Abstract

Background—Angiotensin converting enzyme (ACE) inhibitor therapy improves clinical outcome and ventricular function in adults with heart failure. Infants with single ventricle physiology have poor growth and are at risk for abnormalities in ventricular systolic and diastolic function. The ability of ACE inhibitor therapy to preserve ventricular function and improve somatic growth and outcomes in these infants is unknown.

Methods and Results—The Pediatric Heart Network conducted a double-blind trial involving 230 infants with single ventricle physiology randomized to receive enalapril (target dose 0.4 mg/kg/day) or placebo and followed to 14 months of age. The primary endpoint was weight-for-age z-score at 14 months. The primary analysis was intention-to-treat. A total of 185 infants completed the study. There were 24 and 21 withdrawals/deaths in the enalapril and placebo groups, respectively ($P=0.74$). Weight-for-age z-score was not different between the enalapril and placebo groups (mean±standard error, -0.62 ± 0.13 vs. -0.42 ± 0.13 , $P=0.28$). There were no significant group differences in height-for-age z-score, Ross heart failure class, brain natriuretic peptide concentration, Bayley scores of infant development, or ventricular ejection fraction. The incidence of death or transplantation was 13% and did not differ between groups. Serious adverse events occurred in 88 patients in the enalapril group and 87 patients in the placebo group.

Conflict of Interest Disclosures: None

Conclusions—Administration of enalapril to infants with single ventricle physiology in the first year of life did not improve somatic growth, ventricular function, or heart failure severity. The results of this randomized trial do not support the routine use of enalapril in this population.

Clinical Trials Registration Information—ClinicalTrials.gov NCT00113087 <http://www.clinicaltrials.gov/ct2/show/NCT00113087?term=enalapril+and+single+ventricle&rank=1>

trials; angiotensin; heart defects; congenital; heart failure; pediatrics

Background

Single ventricle physiology results from underdevelopment of the left or right ventricle during fetal life. Although single ventricle defects constitute just over 1% of congenital cardiovascular defects,¹ they account for a disproportionate amount of the morbidity and mortality in infants and children with congenital heart disease. Mortality in the first year of life ranges from 15% to 30%,^{2, 3} and management of these infants is associated with high levels of resource utilization.⁴ Improving survival and decreasing morbidity in children with single ventricle physiology is one of the most challenging problems in pediatric cardiology.

In early infancy the single ventricle has a significant volume overload, because of the need to support both the pulmonary and systemic circulations. The superior cavopulmonary connection (SCPC), performed around six months of age, decreases the volume load on the ventricle, nevertheless maladaptive ventricular hypertrophy and dysfunction have been described in single ventricle patients.⁵⁻⁷ Growth impairment is commonly seen in infants with single ventricle physiology and persistent or progressive abnormalities in ventricular structure and function are likely mechanisms leading to failure to thrive.^{2, 3, 8-10} Previous small studies have shown that, similar to results reported in adults, angiotensin-converting enzyme (ACE) inhibitor therapy can reverse ventricular remodeling and preserve ventricular function in children with volume overload conditions such as atrioventricular valve regurgitation.^{11, 12} ACE inhibitor therapy also improves growth in infants with volume overload secondary to large left to right shunts.¹³⁻¹⁵ Based on these findings, the empiric use of ACE inhibitor therapy in infants with single ventricle is common in many pediatric cardiac centers. However, few data are available regarding the safety and efficacy of this approach.^{16, 17} This trial was designed to determine whether ACE inhibition improves ventricular function and hemodynamic status in infants with single ventricle physiology, thereby improving a clinically important outcome, somatic growth.

Methods

Study Design

The study was a randomized, double-blind, placebo-controlled trial conducted by the Pediatric Heart Network comparing the effects of enalapril with those of placebo in infants with single ventricle.^{18, 19} Patients were enrolled from August, 2003, through May, 2007, at 10 centers in the United States and Canada. A detailed description of the study design and quality assurance methods for anthropometric measurement has been published.¹⁹ In brief, inclusion criteria consisted of age \leq 45 days, age $>$ 1 week if born at 35 weeks gestation, presence of single ventricle physiology, stable systemic and pulmonary blood flow, and planned SCPC surgery. Exclusion criteria included anatomic diagnosis of pulmonary atresia with intact ventricular septum, $<$ 3 days after palliative cardiac surgical procedure (if performed), aortic oxygen saturation $<$ 65%, current mechanical ventilatory or intravenous inotropic support, creatinine $>$ 1.0 mg/dL, absolute neutrophil count $<$ 1000 cells/mL,

chromosomal or recognizable phenotypic syndrome of non-cardiac congenital abnormalities associated with growth failure, and prior ACE inhibitor use for > 7 consecutive days. The protocol was approved by the institutional review boards at the participating institutions, and written informed consent was obtained from the parent or guardian of each patient.

