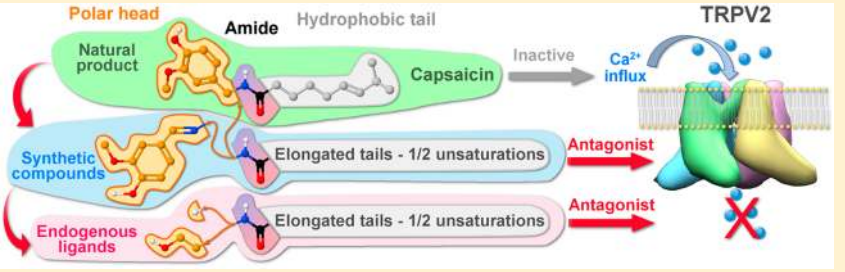
Supporting Information



**ABSTRACT:** The transient receptor potential vanilloid 2 (TRPV2) is a nonselective $Ca^{2+}$ permeable channel member of the TRPV subfamily, still considered an orphan TRP channel due to the scarcity of available selective and potent pharmacological tools and endogenous modulators. Here we describe the discovery of novel synthetic long-chain capsaicin derivatives as potent TRPV2 antagonists in comparison to the totally inactive capsaicin, the role of their hydrophobic chain, and how the structure−activity relationships of such derivatives led, through a ligand-based approach, to the identification of endogenous long-chain fatty acid ethanolamides or primary amides acting as TRPV2 antagonists. Both synthetic and endogenous antagonists exhibited differential inhibition against known TRPV2 agonists characterized by distinct kinetic profiles. These findings represent the first example of both synthetic and naturally occurring TRPV2 modulators with efficacy in the submicromolar/low-micromolar range, which will be useful for clarifying the physiopathological roles of this receptor, its regulation, and its targeting in pathological conditions.

## 1. INTRODUCTION

TRPV2 belongs to the polymodal transient receptor potential (TRP) superfamily of calcium-permeable nonselective cation channels, activated by a wide variety of physical and chemical stimuli. Due to its mechanosensor property, TRPV2 is considered a stretch-modulated channel and a regulator of calcium homeostasis in different tissues and organs, in particular the heart, where it is 10-fold more abundant than in skeletal muscle.[1] Different lines of evidence suggest for TRPV2 a key role in physiological cardiac function as well as in cardiomyopathies and dystrophic diseases.[2−4] Besides the heart, TRPV2 is also found in the brain, vascular smooth muscle cells, the gastrointestinal tract, macrophages, and the urothelial tract,[5] and it is involved in a number of physiopathological processes,[6] including cancer,[7−9] particularly of the urinary tract.[10−13]

Despite its biological and pharmacological relevance, TRPV2 is still considered an orphan TRP channel due to the scarcity of selective drugs and known endogenous ligands. The 2-aminoethoxydiphenyl borate (2APB) is one of the first nonselective activators identified for rat TRPV2 ($EC_{50}$ = 129 $\mu$M),[14] although inactive at the human orthologue, suggesting a strong species specificity.[15,16] *Cannabis sativa* derivatives such as $\Delta^9$-tetrahydrocannabinol ($\Delta^9$-THC), cannabidiol (CBD), and $\Delta^9$-tetrahydrocannabivarin ($\Delta^9$-THCV) are TRPV2 activators[17,18] and so is *p*-(di-*n*-propylsulfamyl)benzoic acid

(probenecid).[19] However, all these agonists are known to modulate other TRP channels. Most TRPV channels are proposed to be modulated also by phosphoinositide lipids.[20] TRPV2-mediated $Ca^{2+}$ influx has been reported following stimulation by endogenous lysophospholipids such as lysophosphatidylcoline (LPC) and lysophosphatidylinositol (LPI),[21] LPC being a relatively potent activator ($EC_{50}$ = 3.4 $\mu$M).[22] To date, the nature of endogenous regulators of TRPV2 activity still remains elusive.[23]

Also synthetic inhibitors of TRPV2 are either not specific or endowed with low potency, as exemplified by ruthenium red ($IC_{50}$ = 0.6 $\mu$M),[24] a pore blocker that inhibits other 12 ion channels;[25] $La^{3+}$ and $Gd^{3+}$;[26] citral;[27] the alkylated imidazole SKF96365;[16] tetraethylammonium and 4-aminopyridine, two potassium channel blockers; 1-(2-(trifluoromethyl)phenyl)-imidazole, an inhibitor of capacitative $Ca^{2+}$ entry;[16] and tranilast,[28] which has been used in several studies,[29−34] even though it has never been validated as TRPV2 antagonist.

TRPV2 shares high sequence identity (>50%) with TRPV1, but its threshold of activation by temperature is higher (>52 °C)[24] and, unlike TRPV1, is not sensitive to capsaicin. The recently solved cryo-EM structures of both TRPV1 and TRPV2,[35,36] along with mutagenesis and computational studies, showed that the TRPV1 binding site of capsaicin is not conserved in TRPV2. Furthermore, the replacement of critical residues leads to a mutant (TRPV2-Quad) against which capsaicin behaves as an antagonist rather than an agonist as in TRPV1.[37] These intriguing results prompted us to investigate a series of capsaicin derivativs in which the vanillylamide polar head of capsaicin bears a longer alkyl chain, featuring different length, unsaturation degree, and type of polar substituents. The structure−activity relationship (SAR) of these synthetic compounds then suggested the screening of structurally related endogenous lipids sharing at least one functional group with the capsaicin derivativs, with the aim of finding new endogenous modulators.

## 2. RESULTS

**2.1. Synthesis.** Commercial fatty acids such as ricinoleic acid, oleic acid, and palmitic acid were used as starting material to synthesize the **23** compounds tested. Scheme 1 shows the synthesis of the $\alpha,\beta$-unsaturated ketone **5** by the ruthenium-catalyzed oxidation in anhydrous toluene of the homoallylic alcohol of the methyl ricinoleate **4**.[38] Shvo's catalyst and acrolein were used as catalyst and hydrogen scavenger, respectively.[39] The addition of bis(pinacolato)diboron $(Bpin)_2$ to the enone **5** in the presence of tri-*n*-butylphosphine $(P(^nBu)_3)$[40] yielded the $\beta$-boronketone **6** in 46% yield. Enzymatically controlled hydrolysis[41] of the methyl ester **6** with Novozym 435 lipase led to the carboxylic acid **7** quantitatively. This acid **7** was coupled, without any further purification, with 4-hydroxy-3-methoxybenzylamine hydrochloride **3** by HATU[42] and DIPEA in anhydrous DMF, achieving the amide **8**. The oxidative hydrolysis of the boron substituent of the compound **8** led to the $\beta$-hydroxyketone **9** in a 76% yield (Scheme 1).

