

GPOPS – III: A MATLAB Software for Solving Multiple-Phase Optimal Control Problems Using hp -Adaptive Gaussian Quadrature Collocation Methods and Sparse Nonlinear Programming

MICHAEL A. PATTERSON and ANIL V. RAO, University of Florida

A general-purpose MATLAB software program called GPOPS – III is described for solving multiple-phase optimal control problems using variable-order Gaussian quadrature collocation methods. The software employs a Legendre-Gauss-Radau quadrature orthogonal collocation method where the continuous-time optimal control problem is transcribed to a large sparse nonlinear programming problem (NLP). An adaptive mesh refinement method is implemented that determines the number of mesh intervals and the degree of the approximating polynomial within each mesh interval to achieve a specified accuracy. The software can be interfaced with either quasi-Newton (first derivative) or Newton (second derivative) NLP solvers, and all derivatives required by the NLP solver are approximated using sparse finite-differencing of the optimal control problem functions. The key components of the software are described in detail and the utility of the software is demonstrated on five optimal control problems of varying complexity. The software described in this article provides researchers a useful platform upon which to solve a wide variety of complex constrained optimal control problems.

Categories and Subject Descriptors: G.1.4 [Numerical Analysis]: Quadrature and Numerical Differentiation

General Terms: Algorithms, Design, Verification

Additional Key Words and Phrases: Optimal control, direct collocation, Gaussian quadrature, hp -adaptive methods, numerical methods, MATLAB, scientific computation, applied mathematics

ACM Reference Format:

1. INTRODUCTION

Optimal control problems arise in a wide variety of subjects including virtually all branches of engineering, economics, and medicine. Because optimal control applications have increased in complexity in recent years, over the past two decades the subject of optimal control has transitioned from theory to computation. In particular, computational optimal control has become a science in and of itself, resulting in a variety of numerical methods and corresponding software implementations of these methods. The vast majority of software implementations of optimal control today are those that involve the direct transcription of a continuous-time optimal control problem

to a nonlinear programming problem (NLP), and the NLP is solved using well-established techniques. Examples of well-known software for solving optimal control problems include SOCS [Betts 1998], DIRCOL [von Stryk 2000], GESOP [Jansch et al. 1994], OTIS [Vlases et al. 1990], MISER [Goh and Teo 1988], PSOPT [Becerra 2009], GPOPS [Rao et al. 2010], ICLOCS [Falugi et al. 2010], JModelica [Åkesson et al. 2010], ACADO [Houska et al. 2011], and Sparse Optimization Suite (SOS) [Betts 2013].

Over the past two decades, direct collocation methods have become popular in the numerical solution of nonlinear optimal control problems. In a direct collocation method, the state and control are discretized at a set of appropriately chosen points in the time interval of interest. The continuous-time optimal control problem is then transcribed to a finite-dimensional NLP. The resulting NLP is then solved using well-known software such as SNOPT [Gill et al. 2002], IPOPT [Wächter and Biegler 2006; Biegler and Zavala 2008], and KNITRO [Byrd et al. 2006]. Originally, direct collocation methods were developed as h methods (e.g., Euler or Runge-Kutta methods) where the time interval is divided into a mesh and the state is approximated using the same fixed-degree polynomial in each mesh interval. Convergence in an h method is then achieved by increasing the number and placement of the mesh points [Betts 2010; Jain and Tsiotras 2008; Zhao and Tsiotras 2011]. More recently, a great deal of research has been done in the class of direct *Gaussian quadrature orthogonal collocation* methods [Benson et al. 2006; Darby et al. 2011a; Elnagar and Razzaghi 1998; Elnagar et al. 1995; Garg et al. 2010, 2011a, 2011b; Gong et al. 2008b; Huntington and Rao 2008; Huntington et al. 2007; Kameswaran and Biegler 2008; Patterson and Rao 2012; Rao et al. 2010]. In a Gaussian quadrature collocation method, the state is typically approximated using a Lagrange polynomial where the support points of the Lagrange polynomial are chosen to be points associated with a Gaussian quadrature. Originally, Gaussian quadrature collocation methods were implemented as p methods using a single interval. Convergence of the p method was then achieved by increasing the degree of the polynomial approximation. For problems whose solutions are smooth and well behaved, a p Gaussian quadrature collocation method has a simple structure and converges at an exponential rate [Canuto et al. 1988; Fornberg 1998; Trefethen 2000]. The most well-developed p Gaussian quadrature methods are those that employ either Legendre-Gauss (LG) points [Benson et al. 2006; Rao et al. 2010], Legendre-Gauss-Radau (LGR) points [Garg et al. 2010, 2011a; Kameswaran and Biegler 2008], or Legendre-Gauss-Lobatto (LGL) points [Elnagar et al. 1995].

In this article we describe a new optimal control software called $\text{GPOPS} - \text{III}$ that employs hp -adaptive Gaussian quadrature collocation methods. An hp -adaptive method is a hybrid between a p method and an h method in that both the number of mesh intervals and the degree of the approximating polynomial within each mesh interval can be varied in order to achieve a specified accuracy in the numerical approximation of the solution to the continuous-time optimal control problem. As a result, in an hp -adaptive method, it is possible to take advantage of the exponential convergence of a global Gaussian quadrature method in regions where the solution is smooth and introduce mesh points only near potential discontinuities or in regions where the solution changes rapidly. Originally, hp methods were developed as finite-element methods for solving partial differential equations [Babuska et al. 1986; Babuska and Rheinboldt 1979, 1981, 1982]. In the past few years, the problem of developing hp methods for solving optimal control problems has been of interest [Darby et al. 2011b; 2011c]. The work of Darby et al. [2011b, 2011c] provides examples of the benefits of using an hp -adaptive method over either a p method or an h method. This recent research has shown that convergence using hp methods can be achieved with a significantly smaller finite-dimensional approximation than would be required when using either an h or a p method.

It is noted that previously the software GPOPS was published in Rao et al. [2010]. While GPOPS is similar to GPOPS – III in that both software programs implement Gaussian quadrature collocation, GPOPS – III is a fundamentally different software program from GPOPS. First, GPOPS employs p (global) collocation in each phase of the optimal control problem. It is known that p collocation schemes are limited in that they have difficulty solving problems whose solutions change rapidly in certain regions or are discontinuous. Moreover, p methods become computationally intractable as the degree of the approximating polynomial becomes very large. GPOPS – III, however, employs hp -adaptive mesh refinement where the polynomial degree, number of mesh intervals, and width of each mesh interval can be varied. The hp -adaptive methods allow for placement of collocation points in regions of the solution where additional information is needed to capture key features of the optimal solution. Next, GPOPS is limited in that it can be used with only quasi-Newton (first derivative) NLP solvers and derivative approximations were performed on high dimensional NLP functions. On the other hand, GPOPS – III implements *sparse derivative approximations* by approximating derivatives of the optimal control functions and inserting these derivatives into the appropriate locations in the NLP derivative functions. Moreover, GPOPS – III implements approximations to *both* first and second derivatives. Consequently, GPOPS – III utilizes in an efficient manner the full capabilities of a much wider range of NLP solvers (e.g., full Newton NLP solvers such as IPOPT [Biegler and Zavala 2008] and KNITRO [Byrd et al. 2006]) and, as a result, is capable of solving a much wider range of optimal control problems as compared with GPOPS.

The objective of this article is to provide researchers with a novel efficient general-purpose optimal control software that is capable of solving a wide variety of complex constrained continuous-time optimal control problems. In particular, the software described in this article employs a differential and implicit integral form of the multiple-interval version of the *Legendre-Gauss-Radau (LGR) collocation method* [Garg et al. 2010, 2011a, 2011b; Patterson and Rao 2012]. The LGR collocation method is chosen for use in the software because it provides highly accurate state, control, and costate approximations while maintaining a relatively low-dimensional approximation of the continuous-time problem. The key components of the software are then described, and the software is demonstrated on five examples from the open literature that have been studied extensively and whose solutions are known. Each of these examples demonstrates different capabilities of the software. The first example is the hypersensitive optimal control problem from Rao and Mease [2000] and demonstrates the ability of the software to accurately solve a problem whose optimal solution changes rapidly in particular regions of the solution. The second example is the reusable launch vehicle entry problem taken from Betts [2010] and demonstrates the ability of GPOPS – III to compute an accurate solution using a relatively coarse mesh. The third example is a space station attitude control problem taken from Pietz [2003] and Betts [2010] and demonstrates the ability of the software to generate accurate solutions to a problem whose solution is not intuitive. The fourth example is a chemical kinetic batch reactor problem taken from Leineweber [1998] and Betts [2010] and shows the ability of the software to handle a multiple-phase optimal control problem that is poorly scaled. The fifth example is a launch vehicle ascent problem taken from Benson [2004], Rao et al. [2010], and Betts [2010] that again demonstrates the ability of the software to solve a multiple-phase optimal control problem. In order to validate the results, the solutions obtained using GPOPS – III are compared against the solutions obtained using the software Sparse Optimization Suite (SOS) [Betts 2013] where SOS is based on the collection of algorithms developed in Betts [2010].

This article is organized as follows: In Section 2, we describe a general multiple-phase optimal control problem. In Section 3, we describe the Radau collocation method

that is used as the basis of GPOPS – III. In Section 4, we describe the key components of GPOPS – III. In Section 5, we show the results obtained using the software on the five aforementioned examples. In Section 6, we provide a discussion of the results obtained using the software. In Section 7, we discuss possible limitations of the software. Finally, in Section 8, we provide conclusions on our work.

