## 1. Introduction

With the fast advancement of electronic technologies, electromagnetic waves have been widely applied in the areas of advanced detectors, radio communications, and military weapons [1, 2], which causes grievous electromagnetic pollution [3, 4].

Wave-absorbing materials can effectively absorb incident electromagnetic waves, converting them into heat or other energy, and have received extensive attention [5, 6]. Wave-absorbing materials are usually composed of matrix materials (*e.g.* paraffin [7], polymers [8], and wave-transparent ceramics [9]) for the transmission of electromagnetic waves and the introduced absorbents (magnetic loss absorbents [10] and dielectric loss absorbents [11]) for the absorption of electromagnetic waves.

Magnetic loss absorbents (such as ferrites [12], carbonyl metals [13], and magnetic metals [14], *etc*) present excellent wave-absorbing performances in relatively low frequency band. However, their practical applications in wave-absorbing field are greatly restricted by high density, easy oxidation, and magnetic agglomeration [15]. Besides, the existing magnetic materials hardly have magnetic response to the high frequency band between 8.2 and 12.4 GHz [16, 17]. In comparison, dielectric loss absorbents (*e.g.*, carbon nanotube (CNT) [18], graphene [19], amorphous carbon [20], ZnO [21], BaTiO<sub>3</sub> [22], and TiO<sub>2</sub> [23], *etc*) have the advantages of low density, high thermal stability, and high dielectric constant value [24, 25]. CNT has attracted much attention in recent years due to its excellent electrical & thermal conductivity, and outstanding mechanical properties [26, 27]. Micheli *et al.* [28] fabricated epoxy resin (EP)/single-walled carbon nanotube (SWCNT) composites by blending-casting method. While the composites contained 3 wt% of SWCNT and with the thickness of 9.7 mm, it displayed the minimum reflection loss (RL<sub>min</sub>) of -19.0 dB and an effective

1 absorption bandwidth (EAB) of 1.7 GHz. Kong *et al.* [29] prepared silicone resin  
2 (PDMS)/multi-walled carbon nanotube (MWCNT) composites. It was found that  
3  
4 when the content of MWCNT was 5 wt% and the thickness was 2.75 mm, the  $RL_{\min}$   
5 and EAB of the composites were -10.0 dB and 0 GHz, respectively. It can be seen that  
6  
7 pure single CNT is insufficient to endow the materials with high wave-absorbing  
8  
9 ability, mainly attributed to the fact that the conductivity ( $\sigma_{dc}$ ) of pure single CNT is  
10  
11 too high to ensure both the real part ( $\epsilon'$ ) and imaginary part ( $\epsilon''$ ) of dielectric constant  
12  
13 ( $\epsilon_r = \epsilon' - j\epsilon''$ ) reach optimal values [30].  
14  
15  
16  
17  
18

19 In order to obtain the wave-absorbing materials with ideal absorbing ability,  
20  
21 researchers prepared wave-absorbing materials by mixing low conductivity materials  
22  
23 with CNT as absorbents [31]. Qing *et al.* [32] fabricated MWCNT/BaTiO<sub>3</sub>/EP  
24  
25 composites employing the mixture of BaTiO<sub>3</sub> and MWCNT as absorbent. When the  
26  
27 composites contained 0.2 vol% MWCNT and 40 vol% BaTiO<sub>3</sub> (the thickness was  
28  
29 1.09 mm), the corresponding  $RL_{\min}$  and EAB reached -12.0 dB and 3.0 GHz,  
30  
31  
32 respectively. Wang *et al.* [33] prepared MWCNT/ZnO/EP composites using the  
33  
34 mixture of nano-ZnO and MWCNT as absorbent. The corresponding  $RL_{\min}$  and EAB  
35  
36 were respectively -13.7 dB and 2.1 GHz when the composites (1.5 mm in thickness)  
37  
38 contained 12 wt% MWCNT and 8 wt% nano-ZnO. Recent years, researchers have  
39  
40 found that loading materials with low conductivity on the surface of CNT can further  
41  
42 optimize the wave-absorbing performances of materials [34]. Song *et al.* [35] loaded  
43  
44 BaTiO<sub>3</sub> on the surface of MWCNT using sol-gel method to obtain BaTiO<sub>3</sub>/MWCNT  
45  
46 hybrid materials, finally to fabricate the BaTiO<sub>3</sub>/MWCNT/paraffin wave-absorbing  
47  
48 composites. When the composites contained 70 wt% BaTiO<sub>3</sub>/MWCNT (the thickness  
49  
50 was 1.4 mm), the  $RL_{\min}$  and EAB were -34.4 dB and 3.5 GHz, respectively. Song *et al.*  
51  
52 [36] prepared ZnO/MWCNT/paraffin wave-absorbing composites from  
53  
54  
55  
56  
57  
58  
59

