petroleum distillate products and can resemble or contain common ignitable liquids.

Tire samples provided by the United States Auto Club (USAC) were prepared for analysis by placing a cut piece of tire into a 20mL headspace vial. The sample is then heated to 40°C and volatiles are extracted using a Poly(DiMethyl)Siloxane (PDMS) SPME fiber for five minutes, followed by analysis using Gas Chromatography/Mass Spectrometry (GC/MS). Thus far, qualitative analyses have been sufficient to determine treated tires from untreated tires. The "plasticized" treatments typically give off compounds such as diethyl pentanedioate and 2-ethyl-1-hexanol. Tires treated with "petroleum distillate" products typically give off complex chromatograms that resemble those of common ignitable liquids. Tires have been seen to have been treated with gasoline as well as medium-heavy aromatics, among others.

Since the beginning of this project, 201 samples have been analyzed. Of those samples, 23 have been flagged as having been treated. A small number of those flagged appeared to have been soaked in gasoline. The minimally destructive nature of the testing has allowed repeat analyses of samples in certain instances. Unless rules change, detection of tire treatments will continue to be an area of interest. SPME is, and will continue to be, a powerful tool within this area of analysis.

This work was funded by Indiana University–Purdue University Indianapolis (IUPUI) and the USAC.

Solid Phase Microextraction, Tire Treatments, GC/MS

B171 Decreasing the Uncertainty of Peak Assignments Using Multidimensional Ultra-High Performance Liquid Chromatography (UHPLC)

Cecilia Marisol Ochoa, BA, 3814 Davis Place, NW, #202, Washington, DC 20007; Peter J. Schoenmakers, Science Park, Amsterdam, NETHERLANDS; Claude Mallet, PhD, Waters Corporation, 34 Maple Street, Milford, MA 01757; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand the potential for multidimensional UHPLC to significantly reduce peak assignment uncertainty based on retention time.

This presentation will impact the forensic science community by demonstrating the utility of multidimensional UHPLC as a separation technique for drug analysis. Screening and identification of emerging drugs can be achieved with significantly decreased uncertainty using multiple dimensions compared to one-dimensional LC. Identification can be accomplished through retention times obtained in the first and second dimensions.

Chromatographic techniques, which are commonly employed in forensic analysis, utilize retention time as an identification parameter. Conventional single-dimension chromatographic techniques, such as Gas Chromatography (GC) and LC, inherently lack the separation power required to resolve the multitude of combinations possible when analyzing emerging drugs. The use of multidimensional chromatography, which significantly increases the resolving power, is a viable means to increase the utility of retention time measurements for compound identification.

One-dimensional UHPLC separations were conducted on mixtures of controlled emerging drugs and mixtures of positional isomers of certain of these solutes for either synthetic cannabinoids, synthetic cathinones, or phenethylamines in order to determine the most orthogonal combination for multidimensional chromatography. The separations utilized several stationary phases for both Reversed Phase Chromatographic (RPC) separations and Hydrophilic Interaction Liquid Chromatographic (HILIC) separations. All separations utilized 2.1mm x 100mm or 2.1mm x 50mm columns with 1.7µm or 1.8µm particle sizes, with either a 10min acetonitrile or methanol gradient (hold up to 5min) with a pH 2.3 formic acid or ammonium bicarbonate pH 11.6 additive, or identical isocratic mobile phases containing acetonitrile and water with an ammonium formate additive for up to 5min HILIC separations. HILIC and high pH separations were only applicable to the basic cathinone and phenethylamine solutes. Peaks were identified through their obtained Ultraviolet (UV) and Mass Spectrometry (MS) spectra. The retention times obtained for each separation were used to determine correlation coefficients (R^2) for two columns, which were then used to determine the Neue selectivity factor (S^2)[1], a measure of the orthogonality for multidimensional chromatography. The peak capacity (n_c) was determined for each separation and the theoretical peak capacity ${}^1n_c * {}^2n_c$ for a multidimensional separation that assumes full coverage of the possible separation space, which is difficult to obtain in practice. Since the actual separation space can be approximated by the S^2 value, the actual peak capacity can be estimated by the following equation: ${}^{2D}[n_c]_{actual}={}^1n_c[1+S^2({}^2n_c-1)]$ with $[1+S^2({}^2n_c-1)]$, which represents the gain factor in going from a one-dimensional separation to a multidimensional separation. In this work, the actual multidimensional peak capacity was also used to measure peak assignment uncertainty. Based on the one-dimensional separations performed, it was determined that a combination of a C8 and a PFP column produced the highest S^2 values, and were thus more orthogonal, for both the controlled synthetic cannabinoids and the JWH-018 positional isomers. For the above column combination, the peak capacity for the controlled synthetic cannabinoids mixture showed an increase from 69 for one-dimensional LC to 3352 for multidimensional chromatography. The gain factor was determined to be approximately 50; thus, the peak assignment uncertainty was decreased by 50x with the use of multidimensional chromatography. Likewise, the JWH-018 positional isomers, which elute in a narrower separation space, showed a peak capacity increase from 5 to 53 and a gain factor of 10. For synthetic cathinones and phenethylamines, it was determined that the best combination would be a C8 and PFP column operated in the RPC and HILIC modes, respectively. For these mixtures of controlled substances, similar peak capacities as synthetic cannabinoids were obtained in the first dimension, with gain factors of nine and five for the synthetic cathinones and phenethylamine, respectively, in going from one-dimensional to two-dimensional separations. Similar to the synthetic cannabinoids, smaller gain factors were obtained for positional isomers of synthetic cathinones and phenethylamines.

Examples of multidimensional separations will be presented. Through the use of multidimensional UHPLC, uncertainty in peak assignments would be significantly reduced, leading to increased accuracy in the identification of seized drugs. The number of chromatographic runs performed can also be reduced as only one chromatographic system would need to be employed to obtain orthogonal separations.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, and the United States Department of Justice. The opinions, findings, and conclusions expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Emerging Drugs, Multidimensional, Chromatography

B172 Assessing the Forensic Utility of a Silicone Rubber Passive Sampler for the Detection of Pollutants in Aqueous Environments

Jonathan W. Bareford, BS, Virginia Commonwealth University, 3215 Ellwood Avenue, Apt C, Richmond, VA 23221; Jon Beihoffer, MS, US EPA NEIC, Bldg 25, Box 25227, Denver Federal Center, Denver, CO 80225; Eric J. Hazelrigg, MS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

The goals of this presentation are to introduce the field of environmental forensics to attendees, provide historical context of passive samplers, illustrate the advantages and disadvantages of silicone rubber as a sampling medium, and discuss these attributes as they relate to a forensic investigation. The findings of the silicone rubber assessment will be presented, and future characteristics that require additional experimentation will be discussed.

This presentation will impact the forensic science community by illustrating how improving the methodology used to detect organic pollutants in aqueous systems will directly benefit the National Enforcement Investigations Center, the forensic laboratory of the Environmental Protection Agency (EPA). By implementing a passive sampler system, the EPA can more efficiently investigate suspected criminal activity, monitor high-risk areas, and increase sample throughput while decreasing costs. These benefits can be extended to environmental regulatory laboratories as well. Most importantly, effectively prosecuting environmental crimes will prevent the continued circumvention of the law, protecting our aquatic ecosystems and primary sources of drinking water. This study seeks to equip investigators with a powerful tool to prosecute environmental crimes by conclusively determining the effectiveness of a silicone rubber sampler for detecting organic pollutants in fresh water systems.

Environmental forensic investigations often center around the illicit release of toxic chemicals into rivers, lakes, and streams. The nature of illegal dumping into these aqueous environments leads to the evidence quickly dissipating and vanishing beyond detection. Organic pollutants are easily transported over large distances through waterways, and due to their highly lipophilic nature, are readily absorbed by the ecosystem.[1] Currently, to determine the presence of a suspected pollutant, analysis begins with "grab" or "active" sampling. This method is performed by repeatedly collecting large amounts of water in glass jars over the course of a predesigned sampling period.[2] The disadvantages of this traditional method are numerous, presenting the forensic chemist with unique sampling challenges. A novel approach to environmental forensic sampling is required to adjust to the concealed nature of the crime. Passive samplers have the potential to fill this role. This study determined if silicone rubber is a sampling medium adequately suited to be utilized by environmental forensics as an investigative tool to uncover clandestine dumping of chemical pollutants into aqueous systems.

To assess the performance of the silicone rubber sheets, the sheets first needed to be prepared for deployment. This procedure was optimized in the initial phase of experimentation and was set at five 2½-hour wash steps. The first three washing steps were in a 1:1 mixture of ethyl acetate and hexane, and the final two were in 1:1 mixture of ethyl acetate and methanol. This washing method was developed by O'Connell et al.[3] Once the commercial-grade silicone rubber was cleaned, it was ready for deployment. Initially, the sheets were tested in a controlled laboratory setting. A known amount of 83 target compounds was added to three liters of deionized water. After a predetermined amount of time, either one day, three days, five days, or seven days, the sheets were removed. Following deployment, the sheets were extracted by Soxhlet for eight hours in a 1:2 mixture of acetonitrile and methanol. This extraction was then solvent-exchanged to methylene chloride and blown down to one milliliter with a nitrogen stream. This condensed extract was analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). Following successful laboratory testing, the silicone rubber sheets were field tested in nearby mountain streams and in the Denver, CO, Metro Wastewater's effluent system to determine resistance to environmental factors. The sheets withstood this harsher testing scenario.

The silicone rubber sampler absorbed a wide array of semi-volatile analytes commonly targeted in environmental analysis during laboratory testing. In field testing, the silicone rubber sampler was also capable of absorbing a range of compounds, including pesticides, polycyclic aromatic hydrocarbons, and various other compound classes at estimated concentration levels below the levels typically observed in environmental investigations. This preliminary testing is encouraging and suggests the silicone rubber sample is well suited for forensic use in investigating environmental crimes.

Environmental Forensics, Semi-Volatile Organic Compound, Passive Sampler

B173 An Investigation of the Correlation Between Human Age and Aspartic Acid and Asparagine Racemization and Isomerization of the Eye Lens Crystallins Proteins

Kaitlin Long, George Washington University, 2850 Cherry Street, Apt 307, Falls Church, VA 22042; and Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will be able to recognize the use of proteomics in the age estimation of human eye lens proteins using high-resolution nano-liquid chromatography (nanoLC) in conjunction with high-resolution high-mass accuracy tandem mass spectrometry. Moreover, attendees will understand the mechanisms of the post-translational modifications (racemization and isomerization) of eye lens proteins and how these modifications can be used as potential biomarkers of aging.

This presentation will impact the forensic science community by demonstrating another method for determining the age of an individual at the time of death.

Isomerization of aspartic acids and asparagines results in the formation of several optical and structural isomers, such as the conversion of L-α-Asp to L-β-Asp, D-α-Asp, and D-β-Asp via succinimide intermediate. Identification of these complex isomers requires a high-resolution separation technique to differentiate between these optical and structural isomers of the tryptic peptides. Since these isomers all have the same *m/z*, their identification requires the use of synthetic peptides. Eye lens samples from 40 patients have been obtained and 28 of them have been analyzed by high-resolution nanoLC in conjunction with a high-resolution mass spectrometer. The samples include both male and female ranging in age from 45 years old to 87 years old. Eye lens proteins were extracted based on their solubility in water and 8M urea solution. The proteins were digested with trypsin and analyzed using a 50cm-long nanoLC column with 0.75µm ID.

To identify and quantify the tryptic isomers, three synthetic peptides (TVLDSGISEVR, IQTGLDATHAER, and DVTIQHPWFK) were prepared and analyzed. Baseline separation of the isomers for each of the peptides were achieved for both the synthetic peptides and for the tryptic digests of the lens samples. These isomers were identified by comparing their retention order with the synthetically prepared peptides containing the four isomers. Preliminary data demonstrated the ability to use high-resolution separation for the identification of aspartic acid and asparagine isomerization. Analysis of eye lens crystallins from individuals with varying ages indicated significant differences in relative intensities of the four isomers for these peptides. Work is underway to correlate the relative intensities of these isomers to the age of the individuals. This study will be expanded to include other tryptic peptides containing single aspartic acids or asparagine.

Human Age Estimation, Eye Lens Proteins Isomerization, High Resolution Proteomics

B174 Experimental Approaches to Study the Degradation of Messenger RNA (mRNA) in Dried Bloodstains Subjected to Storage in the Laboratory

Jun Fu, PhD, 1111 W 17th Street, Tulsa, OK 74107; and Robert W. Allen, PhD, Oklahoma State University, Center for Health Sciences, 1111 W 17th Street, Tulsa, OK 74107-1898*

The goals of this presentation are: (1) to help define the useful roles for the molecular analysis of RNA in evidentiary body fluid stains; (2) to help attendees understand the role of stochastic effects on quantitation of RNA species; and, (3) to educate attendees regarding the molecular mechanism by which RNA degrades once outside the environment of the body.

This presentation will impact the forensic science community by explaining that, when a criminal act is discovered, the role of the investigative process is to answer the "who," "what," "where," and "when" of the crime. Of these questions, the "when" is often the most difficult to pinpoint, especially in identifying how long a sample has been at the scene or when someone has died.

Studies on the degradation of transcripts in dried body fluid stains hold potential for correlating transcript disappearance with the passage of time. If such a relationship could be established confidently, RNA degradation could be used to estimate the length of time since deposition of a body fluid at a crime scene or help estimate the time of death. Quantitative Polymerase Chain Reaction (qPCR) assays directed against one transcript whose abundance changes with time and a second that is stable presumably allows for normalization of results from different qPCR reactions and the delta Ct results (i.e., Ct for changing transcript minus Ct for the stable transcript) can be plotted as a standard curve relating transcript degradation with time. Transcripts from housekeeping genes as well as ribosomal RNA (rRNA) species have served the role of the "stable transcript" for comparative purposes; however, housekeeping transcripts and rRNA also slowly disappear over the time course and, moreover, stochastic effects that manifest in results from one or the other, or both, transcripts during reverse transcription and subsequent qPCR amplification cause unacceptable levels of variability in the quantities of all but the most abundant transcripts.

RNA sequencing data, produced using Ion Torrent™ Next Generation Sequencing (NGS) technology, from the transcriptomes of dried body fluid stains stored for varying periods of time identified collections of transcripts that disappeared from RNA-seq data with differing rates and also revealed the sequencing read depth of nucleotides in the 5' ends of numerous transcripts decreased from sequencing results faster than the read depth for nucleotides at the 3' end.[1] This observation raised questions of how mRNA transcripts degrade in dried body fluid stains and suggested that assessing transcript degradation based on the apparent differential disappearance of the 5' and 3' ends of **a single transcript** would allow for the results to be expressed as ΔCt (i.e., 5' Ct minus 3' Ct) and also perhaps minimize stochastic effects on data reproducibility, thereby improving the overall reliability of time estimates using the transcript degradation curves. Thus, rather than comparing Ct values produced during qPCR for two different transcripts (either or both susceptible to stochastic effects during reverse transcription), this method quantifies the opposite ends of a single transcript. Reported here are findings of this approach with several transcripts present in bloodstains that were aged at room temperature for periods of up to two years. Results suggest that mRNA in dried bloodstains degrades from the 5' end of the transcript and the difference in amplicon abundance from the 5' and 3' ends of several transcripts produces degradation curves that are more consistent and reproducible and thus may more accurately estimate the age of the stain.

RNA Degradation, RNA Quantitation, Sample Age

B175 The Characterization and Persistence of Vaginal Bacteria Under Fingernails

An Truong, BS, 2957 Bowery Lane, San Jose, CA 95135; George Sensabaugh, DCrim, University of CA, Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720; and Cassandra Calloway, PhD, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Junior Way, Oakland, CA 94609*

The goal of this presentation is to inform attendees regarding the usefulness of bacterial flora in determining the biological source for vaginal contact in sexual assault investigations.

This presentation will impact the forensic science community by demonstrating that bacterial flora could be characterized according to their genera and evaluated to determine if there was vaginal contact in sexual assault investigations, which could provide more weight to sexual assault biological evidence.

For sexual assault cases involving digital penetration, probative DNA evidence from the victim's vaginal fluid could be under the suspect's fingernails. This type of DNA evidence can establish a direct link from suspect to the victim; however, the suspect could argue that the accumulation of the victim's DNA under the suspect's fingernails was due to casual or daily contact with the victim. A solution to this problem is to identify the body fluid as vaginal fluid using the presence of *Lactobacillus* bacteria species that are found natively in the vagina. Previous research has shown that it is possible to identify vaginal fluid using the 16-S ribosomal RNA (rRNA) gene of *L. crispatus, L. iners*, *L. gasseri,* and *L. jensenii.* Also, 16-S rRNA can be used to identify bacteria that are associated with a specific part of the human microbiome, such as the human skin. Resident flora that naturally occur on hands include *Staphylococcus*, *Proteus*, *Klebsiella*, and *Acinetobacter*. Further research has shown Next Generation Sequencing (NGS) technology can aid in 16-S rRNA sequencing and classifying bacteria associated with the vagina or skin. The goals of this project are: (1) to characterize the normal bacterial flora found underneath fingernails, in the vagina, and underneath fingernails following digital penetration; and, (2) to study the persistence of vaginal bacteria underneath fingernails following digital penetration.

In this study, 80 samples were collected from four couples (AAAB, BABB, CACB, and DADB) at designated time points (baseline, 0hr, 6hr, 12hr, 18hr, and 24hr) from underneath fingernails after digital penetration. The DNA was extracted, then the 16-S rRNA gene was targeted and amplified. The samples were then analyzed by NGS. A statistically significant difference in *Lactobacillus* frequencies when comparing source (experimental vs. control) was observed using a paired *t*-test (p=<0.0001). Higher frequencies of *Lactobacillus* were observed in experimental samples ranging from 0%-99.6% with a mean of 63.8%. In two couples, AAAB and CACB, the *Lactobacillus* populations were on average 6-11 times higher in experimental samples than control samples. The results were replicated in couple CACB and the experimental samples from that couple were predominately *Lactobacillus* even up to 24 hours ranging from 63.2%-99.6%. Also, a statistically significant difference in *Staphylococcus* frequencies when comparing source (experimental vs. control) was observed using a paired *t*-test (p=0.0046). Higher frequencies of *Staphylococcus* were observed in control samples ranging from 0%-97% with a mean of 41.9%. In two other couples, conversions from a predominately *Lactobacillus* population to predominately *Staphylococcus* population were observed after 6-12 hours.

Based on the results of this small study, it is possible to detect *Lactobacillus* at high frequencies after 24 hours; therefore, *Lactobacillus* could be used a biomarker to determine vaginal contact since a *Lactobacillus* population of a minimum frequency of 27% can suggest vaginal contact; however, a failure to detect *Lactobacillus* does not indicate the absence of prior vaginal contact.

Vaginal Bacteria, Sexual Assault Investigation, Next Generation Sequencing

B176 A Molecular Assessment of DNA Methylation Profiling For Body Fluid Identification in a Forensic Application

Dina A. Shokry, MD, Kasr Alaini, Cairo 00202, EGYPT*

After attending this presentation, attendees will better understand the use of epigenetics and methylated DNA in forensic practice as a tool for the identification of different biological fluids (blood, saliva, semen, and menstrual blood).

This presentation will provide navigation through the roles of epigenetics and DNA methylation in forensic applications and illuminate their uses in the identification of different bio-fluids. This presentation will impact the forensic science community by offering new epigenetic markers that are proven to be of value in this area and will help forensic science practitioners use a simple tool for the identification of blood, saliva, semen, and menstrual blood in different age and gender groups.

Background: Since 1985, when DNA analysis was applied to solving forensic problems, its foremost applications have included criminal investigation, personal identification, and paternity testing. DNA methylation is emerging as an attractive marker in forensic genetics that can provide investigative leads to help solve crimes. Natural roles of DNA methylation in mammalian systems include imprinting, X chromosome inactivation, heterochromatin maintenance, developmental controls, and tissue-specific expression controls.

DNA methylation plays a critical role in normal cellular processes and serves as a mechanism that turns off gene expression. Aberration in DNA methylation has long been linked to diseases such as cancer and is exploited as diagnostic biomarkers, but in forensic analysis, the use of DNA methylation as a tool is still in its infancy; however, there are many advantages to using DNA methylation as a forensic tool, with one of the most important being the stability of the marker, unlike protein or RNA markers that are quickly degraded, thus allowing for quantitative analysis of older samples.

Forensic applications of DNA methylation include: (1) the identification of body fluids; (2) differentiating Monozygotic (MZ) twins; (3) DNA methylation in age estimation; (4) the determination of paternal origin of allele; (5) the determination of cause and circumstances of death; (6) sex determination; and, (7) the authentication of DNA samples.

Goal: This study will explore the different applications of DNA methylation in forensic science with reference to the results of a study on Egyptian DNA methylation profiles of four markers (LINE-1, MT2A, MGMT, and FGF7) in blood, saliva, semen, and menstrual blood in attempt to assess the potential of those markers for identification.

Methodology: For this purpose, 52 samples from female participants and a similar number of samples from male participants were gathered. To explore age variation, each sample was divided into two groups of 26 each, one group more than 30 years of age and the other less than 30 years of age. Each sample was subjected to the following procedures: DNA extraction and amplification of the collected samples, then a bisulfite treatment of the amplified DNA samples. The bisulfate-modified DNA was used as a template for fluorescence quantitative Polymerase Chain Reaction (qPCR) assessment.

Results and Conclusion: The MGMT locus exhibited a differential methylation pattern in blood compared to semen, saliva, and menstrual blood. Therefore, the MGMT marker exhibited significant differences in its methylation patterns for the identification of blood when compared to the other fluids. MT2A was presumed to show a differential methylation pattern in saliva as it displays hyper-methylation state, but hyper-methylation is also seen in semen. No significant difference was seen between menstrual blood and other body fluids. These factors render MT2A not useful in differentiating between body fluids. The FGF7 marker displayed a differential methylation pattern in semen. Methylation values were greater in semen relative to blood, saliva, and menstrual blood. The methylation profile of LINE-1 successfully differentiated saliva from the other three examined biofluids. This marker displayed hyper-methylation in all saliva samples and hypo-methylation in all blood, semen, and menstrual blood samples. Regarding the use of these markers in differentiating between males and females, as well as between the different age groups (less than and more than 30 years of age), highly statistically significant differences were obtained.

DNA Methylation, Biological Fluid, Identification

B177 Can Detection of Testosterone With Anti-Testosterone Antibody Be Used to Identify Male Cells?

Jennifer Miller, BS, 6913 Marlowe Road, Apt 605, Richmond, VA 23225; Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Vamsi Yadavalli, PhD, Virginia Commonwealth University, Dept Chemisty & Life Sciences, 601 W Main Street, PO Box 843028, Richmond, VA 23284-3028; and Susan Greenspoon, PhD, Dept of Forensic Science, 700 N 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will better understand the potential of targeting testosterone to presumptively identify male cells on evidence items and at crime scenes, as well as its potential use for cell separation techniques prior to DNA profiling.

This presentation will impact the forensic science community by introducing a novel screening method for male cells that has the ability to decrease the time spent examining evidence items in the lab and, thus, have a potentially significant impact on casework backlogs.

Currently, research on fluorescent molecules as a screening tool for sex-specific cells has been primarily limited to sperm cell antigens and to Y-chromosome DNA (e.g., Fluorescent *In Situ* Hybridization (FISH)). Given that testosterone is normally present in most non-sperm cell types of males and is at approximately ten times the level of that found in females, it is a promising candidate probe molecule for identifying male cells. Therefore, the goal of this study is to test for the preferential labeling of male versus female cells using fluorescently-tagged anti-testosterone antibodies. The development of a potential screening tool to identify male cells in a biological mixture is the ultimate goal. Initial tests of several fluorescent reporter molecules with common laboratory alternative light sources showed the green CF514 dye (excitation and emission wavelengths, 516nm and 548nm, respectively) was clearly visible up to a 1:10,000 dilution. Based on these findings, an anti-testosterone antibody conjugated to a CF514 dye was investigated along with a Fluorescein Isothiocyanate (FITC) -tagged anti-testosterone antibody (excitation and emission wavelengths, 495nm and 519nm, respectively).

CF514-linked antibody hybridization was performed with buccal and epithelial skin cells of both male and female origin. Male and female buccal cells displayed no clear differences in fluorescence intensity when viewed with a fluorescence microscope after incubation with the anti-testosterone antibody. Epithelial skin cells were then tested because they are a known target tissue of testosterone action. Pressure was applied when retrieving the skin cells to ensure that not just the most outer layer of keratinized cells was collected. An aliquot of the epithelial cells was removed, the DNA extracted and quantitated, and the presence of DNA detected, suggesting the possible presence of deeper epidermal cells.

Due to this finding, antibody hybridization was performed with the epithelial skin cell samples fixed to glass slides. Slides that were dried after the antibody incubation without a coverslip displayed a visible difference in fluorescence between male and female cells and compared to the negative control; however, slides that were hydrated with water after antibody incubation displayed no noticeable difference in fluorescence between sexes. Antibody specificity testing with purified testosterone and estradiol indicated that CF514-linked and FITC-linked anti-testosterone antibodies preferentially bind to testosterone. Therefore, the difference between dry and hydrated cell labeling may be due to other molecular or optical dynamics, which might appear as fluorescence in the hydrated cell samples.

