## **Globalization and Regional Income Inequality**

Empirical evidence from within China

Guanghua Wan,<sup>1</sup> Ming Lu,<sup>2</sup> and Zhao Chen<sup>2</sup>

November 2006

### **Abstract**

China's recent accession to the WTO is expected to accelerate its integration into the world economy, which aggravates concerns over the impact of globalization on the already rising inter-regional income inequality in China. This paper discusses China's globalization process and estimates an income generating function, incorporating trade and FDI variables. It then applies the newly developed Shapley value decomposition technique to quantify the contributions of globalization, along with other variables, to regional inequality. It is found that (a) globalization constitutes a positive and substantial share of regional inequality and the share rises over time; (b) domestic capital, however, emerges as the largest contributor to regional inequality; (c) economic reform characterized by privatization exerts an increasingly significant impact on regional inequality; and (d) the relative contributions of education, location, urbanization and dependency ratio to regional inequality have been declining.

Keywords: globalization, inequality decomposition, Shapley value, China

## Acknowledgements

This study was prepared for the UNU-WIDER project on Inequality and Poverty in China, directed by Guanghua Wan. We are grateful to Tony Shorrocks, an anonymous referee, Stephan Klasen, Eric Thorbecke and Machiko Nissanke for helpful comments on earlier drafts of the paper. Financial support from the Chinese Natural Sciences Foundation (No. 70403004), and the China Center for Economic Studies of Fudan University are acknowledged.

The figures appear at the end of the paper.

*The World Institute for Development Economics Research (WIDER) was established by the United Nations University (UNU) as its first research and training centre and started work in Helsinki, Finland in 1985. The Institute undertakes applied research and policy analysis on structural changes affecting the developing and transitional economies, provides a forum for the advocacy of policies leading to robust, equitable and environmentally sustainable growth, and promotes capacity strengthening and training in the field of economic and social policy making. Work is carried out by staff researchers and visiting scholars in Helsinki and through networks of collaborating scholars and institutions around the world.*

The debate over globalization is lively, often passionate, and has sometimes been violent. Stanley Fischer (2003: 2)

## 1 Introduction

How globalization affects inequality is under heated debate (Fischer 2003: 5). Stiglitz (1998) and Hurrell and Woods (2000), among others, argue that globalization leads to increases in inequality because trade increases differentials in returns to education and skills, globalization marginalizes certain groups of people or geographic regions, and liberalization is not complemented by development of adequate institutions and governance. This view is supported by evidence from China and some transitional economies that are experiencing significant increases in inequality after their opening up to the outside world (Mazur 2000; Birdsall 1999). In developed countries, rising inequalities are being attributed to trade growth or international specialization as well (Atkinson 2001). On the contrary, Srinivasan and Bhagwati (1999) and Ben-David (1993) conclude that globalization helps to reduce inequality. This is also supported by evidence from a number of countries where inequality decreased when they liberalized their economies (Wade 2001). In between these two opposing views, Sala-i-Martin (2002a,b) and Lindert and Williamson (2001) find that a significant globalization-inequality relationship does not exist. Krugman and Venables (1995: 859) deduce a U-shaped pattern between inequality and trade.

A number of factors can explain these mixed findings. First, inequality is measured differently, not only by employing alternative indices. While some consider inequality among individuals, others focus on inequality between countries. Some explore inequality of a country or a few countries, others discuss inequality of the globe. Second, there exist differences in the analytical techniques. Most studies use cross-country regressions; but some simply rely on partial correlations between inequality and globalization defined in various ways.<sup>1</sup> Correlation analysis cannot control for other causal variables and cross-country regressions may produce different results when different control variables or different model specifications are used. Finally, sample coverage (selection of countries and time periods) differs from study to study.

This paper contributes to the literature by examining the impact of globalization on regional income inequality in China. Focusing on China requires little justification,

---

<sup>1</sup> The concept of globalization has many dimensions, ranging from interdependence of economic activities in different countries to flows of ideas across national borders. In this paper, we focus on economic globalization through exchanges of goods and services, and flows of foreign capital. Flows of labour, information, ideology, culture and living styles are not considered as relevant data are unavailable or incomplete. To be more precise, we use openness (trade/GDP ratio) and per capita FDI to represent globalization in this paper.

especially given China's importance in determining the global inequality trend. In addition, it can help alleviate the heterogeneity and data comparability problems often encountered in cross-country studies (Atkinson and Brandolini 2001; Srinivasan and Bhagwati 1999). To enhance the robustness of our empirical results, we first characterize the underlying income generating process by the flexible Box-Cox model and then quantify the globalization impact under all conventional measures of inequality. In decomposing total inequality into components associated with relevant determinants, the Shapley value framework of Shorrocks (1999) is combined with the estimated income generating function. The Shapley methodology is based on the cooperative game theory and is being recently used by Kolenikov and Shorrocks (2005), and Wan (2004).