1 ZnO/MWCNT hybrid materials, which was made by co-precipitation method to coat  
2 ZnO on the surface of MWCNT. The  $RL_{\min}$  of the composites with 40 wt%  
3 ZnO/MWCNT (the thickness was 3.0 mm) reached -30.0 dB and the EAB almost  
4 covered the entire X-band.  
5  
6  
7

8  
9 **TiO<sub>2</sub> with** low conductivity and amorphous carbon in wave-absorbing field have been  
10 discovered due to their light weight, easy fabrication, and excellent chemical stability  
11 [37, 38]. Wan *et al.* [39] synthesized TiO<sub>2</sub>@C core-shell nanocrystals by acetylene  
12 decomposition method, which was used to prepare wave-absorbing composites  
13 applying paraffin **as matrix**. When the thickness of the composites was 2.0 mm and  
14 contained 60 wt% of MWCNT, the  $RL_{\min}$  and EAB reached -16.2 dB and 4.0 GHz,  
15 respectively. Song *et al.* [40] **fabricated** wave-absorbing composites with paraffin as  
16 matrix from highly ordered porous carbon (HOPC) synthesized *via* template method.  
17  
18

19 **When** the composites contained **5 wt% HOPC** and **the** thickness was 2.0 mm, the  
20  $RL_{\min}$  and EAB were -18.0 dB and 4.5 GHz, respectively. Nevertheless, there are few  
21 reports on the optimization of dielectric properties achieved through constructing the  
22 **hetero-structures** by combining CNT, TiO<sub>2</sub>, and amorphous carbon.  
23  
24

25  
26 In our present work, ternary heterogeneous MWCNT@TiO<sub>2</sub>-C absorbent was  
27 prepared using titanium isopropoxide, glucose, and MWCNT as raw materials by  
28 solvothermal process followed by post-heat treatment. Afterwards,  
29 MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites were obtained through  
30 solution casting approach. **Microstructures** and morphologies for MWCNT@TiO<sub>2</sub>-C  
31 were analyzed applying X-ray diffraction (XRD), Raman spectra, X-ray photoelectron  
32 spectroscopy (XPS), and transmission electron microscopy (TEM). In addition, the  
33 mass fraction of **ternary heterogeneous MWCNT@TiO<sub>2</sub>-C fillers** affecting on the  
34 electrical **conductivities, electromagnetic & wave-absorbing performances and**

## 6 7 **2. Experiments**

### 8 9 **2.1 Preparation of ternary heterogeneous MWCNT@TiO<sub>2</sub>-C fillers**

10  
11 1 mL titanium isopropoxide, 0.08 g MWCNT, and 0.2 g glucose were uniformly  
12 dispersed in 15 mL ethanol under sonication. The reaction mixture was subsequently  
13 transferred to a 50 mL autoclave and reacted at 180°C for 40 hrs. After cooled to  
14 ambient temperature, the reaction mixture was processed by centrifuge and the  
15 obtained sludge was then washed using ethanol for several times. The obtained solid  
16 was dried at 75°C for 24 hrs, which was then heated to 500°C at a heating rate of  
17 5°C/min and treated at 500°C for another 3 hrs under Ar atmosphere, finally to obtain  
18  
19 the ternary heterogeneous MWCNT@TiO<sub>2</sub>-C fillers.