Testosterone may be successful in identifying and resolving male components in forensic casework; however, testing with a more sensitive instrument, such as a confocal laser scanning microscope, may prove to be more informative. Moreover, samples may need to be incubated with a reaction mix that contains multiple antibodies in order to enhance the fluorescent signal and assessed using the Fluorescence Activated Cell Sorter (FACS).

Anti-Testosterone Antibody, Male Cell Screening, Fluorescence Microscopy

B178 Toward Implementation of Improved Body Fluid Identification Methods

Toni M. Diegoli, PhD, 251 18th Street, S, Arlington, VA 22202; Karen Olson, PhD, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297; Philip Nase, MS, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297; Rachel Creager, 4930 N 31st Street, Bldg 925, Forest Park, GA 30297; Chinye Obata, BS, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297; Joel D. Sutton, MSFS, 4930 N 31st Street, Forest Park, GA 30297-5205; and Henry P. Maynard, MS, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will better understand the considerations involved in evaluating various novel body fluid identification methods for implementation into the forensic biology workflow. Attendees will be aware of the pitfalls of current serology practice and the benefits of several emerging methods while gaining insight into the challenges associated with operationalizing techniques for which few guidelines exist.

This presentation will impact the forensic science community by highlighting the results of at least three collaborative research efforts that resulted in methods to improve body fluid identification. In addition, this presentation will impact the field by: (1) describing the hurdles that must still be addressed for these methods to be used routinely; (2) proposing potential solutions; and, (3) prompting collaborative progress toward the establishment of guidelines and standard samples for their use.

While DNA technologies have advanced substantially over the past several decades, methods used to determine the presence of a particular body fluid have remained stagnant. Outdated techniques limit testing to three fluids — semen, blood, and saliva — via chemical, immunological, or histological methods. Though generally robust and easy to perform, these methods require a separate test for each fluid, have limited sensitivity, and consume a portion of the biological sample. Often, multiple sequential tests are used in combination to confirm the presence of a fluid, further adding to overall time, cost, and sample consumption. Additionally, known false positives and subjective interpretations hinder the definitiveness of an examiner's conclusions and testimony.

To this end, several emerging methods for body fluid identification are being explored at the Defense Forensic Science Center (DFSC) that could complement or replace these traditional techniques. These new methods simultaneously test for biological markers or signatures that indicate the presence of multiple body fluids, including two for which laboratories cannot routinely test at present: vaginal fluid and menstrual blood. Advanced reporting offers quantifiable results that can be reviewed by other examiners prior to court testimony as part of routine quality assurance measures. Initial results indicate a false positive rate for at least one of these methods of less than 1%.

Despite these benefits, integration into existing laboratory workflows is not straightforward. Additional instrumentation may be required, and an increase in processing time might drive decisions on how best to use the additional information provided by these methods. Though current guidelines exist for the validation of traditional serological and DNA techniques, these methods have not yet been operationalized in United States laboratories, and standard reference samples that allow both meaningful evaluation and subsequent quality control procedures do not exist. Potential strategies to begin addressing these concerns will be described and discussed.

Serology, Body Fluid Identification, mRNA

B179 Victim Sexual Assault Evidence Kits (SAEKs) — Teamwork Between a Crime Lab, Special Victim's Unit, and District Attorney's Office

Jennifer S. Mihalovich, MPH, Oakland Police Department, Criminalistics Division, 455 7th Street, Rm 608, Oakland, CA 94607; Jill Encinias, BS, Oakland Police Department, 455 7th Street, Oakland, CA 94607; and Erin Kingsbury, JD, Alameda County District Attorney, 1225 Fallon Street, 9th Fl, Oakland, CA 94612*

After attending this presentation, attendees will better understand the impact of analyzing all victim SAEKs in one jurisdiction.

This presentation will impact the forensic science community by providing data on how to approach the analysis of victim SAEKs to obtain viable DNA typing data, the use of the analytical results by the Special Victim's Unit (SVU) investigators, and the prosecution outcome.

When California passed the "Sexual Assault Victims' DNA Bill of Rights" in 2003; it was the first law of its kind in the nation. The bill addresses the importance of timely DNA analysis of sexual assault evidence. On January 1, 2016, an amendment to the Section 680 of the California Penal Code encourages law enforcement agencies to submit sexual assault forensic evidence to the crime lab within 20 days after it is booked into evidence. The bill also encourages the crime lab to process that evidence, create DNA profiles when able, and upload qualifying DNA profiles into the Combined DNA Index System (CODIS) within 120 days after initially receiving the evidence.

In May 2014, the Oakland Police Department (OPD) Criminalistics Laboratory developed a plan for analyzing all victim SAEKs as soon as practicable. The laboratory defined this plan as the Contemporary Victim Kit Program. The Program goals are to analyze all victim SAEKs, enter eligible DNA profiles into CODIS within ten business days, and provide reports to the investigators within 20 business days. This Program requires the support of the county hospital Sexual Assault Response Team (SART), OPD investigators, OPD property room staff, Forensic Biology Unit (FBU) scientists, and Alameda County District Attorneys (DA). The Program includes the analysis of all evidence within the SAEK, including clothing. As such, the Program is not considered a Rapid Turnaround DNA program as defined in Assembly Bill (AB) 1517.

The FBU tracks victims' SAEKs submitted to the OPD Property and Evidence Unit weekly. The FBU then communicates to the SVU a list of submitted kits for the week. SVU investigators determine which victim SAEKs are eligible for analysis. Currently, all kits will be examined except those in which the crime occurred in a different jurisdiction or a crime has not been committed.

Currently, the FBU has enrolled 571 victim SAEKs into the Program. The FBU analyzed more than 550 victim SAEKs and, when present, the 95 corresponding suspect SAEKs. Most of the CODIS-eligible DNA profiles originated from the vaginal swab; however, eligible profiles were obtained from oral contact sites, clothing, and other orifice swabs.

The FBU, SVU investigations, and DAs evaluated the efficacy of testing and charging all victims' SAEKs. A subset of the analyzed cases revealed approximately 56% of the victim SAEKs contained CODIS-eligible DNA profiles of which 38% resulted in a named individual association. In addition, a small percentage of cases resulted in an association of one assailant to more than one victim (serial assailant).

Approximately 29% of the analyzed victim SAEKs were submitted to DA's office for charging purposes. The prosecution status of this subset falls into four categories: charged, convicted, requires additional investigation, or will not be charged. The remaining 71% cases not submitted to the DA's office are either under OPD SVU investigation or did not have a CODIS-eligible DNA profile.

This data illustrates the collaboration of three entities to ensure all viable victim SAEKs are analyzed, investigated, and prosecuted in a timely fashion, thus providing justice to survivors, creating safer communities, and convicting serial rapists. The OPD Contemporary Victim Sexual Assault Kit Program will prevent future backlogs by proactively testing kits in a timely manner.

SAEK, Contemporary, DNA

B180 The Mapping of Drug Users in Philadelphia, PA, by Creating DNA Profiles From Trace DNA Evidence Collected From Drug Paraphernalia

Benetta A. George, BA, 201 Royal Avenue, Wyncote, PA 19095; Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038; Jillian C. Fesolovich, Keystone College, One College Green, PO Box 50, La Plume, PA 18440; and Heather L. Harris, MFS, JD, PO Box 43626, Philadelphia, PA 19106*

After attending this presentation, attendees will recognize the potential of trace DNA evidence on syringes that were used to inject illegal drugs. Attendees will also learn about the drug epidemic issue in Philadelphia, PA, which is of great concern to the forensic and public health communities.

This presentation will impact the forensic science community by demonstrating a possibility of distinguishing homicide from suicide in drug overdose cases.

In Pennsylvania in 2015, there were more than 2,000 reported deaths due to drug overdose.[1] These drug overdose deaths are usually considered accidental, or, in some cases, the providers or the drug dealers are charged with murder. In a case in which a second party administers a drug to a user that causes an overdose, the case is closed using circumstantial evidence or confessions from the second party. Many times, there may not be a second party found who will confess to the administration of a drug, causing the case to be deemed accidental. Charging the second party with murder seems to be a gray area in the legal community because, most of the time, the second party is an addict himself/herself without any malicious intent and most likely was not in his/her right mind when injecting the drug; however, in a case in which malicious intent is present, DNA evidence may prove to be valuable. This presentation focuses on the benefits of performing DNA analysis on syringes used to inject drugs.

Improperly discarded syringes were collected from the streets of Philadelphia. These syringes were then brought to the laboratory for DNA collection. Two areas of the syringe were swabbed for DNA extraction. The first area swabbed was the tip of the needle, as it should contain blood, which can allow development of the user's DNA profile. The second swabbed area was the barrel and plunger of the syringe. If the DNA profile obtained from this area is consistent to the one from the needle of the syringe, then the drug was likely self-administered. If the profiles are inconsistent, the drug may have been administered with assistance of a second party. Finally, on a map of Philadelphia, a correlation was made between the area where the syringes were collected and the profiles obtained. This was conducted to see if a particular area is home to many drug users or only a few users. If various profiles are seen on more than one syringe it can be hypothesized that users go to this area to get help from a second party to inject their drugs.

Trace DNA, Drug Overdose, Homicide/Suicide

B181 The Complexities of Interpreting DNA Evidence Obtained in an Uncontrolled Social Setting

Leann G. Rizor, BS, 1427 E Mills Avenue, Indianapolis, IN 46227; Jonah W.P. Stone, BSc*, 3701 Shelby Street, Apt 448, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; Cynthia Cale, BS, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241; and Gay L. Bush, PhD, Strand Diagnostics, 5770 Decatur Boulevard, Ste A, Indianapolis, IN 46241*

The goals of this presentation are: (1) to demonstrate how DNA transfer events may impact the analyst's understanding of the DNA evidence at the crime scene; and, (2) to illustrate the complexity in predicting handling order and mode of transfer (primary, secondary, or tertiary) in an uncontrolled social setting situation.

This presentation will impact the forensic science community by adding to a growing body of knowledge regarding transfer DNA.

Recent advances in DNA typing technology have allowed for the detection of DNA transferred to various everyday objects. As sensitivity in commercial Short Tandem Repeat (STR) kits increases, so does the potential for detecting and amplifying extraneous DNA. A thorough understanding of DNA transfer, including both the active and passive processes that can lead to DNA deposition as well as the various variables that can impact DNA transfer, can assist in the interpretation and explanation of DNA found on evidentiary items. As forensic DNA laboratories continue to see a rise in the number of transfer DNA samples submitted for analysis, studies of transfer DNA that aim to identify the limits of DNA transfer, that investigate the multitude of variables that impact transfer, and that further understanding regarding DNA data interpretation in various real-world settings add to expanding scholarship that can benefit the forensic science field.

This study expands upon an investigation of DNA transfer in a social setting conducted by Goray and van Oorschot.[1] Four participants handled previously sterilized plastic objects (a communal jug and four cups) with their dominant hand to simulate a social gathering involving beverages. The order in which participants handled each object was recorded to test the following null hypotheses: (1) secondary DNA transfer will not occur and will not be detected on dominant hands; (2) tertiary DNA transfer will not occur and will not be detected on the cups; (3) a mixed DNA profile from all participants will not be found on the jug handle; and, (4) the order of handling the objects cannot be discerned from the DNA data. Each of the objects and the dominant hands of the participants were swabbed to test for evidence of primary, secondary, and tertiary DNA transfer. The samples were amplified with the GlobalFiler™ Polymerase Chain Reaction (PCR) Amplification Kit and analyzed on an Applied Biosystems® 3130xl genetic analyzer. The Mixture Analysis Tool within GeneMapper® ID-X version 1.5 was utilized to facilitate data interpretation.

DNA was detected in 41 of the 45 samples (92%) collected in this study. Only 15 samples produced profiles that were suitable for comparison utilizing the laboratory's current interpretation guidelines. Of these, 80% were mixtures containing DNA from two or more individuals and 60% had identifiable major and minor contributors. In the set of samples taken from an individual's hand, where a major profile could be identified, the major profile was consistent with the individual. In the set of samples collected from objects, there was no discernable correlation between the profiles detected and the timing or the length of contact with the object. In other words, the major profile detected did not consistently correlate with either the last person to touch the object or the individual who maintained contact with the object for the longest period of time.

These results illustrate the complex nature of interpreting DNA transfer in a social setting. In this study, the objects were pre-sterilized, the order of handlers and length of contact was recorded, and the handlers' profiles were known; however, the order of handling could not be reconstructed from the DNA profile information. This study demonstrates the ease of DNA transfer in social settings, illustrates the difficulty in predicting mode of DNA transfer based on the DNA typing results, and highlights the difficulty in interpreting the genetic data when multiple transfer events have occurred.

Forensic Science, Transfer DNA, DNA Mixtures

B182 Practical Ways to Address Cognitive Bias in Forensic DNA Decision Making

Amy M. Jeanguenat, MFS, Mindgen, LLC, 8605 Kenilworth Drive, Springfield, VA 22151; Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107; and Itiel Dror, PhD, University College London, Center for the Forensic Sciences, 35 Tavistock Square, London, England WC1H 9EZ, UNITED KINGDOM*

After attending this presentation, attendees will better understand the impacts of cognitive bias and balanced approaches that may be employed to reduce their effect in the context of a forensic DNA workflow.

This presentation will impact the forensic science community by allowing attendees to consider the possible effects of cognitive bias in forensic DNA testing and by providing a roadmap of general pathways to address the influences of cognitive bias on forensic decision making.

Cognitive bias, an inherent part of human intelligence, may influence decision-making and even the workflow processes of individuals and their laboratories. Seven sources of bias have been identified that may affect forensic decision making; they are related to human nature, environment, culture, and experience, as well as case-specific information. While bias in itself may not cause error, the outcome of cognitive bias, if not monitored and addressed effectively, is that analyses and interpretations may be compromised. Nevertheless, practitioners that are unaware of their inherent bias have generated reliable interpretations of DNA results; however, there also are well-documented examples in which bias has indeed negatively impacted decision making and the interpretation of forensic DNA analyses, such as working and reasoning backwards, from the suspect to the evidence (i.e., fitting the DNA profile from the known reference sample to the DNA evidence profile(s)). Through education and training, forensic scientists can be better prepared to reduce error that may be caused by cognitive bias; for example, by using Linear Sequential Unmasking (LSU).

Factors that impact bias cannot be managed by simply listing them or by individual responsibility. In addition to cognitively informed education and training, other mechanisms should be considered. A cognitively informed risk assessment of the entire DNA workflow can explore which procedures are most efficient in reducing the influences of cognitive bias. As an example of an assessment related to DNA technical review, a hierarchical approach has been advocated as a quality assurance practice to resolve disputes between analysts and reviewers. Alternatively, cognitive research indicates a hierarchical approach may introduce a variety of biasing factors that question the process, such as base rate expectations or favoring one individual's opinion over another. Mitigation could perhaps be better addressed by an independent blind review process that documents all opinions. A conclusion can then be determined, including the possibility of reporting the sample as inconclusive.

Context management of irrelevant information is another area to explore to determine how best to provide suitable information to a casework analyst without presenting information that could lead to bias during testing, analysis, or interpretation. The LSU approach requires first determining what information the examiner needs and making sure he/she receives all information required, but making a reasonable effort to minimize exposure to irrelevant information (especially the potentially more biasing irrelevant information). Second, the LSU approach requires managing the time and sequence in which relevant information is provided to the examiner. For example, avoiding working backward from the known suspect to the evidence by first evaluating the evidence from the crime scene, and only subsequently, sequentially, and linearly presenting the known suspect. Alternatively, a strong and effective technical review process could reduce the effects of cognitive bias on the final outcome in a systems-based approach.

This presentation will cover the important need for proper training and education concerning cognitive bias, practical suggestions on methods to control irrelevant task information, interpretation strategies to minimize bias, and suggestions for quality assurance procedures. Proactive mechanisms for quality enhancement are always preferred to reactive approaches to address error that may arise; however, the choice of approaches to improve quality by controlling the effects of cognitive bias must be balanced based on the overall impact on quality, realities, and the constraints of working in a forensic DNA laboratory, the importance of communication with investigators, proper decision making for analysis of samples, and cost-benefits to the system. Procedures that handicap the workings of the crime laboratory or add little value to improving the operation are not advocated, but simple yet effective measures are suggested.

Forensic DNA Decision Making, Cognitive Bias, DNA Workflows

B183 Forensic DNA Errors: Lessons From Innocence Network Cases

Greg Hampikian, PhD, Boise State University, Biology Dept, 1910 University Drive, Boise, ID 83725-1515*

The goal of this presentation is to highlight avoidable errors that can result in wrongful convictions.

This presentation will impact the forensic science community by increasing awareness that higher-sensitivity DNA testing, the demand for high-throughput work, and conflicting mixture interpretation methods have created new opportunities for accidental injustice. Simple procedures will be discussed that can be used to reduce common challenges to DNA evidence in court and reduce the chances of wrongful convictions.

One area that was at first insulated from scrutiny by the Innocence Movement was forensic DNA; however, the report by the President's Council of Advisors on Science and Technology (PCAST) in 2016 critically analyzed certain aspects of DNA analysis, including complex mixture analysis. The PCAST report cited several works and criticized the use of some common forensic methods, such as the Combined Probability of Inclusion (CPI) in complex DNA mixtures. "In summary, the interpretation of complex DNA mixtures with the CPI statistic has been an inadequately specified — and thus inappropriately subjective — method. As such, the method is clearly not foundationally valid."[1]

The study cited by PCAST was published in a 2011 peer-reviewed paper.[2] That study demonstrated that DNA analysts using the same data could reach conflicting conclusions. It was reported that 17 analysts at a single crime lab, given the same DNA data from an actual case in another state, came up with all three possible conclusions concerning a suspect (excluded, cannot be excluded, inconclusive). Most striking was that only 1 of the 17 analysts agreed with the original crime lab's conclusion that the suspect was included in the mixture. Several studies since then, including the Mix13 study by the National Institute of Standards and Technology (NIST), have shown that DNA mixtures can be a serious source of erroneous conclusions.[3] The use of probabilistic genotyping in addressing DNA errors will also be demonstrated by case examples.

A new case report concerning a Y-chromosomal Short Tandem Repeat (Y-STR) coincidental match that led to an exoneration will also be discussed.[4] In that case, a man was convicted of participating in a multiple-perpetrator sexual assault, based on a Y-STR mixture inclusion using a 17-locus kit. The conviction was eventually overturned through collaborative work involving the paper's authors from Boise State University, the Taiwan Association for Innocence, National Chiao Tung University School of Law, and the Taiwan Criminal Investigation Bureau.

This presentation will present problems with coincidental DNA matches, DNA contamination, and serology interpretations that can be addressed through proper processing, analysis, and testimony.

DNA Errors, Wrongful Conviction, Forensic Error

B184 2018 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

The goal of this presentation is to provide the seized-drug community with the most up-to-date information, resources, and documents being developed by the SWGDRUG.

This presentation will impact the forensic science community by increasing awareness of the latest developments in the seized-drug discipline, as well as new documents and resources that can enhance practices.

The SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). The SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will provide attendees with information on the SWGDRUG activities during the past year.

The year 2017 marked the 20th anniversary of the SWGDRUG. As a commemoration of this significant anniversary, the first edition of the SWGDRUG Bulletin was launched shortly after the group's annual meeting, which was held during the week of June 12-16 in St. Louis, MO. The bulletin is intended to provide members of the seized-drugs community with a short summary of the SWGDRUG's activities.

Core committee members are currently working on revisions to the SWGDRUG Recommendations. Part IIIB (Drug Identification) is being revised to clarify the rationale behind the categorization of techniques, with emphasis on the development of robust analytical schemes applicable to multiple jurisdictions. A supplemental document is being developed that will include numerous examples of analytical schemes. This presentation will include discussion of some of those examples and their applicability.

Core committee members are also working on revising Part IVB (Validation of Analytical Methods) of the Recommendations. Revisions will include additional background information and clarifications on the performance characteristics to be evaluated during the validation of both qualitative and quantitative methods. Examples of method validation schemes for routinely used techniques, such as color test, Gas Chromatography/Mass Spectrometry (GC/MS), and Infrared (IR) spectroscopy will be included in this presentation and will also form part of another supplemental document to be published in the near future.

This presentation will also summarize recent updates on the SWGDRUG resources, such as the MS library, IR library, and Drug Monographs. Among the recent developments, the SWGDRUG has partnered with the National Institute of Standards and Technology (NIST) to verify the quality and reliability of the SWGDRUG MS Library, as part of ongoing efforts to provide valuable resources to the community. Drug Monographs continue to be added and disseminated via the SWGDRUG website (www.swgdrug.org) and this often-used resource has recently been enhanced to allow searches and sorting by name, nominal mass, and base peak.

The SWGDRUG core committee includes representatives from federal, state, and local law enforcement agencies in the United States, Canada, Brazil, Great Britain, Germany, Austria, Switzerland, Australia, and Singapore. The following forensic organizations are represented: the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalistica y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC). Core committee members also include forensic science educators and representatives from forensic science organizations across the United States, the American Society of Crime Laboratory Directors (ASCLD), the American Society for Testing and Materials (ASTM), and the NIST.

SWGDRUG, Drug Analysis, Criminalistics

B185 What's in the Bag? Screening Trace Drug Contamination in Baggies by Thermal Desorption Combined With Direct Analysis in Real Time-Mass Spectrometry (TD/DART®-MS)

Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899; Marcela Najarro, MFS, NIST, 100 Bureau Drive, MS 8371, Gaithersburg, MD 20899; and Jennifer R. Verkouteren, MS, 100 Bureau Drive, Mailstop 8371, Gaithersburg, MD 20899*

After attending this presentation, attendees will better understand how TD/DART®-MS can be used to analyze the trace contaminants present on the outside of bags to identify the drugs present within.

This presentation will impact the forensic science community by providing a method for rapid presumptive screening of evidence for the presence and identification of narcotics.

As the presence of increasingly dangerous and toxic narcotics enter forensic laboratories, analysts must be aware of the hazards they may present. Because most evidence looks similar in nature, either pills or powders, it is often difficult for an analyst to know to what degree the evidence must be treated as a hazardous substance. Knowing the contents of the container is crucial to understanding the level of personal protection that is required. Currently, the package (typically a baggie) must be opened to retrieve a small amount of unknown evidence for testing. Spectroscopy techniques, such as Raman spectroscopy, have the ability to analyze the contents through the bag, but struggle to interpret mixtures. This work proposes a new analytical scheme through which a presumptive identification of the compounds inside the bag or container can be made without opening the evidence container.

The theory of trace contamination is well rooted within forensic science. When someone handles a material (in this case, a powder or pills) a trace amount of residue will be transferred onto the person's hands, then onto other surfaces that are subsequently touched. Furthermore, when a powder or pills are poured into a bag, a small amount of fine particulate is suspended in the air and can potentially resettle onto the outside of the bag. This work seeks to take advantage of these principles to establish whether the trace contamination on the outside of a bag or container can provide reliable information as to the constituents of the evidence inside.

In this work, samples of the trace contamination of simulated and real-world samples (bags or containers containing suspected narcotics) were obtained by swiping the exteriors with a meta-aramid wipe. These wipes were subsequently analyzed with TD/DART®-MS. TD/DART®-MS providing a rapid analysis (less than five seconds) with no sample preparation. It has been shown to have sub-nanogram detection limits and can readily handle complex multi-component mixtures. The compounds identified from the exterior of the bag were then compared to compounds identified by analyzing the actual powders or pills by TD/DART®-MS and/or Gas Chromatography/Mass Spectrometry (GC/MS). The ability to correlate the exterior signature to the interior signature was then established.

To date, screening results from swiping the exterior of the bags have matched the TD/DART®-MS and GC/MS results of the interior of the bag. While the sample set is small, current work is focused on expanding the number and variety of samples being tested. Additionally, quantification of the amount of trace contamination on the exterior of bags is also being investigated to establish the level of narcotics present.

DART®-MS, Drug Analysis, Screening

B186 Cannabinoid Vapor Pressure Measurements and Predictions by Porous Layer Open Tubular-Cryoadsorption (PLOT-Cryo)

Tara Lovestead, PhD, NIST, 325 Broadway, Boulder, CO 80305; and Thomas J. Bruno, PhD, NIST, 325 Broadway, Boulder, CO 80305*

After attending this presentation, attendees will be able to apply knowledge of thermophysical properties of cannabis plant compounds Cannabidiol (CBD) and Δ9-Tetrahydrocannabinol (THC) in the design and development of vapor phase, cannabis detection devices.

This presentation will impact the forensic science community by providing insight into how the complex chemistry of cannabinoid compounds complicates breathalyzer development for cannabis detection.

Cannabinoids are large, polar molecules that react with oxygen; thus, thermophysical property data (upon which to base sensor design) for cannabinoid compounds are difficult to measure and find in the literature. Additionally, there are several aspects of THC that make collecting and analyzing it in bodily fluids complex. For one, THC is rapidly metabolized in the body, is excreted in the urine as a glucuronic acid conjugate, and a small portion of THC is stored in adipose tissue and released slowly over long time periods (hours, days, or weeks). Thus, not only is it difficult to measure the thermophysical properties of these compounds, but it is also a measurement challenge to detect the trace amounts of cannabinoids found in exhaled breath.

