Abstract: Due to the openness and easy accessibility of online social media (OSM), anyone can easily contribute a simple paragraph of text to express their opinion on an article that they have seen. Without access control mechanisms, it has been reported that there are many suspicious messages and accounts spreading across multiple platforms. Accordingly, identifying and labeling fake news is a demanding problem due to the massive amount of heterogeneous content. In essence, the functions of machine learning (ML) and natural language processing (NLP) are to enhance, speed up, and automate the analytical process. Therefore, this unstructured text can be transformed into meaningful data and insights. In this paper, the combination of ML and NLP are implemented to classify fake news based on an open, large and labeled corpus on Twitter. In this case, we compare several state-of-the-art ML and neural network models based on content-only features. To enhance classification performance, before the training process, the term frequency-inverse document frequency (TF-IDF) features were applied in ML training, while word embedding was utilized in neural network training. By implementing ML and NLP methods, all the traditional models have greater than 85% accuracy. All the neural network models have greater than 90% accuracy. From the experiments, we found that the neural network models outperform the traditional ML models by, on average, approximately 6% precision, with all neural network models reaching up to 90% accuracy.

Keywords: fake news; machine learning; neural networks; Word2Vec

1. Introduction

Fake news is becoming a common term in the human vocabulary [1,2]. Misinformation continues rife with the use of clickbait stories and polarizing videos, usually distributed over OSM and mainstream news [3]. How much the news impacts our lives can be seen with recent world events. From knowing what is going on with the pandemic to the stock market rally, everyone relies heavily on the news. Headlines, blogs, and social media messages can come across, intentionally misleadingly for several different reasons. They may seek to manipulate elections or policies; they may be a form of cyber combat between states; they may attempt to increase the popularity and power of someone or undermine their opponents. Perhaps they could only make money to produce ad revenue [4].

Some researchers have considered linguistic characteristics to detect false news. Marquardt, D. [5] stated that a significant difference between the true and fake corpora is in the noun-to-verb ratio. In real news, the ratio is higher at an average of 4.27 compared to the fake news corpus at 2.73. The true news corpus has an average of 20.5 word features, whereas the fake news corpus is 14.3 words. Moreover, Fatemeh Torabi Asr [6,7] found that

fake newspapers, on average, use more terms linked to sex, death, and terror. The terminology is also excessively dramatic. In contrast, Genuine News contains a more significant proportion of work (business)- and money (economy)-related words. Hancock et al. [8] analyzed 242 manuscripts and found that liars produced extra words and sense-based words, such as seeing and touching. Additionally, they used more other-oriented pronouns than self-oriented pronouns when lying compared to telling the true pronoun. Rashkin et al. [9] studied the association between specific types of grammar and false news. They concluded that words that can be used to exaggerate in deliberately misleading sources are all found more often. Such contained “best” and “bad” superlatives and so-called subjective, such as brilliant and terrible. The misinformation appears to use vague generalities such as reality and democracy. Additionally, it intriguingly found that the use of the second-person pronoun you is directly related to false news. Jack Grieve [10] notes that academics do not necessarily monitor the genre, and the linguistic variations seen above may only result in the gap between a more formal news story and a more informal Facebook post.

However, with the enormous amount of news that is continually growing day by day, it is difficult to have a reliable way of identifying fake news [11]. In this case, we may need to depend on artificial intelligence (AI) to do the heavy work for us—and tell us if there are unmistakable linguistic patterns. In this paper, we illustrated and implemented a fake news classification with multiple machine learning algorithms based on content level from a large open labeled corpus. The contributions of this paper are listed as follows:

- NLP is combined with traditional ML to build an AI model to classify labeled fake news;
- We compare seven models to find the best model between traditional ML and neural network algorithms on an open public dataset based on content-level features.

The remainder of this work is organized as follows. Section 2 shows the literature review. In Section 3, the system design and implementation are presented. The experimental results are shown in Section 4. The discussion is also presented in this section. Finally, the concluding remarks are given in Section 5.

2. Methods

This section discusses the theories used in this work. The detailed related works are listed in the following subsection.

2.1. Natural Language Processing (NLP)

Natural language processing (NLP) is a subdiscipline of linguistics, computer science, artificial intelligence, and information engineering focusing on bridging the communication between humans and computers. Computers are used to grasp human language through NLP. Natural language relates to spoken and written human language, in which NLP tries to derive information from spoken and written words using algorithms. NLP includes active and passive forms of natural language generation that have the capacity to develop phrases that humans can emit. In addition, NLP has the ability to construct a phrase understanding, what the phrase words refer to, and their meaning [12,13].

2.2. Tokenization

The first thing to do for data preprocessing is Tokenization. Tokenization effectively splits an expression, a sentence, a paragraph, or even a whole document into fine-grained units, for example, individual vocabulary, prefix or terms. Each smaller group is called tokens. Tokenization needs to recognize the words that constitute a string of characters before processing a natural language. That is why Tokenization is the essential step for NLP (text data) to proceed. It is crucial, as an interpretation of the words found in the language might quickly translate the context of the document [14]. The probability of randomly selecting a nonrelevant usage (denoted by \bar{r}) of term t is read as the residual quantity $\log_p(\bar{r}|ted)$ in the fundamental ranking formula. They demonstrate mathematically that

the IDF can be approximated. Using four reference Text REtrieval Conferences (TREC) data collections, they show that the calculation is connected to IDF empirically [15].