### 31 **2.2 Preparation of MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing** 32 33 **composites**

34  
35 Silicone rubber (RTV 107) and appropriate amount of MWCNT@TiO<sub>2</sub>-C fillers were  
36 dissolved in *n*-hexane and mechanically stirred for 24 hrs. Tetraethyl orthosilicate (5  
37 wt% of silicone rubber) was introduced into the above mixture, followed by stirring  
38 for another 1 hr. Consequently, the reaction mixture was poured into a mold at 50°C.  
39  
40 Finally, the obtained mixture was cured at room temperature for 24 hrs, to obtain the  
41 MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites. Prepared samples  
42 were named according to the amount of MWCNT@TiO<sub>2</sub>-C used for fabricating the  
43 composites to be S0, S5, S15, S25, and S35, in responding to the content of 0 wt%, 5  
44 wt%, 15 wt%, 25 wt%, and 35 wt%, respectively.

### 3. Results and discussion

#### 3.1 Ternary heterogeneous MWCNT@TiO<sub>2</sub>-C fillers

**Fig. 1** showed the TEM and SAED images of MWCNT and MWCNT@TiO<sub>2</sub>-C. **Pristine** MWCNT displayed clear lattice **fringes** (**Figs. 1(a, a')**). And the corresponding SAED image (**Fig. 1(a'')**) presented the diffraction rings of (002) and (101) crystal planes. For MWCNT@TiO<sub>2</sub>-C (**Figs. 1(b, b')**), **TiO<sub>2</sub> nanocrystals** were attached **onto** the surface of MWCNT and amorphous carbon (around 5 nm in thickness) was covered on the outermost layer of MWCNT@TiO<sub>2</sub>-C. Meanwhile, apart from the diffraction rings of MWCNT, diffraction rings of anatase TiO<sub>2</sub> (004) and (200) crystal planes also **appeared** (**Fig. 1(b'')**), indicating TiO<sub>2</sub> nanocrystals were sandwiched between outer amorphous carbon and inner MWCNT [41]. **On one hand**, glucose could promote the *in-situ* growth of TiO<sub>2</sub> nanocrystals **onto** the surface of MWCNT. On the other hand, amorphous carbon **from** the carbonization of glucose could restrict the growth of TiO<sub>2</sub> nanocrystals during solvothermal and annealing **process**. Consequently, the nano-sized TiO<sub>2</sub> crystals were generated [42]. As shown in **Figs. 1(b'-1, b'-2, and b'-3)**, MWCNT@TiO<sub>2</sub>-C possessed multiple heterogeneous interfaces, beneficial to the attenuation of electromagnetic waves induced by interfacial polarization [43].

XRD patterns of MWCNT and MWCNT@TiO<sub>2</sub>-C were **shown** in **Fig. 2(a)**. **MWCNT** presented the peak (002) of graphite at 26.4° [44]. In comparison, apart from the peak (002), **the diffraction** peaks at 25.3°, 37.8°, 48.0°, 54.8°, 62.6°, 68.8°, 70.3°, and 75.2° in respective to the (101), (004), (200), (211), (204), (116), (220), and (215) crystal planes of anatase TiO<sub>2</sub> also appeared **for** MWCNT@TiO<sub>2</sub>-C, suggesting the TiO<sub>2</sub> nanocrystals were successfully introduced onto the surface of MWCNT. Moreover,