In this study, the vapor pressure and enthalpies of association of THC and CBD were made possible by the use of the ultra-sensitive, quantitative, trace headspace analysis technique PLOT-cryo.[1-4] The mass collected in the vapor phase will be presented in the form of a van't Hoff equation plot, which expresses the concentration collected as a function of temperature. A linear relationship of the recovered mass as a function of inverse collection temperature reveals the predictive capability of the methodology employed here. The measurements of the vapor pressure data and predictions (based on these measurements) of the Normal Boiling Temperatures (NBTs) and the critical constants will be presented. Additionally, predictions for the vapor pressures at closer to ambient temperatures will be presented. Comparisons of the vapor pressures of both ethanol and n-eicosane will also be discussed.

In conclusion, this study demonstrates that the vapor pressure of cannabinoids at close to ambient temperatures are predicted to be approximately eight orders of magnitude lower than the vapor pressure of ethanol, the rather simple chemical compound that is measured to determine alcohol intoxication. These measurements and predictions lay the foundation for understanding the partitioning of cannabinoids from the blood into the breath, and ultimately pave the way for the design and advancement of breathalyzers in the context of illicit cannabis detection.

Cannabis, Vapor Pressure, Breathalyzer

B187 The Identification of Various Controlled Substances by Headspace Chemical Analysis Using Headspace Solid-Phase Microextraction (HS/SPME) and Gas Chromatography/Mass Spectrometry (GC/MS)

Justin Day, MS, PO Box 129, Mexia, TX 76667; Harry R. Ehmann, MS, Harris County Institute of Forensic Sciences, 1861 Old Spanish Trail, Houston, TX 77054; and Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341*

After attending this presentation, attendees will be familiar with a solventless HS/SPME method with the option of simultaneous headspace derivatization for the analysis of a variety of controlled substances.

This presentation will impact the forensic science community by demonstrating the utility of this method for testing microgram sample levels, reducing the time and number of steps for extraction and/or derivatization, reducing the consumables required, and reducing or eliminating issues arising from "dirty" samples, such as edibles and botanicals.

Controlled substances come in a variety of forms that require a variety of extraction methods to properly isolate analytes of interest. Liquid-Liquid Extraction (LLE), Solid-Phase Extraction (SPE), and dilute and shoot extractions combined with chromatography and mass spectral analysis are the most common techniques for identifying controlled substances. Some samples, including edibles and botanicals, are notorious for causing instrument problems, even when cleanup procedures are utilized. Dirty samples can cause sample carryover during instrumental analysis, requiring additional blanks or cleanups before another sample can be analyzed. In some cases, instrument components may need to be replaced to maintain separation efficiency or eliminate contamination. Furthermore, some substances require derivatization for separation and stability. This often requires caustic reagents, heating blocks, additional chemical cleanup, and significant time. Each additional step in the process presents an opportunity for error, and retesting is not always possible.

Dried analytical controlled substance standards and seized case specimens were tested. Case specimens included crystals, powders, tablets (pharmaceutical and clandestine), liquids, botanicals, and edibles. Sample sizes ranged from micrograms of material to intact tablets. Samples were placed directly into headspace vials and sealed. Using an oil bath and a Polydimethylsiloxane (PDMS) SPME fiber, this study optimized incubation time, extraction temperature, and fiber exposure time for HS/SPME from a sample's headspace. Initial analysis was performed using a GC/Flame Ionization Detector (FID) with a modified injection port to establish retention times, recovery amount, and peak quality. The information from the GC/FID runs was used to program optimal parameters for GC/MS testing. A concurrent study of the viability of headspace derivatization was performed on samples whose analytes would benefit from the process, including the synthetic cathinones, psychedelic mushrooms, and marijuana. Derivatization was achieved by placing a small insert filled with a measured amount of solvated or dry derivatizing agent directly into a headspace vial with a sample. Physical contact of the sample with the agent was not allowed; that is, the entire derivatization process occurred in the headspace during the incubation period. Results from the new method to those from the samples extracted with standard procedures were compared.

It was found that a variety of controlled substances in a variety of forms can be extracted with HS/SPME. The incubation temperature proved to be the most significant variable. Most compounds extracted well at 150°C, but some appeared to need higher temperatures that are beyond the capability of an oil bath. Incubation times ranging from five to ten minutes, with one-minute fiber exposure, proved sufficient for extraction and derivatization. The technique, for the most part, provided similar results; however, sometimes additional compounds not found in standard extractions were able to be extracted. Though not always controlled substances, the presence of these other compounds could serve as unique identifiers for revealing formulation trends, synthesis methods, growing regions, and other information that could be of interest to multiregional agencies. This method also demonstrated that derivatization does occur in the headspace, turning it into one-step process. This technique is simple and, for the most part, non-destructive. No sample required cutting, crushing, scraping, or dissolving, and most exhibited little or no change after testing. The initial work is promising and further study for the optimization of this new technique will be discussed in this presentation.

Headspace/SPME, Solventless, Derivatization

B188 Recent Seizures at the Canadian Border: New Fentanyl Analogues and Other Novel Psychoactive Substances (NPS)

Michael McFarlane, MSc, 79 Bentley Avenue, Ottawa, ON K2E 6T7, CANADA*

After attending this presentation, attendees will better understand the work performed by the Contraband Drug Analysis (CDA) section of the Canada Border Services Agency (CBSA) laboratory in identifying unknown drugs intercepted in shipments crossing the Canadian border.

This presentation will impact the forensic science community by providing recent information regarding NPS, including newer fentanyl analogues, intercepted at the Canadian border. Attendees will be presented with casework derived from both import and export shipments, including shipments crossing the Canada-United States border. Attendees will also be presented with various methods of concealment, analytical challenges in the analysis, and a comprehensive overview of the observed drug trends as seen by the CDA section.

It is increasingly important to be aware of drug trends involving shipments investigated at the border. Often drugs are imported as a pure chemical, which can later be processed into a dosage form prior to being sold on the street. Understanding the trends of drugs being imported can be used to signal law enforcement partners of potential drugs that may appear on the streets in the coming months and assist with their identification.

CBSA delivers a variety of programs and services designed to aid travelers and facilitate legitimate trade, while also focusing on enforcing laws and regulations to ensure the safety and security of Canada and its borders.

Border Service Officers investigate shipments crossing the Canadian border in many routes of entry, including via international mail centers, air cargo, courier, truck, marine, rail, and travelers at airports and land crossings. Shipments which are suspected to be or to contain unknown drug substances are sent to the CDA section within the CBSA, and the results of the analysis may be used for enforcement-related activities, such as controlled deliveries, search warrants, fines, investigations, and possible prosecution.

Exhibits analyzed by the CDA section typically contain controlled drug substances, prescription drug substances, unregulated drug substances, drug-related substances (such as cutting agents and precursors), and non-drug substances (including products of legitimate international trade).

The CDA section has the capability of complete structural elucidation of unknowns. Methods used within the CDA section for the analysis of unknowns include Fourier Transform/Attenuated Total Reflectance/Infrared (FT/ATR/IR), FT-Raman, Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography (LC) Orbitrap/MS, Nuclear Magnetic Resonance (NMR), condensed phase Gas Chromatography coupled with Vapor Phase Infrared Detection (GC/IRD), Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS), and Energy-Dispersive X-Ray Fluorescence (EDXRF).

In 2015, the CDA section identified more than 40 drugs not previously seen by its lab, including U-47700, W-15, butyryl fentanyl, and N,N-dimethylpentylone. Again in 2016, the CDA section identified more than 40 drugs not previously seen by its lab, including dibutylone, N-ethylpentylone, W-18, carfentanil hydrochloride, furanylfentanyl hydrochloride, furanylfentanyl citrate, 4-fluoroisobutyrfentanyl hydrochloride, and 4-fluoroisobutyrfentanyl citrate.

So far in 2017, the CDA section is on pace to identify an even greater number of drugs not previously seen in its exhibits. Some of the new compounds already identified in 2017 include N,N-dimethyl-lanicemine, propylone, U-51754, benzoylfentanyl, 2-methoxy-furanylfentanyl, 2-methyl-furanylfentanyl, 4-chloro-furanylfentanyl, 2-isopropyl-furanylfentanyl, methoxyacetylfenanyl citrate, and cyclopropylfentanyl citrate, with more to come.

Fentanyl, NPS, Import/Export

B189 The Analytical Profile of Fluorobutyryl Fentanyl Isomers

Kelly Song, BS, DEA, 99 10th Avenue, Ste 721, New York, NY 10011; and Adriana M. de Armas, BS, DEA, 99 10th Avenue, Ste 721, New York, NY 10011*

After attending this presentation, attendees will be familiar with approaches for effectively differentiating positional and structural isomers of fluorobutyryl fentanyl. Attendees will better understand the challenges that forensic laboratories may encounter with new fentanyl-related compounds.

This presentation will impact the forensic science community by providing analytical techniques for differentiating fluorobutyryl fentanyl isomers efficiently and effectively. This presentation will also impact the forensic science community by providing different approaches for other similar fentanyl substances forensic drug laboratories may encounter.

Fentanyl, a Schedule II synthetic opioid, was first synthesized in the late 1950s by Paul Janssen and is used licitly to treat severe pain. Presently, there are numerous fentanyl-related compounds.[1] Examples of such compounds include acetyl fentanyl, butyryl fentanyl, furanyl fentanyl, and acryl fentanyl. The identification of isomers of substances presents a challenge to the forensic drug analyst; new compounds are constantly being illicitly synthesized, such as fluorobutyryl fentanyl. The molecular formula of fentanyl is $C_{22}H_{28}N_2O$, whereas fluorobutyryl fentanyl is $C_{23}H_{29}FN_2O$. With an addition of a fluorine and a methyl group, the structure changes from fentanyl to fluorobutyryl fentanyl. Moving the position of the fluorine on the benzene ring allows for three different positional isomers of this compound. Furthermore, substituting the butanamide with isobutanamide allows for a different structural isomer. This study focuses on the identification of various isomers of fluorobutyryl fentanyl (meta-fluorobutyryl fentanyl, ortho-fluorobutyryl fentanyl, para-fluorobutyryl fentanyl, and para-fluoroisobutyryl fentanyl).

Techniques used in the identification of controlled substances must be both selective and sensitive. Sometimes, confirmatory techniques are not selective between isomers; hence, other approaches must be explored. In this study, various instruments were used to analyze four isomers of fluorobutyryl fentanyl, including Gas Chromatograph/Mass Spectrometry-Low Thermal Mass (GC/MS-LTM), Gas Chromatograph/Flame Ionization Detector (GC/FID), Gas Chromatograph/Flame Ionization Detector-Low Thermal Mass (GC/FID-LTM), Fourier Transform Infrared Spectroscopy with an Attenuated Total Reflectance (FTIR/ATR), ion trap (Tandem Mass Spectrometer or MS/MS), and Direct Analysis in Real-Time Mass Spectrometer (/ART®-MS).

Preliminary results demonstrated that GC-FID is an effective instrument in differentiating the two structural isomers of fluorobutyryl fentanyl. Depending on purity, FTIR/ATR can also be a suitable technique in differentiating the four isomers. Due to their very similar structures, these compounds fragment similarly; therefore, the use of GC/MS, DART®-MS, and MS/MS alone has proven to be insufficient in distinguishing isomers of fluorobutyryl fentanyl.

Fentanyl, Fluorobutyryl Fentanyl, Isomer Determination

B190 Separation of Fentanyl Analogues, Homologues, and Positional Isomers by Ultra High-Performance Liquid Chromatography (UHPLC)

Carolyn Angi, 1600 S Eads Street, 1105S, Arlington, VA 22202; Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will be familiar with methods of separation for fentanyl analogues, homologues, and positional isomers, using UHPLC.

This presentation will impact the forensic science community by enhancing the collective expertise in the separation of fentanyl-related compounds using UHPLC. Positional isomers, which have the same mass and similar structure, are particularly difficult to separate using gas and liquid chromatographic methods.

Fentanyl is a Schedule II narcotic opioid that is an agonist at the μ-opioid receptor. While it mimics the effects of morphine, it is structurally different and is 50-100 times more potent. Some analogs of fentanyl, such as carfentanil, can be thousands of times more potent. Given their higher potency, there is a higher risk of overdosing. This poses a significant threat to opioid users and users of street drugs. Many street drugs, most commonly heroin, are being laced with fentanyl or its derivatives, leading to a significant public health problem. Derivatives of fentanyl are designed to avoid legal prosecution, as they are not scheduled. One of the main issues in the field of forensic drug analysis is that they are being produced faster than they can be identified.

Derivatives of fentanyl, including positional isomers, have substituents of varying degrees of polarity, hydrophobicity, and size. The substituents of the derivatives are expected to interact differently with different stationary phases and modes of chromatography. The particular challenge lies in separating the positional isomers, as they have the same substituents attached to different locations on the molecule.

A total of 12 fentanyl derivatives, including positional isomers, were subjected to analysis by UHPLC-time of flight/mass spectrometry. A variety of different 150mm x 2.1mm x2.7μm columns (SPP C18, SPP PFP, SPP Phenyl-Hexyl, and Hydrophilic Interaction Liquid Chromatography (HILIC)) were used in both the Reversed Phase Chromatographic (RPC) and HILIC modes and results were compared. The mobile phase conditions were optimized for each column to obtain the best possible separation.

For RPC, gradient conditions were preferred while for HILIC, isocratic conditions were utilized. Varying performance was found when analyzing positional isomers on different columns. For example, when using the C18 column, despropionyl para- and ortho-fluorofentanyl were separated with a resolution better than 1. Isomers such as ortho- and meta-fluorofentanyl were not separated, resulting in overlapped peaks.

These results both enhance the collective forensic knowledge and may aid forensic laboratories dealing with the influx of fentanyl-related cases by facilitating the identification process. This methodology may also aid in helping in the scheduling of fentanyl derivatives.

Fentanyl, Positional Isomers, UHPLC-TOF/MS

B191 Using Quadropole Time-Of-Flight (qTOF) Liquid Chromatography/Mass Spectrometry (LC/MS) to Distinguish 2- and 3-Furanyl Fentanyl and Other Fentanyl-Related Compounds

Sally F. Ho, PhD, Drug Enforcement Administration, 536 S Clark Street, Chicago, IL 60605*

After attending this presentation, attendees will better understand the analysis of 2- and 3- furanyl fentanyl and the importance of being able to separate and identify positional isomers.

This presentation will impact the forensic science community by providing LC/MS methodology capable of separating and identifying heroin, fentanyl, fentanyl-related compounds, and common adulterants.

The presence of fentanyl and fentanyl-related compounds in drug evidence has been on the rise recently. Two of these fentanyl-related compounds include 2-furanyl fentanyl(N-(1-phenethylpiperidin-4-yl)-N-phenylfuran-2-carboxamide), known colloquially as furanyl fentanyl, and 3-furanyl fentanyl (N-(1-phenethylpiperidin-4-yl)-N-phenylfuran-3-carboxamide). Differing only by the attachment site of the furanyl ring, these two compounds are difficult to distinguish chemically. Effective November 29, 2016, 2-furanyl fentanyl was placed into Schedule I federally; however, because 3-furanyl fentanyl was not specified in the final order, distinguishing between these two positional isomers is essential during analysis.[1]

The separation and identification of these two positional isomers can be accomplished via conventional Gas Chromatography (GC) methods. Standard screening conditions on the Gas Chromatography/Mass Spectrometry (GC/MS) provides a 0.1-minute separation between the isomers; however, the mass spectra of the two compounds have a very similar fragmentation pattern, with the most obvious difference being the presence of the 212m/z ion in the mass spectrum of 2-furanyl fentanyl. Thus, using standard GC/MS methods for identification of these compounds is not considered reliable as the similarities in mass spectra and slight drifts in retention time make their identification difficult. Gas Chromatography coupled with Vapor Phase Infrared Detection (GC-IRD) can provide confirmatory data to distinguish between the two positional isomers as it is apparent that the difference in site attachment of the furanyl ring leads to response differences in the Infrared (IR) fingerprint region.

LC/MS is an alternative methodology for both the separation and the identification of 2- and 3-furanyl fentanyl. Using this method, 2- and 3-furanyl fentanyl are baseline resolved from each other with a calculated resolution of 4.01 between the two compounds. The qTOF LC/MS also provides the exact mass of the analytes. Note that the positional isomers have the same molecular formula and therefore the same exact mass, thus requiring column separation to detect the presence of a mixture of 2- and 3-furanyl fentanyl or to distinguish which positional isomer is present. Confirmatory structural information was obtained through the subsequent fragmentation of each analyte's precursor ion. With an applied collision energy of 30eV, 2- and 3- furanyl fentanyl have similar fragmentation patterns. Therefore, using the combination of the chromatographic separation, molecular weight, and fragmentation patterns, the presence of 2-furanyl fentanyl and 3-furanyl fentanyl can be confirmed in a mixture.

Other fentanyl-related compounds may also present similar analytical challenges, such as their existence at low concentrations in drug evidence. To compensate for these difficulties, the LC/MS methodology was extended to include heroin and a variety of fentanyl-related compounds.

Furanyl Fentanyl, Fentanyl, LC/MS

B192 A 12-Year Study of Brake Dust From 123 Vehicles for Particles Similar to Gunshot Residue

Mary Keehan, MS, Virginia Department of Forensic Science, 700 N 5th Street, Richmond, VA 23219; and Douglas DeGaetano, MS, Commonwealth of VA, Dept of Forensic Science, 700 N 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will better understand the nature and composition of brake dust and its significance for Gunshot Residue (GSR) examinations. Attendees will also learn methods for discriminating brake dust from particles of GSR.

This presentation will impact the forensic science community by documenting clear differences between brake dust samples collected in Virginia over a 12-year period and previous reports of brake dust collected in Europe that contained particles of lead (Pb), barium (Ba), and antimony (Sb). The results suggest that the chance of misidentifying brake dust as GSR can be considered remote.

It has been previously reported that brake dust can contain particles similar in composition to particles characteristic of GSR.[1-3] This is a concern for examiners who may receive samples from people with a profession or hobby that puts them in frequent contact with brake dust. The American Society for Testing and Materials (ASTM) E1588-17 includes as characteristic of GSR: particles with a spherical or molten appearance that contain the elements Pb, Ba, and Sb.[4] This study sought to look at samples of brake dust from vehicles in Virginia to determine if particles with compositions considered characteristic of GSR could be found. An effort was made to include vehicles of the same makes and models previously reported in Europe to produce particles containing Pb, Ba, and Sb, namely: Audi®, Volkswagen®, and Land Rover®.[1,3]

Samples were collected and analyzed over a 12-year period using half-inch-diameter aluminum stubs covered with double-sided carbon tape. Sampling was performed by repeated dabbing of the stub on the brake disc and wheel of the vehicle. Information about the vehicle make and model was recorded and the Vehicle Identification Numbers (VINs) were used to determine the year of the car where possible. Samples were then analyzed using a Scanning Electron Microscope with Energy-Dispersive X-ray Spectrometer (SEM/EDS) including automated GSR software detection capability. An analysis was used that mimicked the analysis used for the identification of GSR in casework samples. From this analysis, particles were either accepted or rejected as being characteristic of, or consistent with, GSR as outlined by the most current ASTM 1588 document and laboratory protocols in use at the time of analysis.

Many particles were placed in classifications during the automated analysis that might be of interest as possible GSR; however, after manual review, none of the particles met the criteria to be considered characteristic of, or consistent with, GSR. The most common reason for exclusion was the presence of high sulfur and the absence of lead in particles that were classified as containing lead. Other reasons for exclusion included high levels of sulfur and iron in particles containing barium and antimony, the presence of disallowable elements, and morphology that was not spherical or molten. The samples were also examined for particles containing barium and aluminum (a type of particle consistent with GSR). Where aluminum was found in association with barium, it was typically at low levels in conjunction with high levels of sulfur. These particles were usually irregular in shape and were not classified as particles consistent with GSR.

After the analysis of samples from 123 vehicles and more than 300,000 particles, no particles were found that could be considered characteristic of, or consistent with, GSR. The exclusion of particles from being classified as characteristic was not only by morphology, as had been previously reported in some European studies, but also because of an absence of lead.[1,3] These results, in addition to a recent study from Australia, primarily on brake pads, suggest that the chance of misidentifying brake dust as GSR can be considered remote.[5]

Gunshot Residue, Brake Dust, Primer Residue

B193 A Framework for the Assessment of Gunshot Residue (GSR) Evidence: Transfer, Contamination, and Preservation

Nick J. Lucas, MSc, Flinders University, College of Science and Engineering, Flinders Drive, Bedford Park, South Australia 5042, AUSTRALIA; Michael Cook, BSc, Forensic Science SA, 21 Divett Place, Adelaide 5000, AUSTRALIA; Paul Kirkbride, PhD, Flinders University, GPO Box 2100, Adelaide 5001, AUSTRALIA; and Hilton Kobus, PhD, Flinders University, Bedford Park, Adelaide 5001, AUSTRALIA*

After attending this presentation, attendees will better understand the factors that could be considered in the assessment of GSR evidence in order to strengthen the value of this evidence when presented in court.

This presentation will impact the forensic science community by reporting the results of a number of surveys for GSR, including an assessment of prevalence within a random population and on the hands of firearms-carrying law enforcement officers, as well as an assessment of the extent of transfer from police to suspects during arrest. Applying the data gathered from these surveys to the assessment of GSR evidence will permit examiners to provide a more informed judgement of the significance of a GSR test result.

A quantitative model for the transfer of GSR and evaluation of the evidence has been elusive thus far, and extensive specific data that can be used to inform casework evidence evaluation in the context of background GSR prevalence and secondary transfer scenarios are lacking.[1,2] To ensure a GSR test result can be given an appropriate and rigorous weighting in court, the deposition, retention, and distribution of GSR in the aftermath of a firing event must be better understood as well as the likelihood of GSR being present on a suspect due to incidences unrelated to the event (e.g., cross-contamination or background prevalence). The goal of the research discussed in this presentation relates to the latter consideration.

In this research, several surveys were conducted in order to determine the prevalence of GSR particles in a wide random population; samples were collected from volunteers in public spaces in order to reach a determination.[3] Further, the prevalence of GSR particles on the hands of police officers is relevant. Even if police officers do not fire a firearm while arresting a suspect, GSR present on police officers' hands as a result their general activities might represent a source of particles capable of being transferred to the suspect. To determine the magnitude of this source, the hands of serving police officers in non-firing situations were sampled for GSR. Although the abundance of GSR particles on police officers' hands is important to determine, it is of greater relevance to determine the extent of transfer of these particles from officers to suspects during arrest. Accordingly, studies of direct transfer of GSR during mock arrests were conducted. Typical hand stub samples were analyzed using Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) coupled with automated GSR analysis software (GSR Magnum™). Particles were confirmed as GSR by manual review. Data were then analyzed and interpreted with a view to contributing to a framework for the evaluation of GSR evidence.

This study explores the hypothesis that understanding a GSR test result in the context of a range of alternate scenarios by which GSR might end up on the suspect is essential in interpreting evidential value.

Gunshot Residue, Criminalistics, Evidence Assessment

B194 A Review of Gunshot Residue (GSR) Evidence in Suicide Cases

Jason L. Schroeder, MS, MBA, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; William M. Davis, PhD, Harris County Institute of Forensic Science, 1861 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1861 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand the role of GSR as evidence in the investigation of suicide cases. This will occur through a review of suicide investigations, including both medical-legal and law enforcement agency settings.

This presentation will impact the forensic science community by reviewing the application of GSR as a form of evidence in the investigation of suicides.

Suicide investigations involving firearms, both witnessed and unattended, can prove difficult for investigators and medical examiners. Several factors can complicate the investigation, including lifesaving efforts and disorganized crime scenes, emotions and demands of loved ones, and civil proceedings such as life insurance considerations. It is key to note that the presence or absence of GSR on the hands of a suicide victim will not resolve the manner of death.

GSR analysis is intended to provide information to an investigation by associating an individual with the discharge of a firearm; it is not beneficial in crime scene reconstruction. GSR cannot conclusively identify a shooter. GSR on a suicide victim's hands may indicate antemortem activities, such as firing a weapon, being in close proximity to a firearm during discharge of a weapon, or handling a firearm, a fired cartridge, or some other surface bearing GSR. A negative GSR result is not evidence of not firing a weapon and a positive test for GSR cannot confirm a suicide. GSR testing is most probative in cases in which an individual claims to have not been in the proximity of a firearm during discharge — something a suicide victim cannot claim. Individuals are not expected to have GSR during everyday activities. For these reasons, GSR findings often do not provide additional details for the investigation of a suicide. Investigators seeking evidence of a suicide must consider GSR within these parameters. With these factors in mind, some laboratories elect not to analyze GSR from suicide victims.

This presentation will provide a review of GSR cases between 2010 and 2015. This review can then be used to assist laboratories in establishing acceptance and analysis criteria as well as to provide information for the significance of the evidence when presented in a court of law. Finally, advantages and disadvantages of performing GSR analysis on suicide cases will be presented.

In conclusion, this presentation will provide a review of the analysis of gunshot residue evidence on cases investigated as suicide between 2010 and 2015.