To elaborate further, in this paper we seek to answer two questions: how globalization and regional income inequality are related in China? And how much does globalization contribute to regional inequality in China? The first question has received some attention. Kanbur and Zhang (2005) obtain a positive relationship between openness (measured by effective tariff rate and the trade/GDP ratio) and interregional inequality. Xing and Zhang (2004) find the same using FDI as a measure of globalization. However, Wei and Wu (2003) conclude with a negative relationship between urban-rural disparity and the trade/GDP ratio. With respect to the second question, little has been published with the exception of Zhang and Zhang (2003). Zhang and Zhang (ibid.) estimate a labour productivity (GDP/labour ratio) function and decompose inequality (measured by the log variance) in labour productivity into a number of components, including those associated with openness. The log variance measure, however, violates the crucial principle of transfers and the GDP/labour ratio does not necessarily relate to personal income in China (Lin and Liu 2003). Bourguignon and Morrisson (2002) appeal for the use of income rather than GDP data in analyzing inequality.

The remainder of this paper is organized as follows. Section 2 presents a background description of China's journey to globalization. Income generating functions are specified and estimated in Section 3, where inequality decomposition results are also discussed. Finally, policy implications are explored in Section 4.

## **2 China's journey to globalization and regional inequality**

As an active participant of the third globalization process, China is fast integrating into the world economy at a pace as remarkable as her economic growth. After over 20 years of opening up, China has become the largest recipient of foreign direct investment (FDI) and the fifth largest trader in the world since 2002.

### **2.1 Growing international trade**

Before 1979, international trade was under the plan of the central government, which controlled more than 90 per cent of trade by monopolizing the imports and exports of over 3,000 kinds of commodities. These commodities can be classified into two

categories: plan-commanded goods (both the value and volume of trade were strictly controlled) and plan-guided goods (only the value of trade was controlled). In 1985, the number of goods under these categories was cut to about 100 each. By 1991, almost all exports were deregulated, with only 15 per cent controlled by specially appointed trading companies. Imports have also been deregulated. The proportion of plan-commanded imports in the total import volume was reduced from 40 per cent in 1985 to 18.5 per cent in 1991. By 1994, almost all planning on imports and exports was abolished with a few exceptions where extremely important goods were traded by specially appointed trading companies.

In pre-reform China, tariff was high and represented the only form of protection. When China initiated significant trade reforms in 1992, the rates of tariff remained high, averaged at 44.05 per cent. Since 1992, China has cut its tariff rates substantially every year. The average tariff rate fell to 17.1 per cent in 1998 (Yin 1998: 126). On the other hand, non-tariff barriers were introduced in the early 1980s. Subsequently, an increasing number of goods were placed under licensed trading and quota. In 1992, some 25 per cent of imports and 15 per cent of exports were managed under licenses. However, the scope of license and quota management has been narrowed down since 1992. By 1997, only 384 categories of imports, a mere 5 per cent of the total, were managed under quota and licenses (Yin 1998: 129).

Both exports and imports have experienced remarkable growth. The growth trend was maintained even during the Asian financial crisis. In 1978, China ranked 32nd in the world in terms of international trade. The ranking improved to 15th in 1989, 10th in 1997 and 6th in 2001. The ratio of international trade to GDP also rose from 9.85 per cent in 1978 to as high as 42.78 per cent in 2001. In 2002, total trade exceeded US\$600 billion, representing more than 50 per cent of China's GDP.<sup>2</sup> This places China as the 5th largest trader in the world. In passing, it is noted that export of manufactured goods has accounted for a larger and larger share since the mid-1980s, while the corresponding import has declined though at a slow rate. Clearly, China has been industrializing and is becoming a major exporter of manufactured commodities.

## **2.2 Increasing cross-boarder capital flows**

In 1979, three Special Economic Zones (SEZs) were set up in Guangdong for attracting FDI.<sup>3</sup> However, not until 1984 did FDI start to pour in. In the same year, twenty-four additional SEZs were opened. Since that time, more and more SEZs are developed to attract FDI and technology transfer, and to enhance exports. The second wave of FDI

---

<sup>2</sup> Unless indicated otherwise, data quoted in this section are all from the National Bureau of Statistics (NBS various years).

<sup>3</sup> See table 3 in Démurger et al. (2002) for the timeline of policy initiatives.

inflow occurred in 1992 when Deng Xiaoping made the well-known tour of south China.

For many years China was the largest recipient of FDI among developing countries, and the second largest in the world since 1993, next to the USA. In 2002, China attracted US\$52.743 billion of FDI and became the number one in the world. The ratio of FDI to GDP was as high as approximately 4 per cent in 2001. Meanwhile, a large amount of foreign loans has been utilized in various areas of development.<sup>4</sup> Also, China has seen an impressive growth of capital outflows in recent years, owing to the rapid growth of domestic enterprises. China's investment abroad nearly tripled from US\$2562.49 million in 1997 to US\$6885.398 million in 2001.

### **2.3 Further opening up after WTO accession**

Since becoming a member of the WTO, China has taken several steps to promote globalization. On 1 January 2002, China cut import tariffs for more than 5,000 goods. The average tariff rate was reduced to 12 per cent from a level of 15.3 per cent in 2001. The rate for manufacturing goods was reduced from 14.7 per cent to 11.3 per cent, while that for agricultural goods, except aquatic products, from 18.8 per cent to 15.8 per cent. At the same time, China abolished quota and license arrangement for grains, wool, cotton, chemical fertilizers, and so on. In addition, China modified or abolished those laws and regulations that are inconsistent with WTO rules. New laws on anti-dumping and anti-subsidy have been implemented since 1 January 2002. Looking into the future, the average tariff rate will be cut from 12 per cent in 2002 to 9.3 per cent in 2005. Non-tariff barriers will be removed for most manufacturing goods by the end of 2004. Small- and medium-sized enterprises and foreign-owned companies will be entitled to participate directly in international trade.