2. GENERAL MULTIPLE-PHASE OPTIMAL CONTROL PROBLEMS

The general multiple-phase optimal control problem that can be solved by GPOPS – III is given as follows. First, let $p \in [1, \dots, P]$ be the phase number where P is the total number of phases. The optimal control problem is to determine the state, $\mathbf{y}^{(p)}(t) \in \mathbb{R}^{n_y^{(p)}}$, control, $\mathbf{u}^{(p)}(t) \in \mathbb{R}^{n_u^{(p)}}$, integrals, $\mathbf{q}^{(p)} \in \mathbb{R}^{n_q^{(p)}}$, start times, $t_0^{(p)} \in \mathbb{R}$, phase terminus times, $t_f^{(p)} \in \mathbb{R}$, in all phases $p \in [1, \dots, P]$, along with the static parameters $\mathbf{s} \in \mathbb{R}^{n_s}$, that minimize the objective functional

$$J = \phi(\mathbf{e}^{(1)}, \dots, \mathbf{e}^{(P)}, \mathbf{s}), \quad (1)$$

subject to the dynamic constraints

$$\dot{\mathbf{y}}^{(p)} = \mathbf{a}^{(p)}(\mathbf{y}^{(p)}, \mathbf{u}^{(p)}, t^{(p)}, \mathbf{s}), \quad (p = 1, \dots, P), \quad (2)$$

the event constraints

$$\mathbf{b}_{\min} \leq \mathbf{b}(\mathbf{e}^{(1)}, \dots, \mathbf{e}^{(P)}, \mathbf{s}) \leq \mathbf{b}_{\max}, \quad (3)$$

the inequality path constraints

$$\mathbf{c}_{\min}^{(p)} \leq \mathbf{c}^{(p)}(\mathbf{y}^{(p)}, \mathbf{u}^{(p)}, t^{(p)}, \mathbf{s}) \leq \mathbf{c}_{\max}^{(p)}, \quad (p = 1, \dots, P), \quad (4)$$

the static parameter constraints

$$\mathbf{s}_{\min} \leq \mathbf{s} \leq \mathbf{s}_{\max}, \quad (5)$$

and the integral constraints

$$\mathbf{q}_{\min}^{(p)} \leq \mathbf{q}^{(p)} \leq \mathbf{q}_{\max}^{(p)}, \quad (p = 1, \dots, P), \quad (6)$$

where

$$\mathbf{e}^{(p)} = [\mathbf{y}^{(p)}(t_0^{(p)}), t_0^{(p)}, \mathbf{y}^{(p)}(t_f^{(p)}), t_f^{(p)}, \mathbf{q}^{(p)}], \quad (p = 1, \dots, P), \quad (7)$$

and the integrals in each phase are defined as

$$q_i^{(p)} = \int_{t_0^{(p)}}^{t_f^{(p)}} g_i^{(p)}(\mathbf{y}^{(p)}, \mathbf{u}^{(p)}, t^{(p)}, \mathbf{s}) dt, \quad (i = 1, \dots, n_q^{(p)}), \quad (p = 1, \dots, P). \quad (8)$$

It is important to note that the event constraints of Eq. (3) can contain any functions that relate information at the start and/or terminus of any phase (including relationships that include both static parameters and integrals) and that the phases themselves need not be sequential. It is noted that the approach to linking phases is based on well-known formulations in the literature such as those given in Betts [1990, 2010]. A schematic of how phases can potentially be linked is given in Figure 1.

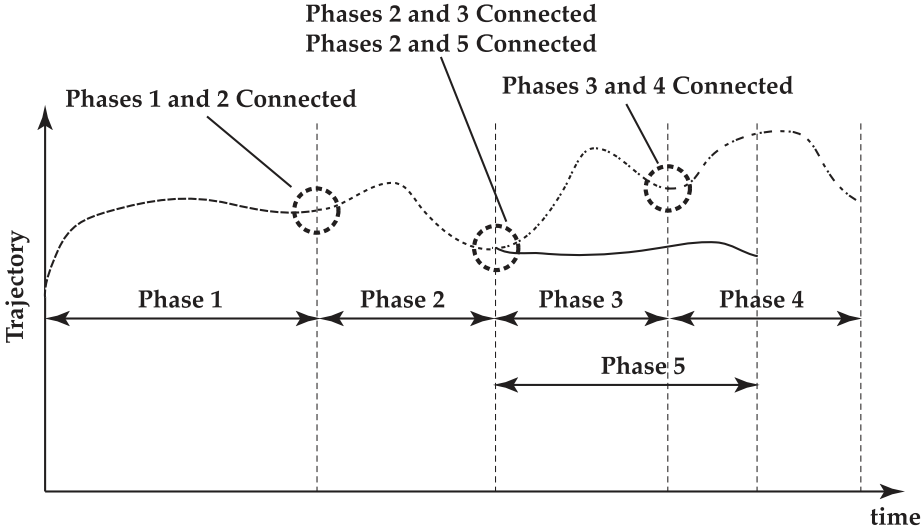

Fig. 1. Schematic of linkages for multiple-phase optimal control problem. The example shown in the picture consists of five phases where the ends of phases 1, 2, and 3 are linked to the starts of phases 2, 3, and 4, respectively, while the end of phase 2 is linked to the start of phase 5.

3. MULTIPLE-INTERVAL RADAU COLLOCATION METHOD

In this section, we describe the multiple-interval Legendre-Gauss-Radau collocation method (referred to hereafter as the Radau collocation method) [Garg et al. 2010, 2011a, 2011b; Patterson and Rao 2012] that forms the basis for GPOPS – III. In order to make the description of the Radau collocation method as clear as possible, in this section we consider only a one-phase optimal control problem. After formulating the one-phase optimal control problem we develop the Radau collocation method itself.

3.1. Single-Phase Optimal Control Problem

In order to describe the hp Radau method that is implemented in the software, it will be useful to simplify the general optimal control problem given in Eqs. (1)–(8) to a one-phase problem as follows. Determine the state, $\mathbf{y}(t) \in \mathbb{R}^{n_y}$, the control, $\mathbf{u}(t) \in \mathbb{R}^{n_u}$, the integrals, $\mathbf{q} \in \mathbb{R}^{n_q}$, the initial time, t_0 , and the terminal time t_f on the time interval $t \in [t_0, t_f]$ that minimize the cost functional

$$\mathcal{J} = \phi(\mathbf{y}(t_0), t_0, \mathbf{y}(t_f), t_f, \mathbf{q}) \tag{9}$$

subject to the dynamic constraints

$$\frac{d\mathbf{y}}{dt} = \mathbf{a}(\mathbf{y}(t), \mathbf{u}(t), t), \tag{10}$$

the inequality path constraints

$$\mathbf{c}_{\min} \leq \mathbf{c}(\mathbf{y}(t), \mathbf{u}(t), t) \leq \mathbf{c}_{\max}, \tag{11}$$

the integral constraints

$$q_i = \int_{t_0}^{t_f} g_i(\mathbf{y}(t), \mathbf{u}(t), t) dt, \quad (i = 1, \dots, n_q), \tag{12}$$

and the event constraints

$$\mathbf{b}_{\min} \leq \mathbf{b}(\mathbf{y}(t_0), t_0, \mathbf{y}(t_f), t_f, \mathbf{q}) \leq \mathbf{b}_{\max}. \tag{13}$$

The functions ϕ , \mathbf{q} , \mathbf{a} , \mathbf{c} and \mathbf{b} are defined by the following mappings:

$$\begin{aligned}\phi &: \mathbb{R}^{n_y} \times \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R} \times \mathbb{R}^{n_q} \rightarrow \mathbb{R}, \\ \mathbf{q} &: \mathbb{R}^{n_y} \times \mathbb{R}^{n_u} \times \mathbb{R} \rightarrow \mathbb{R}^{n_q}, \\ \mathbf{a} &: \mathbb{R}^{n_y} \times \mathbb{R}^{n_u} \times \mathbb{R} \rightarrow \mathbb{R}^{n_y}, \\ \mathbf{c} &: \mathbb{R}^{n_y} \times \mathbb{R}^{n_u} \times \mathbb{R} \rightarrow \mathbb{R}^{n_c}, \\ \mathbf{b} &: \mathbb{R}^{n_y} \times \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R} \times \mathbb{R}^{n_q} \rightarrow \mathbb{R}^{n_b},\end{aligned}$$

where we remind the reader that all vector functions of time are treated as *row* vectors.

In order to employ the *hp* Radau collocation method used in GPOPS – III, the continuous optimal control problem of Eqs. (9)–(13) is modified as follows. First, let $\tau \in [-1, +1]$ be a new independent variable. The variable t is then defined in terms of τ as

$$t = \frac{t_f - t_0}{2} \tau + \frac{t_f + t_0}{2}. \quad (14)$$

The optimal control problem of Eqs. (9)–(13) is then defined in terms of the variable τ as follows. Determine the state, $\mathbf{y}(\tau) \in \mathbb{R}^{n_y}$, the control $\mathbf{u}(\tau) \in \mathbb{R}^{n_u}$, the integral $\mathbf{q} \in \mathbb{R}^{n_q}$, the initial time, t_0 , and the terminal time t_f on the time interval $\tau \in [-1, +1]$ that minimize the cost functional

$$\mathcal{J} = \phi(\mathbf{y}(-1), t_0, \mathbf{y}(+1), t_f, \mathbf{q}) \quad (15)$$

subject to the dynamic constraints

$$\frac{d\mathbf{y}}{d\tau} = \frac{t_f - t_0}{2} \mathbf{a}(\mathbf{y}(\tau), \mathbf{u}(\tau), \tau; t_0, t_f), \quad (16)$$

the inequality path constraints

$$\mathbf{c}_{\min} \leq \mathbf{c}(\mathbf{y}(\tau), \mathbf{u}(\tau), \tau; t_0, t_f) \leq \mathbf{c}_{\max}, \quad (17)$$

the integral constraints

$$q_i = \frac{t_f - t_0}{2} \int_{-1}^{+1} g_i(\mathbf{y}(\tau), \mathbf{u}(\tau), \tau; t_0, t_f) d\tau, \quad (i = 1, \dots, n_q), \quad (18)$$

and the event constraints

$$\mathbf{b}_{\min} \leq \mathbf{b}(\mathbf{y}(-1), t_0, \mathbf{y}(+1), t_f, \mathbf{q}) \leq \mathbf{b}_{\max}. \quad (19)$$

Suppose now that the interval $\tau \in [-1, +1]$ is divided into a *mesh* consisting of K *mesh intervals* $[T_{k-1}, T_k]$, $k = 1, \dots, K$, where (T_0, \dots, T_K) are the *mesh points*. The mesh points have the property that $-1 = T_0 < T_1 < T_2 < \dots < T_K = T_f = +1$. Next, let $\mathbf{y}^{(k)}(\tau)$ and $\mathbf{u}^{(k)}(\tau)$ be the state and control in mesh interval k . The optimal control problem of Eqs. (15)–(19) can then be written as follows. First, the cost functional of Eq. (15) can be written as

$$\mathcal{J} = \phi(\mathbf{y}^{(1)}(-1), t_0, \mathbf{y}^{(K)}(+1), t_f, \mathbf{q}), \quad (20)$$