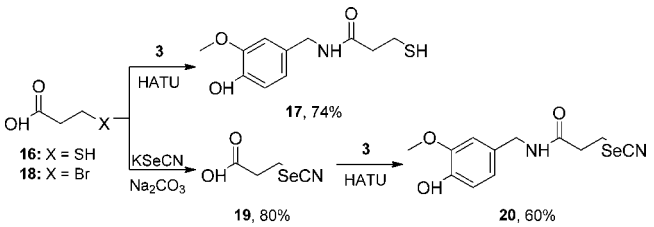
The irradiation of alcohol **4** with diphenyl sulfide[43] in isooctane in a photochemical reactor for 3 h led to the isomer **10** in 37% yield after several recrystallizations at −30 °C. This compound was used to synthesize two new long-chain *N*-vanillylamides (**12**, **15**). The hydrolysis of the methyl ester of

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

**10** led to the corresponding carboxylic acid **11**. The subsequent coupling of **11** with the 4-hydroxy-3-methoxybenzylamine hydrochloride **3** using the same conditions described above yielded compound **12** in a 34% yield. Compound **10** was also oxidized with $CrO_3$ in pyridine[44] to prepare the *trans* ketone **13** (49% yield), which was enzymatically hydrolyzed to synthesize the corresponding acid **14** in a 78% yield. Subsequently, **14** was coupled with the vanillyl amine **3** to yield the (*E*)-*N*-(4-hydroxy-3-methoxybenzyl)-12-oxooctadec-9-enamide **15** after purification by liquid column chromatography (17% yield) (Scheme 2).

Scheme 3 shows the synthesis of the sulfur- and seleno-derivatives of **3**. Mercaptopropionic acid **16** was coupled with 4-hydroxy-3-methoxybenzylamine hydrochloride **3** using HATU and DIPEA in anhydrous DMF, achieving the amide **17** (74% yield). The synthesis of the seleno-derivatives started with bromopropionic acid **18**, which was treated with KSeCN in water: The neutralization with $Na_2CO_3$, yielded the selenocyanatopropionic acid **19** in 80% without purification. Finally, compound **19** was coupled with the 4-hydroxy-3-methoxybenzylamine hydrochloride **3** to obtain compound **20** after purification by liquid column chromatography (60% yield).

**Scheme 3. Synthesis of Sulfur and Seleno Intermediates**



Amide **17** was S-alkylated with the previously synthesized alkylating derivatives **30a−c**, **32**, and **35** (see Supporting Information) in DMF and triethylamine, obtaining the long-chain *N*-vanillylamides **39−43** and **45** in 41−68% yield. *N*-Vanillylamide **44** was successfully achieved after removing the TBDMS protecting group with acetic acid at room temperature (81% yield). New long-chain *N*-vanillylamides were obtained from compound **20**, which was first treated with $NaBH_4$ in ethanol at room temperature to remove the cyano protection and regenerate the selenol group.[45] Subsequent Se-alkylation was carried out in one-pot with the addition of diverse set of alkylating reagents (**30a−c**, **35** ,and **38**). *N*-Vanillylamides **46−49** and **51** were synthesized in 71−87% yields. Compound **50** was successfully prepared after removing the TBDMS protecting group with acetic acid at room temperature (79% yield) (Scheme 4).

Scheme 5 shows the synthesis of amino-branched analogues. The first step consisted of the treatment of L-cystine **21** or L-selenocystine **25** with $Boc_2O$ in the presence of triethylamine to afford the protected derivatives **22**[1] and **26**[2] (quantitative and 65% yield, respectively).[46,47] These compounds were coupled with 4-hydroxy-3-methoxybenzylamine hydrochloride **3** using EDCI, HOBt, and triethylamine (TEA) in anhydrous DMF, achieving the amides **23** and **27** (74% and 88% yield). The reduction of compound **23** with $P(^nBu)_3$ in wet dichloromethane afforded compound **24** in a 73% yield after purification by liquid column chromatography. New long-chain *N*-vanillylamides were afforded from compound **24**, which was S-alkylated with the previously synthesized alkylating derivatives **30a−c** and **32** in the presence of triethylamine, obtaining the long-chain *N*-vanillylamides **52**, **53**, and **54** in moderate yields (50−79% yield). The *N*-Boc deprotection was carried out using trifluoroacetic acid[48] in dichloromethane yielding *N*-vanillylamides **55**, **56**, and **57** as trifluoroacetic salts in quantitative yields. Compound **27** was reduced with $NaBH_4$

in ethanol at room temperature to cleave the diselenium bond.[49] The Se-alkylation was carried out with the addition of the alkylating derivatives **30a,b** to afford the *N*-vanillylamides **58** and **59** in 74−88% yields. Finally, The *N*-Boc deprotection was carried out using the same conditions described above to afford the *N*-vanillylamides **60** and **61** as trifluoroacetic salts.

Acids **63a,b**, which were previously obtained from the hydrolysis of their respective methyl esters **62a,b** (see Supporting Information), were coupled with the 4-hydroxy-3-methoxybenzylamine hydrochloride **3** using HATU and DIPEA in anhydrous DMF, achieving the amides **64** and **65** after purification by liquid column chromatography (64% and 63% yield) (Scheme 6).

Methyl palmitate **28a** was treated with an excess of hydrazine hydrate in ethanol to synthesize the palmitic acid hydrazide **66** (80% yield). The addition of the aromatic aldehyde vanillin **1** to compound **66** in the presence of acetic acid in reflux conditions gave the Schiff's base compound **67** in 58% yield.[50] A similar compound was synthesized starting from oleaic acid **70**, which was coupled to *tert*-butyl hydrazine-carboxylate **69** using HATU and DIPEA in DMF to yield the oleylhydrazide **71** in a 94% yield. The *N*-Boc deprotection of oleylhydrazide **71** with TFA in DCM for 2 h led to oleylhydrazide **72** in 92% yield. Compound **72** refluxed with vanillin **1** in the presence of acetic acid in methanol produced the Schiff base **73** in 22% yield (Scheme 7).