Around China's entry into the WTO, China issued new laws and regulations concerning service trade, covering legal service, telecommunication, financial institution, insurance, audio and video products, and tourism, etc. Laws regarding entry of foreign sales companies and joint ventures of stock exchange are being drawn up. Also, measures have been taken to ensure compliance with rules of the WTO on intellectual property, foreign investment, and information transmission.

### **2.4 Globalization and regional inequality**

Clearly, China as a whole has gone a long way in globalization. However, there exist significant differences in the pace and extent of globalization across regions. This is particularly true when China is divided into three areas: the east, central and west. Figures 1 and 2 plot the ratios of regional per capita FDI and regional openness index to

---

<sup>4</sup> Stock market represents another avenue for attracting foreign capital.

the national averages (selected years). It is clear that east China attracts much more FDI and trade than the central and the west, although convergences appear to have taken place within each area. This pattern also applies to other variables such as income, capital and extent of privatization. Therefore, disparity in globalization is largely an inter-area issue and it is justified to include area dummies in the income generating functions to be considered later.

Such differences in globalization may arise through a number of mechanisms and are expected to affect regional inequality. First, some regions have location advantages thus can better exploit benefits of trade (close to ports, Hong Kong, Macau, Russia, and Vietnam). Second, some regions possess more family ties to overseas investors thus would attract more FDI and associated spill-over effects. Third, some regions are endowed with more or better resources (infrastructure, human capital, market potential) thus can better attract FDI and develop trade. Finally, local culture, customs and traditions differ from region to region. These non-economic factors are embedded in the leadership styles of the regional and local governments thus make regional economies more or less receptive to foreign capitals and technologies. All the above differences lead to different paces of globalization in different regions, despite the uniform national policy of opening up and the appeals of the central government for local governments to actively embrace globalization.

Needless to say, globalization comes with both benefits and costs, which are not evenly distributed among regions or individuals. It is thus imperative to analyze the impact of globalization on income inequality before policy measures can be designed and implemented to curb the fast rising regional income inequality in China.

### **3 Accounting for China's inter-regional income inequality**

As the first step of the regression-based decomposition, an income generating function must be obtained. Specification of such a function usually relies on the human capital theory. However, for modelling regional average income in China, consideration must be given to both human capital theory and production theory. This is because variables other than human capital are important in determining income levels across regions in China. These variables include capital input as argued by Yang (1994), government support as argued by Ma and Yu (2003), and deregulation or reform as argued by Démurger et al. (2002). Capital will be represented by per capita capital stock, government support by fiscal expenditure excluding administrative fees, and reform or deregulation by privatization index defined as the proportion of non-state-owned enterprises employees in total labour force. Meanwhile, it is accepted that geography is important in affecting regional economic development in China. Thus dummy variables for east, central and west China will be used to control for geography and infrastructure (Démurger 2001). Further, urbanization differs from region to region and such differences affect regional per capita income and thus inequality. This can be controlled

by an urbanization index, defined as the proportion of non-agricultural population. Finally, the conventional variables of labour and education must be considered. Given labour surplus in China and the linear relationship between the variables of labour and dependency ratio, we chose to include the latter. The converging trend in the dependency ratio implies a declining contribution of this variable to inequality.

The observations on capital stock are taken from Zhang, Wu and Zhang (2004) (ZWZ hereafter). ZWZ do not include inventory as capital stock while Zhang and Zhang (2003) (ZZ hereafter) do, although both studies use the same data estimation technique. Also, ZWZ construct the time series of capital stock as from 1952 rather than 1978 as in ZZ. Since inventory represents only potential not effective production input and biases in the estimate decrease as time interval expands between the initial year and the current year, data from ZWZ will be used in this paper. Other data are compiled from *Comprehensive Statistical Data and Materials for 50 Years of New China*, as well as various issues of *China Statistical Yearbook*, both published by the National Bureau of Statistics (NBS). See the Appendix for details on data construction.

Largely due to the incompleteness of FDI statistics, the modelling exercise is confined to the period of 1987-2001. With Taiwan, Hong Kong and Macao excluded, there are 31 provinces or regions in China, including four autonomous municipal cities. Chongqing, the youngest region in China, was created in 1997 and is merged with Sichuan. Tibet is excluded because of lack of complete data. Therefore, a total of 29 regions will be covered in this study.