Next, the dynamic constraints of Eq. (16) in mesh interval k can be written as

$$\frac{d\mathbf{y}^{(k)}(\tau^{(k)})}{d\tau^{(k)}} = \frac{t_f - t_0}{2} \mathbf{a}(\mathbf{y}^{(k)}(\tau^{(k)}), \mathbf{u}^{(k)}(\tau^{(k)}), \tau^{(k)}; t_0, t_f), \quad (k = 1, \dots, K). \quad (21)$$

Furthermore, the path constraints of (17) in mesh interval k are given as

$$\mathbf{c}_{\min} \leq \mathbf{c}(\mathbf{y}^{(k)}(\tau^{(k)}), \mathbf{u}^{(k)}(\tau^{(k)}), \tau^{(k)}; t_0, t_f) \leq \mathbf{c}_{\max}, \quad (k = 1, \dots, K). \quad (22)$$

the integral constraints of (18) are given as

$$q_j = \frac{t_f - t_0}{2} \sum_{k=1}^K \int_{T_{k-1}}^{T_k} g_j(\mathbf{y}^{(k)}(\tau^{(k)}), \mathbf{u}^{(k)}(\tau^{(k)}), \tau^{(k)}; t_0, t_f) d\tau, \quad (j = 1, \dots, n_q, k = 1, \dots, K). \quad (23)$$

Finally, the event constraints of Eq. (19) are given as

$$\mathbf{b}_{\min} \leq \mathbf{b}(\mathbf{y}^{(1)}(-1), t_0, \mathbf{y}^{(K)}(+1), t_f, \mathbf{q}) \leq \mathbf{b}_{\max}. \quad (24)$$

Because the state must be continuous at each interior mesh point, it is required that the condition $\mathbf{y}^{(k)}(T_k) = \mathbf{y}^{(k+1)}(T_k)$ be satisfied at the interior mesh points (T_1, \dots, T_{K-1}) .

3.2. Approximation of the Optimal Control Problem via Radau Collocation Method

The method utilized in the software is an implementation of the aforementioned Radau quadrature orthogonal collocation method [Garg et al. 2010, 2011a, 2011b; Patterson and Rao 2012]. In the Radau collocation method, the state of the continuous-time optimal control problem is approximated in each mesh interval $k \in [1, \dots, K]$ as

$$\mathbf{y}^{(k)}(\tau) \approx \mathbf{Y}^{(k)}(\tau) = \sum_{j=1}^{N_k+1} \mathbf{Y}_j^{(k)} \ell_j^{(k)}(\tau), \quad \ell_j^{(k)}(\tau) = \prod_{\substack{l=1 \\ l \neq j}}^{N_k+1} \frac{\tau - \tau_l^{(k)}}{\tau_j^{(k)} - \tau_l^{(k)}}, \quad (25)$$

where $\tau \in [-1, +1]$, $\ell_j^{(k)}(\tau)$, $j = 1, \dots, N_k + 1$, is a basis of Lagrange polynomials, $(\tau_1^{(k)}, \dots, \tau_{N_k}^{(k)})$ are the Legendre-Gauss-Radau [Abramowitz and Stegun 1965] (LGR) collocation points in mesh interval k defined on the subinterval $\tau^{(k)} \in [T_{k-1}, T_k)$, and $\tau_{N_k+1}^{(k)} = T_k$ is a noncollocated point. Differentiating $\mathbf{Y}^{(k)}(\tau)$ in Eq. (25) with respect to τ , we obtain

$$\frac{d\mathbf{Y}^{(k)}(\tau)}{d\tau} = \sum_{j=1}^{N_k+1} \mathbf{Y}_j^{(k)} \frac{d\ell_j^{(k)}(\tau)}{d\tau}. \quad (26)$$

The cost functional of Eq. (20) is then shown as

$$\mathcal{J} = \phi(\mathbf{Y}_1^{(1)}, t_0, \mathbf{Y}_{N_K+1}^{(K)}, t_f, \mathbf{q}), \quad (27)$$

where $\mathbf{Y}_1^{(1)}$ is the approximation of $\mathbf{y}(T_0 = -1)$, and $\mathbf{Y}_{N_K+1}^{(K)}$ is the approximation of $\mathbf{y}(T_K = +1)$. Collocating the dynamics of Eq. (21) at the N_k LGR points using Eq. (26), we have

$$\sum_{j=1}^{N_k+1} D_{ij}^{(k)} \mathbf{Y}_j^{(k)} - \frac{t_f - t_0}{2} \mathbf{a}(\mathbf{Y}_i^{(k)}, \mathbf{U}_i^{(k)}, \tau_i^{(k)}; t_0, t_f) = \mathbf{0}, \quad (i = 1, \dots, N_k). \quad (28)$$

where $\mathbf{U}_i^{(k)}$, $i = 1, \dots, N_k$, are the approximations of the control at the N_k LGR points in mesh interval $k \in [1, \dots, K]$, and $t_i^{(k)}$ are obtained from $\tau_k^{(k)}$ using Eq. (14) and

$$D_{ij}^{(k)} = \left[\frac{d\ell_j^{(k)}(\tau)}{d\tau} \right]_{\tau_i^{(k)}}, \quad (i = 1, \dots, N_k, \quad j = 1, \dots, N_k + 1, \quad k = 1, \dots, K), \quad (29)$$

Fig. 2. Structure of composite Legendre-Gauss-Radau differentiation matrix where the mesh consists of K mesh intervals.

is the $N_k \times (N_k + 1)$ *Legendre-Gauss-Radau differentiation matrix* [Garg et al. 2010] in mesh interval $k \in [1, \dots, K]$. While the dynamics can be collocated in differential form, an alternative approach is to collocate the dynamics using the equivalent *implicit integral form* of the Radau collocation method as described in Garg et al. [2010, 2011a, 2011b]. Collocating the dynamics using the implicit integral form of the Radau collocation method, we have

$$\mathbf{Y}_{i+1}^{(k)} - \mathbf{Y}_1^{(k)} - \frac{t_f - t_0}{2} \sum_{j=1}^{N_k} I_{ij}^{(k)} \mathbf{a}(\mathbf{Y}_i^{(k)}, \mathbf{U}_i^{(k)}, \tau_i^{(k)}; t_0, t_f) = \mathbf{0}, \quad (i = 1, \dots, N_k), \quad (30)$$

where $I_{ij}^{(k)}$, ($i = 1, \dots, N_k, j = 1, \dots, N_k, k = 1, \dots, K$) is the $N_k \times N_k$ *Legendre-Gauss-Radau integration matrix* in mesh interval $k \in [1, \dots, K]$, and is obtained from the differentiation matrix as Garg et al. [2010, 2011a, 2011b]

$$\mathbf{I}^{(k)} \equiv \left[\mathbf{D}_{2:N_k+1}^{(k)} \right]^{-1}.$$

Finally, it is noted for completeness that $\mathbf{I}^{(k)} \mathbf{D}_1^{(k)} = -\mathbf{1}$, where $\mathbf{1}$ is a column vector of length N_k of all ones. It is noted that Eqs. (28) and (30) can be evaluated over all intervals simultaneously using the composite Legendre-Gauss-Radau differentiation matrix \mathbf{D} , and the composite Legendre-Gauss-Radau integration matrix \mathbf{I} , respectively. Furthermore, the sparse structure of the composite Legendre-Gauss-Radau differentiation matrix \mathbf{D} can be seen in Figure 2, and the structure of the composite Legendre-Gauss-Radau integration matrix \mathbf{I} can be seen in Figure 3. Next, the path constraints of Eq. (22) in mesh interval $k \in [1, \dots, K]$ are enforced at the N_k LGR points as

$$\mathbf{c}_{\min} \leq \mathbf{c}(\mathbf{Y}_i^{(k)}, \mathbf{U}_i^{(k)}, \tau_i^{(k)}; t_0, t_f) \leq \mathbf{c}_{\max}, \quad (i = 1, \dots, N_k), \quad (31)$$

the integral constraints of Eq. (23) is then approximated as

$$q_j \approx \sum_{k=1}^K \sum_{i=1}^{N_k} \frac{t_f - t_0}{2} w_i^{(k)} g_j(\mathbf{Y}_i^{(k)}, \mathbf{U}_i^{(k)}, \tau_i^{(k)}; t_0, t_f), \quad (i = 1, \dots, N_k, j = 1, \dots, n_q), \quad (32)$$

Fig. 3. Structure of composite Legendre-Gauss-Radau integration matrix where the mesh consists of K mesh intervals.

where $w_j^{(k)}$, $j = 1, \dots, N_k$ are the LGR quadrature weights [Abramowitz and Stegun 1965] in mesh interval $k \in [1, \dots, K]$ defined on the interval $\tau \in [\tau_{k-1}, \tau_k)$. Furthermore, the event constraints of Eq. (24) are approximated as

$$\mathbf{b}_{\min} \leq \mathbf{b}(\mathbf{Y}_1^{(1)}, t_0, \mathbf{Y}_{N_{K+1}}^{(K)}, t_f, \mathbf{q}) \leq \mathbf{b}_{\max}. \tag{33}$$

It is noted that continuity in the state at the interior mesh points $k \in [1, \dots, K - 1]$ is enforced via the condition

$$\mathbf{Y}_{N_{k+1}}^{(k)} = \mathbf{Y}_1^{(k+1)}, \quad (k = 1, \dots, K - 1), \tag{34}$$

where we note that the same variable is used for both $\mathbf{Y}_{N_{k+1}}^{(k)}$ and $\mathbf{Y}_1^{(k+1)}$ in the software implementation. Hence, the constraint of Eq. (34) is eliminated from the problem because it is taken into account explicitly. The NLP that arises from the Radau collocation method is then to minimize the cost function of Eq. (27) subject to the algebraic constraints of Eqs. (28)–(33).

4. MAJOR COMPONENTS OF GPOPS – III

In this section, we describe the major components of the MATLAB software GPOPS – III that implements the aforementioned Radau collocation method. In Section 4.1, we describe the large sparse nonlinear programming problem (NLP) associated with the Radau collocation method. In Section 4.2, we show the structure of the NLP described in Section 4.1. In Section 4.3, we describe the method for scaling the NLP via scaling of the optimal control problem. In Section 4.4, we describe the approach for estimating the derivatives required by the NLP solver. In Section 4.5, we describe the method for determining the dependencies of each optimal control function in order to provide the most sparse NLP to the NLP solver. In Section 4.6, we describe the hp -adaptive mesh refinement methods that are included in the software in order to iterative determine a mesh that meets a user-specified accuracy tolerance. Finally, in Section 4.7, we provide a high-level description of the algorithmic flow of GPOPS – III.

