Dedicated to Mario Marchi on the occasion of his 70th birthday

#### Abstract

We define generalized Clifford parallelisms in $\mathrm{PG}(3, F)$ with the help of a quaternion skew field $H$ over a field $F$ of arbitrary characteristic. Moreover we give a geometric description of such parallelisms involving hyperbolic quadrics in projective spaces over suitable quadratic extensions of $F$.

Keywords: Clifford parallelism, quadratic forms, quadrics, quaternions
MSC 2000: 51A15, 51J15, 11E04

## 1. Introduction

It is known that the three dimensional real projective space $\operatorname{PG}(3, \mathbb{R})$ can be endowed with two projectively equivalent parallelisms, namely the left and right Clifford parallelisms, related to left and right multiplications in the Hamilton quaternion algebra $\mathbb{H}(\mathbb{R})$ (see e.g. [15]). For these parallelisms there are many equivalent geometric representations (see e.g. [22, Sec. 142], [8, 12 A], [16, Chapter 14]). In particular each parallel class can be described considering the lines that meet a fixed imaginary line (and its conjugate) belonging to one of the two reguli of a complex hyperbolic quadric whose points do not belong to $\mathrm{PG}(3, \mathbb{R})$.

The aim of this work is to extend these notions to the projective 3 -space over a general (commutative) field of arbitrary characteristic. This can be done in several ways, using constructions that involve either rings of generalized quaternions, or the notions of Baer subspace of a projective space and indicator set of

[^0]
a spread of lines (see [12], [13]). All these constructions always give rise to regular parallelisms.

In particular we consider these constructions over a field which admits different quadratic extensions.

For the description of the parallelisms our starting point in Section 4 is the context of projective kinematic spaces (see [15]). Here the lines through the point 1 are the maximal commutative subalgebras of $H$. The set of these lines is partitioned into conjugacy classes with respect to the quaternion multiplication. We show that each conjugacy class of lines corresponds to a different quadratic extension $L$ of the field $F$ and determines by right and left cosets respectively two sets of mutually disjoint spreads which are some of the right and left Clifford parallel classes. Such spreads are indicated by the lines of the two reguli of a quadric in $\operatorname{PG}(3, L)$ with no points in $\mathrm{PG}(3, F)$ (Theorem 4.7). Following this procedure for all quadratic extensions $L / F$ the whole line set of $\operatorname{PG}(3, F)$ is covered, thus obtaining the complete right and left Clifford parallelisms with respect to the given quaternion skew field $H$ (see Theorem 4.10). We remark that different Clifford parallelisms corresponding to different quaternion skew fields over $F$ are not projectively equivalent. Moreover new "non-Clifford" regular parallelisms can be obtained, using a method which has no equivalent in the classical case (see Remark 4.13).

## 2. Quadratic spaces and quaternion algebras

Recall from [19] that a quadratic space $(V(F), q)$ is an $n$-dimensional vector space $V$ over a field $F$ of arbitrary characteristic, endowed with a quadratic form $q$. The bilinear form corresponding to $q$ is $b_{q}(v, w)=q(v+w)-q(v)-q(w)$ for all $v, w \in V$, and the quadratic space $(V(F), q)$ is said to be regular or nondegenerate if $b_{q}$ is non-degenerate, singular otherwise.

If $(V(F), q)$ is a quadratic space, a nonzero vector $v \in V$ is said to be isotropic if $q(v)=0$ and anisotropic otherwise. We say that $(V(F), q)$ is isotropic if it contains an isotropic vector, anisotropic otherwise; a subspace $W$ of $V$ is said to be totally isotropic if $b_{q}(W, W)=0$; an isotropic $n$-dimensional quadratic form is said to be hyperbolic if $n$ is even and $V$ is a direct sum of two totally isotropic ( $n / 2$ )-dimensional subspaces.

If $(V(F), q)$ is a regular $n$-dimensional quadratic space and char $F \neq 2$, the discriminant of $q$ is $d(q)=(-1)^{n(n-1) / 2} \operatorname{det}(q)$ considered as an element of $F^{*} /\left(F^{*}\right)^{2}$, where we denote by $\left(F^{*}\right)^{2}$ the group of squares of $F^{*}$. If, on the contrary, char $F=2$, then the symmetric bilinear form $b_{q}$ is in fact alternating, thus one can fix a symplectic basis $\left(e_{1}, \ldots, e_{n / 2}, f_{1}, \ldots, f_{n / 2}\right)$ of $(V(F), q)$

page 3 / 16

UNIVERSITEIT GENT
(that is a basis such that $b_{q}\left(e_{i}, f_{i}\right)=1$ for every $i=1,2, \ldots, n / 2$, and all other pairs of vectors are orthogonal) and define the discriminant to be $d(q)=$ $q\left(e_{1}\right) q\left(f_{1}\right)+\cdots+q\left(e_{n / 2}\right) q\left(f_{n / 2}\right)$ considered as an element of $F /\left\{x+x^{2} \mid x \in F\right\}$ (see e.g. [19, 9.4.2]).