In summary, the following variables are included in the underlying income generating function: per capita income ( $Y$ ), per capita capital input ( $K$ ), dependency ratio as an alternative of labour ( $Dep$ ),<sup>5</sup> average years of schooling ( $Edu$ ), per capita FDI ( $FDI$ ), trade/GDP ratio ( $Trade$ ), reform or privatization defined as proportion of labour force working in the non-state-owned enterprises ( $Reform$ ), urbanization defined as the proportion of non-agricultural population ( $Urb$ ) that also serves as a proxy for industrialization, location dummies ( $Central$  and  $West$ ),<sup>6</sup> and dummies for the period 1992 onwards ( $D92$ ) and 1996 onwards ( $D96$ ).  $D92$  is used to capture the effects of Deng Xiaoping's South-China tour and  $D96$  to capture a number of significant reforms initiated in 1996, especially the labour market reform characterised by the large-scale laying-off of redundant workers ( $Xiagang$ ). Finally, government support is represented by per capita government expenditure excluding administrative fees ( $Gov$ ). This is a proxy of government involvement in economic activities in general and in public investment in particular. All observations in value terms are deflated by regional CPIs.

---

<sup>5</sup> We tried to add per capita labour input or household size, but neither of them is significant.

<sup>6</sup> Consistent with most studies, central provinces refer to Shanxi, Guangxi, Inner Mongolia, Jilin, Heilongjiang, Anhui, Jiangxi, Henan, Hubei and Hunan, and western provinces include Sichuan, Guizhou, Yunnan, Shaanxi, Gansu, Qinghai, Ningxia, and Xinjiang.

Regarding functional form, most empirical studies in human capital theory adopt the semi-log form or the Mincer model. If one relies on the production theory, Cobb-Douglas (double log), CES (constant elasticity of substitution) or translog specifications are the possible candidates—see Wan (1996) Wan and Cheng (2001). In the inequality decomposition literature, Fields and Yoo (2000: 145) did not explicitly provide theoretical arguments supporting their semi-log specification, except making the casual remark ‘based on human capital theory or some other underlying theoretical model’. Tsui (forthcoming) did exactly the same, with a different remark ‘to render the estimation manageable’. On the other hand, Morduch and Sicular (2002: 101) simply used a strictly linear function without much justification. In this paper, we decide to adopt the combined Box-Cox and Box-Tidwell model in order to minimize misspecification error:

$$Y^{(\lambda)} = a_0 + a_1X_1^{(\theta)} + a_2X_2^{(\theta)} + \dots + a_KX_K^{(\theta)} + \text{dummy terms} + u \quad (1)$$

where  $\lambda$  and  $\theta$  are transformation parameters; other notations are self-explanatory. In this specification,  $Y^{(\lambda)} = \frac{Y^\lambda - 1}{\lambda}$  and  $X_k^{(\theta)} = \frac{X_k^\theta - 1}{\theta}$ . As  $\lambda$  approaches 0, the limit of  $\frac{Y^\lambda - 1}{\lambda}$  is  $\text{Ln } Y$  by L’Hopital’s rule. Hence,  $Y^{(\lambda)} = \text{Ln } Y$  when  $\lambda = 0$  (Judge et al. 1988).

The same arguments apply to  $X_k^{(\theta)}$ . Model (1) encompasses many functional forms, including the semilog income-generating function of Fields and Yoo (2000) and Tsui (forthcoming) if  $\lambda = 0$  and  $\theta = 1$ , and the standard linear function of Morduch and Sicular (2002) if  $\lambda = \theta = 1$ . In the case that  $\lambda = \theta = 0$ , a double-log equation, as used by Zhang and Zhang (2003) is obtained. When  $\lambda = -1$  or  $\theta = -1$ , the relevant variable becomes its reciprocal. Clearly, one can restrict each of the two transformation parameters to be 0, 1, -1 or unrestricted. The 4 by 4 combinations produce 16 different functional forms. Moreover, one can impose  $\lambda = \theta$  although they are not restricted to a particular numerical value. Clearly, our specification (1) is more general and flexible than what has been used in the inequality decomposition literature as it encompasses at least 17 different models.

These 17 models are fitted to the Chinese data using Shazam, which employs an iterative maximum likelihood (ML) estimation procedure.<sup>7</sup> Model selection can be easily undertaken using the conventional  $\chi^2$  test where the test statistic is twice the difference in the loglikelihood values of model (1) and its restricted versions. As reported in Table A1 of the Appendix, the test results indicate rejections of all models

---

<sup>7</sup> Ideally, one should estimate these models for each region or for every year. Due to the limited sample size and also given the flexibility of our functional form, we choose to pool the data for model estimation. As shown later, a re-estimation by GMM under the specification of a dynamic panel data model supports our choice.

with two exceptions. The first case involves imposing  $\lambda = 0$  while  $\theta$  remaining being a free parameter. This amounts to a log-nonlinear model (the  $X$ s are subject to a nonlinear transformation). The second case involves restricting  $\lambda = \theta$ . Statistically speaking, these two models are equivalent to (1) and either of them can be used for inequality decomposition. We choose to use the log-nonlinear model largely because it is consistent with the human capital theory where almost all empirical studies apply logarithm transformation to the dependent variable in modeling the wage or income generating process.