1 the wide background peak (in the region of 20-35°) observed for MWCNT@TiO<sub>2</sub>-C  
2 indicated the existence of amorphous carbon layers. **Fig. 2(b)** depicted the Raman  
3 spectra of MWCNT and MWCNT@TiO<sub>2</sub>-C. Both D peak at 1347 cm<sup>-1</sup> (disordered  
4 carbon) and G peak at 1580 cm<sup>-1</sup> (sp<sup>2</sup> hybrid graphite carbon) were observed for  
5 MWCNT. In addition to the D and G peaks, the characteristic peaks of anatase TiO<sub>2</sub> at  
6 395 (B<sub>1g</sub>), 513 (A<sub>1g</sub>), and 635 cm<sup>-1</sup> (E<sub>g</sub>) appeared as well for MWCNT@TiO<sub>2</sub>-C [45].  
7 According to Gaussian-Lorentzian fitting, the intensity ratio of D-band/G-band (I<sub>D</sub>/I<sub>G</sub>)  
8 for MWCNT was 0.2, whereas the corresponding I<sub>D</sub>/I<sub>G</sub> of MWCNT@TiO<sub>2</sub>-C was 0.5.  
9 This was mainly because the carbon layer decorated on MWCNT@TiO<sub>2</sub>-C was  
10 amorphous [41]. In addition, the existence of TiO<sub>2</sub> could also reduce the sp<sup>2</sup> carbon  
11 domains of MWCNT [46]. In **Fig. 2(c)**, the peaks at 283.1, 532.4, and 978.8 eV  
12 observed for MWCNT respectively corresponded to C 1s, O 1s, and O KLL, revealing  
13 C and O in MWCNT, consistent with the result of **Fig. S1**. For MWCNT@TiO<sub>2</sub>-C,  
14 the characteristic peaks of Ti at 35.6 (Ti 3p), 60.9 (Ti 3s), 458.4 (Ti 2p), and 565.0 (Ti  
15 2s) eV also appeared. In **Fig. 2(c')**, MWCNT consisted of the peaks at 532.0, 532.8,  
16 and 533.8 eV, respectively corresponding to C=O, COO-, and C-OH [47, 48]. These  
17 oxygen-containing functional groups ensured the homogeneous dispersion of  
18 MWCNT in ethanol, beneficial to the formation of MWCNT@TiO<sub>2</sub>-C. Compared  
19 with MWCNT, the new peak of O 1s (**Fig. 2(c'')**) at 530.6 eV and the peaks of Ti 2p  
20 (**Fig. 2(c''')**) at 459.3 and 464.8 eV observed for MWCNT@TiO<sub>2</sub>-C revealed the  
21 success formation of TiO<sub>2</sub> on the surface of MWCNT [49].

### 3.2 MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites

22 **Fig. 3(a)** showed the effect of MWCNT@TiO<sub>2</sub>-C content on the electrical  
23 conductivity ( $\sigma_{dc}$ ) values of the MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing  
24 composites. The  $\sigma_{dc}$  value of pure silicone rubber (S0) was only 6.5×10<sup>-10</sup> S/m. While  
25  
26  
27  
28  
29  
30  
31