If $(V(F), q)$ is an $n$-dimensional regular quadratic space over the field $F$, then associated to $q$ there is a non-degenerate quadric $\mathcal{Q}$ in the projective space $\mathrm{PG}(n-1, F)$, namely the quadric whose points are represented by the isotropic vectors of $q$ ( $\mathcal{Q}=\emptyset$ if $q$ is anisotropic). Conversely, given any non-degenerate quadric in $\operatorname{PG}(n-1, F)$, its equation gives rise to a family of similar regular quadratic forms $q_{\rho}$ over $F^{n}$, i.e. quadratic forms whose elements differ in a proportional factor $\rho \in F^{*}$. Note that the quadratic spaces ( $F^{n}, q_{\rho}$ ) in general are not isometric, but they correspond to the same quadric $\mathcal{Q}$ in $\operatorname{PG}(n-1, F)$ and their discriminant is the same.

If $K$ is any commutative field extension of $F$, then a quadratic form $q$ defined in $V(F)$ can be regarded also as a quadratic form denoted by $q_{K}$ over the extended vector space $V(K)$, and the quadric $\mathcal{Q}$ associated to $q$ in $\operatorname{PG}(3, F)$ as a quadric in $\mathrm{PG}(3, K)$, denoted by $\mathcal{Q}_{K}$.

Let $K$ be a separable quadratic extension of a non-separably closed field $F$, denote by $x \mapsto \bar{x}$ the unique non trivial element of $\operatorname{Gal}(K / F)$ and fix an element $b \in F^{*}$. Then, according to [21], the quaternion algebra $H=(K / F, b)$ is the subring of $\mathrm{M}_{2}(K)$ consisting of matrices of the form

$$
\left(\begin{array}{cc}
x & y \\
b \bar{y} & \bar{x}
\end{array}\right)
$$

and it is a central simple algebra over $F$; if $F$ is separably closed, then the quaternion algebra $H$ over $F$ is $\mathrm{M}_{2}(F)$. In both cases the ground field $F$ can be identified with the subalgebra of scalar matrices. For a quaternion $h \in H$ we define the conjugate of $h$ to be the quaternion

$$
\bar{h}:=\left(\begin{array}{cc}
\bar{x} & -y \\
-b \bar{y} & x
\end{array}\right),
$$

the norm of $h$ to be $n(h):=h \bar{h}=\operatorname{det}(h) \in F$ and the trace of $h$ to be $t(h):=$ $h+\bar{h}=\operatorname{tr}(h) \in F$. Then each $h \in H$ satisfies the quadratic equation $h^{2}-$ $t(h) h+n(h)=0$. Note that $K$, embedded into $H$ as the subring of all matrices

$$
\left(\begin{array}{ll}
x & 0 \\
0 & \bar{x}
\end{array}\right)
$$

is invariant under the conjugation of $H$, which, restricted to $K$, coincides with the conjugation associated to the field extension $K / F$. Note also that $n$ is a

The equivalence (i) $\Leftrightarrow$ (ii) is a well known result, see e.g. [23, Chapter I, Theorem 2.8], [19, Chapter 8, Theorem 5.4] and also [10, 11.A]; in the partic-

quit

UNIVERSITEIT GENT
ular case char $F \neq 2$ we provide a simple and direct proof in [2]. Equivalence (ii) $\Leftrightarrow$ (iii) follows from Theorem 2.1.
2.3 Proposition. Let $q$ be a 4-dimensional regular quadratic form over a field $F$. If $d(q)$ is trivial, then $q$ is similar to the norm form of a suitable quaternion algebra $H$ over $F$, and $H$ is a skew field if and only if $q$ is anisotropic over $F$. If $d(q)$ is nontrivial, then there exists a quadratic extension $F^{\prime}$ of $F$ (namely the discriminant extension) such that $q_{F^{\prime}}$ is similar to the norm form of a quaternion algebra $H$ over $F^{\prime}$, and $H$ is a skew field if and only if $q_{F^{\prime}}$ is anisotropic over $F^{\prime}$. Conversely if $q$ is isometric to the norm form of a quaternion algebra $H$ over a field $F$, then $d(q)$ is trivial.