2.3. Term Frequency-Inverse Document Frequency (TF-IDF)

The Term Frequency-Inverse Document Frequency (TF-IDF) concept has been applied frequently in information retrieval. The method basically evaluates the importance of a tokenized unit in a collected corpus by considering both the number of times a word appeared in a single document and the frequency with which a word has been used among all corpora. Search engines usually rely on versions of the TF-IDF weighting scheme as a critical technique in retrieving and rating the significance of a text given a keyword [16,17].

2.4. Word2Vec

In machine learning, transfer learning refers to the reuse of a previously trained model on a new problem. In this case, a machine uses knowledge from a previous assignment to improve prediction on a new task. Word2Vec is one of the critical concepts of transfer learning to better consider the relationship between word pairs in a high-dimensional vector space. Accordingly, Word2Vec turns text into a numerical form so that a word can be understood by neural networks. Similar feature extraction may also be extended to multiple domains, such as genes or DNA, social media graphs or function execution paths. To avoid the waste of computing resources, Google trained and opened the Word2Vec model, namely, GoogleNews-vectors-negative300.bin, which was trained in approximately 100 billion words [18–21].

2.5. Traditional Machine Learning (ML)

Machine learning (ML) is the process of analyzing data using algorithms, learning from the data analysis, and then making a decision or prediction about something. Instead of regular software development, the machine is trained using vast amounts of data and algorithms that provide the ability to learn how to execute the task. ML definitely came from the thoughts of the early AI community, and the algorithmic methods over the years included the study of the decision tree and inductive logic: clustering, reinforcement learning, and Bayesian networks [22].

2.5.1. Binomial Logistic Regression

A binomial logistic regression (often commonly referred to as logistic regression) estimates the possibility of an event falling into one of two types with a dichotomous dependent variable depending on a combination of independent variables that may either be constant or categorical. If the dependent variable is counted, it is a Poisson regression. Additionally, if it has more than two dependent variable types, it is a multinomial logistic regression [23].

2.5.2. Naive Bayes (NB)

The Naive Bayes classifier can be applied to solve binary classification and multi-class classification problems, simplifying the estimation of the probability for each possibility to make their measurement tractable. In Naive Bayes, the machine learning probability (P) aims to find the best hypothesis (h) from given data (d). Instead of attempting to measure the values of each $P(d_1, d_2, d_3 | h)$ attribute value, they are considered to be conditionally independent of the target value and measured as $P(d_1 | h) \times P(d_2 | h)$ [24,25]. However, the model has several disadvantages: (1) Variables are assumed to be independent; and (2) The order of variable presence does not matter.

2.5.3. Support Vector Machine (SVM)

The Support Vector Machine (SVM) was developed to find an optimal boundary to classify positive and negative data points. With a well-defined kernel function, the original data point can be mapped into a high-dimensional vector space so that features can be

extracted; therefore, SVM is regarded as an important machine learning technique in terms of classification and regression [26].

2.5.4. Random Forest (RF)

Many classification trees develop in Random Forests. The classification method places the input vector down each of the trees in the forest to classify a new object from an input vector. Every tree gives a group, and for that class, we claim the tree votes. The forest prefers the group that has the most votes. More knowledge on how they are measured helps individuals to know and use the different choices. Some of the options rely on two random forest-generated data objects [27].

2.6. Neural Networks

The algorithmic method, artificial neural networks, originated from the early machine-learning community, which mainly went over the decades. Neural networks are motivated by our knowledge of brain biology, all of which are neural interconnections. The difference is that artificial neural networks have distinct structures, links, and paths of data transmission, unlike a human brain where any neuron will link to any other neurons in a certain physical distance.

The neural network allows us to categorize untagged data based on similarities among the example inputs. They categorize the data according to a labeled dataset to train on. Furthermore, they can extract the features that are loaded to other algorithms for classification and clustering. Therefore, deep neural networks are a subdivision of machine learning, including algorithms for classification, reinforcement learning, and regression.

2.6.1. Convolutional Neural Networks (CNN)

Conventional neural networks (CNN) utilize a sliding kernel to convolute original data, being used mainly in computer vision. Since they are sensitive to the location of features for input data, they can help to filter constructive features (edges/contours), referred to by the technical phrase local invariance of translation for an image, followed by maximum pooling computing the maximum value of each convoluted feature map in each round. Accordingly, the result can be attached to fully connected neural networks.

2.6.2. Long Short Term Memory Network (LSTM)

A long short-term memory network (LSTM) is a reform of a recurrent neural network (RNN) that can learn long-term dependencies to avoid vanishing gradient problems. Hochreiter and Schmidhuber (1997) introduced them, and other people improved and popularized them in subsequent work. They perform incredibly well on a wide range of problems and are still commonly used. LSTM was deliberately designed to resolve the problem of long-term dependency. Their normal activity over long periods of time is basically to remember knowledge. Both recurrent neural networks take the form of a sequence of redundant modules in the neural network. In regular RNNs, this repeating module would have a very basic structure, for instance, a single tanh layer [28].