35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50

1 the amount of MWCNT@TiO<sub>2</sub>-C fillers was 5 wt% (S5), the  $\sigma_{dc}$  value reached up to  
2  $9.9 \times 10^{-4}$  S/m. As the content of MWCNT@TiO<sub>2</sub>-C fillers further increased to 35 wt%  
3 (S35), the corresponding  $\sigma_{dc}$  value reached the maximum of 0.6 S/m. This was  
4 because the MWCNT@TiO<sub>2</sub>-C fillers were randomly distributed inner silicone rubber  
5 matrix at lower MWCNT@TiO<sub>2</sub>-C content. Therefore, a small amount of conductive  
6 channels was formed, resulting in the increase of the  $\sigma_{dc}$  value. With the further  
7 introduction of MWCNT@TiO<sub>2</sub>-C fillers, more effectively conductive networks were  
8 formed, leading the further increase of  $\sigma_{dc}$  value [50]. Fig. 3(b) presented the complex  
9 permeability ( $\mu_r = \mu' - j\mu''$ ) of the MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing  
10 composites. For all composites, the real part ( $\mu'$ ) and imaginary part ( $\mu''$ )  
11 approximated to 1 and 0, respectively. And there was no obvious change for  $\mu'$  and  $\mu''$   
12 in the whole X-band (Permeability was mainly reflected in the low frequency band,  
13 and materials hardly had magnetic response in the high frequency band). As a result,  
14 the magnetic properties and losses of our fabricated composites could be ignored. The  
15 complex permittivity ( $\varepsilon_r = \varepsilon' - j\varepsilon''$ ) and dielectric loss tangent ( $\tan\delta$ ) values of the  
16 composites were depicted in Figs. 3(c-f). The average values of real part ( $\varepsilon'$ ),  
17 imaginary part ( $\varepsilon''$ ), and loss tangent ( $\tan\delta$ ) for S0 was 2.88, 0.07, and 0.02,  
18 respectively. With increasing the mass fraction of MWCNT@TiO<sub>2</sub>-C fillers,  $\varepsilon'$ ,  $\varepsilon''$ ,  
19 and  $\tan\delta$  values all showed incremental trend. For instance, the average values of  $\varepsilon'$   
20 increased to 4.21, 5.74, 8.29, and 11.57 for S5, S15, S25, and S35, respectively, while  
21 the average values of  $\varepsilon''$  increased to 1.03, 1.93, 3.13, and 5.08, respectively. Besides,  
22 the average value of  $\tan\delta$  was increased to 0.25, 0.34, 0.38, and 0.44, respectively.  
23  
24 Firstly, with increasing the addition of MWCNT@TiO<sub>2</sub>-C fillers, more effectively  
25 conductive networks were formed (Fig. 3(a)), which would improve the dielectric  
26 properties of the composites. Secondly, introducing the MWCNT@TiO<sub>2</sub>-C fillers

1 could generate many heterogeneous interfaces. Under the external electromagnetic  
2 field, the charges would accumulate at the heterogeneous interfaces and result in the  
3 interfacial polarization relaxation, which would improve the dielectric properties [51].  
4 Polarization relaxation could be studied via Debye relaxation theory (Eq.1), and the  
5 plot of  $\epsilon'$  versus  $\epsilon''$  would be one single semicircle (Cole-Cole semicircle), in which  
6 each semicircle represented one Debye relaxation process [29].

$$\left(\epsilon' - \frac{\epsilon_s - \epsilon_\infty}{2}\right)^2 + (\epsilon'')^2 = \left(\frac{\epsilon_s - \epsilon_\infty}{2}\right)^2 \quad (\text{Eq.1})$$

18 Where  $\epsilon_\infty$  and  $\epsilon_s$  represent relative dielectric permittivity at high frequency limit and  
19 static permittivity, respectively.

23 **Fig. 4** demonstrated the Cole-Cole curves of the MWCNT@TiO<sub>2</sub>-C/silicone rubber  
24 wave-absorbing composites (S5-S35). There was no obvious Cole-Cole semicircle for  
25 S5, which was mainly attributed that the content of MWCNT@TiO<sub>2</sub>-C fillers was too  
26 low to have obvious effects on the dielectric properties of the composites. However,  
27 there were at least four obvious Cole-Cole semicircles in S15, S25, and S35,  
28 corresponding from many heterogeneous interfaces (interfaces between MWCNT and  
29 amorphous carbon, MWCNT and TiO<sub>2</sub>, TiO<sub>2</sub> and amorphous carbon, and amorphous  
30 carbon and silicone rubber).

31 **Fig. 5(a)** demonstrated the reflection loss (RL, calculated according to Eqs. S1-2)  
32 values of the MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites (S0-S35)  
33 with the thickness of 2.5 mm at X-band. Wave-absorbing performance of S0 was very  
34 poor. With increasing the amount of MWCNT@TiO<sub>2</sub>-C fillers, the wave-absorbing  
35 ability of the composites increased firstly before showing a decreased trend. When the  
36 content of MWCNT@TiO<sub>2</sub>-C fillers was 25 wt%, the composites exhibited the  
37 optimal wave-absorbing performance by showing the minimum RL<sub>min</sub> of -53.2 dB and  
38