Proof. Assume $d(q)$ is trivial. Then by [6, Lemma 4.4] $q$ is either hyperbolic or similar to the orthogonal sum of quadratic forms $s_{1} N \perp s_{2} N$ for suitable $s_{1}, s_{2} \in F^{*}$, where $N$ is the norm of a separable quadratic extension $K / F$. In the first case $q$ is similar to the norm form of a split quaternion algebra, and this happens exactly when $q$ is isotropic over $F$. If, on the contrary, $q$ is anisotropic over $F$, then $q$ is similar to the norm form of the quaternion algebra $H=\left(K / F, s_{1}^{-1} s_{2}\right)$. If $d(q)$ is non-trivial and $d$ is a representative for the square class of $d(q)$, the same as above holds over the discriminant quadratic extension $F^{\prime}=F(\sqrt{d})$ of $F$. The converse is obvious.
2.4 Proposition. Let $\mathcal{Q}$ be a quadric of $\mathrm{PG}(3, F)$ and write $q$ for a representative of the similarity class of quadratic forms associated to $\mathcal{Q}$ in the vector space $F^{4}$. Then the following hold:
(i) $\mathcal{Q}$ is hyperbolic if and only if $q$ is isometric to the norm form of the split quaternion algebra $\mathrm{M}_{2}(F)$ over $F$.
(ii) $\mathcal{Q}$ has no points in $\mathrm{PG}(3, F)$ and there exists a separable quadratic extension $K$ of $F$ such that $\mathcal{Q}_{K}$ is hyperbolic in $\mathrm{PG}(3, K)$ if and only if $q$ is isometric to the norm form of a quaternion skew field $H$ over $F$.

Proof. (i) is obvious. To prove claim (ii) note that, if $q$ is anisotropic and $q_{K}$ hyperbolic, by [6, Lemma 4.2], $q$ is similar to the quadratic form $s_{1} N \perp s_{2} N$, where $N$ is the norm of the extension $K / F$, and thus, as in the proof of the previous proposition, $q$ is similar to the norm form of a suitable quaternion algebra $H$. Since $q$ is anisotropic over $F, H$ is a division algebra.

Conversely if $q$ is isometric to the norm form of a quaternion skew field $H$ over $F$, then $\mathcal{Q}$ does not have points in $\mathrm{PG}(3, F)$ by Theorem 2.1. Moreover $H$ contains a maximal separable subfield $K$, so $q_{K}$ is hyperbolic by Theorem 2.2 and $\mathcal{Q}_{K}$ is then hyperbolic in $\operatorname{PG}(3, K)$.

quit
2.5 Remark. Note that Propositions 2.3 and 2.4(ii) characterize the quadrics $\mathcal{Q}$ without points in $\mathrm{PG}(3, F)$ which determine a quaternion skew field $H$ over $F$ as those quadrics whose similarity class of associated quadratic forms consists of anisotropic forms with trivial discriminant.

## 3. Spreads and parallelisms in 3-space

Let $\mathbb{P}=(\mathcal{P}, \mathcal{L})$ be a 3 -dimensional projective space. If $\mathcal{M} \subseteq \mathcal{L}$, then a line $L \in \mathcal{L}$ is said to be transversal to $\mathcal{M}$ if $L$ meets each $M \in \mathcal{M}$ in a unique point.

Using the notion of transversals, we can now state the definition of a regulus in $\mathbb{P}$, due to B. Segre [20, Chapter 18] (see also [14]):

Let $T_{0}, T_{1}, T_{2} \in \mathcal{L}$ be pairwise skew. Then the set

$$
\begin{equation*}
\mathcal{R}:=\left\{L \in \mathcal{L} \mid L \text { transversal to } T_{0}, T_{1}, T_{2}\right\} \tag{3.1}
\end{equation*}
$$

is called a regulus.
The elements of a regulus $\mathcal{R}$ must be pairwise skew, because otherwise the three lines $T_{0}, T_{1}, T_{2} \in \mathcal{L}$ that determine $\mathcal{R}$ could not be pairwise skew.

Given three pairwise skew lines $R_{0}, R_{1}, R_{2}$, there is always at least one regulus containing them, since $R_{0}, R_{1}, R_{2}$ possess at least three transversals $T_{0}, T_{1}, T_{2}$, that are also pairwise skew and hence determine a regulus that of course must contain $R_{0}, R_{1}, R_{2}$. This regulus is unique, i.e., does not depend on the choice of the transversals $T_{0}, T_{1}, T_{2}$, if and only if the field $F$ is commutative. See [14, Chapter 4].

Given a regulus $\mathcal{R}$, we consider

$$
\mathcal{R}_{\text {opp }}:=\{T \in \mathcal{L} \mid T \text { transversal to } \mathcal{R}\} .
$$

By the above, $\mathcal{R}_{\text {opp }}$ is a regulus if and only if $F$ is commutative. In this case, we call $\mathcal{R}_{\text {opp }}$ the regulus opposite to $\mathcal{R}$. Note that in this situation a regulus and its opposite cover the same set of points, namely, a hyperbolic quadric $\mathcal{Q}_{\mathcal{R}}$ in $\mathrm{PG}(3, F)$ (see [4], [5, Chapter 4]).