**2.2. Biological Evaluation. 2.2.1 Capsaicin Derivatives Activate TRPV1 Channel.** The capsaicin scaffold (Figure 1)[51] can be ideally divided into three regions: head, neck, and

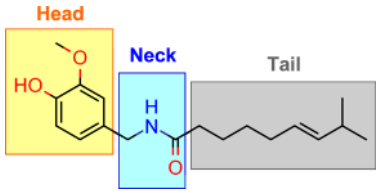

**Figure 1.** Chemical structure of capsaicin. The vanillyl head, the amide neck, and hydrophobic tail are shaded in yellow, cyan, and gray, respectively.

tail, formed by the vanillyl moiety, the amidic group, and the lipophilic alkyl chain, respectively. Structural variations, including incorporation of sulfur atom, into the head and the neck regions have been described in the literature.[52−55]

Instead, the effect of a sulfur atom in the alkyl chain has been less investigated. The recent availability of the 3D structure of TRPV1[56] along with mutagenesis studies[57] allowed the identification of the capsaicin binding site, where the alkyl chain is hosted in a phenylalanine-rich hydrophobic region close to Thr550, a residue involved in H-bond interaction with the ligand amide group. The presence of a sulfur atom near the neck region should in principle lead to an increment of activity due to favorable dipole−dipole and aromatic−sulfur interactions. Since sulfur can be substituted with selenium via isosteric replacement, we also synthesized the corresponding selenium analogs. Selenium is an essential trace element whose role in medicine and biology is just starting to be elucidated. Some selenium-containing compounds have provided protection against many degenerative conditions, including cancer. Thus, a series of novel capsaicin derivativs, i.e., **9**, **12**, **15**, **39**, **46**, **55**, **60**, **42**, **57**, **44**, **56**, **40**, **45**, **65**, **41**, **48**, **64**, **47**, **61**, **51**, **50**, **67**, **73**, whose structures are reported in Tables 1 and 2, featuring the same "head" and "neck" as capsaicin but differing in length and nature of the hydrocarbon tail, were tested on human TRPV1 heterologously expressed in human embryonic kidney (HEK)-293 cells by fluorometric assay (see Tables S1 and S2 in Supporting Information). The predicted activities as TRPV1 agonists were confirmed for many compounds within the series, exhibiting $EC_{50}$ values from high-nanomolar to subnanomolar range. A SAR analysis of the results also disclosed the critical role of the region flanking the amide group in modulating the activity. In fact, the insertion of a positive charge next to the amide group was detrimental for activity (compounds **55**−**57** and **60**), and the introduction of an imido group between the aromatic moiety and the amido group led to totally inactive compounds (compounds **67** and **73**). Conversely, the introduction of a single polar substituent (hydroxyl, ester, or ketone) was well-tolerated, and the introduction of a sulfur or selenium atom in the hydrophobic tail even improved the activity. However, on the basis of the antagonist activity exhibited by capsaicin on TRPV2-Quad,[37] the new compounds were also tested on TRPV2 to determine if the elongation and the functionalization of the alkyl chain could elicit a functional response at this receptor.

**2.2.2. Capsaicin Derivatives Inhibit TRPV2 Channels Activated by LPC.** The activity of the synthesized capsaicin derivativs on TRPV2 was evaluated in vitro. The assays were conducted using a fluorometric assay with rat TRPV2 heterologously expressed in HEK-293 cells. The tested compounds did not significantly activate TRPV2-mediated $Ca^{2+}$ elevation in transfected HEK-293 cells. Instead, preincubation (5 min) of TRPV2-HEK-293 cells with different concentrations of the tested compounds, followed by incubation with LPC (3 $\mu$M), caused inhibition of intracellular $Ca^{2+}$ elevation due to TRPV2 response to LPC. The corresponding $IC_{50}$ values are reported in Table 1.

The structure−activity relationships (SARs) of these compounds suggested a critical influence on the capability to exert TRPV2 antagonism of the alkyl chain and, in particular, of its hydrophobicity, length, and degree of unsaturation. Hydrophobicity is important since, as shown in Table 1, the activity dramatically dropped after introduction in the chain of polar substituents such as hydroxyl, keto, or ester groups (these groups arising from esterification of the hydroxyl group) or their combinations (**42**, **44**, **50**, **45**, **51**, **9**, **12**, **15**). However, the presence of an amino group next to the amide (**55**, **60**, **56**, **61**), which had marginal effects for already active compounds, by only slightly increasing their potency (**60** vs **46**), was instead dramatic for those inactive compounds bearing a hydroxyl or an ester moiety in the alkyl chain, whose activity was completely rescued (see **42** vs **57**). The complete recovery of activity after introduction of an amino group next to the amide in derivatives bearing a polar substituent in the alkyl chain suggests that reinforcement of the polar interactions of the "head" avoids the competition with the polar-substituted alkyl chain for interaction with receptor polar residues in a region where the polar head, but not the alkyl chain, should be hosted to elicit a measurable effect. The chain is fairly more tolerant to changes not substantially affecting the hydrophobicity of the alkyl group: replacement of sulfur with selenium in the alkyl chain did not affect significantly ligand activity (**39** vs **46**); its replacement with a carbon atom determined an increase in potency (**64** vs **40**/**47**). While polar functionalization of the alkyl chain caused a dramatic drop of activity, amino or imino groups (**67**, **73**) were well tolerated in the region close to the amide moiety of capsaicin. In particular, the imino derivatives were among the most active compounds within the series ($IC_{50}$ = 0.28 and 0.12 $\mu$M, respectively). Also length and unsaturation degree of the alkyl chain significantly affected the activities of the tested compounds. The C16:0 and C18:0 saturated analogs were inactive, whereas the C20:0 derivative showed an $IC_{50}$ = 3.1 $\mu$M. The insertion of a single double bond in C18 chain (olvanil) dramatically increased the antagonism, with $IC_{50}$ = 0.16 $\mu$M.