GSR, Suicides, Gunshot Residue

B195 Novel Capabilities for Forensic Gunshot Residue (GSR) Analysis Through Exploitation of Glass Found in Primer Mixes

Kelsey E. Seyfang, BSc, Flinders University, College of Science and Engineering, Physical Sciences Road, Bedford Park, South Australia 5042, AUSTRALIA; Nick J. Lucas, MSc, Flinders University, College of Science and Engineering, Flinders Drive, Bedford Park, South Australia 5042, AUSTRALIA; Paul Kirkbride, PhD, Flinders University, GPO Box 2100, Adelaide 5001, AUSTRALIA; Rachel S. Popelka-Filcoff, PhD, Flinders University, Sturt Road, Bedford Park 5042, AUSTRALIA; Hilton Kobus, PhD, Flinders University, Bedford Park, Adelaide 5001, AUSTRALIA; and Kahlee E. Redman, BSc, Forensic Science SA, GPO 2790, 21 Divett Place, Adelaide, South Australia 5001, AUSTRALIA*

After attending this presentation, attendees will be aware of glass-containing GSRs and be able recognize and identify this particle type in casework. The value of advanced analytical techniques for GSR analysis will be demonstrated and attendees will be made aware of the potential to associate these particles with a firearm source.

This presentation will impact the forensic science community by alerting GSR examiners of a new type of particle that demonstrates strong association with a firearm source. In particular, this presentation illustrates that a high probative value can be attributed to 0.22 caliber GSR and also demonstrates a new approach that can be used by GSR examiners to link GSR with unfired ammunition or spent cartridge cases; this capability is very valuable, but traditional approaches suffered from a relatively high degree of uncertainty.

The highest evidential level of the current American Society for Testing and Materials (ASTM) guidelines for identifying primer GSR involves detection of the characteristic elements Lead/Antimony/Barium (Pb/Sb/Ba) or Lead/Barium/Calcium/Silicon/Tin (Pb/Ba/Ca/Si/Sn) in individual particles by Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS).[1] In Australia, 0.22 caliber weapons are common and rimfire ammunition is most often used in firearms offenses and suicides. Up to 84% of 0.22 rimfire ammunition has a primer that does not include all of the elements required to produce characteristic particles; in particular Sb, Sn, or Ca are often absent; however, the majority of 0.22 caliber ammunition manufacturers include ground glass as a frictionator in their primer formulations.[2] This glass becomes encrusted with Pb and/or Ba when the ammunition is fired, producing particles of glass-containing GSR (gGSR).[3]

The research described in this presentation proposes that Pb/Ba/glass gGSR be considered for acceptance as a member of the characteristic GSR particle class. Evidence will be provided demonstrating that this particle type could be as probative as Pb/Ba/Sb in identifying a particle's source. The gGSR particles also have the potential of adding extra value to GSR analysis, as glass frictionators from different ammunition brands have been shown to often have different elemental signatures, and due to the stability of glass during the firing process, it may act as a means of linking samples of GSR together, to a cartridge case, or to a source ammunition.[4]

The research that will be presented has two primary objectives: (1) to assess the probative value of gGSR particles with regard to their association with a firearm origin; and, (2) to investigate the chemical variation inherent in glass frictionators from different ammunition manufacturers and the scope for linking gGSR with suspected source ammunition or spent cartridges.

Objective 1 was accomplished by using SEM/EDS to compare glassy GSR to known non-firearm sources of GSR-like particles, such as fireworks and brake pad dust. With the exception of other cartridge discharge residues, such as from some older industrial nail guns, no sources of particles indistinguishable from gGSRs were found.

Objective 2 was investigated using SEM/EDS, Time-Of-Flight/Secondary Ion Mass Spectrometry (TOF/SIMS) and Sensitive High-Resolution Ion Microprobe (SHRIMP). First, a survey of the variance of the elemental composition of frictionators across the ammunition market was conducted. Second, experiments were performed to determine whether the elemental composition and stable isotope ratios of the frictionator are preserved during ammunition discharge and whether the composition could be used to link residues to their ammunition source. The application of statistical and chemometric techniques were used to explore variation across the ammunitions available on the Australian market, where it was shown that the total combined pairwise discrimination power of TOF/SIMS, SHRIMP, and SEM/EDS was 97.8% and the discrimination power of TOF/SIMS alone was 94.1%. It was shown that the composition of glass is conserved through firing, and that post-firing samples could often be unambiguously matched to pre-firing samples with the assistance of advanced chemical techniques.

This presentation will alert GSR examiners to a new type of particle that displays strong association with a firearm source. In particular, it reveals that a high probative value can be attributed to 0.22 caliber GSR. It also demonstrates a new approach that can be used by GSR examiners to link GSR with unfired ammunition or spent cartridge cases; this capability is valuable but traditional approaches suffered from a relatively high degree of uncertainty.

Glass-Containing GSR, Characteristic Particles, Advanced Chemical Analysis

B196 The Determination of Gunshot Residue (GSR) Settling Velocity

Cassidy M. Schultheis, 1420 Centre Avenue, Apt 1413, Pittsburgh, PA 15219; Stephanie J. Wetzel, PhD, Department of Chemistry and Biochemistry, 600 Forbes Avenue, Pittsburgh, PA 15282; Stephanie Horner, MS, RJ Lee Group, 350 Hochberg Road, Monroeville, PA 15146; and Allison Laneve, MS, RJ Lee Group, 350 Hochberg Road, Monroeville, PA 15146*

After attending this presentation, attendees will have a preliminary understanding of the approximate rate at which GSR settles to the ground.

This presentation will impact the forensic science community by providing information regarding the potential GSR contamination of those entering the crime scene following the discharge. This information can be used for crime scene reconstruction and could help explain the presence of GSR on a bystander.

GSR is a type of trace evidence that can be used in any type of forensic case involving a discharged firearm. GSR consists of all particulates expelled from a firearm during discharge. This presentation focuses on primer GSR. During primer GSR analysis, the three main elements of interest are barium, lead, and antimony. Most GSR particles have smooth spherical morphologies and are micron sized. GSR is produced when the firing pin hits the cartridge, which activates the primer. The primer then ignites the gunpowder (propellant) that causes a pressure buildup. This pressure then pushes the bullet down the barrel at a high velocity and the particles are released as a vapor through various openings in the firearm. GSR primer residues are typically analyzed using Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy (SEM/EDS). The instrumentation works by irradiating the sample with electrons. The interaction between the sample and the electrons can identify the morphology of the particle and X-rays are emitted to determine the particle's elemental composition.[1]

Previous research has been completed to determine how fast GSR particles settle after discharge. This research used both pistols and revolvers and collected the particles by stacking petri dishes on top of each other.[2] Specific petri dishes were removed at designated time intervals to develop an overall rate.[2] The results demonstrated that the settling velocity ranged between 1.5 to 8 minutes after discharge, depending on the firearm.[2] While this research can be very informative, the mechanism of collection is not advantageous. Contamination may easily occur when entering or leaving the closed room to remove the petri dishes. Also, the stacked petri dishes do not provide a large range in heights that can be used to determine an overall rate because they were only a few inches apart. This research used a more advantageous collection method in determining the GSR settling velocity. The collection method was unique when compared to previous research; GSR samples were collected onto 0.4-micron polycarbonate membrane filters that were held above the ground by metal stands to provide greater height differences. The filters located inside the shooting room were connected to air pumps that were located outside the shooting room; the ability to control all the filters from outside the room limits particle contamination. The filters were placed at various heights above the ground. Once the firearm was discharged, the filters were turned on at different time intervals to determine the settling velocity. The filters were transferred onto SEM stubs and analyzed using the Aspect 75 Scanning Electron Microscope and Zeppelin Energy Dispersive X-ray Spectroscopy Software with a RJ Lee Group Detector. The preliminary data has shown that the particles fall at considerably lower rates than expected. The results revealed that a substantial amount of particles were still in the air after three hours.

Gunshot Residue (GSR), SEM/EDS, Forensic Science

C1 The Walls Are Listening: A Forensic Study of Home Personal Assistants

Jessica Wright, 1616 Spring Valley Drive, Unit 47, Huntington, WV 25704; Ian Levstein, MS, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; Dale Mosley, West Virginia State Police Digital Forensics Unit, 1401 Forensic Science Drive, Huntington, WV 25701; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be more aware of the types of forensic artifacts that can be recovered from devices connected to the Google® Home™ and Amazon® Echo™.

This presentation will impact the forensic science community by providing a method for the digital investigation of the Google® Home™ and Amazon® Echo™ in a controlled environment. Since these devices have only recently been developed, not a lot of forensic research exists. Recently, law enforcement tried to gain access to Amazon® Echo™ cloud data to help solve a murder. It is believed that these home personal assistants store data in places other than the cloud.

Home personal assistants, like the Google® Home™ and Amazon® Echo™, are increasing in popularity around the world. These devices are always on or always listening, waiting for the user to say the wake phrase. This research had three goals: (1) to determine exactly when the Google® Home™ and Amazon® Echo™ were recording an individual by recovering forensic artifacts from the devices that are connected to them; (2) to determine if the wake phrase was necessary for the home personal assistant to be recording and remembering an individual's conversations; and, (3) to see if these home personal assistants are sending data to third parties.

Data collection required a new Google® Home™ and Amazon® Echo™, along with two Android™ phones and two iPhones®. Two user identities were created; each user had an Android™ and an iPhone®. The Androids™ were connected to the Google® Home™ and the iPhones® were connected to the Amazon® Echo™. Two different types of scripts were created, a script in which the user talked directly to the device and a script in which the user talked indirectly to the device. Using a controlled environment, the scripts were read, ensuring the devices heard nothing that was not scripted. The phones were then imaged using Magnet Acquire™, processed with Axiom Process™, and examined with Axiom Examine™. Personal advertisements were checked on each phone on two different occasions by going to four websites that are well known for having a substantial amount of advertisements. The advertisements were counted and the content was noted. A control phone was also checked to make the process more objective. Chi-square statistics was used to find significant differences between categories of personal advertisement.

Artifacts from the Amazon® Echo™ were visible on both iPhones® when viewing the image on Axiom Examine™; however, the artifacts were only from the Alexa application. No artifacts could be recovered from the Google® Home™ application on the Androids™, but several artifacts from other applications that had been used, such as IFTTT™ and Evernote™, could be extracted. The devices showed no sign of recording when they were not being directly spoken to, based on the online history. A significant difference was found between the ads on the Androids™ and iPhones® during the second trial.

C2 Observer Agreement in the Identification and Quantification of Dorsal Hand Traits From Digital Images

Derek A. Boyd, MA, University of Tennessee, Knoxville, 250 S Stadium Hall, Knoxville, TN 37996; Aislynn MacKenzie, Federal Bureau of Investigation, Quantico, VA 22135; Briana M. Turner-Gilmore, Federal Bureau of Investigation, Quantico, VA 22135; Richard Vorder Bruegge, PhD, FBI, OTD, Bldg 27958A, Pod E, Quantico, VA 22135; Walter Bruehs, MS, FBI Academy, ERF-E, Bldg 27958A, Quantico, VA 22135; and Jenna M. Walker, BS, Federal Bureau of Investigation, Quantico, VA 22135*

After attending this presentation, attendees will understand the limitations of relying on dorsal hand traits (e.g., scars, moles, freckles, skin creases) to identify individuals from digital images.

This presentation will impact the forensic science community in terms of competency and performance by calling attention to the underlying reliability of dorsal hand traits in order to minimize the likelihood of false identifications.

Improvements in web-based technologies, in addition to increased human trafficking in the sex tourism industry, have increased the frequency of child pornography cases. Recent studies have demonstrated the potential utility of dorsal hand traits in the identification of perpetrators and victims of these criminal activities through photographic comparison. The qualitative nature of this method prevents it from meeting *Daubert* standards, as there are no known error rates associated with rates of identification of these traits from visual media. Recent studies have attempted to develop likelihood ratios for dorsal hand traits, but there have been few studies of the specific underlying reliability of visual identification and quantification of these traits. The objective of this pilot study was to explore this gap in the literature by conducting an analysis of observer agreement associated with scars, moles, freckles, and knuckle skin-creases, with the hypothesis that all traits would exhibit remarkable levels of intra- and inter-observer error. The study also asked observers to define regions of the hands independently, rather than note all features of the hand holistically.

For this study, digital images of the left dorsal hand of one individual were macroscopically analyzed by three trained examiners and three novice analysts from the Forensic Audio/Video and Image Analysis Unit of the Federal Bureau of Investigation. All images were examined at two time intervals separated by a minimum of 24 hours. One image presented the dorsal aspect of the hand encompassing the second through fifth digits (i.e., fingers). The other image captured only the dorsal aspect of the hand that included the first digit (i.e., thumb). A second set of images was taken of these same portions of the hand, but at different levels of exposure. To maximize the visibility of traits, all images were converted to CYMK in Adobe® Photoshop® CC. The full-color image was then compared with the isolated yellow channel. To examine the amount of variation observed in the data, coefficients of variance were computed for each trait. Afterward, a paired-samples *t*-test was performed for all traits with time set as the grouping variable in order to evaluate intra-observer error. To evaluate inter-observer error, an Analysis Of Covariance (ANCOVA) was performed for the same traits with experience and exposure as the covariates. The threshold for statistical significance for both analyses, which were performed in R (v. 3.4.1), was set at α=0.05.

Overall, the results of this study provided variable support for the expectation that all traits would exhibit remarkable levels of intra- and inter-observer error. Calculated coefficients of variance indicated high levels of data dispersion among scars (cv=1.206), moles (cv=1.546), and freckles (cv=1.270). Coefficients of variance calculated for counts of knuckle skin-creases on each digit suggested comparatively lower levels of dispersion (cv_1=0.419; cv_2=0.404; cv_3=0.450; cv_4=0.530; cv_5=0.354). Tests of intra-observer error indicated a statistically significant difference in mean counts between first and second observations of freckles (t=-2.43, df=11, p=0.034) and knuckle skin-creases on the second digit (t=-2.80, df=11, p=0.017), but not for any other traits observed. All computed ANCOVAs yielded statistically insignificant results for exposure; however, trained examiners and novice analysts significantly differed in their observations of scars (F=17.173, df=1, p=<0.001) and knuckle skin-creases on all five digits of the hand (F_1=4.366, df=1, p=0.049; F_2=9.854, df=1, p=0.005; F_3=24.670, df=1, p<0.001; F_4=25.266, df=1, p<0.001; F_5=14.371, df=1, p=0.001).

This exploratory study found that most traits exhibited statistically minimal intra- and inter-observe disagreement. There is considerable intra- and inter-individual variation in the specific observations made by participants, which calls into question the reliability of dorsal hand traits as suitable points of interest for photographic hand comparison. These findings are consistent with recent studies that show support for qualitative methods of identification and have implications for current efforts to develop quantitative methods based off the traits investigated here.

Identification, Photographic Comparison, Dorsal Hand

C3 United States Army Criminal Investigation Command (USACIDC) Digital Forensics: A Program Overview

Patrick A. Eller, MS, USACIDC, 27130 Telegraph Road, Quantico, VA 22134; Joseph Levi White, MS*, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have gained information on the organizational structure and capabilities of the USACIDC's current digital forensics programs.

This presentation will impact the forensic science community by providing an overview of the services offered to assist criminal investigations involving Digital and Multimedia Evidence (DME) within the United States military.

As the United States Army's primary criminal investigative organization and the Department of Defense's (DoD's) premier investigative organization, the USACIDC, commonly known as CID, is responsible for conducting criminal investigations in which the United States Army is, or may be, a party of interest. The mission of the USACIDC is to investigate and deter serious crimes in which the Army has an interest. The USACIDC collects, analyzes, processes, and disseminates criminal intelligence; conducts protective service operations; provides forensic laboratory support to all DoD investigative agencies; and maintains Army criminal records. The USACIDC also provides criminal investigative support to all United States Army elements and deploys on short notice in support of contingency operations worldwide. The USACIDC Special Agents primarily investigate felony-level crime across the Army and provide investigative support to field commanders. They conduct a wide variety of investigations to include deaths, sexual assault, armed robbery, procurement fraud, computer crimes, counter-drug operations, and war crimes. The USACIDC agents also provide counter-terrorism support, criminal intelligence support, force protection, forensic laboratory investigative support, and protective services for key DoD and senior Army leadership.[1]

Within the hierarchy of the USACIDC, there are two individual organizations that share the responsibility for processing and examining DME to assist in Army criminal investigations: the USACIDC Computer Crimes Program (CCP) and the United States Army Criminal Investigation Laboratory's (USACIL) Documents and Digital Evidence (D2E) Branch.

Along with an overview of the organizational structure of the two USACIDC programs, attendees will be provided with much more information regarding each organization's capabilities, specializations, and examinations. This presentation will describe the types of examinations typically conducted in addition to an outline of the typical types of crimes investigated. This presentation will also include an overview of the anticipated future of the programs, current and anticipated evidence-processing issues, and a potential shift from reactive dead-box forensics to more proactive roles in investigations involving Internet Crimes Against Children (ICAC) and the National Center for Missing and Exploited Children (NCMEC).

Army, Military, Program Overview

C4 Scientific Working Group on Digital Evidence (SWGDE) and Its Current Efforts in Digital Forensics and Forensic Audio — Part 1

Mary F. Horvath, MFS, 10035 Via Colomba Circle, #203, Ft. Myers, FL 33966; Steven B. Watson, BA*, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021-8042; Jeff M. Smith, MS*, National Center for Media Forensics - CU Denver, 1150 10th Street, Arts Building, Suite 177, Denver, CO 80204; and Marla E. Carroll, BS*, Forensic Video & Audio Associates, Inc, 6919 W Broward Boulevard, Ste 222, Plantation, FL 33317*

After attending this presentation, attendees will expand their general understanding of the mission and work of the Scientific Working Group on Digital Evidence (SWGDE), with recent activities and updates in the sub-disciplines of digital forensics and forensic audio.

This presentation will impact the forensic science community by providing an introduction to the SWGDE and their recent activities, with specific concentration on information relevant to best practices, guidelines, and standard developments in the digital evidence sub-disciplines of digital forensics and forensic audio.

This is the first of two presentations that will provide background on, and introduce the efforts of, the SWGDE. This Part 1 presentation will introduce the audience to SWGDE, its current organization, members, efforts, and will provide updates on the efforts of two of its five committees: the Forensics and Forensic Audio Committees.

SWGDE was formally established in 1998 to bring together organizations representing law enforcement, academia, legal, and commercial communities actively engaged in the field of digital and multimedia evidence to foster communication and cooperation. SWGDE's primary efforts include the development of cross-disciplinary guidelines and standards for the recovery, preservation, and examination of digital and multimedia evidence in order to ensure quality and consistency with the forensic community.

SWGDE provides guidance to the digital forensic community through the publication of standards, guidelines, and best practices with a concentration on public outreach and feedback acceptance. SWGDE also encourages a number of its published documents to be used by standard developing organizations in the creation of national and international standards for digital and multimedia evidence. SWGDE is often asked to address various issues from local and national bodies to form consensus feedback and position statements.

SWGDE is currently comprised of over 80 forensic examiners, scientists, and managers from more than two dozen federal, state, and local law enforcement agencies, as well as representatives from the academic, private, and research communities. The membership primarily concentrates its efforts addressing issues within five main technical sub-disciplines – Digital Forensics, Audio, Imaging, Video, and Photography.

This Part 1 presentation will provide informative updates from two of the five standing committees -- the Digital Forensics and Audio Committees. Committee representatives will provide updates regarding the current efforts of each committee, their work products, and the feedback that has been received during public comment periods. These two committees have the following mission statements and the presentations provided will discuss efforts specific to these missions:

Audio Committee: represents the forensic audio community by developing and promoting best practices related to the examination, analysis, comparison or evaluation of audio, evaluating current research, and assessing the forensic impact of new technology.

Digital Forensics (formerly Computer Forensics) Committee: addresses topics and issues facing digital forensics practitioners by developing forensically sound techniques through the assessment of current and emerging technologies. The committee supports the Digital Forensics community by the establishment of core competencies, best practices, forensic methodologies, and through participation in original research.

The opinions or assertions contained herein are the views of the SWGDE member participants and are not to be construed as official or as reflecting the views of the author's employer.

Names of commercial manufacturers or products included are incidental only, and inclusion does not imply endorsement by the authors, member participants, or their employer.

SWGDE, Digital Evidence, Audio

C5 Current Efforts in Video Forensics, Image Analysis, and Photography as It Relates to Digital Evidence From the Scientific Working Group on Digital Evidence (SWGDE) — Part 2

Mary F. Horvath, MFS, 10035 Via Colomba Circle, #203, Ft. Myers, FL 33966; Jesus R. Valenzuela, BA*, Seattle Police Department, 610 5th Avenue, PO Box 34986, Seattle, WA 98104; Marla E. Carroll, BS*, Forensic Video & Audio Associates, Inc, 6919 W Broward Boulevard, Ste 222, Plantation, FL 33317; and Kimberly Meline, BS*, Building 27958A, Quantico, VA 22135*

After attending this presentation, attendees will expand their general understanding of the mission and work of the Scientific Working Group on Digital Evidence (SWGDE), with recent activities and updates in the sub-disciplines of video and image analysis, as well as general photography.

This presentation will impact the forensic science community by providing an introduction to the SWGDE and their recent activities, with specific concentration on information relevant to best practices, guidelines, and standard developments in the digital evidence sub-disciplines of video and image analyses, as well as the field of photography as it intersects the realm of digital evidence.

This is the second of a two-part session that will provide a continuation of presentations discussing the activities and efforts of the SWGDE. In the first session, titled "Scientific Working Group on Digital Evidence (SWGDE) and Its Current Efforts in Digital Forensics and Forensic Audio -- Part 1," an in-depth introduction to the SWGDE organization was provided. The audience learned how SWGDE was established in 1998; about its membership and structure; that its mission is to bring together organizations representing law enforcement, academia, legal, and commercial communities actively engaged in the field of digital and multimedia evidence to foster communication and cooperation; and that SWGDE intends to provide guidance to the digital forensic community through the publication of standards, guidelines, and best practices with a concentration on public outreach and feedback acceptance.

Beginning with the Part 1 session, preceding this one, updates from standing committee members representing digital and multimedia subdisciplines were provided from two of its five standing technical committees -- Digital Forensics and Imaging. This Part 2 session is intended to be a continuation of information provided in the first session by continuing with updates from the remaining standing technical committees. Committee representatives will present the current efforts of the remaining subdisciplines of Video, Imaging, and Photography. An update on current activities, discussion topics and documents, as well as works in progress from each committee will be provided. The mission statements of the remaining technical standing committees are:

Imaging Committee: responsible for producing documents that pertain to the best practices for the examination and evaluation of imagery. This may involve opinions as to the provenance of an image or its content, including photogrammetric analysis, comparative analysis, and/or authentication.

Photography Committee: charged with addressing photographic and imaging issues as they intersect the realm of digital evidence. The committee develops best practices for processes ranging from field photography to the compression and archiving of those images to aid the law enforcement community.

Video Committee: focused on the development of best practices for video recovery and analysis, as well as training guidelines.

One additional non-technical committee, the Quality Standards committee, provides overarching guidelines for the Digital and Multimedia Sciences communities on how to develop and implement a quality management system including topics such as validation, testing, and accreditation to support laboratory competence and continuous improvement.

The opinions or assertions contained herein are the views of the SWGDE member participants and are not to be construed as official or as reflecting the views of the author's employer.

Names of commercial manufacturers or products included are incidental only, and inclusion does not imply endorsement by the authors, member participants, or their employer.

Digital Evidence, Video, Image

C6 Testing Digital Forensic String Search Tools

James R. Lyle, PhD, National Institute of Standards & Technology, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899; and Barbara Guttman, BA, National Institute of Standards & Technology, Mail Stop 8970, Gaithersburg, MD 20899-8970*

After attending the presentation, attendees will be aware of test data for string search tools and of some of the limitations and constraints of testing computer forensic string search tools. Test data and test method documentation is available via the Computer Forensics Tool Testing (CFTT) and Computer Forensic Reference Data Sets (CFReDS) websites (www.cftt.nist.gov and www.cfreds.nist.gov).

This presentation will impact the forensic science community by increasing awareness of tool test strategies and the ability of tool testing to reveal anomalies in string search tool behavior. This presentation will aid the forensic practitioner in recognizing the limitations of testing string search forensic tools and in being aware of the implications of choices of what to test or not test. The goal of testing forensic tools by a forensic laboratory is not to prove the software is always correct but to show evidence that the software is appropriate for the task at hand.

The CFTT project at the National Institute of Standards and Technology (NIST) develops methodologies for testing digital forensic tools. Currently, there are CFTT methodologies for testing the following: disk imaging, write blocking, deleted file recovery, file carving, forensic media preparation, and mobile devices.

A variety of forensic tools in each of these categories have been tested and observed flaws have been documented and reported by the Department of Homeland Security (DHS) and the National Institute of Justice (NIJ). These results can be used as a basis for identifying the types of likely failures that occur in forensic tools.

At an abstract level, string searching involves the following: (1) something to search with (i.e., a search engine); (2) someplace to search (i.e., an image file or a digital storage device); (3) something to search for; and, (4) search results (presented in a useful way).

A search engine implements a search algorithm that performs the search. A digital forensic string search tool provides an interface between a user and a search engine. The search tool interfaces with at least one search engine, but may interface with additional search engines. Most tools make a pass over the data and construct an index of strings that might be searched for or scan the entire data set for each search. Other tools may allow a user to select the search algorithm to use.

