An investigation was carried out with the eighteen high sucrose containing sugarcane clones to estimate the extent of variability for various productive traits under water-logged condition. The analysis of variance revealed highly significant differences among the clones for fourteen traits and significant for rest traits *viz.*, germination % at 45 DAP, plant height at 150 days, single cane weight and purity % at 10 month stage. The Variability studies showed high estimates of GCV and PCV for traits *viz.*, length of aerial root and dry weight of aerial roots. In present set of materials high heritability with high genetic advance as per cent of mean was found in length of aerial root. Similarly, high heritability with moderate genetic advance as percent of means was observed for plant height at 240 days, height at 360 days, pol per cent at 12 month stage and single cane weight, indicating the role of dominant genetic effects in determination of these characters and its improvements.

Introduction

Sugarcane is a perennial, tropical; monocotyledonous crop which is cultivated in tropical and sub-tropical region of the world primarily for its ability to store high concentration of sugar in the inter-node and propagate through stem cutting. It grows under varied soil and climatic conditions, but its productivity is generally limited by abiotic and biotic stresses, as it has to face vagaries of nature during its yearlong life in the field. National production of it is 366.80 million tones and productivity is 69.20 t/ha whereas productivity in Bihar is 50 t/ha (2014-15, Indian Sugar February, 2016). In India 10 -30 per cent of sugarcane area is affected by water

logging which is one of the major constraints affecting crop productivity in the Indo-Gangetic belt and the coastal area about 73 per cent annual rainfall in India is received during the southwest monsoon (June to September) which is primary cause for water logging. North Bihar is main sugarcane growing tract where about 35-40 per cent of sugarcane cultivated area remains water-logging during monsoon season which coincides with the grand growth period of the crop. In water-logged areas, cane yield generally declined by 15-20 per cent. If the water-logging is in the early stage of crop growth it affects the germination, tillering and

cane growth, which may result in crop failure. The knowledge of nature and extent of genetic variation available in the germplasm or breeding material helps the breeder for planning sound breeding programmes. Therefore, present investigation was formulated to Estimate the extent of variability for various productive traits under water-logging condition.

Materials and Methods

The experimental materials were high sucrose containing eighteen sugarcane clones including two checks (BO 91 and CoLk 94184) *namely* CoX 12164, CoX 12236, CoX 12271, CoX 12348, CoX 11506, CoX 12599, CoX 12577, CoX 12191, CoX 12024, CoX 12269, CoX 12137, CoX 12268, CoX 12356, CoX 12086, CoX 12546 and CoX12079 which were planted in Paddy block at Dr. Rajendra Prasad Central Agricultural University, Pusa, Bihar, in a Randomized Block Design with three replications during 2014 - 15 under water logging condition (water depth 45 to 60 cm from July to October).

Observations were record by selecting five random plants per genotype per replication for productive characters *namely*, germination % at 45 DAP, number of shoots at 120 DAP, plant height at 150, 240 and 360 days, cane diameter at harvest, number of millable canes, brix, pol and purity % at 10 and 12 month stage, single cane weight, number of aerial roots/ node, length of aerial root, dry weight of aerial roots during the water-logging period and cane yield.

Brix % at 10 and 12 month stage

It is a measure of total soluble solids present in the juice. It was taken directly by using a Brix hygrometer. 250 ml juice was taken in measuring cylinder and hygrometer dip into the juice then reading was recorded from the

juice level. These readings were corrected to the temperature at 20 °by using temperature correction chart as described by Spencer and Meade (1955).

Pol % at 10 and 12 month stage

Pol refers to the sucrose per cent in juice. It was done according to the method described by Spencer and Meade (1955). It was estimated with the help of Polari scope. First 100 ml juice was taken in conical flask and 4 gm Honey dry lead sub acetate was added and mixed well by shaking the flask. After few minutes this solution was filtered twice through a dry Whatman no. 1 filter paper and the abstract was collected into a clean and dry beaker. The abstract poured into the Polari meter tube. These tubes were placed in the Polari scope. Thereafter Pol values were recorded by polarising the clear juice in Polari scope this value called dial reading. Sucrose per cent in juice was obtained by referring the brix and dial reading to Schmitz's table. Observed data for all the traits of 18 high sucrose containing sugarcane clones were assessed for statistical analysis.

Results and Discussion

Variability is measure by estimation of genotypic and phenotypic variance, genotypic and phenotypic coefficient of variation (GCV and PCV), heritability, genetic advance and genetic advance as per cent of mean. These parameters help in selection for improvement of desired characters. Environment plays an important role in the expression of phenotype. The phenotypic variability which is observable includes both genotypic (heritable) and environmental variation (non-heritable).