4.1. Sparse NLP Arising from Multiple-Interval Radau Collocation Method

The nonlinear programming problem (NLP) associated with the hp Radau discretized scaled continuous-time optimal control problem is given as follows. Determine the decision vector \mathbf{Z} that minimizes the objective function

$$\Phi(\mathbf{Z}) \quad (35)$$

subject to the constraints

$$\mathbf{F}_{\min} \leq \mathbf{F}(\mathbf{Z}) \leq \mathbf{F}_{\max} \quad (36)$$

and the variable bounds

$$\mathbf{Z}_{\min} \leq \mathbf{Z} \leq \mathbf{Z}_{\max}. \quad (37)$$

It is noted that the size of the NLP arising from the hp Radau collocation method changes depending upon the number of mesh intervals and LGR points used in each phase to discretize the continuous-time optimal control problem, however, the structure of the NLP is the same regardless of the number of mesh intervals or number of LGR points used in the discretization.

4.1.1. NLP Variables. The NLP decision vector \mathbf{Z} is given as

$$\mathbf{Z} = \begin{bmatrix} \mathbf{z}^{(1)} \\ \vdots \\ \mathbf{z}^{(P)} \\ s_1 \\ \vdots \\ s_{n_s} \end{bmatrix}, \quad (38)$$

where $\mathbf{z}^{(p)}$ contains all the variables of phase $p = 1 \dots P$, and s_i ($i = 1, \dots, n_s$) are the static parameters in the problem. The phase-dependent variables of Eq. (38) $\mathbf{z}^{(p)}$ ($p = 1, \dots, P$), are given as

$$\mathbf{z}^{(p)} = \begin{bmatrix} \mathbf{V}_1^{(p)} \\ \vdots \\ \mathbf{V}_{n_y^{(p)}}^{(p)} \\ \mathbf{W}_1^{(p)} \\ \vdots \\ \mathbf{W}_{n_u^{(p)}}^{(p)} \\ \mathbf{q}^{(p)} \\ t_0^{(p)} \\ t_f^{(p)} \end{bmatrix}, \quad (p = 1, \dots, P), \quad (39)$$

where $\mathbf{V}_i^{(p)} \in \mathbb{R}^{(N^{(p)}+1)}$ ($i = 1, \dots, n_y^{(p)}$) is the i th column of the matrix

$$\mathbf{V}^{(p)} = \begin{bmatrix} \mathbf{Y}_1^{(p)} \\ \vdots \\ \mathbf{Y}_{N^{(p)}+1}^{(p)} \end{bmatrix} \in \mathbb{R}^{(N^{(p)}+1) \times n_y^{(p)}}, \quad (40)$$

$\mathbf{W}_i^{(p)} \in \mathbb{R}^{N^{(p)}}$ ($i = 1, \dots, n_u^{(p)}$) is the i th column of the matrix,

$$\mathbf{W}^{(p)} = \begin{bmatrix} \mathbf{U}_1^{(p)} \\ \vdots \\ \mathbf{U}_{N^{(p)}}^{(p)} \end{bmatrix} \in \mathbb{R}^{N^{(p)} \times n_u^{(p)}}, \quad (41)$$

$\mathbf{q}^{(p)}$ is a column vector containing the $n_q^{(p)}$ integral constraint variables, and $t_0^{(p)} \in \mathbb{R}$ and $t_f^{(p)} \in \mathbb{R}$ are scalars corresponding to the initial and terminal times in phase $p \in [1, \dots, P]$. We remind the reader again that because the state and control are being treated as *row* vectors, the i th row in the matrices of Eqs. (40) and (40) corresponds to the value of the discretized state and control at the time $\tau_i^{(p)}$. Finally, the bounds \mathbf{Z}_{\min} and \mathbf{Z}_{\max} are defined from the optimal control variable bounds as supplied by the user.

4.1.2. NLP Objective and Constraint Functions. The NLP objective function $\Phi(\mathbf{Z})$ is defined as follows:

$$\Phi(\mathbf{Z}) = \phi, \quad (42)$$

where ϕ is the optimal control objective function evaluated at the discrete variables defined in function of Eq. (1). The NLP constraint function vector $\mathbf{F}(\mathbf{Z})$ is then assembled as

$$\mathbf{F} = \begin{bmatrix} \mathbf{f}^{(1)} \\ \vdots \\ \mathbf{f}^{(P)} \\ \mathbf{b} \end{bmatrix}, \quad (43)$$

where $\mathbf{f}^{(p)}$ are the constraints in phase $p \in [1, \dots, P]$ and \mathbf{b} is the vector of $n_b^{(p)}$ event constraints evaluated at the discrete variables defined in function of Eq. (3). The phase-dependent constraints of Eq. (43) $\mathbf{f}^{(p)}$ ($p \in [1, \dots, P]$) have the structure

$$\mathbf{f}^{(p)} = \begin{bmatrix} \Delta_1^{(p)} \\ \vdots \\ \Delta_{n_y^{(p)}}^{(p)} \\ \mathbf{C}_1^{(p)} \\ \vdots \\ \mathbf{C}_{n_c^{(p)}}^{(p)} \\ \boldsymbol{\rho}^{(p)} \end{bmatrix}, \quad (p = 1, \dots, P), \quad (44)$$

where $\Delta_i^{(p)} \in \mathbb{R}^{N^{(p)}}$ ($i = 1, \dots, n_y^{(p)}$) is the i th column in the defect constraint matrix that results from either the differential or implicit integral form of the Radau collocation method. The defect matrix that results from the differential form is defined as

$$\mathbf{\Delta}^{(p)} = \mathbf{D}^{(p)}\mathbf{Y}^{(p)} - \frac{t_f^{(p)} - t_0^{(p)}}{2}\mathbf{A}^{(p)} \in \mathbb{R}^{N^{(p)} \times n_y^{(p)}}, \quad (45)$$

Fig. 4. Matrix \mathbf{E} corresponding to the defect constraints of Eq. (46) for one phase of a P -phase optimal control problem discretized using the Radau collocation method.

while the defect matrix that results from the implicit integral form is defined as

$$\mathbf{\Delta}^{(p)} = \mathbf{E}^{(p)} \mathbf{Y}^{(p)} - \frac{t_f^{(p)} - t_0^{(p)}}{2} \mathbf{I}^{(p)} \mathbf{A}^{(p)} \in \mathbb{R}^{N^{(p)} \times n_y^{(p)}}, \quad (46)$$

where the matrix \mathbf{A} is the right-hand side of the dynamics evaluated at each collocation point

$$\mathbf{A}^{(p)} = \begin{bmatrix} \mathbf{a}(\mathbf{Y}_1^{(p)}, \mathbf{U}_1^{(p)}, t_1^{(p)}, \mathbf{s}) \\ \vdots \\ \mathbf{a}(\mathbf{Y}_{N^{(p)}}^{(p)}, \mathbf{U}_{N^{(p)}}^{(p)}, t_{N^{(p)}}^{(p)}, \mathbf{s}) \end{bmatrix} \in \mathbb{R}^{N^{(p)} \times n_y^{(p)}}, \quad (47)$$

$\mathbf{E}^{(p)}$ is an $N^{(p)} \times (N^{(p)} + 1)$ matrix that is used to compute the difference $\mathbf{Y}_{i+1}^{(p,k)} - \mathbf{Y}_i^{(p,k)}$ for each interval $k = 1, \dots, K^{(p)}$, and each phase $p = 1, \dots, P$ and has the structure shown in Figure 4, $\mathbf{C}_i^{(p)} \in \mathbb{R}^{N^{(p)}}$, ($i = 1, \dots, n_c^{(p)}$), is the i th column of the path constraint matrix

$$\mathbf{C}^{(p)} = \begin{bmatrix} \mathbf{c}(\mathbf{Y}_1^{(p)}, \mathbf{U}_1^{(p)}, t_1^{(p)}, \mathbf{s}) \\ \vdots \\ \mathbf{c}(\mathbf{Y}_{N^{(p)}}^{(p)}, \mathbf{U}_{N^{(p)}}^{(p)}, t_{N^{(p)}}^{(p)}, \mathbf{s}) \end{bmatrix} \in \mathbb{R}^{N^{(p)} \times n_c^{(p)}}, \quad (48)$$

$\boldsymbol{\rho}^{(p)}$ is a vector of length $n_q^{(p)}$ where the i th element of $\boldsymbol{\rho}^{(p)}$ is given as

$$\rho_i^{(p)} = q_i^{(p)} - \frac{t_f^{(p)} - t_0^{(p)}}{2} [\mathbf{w}^{(p)}]^\top \mathbf{G}_i^{(p)}, \quad (i = 1, \dots, n_q^{(p)}), \quad (49)$$

where $\mathbf{G}_i^{(p)} \in \mathbb{R}^{N^{(p)}}$ ($i = 1, \dots, n_q^{(p)}$) is the i th column of the integrand matrix

$$\mathbf{G}^{(p)} = \begin{bmatrix} \mathbf{g}(\mathbf{Y}_1^{(p)}, \mathbf{U}_1^{(p)}, t_1^{(p)}, \mathbf{s}) \\ \vdots \\ \mathbf{g}(\mathbf{Y}_{N^{(p)}}^{(p)}, \mathbf{U}_{N^{(p)}}^{(p)}, t_{N^{(p)}}^{(p)}, \mathbf{s}) \end{bmatrix} \in \mathbb{R}^{N^{(p)} \times n_q^{(p)}}. \quad (50)$$

It is noted that the defect and integral constraints are all equality constraints of the form

$$\begin{aligned}\Delta^{(p)} &= \mathbf{0}, \\ \rho^{(p)} &= \mathbf{0},\end{aligned}\tag{51}$$

while the discretized path constraints and boundary conditions are inequality constraints of the form

$$\begin{aligned}\mathbf{C}_{\min}^{(p)} &\leq \mathbf{C}^{(p)} \leq \mathbf{C}_{\max}^{(p)}, \\ \mathbf{b}_{\min} &\leq \mathbf{b} \leq \mathbf{b}_{\max}.\end{aligned}\tag{52}$$

4.2. Sparse Structure of NLP Derivative Functions

The structure of the NLP created by the Radau collocation method has been described in detail in Patterson and Rao [2012]. Figures 5 and 6 show the structure of the NLP constraint Jacobian and Lagrangian Hessian for a single-phase optimal control problem using the differential and integral forms of the Radau method. For a multiple-phase optimal control problem, the constraint Jacobian structure in either the differential or integral form is a block-diagonal version of the single-phase NLP constraint Jacobian where, excluding the event constraints and the static parameters, each block has the structure as seen in either Figures 5(a) or 6(a). The derivatives of the event constraints are located in the final rows of the constraint Jacobian, while the derivatives of all functions with respect to the static parameters are located in the final columns of the constraint Jacobian. Similarly, the multiple-phase NLP Lagrangian Hessian using either the differential or integral form of the Radau method consists of a block-diagonal version of the single-phase NLP Lagrangian Hessian where, excluding the static parameters, each block has the structure seen in either Figures 5(b) or 6(b), with additional nonzero elements arising from the second derivatives of the event constraints, \mathbf{b} , and the objective function, ϕ . The second derivatives of the Lagrangian with respect to the static parameters appear in the final rows and columns of the Lagrangian Hessian. More details on the sparse structure of the NLP arising from the multiple-phase Radau collocation method can be found in Patterson and Rao [2012].