A search tool uses text strings to identify files relevant to an investigation. In addition to active files, a search tool may also need to search deleted files and unallocated space.

In the simplest case, the user is looking for a match to a target search string. Sometimes the tool user has a case-specific list of search terms. In other cases, the user wants the tool to find social security numbers (i.e., groups of nine digits). This can be specified as a regular expression (i.e., a pattern) such as [0-9]{9,9} (a string of nine digits with no separators). In addition, the user might need to search for text that is not represented in ASCII, such as searching for a Chinese word. There are multiple possible encodings for the characters (e.g., UNICODE, GB, Big 5, SHIFT JIS, etc.).

Forensic search tools often have a rich set of search parameters that could be tested. In the design of this test method and test data, this study focused on what seemed to be the most useful features in general. For an individual laboratory, other selections might be a better fit. Some common search parameters addressed in the NIST search data sets include: whole word versus substring; match case versus ignore case; character representation — ASCII versus UNICODE; active file versus deleted file versus unallocated space; exact match versus pattern match; clear text (.txt) versus formatted (.doc or .html); and, indexed search versus live search.

In summary, this presentation will describe a publicly available data set for testing forensic string search tools, including search features that can be tested, how to create test data, and the results of applying the test data set to several commonly used forensic tools.

Digital Forensics, Tool Testing, String Search

C7 Validating Mobile Forensics Tools in Your Lab With the National Institute of Standards and Technology's (NIST) Federated Testing

Barbara Guttman, BA, National Institute of Standards & Technology, Mail Stop 8970, Gaithersburg, MD 20899-8970; James R. Lyle, PhD, National Institute of Standards & Technology, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899; Benjamin R. Livelsberger, MS, National Institute of Standards & Technology, 100 Bureau Drive, Mail Stop 8970, Gaithersburg, MD 20899-8970; Richard Ayers, MS, National Institute of Standards & Technology, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899-8970; and Jenise Reyes-Rodriguez, BS, National Institute of Standards & Technology, 100 Bureau Drive, Gaithersburg, MD 20899*

After attending this presentation, attendees will be aware of a tool that can help test mobile forensics tools in a lab using the Computer Forensic Tool Testing (CFTT) Federated Testing Forensic Tool Testing Environment developed by the NIST.

This presentation will impact the forensic science community by increasing awareness of the capabilities of Federated Testing when applied to tools capable of extracting data from mobile devices and associated media (e.g., Universal Integrated Circuit Cards (UICCs)/Subscriber Identity Modules (SIMs)). This presentation will provide examples of using the Federated Testing Mobile Devices Test Suite to test mobile forensic tools in the same fashion as a digital forensics laboratory would conduct validation testing. In addition, by documenting the resource commitment required to perform the tool testing, forensic practitioners will be able to estimate the cost in time and effort to test mobile forensic tools in their laboratory. This presentation will aid the forensic practitioner choosing to use Federated Testing by providing examples of using the Federated Testing Mobile Test Suite to test actual mobile forensic tools, much as a digital forensics laboratory would conduct validation testing.

The CFTT project at NIST develops methodologies for testing digital forensic tools. Currently, there are CFTT methodologies for testing the following: disk imaging, write blocking, deleted file recovery, file carving, forensic media preparation, and mobile devices.

A variety of tools in each of these categories have been tested and observed flaws in the tools have been reported by the National Institute of Justice (NIJ) and the Department of Homeland Security (DHS). These results can be used as a basis for identifying the types of likely failures that occur in forensic tools. Currently, CFTT has implemented testing disk imaging, hardware write blocking and mobile forensics tools into Federated Testing.

Using Federated Testing has several advantages: (1) it relieves a forensic laboratory of the task of developing a test plan for tool testing because Federated Testing generates a test plan based on selections made by the user describing how the laboratory uses the tested tool (a list of test runs; detailed procedures for documenting and populating mobile devices with known active and deleted content; detailed procedures for performing essential and optional test runs; and tools to generate a skeleton test report that can then can be prepared in the style favored by the laboratory); (2) the test reports can be shared with other laboratories; and, (3) completed test reports can be submitted to CFTT for administrative review and, if no issues are found, the report is passed on to the vendor for comment. The final report is published by the DHS, Science & Technology Directorate, Cyber Security Division.

Certain trade names and company products are mentioned in the text or identified. In no case does such identification imply recommendation or endorsement by the authors or the authors' employers, nor does it imply that the products are necessarily the best available for the purpose.

Digital Forensics, Tool Testing, Mobile Forensics

C8 An Audio Enhancement Framework for Forensic Purposes

Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Arts Building, Suite 177, Denver, CO 80204; and James Zjalic, BSc, 22 Lowfield Close, Birmingham, England B62 0ez, UNITED KINGDOM*

After attending this presentation, attendees will better understand digital audio enhancement processes, limitations, and principles in order to inform a framework that will provide optimal results when performing audio enhancement for forensic purposes.

This presentation will impact the forensic science community by demonstrating that although there are many processes available to the forensic audio analyst, the order in which they are executed is vital in achieving the best results possible, as each tool used is used in isolation and modifies the signal in a unique way based on algorithms applied. The input of the next processor in a sequence is determined by the output of the previous, and this chain has a cumulative effect that provides differing enhancement results. A hypothesis that there is an optimal sequence of operations to produce the best results when performing audio enhancement is central to the research conducted for this presentation. There are currently various papers available detailing the individual methods of audio enhancement, but no document exists that provides a framework for the interaction of these processes.

The methodology proposed is agnostic, endorsing no specific software. It is based on scientific principles to future-proof the research from software developments and to allow the framework to apply to a range of individuals, including those who use free open source tools to those who work within agencies that have access to the latest, high-end software.

The goal of a forensic audio enhancement is to improve intelligibility and/or listening quality while maintaining the subjective speech interpretation and/or facilitating scientific measurements (e.g., gunshot, phonemes).[1] For this to occur, it is of the utmost importance that the desired signal is unchanged. To understand how this can be achieved, an investigation in the form of critical listening and Fast Fourier Transform (FFT) signal analysis is first performed to create a strategy that can be followed during the enhancement procedure to produce optimal results.[2] For this to be possible, a scientific review of techniques was performed and a critique of how various processes can be applied to specific issues present in forensic audio recordings was created. A logical framework was then devised, based on the knowledge of how various techniques alter the input of a processor and the signal information that is required by future processes in the chain.

The enhancement processes available to the audio analyst generally fit into six categories: source separation, distortion repair, filtering, noise reduction, de-reverberation, and amplitude correction.[3] Experimental results applied to the same input signal reveal that when several processes using identical settings are applied, the output varies in areas such as speech-to-noise ratio, artifact reduction/accumulation, intelligibility for transcription, and subjective audio quality. As each recording is infinitely different, the structure of the framework is not designed to be strictly adhered to step by step. There may be occasions when some steps are unnecessary due to the inherent character and noise present on each recording, but this will likely be discovered during the analysis stage.

This presentation will illustrate the scientific reasoning behind the proposed framework, results of the experiments, and, finally, an enhancement framework demonstration, from signal analysis to the audio output stage. Best practices such as note-taking, manipulation vs. enhancement, and evidence deliverables will also be highlighted, with the goal of attendees leaving with the practical know-how for optimal enhancement of forensic audio within the working environment.[4]

Forensic Audio, Audio Enhancement, Methodology

C9 Time Domain Analysis of Lossy Compression Decoding Artifacts

Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Arts Building, Ste 177, Denver, CO 80204*

The goal of this presentation is to disseminate important findings related to the behavior of various MP3 decoding libraries and software as they relate to time domain forensic audio analyses and analytical results.

This presentation will impact the forensic science community by providing the results of a study that impacts laboratory performance and best practices in the handling and processing of forensic audio, especially MP3 files.

This presentation reports a preliminary study on the artifacts left by different audio decoders. Lossy compressed files are common in real forensic cases, can be produced with different digital audio hardware and software systems, and their forensic analysis and/or authentication can end up being crucial in the courtroom or other extrajudicial investigations. This study reports on the time domain artifacts introduced by some of the most common freeware and commercial tools (e.g., Adobe® Audition 3.0.1; FFmpeg N-85604-g207e6de; LAME 32/64bits version 3.99.5; MATLAB® 2016a/2017a using the audioread built-in function; mpg123 1.11.0; and QuickTime® Pro 7.7.9 on original MP3 files created with 16 different OLYMPUS® digital audio recorder models: DM-520, DM-620, VN-713PC, VN-722PC, WS-550M, WS-560M, WS-600S, WS-700M, WS-750M, WS-760M, WS-802, WS-811, WS-821, WS-822, WS-823, and WS-853). Extending a previous paper presenting the zero-level sample padding problems of various MP3 decoders, the following table provides examples of the materials and results collected in this study.[1]

OLYMPUS®	Adobe® Audition		FFmpeg		LAME		MATLAB®		mpg123		QuickTime® Pro	
	median	std	median	std	median	std	median	std	median	std	median	std
MP3 Recordings	234	155	22	143	49	180	239	162	0	82	0	95

Table 1. The number of zero-level samples after decoding

The preliminary results of this study indicate that different decoders pad with a different number of zero level samples at the beginning of the Pulse Code Modulation (PCM) decoded files. The tested versions of mpg123 and QuickTime® Pro decode the original .MP3 files with minimum zero padding while Adobe® Audition, FFmpeg, LAME, and MATLAB®, using the built-in audioread function, pad with greater numbers of zero-level samples at the beginning of the PCM converted files. The artificially introduced zeros affect results of time domain processes and measurements like Quantization Levels (QL), energy, power, and Direct Current (DC) component. This can also lead to inconsistent results when the same analysis of the same acoustic event is conducted by two different scientists using different decoding tools (e.g., butt-splice detection) that will produce results at different counters. Another challenging problem can be found in forensic video where the transcoding can introduce an offset between audio and video streams. With these findings, this study proposes the use of different decoding libraries and settings that are cross-verified in forensic analyses and presented in accompanying reports.

Audio Forensics, Multimedia, Digital Evidence

C10 Analyzing Video Evidence in Officer-Involved Shooting Cases

Parris Ward, JD, Biodynamics Engineering, Inc, 1011 Swarthmore Avenue, Ste 1, Pacific Palisades, CA 90272*

After attending this presentation, attendees will understand how enhancement and analysis of video evidence, in conjunction with a computer animation, led to the acquittal of a police officer who was criminally charged in a controversial high-profile officer-involved shooting.

This presentation will impact the forensic science community by demonstrating how video evidence becomes more prolific in police use-of-force cases through the increasing use of body cameras, cell phones, and surveillance systems. This presentation will indicate how to properly analyze such evidence and understand its limitations.

On September 16, 2016, a White female police officer shot and killed an unarmed Black man while he was standing next to a Sports Utility Vehicle (SUV) in the middle of a road in Tulsa, OK. The incident led to protests in Tulsa and the case received national attention when video of the event, taken from a helicopter and police dashcams, was released to the media by the Tulsa Police Department two days later. On September 22, the Tulsa district attorney filed first-degree manslaughter charges against the officer involved, a charge which carries a maximum penalty of life in prison. After a seven-day trial, in which the video evidence was carefully considered, the officer was found not guilty.

At approximately 7:30 p.m., Officer Betty Shelby encountered an abandoned vehicle in the middle of a two-lane road, blocking on-coming traffic. After stopping to check for people inside the vehicle, she walked back to her own vehicle where she was approached by an incoherent Black man, later identified as Terence Crutcher. The man was mumbling and reaching into his pockets despite repeated commands to keep his hands out of his pockets. Officer Shelby radioed for help stating, "I have a suspect not showing his hands." The man walked around the rear of Shelby's police cruiser as she followed, stopping at various points and reaching into his pockets. The helicopter video of the event begins as the man starts walking toward the SUV with his hands raised. Officer Shelby stated that she pointed her gun at Mr. Crutcher and ordered him to stop and get down on the ground. Mr. Crutcher ignored her commands and kept walking, eventually stopping next to the driver-side window of the SUV. At this point, another officer arrived on scene and stood next to and slightly behind Officer Shelby, pointing his TASER® at Mr. Crutcher. Both officers stated that Mr. Crutcher dropped his left hand and reached into the open window of the vehicle, at which point both officers fired their weapons simultaneously. The single shot fired by Officer Shelby entered Mr. Crutcher's right chest and damaged his heart and lungs, resulting in his death. The autopsy revealed Mr. Crutcher to be under the influence of PCP. No weapon was found inside the SUV.

The helicopter and dashcam videos became the central evidence in the case, although neither was clear enough to be definitive as to whether Mr. Crutcher reached into the window under normal viewing. The helicopter Forward Looking Infrared Radar (FLIR) camera provided the best viewing angle of the event; however, it only produced a standard-definition interlaced recording. Due to the motion of both the camera and helicopter, the individual interlaced video frames lacked clarity.

Using forensic video analysis software, the helicopter video was de-interlaced, stabilized, clarified, and enlarged in order to facilitate a frame-by-frame analysis that showed that Mr. Crutcher's arm was inside the window opening at the time he was shot. Audio from the dashcam video recorded the sound of a single shot, confirming that the TASER® and gun were fired simultaneously.

Since the video evidence only revealed the end of Shelby's encounter with Crutcher, her defense team looked at ways to tell the story of how the event unfolded. A synchronized video narrative was produced, tying together initial 911 calls, radio transmissions, multiple dashcam recordings of responding units, and the helicopter video into a single timeline. A computer animation was created showing the various locations Officer Shelby and Mr. Crutcher prior to the beginning of the helicopter video. These videos, together with the enhanced helicopter video, will be presented in addition to a detailed discussion of how they were created.

Shootings, Video Analysis, Computer Animation

C11 Video Datasets for Developing Image Forensic Techniques

Manato Hirabayashi, MS, National Research Institute of Police Science, 6 3 1 Kashiwanoha, Kashiwa 277-0882, JAPAN; Kenji Kurosawa, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Norimitsu Akiba, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Daisuke Imoto, MS, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa 277-0882, JAPAN; Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Physics Section, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Ken'ichi Tsuchiya, PhD, 6-3-1 Kashiwanoha, Kashiwa, Chiba 2770882, JAPAN; and Kenro Kuroki, PhD, 6-3-1 Kashiwanoha, Kashiwa 277-0882, JAPAN*

After attending this presentation, attendees will better understand two newly constructed video datasets that will accelerate the development of various image forensic techniques, as well as contents and applications of the datasets.

This presentation will impact the forensic science community by announcing newly constructed datasets to evaluate image forensic techniques, especially for suspicious activities detection and forgeries detection. The fact that novel datasets were constructed will be beneficial information for forensic image analysts.

Improvement of video and image analysis techniques have provided significant benefits for information analysis in various fields such as prevention and investigation of crimes and terrorism. In order to drive development of such analyzing techniques that assist public safety and security, this study constructed two types of video datasets so practical technique evaluations and comparisons can be made. The datasets presented are: (1) a dataset of crowds and suspicious activity videos; and, (2) a dataset of forgery videos. These were created based on factors such as experiences with a variety of forensic image analyses. It is thought that these datasets are helpful for furthering research in this area and for the efficient social implementation of various novel video and image analysis techniques. It is planned that these datasets will become available for researchers by the conclusion of a joint research contract. A brief overview of each dataset is described in the following sections.

The first section is a set of videos containing crowds of people and a few suspicious activities happening in the crowds. This set seeks to drive the development of techniques for detecting suspicious activities from videos. Five situations, including a sightseeing spot, a sports stadium, and a meeting place such as a station, are assumed and up to 100 extras appear in the videos. In the videos, nearly all people in the crowds behave typically, but some are engaged in suspicious activities. Each scene was shot by three to four High-Definition (HD) -resolution cameras and one spherical camera from different angles simultaneously. Suspicious activities are defined based on comments from police officers and embedded into the scenarios. Annotation data is also provided.

The second section is a set of forgery videos. This set contains material videos that are used to make forgeries as well as six types of forgeries. The goal of this set is to further development of techniques for detecting forgeries in videos. In the videos, for example, removing a person or tampering with a traffic light color are performed as forgeries. One of the remarkable points of this set is that approximately 40–50 seconds of each video is tampered with. Furthermore, as the quality of forgery videos is significantly affected by the technical level of the forger, each forgery type of this set contains tampered videos with three different levels of technical quality from expert level to amateur level of forgery using the same materials.

Suspicious Activity Detection, Forgery Detection, Video Dataset

C12 Another Forensic Image Data Set (AFIDS)

Mark D. Guido, MS, The MITRE Corporation, 7515 Colshire Drive, Mclean, VA 22102; and Michael McCarrin, PhD*, Naval Postgraduate School, 507 Koshland Way, Santa Cruz, CA 95064*

The goal of this presentation is to raise awareness and interest in a new and available research data set that will be composed of real-world forensic images from around the world. This increased awareness of AFIDS is primarily targeted at the Digital & Multimedia Sciences Section of the American Academy of Forensic Sciences due to its diverse member population across industry, academia, and law enforcement/government/military arenas.

This presentation will impact the forensic science community by providing a real-world, reasonably safe, and unique dataset to aid researchers in tool development and testing of forensic tools and related capabilities.

In 2009, Garfinkel et al. made the case for standardized forensic corpora to foster scientific approaches and progress in digital forensics.[1] Of the datasets that resulted from this effort, the Real Data Corpus (RDC) was by far the largest and most representative of the variety and complexity of data encountered during digital forensic investigations. Its use in the development and de-bugging of widely used tools such as bulk extractor and The Sleuth Kit testify to the success of the project; however, though this dataset is still actively maintained, challenges relating to cost as well as institutional policies have prevented the addition of new drive images for several years. Consequently, new applications and operating systems are absent, and the versions of software represented are long out of date. The current RDC continues to suffer from entrenched problems related to policy, operations, and oversight.

The development of AFIDS is therefore proposed. The intent is to define a community resource to enable the advancement of digital forensics research while incorporating from the outset lessons learned from previous work on large-scale restricted datasets such as the RDC and the National Software Reference Library (NSRL). AFIDS can leverage Amazon® Web Services GovCloud infrastructure to reduce costs of long-term storage and to allow controlled access by researchers without the additional privacy risks associated with distributing copies of the data. AFIDS can provide a managed interface by which researchers can submit "queries" to the dataset (ranging from simple functions to custom forensic analysis tools) that will be assessed in terms of their risk of exposing personally identifiable information before being run across the dataset via Cloud technologies. It is expected this risk assessment will facilitate Institutional Review Board oversight and reduce researcher overhead. Query results, moreover, can be cached and made available, preventing the need to repeat expensive computations.

In conclusion, a study to identify improvements over the current RDC is already being conducted; the plan is to bring AFIDS online and make it available for researchers from industry, academia, and law enforcement/government/military. The current status of AFIDS will be provided to attendees.

Real Data Corpus, Forensic Images, Research

C13 Digital Image Recompression Analysis: Twitter®

Gretchel Lomboy, 3214 26th Avenue, W, Seattle, WA 98199; Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Arts Building, Ste 177, Denver, CO 80204*

After attending this presentation, attendees will have gained insight into the interpretation of embedded data that can be found within the construct of images shared and downloaded via Twitter® and, with this newfound knowledge, be better equipped to analyze and understand differing image file structures as they pertain to particular social media networks.

This presentation will impact the forensic science community by illustrating that, because of the ubiquitous use of social media in this day and age, a higher understanding of data attributed to individual social media networks is necessary for the digital forensic analyst. Research of information provided by and attributed to Twitter® is a stepping stone to understanding how social media networks compare to, as well as differ from, each other in terms of the metadata associated with and attributed to each network.

This presentation offers insight into the identification of the effect of mobile and desktop uploading and downloading of images shared through Twitter®. A hypothesis statement that "useful information pertaining to the location and interpretation of embedded data encoded within digital images can be of aid to forensic digital image analysis" is central to the research conducted in this presentation.

The functionalities and prolific use of social media networks have evolved over time, constantly changing how people connect to and communicate with other individuals around the world. Within the numerous variations of social media networks, a constant function is apparent throughout the uploading and sharing of images to be viewed and, oftentimes, re-shared by friends or those who subscribe to a particular feed.

This research follows a method of looking at metadata, binary data, and quantization tables of image types on image files before the upload process to Twitter®, then looking at the same data on images after the download process. A comparison of the changes between the original and Twitter®-downloaded files will be discussed, as well as the effect on image dimensions throughout the process.

Throughout each instance of submission pertaining to images being uploaded online or through a social media network, some forms of compression are needed in differing sorts of ways. This research seeks to identify as well as interpret the embedded data encoded throughout the compression process within digital images associated with Twitter®. Knowledge gained through this research can be added to a growing database of information attributed to different social media sites.

Image Analysis, Social Networks, Twitter®

C14 Deep Learning With Camera Identification

Eleni Athanasiadou, BSc, NFI, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS; Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; and Erwin Van Eijk, MS, NFI, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS*

After attending this presentation, attendees will better understand the limitations and possibilities of camera identification.

This presentation will impact the forensic science community by providing deep learning techniques that can be used for a variety of databases. It appears that the right clustering was found for only for a few cameras based on the Photo Response Non-Uniformity (PRNU) pattern.

In this presentation, a camera model identification using a deep learning technique is introduced. The PRNU noise pattern, the fingerprint of the camera, is extracted to classify and identify the camera model. Deep learning is a subfield of machine learning, which trains the computer as a human brain to recognize similarities and differences by scanning in order to identify an object. In forensic science, it is important, especially for child pornography cases, to link a photo or a set of photos with a specific camera.

Each different camera has a different noise pattern, the so-called PRNU noise pattern. Each camera has an imaging sensor that converts the light into an electrical signal. Charge-Coupled Device (CCD), Complementary Metal-Oxide Semiconductor (CMOS), Junction Field-Effect Transistor (JFET) and Foveon® X3 are some of the popular imaging sensors, with the CCD being most common.

For the experiments, NVIDIA® DIGITS, an interactive deep learning Graphics Processing Unit (GPU) training system, is used for the implementation of the project. DIGITS applies deep learning to the database that is uploaded, then classified. In the next step, the appropriate network is chosen depending on the size of the dataset. During the second step, the model is trained in order to extract features and find similarities and differences between the categories. There are three given networks: LeNet, AlexNet, and GoogleNet. Furthermore, a graph is provided informing the user of the success of the training. The most important aspects are the accuracy of the trained model and the loss of data during the process of training and validation. In the last step, the user uploads a single image and the program provides the top five predictions.

By modifying the AlexNet, the results improved, providing material for further research. The accuracy rate was high (80%-90%); however, DIGITS was able to successfully identify only 3 camera models out of 17 from the database. Furthermore, individualization of a camera was unsuccessful. In a database containing more than one camera of the same model, the accuracy rate was extremely low. In both cases, the problem was expected to be the imaging sensor. Manufacturers use the same imaging sensors, which result in similar PRNU noise patterns. As a result, DIGITS cannot distinguish the similarities and the differences of the images. It is important for future research to create a much larger database, as the one used contained 200 images per class. A larger database will feed the program with much more information.

Deep Learning, PRNU, Camera Identification

C15 Curating Forensic Image Collection Using Machine Learning

Wangcheng Yan, BS, The University of Tennessee, Knoxville, SMC 230, 916 Volunteer Boulevard, Dept of Business Analytics and Statistics, Knoxville, TN 37996-0532; Audris Mockus, PhD, University of Tennessee, Knoxville, Min H. Kao Bldg, Rm 613, 1520 Middle Drive, Knoxville, TN 37996-2250; Tiffany B. Saul, PhD, Forensic Institute for Research and Education, Middle Tennessee State Univ, 1301 E Main Street, Box 89, Murfreesboro, TN 37132; and Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 1621 Cumberland Avenue, Ste 502A Strong Hall, Knoxville, TN 37996*

After attending this presentation, attendees will understand the opportunities afforded by machine learning for automatic classification or detection of forensically relevant features in images documenting human decomposition.

This presentation will impact the forensic science community by introducing new approaches to automate the annotation of digital collections and by discussing how this can transform research on human decomposition.

Some areas of forensic anthropology have accumulated large collections of digitized data. Despite the curation approaches of traditional collections that involve manual and painstaking labor analyzing individual samples, digital collections offer a tantalizing opportunity to automate some of the most tedious parts of curation work through the application of modern machine learning. These opportunities were investigated using a collection of one million photos documenting human decomposition collected at the Anthropology Research Facility (ARF) at the University of Tennessee, Knoxville. The research was conducted in stages, beginning with checking the feasibility of the approach and ending with object detection and classification.

Experiment 1 was conducted to verify the feasibility of using machine learning for images of human decomposition. While such tools are highly advanced in certain domains, for example, for recognizing faces of living individuals, they are not likely to work well on images depicting decomposing bodies. Image analysis algorithms that can detect forensically relevant features are not well known. The specific goal of this experiment was to accurately classify images annotated with tags indicating body parts by an expert. The expert used a web-based tool to interactively highlight an interesting forensic feature within an image and then provide a tag indicating body part (e.g., left foot) and a forensic feature (e.g., egg mass). A Convolutional Neural Network (CNN) structure was used to perform binary classification of these subimages based on body-part tags. A CNN structure was made of several convolutional layers, pooling layers, and dropout layers. In the model training, the loss metric, evaluation metric, and optimizer were binary cross entropy, accuracy, and Stochastic Gradient Descent (SGD), respectively. It was implemented using the sequential model in Keras, an open source deep learning Python library. Ten-fold cross-validation was used to avoid overfitting, measure performance, and select suitable parameters for training. The classification yielded high accuracy, for instance, 91.02% when classifying eye and left foot. For particularly challenging cases, such as eye versus mouth, it was lower at 62.43%. These results indicate that machine learning is capable of accurately classifying images with different shapes.