2.7. Model Evaluation

The model performance is measured based on the RMSE, accuracy, precision, recall, and F1 score.

2.7.1. Accuracy

Accuracy reflects the most intuitive indicator of performance, which is the ratio of correctly expected observations to total observations. Accuracy might assume when there are extremely reliable data, and then the model is best. The equation is as follows:

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{FN} + \text{TN}} \quad (1)$$

- True Negatives (TN): These are the accurately predicted negative values, meaning the current class value is no, and the expected class value is no as well;
- False Positives (FP): When the real class is negative, and the class is expected to be positive;
- False Negatives (FN): The real class is positive, but the class is expected to be negative.

2.7.2. Precision

Precision stands for the ratio of positive observations correctly predicted from all positive observations predicted. The query that this metric answers is, how much misclassification happened in each class? The low false-positive rate is related to high precision. The equation is as follows:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}. \quad (2)$$

2.7.3. Recall (Sensitivity)

The recall is the percentage of accurately expected optimistic findings to all of the real class findings—yes. The question that recall asks is: How many of all the remaining data have been labeled? The excellent score is above 0.5. The equation is as follows:

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}. \quad (3)$$

2.7.4. F1 Score

Due to the consideration of balanced precision and recall, the F1 score considers:

$$\text{F1 Score} = \frac{2 \times (\text{Recall} \times \text{Precision})}{\text{Recall} + \text{Precision}}. \quad (4)$$

2.7.5. Root Mean Square Error (RMSE)

The standard deviation of residuals (prediction errors) is the root mean square error (RMSE). Residuals are a measure of how far these data points are from the regression line. RMSE is a calculation of how many residuals are spaced out. That is, RMSE shows how clustered the data are along the best match axis. The equation is as follows:

$$\text{RMSE} = \sqrt{\frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n}}. \quad (5)$$

2.8. Related Studies

Ahmed et al. [29] developed a new n-gram model to automatically identify false content with a clear emphasis on fake comments and fake news. They implemented TF-IDF for the extraction of features and six methods for classifying machine learning: SVM, Linear Support Vector Machine (LSVM), K-nearest neighbors (KNN), Decision Tree (DT), Stochastic Gradient Descent (SGD), and LR. Their experiments demonstrate very promising and enhanced results compared with traditional approaches. The best result is LSVM at 90% accuracy.

Reis et al. [30] presented various types of news story features, including source and social media posts. They demonstrate a new set of features and measure the predictive performance of KNN, NB, RF, SVM, and XGBoost (XGB) to automatically detect fake news. The best model is XGB with 86% accuracy.

Asghar et al. [31] investigated the problem of rumor detection by exploring different models of deep learning with a focus on contextual consideration. The proposed system is bidirectional long-dependent short-term memory via a convolutionary neural network. Their experiments essentially classified tweets into rumors and nonrumors. Experimental results show that with 86.12% accuracy, the proposed method outperformed the baseline method and was more successful than the comparable approaches.

Goldani et al. [32] proposed a convolutional neural network (CNN) with margin loss and several embedding models for detecting false news. Static word embeddings are compared to nonstatic word embeddings, which allow for gradual uptraining and updating of word embeddings during the training process. Two recent well-known datasets in the field, ISOT and LIAR, are used to test their suggested designs. The results on the optimal architecture indicate promising results, exceeding state-of-the-art approaches by 7.9% on ISOT and 2.1% on the LIAR dataset test set.

Hakak et al. [33] present an ensemble classification model for detecting false news that outperforms the current state-of-the-art models in terms of accuracy. The proposed technique collects key features from false news datasets, which are then identified using an ensemble model that combines three common machine learning models: decision tree, random forest, and extra tree classifier. On the Liar dataset, they achieved training and testing accuracies of 99.8% and 44.15%, respectively. Additionally, they were able to obtain 100% training and testing accuracy with the ISOT dataset.

Umer et al. [34] proposed a hybrid neural network design that combines the capabilities of CNN and LSTM, as well as two alternative dimensionality reduction algorithms—PCA and chi-square. Before providing the feature vectors to the classifier, this work advocated using dimensionality reduction techniques to minimize their dimensionality. This research used a dataset from the Fake News Challenges (FNC) website to create the logic. The dataset contains four sorts of stances: agree, disagree, discuss, and unrelated. PCA and chi-square are fed the nonlinear features, which provide more contextual features for fake news detection. The goal of this study was to determine what the position of a news article is in relation to its headline. In terms of accuracy and F1 score, the suggested model increases the results by 4% and 20%, respectively. The experimental results reveal that PCA surpasses chi-square and other state-of-the-art approaches by 97.8%.

