## Abstract

A variety of amide-substituted anthracene derivatives have been synthesised and their anion complexation properties studied using <sup>1</sup>H-NMR titration techniques. Additionally, bis-urea functionalised anthracene derivatives have been shown to serve as excellent receptors for oxo-anions and to function as sensors *via* fluorescence quenching in DMSO-d<sub>6</sub>/0.5% water and MeCN/DMSO (96.5:3.5 v/v).

## Introduction

The development of simple hydrogen-bond donor anion receptors and sensors is an area of anion complexation that is yet to be fully explored.<sup>1</sup> In 1997, Crabtree<sup>2</sup> and Smith<sup>3</sup> independently discovered that simple isophthalamides function as effective anion receptors. Since this discovery, this motif has been further exploited in the formation of new anion<sup>4</sup> and ion-pair receptors<sup>5</sup> along with anion-templated helices<sup>6</sup>, catenanes<sup>7</sup> and

1  
2  
3  
4 rotaxanes.<sup>8</sup> Similarly, ureas<sup>9</sup> and thioureas<sup>10</sup> have been used for anion complexation due  
5  
6 to both the relative ease in which they can be synthesized and for their propensity to  
7  
8 form strong complexes with oxo-anions such as carboxylates and phosphates. Much  
9  
10 effort has also been devoted to the production of anion sensors that combine both an  
11  
12 anion binding site and either a chromophore<sup>11</sup> or a redox active group<sup>12</sup> that in the  
13  
14 presence of a coordinating anion show a perturbation in their optical or electrochemical  
15  
16 properties.  
17  
18  
19

20 We have recently reported the synthesis of receptors based upon anthraquinone that  
21  
22 contain a 'twisted' isophthalamide-like hydrogen-bonding cleft that show an increase in  
23  
24 oxo-anion selectivity, relative to non distorted isophthalamides<sup>13</sup>, and also receptors  
25  
26 based upon 1,2-phenylenediamine that contain amide or urea groups that can adopt a  
27  
28 more planar geometry.<sup>14</sup> We wished to further investigate the relative merits of each  
29  
30 hydrogen bonding motif in terms of both its strength and selectivity of anion  
31  
32 coordination in potential anion sensor system that would potentially show a change in  
33  
34 fluorescence properties upon the addition of coordinating anions. Previously, numerous  
35  
36 research groups have produced anthracene based anion sensors<sup>15</sup> including those  
37  
38 reported by Gunnlaugsson and coworkers that demonstrated high affinities for oxo-  
39  
40 anions. Therefore receptors **1-4** based upon 1,2- and 1,3-substituted anthracenes were  
41  
42 synthesised in an attempt to establish how effective each motif would be at complexing  
43  
44 anions in both non-polar and competitive solvent mixtures when appended to an  
45  
46 anthracene backbone by means of <sup>1</sup>H-NMR titrations.  
47  
48  
49  
50  
51  
52

53 We also wished to investigate the use of bis-urea based anthracene receptors as an  
54  
55 alternative method for complexing anions. Das and coworkers have demonstrated that  
56  
57 bis-urea and bis-thiourea receptors based upon 1,2-diaminoanthraquinone can form  
58  
59  
60

1  
2  
3  
4 strong complexes with a variety of anions in MeCN/DMSO (90/10 v/v) solution.<sup>16</sup>  
5  
6  
7 More recently we have demonstrated that in simpler systems based upon 1,2-  
8  
9 phenylenediamine, carboxylate anions can be coordinated to this type of motif in a 1:1  
10  
11 anion :receptor stoichiometry through four hydrogen bonds with relatively strong  
12  
13 stability constants obtained in DMSO/water solvent mixtures.<sup>17</sup> We hoped similarly  
14  
15 strong complexes would be formed with receptors based upon the 1,2-  
16  
17 diaminoanthracene subunit. For these reasons we synthesised compounds **5** and **6** and  
18  
19 we studied their ability in binding anions by means of <sup>1</sup>H-NMR titrations in DMSO-  
20  
21 *d*<sub>6</sub>/0.5% water and fluorescent titrations both in DMSO and in MeCN/DMSO (96.5:3.5  
22  
23 v/v).