The primary outcome was weight-for-age z-score at 14 months of age. Patients were followed until 14 months of age to allow assessment of the effects of ACE inhibitor therapy for at least 6 months after the volume-unloading that occurs after the SCPC surgery. Secondary endpoints included other measures of somatic growth, Ross heart failure class²⁰, brain natriuretic peptide (BNP) concentration, ventricular geometry and function obtained by two-dimensional echocardiography, and neurodevelopmental and functional status. Echocardiograms were analyzed centrally by a single core laboratory observer. The methods used for measuring ventricular volumes and assessment of intraobserver variability in single ventricle patients have been detailed previously.²¹ In brief, echocardiographic images were analyzed from the apical (ventricular long-axis) and parasternal short-axis views. The endocardial border of the single ventricle was traced at end-diastole and end-systole and the epicardial border was traced at end-diastole in both planes. End-diastolic volume, end-systolic volume, and mass were calculated using a biplane-modified Simpson's rule. The EF was calculated as (end-diastolic volume – end-systolic volume)/end-diastolic volume. Ventricular mass was calculated as myocardial end-diastolic volume (epicardial volume – endocardial volume) × myocardial density (1.05 g/ml). Echocardiographic measurements and derived indexes were expressed as z-scores relative to body surface area (BSA) or age in normal children.²² BNP concentration was analyzed centrally. Endpoints were measured at the study visit performed immediately prior to the SCPC surgery (mean age 5.1±1.8 months) and at the final study visit (mean age 14.1±0.9 months).

Patients were randomly assigned in a 1:1 ratio to the enalapril and placebo treatment groups using randomly permuted blocks within strata defined by the presence or absence of hypoplastic left heart syndrome, with dynamic balancing within center. The initial enalapril dose was 0.1 mg/kg/day. Medication was uptitrated as tolerated over a period of two weeks to the target dose of 0.4 mg/kg/day given in two divided doses. The dose of study drug was adjusted for weight gain.

Adverse events were classified as non-serious, moderately serious and serious using the Common Terminology Criteria for Adverse Event v.3.0 categories²³ and compared between groups. All serious adverse events were adjudicated by an independent physician who was unaware of treatment group assignment.

Statistical Analysis

The trial design allowed 85% power to detect a 0.5 mean difference in weight-for-age z-score at the final study visit, with 23% inflation for dropout and interim analysis. The primary analysis was performed according to the intention-to-treat principle. A mixed model with a piecewise linear fit for age at measurement for longitudinal analysis of growth z-scores by treatment arm was used as the primary analysis to account for intra-patient correlation. This model included an interaction term for age by treatment assignment. A secondary analysis was performed comparing the raw mean growth z-scores at the pre-SCPC surgery and final study visits by treatment group using the t-test and Wilcoxon rank sum test. A secondary non-intention-to-treat analysis was also performed.

The continuous echocardiographic outcomes and neurodevelopmental scores were compared by treatment group using the Student's t-test for non-skewed variables and the Wilcoxon rank sum test for other measures. Categorical measures by treatment group were compared using a Fisher exact test. Adverse event rates were compared using Poisson regression.

Prespecified subgroup analyses were performed according to single left ventricle vs. single non-left ventricle; Norwood vs. other neonatal palliation; and, among patients who underwent a Norwood procedure, systemic-to-pulmonary artery vs. right ventricle-to-pulmonary artery shunt. The presence or absence of heterotaxy was a prespecified subgroup; however, the small number of patients with heterotaxy in the study sample (n=10) precluded analysis. Covariate-by-treatment interaction tests were performed to assess the treatment effect across subgroups. Subgroup analyses of growth outcomes were adjusted for baseline value and gestational age.