Nasir et al. [35] applied artificial intelligence and machine learning to develop automatic detection algorithms. The recent breakthroughs in deep learning techniques in complicated natural language processing tasks make them a plausible answer for detecting fake news as well. For false news classification, the paper introduces a novel hybrid deep learning model that blends convolutional and recurrent neural networks. On two fake news datasets (ISO and FA-KES), the model was effectively verified, yielding detection results that were much superior to nonhybrid baseline approaches. Further tests of generalization over multiple datasets yielded promising findings.

Our paper integrated natural language processing (NLP) methods, such as Tokenization, and calculated TF-IDF with machine learning (ML). In this case, our focus is not only on the accuracy but also on the function of ML and NLP to enhance, speed up, and automate the analytical process.

3. System Design and Implementation

The experimental procedures are presented in this section, including the system architecture, workflows, dataset preparation and training methods.

3.1. System Architecture

The system architecture is required in a specific environment to provide machine learning experiments. The datasets of fake and real news disease are trained using traditional ML and neural network models. The library used NumPy and Pandas to process data manipulation and preprocessing. Matplotlib was used to visualize real and predictive information. Scikit-learn was applied to evaluate the accuracy of the model. Figure 1 describes the architecture of the environmental scheme used in the project.

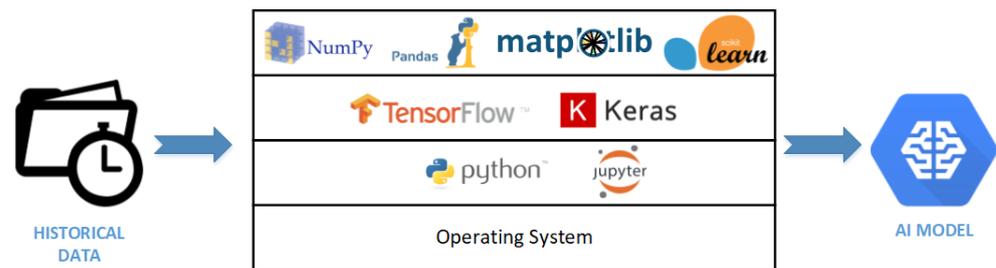

Figure 1. System Architecture.

3.2. WorkFlows

Figure 2 describes the experimental procedure. First, data preprocessing was conducted using certain methods. Second, there are two kinds of training methods, using traditional ML and neural network models. Third, a comparison of ML and neural network models was presented.

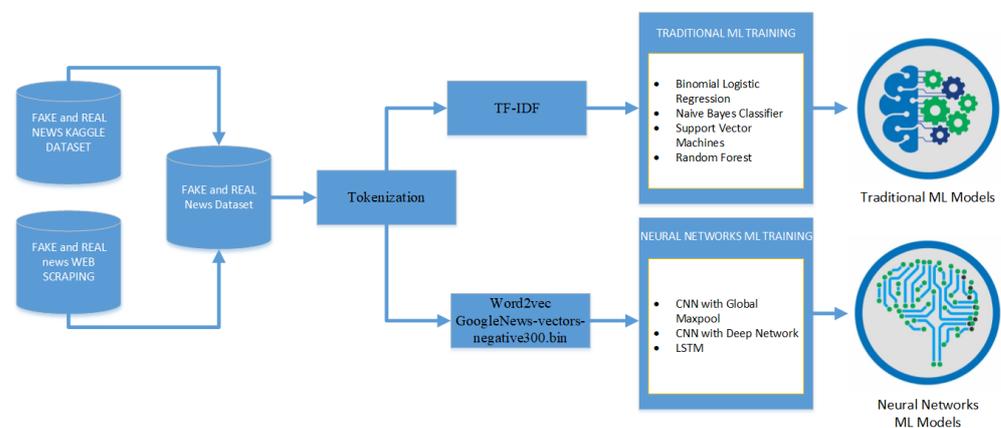

Figure 2. Workflows Diagram.

3.3. Dataset Preparation

The dataset was collected from the Kaggle dataset and scraped articles. The scraped articles are from 40 link sources of news and contain 24 accountable news links and 16 unclear links. First, the dataset from Kaggle and scraped articles were integrated, and articles with only pictures or no text were removed. Additionally, because there were no clear subject categories, especially within Fake News, we removed one column of the subject. Therefore, the final column of the dataset is in four columns. Then, the dataset was split into two kinds of corpora—Fake and Real News. Next, the Tokenization process was applied to these datasets using the Natural Language Toolkit (NLTK). The detail shaped of two resources are as follows:

- Kaggle, the Kaggle dataset contains fake and true news articles from 2015–2018.
FAKE SHAPE (23.481, 5)
TRUE SHAPE (21.417, 5)
- Forty web-scraped news articles, from 24 accountable resources and 16 unclear resources.
FAKE SHAPE (723, 5)
TRUE SHAPE (1553, 5)
- Therefore, all datasets shaped are:
FAKE (24.204, 4)
TRUE (22.970, 4)

3.4. Training Methods

There are two kinds of training methods that use traditional ML and neural network models. For the ML model, we used TF-IDF to score the words. For neural network models,

we used Word2vec by Google using GoogleNews-vectors-negative300.bin. The traditional ML models implement four types of algorithms: binomial logistic regression, naive Bayes classifier, support vector machines, and random forest. The neural network models applied three kinds of algorithms: CNN with global max pool, CNN with deep networks, and LSTM. The detailed model interpretation of each algorithm is presented as follows.