4.3. Optimal Control Problem Scaling for NLP

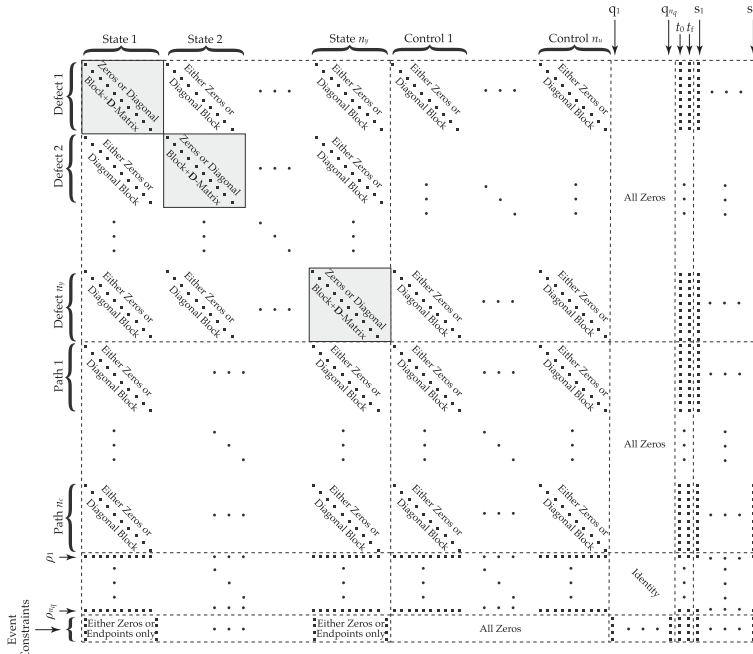

The NLP described in Section 4.1 must be well scaled (that is, the variables and constraints should each be as close as possible $\mathcal{O}(1)$ as described in Gill et al. [1981]) in order for the NLP solver to obtain a solution. GPOPS – III includes the option for the NLP to be scaled automatically by scaling the continuous-time optimal control problem. The approach to automatic scaling is to scale the variables and the first derivatives of the optimal control functions to be $\approx \mathcal{O}(1)$. First, the optimal control variables are scaled to lie on the unit interval $[-1/2, 1/2]$ and is accomplished as follows: Suppose it is desired to scale an arbitrary variable $x \in [a, b]$ to \tilde{x} such that $\tilde{x} \in [-1/2, 1/2]$. This variable scaling is accomplished via the affine transformation

$$\tilde{x} = v_x x + r_x,\tag{53}$$

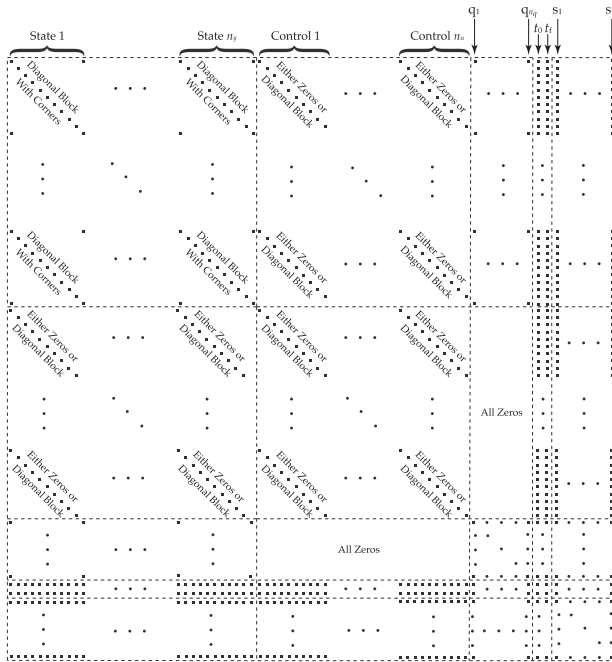

where v_x and r_x are the variable scale and shift, respectively, defined as

$$\begin{aligned}v_x &= \frac{1}{b-a}, \\ r_x &= \frac{1}{2} - \frac{b}{b-a}.\end{aligned}\tag{54}$$

Every variable in the continuous-time optimal control problem is scaled using Eqs. (53) and (54). Next, the Jacobian of the NLP constraints can be made approximately $\mathcal{O}(1)$

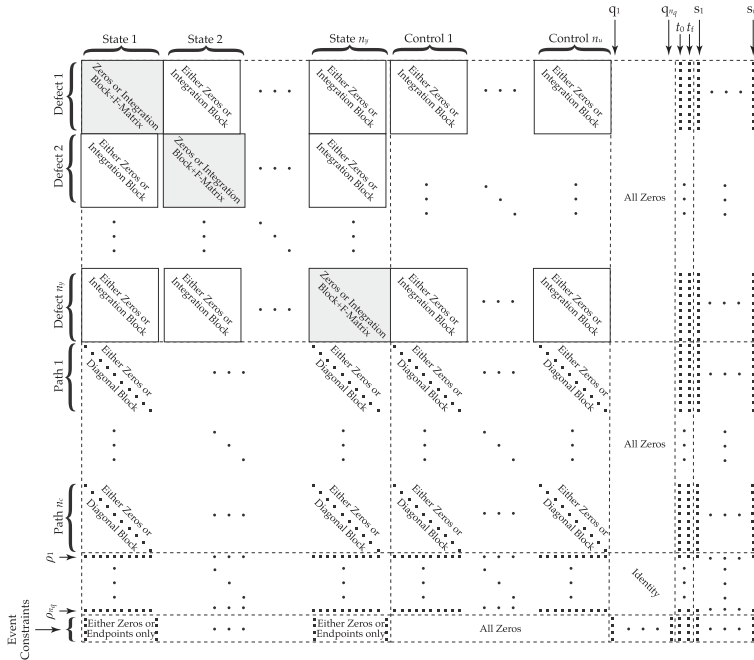

(a) One-Phase NLP Jacobian.

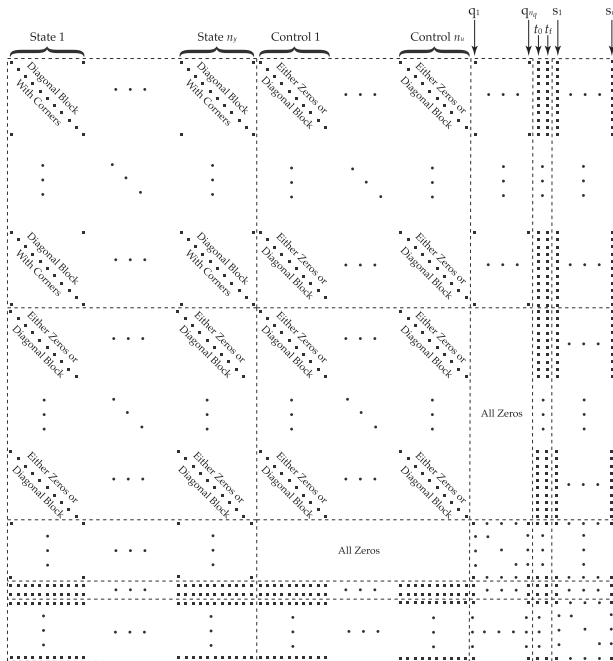

(b) One-Phase NLP Lagrangian Hessian.

Fig. 5. One-phase differential Radau collocation NLP constraint Jacobian and Lagrangian Hessian.

(a) One-Phase NLP Jacobian.

(b) One-Phase NLP Lagrangian Hessian.

Fig. 6. One-phase integral Radau collocation method NLP constraint Jacobian and Lagrangian Hessian.

by scaling the derivatives of the optimal control functions to be approximately unity. First, using the approach derived in Betts [2010], in `GPOPS – III` the defect constraints are scaled using the same scale factors as was used to scale the state. Next, the objective function, event constraint, and path constraint scale factors are obtained as the average norm of each gradient across a variety of sample points within the bounds of the unscaled optimal control problem, where the scale factor is the reciprocal of the appropriate average norm.