Results

Patient population

A total of 1245 infants with single ventricle anatomy <45 days old were screened, 533 (43%) were eligible, and 230 (115 in each group, 43% consent rate) were randomized (Figure 1). The eligible patients who were not enrolled were younger (11 ± 8 vs. 14 ± 9 days, $P<0.001$), less likely to be male (61% vs. 70%, $P=0.02$) and less likely to have hypoplastic left heart syndrome (54% vs. 63%, $P=0.04$) compared to those who were enrolled. Race, gestational age, birth weight, and type of surgery did not differ between the eligible enrolled and not enrolled patients.

Baseline characteristics were similar for the two groups (Table 1), except for gestational age, which was higher in the enalapril group (median 39 vs. 38 weeks, $P=0.01$). Of the 230 patients in the study, 45 patients did not complete the final study visit (24 in the enalapril and 21 in the placebo group $P=0.74$), leaving 185 patients with data for primary endpoint analysis (Figure 1). For patients who completed the study (and were randomized to enalapril), the mean enalapril dose administered was 0.31 ± 0.13 mg/kg/day. The percentage of patients who did not reach the target volume of study drug did not differ between groups (enalapril 43% and placebo 33%). The mean age at the SCPC surgery did not differ by treatment assignment (5.6 ± 1.8 vs. 5.4 ± 1.8 months, $P=0.52$). Median hospital stay after the SCPC surgery was 7 days for both treatment groups (interquartile range, 6 to 10 days, $P=0.76$).

Primary Outcome

Intention to treat analysis—Weight-for-age, height-for-age and weight-for-height z-scores analyzed longitudinally did not differ between the enalapril and placebo groups at age 14 months (Table 2, weight-for-age estimated mean \pm SE: -0.62 ± 0.13 vs. -0.42 ± 0.13 , respectively, $P=0.28$). Furthermore, there were no age-specific treatment group differences (weight-for-age z-score interaction $P=0.29$, Figure 2). Mean head circumference-for-age z-score at age 14 months was lower in the enalapril group compared to the placebo group ($P=0.008$); the mean head circumference was 45.7 ± 1.8 cm in the enalapril group and 46.4 ± 2.2 cm in the placebo group. Secondary analysis of visit-specific raw mean growth z-scores (see Methods) at the final study and pre-SCPC surgery time points also did not differ by treatment group with the exception of head circumference-for-age z-score at the final study visit (Table 2). Inferences were unchanged after adjustment for gestational age.

Non-intention-to-treat Analysis—A non-intention-to-treat analysis was performed because of the high proportion (53/185, 29%) of patients who discontinued study drug during the course of the study. Among those who remained in the study, twenty patients in the enalapril group and 33 patients in the placebo group permanently discontinued study drug ($P=0.05$). Patients who received at least 10 consecutive months of study drug and/or open-label enalapril (n=81) were compared to patients who received at least 10 consecutive months of placebo or no ACE inhibitor therapy (n=73). The results confirmed those of the

primary analysis, with no difference seen in any of the growth z-scores at the pre-SCPC or final study visit except for a lower head circumference-for-age z-score at the final study visit in the enalapril group ($P=0.04$). Similar results were also obtained for the subset of 132 patients who received study drug throughout the course of the study.

Secondary Outcome Comparisons

Compared to normal values, the ventricular mass-to-volume ratio and mass-to-volume ratio z-scores were higher in both groups at the pre-SCPC surgery and final study visits ($P<0.01$). However, the mean ventricular mass-to-volume ratio and mass-to-volume ratio z-scores were significantly lower in the patients in the enalapril group compared to those in the placebo group at the pre-SCPC visit ($P=0.02$), but not at the final study visit ($P=0.34$). Moderate to severe atrioventricular valve regurgitation was present in 12% of the enalapril group and 24% of the placebo group at the final study visit ($P=0.06$). Mean z-scores at the final study visit were higher in the enalapril group for three of the four domains of the MacArthur-Bates Communicative Development Words and Gestures Inventory, a measure of early language development. No other differences were found between the treatment groups (Table 3).

Subgroup Analyses

There was no difference in the effect of enalapril on the primary endpoint of weight-for-age z-score at the final study visit across the predetermined subgroups defined by anatomy or type of palliation. Furthermore, no other endpoints had a treatment group interaction with a subgroup factor below the 0.05 level.