Could the log-nonlinear model be spurious? After all, the panel data we use contain fifteen years of time series observations thus the variables may be non-stationary. Employing the popular unit-root test of Im et al. (2003) or IPS test for heterogeneous panel data, we found that FDI and education are stationary, but all other variables are non-stationary. Consequently, it is necessary to test for co-integration (McCoskey and Kao 1999). The literature on co-integration test in panels is large and fast growing. Baltagi and Kao (200) provide a comprehensive survey. For a more recent review, see Breitung and Pesaran (2005). Consequently, many testing procedures are available and each has its own merits and disadvantages. We chose to employ the residual-based test of Im et al. (2003) or IPS due to its popularity.<sup>8</sup> Relying on IPS, the residual is found to be stationary when the order of lag is set to two. The test statistic is found to be -1.71 while the critical value is -1.66, indicating rejection of the null hypothesis of unit roots. According to this test result, the log-nonlinear model we obtained earlier can be said to represent a valid long-run regression relationship.<sup>9</sup>

One may argue that one or more of the independent variables could be endogenous, such as trade and FDI. Consequently, we re-estimate the log-nonlinear model using the generalized method of moment or GMM technique of Blundell and Bond (1998) and then apply the Hausman test (Hausman 1978). The resultant  $\chi^2$  statistic is 0.86, indicating absence of endogeneity in our log-nonlinear model. It is noted that all GMM estimates except that for government support (*Gov*) possess the same signs as the ML estimates, confirming the robustness of the latter. However, most GMM estimates including that for *Gov* are insignificant. This is not surprising as GMM estimation can only guarantee consistency but not efficiency. Consequently, we disregard the GMM estimation results hereafter as ML estimation of our model is both efficient and consistent.

---

<sup>8</sup> IPS is the only unit roots test for panel models that is coded in TSP and Stata.

<sup>9</sup> Caution must be exercised here as the IPS test, as with many other co-integration tests, cannot guarantee co-integration in all units/groups in the panel when the null hypothesis of unit roots is rejected.

Table 1 reports ML estimation results for the log-nonlinear model. No  $t$ -ratio is reported for the  $\theta$  coefficient as it is obtained by grid search. Earlier rejection of the double-log model implies that  $\theta$  is significantly different from zero. It is clear that the model fits the data quite well as indicated by the high  $R^2$ . All parameters are different from 0 at the 1 per cent or 5 per cent level of significance. Further, the signs of all parameter estimates are consistent with expectations. In particular, the coefficient estimates for the location dummies match the fact that western regions are poorer than central regions, which, in turn, are poorer than eastern regions. In terms of elasticity estimates, income growth is quite responsive to reform, education, government support, urbanization and domestic capital. The low elasticity of FDI is acceptable given its small sample mean value (517 yuan) relative to domestic capital (4403 yuan). Since per capita domestic capital is 8.5 times that of per capita FDI, the marginal impact of FDI on income is 45 per cent larger than that of domestic capital, which corroborates well with conventional wisdoms.

Table 1: Estimated income generating function (sample size = 435)

Variable	Coefficient estimate	t-ratio	p-value	Elasticity at means	Loglikelihood value	Adj-R <sup>2</sup>
Capital	0.034	4.612	0.000	0.105

To analyze inequality of income rather than inequality of logarithm of income, it is necessary to solve the estimated log-nonlinear income generating function for the income variable  $Y$ :

$$Y = \exp(\hat{a}_0) \cdot \exp(\hat{a}_1 X_1^{(\theta)} + \hat{a}_2 X_2^{(\theta)} + \dots + \hat{a}_K X_K^{(\theta)}) \cdot \exp(\text{dummy terms}) \cdot \exp(\hat{u}) \quad (2)$$

The term  $\exp(\hat{a}_0)$  is a scalar in (2) and can be removed from the equation without any consequence when relative measures of inequality are used, as in this paper. By the same token, year dummy terms can be removed since inequality will be measured and decomposed on a year-by-year basis.

To decompose total inequality in  $Y$  using (2), the first step is to identify the contribution of the residual term  $\hat{u}$ . This can be achieved by adopting the before-after principle of Cancian and Reed (1998). In other words, the contribution can be calculated as the difference between inequality of the original income  $Y$  and that of income given by (2) when assuming  $\hat{u} = 0$ . Denote this income by  $\tilde{Y}$  and an inequality index by  $I$ , the residual contribution is simply equal to  $I(Y) - I(\tilde{Y})$ , where:

$$\tilde{Y} = \exp(\hat{a}_0) \cdot \exp(\hat{a}_1 X_1^{(\theta)} + \hat{a}_2 X_2^{(\theta)} + \dots + \hat{a}_K X_K^{(\theta)}) \cdot \exp(\text{dummy terms}) \quad (3)$$

Again, the year dummy terms and  $\exp(\hat{a}_0)$  can be removed from (3) without affecting the analytical results. In passing, it is noted that  $\tilde{Y}$  differs from the usual predicted  $Y$  under a semilog econometric model by a factor of  $\exp(0.5 \hat{\sigma}^2)$ , where  $\hat{\sigma}^2$  is the estimated variance of the error term (see Wan 1996).

Using the Gini index as an example measure, total income inequality and the residual contribution for China are tabulated in Table 2 (for results using other measures, see Tables A2-A5 in the Appendix). The total inequality displays a clear upward trend, increased over 24 per cent from 1987 to 2001. This increase is also evident when other inequality indices are used. The values of Gini may appear smaller than some would expect. This is because they represent the between component—inequality between regions only, excluding the within component. To calculate the latter requires data at the individual or household level. Also, deflation by regional CPIs produces smaller regional inequality estimates (Wan 2001).