In pappian spaces, one can also define reguli as follows (see, e.g., [9, 17]): A regulus $\mathcal{R}$ is a set of pairwise skew lines, such that each line that meets three lines of $\mathcal{R}$, is a transversal of $\mathcal{R}$, and each point on a transversal of $\mathcal{R}$ lies on an element of $\mathcal{R}$.

Recall that a set $\mathcal{S} \subseteq \mathcal{L}$ is called a spread of $\mathbb{P}$, if each point $p \in \mathcal{P}$ lies on exactly one line $L \in \mathcal{S}$. So $\mathcal{S}$ is a partition of the point set $\mathcal{P}$ into lines. In particular, any two elements of a spread $\mathcal{S}$ are skew. A spread $\mathcal{S}$ in a pappian

page 7 / 16

full screen
close
quit

UNIVERSITEIT
GENT

3 -space is called regular, if with any three pairwise skew lines $S_{1}, S_{2}, S_{3} \in \mathcal{S}$ also all other lines of the unique regulus through $S_{1}, S_{2}, S_{3}$ belong to $\mathcal{S}$.

A partial parallelism of $\mathbb{P}$ is a set of mutually disjoint spreads. A parallelism of $\mathbb{P}$ is a partial parallelism which covers the whole line set $\mathcal{L}$ of the projective space; a regular parallelism is a parallelism consisting of regular spreads only. Given a parallelism of $\mathbb{P}$ we say that two lines $L, M \in \mathcal{L}$ are parallel $(L / / M)$ if they belong to the same spread.

From now on we study the pappian projective space $\mathbb{P}=\mathrm{PG}(3, F)$ over a commutative field $F$.

By [1], there is a regular spread in $\mathrm{PG}(3, F)$ if and only if the field $F$ admits a quadratic extension $K$. In this case $\mathrm{PG}(3, F)=(\mathcal{P}, \mathcal{L})$ can be embedded in $\mathrm{PG}(3, K)=\left(\mathcal{P}^{\prime}, \mathcal{L}^{\prime}\right)$ as a Baer subspace, i.e. a projective subgeometry such that each point $p \in \mathcal{P}^{\prime}$ is incident with at least one line $L \in \mathcal{L}$. This means that, given any line $I \in \mathcal{L}^{\prime}$ not intersecting $\mathcal{P}$, through any point $p$ of $I$ there is exactly one line $L_{p} \in \mathcal{L}$; so $I$ defines the set of lines

$$
\mathcal{S}(I):=\left\{L_{p} \mid p \in I\right\} \subseteq \mathcal{L}
$$

which turns out to be a regular spread of $\mathrm{PG}(3, F)$ (see [1, Theorem 3.6]).
Conversely, any regular spread of $\mathrm{PG}(3, F)$ can be obtained as a set $\mathcal{S}(I)$ as above, where $K$ is a suitable quadratic extension of $F$. We say that the line $I$ indicates, or is an indicator set of, the spread $\mathcal{S}(I)$ (see e.g. [11]). If $K / F$ is a separable field extension and $\bar{I}$ denotes the line (which is necessarily skew to $I$ ) conjugate to $I$ with respect to this extension, then $\mathcal{S}(I)=\mathcal{S}(\bar{I})$. Note that different spreads of $\mathrm{PG}(3, F)$ may give rise to different quadratic extensions of the ground field $F$ (see [3]).

## 4. Clifford parallelisms

Let now $H=(K / F, b)$ be a quaternion skew field over $F$. We consider $H \cong$ $F^{4}$ as the underlying vector space of $\mathrm{PG}(3, F)$. The group $H^{*}$ acts on $H$ via right (or left) multiplications. Since these are $F$-linear bijections they induce collineations of PG $(3, F)$. Now the right and left Clifford parallelisms on PG $(3, F)$ can be defined as follows:

$$
\begin{array}{ll}
L / / r M: \Leftrightarrow L=M h \text { for some } h \in H^{*} & \text { (right Clifford parallel) } \\
L \| \ell M: \Leftrightarrow L=h M \text { for some } h \in H^{*} & \text { (left Clifford parallel) }
\end{array}
$$

One can easily check that these two relations are in fact parallelisms. By definition, right multiplications map each line to a right parallel one. Moreover, left

page 8 / 16
go back
full screen
close
quit
and

$$
\left(\mathcal{R}_{L}\right)_{\mathrm{opp}}=\left\{I^{U} \mid U \leq L^{2}, \operatorname{dim} U=1\right\} .
$$

Proof. For each $U \leq L^{2}$ with $\operatorname{dim} U=1$ the set $I_{U}$ is a 2-dimensional subspace of $\mathrm{M}_{2}(L)$, since for a fixed $u \in U \backslash\{0\}$ the mapping $\mathrm{M}_{2}(L) \rightarrow L^{2}: M \mapsto u M$ is linear and surjective with kernel $I_{U}$. Similarly, one can see that $I^{U}$ is a 2-dimensional subspace of $\mathrm{M}_{2}(L)$. So all $I_{U}$ and all $I^{U}$ are lines in $\mathcal{Q}_{L}$. Clearly, two such lines meet if and only if they are of different types, and each point $L M$ in $\mathcal{Q}_{L}$ belongs to a line of each type.