Adverse Events

No difference in number of adverse events was observed between the treatment groups (423 in the enalapril group and 389 in the placebo group, $P=0.23$). Four or more events per patient occurred in 37% of the enalapril group and in 30% of placebo group. Serious adverse events occurred in 88 of the enalapril group patients (220 events) and 87 of the placebo group patients (208 events). The proportions of serious adverse events in the categories of general cardiac (non-arrhythmia), gastrointestinal, infection, pulmonary, and vascular were similar in the enalapril and placebo groups: 86% and 81%, respectively. Serious cardiac events occurred in 29 patients in the enalapril group and 19 patients in the placebo group, $P=0.14$. Death occurred in 24 patients, 12 in each group. Three patients in the enalapril group and 4 patients in the placebo group underwent transplantation. A serious renal adverse event occurred in one patient in the enalapril group (1 event) and in one patient in the placebo group (2 events).

Discussion

This trial is the largest randomized, double-blind study performed to date to assess the impact of a medical intervention in infants with single ventricle. Despite standard surgical palliation, there was a high incidence of death, heart transplantation, ventricular dysfunction, growth failure, neurodevelopmental delay, and other complications during the course of this study, and these outcomes highlight the need for better evidence-based therapies in this population. This study, however, failed to demonstrate a beneficial effect of enalapril therapy on the primary endpoint of weight-for-age at 14 months of age, or on the secondary endpoints of height-for-age, head circumference-for-age, ventricular structure and function or clinical heart failure in this population of infants with single ventricle, the majority of whom had normal ventricular function and no significant atrioventricular valve regurgitation. Although this study was not designed to analyze the effect of enalapril on the subset of infants with ventricular dysfunction, there was no difference in the proportion of

patients who died or underwent cardiac transplantation between the two groups, implying that enalapril was not protective against end-stage heart failure or death. There was no treatment effect identified within pre-specified subgroups, suggesting that enalapril is not beneficial even for targeted subsets of patients.

The failure of enalapril to improve somatic growth is likely multifactorial. Enalapril failed to cause a sustained improvement in ventricular structure and function indicating that enalapril did not result in hemodynamic improvement and promotion of somatic growth. The lack of a remodeling effect of enalapril may be a result of differences in RAAS activation in the single ventricle population compared to adult patients with heart failure.²⁴ Coupled with the recent negative trial results of carvedilol in pediatric heart failure²⁵, our findings suggest that standard heart failure therapy may not be beneficial in patients with complex single ventricle physiology. The SCPC surgery resulted in significant ventricular remodeling and catch-up growth suggesting that surgical volume unloading is a more effective strategy than ACE inhibitor therapy for improving cardiac performance in these patients. In addition, growth failure in single ventricle patients often results from non-cardiac causes such as chronic feeding difficulties, gastrointestinal reflux, or unknown or uncharacterized genetic influences. These factors may not be modified by enalapril therapy, and may be more important than any potential hemodynamic effect of enalapril.²⁶ The clinical implications of the findings of better catch-up growth in head circumference-for-age in the placebo group and higher MacArthur Bates Communicative Development Index scores (indicating more advanced language and communication skills²⁷) in the enalapril group are unclear. Further investigation is needed since there is no known physiologic basis for a primary effect of enalapril on either of these outcomes.

An important adverse effect of volume loading shown in this study was an inappropriate degree of ventricular hypertrophy with a marked increase in the ventricular mass that was disproportionate to the degree of ventricular dilation, as seen by the increased mass-to-volume ratio. This effect was present before the SCPC surgery in both treatment groups. Although volume-unloading surgery reduced ventricular mass and volume, it failed to normalize the ventricular mass-to-volume z-score. The lower mass-to-volume z-scores seen in the enalapril group compared to the placebo group before the SCPC surgery suggest that enalapril may have an anti-hypertrophic effect on the volume-loaded single ventricle. By the final study visit, the ventricular mass, volume, and mass-to-volume ratio did not differ between the groups.

There are several important limitations to this study. The 20% loss-to-follow-up rate was high, although anticipated in the study design. The permanent discontinuation of study drug in 29% of the patients who completed the trial is substantial. However, in the secondary non-intention-to-treat analysis, even patients who received enalapril for at least 10 months did not differ from those who received placebo. The high number of patients included in the intention-to-treat analysis who did not reach the target dose of enalapril raises the possibility that the lack of effect may reflect a sub-therapeutic dose. Overall, the failure to achieve the target dose in many patients reflects the challenges of administering an afterload-reducing agent to fragile infants with single ventricle physiology, even in those with normal single ventricle function. Treatment guidelines do not recommend the use of ACE inhibitor therapy in adult patients with atrioventricular valve regurgitation and normal ventricular function.²⁸ This study was not designed to determine the effect of enalapril on the subset of patients with significant atrioventricular valve regurgitation at baseline and the small number of patients with this finding limited further analysis. Finally, the trial may have been inadequately powered to detect a treatment effect in patient subgroups.