## Experimental

### General Methods

Reagents were purchased from the Aldrich Chemical Co. Deuterated solvents were purchased from Apollo Ltd. Chemical shifts reported in ppm and are referenced to the solvent. Proton and  $^{13}\text{C}$ -NMR spectra were recorded on a Bruker AV-300 NMR spectrometer. UV/vis absorbance spectra were recorded on a Hitachi U-2001 spectrophotometer with fluorescence emission spectra recorded on a Hitachi F-2000 spectrofluorimeter with a 150W Xenon lamp. The photomultiplier voltage was set to 400V with excitation and emission slits set to 10 mm. Fluorescence titrations were performed by adding to a solution of the receptors ( $1 \times 10^{-6}$  M) in DMSO and MeCN/DMSO (96.5/3.5 v/v) solutions of anions ( $2.5 \times 10^{-3}$  M) in a solution of the receptor in order to keep constant the concentration of the receptor during the titration.

Luminescence quantum yields were determined using quinine sulphate in 1M  $\text{H}_2\text{SO}_4$  aqueous solution ( $\Phi = 0.546$ ) as reference.

Elemental analyses were performed by Medac Ltd.

### Synthesis

#### $N^1, N^2$ -Dibutylanthracene-1,2-dicarboxamide (1).

Anthracene-1,2-diamine (0.50 g, 2.4 mmol), triethylamine (0.74 mL, 5.3 mmol) and DMAP (a few mg, cat.) were stirred together for 15 minutes in dry DCM (15 mL) before the dropwise addition of valeroyl chloride (0.56 mL, 4.8 mmol). The reaction was stirred at ambient temperature under nitrogen for 18 hours. After this time the reaction solvent was washed with water ( $3 \times 25$  mL) before the remaining solvent was removed *in vacuo*. The residue was recrystallized from hot ethyl acetate and purified by

### **$N^1, N^3$ -Dibutylanthracene-1,3-dicarboxamide (3).**

*n*-Butylamine (0.43 mL, 4.4 mmol) was dissolved in dry DCM (25 mL). Trimethylaluminium solution (2M) in hexane (2.2 mL, 4.4 mmol) was added dropwise to the solution and the mixture stirred for 30 minutes. 1,3-Anthracenedimethyl ester (0.64 g, 2.2 mmol) was added and the reaction heated at reflux for 5 days. The reaction mixture was allowed to cool and aqueous HCl solution (1:10 v/v) added until bubbling ceased. A further 50 mL of water was added and the reaction was stirred for a further 30 minutes. The reaction mixture was washed with water ( $3 \times 50$  mL) and the organic phase containing the suspended compound retained. The remaining solvent was removed *in vacuo* and the residue dried under high vacuum. The product was isolated as a pale yellow solid. Mass of product = 0.26 g. Yield = 32%.  $^1\text{H}$  NMR 300 MHz in  $\text{CDCl}_3-d_1$   $\delta$  (ppm): 8.65 (s, 1H, NH), 8.02 (s, 1H, NH), 7.99 (s, 1H, ArH), 7.86 (d, 1H, J = 8.4 Hz, ArH), 7.68 (d, 1H, J = 8.4 Hz, ArH), 7.62 (d, 1H, J = 1.1 Hz, ArH), 7.40 (m, 2H, ArH), 6.79 (m, 2H, ArH), 3.50 (q, 2H, J = 7.0 Hz,  $\text{CH}_2$ ), 3.40 (q, 2H, J = 6.9 Hz,  $\text{CH}_2$ ), 1.64 (m, 4H, overlapping  $\text{CH}_2$ ), 1.43 (m, 4H, overlapping  $\text{CH}_2$ ), 0.97 (m, 6H, overlapping  $\text{CH}_3$ ).  $^{13}\text{C}$  NMR 75.4 MHz in  $\text{CDCl}_3-d_1$   $\delta$  (ppm): 169.3 (CO), 167.4 (CO),

## Results and Discussion

Compounds **1** and **2** were synthesised from an acid chloride condensation reaction between 1,2-diaminoanthracene<sup>18</sup> and valeroyl and benzoyl chloride in the presence of triethylamine and a catalytic quantity of DMAP to afford the products in 39% and 82% respective yields. Receptors **3** and **4** were synthesised by reaction of the 1,3-dimethyl anthracenedicarboxylate<sup>19</sup> and either *n*-butylamine or aniline in the presence of trimethylaluminium solution 2M in dry dichloromethane that afforded the products in 32 and 82% respective yields. Compounds **5** and **6** were synthesized from 1,2-diaminoanthracene and butylisocyanate or phenylisocyanate yielding the two products in 54% and 49% yield respectively.