The analysis of variance (Table 1) showed highly significant differences for almost all the eighteen high sucrose containing clones for 14 traits in water-logging condition. This indicated that there is presence of sufficient

variability in the material studied for water-logging condition. The mean sum of square due to treatments was found highly significant for all the traits except germination per-cent at 45 DAP, plant height at 150 days, purity per cent at 10 month stage, purity per cent at 12 month stage under water logging condition, these traits exhibit significant differences. Thus, it implied that there is reasonably sufficient variability in material used for their study, which provides ample scope for selecting superior and desire clone by the plant breeder for further improvement. Many earlier workers Doule and Balasundaram (2003), Singh *et al.*, (2010) reported high variability for different traits in sugarcane. To decipher the amount of existing variability in the present clones, range, mean and standard error were calculated (Table 2) However, range is the crude method of estimation of variability, which indicates observed phenotypic variability only. From the perusal

of table 3, it is observed that phenotypic variances for all the characters under study are higher than genotypic variances. This may be due to the non-genetic factor which played an important role in the manifestation of these characters. Comparatively the maximum phenotypic and genotypic variances were exhibited by the traits *viz.* plant height at 240 and 360 days, cane yield, number of millable canes, number of shoots at 120 DAP, plant height at (150) days, length of aerial roots, germination per cent at 45 DAP, number of aerial roots/ node. These findings were in accordance of Ravishankar *et al.*, (2004) for cane yield/ plot and number of millable cane/ plot. The numerical value of phenotypic coefficient of variation is higher than their genotypic counterpart indicating that apparent variation is not only due to genotypes but also due to influence of environment. The narrow difference between PCV and GCV were recorded for most of the traits.

Table.1 Analysis of variance for eighteen traits in high sucrose containing sugarcane clones under water-logging condition

Sl. No.	Character	Mean sum of square		
		Replication (d.f.=2)	Treatment (d.f.=17)	Error (d.f.=34)

Table.3 genetic parameters for eighteen characters in high sucrose containing Sugarcane clones under water-logging condition

Sl. No	Characters	σ^2G	σ^2P	GCV	PCV	h^2 (bs)	GA M
1.	Germination per cent at DAP	4.99	17.16	6.50	12.04	29	7.22
2.	Number of shoots at 120 DAP (000/ ha)	30.71	73.81	4.43	6.86	42	5.88
3.	Plant height at 150 days (cm)	21.72	64.83	4.23	7.31	34	5.05
4.	Plant height at 240 days (cm)	325.25	434.07	10.03	11.58	75	17.88
5.	Plant height at 360 days (cm)	324.70	431.64	9.48	10.93	75	16.93
6.	Cane diameter at harvest (cm)	0.08	0.14	11.97	15.91	57	18.55
7.	Number of millable canes (000/ ha)	31.49	89.37	6.80	11.46	35	8.32
8.	Single cane weight (kg)	0.01	0.01	11.68	14.46	65	19.43
9.	Brix at 10 month (%)	0.64	0.80	4.37	4.90	80	8.03
10.	Pol at 10 month (%)	0.40	0.71	3.90	5.21	56	6.01
11.	Purity at 10 month (%)	1.37	6.35	1.33	2.86	22	1.27
12.	Brix at 12 month (%)	1.76	1.93	7.24	7.58	91	14.27
13.	Pol at 12 months (%)	1.74	1.90	8.18	8.54	92	16.12
14.	Purity at 12 month (%)	1.23	4.95	1.26	2.53	25	1.30
15.	Number of aerial roots/ node	6.17	11.29	18.69	25.28	55	28.46
16.	Length of aerial roots (cm)	27.16	32.69	29.85	32.75	83	56.05
17.	Dry weight of aerial roots (g)	2.93	4.96	49.21	64.45	59	79.42
18.	Cane yield (t/ ha)	47.17	103.98	9.88	14.67	45	13.71

Among morphological characters of clones higher phenotypic and genotypic coefficient of variation were recorded for dry weight of

aerial roots, length of aerial roots, number of aerial roots/ node The magnitude of phenotypic and genotypic coefficient of

variations were moderately higher order for number of cane diameter at harvest, cane yield, single cane weight, germination per cent at 45 DAP, plant height at 240 days, number of millable canes and plant height at 360 days. The PCV and GCV of qualitative characters like brix, pol and purity per cent at 10 and 12 months were comparatively of lower magnitude. The high heritability in broad sense was recorded for pol per cent at 12 month stage, followed by brix per cent at 12 month stage, length of aerial roots, brix per cent at 10 month stage, plant height at 240 days, plant height at 360 days and single cane weight while dry weight of aerial roots, length of aerial roots and number of aerial roots/node exhibited high genetic advance as per cent of mean.

In conclusion, High heritability coupled with high genetic advance as percent of means was observed for Length of aerial roots, suggesting the preponderance of additive genetic effect in the determination of these characters. It also indicated that selection for these characters will be effective for future improvement of clones under water logged condition. However, high heritability with moderate genetic advance as percent of means was observed Plant height at 240 days, plant height at 360 days, pol per cent at 12 month stage and single cane weight indicating the role of dominant genetic effects in determination of these characters and it require careful selection for the desired improvements in the characters.

Acknowledgement

Authors are thankful to Sugarcane Research Institute Pusa, Samastipur for providing suitable sugarcane clones for water-logged condition and all the members of Department of Genetics and Plant Breeding for their encouragement, support and providing necessary facilities.