Thus, the screening led to the identification of several very potent TRPV2 antagonists, exhibiting $IC_{50}$ values in the subnanomolar to low-micromolar range. This result is quite remarkable since, despite its close homology to TRPV1, TRPV2 is insensitive to capsaicin, the residues being responsible for capsacin binding and receptor activation in TRPV1 not conserved in TRPV2.[58]

The most striking result from the SAR of capsaicin derivativs against LPC is that the elongation of the alkyl chain of capsaicin causes a switch of such scaffold from inactivity toward potent antagonism at rat recombinant TRPV2. Intriguingly, the dependence of TRPV2 modulation on the length of the ligand alkyl chain has already been observed for lysophospholipids, which require a carbon chain longer than C12 to stimulate the receptor.[21]

profile between LPC and cannabidiol (CBD) (see Figure 2), we also investigated the effect of a representative panel of capsaicin derivatives against CBD to ascertain whether the inhibitory activity/potency would vary against agonists exhibiting different kinetics of action. Also in this case, the assays were conducted using a fluorometric assay with recombinant rat TRPV2 heterologously expressed HEK-293 cells. The preincubation (5 min) of TRPV2-HEK-293 cells with different concentrations of the tested compounds, followed by incubation with CBD (2 $\mu$M), caused an inhibition of the $Ca^{2+}$ elevation due to the TRPV2 response to CBD. The corresponding $IC_{50}$ values of the tested compounds are reported in Table 1. While the trend identified in LPC antagonism for capsaicin derivatives bearing all carbon atoms, selenium, or sulfur was substantially conserved, a different behavior was observed with those derivatives featuring polar substituents (i.e., **50**/**51**), since their activity against CBD was not negatively affected by these functional groups, as instead observed against LPC. The imino-derivatives **67** and **73** (see Table 2), i.e., the two most active compounds against LPC (0.28 and 0.12 $\mu$M, respectively), were less potent against CBD ($IC_{50}$ = 6.0 and 3.0 $\mu$M, respectively). The trend of activity of C16:0, C18:0, and C18:1 derivatives was similar to that observed for LPC, although C18:1 (olvanil) was less potent as an antagonist ($IC_{50}$ = 1.7 $\mu$M), whereas, different from what observed with LPC, C20:0 was totally inactive. These results demonstrate a dependence of the antagonist activity on the type of agonist against which antagonism is tested.

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

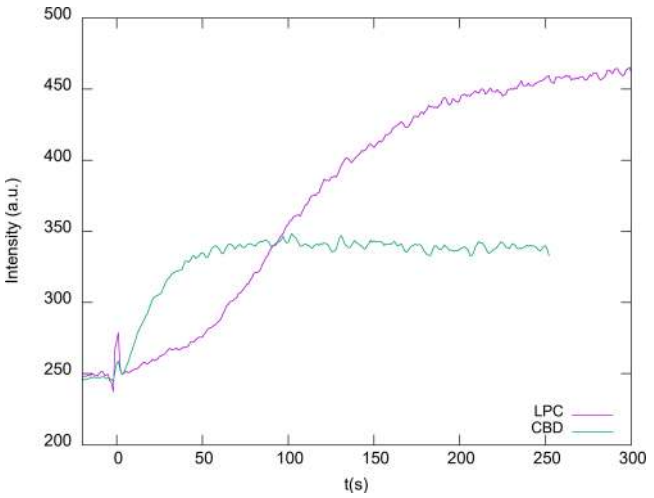

**Figure 2.** TRPV2 is activated by LPC (3 $\mu$M) and CBD (2 $\mu$M). The graph shows the representative traces of $[Ca^{2+}]_i$ increase evoked by the two agonists in HEK293 cells overexpressing TRPV2.

**2.2.4. Evaluation of Endogenous Lipids as Potential TRPV2 Antagonists.** Since the activity of the tested compounds appears to critically depend on the nature of alkyl chain but is less affected by changes in the polar head, we decided to ascertain the role of the head group of capsaicin, i.e., the vanillyl moiety, by testing a series of naturally occurring lipids bearing different polar heads and differing in length and unsaturation of the alkyl chain in order to determine the structural and functional requisites for TRPV2 modulation.

**2.2.5. Long-Chain Ethanolamides Exhibit Differential Inhibition of TRPV2 upon Activation by LPC or CBD.** To evaluate the contribution of the aromatic moiety to the overall activity, a panel of natural occurring ethanolamides differing in length and unsaturation degree was tested for both agonism and antagonism at TRPV2, using both LPC and CBD as reference activators. Ethanolamides share with the tested capsaicin derivativs the nature of both the alkyl chain and the hydrophilic groups (amide and hydroxyl moieties) in the polar head. The $IC_{50}$ values (against CBD 2 $\mu$M and LPC 3 $\mu$M) are reported in Table 3. Ethanolamides featuring saturated alkyl chains, regardless of their lengths, were inactive against both agonists, whereas the introduction of a single double bond was sufficient to switch from inactivity to activity against both agonists (see PEA vs POEA, or SEA vs OEA), similar to what was already observed for capsaicin derivativs. However, while the C20:0 capsaicin derivative was active against LPC, the homolog ethanolamide was inactive. Moreover, while OEA was less active than the counterpart olvanil, LEA was more potent than livanil against both reference agonists. Increasing the

number of double bonds increased the potency against CBD but not LPC.

**2.2.6. Long-Chain Primary Amides Exhibit Differential Inhibition of TRPV2 Channels upon Activation by LPC or CBD.** To also evaluate the role of the hydroxyl group, we tested a series of amide derivatives. As for capsaicin- and ethanolamine-derivatives, also for the amides the activity strongly depended upon the presence of at least one double bond. In particular, erucamide is active as TRPV2 antagonist with a potency comparable to that of its capsaicin derivative (0.67 vs 0.49 $\mu$M) against LPC, but it is less potent than the capsaicin counterpart against CBD (7.1 vs 1.5 $\mu$M). As observed with the ethanolamides, also the C20:0 amide derivative was inactive against both activators (Table 4).

**2.2.7. Free Fatty Acids Are Poor Inhibitors of TRPV2 Channels.** Finally, to investigate the role of the amide group, we tested against both LPC and CBD a panel of long-chain fatty acids, featuring alkyl chains comparable with those occurring in the already-tested compounds. The results are reported in Table 5. Fatty acids with alkyl chains from C16 up

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

to C22 are by far less potent antagonists against both reference agonists than the other classes of compounds bearing similar alkyl chains, thus suggesting that the amide group is mandatory for potent antagonism.

**2.2.8. Schild Analysis on Selected TRPV2 Antagonists.** The effects of increasing concentrations of antagonist **61**, olvanil, and docosaenoyl-EA vs LPC and **61**, olvanil, and **50** vs CBD were tested against concentration−response curves of LPC and CBD (where the effects of each concentration of LPC and CBD were expressed as percent of their effect of $2 \times 10^{-4}$ M in the absence of the antagonist) to calculate Schild's plots. These compounds have been selected as representative of antagonists active either against both activators (**61**, olvanil) or selectively toward LPC (docosaenoyl-EA)/CBD (**50**) alone. In all cases, the plots analyzed by linear regression gave slope values significantly less than unity, as reported in Table 6, indicative of a noncompetitive behavior. However, this result may also be indicative of a nonequilibrium condition, and we do not definitely rule out a competitive behavior.