To a large extent, the residual contribution can be interpreted as that part of inequality not accounted for by the included variables. That is, it represents the effect on inequality of excluded variables. In a hypothetical though unrealistic situation where all variables are included and there exists no model misspecification, the residual would disappear so that exactly 100 per cent of total inequality is explained.<sup>10</sup> Generally speaking, it is a rule rather than exception that the residual contribution is non-zero. Both negative and positive residual contributions indicate some lack of explanatory power of the estimated model. A positive (negative) contribution implies that the effects of excluded variables are more beneficial to the rich (poor).<sup>11</sup> It is thus reasonable to use the ratio of the absolute value of the residual contribution over total inequality to indicate the proportion of inequality not explained. Consequently, one minus this proportion can be defined as the explained proportion, which reflects the quality of the modeling work.

---

<sup>10</sup> An identity, expressing total income as a sum of source incomes, can be thought of as a special income generating function (not an econometric function) with no residual term. In this case, our decomposition can explain 100 per cent of the total inequality.

<sup>11</sup> It is possible, at least hypothetically, that the residuals are all positive for the poor and negative for the rich. In this case, the contribution of the residual term must be negative as it is an equalizing factor.

When the model fits the data poorly, the explained proportion would be low and the corresponding research findings would be of little value as policy initiatives based on these findings would be ineffective.<sup>12</sup> From this perspective, our modeling exercise is quite successful as we can explain up to 99.4 per cent of total inequality (last column of Table 2). Even in the worst case of 1993, almost 90 per cent of total inequality is explained.

Table 2: Total inequality and explained proportion

Year	Total Gini	Contribution by		Proportion explained* = 100× (1- Residual /Total)
		Independent variables	Residual	
1987	0.172	0.159	0.013	92.4
1988	0.176	0.163	0.012	93.2
1989	0.183	0.167	0.016	91.3
1990	0.174	0.173	0.001	99.4
1991	0.182	0.172	0.011	94.0
1992	0.187	0.172	0.014	92.5
1993	0.201	0.178	0.022	89.1
1994	0.206	0.187	0.019	90.8
1995	0.210	0.198	0.012	94.3
1996	0.206	0.202	0.004	98.1
1997	0.203	0.206	-0.003	98.5
1998	0.199	0.204	-0.004	98.0
1999	0.206	0.209	-0.003	98.5
2000	0.208	0.211	-0.003	98.6
2001	0.214	0.210	0.003	98.6

Note: \*A negative (positive) residual contribution implies that variables not considered are (dis-) equalizing forces. As discussed in the paper, the ratio of the absolute value of residual contribution to the total inequality indicates the proportion of inequality not explained and 1 minus this proportion can be defined as the explained proportion.

Source: See text.

The difference between the total inequality and the residual contribution equals the contributions of those independent variables included in the income generating function. To obtain contributions of individual variables, the Shapley value procedure of Shorrocks (1999) is adopted here.<sup>13</sup> The full decomposition results are presented in Table 4 and in the Appendix as Tables A2-A5, with inequality measured respectively by

<sup>12</sup> It can be shown that when  $R^2 = 1$  or 0, the explained proportion is 100 or 0 per cent. In the case that  $CV^2$  is used as the measure of inequality, the explained proportion is always identical to the  $R^2$ .

<sup>13</sup> For this purpose, a Java programme is developed by the World Institute for Development Economics Research of the United Nations University (UNU-WIDER). This programme allows decomposition of inequality of a dependent variable into components associated with any number of independent variables and under any functional form. Readers interested in the Shapley procedure should consult Shorrocks (1999) for technical details and Wan and Zhou (2005) for an intuitive explanation.

the Gini coefficient, the generalized entropy measures ( $GE_0$  and  $GE_1$ ), the Atkinson index, and the squared coefficient of variation (CV). As expected, the decomposition results differ depending on the indicator of inequality used. This is not surprising because different indicators are associated with different social welfare functions and presume different aversions to inequality. They also place different weights to different segments of the underlying Lorenz curve. It is noted, however, that the squared CV violates the principle of transfer and the Atkinson index is ordinally equivalent to the GE measures as its entire family can be expressed as a monotonic transformation of the latter (Shorrocks and Slottje 2002). Consequently, we only use results under the Gini, the Theil Index ( $GE_1$ ) and the mean logarithmic deviation ( $GE_0$ ) in the following discussions.

Table 3: Ranks of inequality contribution by alternative inequality measures

Year	K	Dep	Edu	Gov	FDI	Trade	Reform	Urb	Location
1987	3	9	7,7,6	4	8	5	6,6,7	1	2

2000	1	9	8	4,2,2	7	5,3,3	2,4,4	6	3,5,5
2001	1	9	8	5,3,2	7	4,2,3	3,4,4	6	2,5,5

Note: One number indicates consistent ranking. Three numbers indicate ranks by Gini,  $GE_0$  and  $GE_1$ , respectively.