1 EAB of 3.1 GHz. Firstly, the impedance matching of MWCNT@TiO<sub>2</sub>-C fillers could  
2 reduce the electromagnetic waves on the surface of the composites, to ensure the  
3 unhindered entry of electromagnetic waves [52]. Secondly, the dielectric loss  
4 generated by MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites could  
5 attenuate electromagnetic waves that entered the composites [53]. However, with the  
6 further addition of MWCNT@TiO<sub>2</sub>-C fillers, the deviated dielectric constant of S35  
7 from the optimal value caused the impedance difference, which would result in strong  
8 electromagnetic waves reflecting on the surface of the composites [53]. Therefore, the  
9 wave-absorbing performance was deteriorated and the respective RL<sub>min</sub> and EAB  
10 were only -24.0 dB and 1.95 GHz, respectively.

11 **Fig. 5(b)** showed the RL values of the MWCNT@TiO<sub>2</sub>-C/silicone rubber  
12 wave-absorbing composites S25 with various thicknesses. While the thickness of the  
13 sample was less than 2.5 mm, the wave-absorbing performances of S25 were  
14 gradually improved as the thickness increased. As the thickness reached 2.5 mm, the  
15 composite exhibited the optimal wave-absorbing performance, with the RL<sub>min</sub> and  
16 EAB being -53.2 dB and 3.1 GHz, respectively. However, when the thickness was  
17 more than 2.5 mm, the corresponding wave-absorbing performance of S25 gradually  
18 deteriorated. This phenomenon was attributed to the destructive interference effects.  
19 While the thickness was an odd time of a quarter of wavelength, the reflected wave  
20 phase of upper surface was inverse to that of bottom surface, thus resulting in the  
21 destructive interference effects and the effective improvement of wave-absorbing  
22 performance [52]. In our work, 2.5 mm was an odd time of a quarter of wavelength,  
23 which thus resulted in the optimal wave-absorbing ability. Compared to the  
24 wave-absorbing performances for the composites reported in other works (Table S2),  
25 our fabricated MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites also

demonstrated the optimal wave-absorbing performance.

#### 4. Conclusions

XRD, Raman, XPS, and TEM analyses demonstrated the ternary heterogeneous MWCNT@TiO<sub>2</sub>-C fillers were successfully synthesized. When the MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites contained 25 wt% MWCNT@TiO<sub>2</sub>-C fillers and with the thickness of 2.5 mm, it displayed the minimum reflection loss of -53.2 dB and the corresponding effective absorption bandwidth of 3.1 GHz. Remarkable wave-absorbing ability was mainly attributed to the synergetic effect of interfacial polarization loss and conduction loss. Our fabricated MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites possess potential applications in the field of electromagnetic protection.