3.4.1. ML Training Model

The ML models summary is listed as follows.

Binomial Logistic Regression

Figure 3 shows the binomial logistic regression model.

```
LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
intercept_scaling=1, max_iter=100, multi_class='warn',
n_jobs=None, penalty='l2', random_state=None, solver='warn',
tol=0.0001, verbose=0, warm_start=False)
```

Figure 3. Binomial Logistic Regression Model.

Naive Bayes Classifier

MultinomialNB (alpha=1.0, class_prior=None, fit_prior=True)

Alpha set = 1 means Additive (Laplace/Lidstone) is smoothing. Class_prior = None means prior probabilities of the classes re adjusted according to the data. Fit_prior = True means whether to learn class prior probabilities or not.

Support Vector Machines

C is the regularization parameter, the default is 1.0, cache size is the size of the kernel cache, the default is 200.

class weight is none means that all classes supposed to have weight one.

Coef0 is 0.00, this is the the default parameter for independent term in kernel function. Because we used “linear” for the kernel type, then no need to set the coef0, it is only significant in “poly” and “sigmoid”.

Decision function shape “ovr” means return a one-vs-rest (ovr) decision function of shape.

Degree 3, the degree setting is ignored by all other kernels, except “poly”.

Gamma setting is auto deprecated means that we used 1/n_features.

Kernel is “linear” means that we specify the linear kernel type to be used in the algorithm.

max_iter -1 means no limit iterations.

Probability is False means that we did not enable the probability estimation.

random_state 1 is to shuffling the data to generate the pseudo random number.

Shrinking default is True means that we use the shrinking heuristic.

tol 0.001 means the tolerance for stopping criterion, the default is 1×10^{-3} , we set it at 0.001.

Verbose false means we disable verbose output.

Figure 4 shows the model of support vector machines.

```
SVC(C=1.0, cache_size=200, class_weight=None, coef0=0.0,
decision_function_shape='ovr', degree=3, gamma='auto_deprecated',
kernel='linear', max_iter=-1, probability=False, random_state=1,
shrinking=True, tol=0.001, verbose=False)
```

Figure 4. Support Vector Machines Model.

Random Forest

'max_depth': 60, 'n_estimators': 200

Max_depth = 60 means that the maximum depth of the tree is 60. N_estimator = 200 means that the number of trees in the forest is 200.

3.4.2. Neural Networks Training Model

The neural network model summary is listed as follows.

CNN with GlobalMaxpool

Figure 5 shows the CNN model with GlobalMaxpool.

Model: "sequential_1"

Layer (type)	Output Shape	Param #
embedding_1 (Embedding)	(None, 500, 300)	60254400
dropout_2 (Dropout)	(None, 500, 300)	0
conv1d (Conv1D)	(None, 497, 128)	153728
global_max_pooling1d (Global	(None, 128)	0
dropout_3 (Dropout)	(None, 128)	0
dense_2 (Dense)	(None, 250)	32250
dense_3 (Dense)	(None, 1)	251
Total params: 60,440,629		
Trainable params: 186,229		
Non-trainable params: 60,254,400		

Figure 5. CNN with GlobalMaxpool Model.

CNN with DeepNetwork

Figure 6 shows the model of CNN with DeepNetwork.

Model: "sequential_2"

Layer (type)	Output Shape	Param #
embedding_2 (Embedding)	(None, 500, 300)	60254400
conv1d_1 (Conv1D)	(None, 497, 128)	153728
max_pooling1d (MaxPooling1D)	(None, 124, 128)	0
dropout_4 (Dropout)	(None, 124, 128)	0
conv1d_2 (Conv1D)	(None, 121, 128)	65664
max_pooling1d_1 (MaxPooling1	(None, 30, 128)	0
conv1d_3 (Conv1D)	(None, 27, 128)	65664
max_pooling1d_2 (MaxPooling1	(None, 6, 128)	0
dropout_5 (Dropout)	(None, 6, 128)	0
flatten (Flatten)	(None, 768)	0
dense_4 (Dense)	(None, 128)	98432
dense_5 (Dense)	(None, 1)	129
Total params: 60,638,017		
Trainable params: 383,617		
Non-trainable params: 60,254,400		

Figure 6. CNN with DeepNetwork Model.

LSTM

Figure 7 shows the model of LSTM.

Model: "sequential"

Layer (type)	Output Shape	Param #
embedding (Embedding)	(None, 500, 300)	60254400
lstm (LSTM)	(None, 500, 128)	219648
dropout (Dropout)	(None, 500, 128)	0
lstm_1 (LSTM)	(None, 64)	49408
dropout_1 (Dropout)	(None, 64)	0
dense (Dense)	(None, 32)	2080
dense_1 (Dense)	(None, 1)	33

Total params: 60,525,569
 Trainable params: 271,169
 Non-trainable params: 60,254,400

Figure 7. LSTM Model.