Now we turn to the quaternion skew field $H=(K / F, b)$ over $F$ and consider a maximal commutative subfield of $H$, i.e. a quadratic field extension $L$ of $F$ with $F \subseteq L \subseteq H$. Then the following holds true.

page 9 / 16

quit

UNIVERSITEIT
GENT
4.2 Proposition ([7, p. 104]). Let $H$ be a quaternion algebra over $F$ and $L$ any quadratic subfield of $H$.
(i) If $L / F$ is separable, then there exists $d \in F^{*}$ such that $H \cong(L / F, d)$.
(ii) If char $F=2$ and $L=F(h)$ is inseparable, then there exists a separable quadratic extension $F \subseteq L^{\prime} \subseteq H$ such that $H \cong\left(L^{\prime} / F, c\right)$, where $c=n(h)$.

According to this result in the following, whenever we consider a quadratic subfield $L$ of $H$, me may assume without loss of generality $L=K=F+F i$ if $L / F$ is a separable extension, or $L=K^{\prime}:=F+F j$ if $L / F$ is an inseparable extension.
4.3 Lemma. Consider the quaternion skew field $H=(K / F, b)$, write $K^{\prime}=F+F j$ and consider the matrix algebras $H_{K}=\mathrm{M}_{2}(K)$ over $K$ and $H_{K^{\prime}}=\mathrm{M}_{2}\left(K^{\prime}\right)$ over $K^{\prime}$.
(i) The elements of $H \subseteq H_{K}$ are exactly those matrices that are fixed by the bijection

$$
\kappa:\left(\begin{array}{cc}
x & y \\
z & t
\end{array}\right) \mapsto\left(\begin{array}{cc}
\bar{t} & b^{-1} \bar{z} \\
b \bar{y} & \bar{x},
\end{array}\right),
$$

which is involutory and $K$-semilinear with respect to conjugation.
(ii) If char $F=2$, the $F$-algebra $H$ can be embedded in the $K^{\prime}$-algebra $H_{K^{\prime}}$ via the correspondence $\varphi$ mapping

$$
\begin{aligned}
& 1 \mapsto\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right), \quad i \mapsto\left(\begin{array}{cc}
a+1 & a \\
a & a
\end{array}\right), \\
& j \mapsto\left(\begin{array}{ll}
0 & j \\
j & 0
\end{array}\right), \quad i j \mapsto j\left(\begin{array}{cc}
a & a+1 \\
a & a
\end{array}\right) .
\end{aligned}
$$

(iii) If char $F=2$, the embedding $\varphi$ described above is an isometry, i.e. for each $h \in H, n(h)=\operatorname{det} \varphi(h)$.

Proof. Direct computation.
4.4 Remark. Since $K / F$ is quadratic, the projective space $\mathrm{PG}(3, F)$ is a Baer subspace of $\mathrm{PG}(3, K)$. Describe the projective spaces with the help of the 4 -dimensional vector spaces $H$ and $H_{K}$, respectively. Then, the collineation $\tilde{\kappa}$ induced by $\kappa$ is a Baer collineation of $\operatorname{PG}(3, K)$, fixing exactly the points and lines of $\mathrm{PG}(3, F)$. The quadric $\mathcal{Q}_{K}$ is invariant under $\tilde{\kappa}$. In particular, lines in $\mathcal{Q}_{K}$ are mapped to lines in $\mathcal{Q}_{K}$. Assume that for a line $R \in \mathcal{R}_{K}$ we have $R^{\tilde{\kappa}} \in\left(\mathcal{R}_{K}\right)_{\text {opp }}$. Then $R$ and $R^{\tilde{\kappa}}$ meet in a point, which must belong to $P G(3, F)$. But $\mathcal{Q}_{K}$ contains no points of $P G(3, F)$ since the norm of $H$ is anisotropic, a contradiction. Hence the reguli $\mathcal{R}_{K}$ and $\left(\mathcal{R}_{K}\right)_{\text {opp }}$ are invariant under $\tilde{\kappa}$. Each line of $\mathcal{R}_{K}$ (and,

page $10 / 16$
go back

close
quit
4.7 Theorem. The regular spreads $\mathcal{S}(I)$ indicated by lines $I \in \mathcal{R}_{L}$ (or $\left(\mathcal{R}_{L}\right)_{\mathrm{opp}}$, respectively) are exactly the right (left) parallel classes of lines $R$ through 1 that are conjugate to $L$.