X-ray quality crystals of **1** were obtained *via* slow evaporation of an acetonitrile solution of the compound. As shown in Figure 1, in the solid-state, the receptor forms an infinite hydrogen bonded chain with bonding interactions between the amide NH groups and the carbonyl groups of an adjacent molecule of **1** [N··O 2.844(2) and 2.910(2) Å]. The structure indicates that both amide NH groups are able to adopt an almost parallel geometry in the solid state and therefore may facilitate the coordination of oxo-anions separate interactions to different oxygen atoms in the anion.

The presence of the butyl groups in **1** and **3** conferred solubility on these compounds in weakly coordinating dichloromethane (DCM) solution. It was therefore decided to initially investigate the anion binding properties of **1** and **3** in DCM- $d_2$  using  $^1\text{H}$  NMR titration techniques (Table 1).

Compound **1** was found to possess a slightly higher oxo-anion affinity than compound **3** under these solvent conditions however, overall the affinity of the two compounds for anionic guests was very similar. In order to provide greater insight into the anion binding behaviour of receptors **1** and **3** and to evaluate the properties of aryl functionalized receptors **2** and **4**, further  $^1\text{H}$ -NMR titration experiments were performed in the more competitive solvent mixture of DMSO- $d_6$ /0.5% water (Table 2). As expected, in, with the exception of dihydrogen phosphate all of the anions are bound more weakly. Interestingly the halide selectivity displayed by isophthalamide type receptor **3** in dichloromethane is not observed in DMSO- $d_6$ /0.5% water, with both phosphate and carboxylate anions bound more strongly in this solvent mixture. Compound **4** displays the highest observed stability constant with dihydrogen phosphate of  $122 \text{ M}^{-1}$ , consistent with the increase in acidity of the amide NH groups relative to alkyl derivative **3**.

Anion stability constants with compounds **5** and **6** were also elucidated *via*  $^1\text{H}$ -NMR titration experiments performed in DMSO- $d_6$ /0.5% water revealing a significant increase in the values obtained for compounds **1-4** under the same conditions, however a similar trend of oxo-anion selectivity was observed (Table 3). Of the two compounds the bis-phenylurea **6** displayed stability constants approaching an order of magnitude higher than those of **5** (c.f. acetate  $277$  vs  $2540 \text{ M}^{-1}$ ) presumably arising from the greater acidity of the outer urea NH protons of receptor **6** due to the presence of the

1  
2  
3  
4 electron-withdrawing aryl substituents. The titration curves for this compound are  
5  
6 shown in Figure 2.