## 3. DISCUSSION

Novel capsaicin derivativs, initially designed as TRPV1 agonists, behave as potent TRPV2 antagonists. The different types of modifications introduced in these compounds determine different agonist/antagonist profiles and, in particular, opposite behaviors in terms of relative potency/efficacy within a derivative series on the two channels. In fact, the insertion of a positive charge or an imido group close the amido group, detrimental for TRPV1 agonism, is well-tolerated for TRPV2 antagonism and even leads in some cases to an increment or a rescue of activity. Conversely, the insertion of a sulfur/selenium atom and/or the presence of a polar group, which increases TRPV1 agonism, leaves unaffected, or even decrease, TRPV2 antagonism.

Given the scarcity of known endogenous ligands for TRPV2, the discovery of such long-chain capsaicin derivativs as potent TRPV2 antagonists prompted us to investigate the following classes of long-chain fatty acid derivatives with at least one functional group in common with capsaicin derivatives as potential TRPV2 modulators: (i) ethanolamides, (ii) primary amides, and (iii) free fatty acids, to evaluate the role of the amide group itself. Antagonists were found in both the ethanolamide and primary amide, but not in fatty acid, series.

Activities for both synthetic and endogenous ligands were tested against either LPC or CBD as activators, since, on the basis of their different kinetics of activation, CBD can be defined as a direct TRPV2 agonist, whereas LPC induces TRPV2 activation indirectly, via its G-protein-coupled receptors and PI3,4 kinase mediated pathways.[21] We found that this different mode of activation is differentially counteracted by the investigated compounds, which can be classified as follows: (a) compounds endowed with similar antagonist efficacy against both agonists, (b) compounds selectively active against LPC, (c) compounds selectively active against CBD. To determine the nature of antagonism, a Schild regression was carried out for the representative members of each class, i.e., olvanil, docoesanoyl-EA, and compound **50**, and in all three cases the antagonists behaved as noncompetitive ligands, suggesting that these compounds may act as allosteric antagonists. However, we cannot completely rule out a competitive behavior since a Schild plot slope of <1 may also suggest nonequilibrium conditions. Moreover, since the hydrophobicity of the alkyl chain of the investigated compounds is a critical requisite for LPC but not for CBD inhibition, it is reasonable to speculate that a different binding site is involved in LPC antagonism, with structural/functional requisites different from those of CBD. This site might be either on TRPV2 or on other targets activated by LPC in its signaling cascade and would be the target of those compounds selectively antagonizing activation by LPC. A common critical requisite for activity of both ethanolamides and amides as TRPV2 antagonists is the occurrence of at least one double bond in the alkyl chain, since saturated lipids, regardless of the length of their acyl chains, are totally inactive. This suggests that a bent conformation of the alkyl chain is required for a better accommodation into the active site, as previously reported for other TRPV1 agonists.[59] Also C16:0 and C18:0 derivatives of capsaicin are inactive against both CBD and LPC, whereas the C20:0 derivative is selectively active against LPC. Instead, a different behavior is observed with imino-capsaicin derivatives since they are active also when bearing saturated alkyl chain. The aromatic moiety contributes to the overall activity at TRPV2 of the compounds characterized in the present work, since it occurs in the most active antagonists.

## 4. CONCLUSIONS

In summary, the search for structurally related synthetic or endogenous lipids with structural similarity to capsaicin derivativs led to identification of olvanil and **73** as potent TRPV2 antagonists against LPC (0.16 and 0.12 $\mu$M, respectively) and of LEA (linoleoylethanolamide) as potent TRPV2 antagonist against CBD (0.65 $\mu$M). This finding is both surprising, since all other synthetic and endogenous compounds tested here on TRPV2 behave as antagonists and capsaicin is inactive at this channel, and of great physiological importance, since novel potent endogenous antagonists were been identified following this study.

In conclusion, starting from the testing of a series of synthetic capsaicinoids as modulators of rat TRPV2, we discovered not only new tools for the pharmacological manipulation of the latter but also that previously described endogenous lipids, i.e., long chain fatty acid ethanolamides and primary amides, behave as negative modulators of this channel. These data are of great potential importance given the increasingly important role assigned to TRPV2 in temperature sensing, pain, insulin secretion, immune response, muscle and heart function, and cancer.[58]

## 5. EXPERIMENTAL SECTION

**5.1. Compounds.** Stevanil, livanil, ethanolamides, amides, and fatty acids when not described in the synthetic section have been purchased from Cayman-Vinci Biochem. Palvanil and PEA are kind gifts from Epitech Group SpA, Saccolongo, Padova, Italy, whereas olvanil is a precious gift from Dr. Alberto Minassi, Dipartimento di Scienze del Farmaco, Università del Piemonte Orientale, Novara, Italy.

**5.2. Synthetic Procedures.** Reactions requiring anhydrous conditions were performed in blazed or oven-dried glassware using anhydrous solvents and under inert atmosphere (argon). The solvents and reagents were purchase from Acros Organics, Sigma-Aldrich, Fluka, Merk, Panreac, Strem Chemicals, or TCI Chemicals. Petroleum ether, EtOAc, DCM, and MeOH were used without further purification. In the case of anhydrous reactions, solvent and reagents were properly dried. Acrolein was distilled at atmospheric pressure and used immediately. The reactions were monitored until completion by TLC on silica gel 60F-254 precoated plates (Merck). Visualization of the compounds was performed by UV light (254 nm),