Source: See text.

Although pointing to a similar increasing trend in total inequality, different indicators of inequality rank individual variables differently (Table 3). Nevertheless, they are largely consistent in ranking the less important contributors. For example, all three indices show that dependency ratio is the least important variable and they are broadly consistent in ranking FDI and education as the second and third least important factors. Further, some agreement is seen with respect to capital and urbanization as the most important contributors. In the early years, consistent ranking is evident for reform and trade, even government support. In later years, differences in the ranking emerge regarding contributions of variables such as location and government support for economic development.

Faced with the inconsistency, one can either choose a particular measure or take the average across different indicators (only applicable to the percentage contributions, not absolute contributions) and then proceed to interpretation and discussions. We chose to report the decomposition results under the Gini coefficient in Table 4. The contributions are calculated using the total explained portion as the denominator thus they sum to 100 per cent. According to Table 4, the least important variable is still the dependency ratio.

This is attributable to the converging trend in this variable, partly driven by the nationwide policy of birth control. This result also reflects the fact of surplus labour in China, thus differences in dependency ratio across regions are of little significance in income generation. It must be noted that this is only true at the highly aggregate level. Labour input and dependency ratio are still important for income generation at the household level.

The stock of physical capital has always been important. Its importance increased over time and it now constitutes almost 20 per cent of total inequality, making it the largest contributor since 1995. On the other hand, urbanization was the number one or two factor until 1992, but its role quickly declined. It dropped to the third or fifth position and finally settled at the sixth position. This reflects well the converging trend in urbanization across China. Despite so, urbanization still contributes about 12 per cent to total inequality. Sharing a similar trend with urbanization, location has become less important with its ranking dropped from the first until 1994 (second in 1987) to the second position since 1995. The declining contribution does not necessarily mean narrowing gaps in factors associated with location (natural resources, weather, proximity to markets and ports). It means that other factors become more unequally distributed across China.

It is clear that FDI ranks the second least important determinant of regional inequality in China till the early 1990s. However, it has gained importance in recent years. The impact of trade on total inequality has been moderate. If one combines trade and FDI as an overall indicator of globalization, the contribution is quite substantial, particularly in the later years. The combined contribution was around 16 per cent earlier but now around 22 per cent, surpassing the capital variable. It is important to note that this finding is robust to inequality measures. Therefore, globalization does deserve serious consideration owing to its large and increasing effects on regional inequality, which has implications for poverty and poverty reduction in China. The increasing contribution of globalization is a result of increased trade and FDI inflow.

Source: See text.

Over time, a number of factors gained prominence. Reform or privatization was in the sixth position but moved up to third position, highlighting the unequal pace in privatizing state-owned entities and the importance of privatization on income growth. It is interesting to observe that government support for economic development is diverging. The positive contribution implies less (more) developed areas provide less (more) support. The diverging trend may have to do with the taxation reform initiated in 1994 which significantly enhances the budgeting and spending power of local governments. The reform allows rich regions to collect more taxes and fees to finance economic activities.

The small and stable contribution of education is likely attributable to the many years of public provision of basic education in China, particularly in the urban areas. A surprising result is that the contribution of education only ranks the second or third from the last, a finding not inconsistent with ZZ. Conversely, the impacts of reform and urbanization on inequality are expected to decline in the long run because slow reformers or late comers are bound to catch up. After all, these two variables have a maximum value of 100. It should be noted that the role of location will diminish as technology development in transportation and communications are helping to downplay the importance of physical isolation or distance. This diminishing role is reinforced by the historical campaign of western development characterized with huge amounts of infrastructure investment in the location-disadvantageous regions. As known, the effects of infrastructural investment on development are typically lagged.

It is worth noting that a declining percentage contribution does not necessarily mean a decreasing absolute contribution. A careful examination of Table 4 and Tables A2-A5 reveals that apart from the dependency ratio and urbanization, all other variables contribute more and more to total inequality. Dependency ratio is the only variable with declining contribution in both relative and absolute terms. Urbanization more or less maintained its absolute contribution but displayed a declining relative contribution because of the increasing trend in the total inequality.

It may seem sensible to discuss our findings in relation to ZZ. However, this is not appropriate for a number of reasons. First, we focus on income inequality while ZZ on partial labour productivity. Second, ZZ employ a double log model which is rejected in this paper. Third, ZZ relies on the logarithmic variance as the only measure of inequality. Our results are robust to inequality measures and based on a flexible modeling strategy. An indication of inadequacy of ZZ lies in that domestic capital is more productive than FDI, which is difficult to justify.

#### 4 Concluding remarks

This paper provides an accounting for China's regional income inequality, with a special emphasis on the impact of globalization. Relying on a carefully constructed panel data set, the flexible Box-Cox specification is adopted to minimize modelling errors. The income generating function is estimated successfully and the decomposition results are based on a recently developed methodology of Shorrocks (1999). It is found that (a) globalization constitutes a positive and substantial share of China's regional inequality and the share rises over time;<sup>14</sup> (b) capital is one of the largest and increasingly important contributor to regional inequality; (c) economic reform characterized by privatization exerts a significant impact on regional inequality; and (d) the relative contributions of education, location, urbanization and dependency ratio to regional inequality have been declining.