page 11 / 16
go back
full screen
close
quit

UNIVERSITEIT GENT

Proof. We distinguish the cases $L=K=F+F i$ and $L=K^{\prime}=F+F j$. First consider the line $L=K$. Each line of the right parallel class of $K$ has the form $K h$ for some $h \in H^{*}$, thus it is spanned by $h=\left(\begin{array}{cc}x & y \\ b \bar{y} & \bar{x}\end{array}\right)$ and $i h=\left(\begin{array}{cc}i x & i y \\ b \bar{i} \bar{y} & \bar{i} \bar{x}\end{array}\right)$. The points of intersection of $K h$ and $\mathcal{Q}_{K}$ are exactly the points $p=K M$, where $M$ is a non-invertible $K$-linear combination of these two matrices. One obtains the two solutions

$$
\begin{aligned}
& p=K M, \quad \text { with } M=-\bar{i}\left(\begin{array}{cc}
x & y \\
b \bar{y} & \bar{x}
\end{array}\right)+\left(\begin{array}{cc}
i x & i y \\
b \bar{i} \bar{y} & \bar{i} \bar{x}
\end{array}\right)=(i-\bar{i})\left(\begin{array}{ll}
x & y \\
0 & 0
\end{array}\right) \quad \text { and } \\
& p^{\prime}=K M^{\prime} \text {, with } M^{\prime}=-i\left(\begin{array}{cc}
x & y \\
b \bar{y} & \bar{x}
\end{array}\right)+\left(\begin{array}{cc}
i x & i y \\
b \bar{i} \bar{y} & \bar{i} \bar{x}
\end{array}\right)=(\bar{i}-i)\left(\begin{array}{cc}
0 & 0 \\
b \bar{y} & \bar{x}
\end{array}\right) .
\end{aligned}
$$

Obviously (cfr. Proposition 4.1), the matrices $M$ from above, with $x, y \in K$, are exactly the elements of $I=I_{U} \in \mathcal{R}_{K}$, where $U=K(0,1)$. In particular, the right parallel class of $K$ is indicated by $I$. Similarly, one can show that the left parallel class of $K$ is indicated by $J=I^{V} \in\left(\mathcal{R}_{K}\right)_{\text {opp }}$, where $V=K(1,0)$.

Assume now char $F=2$ and consider the inseparable extension $L=K^{\prime}=$ $F+F j$. Again each line of the right parallel class of $K^{\prime}$ is spanned by $h$ and $j h$ for a suitable $h \in H^{*}$. We consider $H$ as a subring of $H_{K^{\prime}}$ (cfr. Lemma 4.3(ii)), and thus $h=\left(\begin{array}{ll}x & y \\ z & t\end{array}\right)$ and $j h=\left(\begin{array}{ll}j z & j t \\ j x & j y\end{array}\right)$. The points of intersection of $K^{\prime} h$ and $\mathcal{Q}_{K^{\prime}}$ are the points $p=K^{\prime} M$ where $M$ is a non-invertible $K^{\prime}$-linear combination of $h$ and $j h$. A straightforward computation shows that, assuming as a consequence of $h \in H^{*}$ that $\operatorname{det}(h) \neq 0$, the only solution is

$$
p=K^{\prime} M, \text { with } M=j\left(\begin{array}{ll}
x+z & y+t \\
x+z & y+t
\end{array}\right)
$$

and, again by Proposition 4.1, the matrices $M$ of this form are the elements of $I=I_{U} \in \mathcal{R}_{K^{\prime}}$, where $U=K^{\prime}(1,1)$. Similarly one can show that the left parallel class of $K^{\prime}$ is indicated by $J=I^{U} \in\left(\mathcal{R}_{K^{\prime}}\right)_{\text {opp }}$.

In the remainder of this proof there is no need to distinguish any more the separable case from the inseparable one, thus, from now on, writing $L$ we mean either $K$ or $K^{\prime}$. We consider now $R=c^{-1} L c, c \in H^{*}$. Let $\alpha$ be the collineation of $\mathrm{PG}(3, L)$ induced by the conjugation $x \mapsto c^{-1} x c$. Then $\alpha$ leaves both $\mathrm{PG}(3, F)$ and $\mathcal{Q}_{L}$ invariant. Moreover,

$$
\begin{equation*}
u \in \operatorname{ker} M \Longleftrightarrow u c \in \operatorname{ker} c^{-1} M c, \quad u \in \operatorname{im} M \Longleftrightarrow u c \in \operatorname{im} c^{-1} M c \tag{4.1}
\end{equation*}
$$

implies that $\alpha$ leaves $\mathcal{R}_{L}$ and $\left(\mathcal{R}_{L}\right)_{\text {opp }}$ invariant. Since $\alpha$ maps the right (left) parallel class of $L$ to the right (left) parallel class of $R$ we conclude that the right (left) parallel class of $R$ is indicated by $I^{\alpha} \in \mathcal{R}_{L}$ (or $J^{\alpha} \in\left(\mathcal{R}_{L}\right)_{\mathrm{opp}}$, respectively).