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

and staining was performed by immersion in a 5% solution of concentrated $H_2SO_4$ in methanol or 5% w/v phosphomolibdic acid in ethanol followed by heating. Flash column chromatography was performed using silica gel (technical grade, 60 Å, 40−63 μm) (Sigma-Aldrich) under air pressure. NMR spectra were recorded on a MERCURYplus AS400 MHz Varian spectrometer. Chemical shifts are reported in parts per million (ppm, $\delta$ units). Coupling constants ($J$) are reported and expressed in hertz (Hz). Ssplitting patterns are designated as br (broad), s (singlet), d (doublet), dd (double doublet), t (triplet), q (quartet), dt (double triplet), td (triple doublet), ddd (double double doublet), p (pentuplet), and m (multiplet). All $^{13}C$ NMR spectra were proton decoupled. High resolution mass spectra (HR-MS) were recorded on at the Serveis Cientificotècnics of Universitat de Lleida (SCT-UdL) and Servei de Recursos Científics i Tècnics of Universitat Rovira i Virgili (URV) with an Agilent G6510AA Q-TOF MS spectrometer in positive electrospray ionization ($ESI^+$) and Agilent LC1200 series coupled to MS6210 TOF spectrometer in electrospray ionization ($ESI^+$) respectively. Mobile phase was composed of ACN/MeOH 50:50. Flow rate: 0.6 mL/min. Infrared spectra were recorded on Jasco FT-IR 6300 using a diamond ATR crystal cell. Melting points were measured using Gallenkamp capillary apparatus and are uncorrected. Optical rotations were measured at 20 °C with a PerkinElmer 241 nc polarimeter ($\lambda$ = 589 Na, path length 1 dm). Some recorded values were within the error limit of the polarimeter, and therefore it was not possible to determine them. It has been indicated as $[\alpha]_D^{20} < 1°$. Analytical UPLC−MS was performed on a binary Acquity UPLC with a Acquity PDA UPLC eLambda 800 nm triple quadrupole mass spectrometer (Xevo TQ-S) using a Acquity UPLC BEH C18 50 × 2.1 mm, 1.7 μm C18 column. UV detection = 210−500 nm, mass spectrometry= ESI+ (scan 100−850 $m/z$). Flow rate was 0.3 mL/min using a solvent gradient of B 100% over 6 min (total run time with equilibration back to starting conditions = 2 min) where A = MeOH and B = 85/15/0.2 MeOH/H2O/AcOH. Purities were measured by UV absorption at 254 nm or TIC and are ≥95% unless otherwise stated. Purity of final compounds was assessed by reversed-phase UHPLC with UV diode array detection; all tested compounds were >95% pure.

**5.2.1. Procedure I. Amine Bond Formation.** To a 0.35 M solution of starting material in anhydrous DMF were added the amine **3** (1.1 equiv), HATU (1.5 equiv), and DIPEA (3 equiv). The mixture was stirred at room temperature for 20 h. To the mixture were added EtOAc and brine, and the aqueous phase was extracted with EtOAc. The combined organic phases were washed with 1 M HCl, saturated solution of $NaHCO_3$ and brine. The organic phase was dried over anhydrous $Na_2SO_4$, filtered and the solvent was removed under reduced pressure. The crude residue was purified by silica gel column chromatography.

**5.2.2. Procedure II. Ester Hydrolysis.** To a 0.2 M solution of starting material in THF/$H_2O$ (1:1) LiOH·$H_2O$ (3 equiv) was added. The mixture was stirred at room temperature until completion of the reaction. The reaction mixture was acidified with 1 M HCl until pH 1 and extracted with EtOAc. The organic phase was dried over anhydrous $Na_2SO_4$, filtered, and the solvent was removed under reduced pressure to afford the corresponding compound.

**5.2.3. Procedure III. Boc Protection.** $Et_3N$ (1.5 equiv) was added to a 0.3 M aqueous solution of starting material, cooled in an ice bath. Then $Boc_2O$ (1.5 equiv) was added dropwise and stirred overnight. After completion of the reaction, the solvent was evaporated under reduced pressure. The residue was dissolved in EtOAc, washed with 1 M HCl and brine, dried over anhydrous $Na_2SO_4$, filtered, and evaporated under reduced pressure. The crude residue was thoroughly washed with hexane several times.

**5.2.4. Procedure IV. SS/SeSe Bond Cleavage.** *SS Bond Cleavage.* To a 0.15 M solution of starting material in wet THF was added tri-*n*-butylphosphine ($P(^nBu)_3$) (1.05 equiv). The reaction mixture was stirred at room temperature for 2 h. After completion of the reaction, the solvent was removed under reduced pressure to afford the crude product, which was purified by silica gel column chromatography.

*SeSe Bond Cleavage and Se-Alkylation.* To a 0.13 M solution of starting material in ethanol was added $NaBH_4$ (2.5 equiv) at 0 °C. The reaction mixture was stirred for 20 min, followed by addition of the respective iodinated compound. The reaction mixture was stirred at room temperature for 16 h. Then, the reaction was quenched with 1 M HCl and extracted with EtOAc. The organic phase was dried over anhydrous $Na_2SO_4$, filtered, and the solvent was removed under reduced pressure. The crude residue was purified by silica gel column chromatography.

**5.2.5. Procedure V. Reduction of Methyl Ester.** To a 0.2 M solution of starting material in anhydrous THF, $LiAlH_4$ (2 equiv) was added at 0 °C. The reaction mixture was stirred at room temperature for 24 h. Then, the reaction was quenched with 1 M HCl, followed by extraction with DCM. The combined organic phases were dried over anhydrous $Na_2SO_4$, filtered, and the solvent was removed under reduced pressure. The solid residue was purified by silica gel column chromatography.

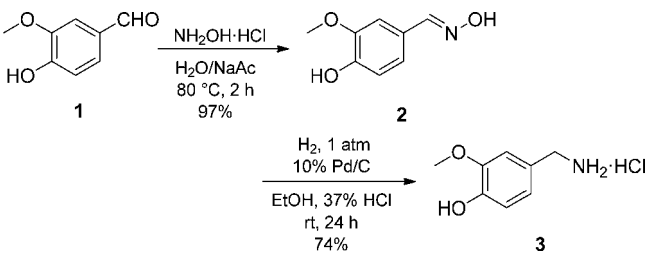
**5.2.6. Procedure VI. Iodination.** To a 0.25 M solution of starting material in toluene iodine (1.2 equiv), imidazole (3 equiv) and $PPh_3$ (1.2 equiv) were added. The mixture was stirred at 90 °C for 2 h. The solvent was evaporated under reduced pressure. The residue was dissolved in EtOAc, washed with saturated aqueous solution of $KMnO_4$, water, and brine, dried over anhydrous $Na_2SO_4$, filtered, and evaporated under reduced pressure. The solid residue was purified by silica gel column chromatography.

**5.2.7. Procedure VII. S-Alkylation.** To a 0.2 M solution of starting material in DMF, TEA (1.5 equiv) and the corresponding iodinated compound (1.12 equiv) were added. The reaction mixture was stirred at 90 °C overnight. To the mixture were added EtOAc and brine, and the aqueous phase was extracted with EtOAc. The combined organic phases were washed with 1 M HCl, saturated solution of $NaHCO_3$, and brine. The organic phase was dried over anhydrous $Na_2SO_4$, filtered, and the solvent was removed under reduced pressure. The crude residue was purified by silica gel column chromatography.