In conclusion, this randomized trial did not show a favorable effect of enalapril on somatic growth, clinical outcomes, ventricular function or overall neurodevelopmental outcomes in infants with single ventricle physiology and does not support the routine use of enalapril in this population. These results highlight the need to develop newer and more specific therapies targeted to this complex and growing population of patients.

Figure 1.

Trial Flow Diagram.

SCPC – superior cavopulmonary connection

*Two patients who did not undergo the pre-SCPC visit are excluded from analysis at this time point, but they remained in the trial and are included in the final analysis.

‡Includes one patient who had growth measurements obtained at the final study visit but died prior to the neurodevelopmental testing.

§Among the patients who completed the study, 20 patients in the enalapril group and 33 patients in the placebo group discontinued study drug prior to the final study visit.

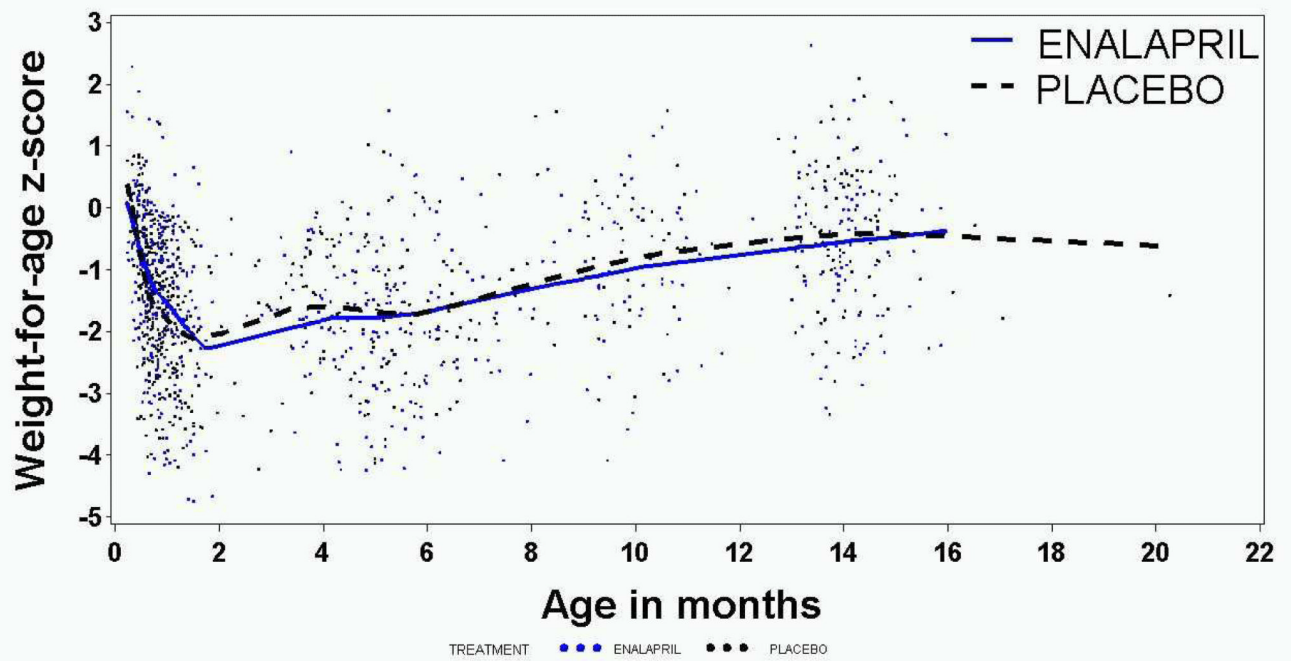

Figure 2.

Lowess-smoothed curves of weight-for-age z-score by treatment assignment vs. age in months. The default smoothing parameter is 0.26. All final-study visit data (target age 14 months; actual mean age 14.1 ± 0.9 months) were included. Blue points denote assignment to enalapril and black points denote assignment to placebo.