Experiment 2 was conducted to investigate the ability of machine learning algorithms to detect relevant features, such as body parts, in a full image that may include several (or none) of the body parts. This is a much harder (and more practical) problem, since the ability to automate the annotation of the body parts could be a powerful curation aid. Keypoint identification algorithms were used to discover areas of an image that represent certain high-level features (objects). Oriented Function Analysis System Technique (FAST) and Rotated BRIEF (ORB) algorithms from OpenCV were used. Keypoint approach is appealing because of its clear interpretation and extensive use in object detection. Meanwhile, it does not require that the input images have the same input size. The effectiveness of using keypoint approach was demonstrated by classifying annotated body parts with clustered keypoints. The k-medoids were used to cluster keypoints, some of which may be spurious as not all keypoints are necessarily representative of the classification label. To address that, each image was treated as a mixture of keypoint proportions within each cluster. With the labeled class, logistic regression was used to train the classifier. For example, when classifying eye and left foot with 100 clusters of useful keypoints, a high accuracy of 94.43% was reached. In more challenging cases, such as mouth versus eye, the number of useful keypoints in each image may be too small and not enough features will be detected. Overall, the approach works well if the image contains relevant features of the body parts. As further research, these algorithms will be applied to detect forensically relevant features, such as “larvae,” “scavenging,” and “marbling” and apply the approach to a large collection of images stored with the Forensic Anthropology Center. The results suggest clear avenues for further research toward automation of the curation for large collections of forensic images.

Human Decomposition, Image Analysis, Forensic Databases

C16 Source Camera Comparison Using Photo Response Non-Uniformity (PRNU) on WhatsApp

Christiaan Meij, BSc, NFI, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS; and Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS*

After attending this presentation, attendees will be aware of the possibilities and limitations of PRNU on WhatsApp.

This presentation will impact the forensic science community by illustrating how the use of PRNU on images transmitted with WhatsApp can be used even if the file is converted. Depending on the version of the operating system and app, the PRNU will be filtered and a weaker conclusion can be given.

In digital footage, different types of noise, such as dark current, reset noise, circuit noise, and PRNU, are present. PRNU is caused by the imperfection of the camera sensor created during the manufacturing process. Not every pixel of the sensor is identical and will, therefore, respond differently to the same amount of light. This is called the non-uniformity of pixels. When the camera sensor, for example, will be illuminated equally, not all pixels will measure the same amount of light. This is caused by the difference of the sensitivity of pixels to light. Over the sensor surface, this creates a pixel non-uniformity pattern which is called the PRNU pattern. Because the PRNU pattern originates from the camera sensor, the pattern will be present in all footage taken with this camera sensor. The PRNU pattern is specific for a camera sensor and is also called the fingerprint of a camera.[1-3]

To determine if a video is created with a specific camera, the PRNU patterns from the disputed video and the disputed camera are needed. Using software, the PRNU patterns can be extracted from a video. The first step of the extraction is to average groups of individual frames of the video. A parameter, the frame averaging rate, can be set to determine how many frames per group will be averaged. For example, a video with a thousand frames will be averaged with a frame-averaging rate of ten. Per ten frames, an averaging will be determined that delivers a hundred averaged frames in total. The second step is to extract the noise per averaged frame. Research has shown that better results were made with the second order (FSTV) filter.[3] With this filter, the noise will be removed from the footage. By subtracting the averaged frame without the noise from the averaged frame with the noise, the noise pattern will be obtained. Then, as the third step, the noise patterns from all the averaged frames will be averaged. With this step, noise that is not present in every frame, like the PRNU pattern, will be restrained and the PRNU pattern becomes clearer. Due to electronic imperfections, some rows and columns of pixels can be systematically brighter or darker. This noise can be removed with step four by using a zero mean filter.[4] The last step in the extraction method is to remove artifacts created due to compression. Groups of pixels that share information to reduce data size create a pattern over the surface of the footage. To remove this pattern, a Wiener filter is used. Finally, the PNRU pattern is as clear as possible.[4]

To obtain the PRNU pattern from the disputed camera, a reference video is needed. These reference videos are called flat field videos. A flat field video is taken by moving the camera over a gray surface. By moving the camera over a grey surface, the camera sensor is illuminated as equally as possible and no objects will be present in the video. This causes the PRNU pattern to be as clear as possible.

When the PNRU patterns from the disputed video and the disputed camera are extracted, the two PRNU patterns can be compared. This can also be accomplished by using PRNUCompare. PRNUCompare compares the patterns and calculates the Peak to Correlation Energy (PCE).

In this research, cameras of different Android® brands as well as iPhones® were used. The PCE is lower after transmission with WhatsApp. With several phones from Samsung™ and Huawei, the likelihood ratio is low. With other cameras, a higher conclusion in likelihood ration can be drawn. The video material is re-encoded by WhatsApp and, with some cameras, the PRNU is no longer available with the method used. With the Apple® iPhone®, the PRNU pattern remained and a conclusion could be drawn if the video was created with the same source camera.

WhatsApp, PRNU, Source Camera Comparison

C17 Forensic Identification of the Source Smart Phone Camera From a Digital Image

Rajesh Kumar, PhD, Institute of Forensic Science, Nipatniranjan Nagar, Caves Road, Aurangabad, Maharashtra 431004, INDIA; Arvind Mudaliyar, MSc, Institute of Forensic Science, Nipatniranjan Nagar, Caves Road, Aurangabad 431004; and ShantiKumar Gupta, PhD, Institute of Forensic Science, Nipatniranjan Nagar, Caves Road, Aurangabad 431004, INDIA*

After attending this presentation, attendees will understand how an image suspected to be captured through a mobile phone camera can be linked though the source mobile phone and the processing required to complete the linking process.

This presentation will impact the forensic science community in terms of an extensive study over a database containing 4,950 images captured through 30 mobile handsets of various makes and models, proposing a novel classifier-based mechanism for the image-linking process. This presentation will further provide an insight to the community to further carry out research in this domain.

Currently, a smart phone is more than a calling device. Other than making telephone calls, taking photographs is the most popular task performed by a smart phone. A recent study revealed that 90% of people have taken a photograph for the first time in their lives with the help of a camera phone. The increasing use of the camera phone has also resulted in the use of images captured through it for criminal intent. In such a scenario, one of the most relevant facts that has to be proved in a court of law is the source camera through which the digital image was taken. Regarding connecting a source camera to a specific image, only a few systematic studies have been reported in this domain. Gul and Avcibas proposed their work on smart phone camera identification based on Singular Value Decomposition.[1] Further, Sandoval et al. proposed a wavelet-based technique over sensor imperfections of mobile devices.[2] Recently, Biney and Sellahewa proposed smart phone model identification based on image features.[3] In spite of the available literature, there is a lack of extensive study in this domain.

In this present study, a modified feature set based on Photo Response Non-Uniformity (PRNU) has been proposed for the identification of smart phone cameras with the query digital images.[4] An extensive study has been conducted on more than 4,950 images captured through 30 cameras of different make and models. Moreover, several attacks were made on the metadata to explore the efficacy of commercially available tools for source camera identification based on metadata information. Results of the proposed scheme are quite encouraging.

In conclusion, this study provides a reliable method for source camera identification as the data from the metadata can be easily modified to make most of the commercially available tools intended for source camera identification foolproof. In such a scenario, image analysis-based method as proposed here results in more reliable results.

Metadata, Photo Response Non-Uniformity, Image Analysis

C18 A Case Study: Ransomware Containing Child Pornography Observed on an Android™ Mobile Device

Joseph Levi White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will expand their general understanding of malicious software through the presentation of a case study involving ransomware observed on an Android™ mobile device.

This presentation will impact the forensic science community by providing an overview and example of forensic analysis performed on ransomware discovered on a mobile device.

Malicious software that is designed to cause harm to an electronic device (computer, mobile device, etc.) may be considered malware. There are multiple types of malware, such as programs to allow one user to control another user's device, programs to allow one user to spy on another, programs to display advertisements on an infected machine, and programs designed to disrupt a device's ability to function normally.

Ransomware is a type of malware designed to threaten the user unless a ransom is paid. Examples of ransomware include the WannaCry ransomware attack of May 2017, which affected several electronic systems worldwide. Ransomware threats may come in the form of data hijacking, data encryption (such as the WannaCry attack), or unwanted data disclosure (such as revealing private records or potentially embarrassing information to either the public or a specific individual).

This presentation follows the examination of a cellular phone submitted for examination to the United States Army Criminal Investigation Laboratory (USACIL). The device was owned by a soldier accused of downloading and possessing child pornography utilizing his Android™ cellular phone. Examination of the device indicated the soldier was actually the victim of a ransomware attack.

The particular ransomware located on the soldier's device was found within Android™ Package (APK) files typically associated with Android™ application installations. Forensic software allowed for unpacking the APK files to explore the contents more thoroughly. In this case, the APK files contained two Hypertext Markup Language (HTML) files (web pages). One of the files displayed obvious child pornography to the user of the device. The second displayed a fraudulent notice from the "DEPARTMENT OF JUSTICE FEDERAL BUREAU OF INVESTIGATION" imposing a $500 fine for the user's "ATTENDANCE OF THE FORBIDDEN PORNOGRAPHIC SITES."

This presentation will include an overview of the case described above and explore the inner workings of the APK ransomware malware files.

Ransomware, Malware, Examination

C19 Android™ Thumbnails: Is There More? An In-Depth Analysis of the Android™ Photo Gallery and Camera Processes Looking for Metadata

Mary F. Horvath, MFS, 10035 Via Colomba Circle, #203, Ft. Myers, FL 33966; and Steven B. Watson, BA*, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021-8042*

After attending this presentation, attendees will expand their general understanding of how the Android™ mobile operating system's Gallery application interacts with the camera application/device and how to identify metadata that has being missed in current forensic software tools.

This presentation will impact the forensic science community by providing advanced forensic processing techniques intended to be used to recover critical metadata never before seen in mobile device analysis and image recovery. It will provide an in-depth understanding of the Android™ image processing subsystems as well as provide novel techniques for the manual analysis of the related data files.

The forensic analysis of mobile devices is one of the most critical components of many criminal investigations but never more so than with those involving child exploitation. With the ease of use and access to mobile devices, combined with the inexpensive availability of large data storage, cameras on mobile devices are becoming the default mechanism for picture taking by many communities, especially those which partake in matters of child pornography and exploitation.

One such case involves pictures of a missing girl assumedly taken with, and later deleted on, a Samsung™ mobile phone running the Android™ operating system. The thumbnail images were easily recovered through the use of common forensic software tools; however, since the images were recovered from the Gallery application's cache files, no metadata was recovered that was directly connected to the images in question. The question arose as to whether it can be proven that the actual camera on the cell phone took the pictures and whether the pictures could have been taken around the same time the child went missing. The answers to these questions could provide demonstrable proof of a suspect's participation with a victim at the time of a suspected criminal act.

Deleted pictures on a mobile phone are not uncommon and often only the thumbnail images remain recoverable by current forensic software tools. Thumbnail image recovery is a common technique utilized by mobile forensic analysts during typical cell phone examinations and is usually completed through the carving of graphic file formats from cached storage areas on the device, such as a thumbnail cache. On an Android™ operating system, this is usually accomplished by performing a carving process on the "imgcache" file (a common name, not literal filename) or set of files. While the cache file itself has been fairly well documented, the processes behind the creation and writing to these files and the entire Gallery cache subsystem, as well as what interactions with the device impact these files and how, have not been documented in much detail. There are multiple files that can be impacted by the Gallery application, one of which has been overlooked to date, and it may hold the clues to a missing girl's demise.

The files created by the Gallery application were analyzed for this research to determine whether metadata beyond the thumbnail image itself can be recovered. The entire Gallery process was researched, tested, and analyzed to make a more thorough determination as to the operations of the Gallery application, its interaction with the camera subsystem, and whether advanced forensic processing techniques could be used to successfully recover critical metadata never before seen. This presentation will provide the methods of testing designed and implemented to attempt to answer the investigative questions and determine whether additional metadata is available for recovery. The results of the testing processes and research will be provided, along with new defined processes that can be implemented for data recovery and extraction.

Digital Evidence, Mobile Forensics, Data Recovery

C20 An Analysis of Apple® Mobile Devices to Support or Refute Claims of Spoliation of Data

Andrew N. Crouse, BA, Epiq Systems, Inc, 1300 Pennsylvania Avenue, NW, Ste 851, Washington, DC 20004; and Samuel I. Brothers, BBA*, 6643 Patent Parish Lane, Alexandria, VA 22315*

The goal of this presentation is to present forensic analysis and case studies of Apple® iOS® mobile device data in connection with claims of data spoliation.

This presentation will impact the forensic science community by discussing various key forensic artifacts analysts can use to confirm or refute claims of data spoliation from Apple® mobile devices that may arise during civil proceedings.

In both criminal and civil court proceedings, the hiding or destruction of digital evidence can be an obstruction investigators and attorneys encounter. These same acts can also provide key evidence in both criminal and civil cases. Specifically, in civil cases, the intentional or negligent act of destroying evidence that is relevant to a legal matter can lead to spoliation sanctions against one party, including financial penalties and dismissal of a case with prejudice. Spoliation claims involving digital evidence have been routinely investigated on computer hard drives using standard digital forensic methods and tools. With the ever-rising popularity of mobile devices in the business world, especially Apple® iPhones® and iPads®, more and more relevant digital evidence is being stored on these devices, requiring digital forensic examiners to confirm or refute claims of spoliation in civil proceedings.

The examination of deleted data is generally performed on physical images of storage media. Ever since the release of the iPhone® 4s and the iPad® 2, Apple® iOS® technology has enabled security features that do not permit the capture of full physical images of Apple® mobile devices without first circumventing the native iOS® security layers, otherwise called "jail breaking." E-Discovery collections for civil matters do not generally involve the bypassing of iOS® security layers or jail breaking custodian devices in order to obtain a physical image. As a result, digital forensic practitioners performing data collections and forensic analysis in civil matters have had to rely on available evidence from logical file systems (as opposed to physical images) obtained through items such as Apple® iTunes® and iCloud® backups, as well as Apple® File Connection (AFC) data.

This presentation will focus on key data areas within an iOS® mobile device that can help digital forensic examiners confirm or refute spoliation claims. Analysis of various areas of mobile devices will include artifacts relating to Mobile Device Management (MDM) policies, various device reset actions, and text message retention/forwarding policies. An analysis of artifacts present on erased iPhones® will be discussed, along with a comparison of extracted data from erased iPhones® that have been restored with previously backed up data using both Apple® iCloud® and Apple® iTunes®. Case studies involving the forensic analysis of spoliation claims from Apple® mobile devices will also be presented with the analysis to demonstrate real-world practical scenarios.

Apple® iOS®, Data Spoliation, Mobile Devices

C21 Snapchat® Data Recovery Capabilities

Joseph Levi White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297; and Christina A. Malone, MSFS, Defense Forensic Science Center, Forest Park, GA 30305*

After attending this presentation, attendees will expand their general understanding of the methods used to recover Snapchat® content from mobile devices, comparing the ability to recover data from both Apple® and Android™ platforms.

This presentation will impact the forensic science community by providing an outline of the current capabilities for the recovery of mobile device Snapchat® data.

Forensic analysis of mobile devices is one of the most quickly evolving areas of Digital and Multimedia Sciences (DMS). With the development and release of mobile devices occurring at a very rapid pace, Digital Forensic Examiners (DFEs) and mobile forensic software companies are faced with the task of determining how to extract and interpret data from the constantly evolving hardware and software of mobile devices. As each new iteration of mobile device and/or mobile device Operating System (OS) is released, it must be determined how to not only extract data from the device, but how to convert the raw data into a format that makes sense to the end user. The use of mobile device applications, or apps, further complicates data analysis of mobile devices. Not only is the base OS of mobile devices under constant development, but individual application developers release and update apps at a surprising pace.

Snapchat® is a mobile device application that allows users to send and receive multimedia content, such as pictures and video, between specified individual contacts. The transferred multimedia is termed a "Snap." Settings within the sender's Snapchat® application determine how long the sent content will be viewable on the receiver's mobile device, from one to ten seconds. After the time limit has expired on the receiver's device, an attempt is made by the Snapchat® software to delete the data. Security features of the Snapchat® application are also designed to prevent users from taking screen captures of received content through other mobile device applications.

A previous presentation on this topic provided an overview of the examination of an Android™-based mobile device submitted for examination to the United States Army Criminal Investigation Laboratory (USACIL) in a case involving the Snapchat® application. Upon completion of the case, it was determined that traditional *mobile device* forensic software packages were at that time unable to extract any deleted Snapchat® pictures from the mobile device; however, traditional *computer forensic* software was successful at recovering the pertinent content. Further research determined that additional functionalities of the Android™ OS, such as facial recognition capabilities, may be responsible for capturing Snapchat® image data independent of the Snapchat® application on the particular device under examination.

This presentation will provide the outcomes of a research study developed as a result of the aforementioned case and the previously conducted research, comparing the ability (or lack thereof) to recover Snapchat® data from both Android™ and Apple® devices. This research takes into account the potential additional functionalities of the Android™ and Apple® operating systems that may circumvent the data deletion design of the Snapchat® application.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army (DA) or the Department of Defense (DoD). Names of commercial manufacturers or products included are incidental only, and inclusion does not imply endorsement by the authors, the Defense Forensic Science Center (DFSC), the Office of the Provost Marshal General (OPMG), the DA, or the DoD.

Mobile Device, Snapchat®, Data Recovery

C22 Skimmer Forensics: The Identification, Seizure, and Analysis of These Problematic Little Devices

James Darnell, BS, US Secret Service, University of Tulsa, Fisher Hall, 2821 E 8th Street, Tulsa, OK 74104; and John Simonello, MSc, United States Secret Service, 335 Adams Street, Ste 3200, Brooklyn, NY 11201*

The goal of this presentation is to educate attendees on identifying, seizing, and examining credit and debit card skimmers.

This presentation will impact the forensic science community by illustrating how an examiner must resolve the stored information on these devices to actual account numbers, otherwise there is nothing with which to charge the subject of the investigation.

When magnetic card readers are used to steal Personal Identity Information (PII) (e.g., credit or debit card numbers), they are known as skimmers. Many people still associate a skimmer as the hand-held device a waiter or waitress uses to steal a person's credit card number when paying for dinner in a restaurant, but the world of skimmers has matured and evolved. They are custom made and can be placed inside gas pumps, on top of ATMs and point-of-sale terminals, or even secreted inside door access readers. With the emergence of Bluetooth® skimmers, the suspect no longer has to retrieve the device but only has to be in close proximity to pair to the Bluetooth® and retrieve the stolen numbers. To further complicate matters, the manner in which the information is stored on the skimmer can be widely varied using different types of modulation, encoding, and encryption. So even if the odd electronic components of a skimmer, when mashed together, look "illegal," if an examiner is not able to resolve any stored information on the device to actual account numbers, there is nothing with which to charge the person who had the device.

Skimmers are created with various designs, form factors, and architectures and are intended to be hidden from the victim, so they are not necessarily easily identified. Once identified, the seizure, handling, and packaging of skimmers differ from that of other digital evidence and, given their unique nature, there is a lack of vendor tools and processes available to examine skimmers. All of these issues combined equate to one general problem — skimmers present a challenge for law enforcement and the banking system.

Due to the responsibility of enforcing Title 18, USC, Section 1029 — Fraud and related activity in connection with access devices (yes, a credit card or debit card account number is an "access device") — the United States Secret Service created a process for examining credit card skimmers. Not only does the Secret Service process these devices for examination, but educates other state, local, and federal agencies in regard to the methodology. This presentation will walk attendees through skimmer identification, seizure, and analysis. Chip-off processes, python scripting with examiner validation, and Bluetooth® module interrogation will all be discussed. Future work for encrypted skimmers and the emergence of shimmers (a skimming device designed to compromise Europay, MasterCard℠, and Visa℠ (EMV) chip cards) will also be presented.

Much of the material presented will be incorporated into updated versions of a Scientific Working Group on Digital Evidence (SWGDE) document and an American Society for Testing and Materials (ASTM) standard practice, both derived from the United States Secret Service's skimmer examination process.[1,2]

Skimmer, Credit Card Fraud, Digital Evidence

C23 Darknet Investigation and Forensic Techniques

Sarah Cortes, PhD, Inman Technology, 899 Green Street, San Francisco, CA 94133*

After attending this presentation, attendees will be made aware of the utility of using darknet tools to conduct investigations. Attendees will be able to define the darknet in technical terms, know how to install darknet software in the lab, and be able to conduct a darknet investigation. Attendees will learn about recent darknet cases, and how investigators can make use of darknet tools to assist in their investigations.

This presentation will impact the forensic science community by increasing awareness of the darknet and the capabilities of darknet tools and investigative techniques. Further, this presentation will inform attendees regarding the use of darknet tools and investigative techniques in current cases, detailing results and conclusions as to effective techniques based on lab testing.

By reviewing several recent darknet operations, this presentation will explain how others have successfully employed digital and network evidence extraction techniques to investigate darknet cases and how one successful darknet case can jumpstart another. Understanding these darknet investigation techniques impacts the forensic science community by increasing investigator capabilities and options when facing darknet technology, illustrated by their use across several major cases.

The shutdown of online drug and contraband marketplaces AlphaBay and Hansa swept headlines in July 2017; however, prior to AlphaBay, Law Enforcement Agencies (LEAs) prevailed in a number of darknet cases. An increasing number of global darknet investigations have identified suspects and opened cases in jurisdictions across the United States, ultimately pushing arrests down to the state and local level. This presentation reviews darknet technology and techniques such as the ones deployed in these actual investigations.

In one case, unknown to the general public, in the predawn hours beginning April 4, 2015, in time zones across the world, LEAs in nearly every state in the United States and in 17 other countries started knocking on doors, surprising occupants, and handcuffing suspects in one of the most far-reaching child abuse darknet cases in history: Operation Pacifier. Over 200 prosecutions have followed in jurisdictions across the United States. Based on extensive appeals, some are still ongoing as of 2017. In the weeks that followed, defense attorneys, journalists, and the public wanted to know how investigators identified the defendants. This presentation reviews how darknet suspects may be deanonymized in theory and in actual cases.

The scale and scope of the recent and ongoing Operation Pacifier darknet cases is unprecedented. Globally, it encompasses more than 17 countries' Law Enforcement Agencies (LEAs), Europol, and, in the United States, the Federal Bureau of Investigation (FBI) and more than 200 cases in more than half of the United States state judicial systems. Operation Pacifier and other recent darknet cases, such as Silk Road and Operation Onymous, have raised myriad new technical issues, as well as legal issues and rule changes, across many jurisdictions.

While the darknet has a number of legitimate uses, it has also become a haven for criminals.[1-3] Investigators have been developing, refining, and implementing techniques to infiltrate the darknet and use them to solve cases involving narcotics trafficking, carding, identity theft, child abuse, and other illegal activities.[4-7]

Darknet cases and issues reflect that, as technology advances, so do criminal methods. Like a technological cat-and-mouse game, law enforcement has had to develop compensating online darknet tools and tactics. The darknet has spawned unique legal and technical issues, which has required a fundamental change in investigative ground rules, because it conceals suspects' identities by concealing their Internet Provider (IP) address. In order to attack and defeat darknet technology and its anonymity, LEAs have adapted, from use on the surface web, what are broadly called Network Investigative Techniques (NITs). NIT is a term covering a wide scope of investigative strategies, tools, and approaches, including scripts, server takeovers, or simply observing email header information.

Legally, NITs are generally used in searches and seizures of computers, devices, or other technology, which means they may fall under the scope of the Fourth Amendment. Because they are often performed blind with respect to the target's identity and therefore location, they can, and frequently do, involve criminal investigation searches outside the United States, including searches of non-United States citizens.

This study selected and reviewed eight related darknet investigative operations, including Operation DarkNet-Lolita City (2011), Operation TorPedo-PedoBoard (2011-13), Operation Freedom Hosting (2013), Operation Silk Road (2013), Operation Onymous-Silk Road 2.0 (2014), Task Force Argos KidClub (2014), Task Force Argos LoveZone (2014), and Operation Pacifier-Playpen (2014-15). Prosecutions in many of these cases are still ongoing today, as appeals reach higher courts and constitutional and other issues are adjudicated.

Darknet cases and evolving investigative techniques have also raised legal challenges.[8] These include Fourth Amendment search and seizure issues, challenges to the Fifth and Fourteenth Amendments, *Daubert*, and Rule 702 and evidence issues, NIT usage, the standards for scientific validity (to which the President's Council of Advisors on Science and Technology (PCAST) creates new perspective), Sixth Amendment discovery scope issues, and issues of international law, including the role of Mutual Legal Assistance Treaties (MLATs). How these issues have played out in actual prosecutions, as the law advances in response to technology innovations, are reviewed.