It remains to show that all spreads indicated by a line of $\mathcal{R}_{L}$ (or $\left.\left(\mathcal{R}_{L}\right)_{\text {opp }}\right)$ are right (left) parallel classes of lines $c^{-1} L c$. But this follows from the above by (4.1), since for each 1-dimensional subspace $W \leq L^{2}$ there is a $c \in H^{*}$ with $W=U c$ (or $W=V c$, respectively).

Note that, in the proof above, in the separable case we have $p^{\prime}=p^{\tilde{\kappa}}$ (see Remark 4.4). So the right parallel class of $K$ is also indicated by $I^{\prime}=I^{\tilde{\kappa}}$.

Since each (right or left) parallel class has a representative through 1, which is a maximal commutative subfield of $H$, by Proposition 4.2 we can describe it as $\mathcal{S}(I)$, with $I$ a line in an appropriate Baer superspace of $\mathrm{PG}(3, F)$. In particular, we get the following.
4.8 Corollary. The right and left Clifford parallelisms are regular.

In the special case that $F$ admits only one quadratic extension $K$ (and hence $K / F$ is separable, thus char $F \neq 2$ ), the Clifford parallelisms are indicated by exactly the lines of a regulus and its opposite in $\mathrm{PG}(3, K)$. For $F=\mathbb{R}$ and $K=\mathbb{C}$ this is well known, see e.g. [8, 12 A ]. This observation leads to the following corollary.
4.9 Corollary. Let $F, K$ and $H$ be as before. Then all quadratic extensions of $F$ in $H$ are conjugate to $K$ if and only if there exists a hyperbolic quadric $\mathcal{Q}$ in $\operatorname{PG}(3, K)$ having no points in $\mathrm{PG}(3, F)$ and incident with every line of $\mathrm{PG}(3, F)$.

In general, however, we need more than one Baer superspace $\operatorname{PG}(3, L)$. In order to get a unified description of the entire parallelisms, we proceed as follows: Let $\widehat{F}$ be the quadratic closure of $F$. Then all quadratic extensions $L$ of $F$ are contained in $\widehat{F}$. We consider $\mathrm{PG}(3, F)$ and all $\mathrm{PG}(3, L)$ as subspaces of $\mathrm{PG}(3, \widehat{F})$. More explicitly, we take $H$ as underlying vector space of $\mathrm{PG}(3, F)$ and $H_{L}$ or $H_{\widehat{F}}$ (with the same basis $(1, i, j, i j)$ ) as underlying vector spaces of $\mathrm{PG}(3, L)$ or $\mathrm{PG}(3, \widehat{F})$, respectively. In particular, for any two distinct separable quadratic extensions $L, L^{\prime}$ we have $\mathrm{PG}(3, L) \cap \mathrm{PG}\left(3, L^{\prime}\right)=\mathrm{PG}(3, F)$.

In addition, we consider in $\mathrm{PG}(3, \widehat{F})$ and in all $\mathrm{PG}(3, L)$ the quadrics $\mathcal{Q}_{\widehat{F}}$ and $\mathcal{Q}_{L}$ associated to the norm of $H$. By Theorem 2.2 the quadric $\mathcal{Q}_{L}$ is empty exactly if $L$ is not a subalgebra of $H$, and hyperbolic otherwise. This implies that also $\mathcal{Q}_{\widehat{F}}$ is hyperbolic. Let the reguli $\mathcal{R}_{\widehat{F}}$ on $\mathcal{Q}_{\widehat{F}}$ and $\mathcal{R}_{L}$ on $\mathcal{Q}_{L}$ be defined as in Proposition 4.1. Then $\mathcal{R}_{L}$ consists exactly of those lines of $\mathcal{R}_{\widehat{F}}$ that belong to $\mathrm{PG}(3, L)$, the same holds for the opposite reguli. In case that $\mathcal{Q}_{L}=\emptyset$ we set $\mathcal{R}_{L}:=\emptyset=:\left(\mathcal{R}_{L}\right)_{\text {opp }}$.

For a line $I$ on $\mathcal{Q}_{\widehat{F}}$ we can define $\mathcal{S}(I)$ only if $I$ belongs to some $\operatorname{PG}(3, L)$; note that of course we then only consider the points of $I$ that are points of PG $(3, L)$.