4.4. Computation of Derivatives Required by the NLP Solver

The optimal control problem derivative functions are obtained by exploiting the sparse structure of the NLP arising from the *hp* Radau collocation method. Specifically, in Patterson and Rao [2012], it has been shown that using either the derivative or integral form of the Radau collocation method the NLP derivatives can be obtained by computing the derivatives of the optimal control problem functions at the LGR points and inserting these derivatives into the appropriate locations in the NLP derivative functions. In `GPOPS – III`, the optimal control derivative functions are approximated using sparse forward, central, or backward finite-differencing of the optimal control problem functions. To see how this sparse finite differencing works in practice, consider the function $\mathbf{f}(\mathbf{x})$, where $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ is one of the *optimal control functions* (i.e., n and m are, respectively, the size of an optimal control variable and an optimal control function). Then, $\partial\mathbf{f}/\partial\mathbf{x}$ is approximated using a forward finite difference as

$$\frac{\partial\mathbf{f}}{\partial x_i} \approx \frac{\mathbf{f}(\mathbf{x} + \mathbf{h}_i) - \mathbf{f}(\mathbf{x})}{h_i}, \quad (55)$$

where \mathbf{h}_i arises from perturbing the i th component of \mathbf{x} . The vector \mathbf{h}_i is computed as

$$\mathbf{h}_i = h_i \mathbf{e}_i \quad (56)$$

where \mathbf{e}_i is the i th row of the $n \times n$ identity matrix and h_i is the perturbation size associated with x_i . The perturbation h_i is computed using the equation

$$h_i = h(1 + |x_i|), \quad (57)$$

where the base perturbation size h is chosen to be the optimal step size for a function whose input and output are $\approx \mathcal{O}(1)$ as described in Gill et al. [1981]. Second derivative approximations are computed in a manner similar to that used for first derivative approximations with the key difference being that perturbations in two variables are performed. For example, $\partial^2\mathbf{f}/\partial x_i \partial x_j$ can be approximated using a second forward difference approximation as

$$\frac{\partial^2\mathbf{f}}{\partial x_i \partial x_j} \approx \frac{\mathbf{f}(\mathbf{x} + \mathbf{h}_i + \mathbf{h}_j) + \mathbf{f}(\mathbf{x}) - \mathbf{f}(\mathbf{x} + \mathbf{h}_i) - \mathbf{f}(\mathbf{x} + \mathbf{h}_j)}{h_i h_j}, \quad (58)$$

where \mathbf{h}_i , \mathbf{h}_j , h_i , and h_j are as defined in Eqs. (56) and (57). The base perturbation size is chosen to minimize round-off error in the finite difference approximation. Furthermore, it is noted that $h_i \rightarrow h$ as $|x_i| \rightarrow 0$.

4.5. Method for Determining the Optimal Control Function Dependencies

It can be seen from Section 4.2 that the NLP associated with the Radau collocation method has a sparse structure where the blocks of the constraint Jacobian and Lagrangian Hessian are dependent upon whether a particular NLP function depends upon a particular NLP variable as was shown in Patterson and Rao [2012]. The method for determining the optimal control function dependencies in `GPOPS – III` utilizes the IEEE arithmetic representation of “not-a-number” (NaN) in MATLAB. Specifically,

MATLAB has the feature that any function evaluated at NaN will produce an output of NaN if the function depends upon the variable. For example, suppose that $\mathbf{f}(\mathbf{x})$ is a function where $\mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $\mathbf{x} = [x_1 \dots x_n]$. Suppose further that we set $x_i = \text{NaN}$. If any of the components of $\mathbf{f}(\mathbf{x})$ is a function of x_i , then those components of $\mathbf{f}(\mathbf{x})$ that depend on x_i will each be NaN. In this way, the dependence of the optimal control problem functions on a particular input component can be determined by evaluating the functions with that component of the input set to NaN using a single function evaluation. Furthermore, the complete first-derivative dependencies of the optimal control problem functions are found by repeating this process for each component of the input. These dependencies then provide a map as to which finite differences need to be taken when computing the first derivatives of the optimal control functions for determining the NLP derivative functions as described in Section 4.4.

Suppose now that we denote $\mathbf{f}(\mathbf{z})$ generically as one of functions defined in the continuous-time optimal control problem of Eqs. (1)–(8) and that $\mathbf{Jf} = \partial\mathbf{f}/\partial\mathbf{z}$ is the Jacobian of \mathbf{f} with respect to \mathbf{z} . Furthermore, suppose that $\mathbf{S}_1 = \mathbf{struct}(\mathbf{Jf})$ is a matrix of ones and zeros that contains the structure the first derivatives of the optimal control function $\mathbf{f}(\mathbf{z})$. The second derivative dependencies are then obtained as the matrix of ones and zeros given by $\mathbf{S}_2 = \mathbf{struct}(\mathbf{S}_1^\top \mathbf{S}_1)$. Now, while it may be the case for some problems that \mathbf{S}_2 contains an overestimate of the second derivative dependencies of the function $\mathbf{f}(\mathbf{z})$, for most problems to which GPOPS – III may be applied (namely, nonlinear optimal control problems), the estimate obtained in \mathbf{S}_2 will be quite close to the exact second derivative dependencies of the function $\mathbf{f}(\mathbf{z})$. In addition, our approach is robust in that it will never underestimate the second derivative dependencies (where an underestimate may prove to be catastrophic because second derivatives that are nonzero in the optimal control problem would be incorrectly estimated to be zero in the approximation of the Lagrangian Hessian). Finally, our approach for determining second derivative dependencies incurs minimal additional computational expense above that required to determine the first derivative dependencies.

4.6. Adaptive Mesh Refinement

In the past few years, the subject of variable-order mesh refinement has been a topic of considerable study in developing efficient implementations of Gaussian quadrature collocation methods. The work on variable-order Gaussian quadrature mesh refinement has led to several articles in the literature including those found in Gong et al. [2008a], Darby et al. [2011b, 2011c], and Patterson et al. [2014]. GPOPS – III employs the two latest variable-order mesh refinement methods as described in Darby et al. [2011c] and Patterson et al. [2014]. The mesh refinement methods of Darby et al. [2011c] and Patterson et al. [2014] are referred to as the *hp* and the *ph* methods, respectively. In either the *hp* and the *ph* mesh refinement methods the number of mesh intervals, width of each mesh interval, and the degree of the approximating polynomial can be varied until a user-specified accuracy tolerance has been achieved. When using either of the methods in GPOPS – III, the terminology *hp* – (N_{\min}, N_{\max}) or *ph* – (N_{\min}, N_{\max}) refers to a method whose minimum and maximum allowable polynomial degrees within a mesh interval are N_{\min} and N_{\max} , respectively. Each method estimates the solution error using a relative difference between the state estimate and the integral of the dynamics at a modified set of LGR points. The key difference between the *hp* and the *ph* methods lies in the manner in which the decision is made to either increase the number of collocation points in a mesh interval or to refine the mesh. In Darby et al. [2011c], the degree of the approximating polynomial is increased if the ratio of the maximum curvature over the mean curvature of the state in a particular mesh interval exceeds a user-specified threshold. On the other hand,

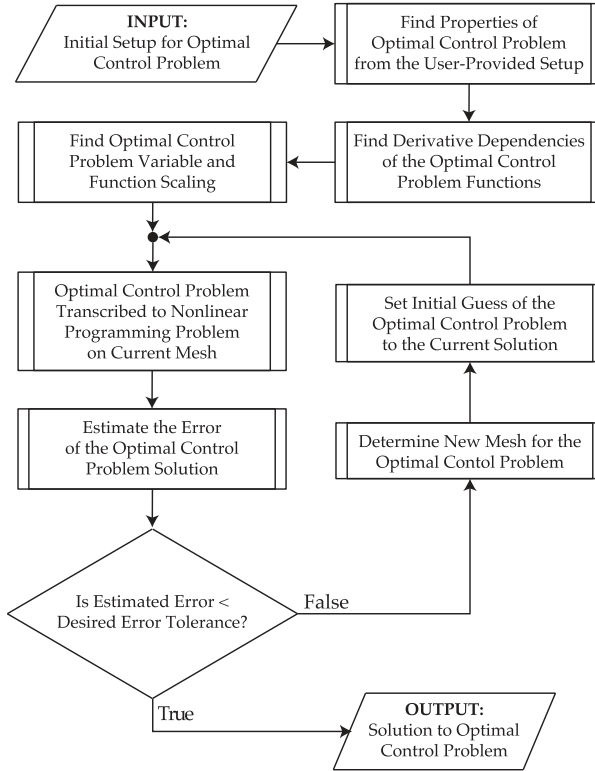

Fig. 7. Flowchart of the GPOPS – III algorithm.

Patterson et al. [2014] uses the exponential convergence property of the Radau collocation method and increases the polynomial degree within a mesh interval if the estimate of the required polynomial degree is less than a user-specified upper limit. If the estimate of the polynomial degree exceeds the allowed upper limit, the mesh interval is divided into more mesh intervals. In GPOPS – III, the user can choose between these two mesh refinement methods. Finally, it is noted that GPOPS – III has been designed in a modular way making it possible to add a new mesh refinement method in a relatively straightforward way if it is so desired.

4.7. Algorithmic Flow of GPOPS – III

In this section, we describe the operational flow of GPOPS – III with the aid of Figure 7. First, the user provides a description of the optimal control problem that is to be solved. The properties of the optimal control problem are then determined from the user description from which the state, control, time, and parameter dependencies of the optimal control problem functions are determined. Subsequently, assuming that the user has specified that the optimal control problem be scaled automatically, the optimal control problem scaling algorithm is called and these scale factors are used to scale the NLP. The optimal control problem is then transcribed to a large sparse NLP and the NLP is solved on the initial mesh, where the initial mesh is either user-supplied or is determined by the defaults set in GPOPS – III. Once the NLP is solved, it is untranscribed to a discrete approximation of the optimal control problem and the error in the discrete approximation for the current mesh is estimated. If the user-specified accuracy tolerance is met, the software terminates and outputs the solution.

Otherwise, a new mesh is determined using one of the supplied mesh refinement algorithms and the resulting NLP is solved on the new mesh.

5. EXAMPLES

GPOPS – III is now demonstrated on five examples taken from the open literature. The first example is the hypersensitive optimal control problem from Rao and Mease [2000] and demonstrates the ability of GPOPS – III to efficiently solve problems that have rapid changes in dynamics in particular regions of the solution. The second example is the reusable launch vehicle entry problem taken from Betts [2010] and demonstrates the efficiency of GPOPS – III on a problem whose dynamic model is representative of a real physical system. The third example is the space station attitude optimal control problem taken from Pietz [2003] and Betts [2010] and demonstrates the efficiency of GPOPS – III on a problem whose solution is highly nonintuitive. The fourth example is a kinetic batch reactor problem taken from Betts [2010] and demonstrates the ability of GPOPS – III to solve an extremely poorly scaled multiple-phase optimal control problem. The fifth example is a multiple-stage launch vehicle ascent problem taken from Benson [2004], Rao et al. [2010], and Betts [2010] and demonstrates the ability of GPOPS – III to solve a problem with multiple-phases. The first four examples were solved using the open-source NLP solver IPOPT [Biegler et al. 2003] in second derivative (full Newton) mode with the publicly available multifrontal massively parallel sparse direct linear solver MUMPS [MUMPS 2011], while the fifth example was solved using the NLP solver SNOPT [Gill et al. 2002]. The initial guess of the solution is provided for all examples, where the function $\mathbf{linear}(t_0, t_f, a, b)$ is a linear interpolation over the range $[a, b]$ on the domain $[t_0, t_f]$. All results were obtained using the implicit integration form of the Radau collocation method and various forms of the aforementioned ph mesh refinement method using default NLP solver settings and the automatic scaling routine in GPOPS – III.