Table 1
Baseline Characteristics by Treatment Assignment*

Characteristic	Enalapril	Placebo
N	115	115
Male sex (%) (230 patients)	65	76
Mean age at enrollment (days) (230 patients)	20.1±8.9	20.7±9.1
Male (days)	19.3±9.0	19.6±8.3
Female (days)	21.6±8.7	24.3±10.8
Race (229 patients)		
White (%)	83	77
Black or African-American (%)	11	17
Asian (%)	4	3
Other (%)	3	3
Hispanic (%) (225 patients)	14	16
Gestational age [†] (230 patients)		
Median (weeks)	39	38
IQR (weeks)	38-40	37-39
Gestational age < 37 weeks (%)	6	11
Weight (kg) (229 patients)	3.4±0.6	3.4±0.5
Weight-for-age z-score (229 patients)	-1.18±1.29	-1.36±1.24
Weight-for-height z-score (229 patients)	-0.76±1.28	-0.92±1.27
Height (cm) (229 patients)	51.1±2.3	51.1±2.5
Height-for-age z-score (229 patients)	-1.02±1.27	-1.08±1.28
Head circumference (cm) (228 patients)	34.4±1.5	34.2±1.5
Head circumference z-score (228 patients)	-1.58±1.39	-1.84±1.35
SV anatomic diagnosis (230 patients)		
Single ventricle (%)	30	28
Hypoplastic left heart syndrome (%)	63	64
Other functional SV (%)	7	8
Unclassified (%)	1	0
Type of surgery (225 patients)		
Norwood (%)	69	79
Systemic-to-pulmonary shunt (%)	20	15
PA band (%)	8	4
Damus-Kaye-Stansel (%)	4	3
Overall AV valve regurgitation (229 patients)		
None (%)	22	25
Mild (%)	57	51
Moderate (%)	22	24
Severe (%)	0	1
Systemic ventricular dysfunction (229 patients)		
None (%)	83	77

Characteristic	Enalapril	Placebo
Mild (%)	12	17
Moderate (%)	5	4
Severe (%)	0	1

AV- atrioventricular, IQR- interquartile range, PA- pulmonary artery, RAAS- renin-angiotensin-aldosterone system, SV- single ventricle

* Plus-minus sign indicates mean \pm SD. IQR denotes inter-quartile range. Percentages may not add to 100 because of rounding. All z-scores are calculated using World Health Organization standards. No between-group comparisons were significant (all P values >0.10) except for gestational age (P=0.01).

[†] Gestational age imputed as 40 weeks for 5 full-term patients

Table 2
World Health Organization Growth Z-scores by Treatment Assignment*

	Enalapril	Placebo	Difference [†]	P Value [§]
Predicted Means at Age 14 months based on Longitudinal Modeling[‡]				
Variable	Predicted mean±SE (no. of patients)		Predicted mean±SE (95% CI)	
Weight-for-age z-score	-0.62±0.13 (91)	-0.42±0.13 (94)	-0.20±0.18 (-0.56 to 0.16)	0.28
Weight-for-height z-score	-0.18±0.13 (91)	-0.08±0.13 (94)	-0.11±0.18 (-0.47 to 0.25)	0.55
Height-for-age z-score	-1.00±0.13 (91)	-0.86±0.13 (94)	-0.14±0.18 (-0.50 to 0.21)	0.42
Head circumference-for-age z-score	-0.55±0.17 (91)	0.09±0.17 (94)	-0.64±0.24 (-1.11 to -0.17)	0.008
Raw Means at Pre-SCPC Surgery and Final Study Visits^{**}				
Variable	Mean±SD (no. of patients)		Mean±SD (95% CI)	
Pre-SCPC Surgery Visit^{††}				
Weight-for-age z-score	-1.60±1.16 (97)	-1.66±1.12 (100)	0.07±1.14 (-0.25 to 0.39)	0.69
Weight-for-height z-score	-0.88±1.18 (97)	-1.03±1.28 (100)	0.14±1.23 (-0.20 to 0.49)	0.42
Height-for-age z-score	-1.30±1.37 (97)	-1.28±1.17 (100)	-0.02±1.27 (-0.37 to 0.34)	0.93
Head circumference-for-age z-score	-1.49±1.33 (97)	-1.32±1.05 (99)	-0.17±1.20 (-0.51 to 0.17)	0.32
Final Study Visit				
Weight-for-age z-score	-0.54±1.09 (91)	-0.43±1.13 (94)	-0.11±1.11 (-0.44 to 0.21)	0.49
Weight-for-height z-score	-0.16±1.04 (91)	-0.00±1.16 (94)	-0.16±1.10 (-0.48 to 0.16)	0.34
Height-for-age z-score	-0.92±1.20 (91)	-0.94±1.13 (94)	0.02±1.16 (-0.32 to 0.35)	0.92
Head circumference-for-age z-score	-0.40±1.28 (91)	0.09±1.59 (94)	-0.48±1.44 (-0.90 to -0.06)	0.02