C24 A Freedom Hosting Darknet Case Study: Anatomy of a Takedown

Sarah Cortes, PhD, Inman Technology, 899 Green Street, San Francisco, CA 94133; and Gareth Owenson, PhD*, University of Portsmouth, University House, Winston Churchill Avenue, Portsmouth, HANTS PO1 2UP, UNITED KINGDOM*

After attending this presentation, attendees will better understand the step-by-step techniques by which the suspects in a famous darknet case were apprehended.

This presentation will impact the forensic science community by increasing awareness of the darknet, the capabilities of darknet tools, and the investigative techniques used in current cases. This presentation will detail results and conclusions as to effective techniques based on lab testing and increase awareness of criminal capabilities and how to counter them, as well as the legal issues that arise in these cases, and important implications for warrants and rules of evidence.

Using reverse engineering and other techniques, it will be demonstrated how security vulnerability exploits can help in investigating specific darknet cases. Additionally, this presentation will show how these techniques impact the forensic science community by increasing investigator capabilities and options in darknet cases, illustrated by their use in a major case — Freedom Hosting.

When the shutdown of online drug and contraband marketplaces AlphaBay and Hansa swept headlines in July 2017, United States Attorney General Jeff Sessions said: "... the forces of law and justice face a new challenge from the criminals and transnational criminal organizations who think they can commit their crimes with impunity by 'going dark.' "[1,2]

While the darknet has a number of legitimate uses, it has also become a haven for criminals.[3,4] Investigators have been developing, refining, and implementing techniques to infiltrate the darknet and use them to solve cases involving narcotics trafficking, carding, identity theft, child abuse, and other illegal activity which may be found there.[5-7] Here, one famous case, Freedom Hosting, is reviewed. This presentation will present a deep dive into technical options available and methods required to solve this, and other darknet cases, and to identify, apprehend, and arrest the suspect, Eric Eoin Marques.[8] A combination of techniques to de-anonymize darknet users will be shown.

Freedom Hosting was first targeted by the hacker collective calling itself "Anonymous" in what they called "Operation Darknet" around October 14, 2011.[9] Their attack targeted Lolita City and other child abuse websites on the darknet host Freedom Hosting. The attack, a vigilante operation, was not conducted by Law Enforcement Agencies (LEA). It disrupted but did not succeed in shutting down Freedom Hosting or its darknet websites. Its history helps illuminate the roots of later major darknet operations, including one referred to as Operation Freedom Hosting-2013, conducted by a collaboration of LEAs on the very same darknet host (Freedom Hosting) as Operation Darknet in 2011.

News of the 2013 operation came to light on August 1, 2013, when a reddit user mentioned in an obscure post that he had noticed some unusual "iframe" code on darknet internet service provider Freedom Hosting's websites.[10] On August 3, the local Dublin news service *Irish Independent* reported that Eric Eoin Marques, owner and administrator of Freedom Hosting, a website hosting company, had been arrested five days earlier in a classic phase A (website administrator) sting.[11,12] On August 4, 2013, Tor Project Executive Director Andrew Lewman confirmed to the world that a number of darknet sites had indeed disappeared from vendor platform Freedom Hosting.[13] On August 5, *Ars Technica* put together the local Dublin arrest story and the disappearing darknet sites, and the story went international.[13] We now know of this July 29, 2013, website host sting as a phase A of Operation Freedom Hosting.

What was also not publicly known for another year was that phase B of Operation Freedom Hosting was already underway. LEA deployed an investigative technique referred to as a Network Investigative Technique (NIT) for phase B on August 1-4, 2013. During this time, the Federal Bureau of Investigation (FBI) secretly controlled about 23 live Freedom Hosting sites, including some relatively innocuous sites, such as TorMail.[14,15] They displayed only an error message, while quietly deploying a NIT to catch users.[15] The sting had expanded to target not only the host's administrator, but also site users. In 2014, FBI and Department Of Justice (DOJ) warrants, complaints, and affidavits became public, confirming the operation. The press and public had been distracted with the report of Marques's arrest, not widely realizing that another, wider sting was already underway.

Documents indicate that a NIT had revealed the identities not only of child abuse site administrators, but also of site users. In phase B, the FBI seized and operated the 23 Freedom Hosting websites, deployed NITs, identified site users, and set in motion the arrest and prosecution of users. These users included David and Teri Schell, who were also Silk Road 2.0 sellers, and Grant Klein for child abuse offences.[16,17] While investigators have prevailed in this and many other darknet cases, it is sobering to note that as of February 2017, a darknet website calling itself Freedom Hosting still operates on the darknet.[18]

C25 A Digital Forensics Tool for the Language-Based Analysis of Child Sex Offender Chats

Kathryn C. Seigfried-Spellar, PhD, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907; and Marcus Rogers, PhD*, Purdue University, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will have a better understanding of the language-based differences of chats between minors and contact-driven vs. fantasy-driven internet offenders. In addition, attendees will learn about a new digital forensic tool being developed for law enforcement that automatically analyzes minor-offender chats extracted from digital devices.

This presentation will impact the forensic science community through a discussion of the language-based differences of chats between minors and different internet sex offenders. In addition, this presentation will discuss a new tool being developed for law enforcement to assist with their investigations involving internet crimes against children.

Internet crimes against children are technology-facilitated crimes committed against minors involving sexual exploitation. In 2016, the Internet Crimes Against Children (ICAC) task force and affiliates conducted more than 61,000 investigations and 77,800 digital forensic examinations resulting in the arrests of more than 9,300 offenders.[1] Not only is law enforcement swamped by the number of cases and sheer volume of data involved, but child sex offenders are not a homogenous group. Some child sex offenders are contact-driven, and their goal is to meet with the minor in the physical world for sex. Others are fantasy-driven and interested in cyber-sex rather than meeting the minor in the physical world.

It is possible to differentiate a contact-driven offender from a fantasy-driven offender based on linguistic differences in their chats with minors. Chiu, Seigfried-Spellar, and Ringenberg collected chat logs between minors and arrested contact-driven vs. fantasy-driven offenders from Ventura County Sheriff's Department.[2] Based on the preliminary findings, Chiu et al. identified language-based differences in the chats; specifically, contact-driven offenders were more likely to share their negative experiences and emotions with the minor compared to fantasy-driven offenders, which is a self-disclosure grooming tactic.

Based on these results, Seigfried-Spellar, Ringenberg, Chiu, and Rogers proposed a digital forensics tool to assist law enforcement in their ability to triage cases based on the probability of the offender being contact-driven vs. fantasy-driven.[3] Ultimately, this digital forensic tool will assist law enforcement in their ability to efficiently and effectively analyze chats between offenders and minors, possibly preventing contact-driven offences by allocating resources to the more dangerous offenders.

Language-based differences between contact- and fantasy-driven offenders will be discussed, and the prototype of this tool will be presented.

Child Sex Offender, Digital Forensics Tool, Linguistics

C26 Defining a Taxonomy of Digital Evidence Artifacts Available From Small Unmanned Aircraft Systems

Steven B. Watson, BA, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021-8042; and David Rathbone, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021*

After attending this presentation, attendees will better understand that data of evidentiary value exists on small unmanned aircraft systems, the affiliated devices and applications, and that a logical taxonomy of data can be observed among the data types present on the devices.

This presentation will impact the forensic science community by sharing the results of data acquisitions from a variety of consumer and professional drones and by increasing comprehension of a taxonomy of the data existing on small unmanned aircraft systems as a starting point for reporting, artifact identification, and support by tools and techniques.

In the past ten years, a technology expansion on traditional remote-controlled aircraft has emerged globally. Consumer- and professional-level drones, referred to as Small Unmanned Aircraft Systems (SUAS), resemble miniature planes or helicopters and range in weight from less than 1 pound to more than 50 pounds. Prices range from a few hundred dollars to thousands of dollars.

Data of evidentiary value exists on small unmanned aircraft systems and the affiliated devices and applications. Law enforcement agencies are already receiving SUAS devices as evidence, but limited tools and techniques exist within the digital forensics community to address this new technology. Law enforcement, forensic service providers, and forensic tool vendors are actively seeking to identify what types of data exist on SUAS systems to determine if SUAS systems should be interrogated for digital evidence artifacts.

Data is acquired from data storage locations of the small unmanned aircraft systems using logical, serial, and physical acquisitions as defined in industry best practices published by the Scientific Working Group on Digital Evidence (SWGDE).[1] Where available, data is parsed with industry-available tools or using custom development when no industry tools are available. The data artifacts are examined and classified to identify a taxonomy of what data presently exists on small unmanned aircraft systems.

This study examines the data types presently on SUAS systems and seeks to define a taxonomy for use by the digital forensics community and law enforcement agencies. The outcome of this study is a proposed initial taxonomy of data from SUAS devices that can be expanded as technology evolves and additional data artifacts are discovered.

The classification of data of evidentiary value from small unmanned aircraft systems will guide law enforcement, forensic service providers, and the digital forensics community as they encounter these new technology devices during investigations.

C27 Vehicle Forensics: A Method of Validation for Infotainment System Tracklog Maps Using Java™ OpenStreetMap Editor®

Christopher D. Jenkins, Marshall University, 2717 3rd Avenue, Huntington, WV 25702; John E. Sammons, MS, 18 Quail Drive, Ona, WV 25545; Ian Levstein, MS, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; and Terry Fenger, PhD, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand potential methods for creating and validating infotainment system tracklog maps recovered using a commercial vehicle forensics tool and the free, open source Java™ OpenStreetMap Editor®.

This presentation will impact the forensic science community by introducing a means of validation for infotainment system tracklog maps.

Traditionally, the majority of digital forensic evidence comes from personal computers and digital devices. The locations where digital evidence can be found continue to expand as technology further develops. Vehicles provide a medium for new technologies. Today's vehicles consist of a series of computers and Electronic Control Units (ECUs) ranging from navigation and communication units to automatic, rain-sensing wipers. Newer vehicles can contain more than 70 ECUs, each handling a separate task.[1] Infotainment, a portmanteau of information and entertainment, is a computer system that combines tasks such as navigation, communication, cell phone operations, and internet functions.

There are three main types of stored data found on infotainment systems: navigational data, vehicle event data, and user data.[2] This research focuses on navigational data; more specifically, tracklog maps which consist of data generated by the Global Positioning System (GPS). Tracklog maps contain a series of connected nodes that show the path the car traveled at a given moment. This can include speed, bearing, and distance traveled. Navigational data can also include recent locations, favorite places, waypoints, and trackpoints.

Research and method validation of obtaining digital artifacts from vehicle infotainment systems have been limited to this point, most likely due to the newness of the vehicle forensics field. At this time, there is only one vehicle infotainment system forensic tool that is currently available in the commercial marketplace.[2,3] This means there is currently not another tool to validate evidence obtained by this commercial tool. While this tool is still relatively new in the digital forensic field, it currently supports over 5,200 different models of vehicles from 22 different vehicle manufacturers.[3] This research provides a means of validation for tracklogs not found in any previous research regarding vehicle forensics.

This research was guided by the following questions: What third-party tools can be used to map coordinates with existing road overlays? How do tracklog maps produced by commercial tools compare to tracklog maps produced by other third-party tools? How accurate are tracklog maps created by both the commercial and third-party tools? How can a third-party tool be used to validate the commercial tool's method of creating tracklog maps?

For this study, data from a physical acquisition of a 2015 Ford® F-150 was used. An abundance of data was recovered from the acquisition, including all three types of data found on infotainment systems. Tracklog maps were produced automatically by the commercial tool for three years of the vehicle's life. Third-party tools such as Google® Maps™, Google® Earth™, and Java™ OpenStreetMap Editor® were evaluated as possible useful applications in the validation process. Google® Maps™ and Google® Earth™ did not have a convenient means of entering data to map a tracklog. Java™ OpenStreetMap Editor® was found to have the functions necessary for use as a third-party tool to validate the tracklog mapping function of the commercial tool.

Mapping tracklogs using Java™ OpenStreetMap Editor® produced route maps that were identical to the ones produced by the commercial tool's mapping function. It was found that Java™ OpenStreetMap Editor® could enhance the data obtained by the commercial tool by creating an overlay of street maps and satellite imagery. This provided a visual representation of the actual route taken by the vehicle. Lastly, a validation method was produced using Java™ OpenStreetMap Editor® as a third-party tool to validate the mapping functions of the commercial vehicle's forensics software.

C28 Is Your Home Secretly a Confidential Informant for the Police? The Potential of Smart Home Devices to Serve as Evidence in Criminal Cases

Jason Lewis, PhD, University of the Virgin Islands, Dept of Computer & Computational Sciences, No 2 John Brewers Bay, Saint Thomas, VI 00802; Arl Polydore, University of the Virgin Islands, No 2 John Brewers Bay, College of Science and Mathematics, Saint Thomas, VI 00802; Lawrence White, University of the Virgin Islands, No 2 John Brewers Bay, College of Science and Mathematics, Saint Thomas, VI 00802; Jair Smith, University of the Virgin Islands, No 2 John Brewers Bay, College of Science and Mathematics, Saint Thomas, VI 00802; K'Mari McClean, University of the Virgin Islands, No 2 John Brewers Bay, College of Science and Mathematics, Saint Thomas, VI 00802; and Roberto Tirado, University of the Virgin Islands, No 2 John Brewers Bay, College of Science and Mathematics, Saint Thomas, VI 00802*

After attending this presentation, attendees will better understand what data of evidential value is contained on various smart home devices as well as techniques to forensically acquire the data.

This presentation will impact the forensic science community by providing the techniques to acquire data of forensic value from various smart home devices.

We are living in a society where more and more of the items that we come into contact with each day are connected to the internet. This phenomenon has powered an entire technological industry known as the Internet of Things (or IoT). Nowhere can this idea be better exemplified then in the modern home. As recently as ten years ago, the average home would have been lucky to have one device connected to the internet, namely the home Personal computer (PC). Now we are seeing a diverse range of devices in the modern home that are also connected to the internet (from the light switch to the kitchen sink and everything in-between). This has given rise to the new smart home, where these devices are constantly monitoring activity and trying to help make people's daily lives easier.

This explosion in internet-connected devices (and the terabytes of data that comes with them) brings an interesting question to the forefront for law enforcement: Can these smart devices act as eyes and ears for the police and help solve modern crimes? It is already known that the Amazon® Echo™ must be continually listening to every spoken word in order to be at our beck and call, but does this mean that it can also record the voice of the home intruder, and if so, can that voice be easily recovered *without* the help of Amazon®?

The goal of this study was to determine the forensic value of several common smart home devices and the techniques to acquire the relevant data from these devices. The research focused on the Amazon® Echo™ and Google® Home Smart Hubs™, the D-Link® 965 Wi-Fi Video Security Camera, the Logitech® Logi Circle Wireless HD Video Security Camera with 2-Way Talk, and the August® Smart Lock. This study determined what data was stored locally on these devices versus stored in the Cloud and explored techniques to extract that data.

Smart Home, Smart Devices, Internet of Things

C29 Smart Home (Home Automation) Forensics: An Analysis of an Amazon® Echo™

Carl R. Kriigel, MA, US Army Criminal Investigation Laboratory, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297; Joseph Levi White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297; and Christina A. Malone, MSFS, US Army Criminal Investigation Laboratory, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30305*

After attending this presentation, attendees will obtain the results of research regarding the availability of forensic artifacts maintained by smart home (home automation) devices such as the Amazon® Echo™.

This presentation will impact the forensic science and investigative communities by providing sources for data potentially relevant to criminal investigations maintained within home automation devices such as the Amazon® Echo™.

Digital Forensic Examiners (DFEs) are responsible for extracting data from a growing number of electronic devices and performing analyses on a multitude of different resultant data types. It is the responsibility of the members of the Digital and Multimedia Evidence (DME) community (DFEs and researchers) to determine how to extract data maintained on these new electronic devices, interpret the extracted data correctly, and discover if the data may be a potentially useful source of information to aid in future investigations. With the expansion of smart home devices, it has become the responsibility of the DME community to search for potentially pertinent data stored within devices such as the Amazon® Echo™.

The Amazon® Echo™ is a voice-enabled wireless smart speaker developed by Amazon.com, Inc. and released in the United States in 2015. The device consists of a cylindrical speaker with a seven-piece microphone array. A smaller version of the device was released as the Amazon® Echo Dot™. The device connects to the voice-controlled intelligent personal assistant service, Alexa™, which responds to a "wake word" of the name "Alexa." The device is capable of voice interaction, music playback, making to-do lists, setting alarms, streaming podcasts, playing audio books, and providing weather, traffic, and other real-time information. It can control several smart devices using itself as a home automation hub. In the default mode, the device continuously listens to all speech, monitoring for the wake word to be spoken. The device hears from across the room with far-field voice recognition, even while music is playing.

This presentation will consist of an overview of the Amazon® Echo™ device, a history of the device's usage in police investigations, and an overview of data types extracted from exemplar devices. This presentation will provide the results of an exploratory study into forensic artifacts left behind on the Amazon® Echo™ and explore how these artifacts may be used to aid future criminal investigations.

C30 The Virtual Crime Scene: The Role of 3D Motion Capture and 3D Model Buildings for the Reconstruction of Dynamics and Reproduction of Settings in a Case of Murder

Isabella Aquila, MD, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Alfredo Manca, Public Prosecutor, Corso Mazzini, Crotone 88900, ITALY; Giuseppe Ivan Aquila, Via Dante Alighieri, Crotonw, ITALY; Roberto Raffaele*, Via Thailandia N 1, Crotone, ITALY; Giuseppe Capoccia, Public Prosecutor, corso mazzini, Crotone 88900, ITALY; Manolo Vozza, Arms of the Carabinieri, Investigative Unit of Crotone, Crotone 88900, ITALY; Antonio Rocca, Arms of the Carabinieri, Investigative Unit of Crotone, Crotone, ITALY; Salvatore Gagliano, Arms of the Carabinieri, Investigative Unit of Crotone, Crotone, ITALY; Matteo Antonio Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Viale Europa, Loc Germaneto, Catanzaro 88100, ITALY; Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will better understand the role of virtual reality through the use of 3D Motion Capture (Mocap) and settings reconstruction technology.

This presentation will impact the forensic science community by demonstrating how these techniques are fundamental to accurately recreating scenes and environments in cases of murder, accidents, suicides, or altercations where it is important to determine the dynamics of the event.

The use of images is a fundamental aspect in a forensic pathologist's work. To date, photographic surveying is performed primarily by using 2D images; however, in recent years, the application of 3D technologies has gained importance. In the literature, various methods have been studied, including virtopsy, 3D printing, scanners, cameras, 3D modeling software, photogrammetry, superimposition, and satellite navigation programs. The applications were personal identification, estimation of age, sex, height, body mass, injury analysis, weapon identification, crime scene scanning, and Bloodstain Pattern Analysis (BPA). Very few studies have proposed a method for reproducing the dynamics of a crime. This study presents a virtual model created using 3D Mocap and modeling, namely the reproduction of settings. Mocap is a photogrammetric system designed to capture the movements of a person who wears tracks equipped with markers and is recorded by cameras through an algorithm to realistically reproduce movements. It also offers the ability to perform object tracking in space and head tracking to capture the person's facial movements. The recorded movements are interoperable with Motion Builder®, Max®, Maya®, Xsi®, Blender®, C4d®, Poser®, Daz® Studio, Face Robot®, and the Autodesk® Gameware product series, including HumanIK® used to create video game characters.

This presentation describes the method for producing a 3D video that reproduces the dynamics and the scene of a murder, later used in court. The device used was a stereophotogrammetric system, consisting of infrared OptiTrack® cameras capable of capturing movements up to 100 frames per second (fps). Some objects have been modeled in 3D manually, taking into account the original measurements.

A woman was found dead in her apartment with multiple injuries on her head, chest, and hands. A judicial inspection was conducted in which the planimetry of the apartment was requested. Each object was cataloged, photographed, and annotated. The analysis focused on the entrance (where the victim had been found) and the kitchen (an area to the left of the entrance where items on the ground were found). The choice of these areas resulted from the analysis of the other rooms that showed no trace of blood or signs of a scuffle. An autopsy was performed to topographically identify the injuries present on the anterior and posterior surface of the corpse, inflicted with a knife (12 lesions) and a blunt object (22 lesions). Each injury was numbered, photographed, and measured. The height and weight of the victim were recorded. During the investigation, the suspect focus was on a man. An external inspection was conducted on the man, whose height and weight were noted, and some abrasions on his face were also measured. Finally, a BPA of the house was performed. All data were compared and the dynamics were reconstructed. By comparing the data discovered at the scene, on the victim, and on the aggressor, the 3D computer technician was able to virtually recreate the environments in which two people, of the same heights and constitutions as the victim and the aggressor, mimicked the movements before the murder and the blows made during the murder. At this stage, the rendering of frames was conducted: this is one of the fundamental aspects of 3D computer graphics. It is the last stage that generates the representation of the final image, with the help of algorithms that define the color of each point. The rendering was entrusted to Supermicro® systems with multiprocessor Xeon® Quad and NVIDIA® Quadro® Plex systems for Graphics Processing Unit (GPU) rendering projects. This reconstruction allowed the forensic pathologist to give credibility to the hypothesized reenactment by making clear to the public prosecutor and to the investigators the dynamics and the cruelty of the blows. Therefore, the use of these forensic techniques is emphasized for their contribution in exploring the dynamics that otherwise would be difficult to demonstrate.

Forensic Science, Virtual Crime Scene, 3D Motion Capture

C31 Overcoming the Hurdles of Imaging, Storing, and Archiving Digital Evidence

Kristy Tredway, 1220 6th Street, Huntington, WV 25701*

The goals of this presentation are to determine the best ways to increase efficiency and decrease storage space during digital imaging.

This presentation will impact the forensic science community by helping digital forensic examiners reduce imaging time and decrease the amount of storage each image takes.

Digital forensics is an integral part of the forensics field. Digital evidence is information stored or transmitted in binary form that may be introduced and relied on in court. Digital evidence can be found on a computer hard drive, a mobile phone, a Personal Digital Assistant (PDA), a Compact disc (CD), and a flash card in a digital camera, among other places. Digital evidence is commonly associated with electronic crime, or e-crime, such as child pornography or credit card fraud.[1]

When digital forensic examiners obtain a digital device to be analyzed, they first image and save an exact, bit-for-bit copy of the original storage media on another storage device, such as a hard drive. This is known as the forensic image. Forensic imaging involves two types of images: a logical image and a physical image. A logical image is a copy of all the files on a storage device, except deleted files, file fragments, and deleted space from a partition. This allows an investigator to quickly scan the contents of a hard drive. An E01 file is an example. A physical image is a bit-for-bit copy of the storage device, including the deleted files and file fragments. A RAW file is an example.

Once imaging is completed, a digital fingerprint of the media is acquired, known as a hash. The hash generation process involves an algorithm calculation of all the zeros and ones that exist across the sectors examined. Altering a single zero to a one or a one to a zero will cause the resulting hash value to be different. If the hash values match, then the image is an exact copy and is used as the working copy to analyze the data.[2]

Because of the increase of digital evidence being submitted for analysis and the length of time evidence is required to be kept, untested digital evidence and already processed evidence are accumulating. The purpose of this research was to look at ways to image, store, and archive digital data to take up less storage space and provide greater efficiency. This will help decrease the time spent to test pieces of evidence, thereby decreasing backlogs, and decreasing costs.

The following questions guided the research: (1) What is the best way to create a forensic image (E01 file or RAW file)?; (2) What is the best way to store that E01/RAW file?; (3) What is the most efficient way to process that image?; and, (4) In the most efficient, cost-effective way, how should that data be archived?

Eight different types of storage devices were imaged using two different types of files, E01 and RAW. This was performed with two forensic imager tools, AccessData® FTK® and SUMURI® PALADIN®. A comparison was performed using different paths, with and without a write blocker, and using different levels of data compression. This determined the fastest way to image digital evidence and the best way to minimize the space taken by saved evidence. Since PALADIN® has a software write blocker, the images produced using the hardware write blocker in FTK® were compared to the images without an additional hardware write blocker in PALADIN® (only using the software as write protection).

The results demonstrate that RAW images sent directly to the server using PALADIN® without a hardware write blocker was the fastest and most efficient way to image, but E01 in FTK® took up 5%–18% less storage space. Imaging E01 files in PALADIN® resulted in failure approximately 50% of the time, especially when using an additional hardware write blocker. In FTK®, adding compression did not change the amount of time or storage space taken. In PALADIN®, adding compression increased the time while decreasing space. Future research would include imaging larger storage devices, testing different software and write blockers, and adding a virtual machine.

Digital, Forensic, Imaging

C32 Measuring the Hygroscopic Capacity of Integrated Circuit Packages and Circuit Boards

Steven B. Watson, BA, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021-8042; and David Rathbone, VTO, 325 Interlocken Parkway, Bldg C, Broomfield, CO 80021*

After attending this presentation, attendees will understand: (1) that integrated circuit packages (computer chips) and printed circuit boards have the capacity to absorb water they come in contact with; (2) the variables affecting the amount of water absorbed; and, (3) the implications of hygroscopic capacity when addressing electronic devices that have been exposed to or damaged by liquids.

This presentation will impact the forensic science community by providing results from direct methods experiments guided by extensive research in other science disciplines, but with little previous research applied to digital forensic science. This presentation seeks to broaden the understanding of the impact of liquid exposure to electronic devices by examining the effect on the two primary discreet parts of electronic devices.