**5.2.8. Procedure VIII. TBDMS Deprotection.** A 0.25 M solution of the starting material in a mixture of AcOH/THF/$H_2O$ was stirred at room temperature until deprotection was complete. The solvent was evaporated under reduced pressure to obtain the reaction crude, which was purified by silica gel column chromatography.

**5.2.9. Procedure IX. Boc Deprotection.** To a 0.3 M solution of starting material in DCM, TFA (10 equiv) was added. The reaction mixture was stirred for 1 h, followed by removal of the solvent under nitrogen stream and drying in vacuo to afford the trifluoroacetate salt of the compound.

**5.2.10. Procedure X. Base Schiff Formation.** To a 0.03 M solution of starting material in MeOH, vanillin **1** (1 equiv) was added. The mixture was refluxed for 2 h in the presence of small amount of glacial AcOH. After cooling, the reaction mixture was filtered to recover a solid, which was recrystallized from hot MeOH to afford the corresponding compound.

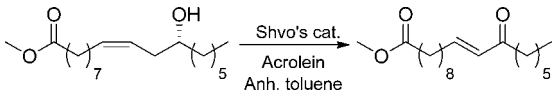


**(*E*)-4-Hydroxy-3-methoxybenzaldehyde Oxime (2).** Hydroxylamine hydrochloride (2.37 g, 34.0 mmol) in $H_2O$ (10 mL) and sodium acetate trihydrate (4.48 g, 32.9 mmol) in $H_2O$ (10 mL) were successively added to a solution of vanillin **1** (5.00 g, 32.9 mmol) in $H_2O$ (30 mL). The reaction mixture was stirred at 80 °C for 2 h. The reaction mixture was extracted with EtOAc, and the organic layer was dried over anhydrous $Na_2SO_4$ and filtered. The solvent was evaporated under reduced pressure to yield the oxime **2**[1] (5.26 g,

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

97%) as an off-white solid. Mp = 118−119 °C. IR (ATR) $\nu$ = 3444, 3213, 3008, 2941, 1596, 1513, 1428, 1027, 969 $cm^{-1}$. $^1H$ NMR (400 MHz, $(CD_3)_2SO$) $\delta$ = 3.77 (s, 3H, $CH_3O$), 6.77 (d, 1H, $J$ = 8.1 Hz, $H_{Ar}$), 6.97 (dd, 1H, $J$ = 8.1, 2.0 Hz, $H_{Ar}$), 7.16 (d, 1H, $J$ = 2.0 Hz, $H_{Ar}$), 7.99 (s, 1H, CH=N), 9.33 (s, 1H, OH), 10.84 (s, 1H, N-OH). $^{13}C$ NMR (101 MHz, $(CD_3)_2SO$) $\delta$ = 55.50 ($CH_3O$), 109.21 ($C_{Ar}$), 115.49 ($C_{Ar}$), 120.52 ($C_{Ar}$), 124.47 (CCHN), 147.85 (COH), 148.01 ($CCH_3O$), 148.10 (CH=N).

**4-Hydroxy-3-methoxybenzylamine Hydrochloride (3).** 37% HCl (20 mL, 0.26 mol) and Pd/C (10 wt % loading) (20% w/w, 1.05 g) were added to a solution of **2** (5.2 g, 0.03 mol) in EtOH (150 mL). The reaction mixture was hydrogenated at 1 atm at room temperature for 24 h. The reaction mixture was filtered over Celite, and the solvent volume was reduced under pressure. The residue was crystallized from EtOAc and filtered to yield the amine hydrochloride salt **3**[2] (4.2 g, 74%) as a white solid. Mp = 219−222 °C. IR (ATR) $\nu$ = 3112, 3024, 2805, 1763, 1377, 1033, 828, 670 $cm^{-1}$. $^1H$ NMR (400 MHz, $(CD_3)_2SO$) $\delta$ = 3.77 (s, 3H, $CH_3O$), 3.83−3.90 (m, 2H, $CH_2NH_2$), 6.79 (d, 1H, $J$ = 8.1 Hz, $H_{Ar}$), 6.85 (dd, 1H, $J$ = 8.1, 2.0 Hz, $H_{Ar}$), 7.18 (d, 1H, $J$ = 2.0 Hz, $H_{Ar}$), 8.40 (br, s, 3H, $NH_2$, HCl), 9.19 (s, 1H, OH). $^{13}C$ NMR (101 MHz, $(CD_3)_2SO$) $\delta$ = 42.19 ($CH_2NH_2$), 55.70 ($CH_3O$), 113.45 ($C_{Ar}$), 115.27 ($C_{Ar}$), 121.74 ($C_{Ar}$), 124.64 (CCHN), 146.81 (COH), 147.51 ($CCH_3O$).



**4** **5**

**Methyl 12-Oxooctadec-(10*E*)-enoate (5).** Shvo's catalyst (9 mg, 8 $\mu$mol) and acrolein freshly distilled (390 $\mu$L, 4.80 mmol) were added to a solution of methyl ricinoleate **4** (500 mg, 1.60 mmol) in anhydrous toluene (15 mL). The reaction mixture was purged with $N_2$ and stirred under reflux for 45 min. The solvent was evaporated under reduced pressure, and after the purification by silica gel column chromatography (petroleum ether/$Et_2O$ 95:5) the enone **5**[3] (348 mg, 70%) was obtained as a yellowish oil. $R_f$ = 0.50 (petroleum ether/$Et_2O$ 9:1). IR (ATR) $\nu$ = 2927, 2855, 1736, 1709, 1436, 1195, 1169, 1104, 979, 880, 752 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$) $\delta$ = 0.86 (t, 3H, $J$ = 6.9 Hz, $CH_3$), 1.23−1.33 (m, 14H, $CH_2$), 1.38−1.48 (m, 2H, $CH_2$), 1.52−1.65 (m, 4H, $CH_2$), 2.18 (q, 2H, $J$ = 6.4 Hz, $CH_2$), 2.29 (t, 2H, $J$ = 6.9 Hz, $CH_2$), 2.51 (t, 2H, $J$ = 6.9 Hz, $COCH_2$), 3.65 (s, 3H, $CH_3O$), 6.07 (dt, 1H, $J$ = 15.9, 1.5 Hz, CH=CH), 6.80 (dt, 1H, $J$ = 15.9, 6.9 Hz, CH=CH). $^{13}C$ NMR (101 MHz, $CDCl_3$) $\delta$ = 14.01 ($CH_3$), 22.48 ($CH_2$), 24.27 ($CH_2$), 24.86 ($CH_2$), 28.04 ($CH_2$), 28.96 ($CH_2$), 29.07 (4 × $CH_2$), 31.59 ($CH_2$), 32.38 ($CH_2$), 34.02 ($CH_2$), 40.08 ($COCH_2$), 51.41 ($CH_3O$), 130.28 (CH=CH), 147.20 (CH=CH), 174.24 (COO-), 200.99 ($COCH_2$).