* CI- confidence interval, SE- standard error, SD- standard deviation, SCPC- superior cava pulmonary connection.

[†] Difference was defined as the mean for the enalapril group minus the mean for the placebo group.

[§] P values for predicted means were calculated using a contrast of the estimated group means at 14 months and their associated standard errors from longitudinal modeling. P values for raw means were based on the two-sample t-test (inferences were similar with the use of a Wilcoxon rank-sum test, and after adjustment for gestational age). P values are unadjusted for the one interim look at the data.

[‡] The data from all 230 subjects were used in longitudinal analysis (see Methods).

^{**} All mean z-scores differ from zero (the normal population mean), P<0.05 by one-sample t-test with three exceptions, all at the final study visit: weight-for-height z-score for both treatment arms and head circumference-for-age z-score for the placebo group are not significantly different from zero.

^{††}Weight measurements were not available in 1 patient in the enalapril group and 2 patients in the placebo group at the pre-SCPC visit.

Table 3

Secondary Outcomes by Treatment Assignment

Variable	Pre-SCPC Surgery			Final-study visit		
	Enalapril	Placebo	P Value*	Enalapril	Placebo	P Value*
BNP (pg/ml)						
Median (no. of patients)	79.0 (83)	84.0 (90)	0.74	25.0 (69)	39.0 (65)	0.22

Psychomotor Developmental Index z-score				-1.29±1.19 (86)	-1.32±1.22 (83)	0.88
Total Behavior Rating Scale						
Median (no. of patients)				58.0 (87)	49.0 (82)	0.19
IQR				29-83	23-71	
Functional Status II(Revised) Total Score						
Median				96.4 (89)	96.4 (89)	0.60
IQR				89-100	86-100	
MacArthur-Bates Communicative Development Inventory (Words and Gestures)						

Variable	Pre-SCPC Surgery		Final-study visit		P Value*
	Enalapril	Placebo	Enalapril	Placebo	
Phrases Understood z-score	-0.48±1.11 (90)	-0.92±1.17 (87)	-0.46±0.91 (90)	-0.82±0.83 (87)	0.01
Words Understood z-score	-0.46±0.91 (90)	-0.82±0.83 (87)	-0.86±1.07 (90)	-1.31±0.97 (87)	0.008
Total Gestures z-score					0.004
Words Produced z-score					0.31
Median (no. of patients)	-0.60 (90)	-0.63 (87)			
IQR	-0.72 to 0.41	-0.75 to 0.42			

AV- atrioventricular valve; BNP- brain natriuretic peptide; IQR- interquartile range; no.- number of patients; SCPC- superior cava pulmonary connection.

Note. The one-sample t-test and Wilcoxon signed-rank test were used to compare the distribution of the Bayley Scales of Infant Development and MacArthur Communicative Development Inventory z-scores from the trial (presented in Table 3) with the normal population. These z-scores differ from zero (P<0.02). The Bayley Total Behavior Rating Scale percentile did not differ from the 50th percentile in either treatment arm. All echocardiographic z-scores differ from zero (P<0.01).

* The P values for categorical variables were calculated with the use of a Fisher exact test. P values for variables presented as means and medians were calculated using a two-sample t-test and a Wilcoxon rank-sum test, respectively. The P value for BNP is calculated using a two-sample t-test of the natural logarithm of BNP.

[†] Mass:volume ratio z-score was slightly skewed. Medians for the enalapril and placebo groups were 1.00 vs. 2.05 (Wilcoxon P=0.03), respectively, at pre-SCPC Surgery. Mass:volume ratio z-score medians for the enalapril and placebo groups were 0.96 vs. 1.10 (Wilcoxon P=0.57), respectively, at the final-study visit.