3.5. Exploratory Analysis

The exploratory data analysis describes the insight of the data. Figure 8 shows the average and standard deviation of body text.

The average number of words in a real news article is 399.48680888114933
 The average number of words in a fake news article is 427.86477441745166
 The standard deviation in real news article lengths is 330.7416435291783
 The standard deviation in fake news article lengths is 410.8457989065262

Figure 8. The average and standard deviation of body text.

Figure 9 presents the distribution of fake and true news body text.

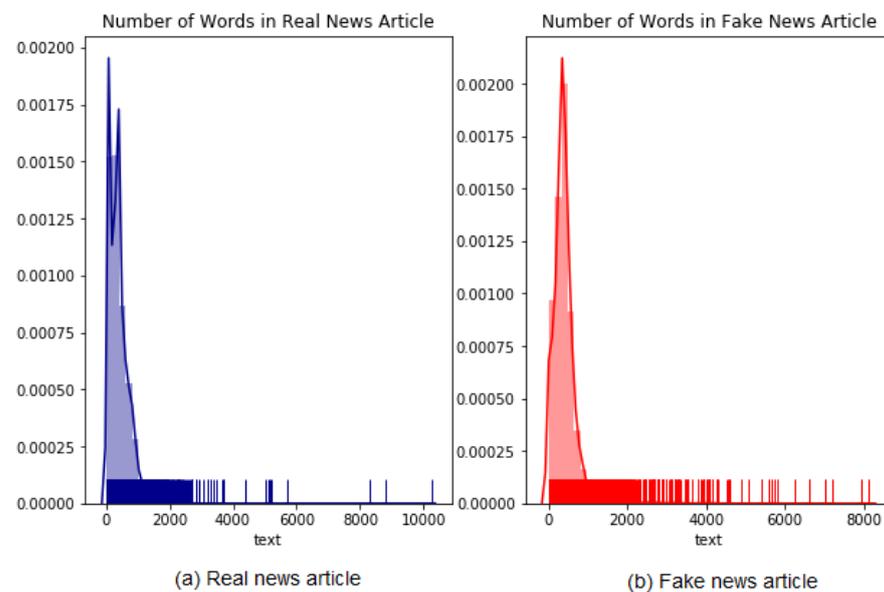

Figure 9. The distribution of Real and Fake news body text.

The average number of body text real news items is approximately 400, and the number of fake news items is 428. Therefore, the number of fake news articles is longer than the number of real news articles by approximately 28 words.

Figure 10 shows the average and standard deviation of headline text.

```
The average number of words in a real news article is 10.023073574227253
The average number of words in a fake news article is 14.618947281441084
The standard deviation in real news article lengths is 1.9128307906744992
The standard deviation in fake news article lengths is 4.3460435436375295
```

Figure 10. The average and standard deviation of headlines text.

Figure 11 presents the distribution of fake and true news headline text.

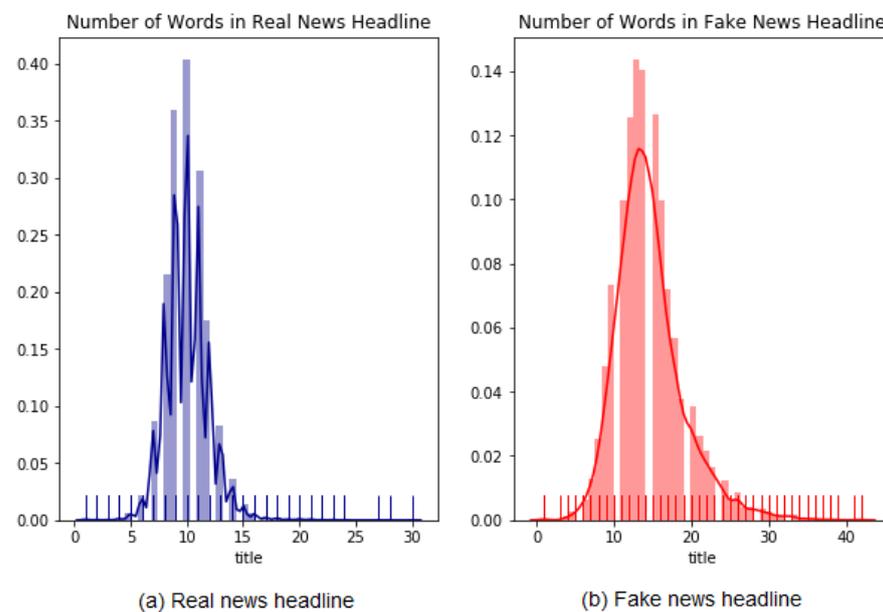

Figure 11. The distribution of Real and Fake news headlines text.

The average number of titles or headlines of real news is approximately 10, and the average number of fake news is 15. Therefore, the number of fake news articles is longer than the number of real news articles by approximately five words.

4. Experimental Result

This section demonstrates the results of the training models, consisting of the RMSE, accuracy and the classification metrics of precision, recall, and F1 score.