**Methyl 12-Oxo-10-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)octadecanoate (6).** Tri-*n*-butylphosphine (26 $\mu$L, 0.10 mmol) was added to a solution of anhydrous CuCl (10 mg, 0.10 mmol) in anhydrous DMF (4.5 mL) under argon atmosphere. In another reaction vessel, bis(pinacolato)diboron (283 mg, 1.12 mmol) was added to a solution of methyl 12-oxooctadec-(10*E*)-enoate **5** (290 mg, 0.93 mmol) in anhydrous DMF (4.5 mL) under argon atmosphere. This solution was transferred to the tri-*n*-butylphosphine solution. The reaction mixture was stirred at room temperature for 48 h. The crude was taken up in $H_2O$ and extracted with petroleum ether. The organic solution was dried over anhydrous $Na_2SO_4$, filtered and the solvent was evaporated under reduced pressure to yield the $\beta$-boron ketone **6** (190 mg, 46%) as a yellow oil after the purification by silica gel column chromatography (petroleum ether/EtOAc 95:5). $R_f$ = 0.49 (petroleum ether/$Et_2O$ 9:1). $^1H$ NMR (400 MHz, $CDCl_3$) $\delta$ = 0.84 (t, 3H, $J$ = 6.9 Hz, $CH_3$), 1.18−1.28 (m, 30H, $(CH_3)_4$, $CH_2$), 1.34−1.39 (m, 1H, CHB), 1.49−1.60 (m, 4H, $CH_2$), 2.27 (t, 2H, $J$ = 6.9 Hz, $CH_2$), 2.33 (td, 2H, $J$ = 7.4, 3.7 Hz, $COCH_2$), 2.50 (d, 2H, $J$ = 6.8 Hz, $CHBCH_2CO$), 3.64 (s, 3H, $CH_3O$).

**12-Oxo-10-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-octadecanoic Acid (7).** Novozym 435 (83 mg, 50% w/w) was added to a solution of the methyl ester **6** (190 mg, 0.43 mmol) in a mixture of $H_2O$ (308 $\mu$L) and *tert*-BuOH (922 $\mu$L). The reaction mixture was stirred at 45 °C for 24 h. The mixture was filtered and the solvent was evaporated under reduced pressure to yield the acid **7** (180 mg, quantitative) as a yellow oil. $^1H$ NMR (400 MHz, $CDCl_3$) $\delta$ = 0.87 (t, 3H, $J$ = 6.9 Hz, $CH_3$), 1.20−1.34 (m, 30H, $(CH_3)_4$, $CH_2$), 1.38−1.44 (m, 1H, CHB), 1.51−1.58 (m, 2H, $CH_2$), 1.59−1.66 (m, 2H, $CH_2$) 2.30−2.40 (m, 4H, $CH_2$, $COCH_2$), 2.53 (d, 2H, $J$ = 6.8 Hz, $CHBCH_2CO$).

**5.3. TRP Channels Assays.** Assays of TRP-mediated elevation of $[Ca^{2+}]_i$ were performed as previously described.[60] HEK-293 (human embryonic kidney) cells wild-type or stably overexpressing recombinant human TRPV1 or rat TRPV2 were grown on 100 mm diameter

DOI: 10.1021/acs.jmedchem.8b00734
J. Med. Chem. XXXX, XXX, XXX−XXX

Petri dishes as monolayers in Eagle's minimum essential medium (EMEM) supplemented with 1% nonessential amino acids, 10% fetal bovine serum (FBS), 50 U/mL penicillin plus 50 μg/mL streptomycin, and 2 mM glutamine, maintained under 5% $CO_2$ at 37 °C and only for the overexpressing cells selected by G-418 (Geneticin, 600 mg $mL^{-1}$; Thermo-Fisher Scientific). On the day of the experiment, the cells were loaded for 1 h at 25 °C with the $Ca^{2+}$ indicator Fluo-4-AM (Thermo-Fisher Scientific) 4 μM in DMSO containing 0.02% Pluronic F-127 (Thermo-Fisher Scientific) in EMEM without FBS. After loading, cells were washed twice in Tyrode's buffer (145 mM NaCl, 2.5 mM KCl, 1.5 mM $CaCl_2$, 1.2 mM $MgCl_2$, 10 mM D-glucose, and 10 mM HEPES, pH 7.4), resuspended in the same buffer, and transferred, about 100 000 cells for each determination, to the quartz cuvette of the spectrofluorimeter ($\lambda_{ex}$ = 488 nm; $\lambda_{em}$ = 516 nm) PerkinElmer LS50B equipped with PTP-1 fluorescence Peltier system (PerkinElmer Life and Analytical Sciences, Waltham, MA, USA) under continuous stirring at 25 °C. Experiments were carried by measuring cell fluorescence before and after the addition of test compounds at various concentrations. The values of the effect on $[Ca^{2+}]_i$ in wild-type (i.e., not transfected with any TRP construct) HEK-293 cells were taken as baselines. Potency ($EC_{50}$ values) was determined as the concentration of test compounds exerting a half-maximal agonist effect (i.e., half-maximal increases in $[Ca^{2+}]_i$). The efficacy of the agonists was determined by comparing their effect to the maximal effect on $[Ca^{2+}]_i$ observed with 4 μM ionomycin. Antagonist/desensitizing behavior was evaluated against the agonist capsaicin 0.1 μM (Sigma-Aldrich) for TRPV1 and the agonists lysophosphatidylcholine (LPC) (Sigma-Aldrich) 3 μM and cannabidiol (CBD) 2 μM (a kind gift by GW Pharmaceuticals) for TRPV2 by adding the test compounds in the quartz cuvette 5 min before stimulation of cells with the agonist. The effect on $[Ca^{2+}]_i$ exerted by agonist alone was taken as 100%. Data are expressed as the concentration exerting a half-maximal inhibition of agonist-induced $[Ca^{2+}]_i$ elevation ($IC_{50}$). Concentration–response curves were fitted by a sigmoidal regression with variable slope. Curve fitting and parameter estimation were performed with GraphPad Prism (GraphPad Software Inc., San Diego, CA). Determinations were performed at least in triplicate. Statistical analysis of the data was performed by analysis of variance at each point using ANOVA followed by Bonferroni's test.