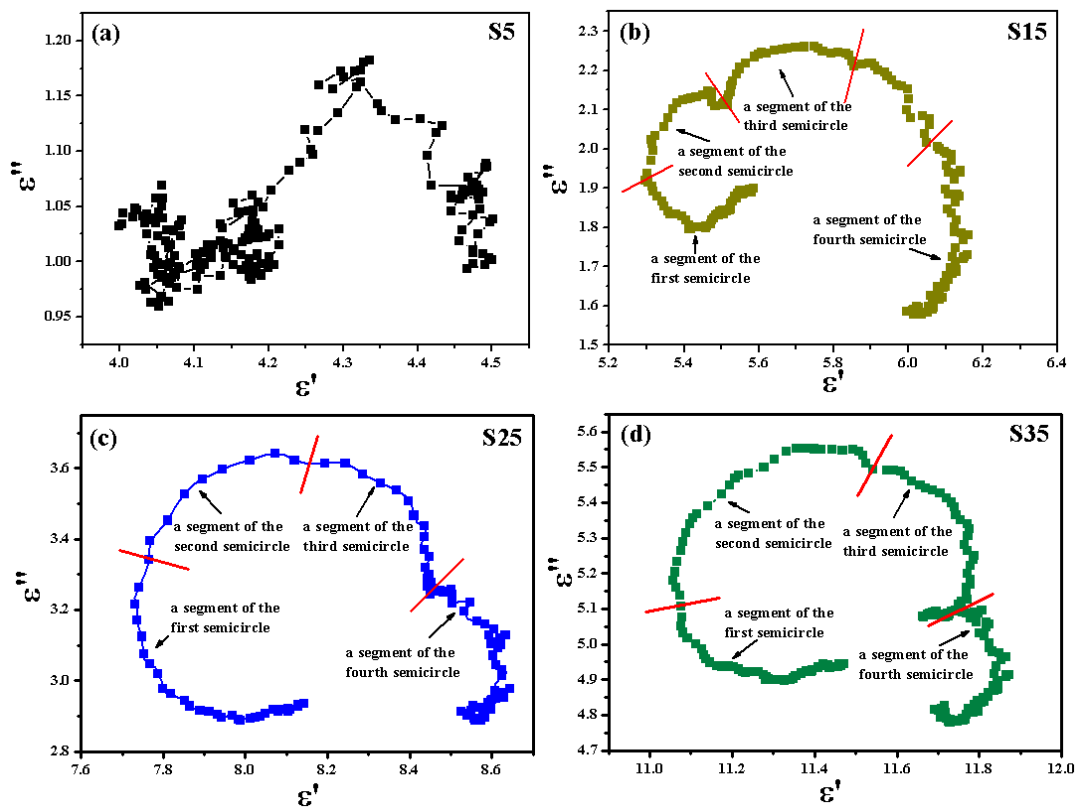

**Fig. 1** TEM images of MWCNT (a) and MWCNT@TiO<sub>2</sub>-C (b); HRTEM images of MWCNT (a') and MWCNT@TiO<sub>2</sub>-C (b'); SAED patterns of MWCNT (a'') and MWCNT@TiO<sub>2</sub>-C (b''); b'-1, b'-2, and b'-3 represent the magnified TEM images of regions marked with red rectangles 1, 2, and 3 in b', respectively.

**Fig. 2** XRD (a), Raman (b), and XPS wide-scan spectra (c) of MWCNT and MWCNT@TiO<sub>2</sub>-C; O 1s high resolution XPS spectra of MWCNT (c') and MWCNT@TiO<sub>2</sub>-C (c''); Ti 2p high resolution XPS spectra of MWCNT@TiO<sub>2</sub>-C (c''').

