

**Experimental Evaluation of TCP
Performance and Fairness in an 802.11e
Test-bed**

802.11b TCP Performance

12 uploads

6 up, 6 down

Have proposed fixes, want to test in practice.

802.11(e) Summary

- After TX choose $\text{rand}(0, CW_{\min} - 1)$.
- Wait until medium idle for DIFS($50\mu s$),
- While idle count down in slots ($20\mu s$).
- TX when counter gets to 0, ACK after SIFS ($10\mu s$).
- If ACK then $CW = CW_{\min}$ else $CW* = 2$.

Ideally produces even distribution of packet transmissions.

In 11e have multiple queues. Each has own CW_{\min} , DIFS(aka AIFS) and can have TXOP.

Why use a testbed?

- Can we believe ns?
Bugs: aCCATime, virtual collisions.
- Can we believe the standard?
- Can we believe models?
- What are the practical issues?

Testbed setup

Number of identical stations (Linux) connection to AP (Linux hostap).

1× AP	Dell GX 280	2.8Ghz P4
12× STA	Soekris net4801	266Mhz 586
WLAN	D-Link DWL-G520	Atheros AR5212

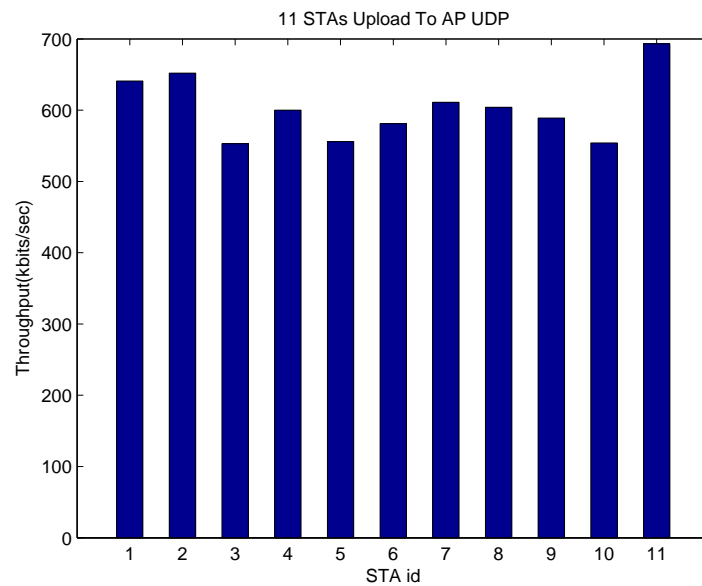

Cards have external antenna, PCI interface, Madwifi driver with local patches for 11e parameter setting.

MGEN and iperf used for traffic generation.

Practical Issue: Calibration

UDP up

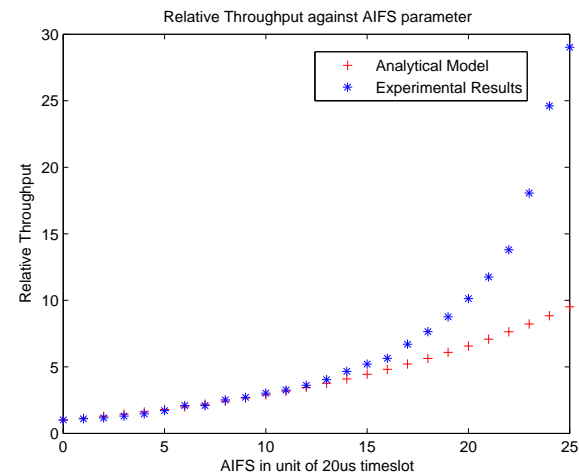

TCP up

Small changes until well behaved.

Validation

Measure relative performance of two saturated flows while varying TXOP, AIFS and CW_{\min} . Compare to well-known models.

Proposed settings

		AIFS (slots)	CW _{min}	TXOP (packets)
AP	Upload ACKs	0	4	1
	Download data	4	32	n_d
wireless	Download ACKs	0	32	1
station	Upload data	4	32	1

Derived using analytical modeling and ns.

Will they work in practice?

6 up, 6 down

Conclusions

- Small operational testbed.
- Hardware seems to behave as expected.
- Radio issues can be amplified by other issues.
- 11e can be used to combat MAC/TCP issues.
- Now looking at mixed voice/data networks.