A number of major policy implications are readily derivable from our empirical results. Further globalization will lead to higher regional inequality in China unless concerted efforts are devoted to promote trade in and FDI flows to west and central China. Policy biases which promoted trade and FDI but are gradually phasing out in coastal China should be implemented in other parts of China. Market potential and location consideration place the poor regions in a disadvantageous position in attracting FDI and promoting trade. However, a converging trend in FDI and trade is encouraging. More important is the domestic capital; equalization of which across regions will cut regional inequality by 20 per cent. To narrow down gaps in capital possession, it is necessary though difficult to break the vicious circle existing in capital formation. This calls for development of financial market in China, especially in poor rural areas. Again, policy support for investment in the poor regions is needed in terms of tax concession and bank lending. In particular, continued financial reforms are necessary in order to eliminate discriminations against small farmers and rural activities. Finally, changes are needed in the collection and allocation of fiscal resources which so far have favoured the developed regions. An equalization in fiscal support would lead to an almost 15 per cent drop in regional inequality and a progressive fiscal scheme would result in a much larger impact. Adding together, these three variables contribute over half of the total regional inequality in China.

---

<sup>14</sup> One of the referees suggested confirming this conclusion by running a regression of inequality on a set of regressors. This useful suggestion was not taken up because we can only have a total of fifteen observations on regional inequality (one for each year) for this kind of regression. Even with five or six explanatory variables, the degrees of freedom would drop below ten. Such a model is rather unreliable. More importantly, our decomposition results are sufficient for gauging the impact of globalization on regional inequality in China.

## Data Appendix

(1) Unless indicated otherwise, data for the period 1987-98 are all from *Comprehensive Statistical Data and Materials for 50 Years of New China* (NBS 1999). Data for years 1999-2001, unless indicated otherwise, are from *China Statistical Yearbook*, 2000, 2001 and 2002 (NBS various years).

(2) *Income*: Regional income is the weighted average of urban and rural per capita incomes, with non-agricultural and agricultural population shares as weights. Both urban and rural incomes are deflated by regional urban and rural CPIs. For Shanghai, Beijing and Tianjin, urban and rural CPIs are the same.

(3) *Capital*: Using perpetual stock method, Zhang *et al.* (2004) constructed capital stock data at the 1952 price. They provide estimates for 1952-2000, and the authors extend the data to 2001. Capital stock in 1952 is given by

$$K_0 = \frac{I_0}{\delta + r}$$

where  $K_0$  is the capital stock in 1952,  $I_0$  investment in the same year,  $\delta$  depreciation rate, and  $r$  average growth rate of real investment before 1952. This method is used in Hall and Jones (1999), Young (2000) and also ZZ.

(4) *Dependency*: Dependency ratio is computed as:

$$\text{Dependency} = \frac{\text{total population} - \text{employment}}{\text{employment}} \times 100\%$$

(5) *Education (edu)*: *China Population Yearbooks* report regional population by education attainment as from 1987. Unfortunately, such data were not published for 1989, 1991 and 1992, and data for 1987 and 1988 are incomplete as illiterate population are not reported. Also, unlike data for other years, the 1994 data did not consider population below the age of 15. To estimate data for these years, we compute average years of schooling using data for the other years and then fit the model:

$$\ln(\text{edu}) = f(\cdot) + \mu,$$

where  $\text{edu}$  is per capita years of schooling,  $f(\cdot)$  is simply a linear function of time trend and regional dummies,  $\mu$  the error term. This model is estimated by GLS technique,

allowing for heteroskedasticity in the panel data. The  $R^2$  of the estimated equation is 0.966. Denote the predicted value by  $\hat{\cdot}$ , we have:

$$\hat{edu} = \exp[\ln(\hat{edu})] \exp(0.5 \hat{\sigma}^2),$$

where  $\ln(\hat{edu})$  denotes the predicted values of  $\ln(edu)$  and  $\hat{\sigma}^2$  is the estimated variance of  $\mu$ . Data for 1987-89, 1991, 1992 and 1994 are estimated by the above model.

(6) *FDI*: *FDI* is defined as per capita FDI. The 1987-89 data for Sichuan are from *China Statistical Yearbook*. The Qinghai data for 1988 and 2000 are the average of the neighbouring two years. FDI data are converted into RMB, using medium exchange rate available in *China Statistical Yearbooks*.

(7) *Trade*: *Trade* is computed as the trade/GDP ratio. Trade data are converted into RMB.

(8) *Reform*: *Reform* is computed as the proportion of workers and staff in non-state-owned entities.

(9) *Urbanization*: Urbanization is defined as the proportion of non-agricultural population in the total. Except for Hebei, Heilongjiang and Gansu, 1999-2001 data of agricultural and non-agricultural population are from provincial statistical yearbooks. Total population of Hebei, Heilongjiang and Gansu in 2000 are from *China Statistical Yearbook, 2001*. For these three regions, the 1999 population data are the averages of the neighbouring two years, and the 2001 data are forecast based on data in 2000 and the growth rate during 1999-2000.

(10) *Gov*: This is per capita government expenditure excluding administration fees, deflated by regional CPI.