5.1. Hypersensitive Problem

Consider the following *hypersensitive* optimal control problem taken from Rao and Mease [2000]:

$$\text{minimize } \frac{1}{2} \int_0^{t_f} (x^2 + u^2) dt \text{ subject to } \begin{cases} \dot{x} &= -x^3 + u, \\ x(0) &= 1, \\ x(t_f) &= 1.5, \end{cases} \quad (59)$$

where $t_f = 10000$. It is known for a sufficiently large value of t_f the interesting behavior in the solution occurs near $t = 0$ and $t = t_f$ (see Rao and Mease [2000] for details), while the vast majority of the solution is a constant. Given the structure of the solution, a majority of collocation points need to be placed near $t = 0$ and $t = t_f$.

The hypersensitive optimal control problem was solved using GPOPS – III with the $ph - (3, 10)$ method, an initial mesh consisting of ten evenly spaced mesh interval with three LGR points per mesh interval, and the following initial guess:

$$\begin{aligned} x^{\text{guess}} &= \mathbf{linear}(0, t_f, x(0), x(t_f)), \\ u^{\text{guess}} &= 0, \\ t_f^{\text{guess}} &= t_f. \end{aligned}$$

The solution obtained using GPOPS – III is shown in Figure 8 alongside the solution obtained with the software Sparse Optimization Suite (SOS) [Betts 2013]. It is seen that the GPOPS – III and SOS solutions are in excellent agreement. Moreover, the optimal cost obtained using GPOPS – III and SOS are extremely close, with values 3.3620563 and 3.3620608, respectively. In order to demonstrate how GPOPS – III is capable of

Fig. 8. GPOPS – II and Sparse Optimization Suite solutions to hypersensitive optimal Control Problem.

Fig. 9. GPOPS – III and Sparse Optimization Suite solutions to hypersensitive optimal control problem near $t = 0$ and $t = t_f$.

capturing the interesting features of the optimal solution, Figure 9 shows the solution on the intervals $t \in [0, 15]$ (near the initial time) and $t \in [9985, 10000]$ (near the final time), while Figure 10 shows the mesh refinement history. It is seen that GPOPS – III accurately captures the rapid decay from $x(0) = 1$ and the rapid growth to meet the terminal condition $x(t_f) = 1.5$, and the density of the mesh points near $t = 0$ and $t = t_f$ increases as the mesh refinement progresses. Finally, Table I shows the estimated

Fig. 10. Mesh refinement history for hypersensitive problem using GPOPS – III.

Table I. Mesh Refinement History for Hypersensitive Problem

Mesh	Relative Error Estimate
1	2.827×10^1
2	2.823×10^0
3	7.169×10^{-1}
4	1.799×10^{-1}
5	7.092×10^{-2}
6	8.481×10^{-3}
7	1.296×10^{-3}
8	5.676×10^{-7}

error on each mesh, where it is seen that the solution error decreases steadily with each mesh refinement iteration, finally terminating on the eighth mesh (i.e., the seventh mesh refinement).

5.2. Reusable Launch Vehicle Entry

Consider the following optimal control problem of maximizing the crossrange during the atmospheric entry of a reusable launch vehicle and taken from Betts [2010] where the numerical values in Betts [2010] are converted from English units to SI units. Maximize the cost functional

$$J = \phi(t_f) \tag{60}$$

subject to the dynamic constraints

$$\begin{aligned} \dot{r} &= v \sin \gamma, & \dot{\theta} &= \frac{v \cos \gamma \sin \psi}{r \cos \phi}, & \dot{\phi} &= \frac{v \cos \gamma \cos \psi}{r}, \\ \dot{v} &= -\frac{D}{m} - g \sin \gamma, & \dot{\gamma} &= \frac{L \cos \sigma}{mv} - \left(\frac{g}{v} - \frac{v}{r}\right) \cos \gamma, & \dot{\psi} &= \frac{L \sin \sigma}{mv \cos \gamma} + \frac{v \cos \gamma \sin \psi \tan \phi}{r}, \end{aligned} \tag{61}$$

and the boundary conditions

$$\begin{aligned} h(0) &= 79248 \text{ km}, & h(t_f) &= 24384 \text{ km}, & \theta(0) &= 0 \text{ deg}, & \theta(t_f) &= \text{Free}, \\ \phi(0) &= 0 \text{ deg}, & \phi(t_f) &= \text{Free}, & v(0) &= 7.803 \text{ km/s}, & v(t_f) &= 0.762 \text{ km/s}, \\ \gamma(0) &= -1 \text{ deg}, & \gamma(t_f) &= -5 \text{ deg}, & \psi(0) &= 90 \text{ deg}, & \psi(t_f) &= \text{Free}, \end{aligned} \tag{62}$$

Table II. Performance of GPOPS – III on the Reusable Launch Vehicle Entry Optimal Control Problem

Mesh Iteration	Estimated Error (GPOPS – III)	Number of Collocation Points	Estimated Error (SOS)	Number of Collocation Points
1	2.463×10^{-3}	41	1.137×10^{-2}	51
2	2.946×10^{-4}	103	1.326×10^{-3}	101
3	1.202×10^{-5}	132	3.382×10^{-5}	101
4	8.704×10^{-8}	175	1.314×10^{-6}	101
5	–	–	2.364×10^{-7}	201
6	–	–	2.364×10^{-7}	232
7	–	–	1.006×10^{-7}	348
8	–	–	9.933×10^{-8}	353

where $r = h + R_e$ is the geocentric radius, h is the altitude, R_e is the polar radius of the Earth, θ is the longitude, ϕ is the latitude, v is the speed, γ is the flight path angle, and ψ is the azimuth angle. Furthermore, the aerodynamic and gravitational forces are computed as

$$D = \frac{\rho v^2 S C_D}{2}, \quad L = \frac{\rho v^2 S C_L}{2}, \quad g = \frac{\mu}{r^2}, \quad (63)$$

where $\rho = \rho_0 \exp(-h/H)$ is the atmospheric density, ρ_0 is the density at sea level, H is the density scale height, S is the vehicle reference area, C_D is the coefficient of drag, C_L is the coefficient of lift, and μ is the gravitational parameter.

The reusable launch vehicle entry optimal control problem was solved with GPOPS – III using the $ph - (4, 10)$ mesh refinement method, an initial mesh consisting of ten evenly spaced mesh intervals with four LGR points per mesh interval, and a mesh refinement accuracy tolerance of 10^{-7} , and the following initial guess:

$$\begin{aligned} h &= \mathbf{linear}(0, t_f, h(0), h(t_f)), \\ \theta &= \theta(0), \\ \phi &= \phi(0), \\ v &= \mathbf{linear}(0, t_f, v(0), v(t_f)), \\ \gamma &= \mathbf{linear}(0, t_f, \gamma(0), \gamma(t_f)), \\ \psi &= \psi(0), \\ \alpha &= 0, \\ \sigma &= 0, \\ t_f &= 1000 \text{ s.} \end{aligned}$$

The solution obtained using GPOPS – III is shown in Figures 11(a)–11(f) alongside the solution obtained using the software *Sparse Optimization Suite* (SOS) [Betts 2010], where it is seen that the two solutions obtained are virtually indistinguishable. It is noted that the optimal cost obtained by GPOPS – III and SOS are also nearly identical at 0.59627639 and 0.59587608, respectively. Table II shows the performance of both GPOPS – III and SOS on this example. It is interesting to see that GPOPS – III meets the accuracy tolerance of 10^{-7} in only four mesh iterations (three mesh refinements) while SOS requires a total of eight meshes (seven mesh refinements). Finally, the number of collocation points used by GPOPS – III is approximately one half the number of collocation points required by SOS to achieve the same level of accuracy.

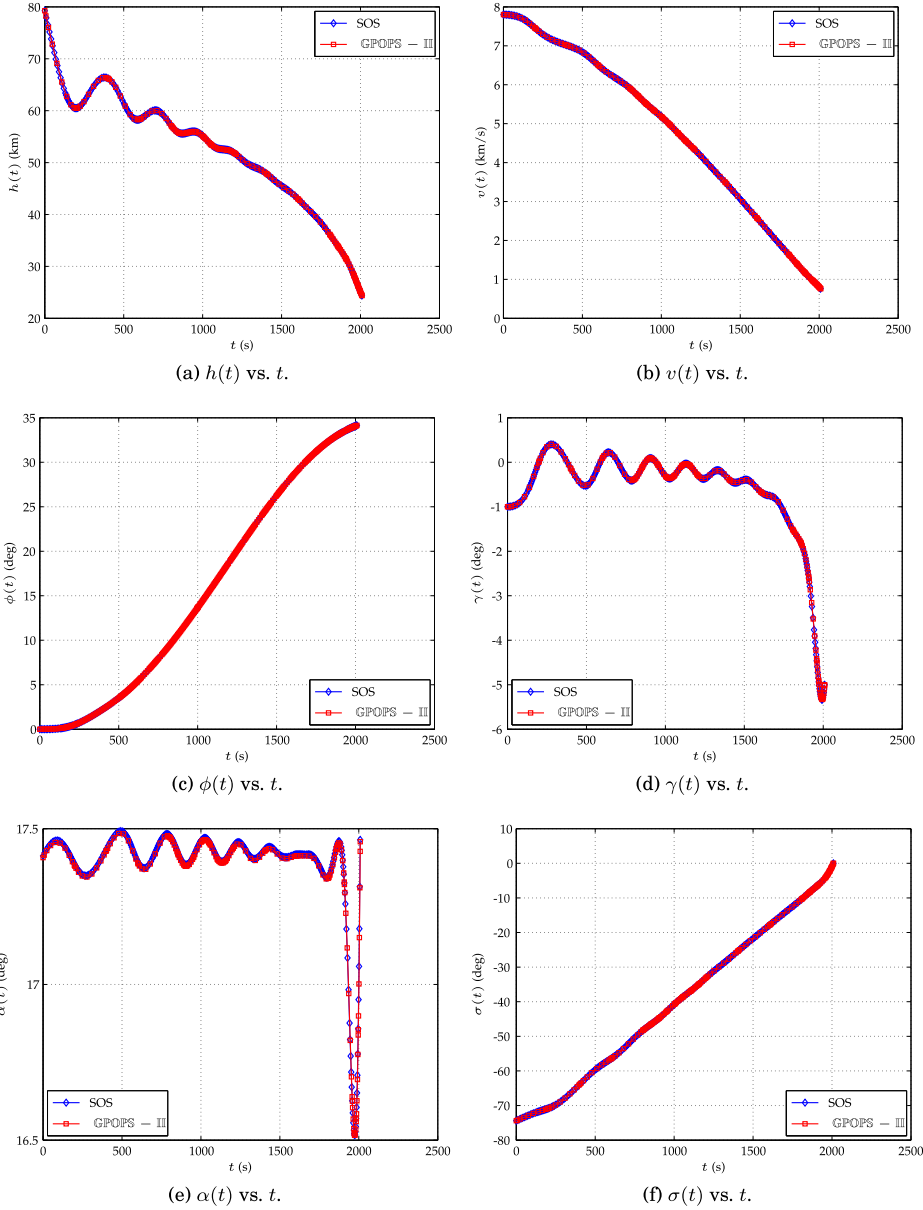

Fig. 11. Solution to reusable launch vehicle entry problem using GPOPS – III and Sparse Optimization Suite.