4.10 Theorem. Let $F$ be a (commutative) field, $H$ be a quaternion skew field over $F$ and, for any quadratic extension $L$ of $F$, let $\mathcal{Q}_{L}$ be the quadric of $\mathrm{PG}(3, L)$ associated to the norm of $H$ and $\mathcal{R}_{L}$ and $\left(\mathcal{R}_{L}\right)_{\text {opp }}$ the reguli of $\mathcal{Q}_{L}$ defined as above. Then the set

$$
\left\{\mathcal{S}(I) \mid I \in \mathcal{R}_{L}, L / F \text { quadratic extension }\right\}
$$

is the right Clifford parallelism of PG $(3, F)$. Analogously,

$$
\left\{\mathcal{S}(I) \mid I \in\left(\mathcal{R}_{L}\right)_{\text {opp }}, L / F \text { quadratic extension }\right\}
$$

is the left Clifford parallelism of $\mathrm{PG}(3, F)$.
Proof. This follows from Theorem 4.7. The change of basis we employed in order to prove that theorem (depending on $L$, and writing the elements of $H$ and of $H_{L}$ as matrices) does not affect the statements needed.
4.11 Remark. Note that, according to Proposition 2.4, any quadric of $\mathrm{PG}(3, F)$ which has no points in $\mathrm{PG}(3, F)$ and is hyperbolic in a quadratic field extension of $F$ is in fact the quadric associated to the norm form of a quaternion skew field over $F$, and thus, according to the previous theorem, it defines a Clifford parallelism in $\mathrm{PG}(3, F)$. Moreover any two such quadrics which are not projectively equivalent on $F$ (i.e. such that there is no projective collineation of $\mathrm{PG}(3, \widehat{F})$ with coefficients in $F$ mapping one to the other) define non projectively equivalent Clifford parallelisms in $\mathrm{PG}(3, F)$.
4.12 Example. In order to illustrate that in fact many different Baer superspaces may be needed, we consider an example. First, we make some general observations: Consider a field $F$ of characteristic different from 2. A quadratic extension $K=F(\sqrt{c})$ of $F$ (with $c \in F$ a non-square) appears as a maximal commutative subfield of $H$, if $K=F+F x$ with $t(x)=0$ and $n(x)=-c$. Two subfields $F+F x, F+F y$ of $H$ with $t(x)=0=t(y)$ are isomorphic as $F$-algebras if and only if they are conjugate in $H$ (by the classical Skolem-Noether Theorem), i.e., if and only if $n(x)$ and $n(y)$ are in the same square class of $F^{*}$. So the conjugacy classes of maximal commutative subfields of $H$ are in 1-1 correspondence with the square classes of the subgroup $\left\{n(x) \mid x \in H^{*}, t(x)=0\right\}$ of $F^{*}$.

Let us take the special case of the ordinary rational quaternions, i.e., $F=\mathbb{Q}$ and $H=(K / \mathbb{Q}, b)$, where $K=\mathbb{Q}(i)$ with $i^{2}=-1=b$. Then for $x \in H$ with $t(x)=0$ we have $n(x)=x_{2}^{2}+x_{3}^{2}+x_{4}^{2}$, whence each field $\mathbb{Q}(\sqrt{-d})$, with $d \in \mathbb{Q}$ sum of three squares, appears as a subfield of $H$. Among many others, $H$ contains the non-conjugate subfields $\mathbb{Q}(\sqrt{-1}), \mathbb{Q}(\sqrt{-2}), \mathbb{Q}(\sqrt{-3})$, each of which gives rise to (only) a part of the Clifford parallelisms.

4.13 Remark. Assume that the 2-dimensional subalgebras of a quaternion skew field $H$ over $F$ do not belong to the same conjugacy class, or equivalently that the field $F$ has non isomorphic quadratic extensions that are subalgebras of $H$. In this case the projective space $\mathrm{PG}(3, F)$ can be endowed with new parallelisms in the following way. Consider the right and left Clifford parallelisms defined in Theorem 4.10, fix a family $\mathscr{F}$ of quadratic extensions $L$ of $F$ with $F \subseteq L \subseteq H$ and define the following family of spreads:

$$
\begin{aligned}
& \mathscr{C}(\mathscr{F}):=\left\{\mathcal{S}(I) \mid I \in \mathcal{R}_{L}, L / F \text { quadratic extension, } L \notin \mathscr{F}\right\} \\
& \cup\left\{\mathcal{S}(I) \mid I \in\left(\mathcal{R}_{L}\right)_{\mathrm{opp}}, L \in \mathscr{F}\right\} .
\end{aligned}
$$

Then $\mathscr{C}(\mathscr{F})$ is a covering of the line set of $\mathrm{PG}(3, F)$, and any two spreads of this family are disjoint, for, a line $R h$ through a generic point $h$ of $\operatorname{PG}(3, F)$ belongs to a left parallel class if and only if there exists a line $R^{\prime}$ through 1 such that $R h=h R^{\prime}$, and hence if and only if $R$ and $R^{\prime}$ are conjugate in $H$. By Theorem 4.7 this happens if and only if the parallel classes are indicated by lines belonging to the same quadratic extension $L$ of $F$.

These new "Clifford-like" parallelisms will be the target of more investigations in forthcoming papers.