4.1. Traditional ML Training Results

In this section, the training results are demonstrated and compared based on each model.

Binomial Logistic Regression

The binomial logistic regression results of the accuracy training, testing, and RMSE values are listed as follows.

Accuracy Train: 88.87357905614881

Accuracy Test: 88.88182299947006

Mean Squared Error is: 0.3334393048296787

Figures 12 and 13 describe the metrics and confusion matrix of the training model.

	precision	recall	f1-score	support
0	0.89	0.88	0.89	4633
1	0.89	0.89	0.89	4802
micro avg	0.89	0.89	0.89	9435
macro avg	0.89	0.89	0.89	9435
weighted avg	0.89	0.89	0.89	9435

Figure 12. Binomial Logistic Regression metrics.

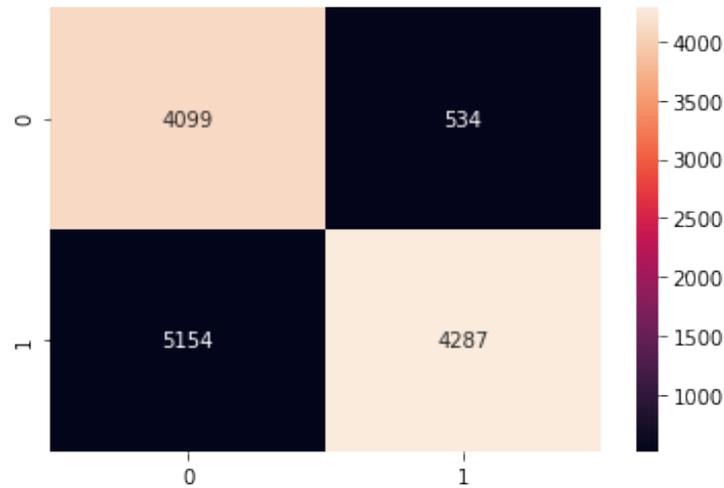

Figure 13. Binomial Logistic Regression confusion matrix.

4.2. Naive Bayes

The naive Bayes results of the accuracy training, testing, and RMSE values are listed as follows.

Accuracy Train: 85.80513527120486

Accuracy Test: 85.39480657127716

Mean Squared Error is: 0.382167416569268

Figures 14 and 15 describe the metrics and confusion matrix of the training model.

	precision	recall	f1-score	support
0	0.85	0.86	0.85	4633
1	0.86	0.85	0.86	4802
micro avg	0.85	0.85	0.85	9435
macro avg	0.85	0.85	0.85	9435

The training and loss graphs are visualized in Figures 30 and 31, as follows.

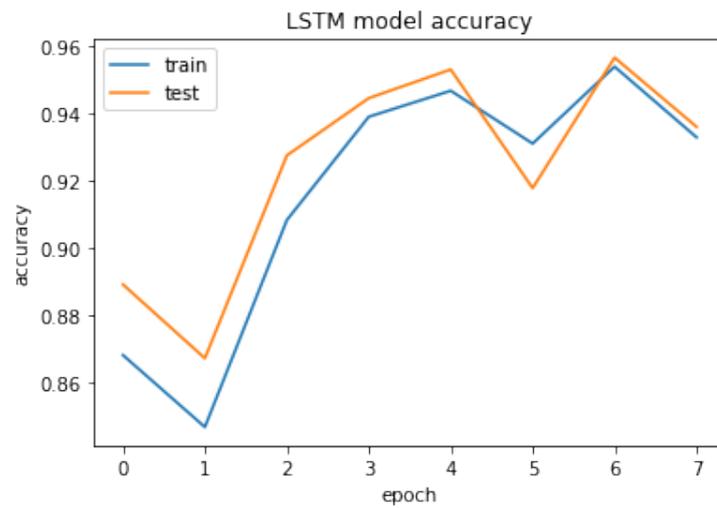

Figure 30. LSTM model accuracy.

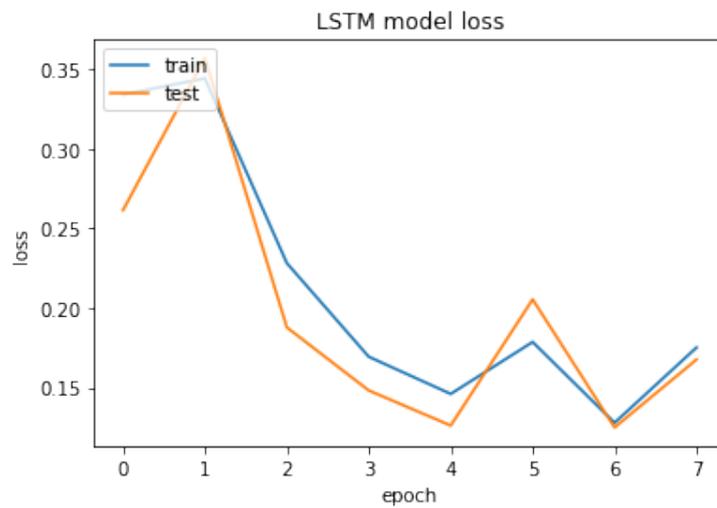

Figure 31. LSTM model loss.