The electronics manufacturing and assembly industry has well-defined standards regarding moisture sensitivity of electronic device components related to manufacturing and assembly of electronic devices.[1,2] These known industry standards have yet to be applied and inform the manner in which digital forensic scientists are addressing electronic devices exposed to or damaged by water or other liquids.

Significant risk exists to data stored within integrated circuit packages if specific steps are not followed when addressing electronic devices that have been exposed to water or other liquids. Liquid absorbed within the integrated circuit packages may turn into a vapor, creating damaging expansion within the chip if the device is exposed to heat.[3]

In this study, integrated circuit packages (computer chips) and printed circuit boards were exposed to a variety of liquids to understand the amount of liquid the discreet devices will absorb over a defined duration. The hygroscopic coefficient is the equilibrium when the maximum amount of liquid can be absorbed. This study sought to identify the time duration at which the hygroscopic coefficient is achieved on integrated circuit packages and printed circuit boards.

By understanding the amount of liquid absorbed in a given duration, the results may inform digital forensic science practitioners on the duration of drying that will be required to safely remove the absorbed liquid from the devices. Additionally, different liquid types (e.g., freshwater, salt water, and brackish water) may absorb at different rates, requiring different techniques based on the type of liquid exposure.

Testing for this study included the use of laboratory-grade water testing equipment and analytical balances to measure the impact of liquid and duration against the materials composition of the electronic devices.

The results of this study may impact the direction provided to Forensic Service Providers (FSP) and the practices used by FSPs when addressing evidence that has been exposed to or damaged by liquid.

Hygroscopic Capacity, Liquid Damage, Water Damage

C33 Electromagnetic "Soundscapes" and Their Relevance in Media Forensics

Eddy B. Brixen, BA, EBB-Consult, 108 Aeblevangen, Smorum DK-2765, DENMARK*

After attending this presentation, attendees will understand: (1) Electromagnetic Fields (EMF) and their origins; (2) quantification of the electromagnetic soundscapes in urban areas and in buildings; (3) the recording equipment and its susceptibility to EMF measurements; and, (4) what traces are left in audio recordings.

This presentation will impact the forensic science community by demonstrating how EMFs stemming from the Electric Network Frequency (ENF) have value for the authentication and "time stamping" of digital recordings carrying audio; however, EMFs stemming from other sources may have a value for the determination of the site of recording.

EMFs stemming from the ENF has, when accidentally recorded, proven to have a value for the authentication and "time stamping" of digital recordings carrying audio; however, magnetic fields stemming from sources other than power lines may, when present and recorded, also become useful for the forensic investigation of digital (and analog) recordings.[1] The electromagnetic signature recorded as audio may provide information of the site of recording.

This paper presents the results of an initial study in the field.

In urban planning as well as in sound art, the term "soundscape" has been applied to site-specific recordings since being introduced by Michael Southworth in 1969.[2] The analysis of the soundscape reflects incidents of the environment (i.e., noise in or around urban spaces (near or distant), buildings, traffic, natural sources, installations, peoples' activity, music, etc.). This type of analysis is also valuable for the assessment of background sounds on forensic recordings.

For years, artists have also searched for the sound of underwater locations using hydrophones, the sound of vibrating structures using accelerometers, and the sound of electromagnetic fields using various forms of coils connected to the input of audio recorders. Work of this type has now and then revealed various interesting electromagnetic signatures, which to some extent are regarded as site specific.

That said, no recording device should ever transform the EMFs into audio. The general standards (IEC 61000, CISPR 1x, etc.) for Electromagnetic Compatibility (EMC) provide a set of rules that ensures that no generator of such electromagnetic disturbances exhibits a magnitude large enough to be detected in audio recorders; however, casework has shown that site-specific electromagnetic events accidentally have been recorded/transmitted by (mobile) recording systems, such as voice recorders and cell phones. These incidents are the motivation for an initial study to indicate whether or not this a serious matter in media forensics. The magnitude of ENF-related electromagnetic fields in different (urban) environments has been previously documented.[3] This presentation discusses some of the other electromagnetic sources and some possible ways they end up as audio.

Examples of sources (Audio Frequency (AF) -range) occasionally appearing in forensic audio recordings are: (1) ignition noise (cars, bikes); (2) noise on power lines (machinery-induced noise, for instance, spot-welding devices); (3) noise in public transportation (electric trains, subways, light rail); (4) induction loops for assisted listening (spill); (5) elevators (relays and motors); Nad, (6) other sources.

Examples of recording devices are: (1) cell phones with and without a headset attached; (2) voice recorders (analog and digital) with and without an external microphone: and, (3) laptops with gamer gear.

The test was conducted by feeding a sine sweep into a power amplifier loaded by a 3.3-ohm resistor in series with a .47mH coil. The Device Under Test (DUT) was placed 10cm above the coil. The system was calibrated using a reference coil system (400mA/m ~ 0.775V). Devices were tested in EM-fields up to 1A/m, operating the unit alone with no attachments and also using the unit with external earbuds and microphone.

The general result demonstrates that modern mobile recording devices tested exhibit high susceptibility to Audio Frequency (AF) broadband electromagnetic signals; however, of course, old tape-based systems are indeed sensitive. The conclusion from this survey is that electromagnetic fields above 100Hz and with a field strength below 100mA/m are hardly detectable in modern digital devices.

In normal urban surroundings, a field strength above 100Hz and higher than 100 mA/m is rare. When audible in digital recordings, it typically concerns recording/phone units mounted with external microphones or units connected to poorly filtered power lines.

The impact on crime scene analyses is relatively small as it seldom occurs; however, one must be aware of the existence of the phenomenon.

Electromagnetic Field (EMF), Soundscape, Site-Specific EMF

D1 Quantifying 3D Gait Reconstruction With a Single Camera

Jungbin Lee, BS, Chung-Ang University, Rm 115, Bldg 207, 84 Heukseokro, Dongjakgu, Seoul 06974, SOUTH KOREA; Cong-Bo Phan, Chung-Ang University, Rm 115, Bldg 207, 84 Heukseokro, Dongjakgu, Seoul 06974, SOUTH KOREA; and Seungbum Koo, PhD, Chung-Ang University, Rm 535, Bldg 310, 84 Heukseokro, Dongjakgu, Seoul 06974, SOUTH KOREA*

After attending this presentation, attendees will understand the usefulness and methodology of reconstructing 3D human movements from sequential images, such as Closed-Circuit Television (CCTV), and of estimating the lengths of body segments and joint angles. Attendees will understand 3D body movement estimation using Principal Component Analysis (PCA) and the effect of the camera angle on the estimation accuracy.

This presentation will impact the forensic science community by providing relevant information on quantifying 3D gait parameters and body segment lengths from 2D images.

Gait has been studied as a biometric parameter useful for identifying individuals. Human gait is influenced by biomechanical and physiological factors such as weight and height as well as injuries associated with the skeleton or the brain. Therefore, by measuring an individual's gait, his or her personal biometrics can be estimated. Thus, it is possible to verify a person's identity using an analysis of his or her gait on CCTV even when the person's face is obscured. Currently, there have been several studies that attempt to recognize gait from single images.[1,2] Recently, 3D gait reconstructions were performed from 2D images using PCA.[3] In some studies, the results of observing 2D images may vary depending on camera angles.[2,4] Also, to reconstruct 3D gait, major joint points should be recorded; however, marking such points on every image frame is time consuming. The objectives of this study were to develop a method to reconstruct 3D body movements from sequential 2D images and to analyze the effect of camera angle on the accuracy of the gait-related movement reconstruction.

3D gait data were collected from each of the 30 recruited subjects using a motion capture system. 3D coordinates of each joint in each image frame were obtained and subjected to PCA analysis to obtain mean posture and principal component data. Following acquisition of the 3D joint coordinate data, the position and orientation of the camera could then be changed to obtain projected 2D images. 3D gait data were used to create 2D images taken from a virtual camera at 0º to 60º elevation and 0º to 180º azimuth angle. The 3D posture of each subject was reconstructed using PCA for the key frame image at each camera angle by optimizing the weight of principal components of posture and the transformation matrix. Also, the study developed a robust method using information from the phase of gait to lessen the effect of camera angle. From the reconstructed posture, segment lengths were calculated by measuring the distance between joints. Major joint angles were extracted from reconstructed full-gait cycle images through movement estimation accomplished by interpolating positions between key frames.

The results of this study confirmed that gait analysis for identification is best performed by viewing subjects from the sagittal plane rather than the coronal plane. Also, the higher the elevation angle of the gait imaging camera, the better the reconstruction accuracy. The phase of subject gait was shown to be an input parameter; consideration of this parameter reduced inaccuracies occurring from varying camera angles. This study was limited by the use of manually identified joint markers and interpolation of gait-related continual images. The results of this study support the argument that individual human subjects can be identified from analysis of their optically recorded 3D gait cycle.

This work was supported by Projects for Research and Development of Police Science and Technology through CRDPST and KNPA (PA-C000001) funded by the Ministry of Science, ICT, and Future Planning of the Republic of Korea.

D2 The Advancement of the Evaluation Method of Fracture Risk by a Blow Using Computer Simulation-Calibration by an Actual Fracture Experiment

Tatsuya Fukuoka, University of Yamanashi, 4-3-11 Takeda, Kofu, Yamanashi 400-8511, JAPAN; Yasumi Ito, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu 400-8511, JAPAN; Momoko Watanabe, University of Yamanashi, A1-157, 4-3-11, takeda, Kofu-si, Yamanashi 4008511, JAPAN; Yoshiyuki Kagiyama, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu-shi 400-0001, JAPAN; and Tetsuya Nemoto, PhD, 36-3, Gengo, Morioka, Obu 474-8522, JAPAN*

After attending this presentation, attendees will understand the advanced fracture risk evaluation method using computer simulation.

This presentation will impact the forensic science community by providing an advanced fracture risk evaluation method using computer simulation.

To aid in the determination of intent, specifically in cases of assault, child abuse, and negligence, it is necessary to establish the relationship between the type and magnitude of external force associated with human injury. While the relationship between force and injury has been studied for many years, recent studies reveal that the presence of soft tissues, such as skin and muscles, have a large influence on this relationship, particularly those resulting in bone fracture; however, since the dynamic mechanical properties of soft tissues are difficult to measure, they are not sufficiently clarified, and thus it is currently impossible to quantitatively evaluate the role of soft tissue. While laboratory studies imposing quasi-static loading have shown a relationship between bone mineral density and bone strength, evaluation of bones resistance to high strain rate loading (i.e., fracture from high-impact, sudden intentional injury) has not been well studied. The former studies have been accepted by Japan's Ministry of Health, Labor, and Welfare, but injuries from the latter mechanism are not well understood. Computer simulation of these injuries is confounded by: (1) lack of understanding of the viscoelastic (energy absorbing) properties of soft tissue; (2) the inability to verify the results of such simulations using actual representative human bones; and, (3) immature bones from children and infants. Thus, the purpose of the present study was to quantitatively evaluate the biomechanical buffering properties of soft tissue on the maximum load-bearing properties of human finger bone.

Drop-weight tests were performed using weights, impact velocities, and soft tissue thicknesses (actual and "dummy") skin. The influence of these variables on the buffering properties was investigated. In addition, for verification targeted at advanced fracture risk evaluation using computer simulation, fracture experiments and computer simulations were performed on pig tails to simulate human fingers. Data obtained from the experiments were compared with the results of the simulations. The fracture experiments used static compression testing to quantify the force required to produce a fracture. The computer simulations used Finite Element Analysis (FEA) to estimate the force to fracture. To gain information about the force necessary to fracture infant bone, fracture experiments and computer simulations were performed on young animal bone.

As a result, in the quantitative evaluation method of fracture risk using dummy skin, it is obvious that the maximum permission load is the same when the impact energy is the same, regardless of impact velocity at the soft tissue and dummy skin of 10mm or more. For example, when the soft tissue thickness is 10mm, the relationship between impact energy E_{imp} and maximum transmission load F_{max} can be expressed as F_{max}=764.11 E_{imp}. From this, it became possible to calculate the load applied to the bone through the human skin from the impact energy calculated using the dummy skin. Moreover, in the comparison of the fracture load value obtained from the fracture experiment with the numerical analysis result by FEA, it was found that the calculated fracture load (i.e., 1,883N–2,118N) was nearly equivalent to the result of the fracture experiment (i.e., 1,940N–2,150N). These results demonstrate that the accuracy of fracture risk prediction may be improved using computer simulation. The results also demonstrate that computer simulation is an effective tool in finger fracture risk evaluation and may also be applied in future studies to understand the dynamic mechanical properties of soft tissue and how it affects bone fracture loads.

Fracture Risk Evaluation, FEM Analysis, Dummy Skin

D3 Fulgurites in Litigation

Christopher S. Palenik, PhD, Microtrace, 790 Fletcher Drive, Ste 106, Elgin, IL 60123-4755*

The goal of this presentation is to illustrate the way in which a detailed microanalytical characterization of a relatively novel material, a fulgurite (amorphous silica produced by an energetic event), can provide detailed information about the origin of a fire.

This presentation will impact the forensic science community in two ways: (1) by illustrating the ways in which a novel material and creative analytical approach can provide critical scientific evidence in a forensic investigation; and, (2) by providing the community with a baseline of specific analytical data concerning the use of a fulgurite as forensic evidence.

The term fulgurite, which derives from the Latin *fulgur* (meaning "thunderbolt"), was originally intended to refer to amorphous silica produced by lightning strikes. Over time, this term has been more broadly applied throughout the literature to include amorphous silica (or related compositions) produced as a result of high-temperature or high-pressure events, which can also include anthropogenic activities.

A suspected fulgurite can be identified as such on the basis of specific analytical characteristics, which can include: morphology (a tube that can take on a dendritic shape); size (fulgurites typically range in volume from a cubic centimeter to a cubic meter); an amorphous structure; marginal zones that include transition grains in which a single grain can range from crystalline to amorphous; a hollow central channel that is often nearly circular; the presence of one or more silica high-temperature/high pressure-polymorphs (e.g., tridymide, cristobalite); gas inclusions; and flow lines captured in the quenched amorphous matrix. Such characteristics can be identified over a variety of length scales that range from field-level observations (centimeters to meters) to nanoscopic features (nanometers).

Once identified as a fulgurite, analytical characterization over this range of length scales can provide information about the mechanism by which it formed. In the context of a forensic fire investigation, the need may arise to determine whether a fire was started by a lightning strike or a power line discharge. While both events are the result of an electrical discharge of power, the magnitude and duration of such power transfers can vary dramatically. As such, certain features may be used to distinguish between the origin of this electrical discharge.

While analytical approaches will vary based upon the circumstances of a given case, the features that may be exploited to assist with such a determination include the composition of the fulgurite and surrounding host rock, the crystallography of the transition zone grains, the potential transfer of metal particles, and the macroscopical and microscopical morphology of the fulgurite. The mineral phase of certain grains as well as the microstructure (through analysis by Raman spectroscopy) can provide specific constraints on the pressure-temperature history of a sample. The above analytical data can be coupled with thermodynamic modeling of the possible scenarios. This combination of analyses and calculations can provide an independent means by which to elucidate the origin of the discharge that produced the fulgurite.

This approach may provide constraints on the cause and conditions of fulgurite formation, distinguish between natural and anthropogenic origins, and, in some cases, provide insight into the relative timing of fulgurite formation. This presentation will provide analytical and modeled data derived from the study of several fulgurite samples produced both anthropogenically and naturally, which will illustrate the ways in which fulgurites may be recognized and exploited in a forensic investigation. Ultimately, the application of such a seemingly esoteric material can provide pivotal information as to the cause of a fire during the course of a forensic investigation.

Fulgurite, Amorphous Silica, Lightening

D4 The Role of Engineering Sciences in Forensic Fire Investigation

S.B. Addison Larson, MS, Sherman, CT 06784*

After attending this presentation, attendees will better identify how current misconceptions within the forensic science community regarding the role of the engineering sciences in forensic fire investigation have improperly confined the dynamic and multidisciplinary field of forensic fire investigation and placed too much emphasis on arson detection.

This presentation will impact the forensic science community by identifying organizational guidelines, policies, and procedures that are needlessly inhibitory and by substantiating the position that forensic fire investigation may be better aligned with the engineering sciences than general investigation sciences.

In April 2017 at the Congressional Fire Services Institute (CFSI), the American Academy of Forensic Sciences (AAFS) and the International Association of Arson Investigators (IAAI) affirmed a mutual desire for "a strong and mutually beneficial relationship between the two organizations."[1] IAAI was accredited by the Forensic Specialties Accreditation Board (FSAB) in March 2015.[2] The official position statement from IAAI recognizes the authority of the National Fire Protection Association (NFPA) and the value of NFPA 921: Guidelines for Fire and Explosion Investigation which is the "foundation for its training and certification programs."[3,4] It would stand to reason that AAFS also considers NFPA an acceptable source.

NFPA 1033 Standard for Professional Qualifications for Fire Investigator lists several areas of up-to-date knowledge a (fire) investigator shall have and maintain beyond the high school level, but does not require an engineering degree. One-third of the topics listed are largely engineering specialties — thermodynamics, fire dynamics, explosion dynamics, failure analysis/analytical tools, and fire protection systems.[5] NFPA standardizes fire protection engineering but makes distinctions within the field in terms of formal education. A fire engineering technologist (or technician) is an individual who does not hold an engineering degree, but has obtained a secondary education in "fire engineering technology, fire and safety engineering technology, or a similar discipline."[6]

Fire investigation guidelines/methods (NFPA 921) are closely related with fire safety code (e.g., NFPA standards 2217, 5578,) and building codes (i.e., general design requirements, structural tests, inspections, acceptable building materials) and the application of engineering principles to fire protection. This is of interest in civil litigation due to increased liability and can be useful in all phases of building construction, industrial losses and disputes, product liability and forensic analysis, and plan review.

Among the multiplicity of forensic professions that incorporate a broad range of knowledge is the local fire marshal, the authority having jurisdiction. The fire marshal's regulatory function "often overlaps with the building official…[and] planning departments...[and] engineering departments."[9] Code interpretation is considered a "higher level activity," particularly reviewing proposals for performance-based design. The relationship between engineering and fire science is intrinsic, just as fire science is to fire investigation.

This presentation will address conflicting definitions which contrast the term "arson investigation" with the preferred term, "fire investigation" — the interpretation of fire pattern evidence which, until demonstrated otherwise, may be the result of accidental or natural causes. If the authority having jurisdiction believes the fire may have incendiary cause and origin, the investigation will become an arson investigation and may likely incorporate other forensic tools, such as toxicology and analytical chemistry, etc. An engineering approach can be useful to correctly exclude other causes, after which the investigator can work inductively to demonstrate incendiary causation through laboratory and other testing.

D5 The Impact of Ventilation on Fire Damage Patterns From Room Fires in Full-Scale Structures

Daniel Madrzykowski, MS, UL Firefighter Safety Research Institute, 6200 Old Dobbin Lane, Ste 150, Columbia, MD 21045-5887; and Craig G. Weinschenk, PhD, UL Firefighter Safety Research Institute, 6200 Old Dobbin Lane, Ste 150, Columbia, MD 21045*

After attending this presentation, attendees will better understand the cause-and-effect relationship between ventilation and fire damage inside of full-scale residential structures. This research addresses a topic that, in the past, has challenged arson investigation findings.

This presentation will impact the forensic science community by providing data and analysis from ventilation-limited structure fires and the flow path(s) within the fire structure. This type of analysis is essential for accurately determining the area of origin based on the fire damage patterns. The results from a series of full-scale fire experiments document the repeatability and development of fire patterns based on the availability of oxygen within the structures and how this aids in determining the area of origin.

During the past decade, research conducted for the purpose of examining fire-fighting tactics has brought to light the impact that changes in home construction materials, contents, size, and geometry have had on fire incidents. Today, fires are predominantly fueled by synthetic contents. The combination of energy-efficient construction and high-heat release-rate fuel loads commonly lead to ventilation-limited fire conditions. Therefore, how and where the fire receives oxygen for combustion impacts the fire dynamics and subsequent fire-damage patterns.

The experiments were planned with the assistance of a technical panel that included members of the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF), International Association of Arson Investigators (IAAI), National Association of State Fire Marshals (NASFM), National Institute of Standards and Technology (NIST), NIST Organization of Scientific Area Committees (OSAC), and National Fire Protection Association (NFPA) 921. The test scenarios ranged from fires in the structures with no exterior ventilation to room fires with flow paths that connected the fires with remote intake and exhaust vents throughout the structures. Room-of-origin scenarios included the living room, bedroom, and kitchen.

An overview of the results from a series of 20 full-scale residential-style structure experiments examining the impact that changes in ventilation had on the fire damage inside will be presented. The test structures included a one-story ranch and a two-story colonial. The floor area of the ranch was approximately 110m^2 (1,200ft^2). The colonial had a two-story family room and open foyer with an approximate floor area of 300m^2 (3,200ft^2). Each of the comparable experiments used similar furnishings and interior finishes, providing a level of repeatability between the experiments. Each structure had more than 200 channels of instrumentation. Sensors to monitor temperature, pressure, gas velocity, and oxygen concentration were located at strategic points throughout the structures. Video and infrared imaging cameras were also used to document the experiments.

This research demonstrated how combining a basic knowledge of fire dynamics with an understanding of the flow paths of oxygen and heat through a given structure can serve as a tool for analyzing the movement of the fire through the structure as well as identifying the area of origin.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice.

Fire, Investigation, Ventilation

D6 Steering Failure in a Triple Fatality Crash

David Hallman, MS, Hallman Engineering LLC, 14040 96th Avenue, N, Maple Grove, MN 55369*

After attending this presentation, attendees will have a basic understanding of vehicle steering systems, the role of steering system failure in this particular crash, and the interpretation of available evidence that indicated the root cause of failure in relationship to the timing and location of the crash.

This presentation will impact the forensic science community by identifying a pre-crash failure that could easily be overlooked by an investigator unfamiliar with vehicle steering systems and the evidence and interpretation of the evidence that led to the discovery of this failure.

Crash reconstruction is the investigative process of examination and evaluation of all available physical evidence related to the crash in an attempt to determine the sequence of events prior to, during, and immediately after the crash. This is accomplished through an evaluation of the vehicles, tire marks, and potential electronic crash data imaged from vehicle control modules. Collectively, this evidence can be interpreted by a trained crash investigator and used to determine crash causation. This presentation will discuss the evidence and the interpretation of that evidence, which led to the determination of the root cause of a particular steering failure-related crash.

The physical evidence evaluated during a crash reconstruction includes, but is not limited to, the involved vehicle or vehicles (physical and electronic data), the roadway where the crash occurred, injuries to the vehicle occupants, and witness statements. Roadway evidence can be subdivided into pre-crash evidence, crash event evidence, and post-crash evidence. The point of crash impact separates these three roadway evidence subsections. Roadway evidence may include, but is not limited to, debris, tire marks, fluid trails, or vehicle components. Prior recall and repair history of the involved vehicles must be examined as this information may be vital in determining causation. Post-crash examination of the vehicles will reveal evidence about contact between the vehicles and specific damage, but combining vehicle evidence with evidence observed at the collision site, either physically or through the use of scene photographs, will provide a more complete reconstruction of the crash and crash sequence.

The case presented incorporates all of these factors and involves a late model Ford® E150 van that crossed over the center line on a two-lane road and struck a late model Toyota® Sienna® van. Both vehicles were traveling at approximately 55 miles per hour, pre-impact. Little to no pre-crash braking occurred before the driver's side front of the Ford® van impacted the driver's side front of the Toyota® van. Three of the four occupants of the Toyota® van were pronounced deceased at the crash site.

A detailed examination of both vehicles occurred prior to an evaluation of the available roadway and vehicle recall and repair history. While examining the Ford® van, it was discovered that the passenger-side outer tie rod had separated. The tie rod end ball stud was intact and had apparently "pulled out" of the socket; however, the tie rod end socket appeared relatively undamaged. This is not the typical observation made in this type of failure. Generally, if the ball stud pulls out of the socket, the socket is substantially deformed or broken. Furthermore, the typical failure mode for an outer tie rod end in a collision is fracture of the stud that secures the tie rod end to the steering knuckle as it is generally the smallest section and being threaded creates a ready-made notch for failure initiation and stud fracture.

Evaluation of the pre-crash roadway evidence, particularly the pre-crash tire marks left by the Ford® van, indicated that the passenger-side front tire had left an unexpected, non-braking marking on the roadway leading to the point-of-impact. The mark exhibited indications that the passenger-side front tire had been nearly perpendicular to the travel direction of the Ford® van, first to the left and then to the right, while this van continued its approximate forward travel direction.

Crash Reconstruction, Steering Failure, Tire Marks

D7 A Forensic Engineering Review of the TAU Phenomenon (Looming) and a Cautionary Application to Crashes

Adam Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

The goal of this presentation is to inform attendees of the phenomenon of looming, namely the rate of change of the image of approaching objects on the retina, and its threshold values.

This presentation will impact the forensic science community by presenting alternative arguments and pointing out the contrasts to attendees, who will benefit from this discussion by appreciating the complexity of this topic and the apparent ten-fold variability in the threshold detection level of the human visual system.

This aspect of human vision has been studied for more than 40 years, and as yet, there is no general acceptance of this theory as being a critical determinant in crashes, in particular regarding rear-end collisions.