7  
8  
9 Because receptors **5** and **6** formed complexes with considerably improved stability with  
10  
11 respect to those formed by compounds **1-4**, we decided to investigate the photophysical  
12  
13 properties of these systems to determine their effectiveness as fluorescent anion  
14  
15 sensors. Fluorescence titrations were performed both in DMSO and in the relatively  
16  
17 non-competitive MeCN/DMSO (96.5/3.5 v/v) solvent mixture. The UV/vis absorbance  
18  
19 spectra of compounds **5** and **6** in DMSO both display similar characteristic shapes, with  
20  
21 maximum absorbances centred at 370 ( $\epsilon = 4600 \text{ dm}^3\text{mol}^{-1}\text{cm}^{-1}$ ) and 368 nm ( $6300$   
22  
23  $\text{dm}^3\text{mol}^{-1}\text{cm}^{-1}$ ) respectively. Excitation of the compounds at these wavelengths  
24  
25 provided maximum fluorescent emission peaks that were broad in appearance and  
26  
27 centred at 493 and 477 nm respectively. The two receptors show very good  
28  
29 fluorescence quantum yields ( $\Phi = 0.44$  and  $0.50$  for **5** and **6**, respectively). The effect of  
30  
31 increasing concentration of coordinating oxo-anions in the form of their  
32  
33 tetrabutylammonium salts upon the fluorescent emission of both receptors **5** and **6** was  
34  
35 investigated. Whilst only relatively small changes in the UV/vis absorbance spectra  
36  
37 were recorded, a significant reduction in the fluorescence emission was observed  
38  
39 (Figures 3 and 4) when a large excess of anion (up to 300 equivalents) was added to the  
40  
41 solution of both compounds **5** and **6** in DMSO. We decided to repeat the titrations in a  
42  
43 mixture of MeCN/DMSO (96.5/3.5 v/v) and found that the absorption and emission  
44  
45 properties of both ligands were similar to those observed in DMSO. We recorded the  
46  
47 fluorescence emission exciting both the compounds at 362 nm and found that the  
48  
49 maximum emission was at 458 and 465 nm for receptors **5** and **6** respectively. In the  
50  
51 case of receptor **6** a partial quenching of the fluorescence emission was evident with  
52  
53  
54

3  
4 acetate ( $I_{res} = 21\%$ ) and in less extent with benzoate ( $I_{res} = 53\%$ ), dihydrogen phosphate  
5  
6 ( $I_{res} = 70\%$ ) and chloride ( $I_{res} = 96\%$ ) upon addition of 30 equivalents of anions (Figure  
7  
8  
9 5). For receptor **5** we did not observed any significant changes in the fluorescence  
10  
11 emission upon addition of anions (see Supplementary Informations).  
12

13  
14 Slow evaporation of an acetonitrile solution of **5** in the presence of excess  
15  
16 tetrabutylammonium benzoate yielded X-ray quality crystals of the complex. The  
17  
18 benzoate anion is bound by the receptor through four hydrogen bonds with both the  
19  
20 inner urea NH groups [ $N \cdots O$  2.851(6) and 2.839(6) Å] and external urea NH groups  
21  
22 [ $N \cdots O$  2.890(6) and 2.830(6) Å] coordinating both of the oxygen atoms of the anion  
23  
24 (Figure 6).  
25  
26

27  
28 Similarly, slow evaporation of an acetonitrile solution of **6** in the presence of excess  
29  
30 tetrabutylammonium benzoate yielded X-ray quality crystals of the complex. The  
31  
32 benzoate anion is bound by the receptor *via* four hydrogen bonds with both the inner  
33  
34 urea NH groups [ $N \cdots O$  2.828(9) and 2.783(9) Å] and external urea NH groups [ $N \cdots O$   
35  
36 2.837(10) and 3.074(9) Å] coordinating both of the oxygen atoms of the anion (Figure  
37  
38 7).  
39  
40  
41  
42  
43

## 44 Conclusions

45  
46  
47 The variation of the hydrogen bonding motifs of bis-amide receptors allows the  
48  
49 selectivity to be tuned to a certain extent in weakly coordinating dichloromethane  
50  
51 solution. However in DMSO solution there is little difference between the anion  
52  
53 affinity of the two motifs studied. The bis-urea motif forms stronger complexes with  
54  
55 oxo-anions under more competitive conditions due to the ability of the receptors to  
56  
57 form up to four simultaneous hydrogen bonds to the anion. The incorporation of an  
58  
59  
60

1  
2  
3  
4 anthracene fluorophore enables the receptor to function as a sensor for carboxylate  
5 anions with a good selectivity in a mixture of MeCN/DMSO (96.5/3.5 v/v). We are  
6 currently investigating alternative methods of incorporating the bis-urea motif into both  
7 optical and electrochemical sensors, the results of which will be published in due  
8 course.

### Acknowledgements

20  
21 We would like to thank the EPSRC for a DTA studentship (SJB) and the EPSRC  
22 together with Professor Mike Hursthouse for use of the crystallographic facilities at  
23 the University of Southampton. We would also like to thank Professor Mike Gore  
24 for the use of fluorescence facilities at the school of Biological Sciences at the  
25 University of Southampton. CC would like to thank Regione Sardegna for a Master  
26 & Back grant.