4.4. Model Comparison

Figure 32 describes the model comparison. From the graph, neural network models can be seen to outperform ML models with an accuracy of more than 90%. The RMSE values also show a lower value compared to the ML models.

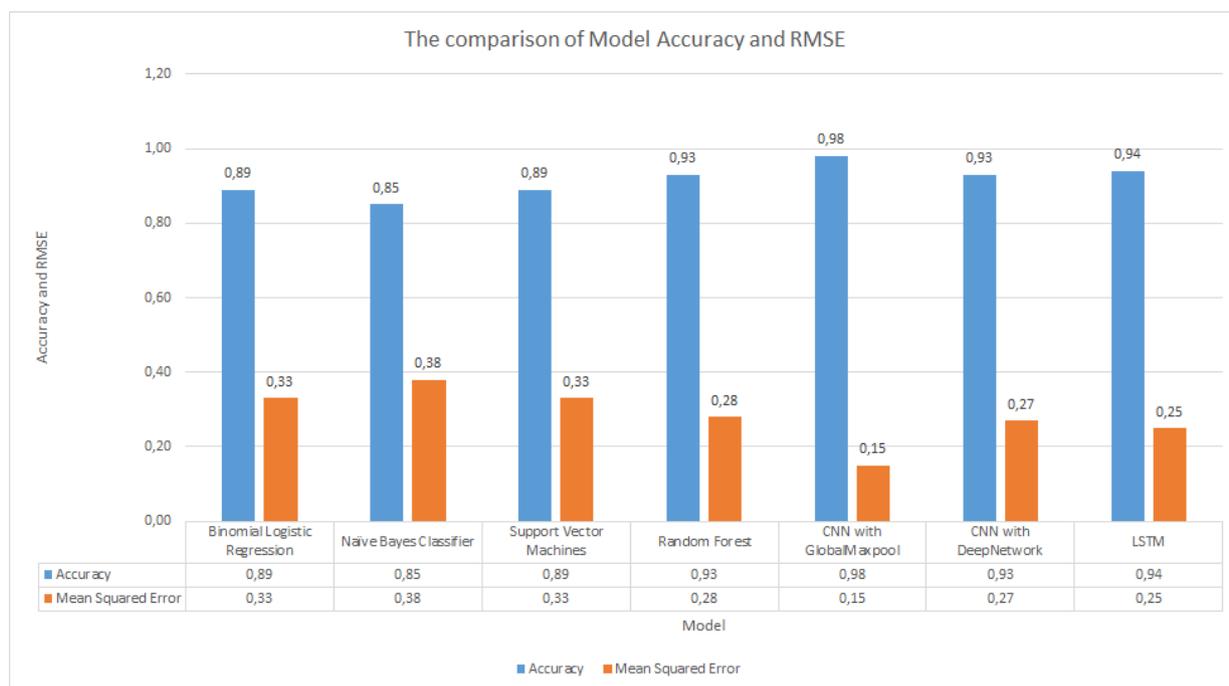

Figure 32. The comparison of model Accuracy and RMSE.

4.5. Discussion

By implementing NLP methods, both ML models and neural network models have an excellent performance, with greater than 85% accuracy for all models. The neural network models outperform traditional ML models, with all neural network models reaching a greater than 90% accuracy. The best accuracy was achieved by the CNN with Global Maxpool model. There is an approximately 6% higher accuracy in neural network models than in ML models.

5. Conclusions and Future Works

This paper implemented fake news classification using machine learning, deep learning and natural language processing. NLP methods, such as Tokenize, TF-IDF and Word2vec, were applied to increase the accuracy. Traditional ML models implement four algorithms—binomial logistic regression, naive Bayes classifier, support vector machines and random forest. The neural network models utilized three algorithms—CNN with GlobalMaxpool, CNN with DeepNetwork and LSTM. The novel empirical studies from previous works were to classify tagged false news, and NLP is integrated with classical machine learning to create an AI model. On an open public dataset based on content-level attributes, we evaluate seven models to discover the best model between classical ML and neural network approaches. From the experiments, we can see that the random forest model achieves excellent accuracy compared to the other traditional ML models. CNN with GlobalMaxpool is the best neural network model among the other two models. By implementing NLP methods, all the models have a greater than 85% accuracy. All the neural network models have a greater than 90% accuracy.

In the future, various models and methods can be improved, such as using bidirectional encoder representations from transformers (BERT), applying LSTM sequences to sequences, implementing bigrams and trigrams in training traditional ML and neural network models.

Author Contributions: Conceptualization, C.-M.L. and M.-H.C.; methodology, C.-T.Y. and V.K.V.; software, E.K.; validation, V.K.V. and C.-T.Y.; formal analysis, C.-M.L. and M.-H.C.; data curation, E.K.; writing—original draft preparation, E.K.; writing—review and editing, C.-T.Y., C.-M.L. and M.-H.C. All authors have read and agreed to the published version of the manuscript.