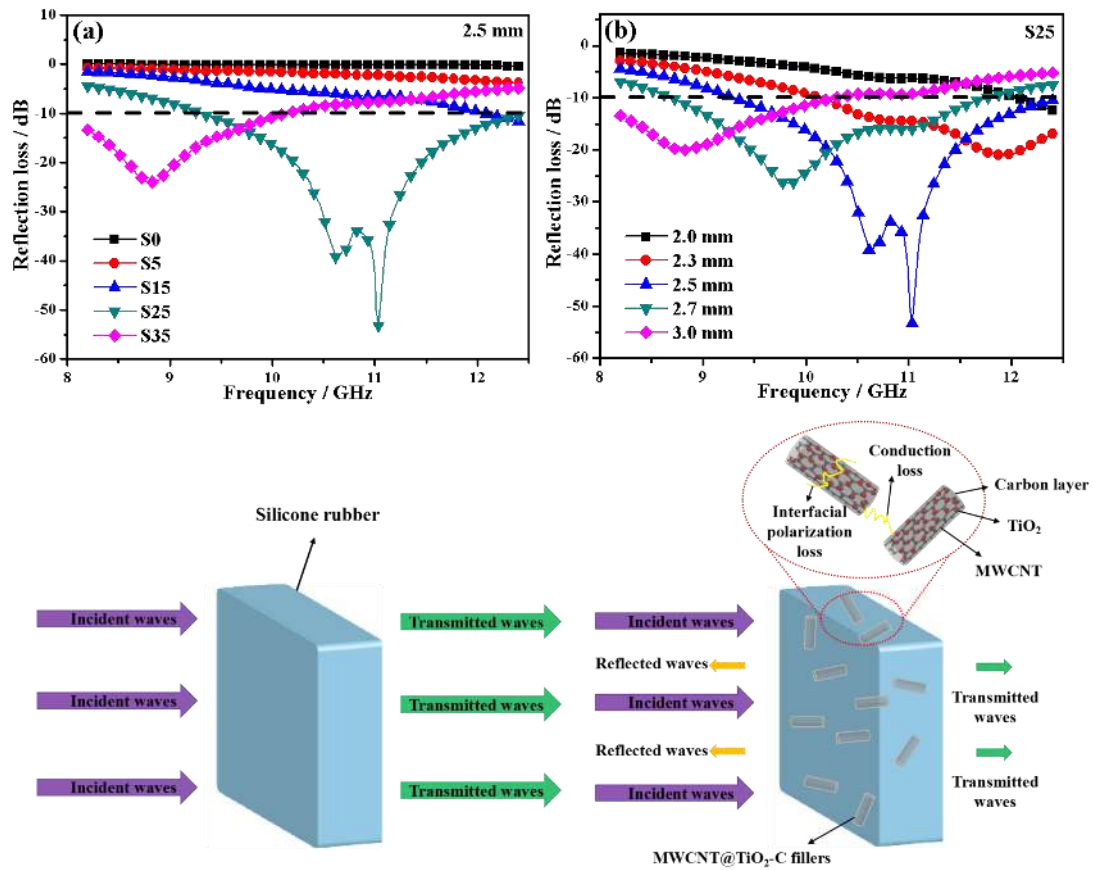

**Fig. 3** Electrical conductivity (a), complex permeability (b), real permittivity (c), imaginary permittivity (d), dielectric loss tangent (e), and average value of complex permittivity (f) for MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites.

**Fig. 4** Cole-Cole curves of MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites (S5-S35).

**Fig. 5** Reflection loss values of the MWCNT@TiO<sub>2</sub>-C/silicone rubber wave-absorbing composites (a); Reflection loss values for S25 with different thicknesses (b); Schematic illustration of electromagnetic waves absorption mechanism (c).

## Conflict of Interest

We wish to confirm that there are no known conflicts of interest associated with this publication and there has been no significant financial support for this work that could have influenced its outcome.

We confirm that the manuscript has been read and approved by all named authors and that there are no other persons who satisfied the criteria for authorship but are not listed.

We further confirm that the order of authors listed in the manuscript has been approved by all of us.

We confirm that we have given due consideration to the protection of intellectual property associated with this work and that there are no impediments to publication, including the timing of publication, with respect to intellectual property. In so doing we confirm that we have followed the regulations of our institutions concerning intellectual property.

We understand that the Corresponding Author is the sole contact for the Editorial process (including Editorial Manager and direct communications with the office). Junwei Gu is responsible for communicating with the other authors about progress, submissions of revisions and final approval of proofs. We confirm that we have provided a current, correct email address which is accessible by the Corresponding Author and which has been configured to accept email from [gjw@nwpu.edu.cn](mailto:gjw@nwpu.edu.cn) & [nwpugjw@163.com](mailto:nwpugjw@163.com).

Signed by all authors as follows:

Jia Zhao Junliang Zhang Lei Wang Shanshan Yu, Wenlong Ye  
Ben Bin Xu, Huqiu Lixin Chen, Junwei Gu.

## Author Contribution Statement

**Jia Zhao:** Conceptualization, Fabrication on the MWCNT@TiO<sub>2</sub>-C fillers, Writing- Original draft preparation

**Junliang Zhang:** Composites fabrication, Writing- Original draft preparation

**Lei Wang:** Mechanism analysis

**Shanshan Lyu:** Methodology

**Wenlong Ye:** Data curation

**Ben Bin Xu:** Writing- Reviewing and Editing

**Hua Qiu:** Performance tests

**Lixin Chen:** Supervision

**Junwei Gu:** Supervision