5.3. Space Station Attitude Control

Consider the following space station attitude control optimal control problem taken from Pietz [2003] and Betts [2010]. Minimize the cost functional

$$J = \frac{1}{2} \int_{t_0}^{t_f} \mathbf{u}^T \mathbf{u} dt \tag{64}$$

subject to the dynamic constraints

$$\begin{aligned}\dot{\boldsymbol{\omega}} &= \mathbf{J}^{-1} \{ \boldsymbol{\tau}_{gg}(\mathbf{r}) - \boldsymbol{\omega}^{\otimes} [\mathbf{J}\boldsymbol{\omega} + \mathbf{h}] - \mathbf{u} \}, \\ \dot{\mathbf{r}} &= \frac{1}{2} [\mathbf{r}\mathbf{r}^{\top} + \mathbf{I} + \mathbf{r}] [\boldsymbol{\omega} - \boldsymbol{\omega}(\mathbf{r})], \\ \dot{\mathbf{h}} &= \mathbf{u},\end{aligned}\quad (65)$$

the inequality path constraint

$$\|\mathbf{h}\| \leq h_{\max}, \quad (66)$$

and the boundary conditions

$$\begin{aligned}t_0 &= 0, \\ t_f &= 1800, \\ \boldsymbol{\omega}(0) &= \bar{\boldsymbol{\omega}}_0, \\ \mathbf{r}(0) &= \bar{\mathbf{r}}_0, \\ \mathbf{h}(0) &= \bar{\mathbf{h}}_0, \\ \mathbf{0} &= \mathbf{J}^{-1} \{ \boldsymbol{\tau}_{gg}(\mathbf{r}(t_f)) - \boldsymbol{\omega}^{\otimes}(t_f) [\mathbf{J}\boldsymbol{\omega}(t_f) + \mathbf{h}(t_f)] \}, \\ \mathbf{0} &= \frac{1}{2} [\mathbf{r}(t_f)\mathbf{r}^{\top}(t_f) + \mathbf{I} + \mathbf{r}(t_f)] [\boldsymbol{\omega}(t_f) - \boldsymbol{\omega}_0(\mathbf{r}(t_f))],\end{aligned}\quad (67)$$

where $(\boldsymbol{\omega}, \mathbf{r}, \mathbf{h})$ is the state and \mathbf{u} is the control. In this formulation, $\boldsymbol{\omega}$ is the angular velocity, \mathbf{r} is the Euler-Rodrigues parameter vector, \mathbf{h} is the angular momentum, and \mathbf{u} is the input moment (and is the control).

$$\begin{aligned}\boldsymbol{\omega}_0(\mathbf{r}) &= -\omega_{\text{orb}} \mathbf{C}_2, \\ \boldsymbol{\tau}_{gg} &= 3\omega_{\text{orb}}^2 \mathbf{C}_3^{\otimes} \mathbf{J} \mathbf{C}_3,\end{aligned}\quad (68)$$

and \mathbf{C}_2 and \mathbf{C}_3 are the second and third column, respectively, of the matrix

$$\mathbf{C} = \mathbf{I} + \frac{2}{1 + \mathbf{r}^{\top}\mathbf{r}} (\mathbf{r}^{\otimes}\mathbf{r}^{\otimes} - \mathbf{r}^{\otimes}). \quad (69)$$

In this example, the matrix \mathbf{J} is given as

$$\mathbf{J} = \begin{bmatrix} 2.80701911616 \times 10^7 & 4.822509936 \times 10^5 & -1.71675094448 \times 10^7 \\ 4.822509936 \times 10^5 & 9.5144639344 \times 10^7 & 6.02604448 \times 10^4 \\ -1.71675094448 \times 10^7 & 6.02604448 \times 10^4 & 7.6594401336 \times 10^7 \end{bmatrix}, \quad (70)$$

while the initial conditions $\bar{\boldsymbol{\omega}}_0$, $\bar{\mathbf{r}}_0$, and $\bar{\mathbf{h}}_0$ are

$$\begin{aligned}\bar{\boldsymbol{\omega}}_0 &= \begin{bmatrix} -9.5380685844896 \times 10^{-6} \\ -1.1363312657036 \times 10^{-3} \\ +5.3472801108427 \times 10^{-6} \end{bmatrix}, \\ \bar{\mathbf{r}}_0 &= \begin{bmatrix} 2.9963689649816 \times 10^{-3} \\ 1.5334477761054 \times 10^{-1} \\ 3.8359805613992 \times 10^{-3} \end{bmatrix}, \\ \bar{\mathbf{h}}_0 &= \begin{bmatrix} 5000 \\ 5000 \\ 5000 \end{bmatrix}.\end{aligned}\quad (71)$$

A more detailed description of this problem, including all of the constants \mathbf{J} , $\bar{\boldsymbol{\omega}}_0$, $\bar{\mathbf{r}}_0$, and $\bar{\mathbf{h}}_0$, can be found in Pietz [2003] or Betts [2010].

Fig. 12. State solution to space station attitude control problem using GPOPS – III with the NLP solver IPOPT and a mesh refinement tolerance of 10^{-6} alongside solution obtained using optimal control software Sparse Optimization Suite.

The space station attitude control example was solved with GPOPS – III using the $ph - (4, 10)$ mesh refinement method with an initial mesh consisting of ten uniformly spaced mesh intervals and four LGR points per mesh interval, a finite-difference perturbation step size of 10^{-5} , and the following initial guess:

$$\begin{aligned}
 \boldsymbol{\omega} &= \bar{\boldsymbol{\omega}}_0 \\
 \mathbf{r} &= \bar{\mathbf{r}}_0 \\
 \mathbf{h} &= \bar{\mathbf{h}}_0 \\
 \mathbf{u} &= \mathbf{0}, \\
 t_f &= 1800 \text{ s.}
 \end{aligned}$$

The state and control solutions obtained using GPOPS – III are shown, respectively, in Figures 12 and 13 alongside the solution obtained using the optimal control software Sparse Optimization Suite (SOS) [Betts 2013]. It is seen that the GPOPS – III solution is in close agreement with the SOS solution. It is noted for this example that the mesh refinement accuracy tolerance of 10^{-6} was satisfied on the second mesh (i.e., one mesh refinement iteration was performed) using a total of 46 collocation (LGR) points (i.e., 47 total points when including the final time point).

Fig. 13. Control solution to space station attitude control problem using GPOPS – III with the NLP solver IPOPT and a mesh refinement tolerance of 10^{-6} alongside solution obtained using optimal control software Sparse Optimization Suite.

5.4. Kinetic Batch Reactor

Consider the following three-phase kinetic batch reactor optimal control problem that originally appears in the work of Leineweber [1998] and later appears in Betts [2010]. Minimize the cost functional

$$J = \gamma_1 t_f^{(3)} + \gamma_2 p \quad (72)$$

subject to the dynamic constraints

$$\begin{aligned} \dot{y}_1^{(k)} &= -k_2 y_2^{(k)} u_2^{(k)}, \\ \dot{y}_2^{(k)} &= -k_1 y_2^{(k)} y_6^{(k)} + k_{-1} u_4^{(k)} - k_2 y_2^{(k)} u_4^{(k)}, \\ \dot{y}_3^{(k)} &= k_2 y_2^{(k)} u_2^{(k)} + k_3 y_4^{(k)} y_6^{(k)} - k_{-3} u_3^{(k)}, \\ \dot{y}_4^{(k)} &= -k_3 y_4^{(k)} y_6^{(k)} + k_{-3} u_3^{(k)}, \\ \dot{y}_5^{(k)} &= k_1 y_2^{(k)} y_6^{(k)} - k_{-1} u_4^{(k)}, \\ \dot{y}_6^{(k)} &= -k_1 y_2^{(k)} y_6^{(k)} + k_{-1} u_4^{(k)} - k_3 y_4^{(k)} y_6^{(k)} + k_{-3} u_3^{(k)}, \end{aligned} \quad , \quad (k = 1, 2, 3), \quad (74)$$

the equality path constraints

$$\begin{aligned} p - y_6^{(k)} + 10^{-u_1^{(k)}} - u_2^{(k)} - u_3^{(k)} - u_4^{(k)} &= 0, \\ u_2^{(k)} - K_2 y_1^{(k)} / (K_2 + 10^{-u_1^{(k)}}) &= 0, \\ u_3^{(k)} - K_3 y_3^{(k)} / (K_3 + 10^{-u_1^{(k)}}) &= 0, \\ u_4^{(k)} - K_4 y_5^{(k)} / (K_4 + 10^{-u_1^{(k)}}) &= 0, \end{aligned} \quad , \quad (k = 1, 2, 3), \quad (75)$$

the control inequality path constraint

$$293.15 \leq u_5^{(k)} \leq 393.15, \quad (k = 1, 2, 3), \quad (76)$$

the inequality path constraint in phases 1 and 2

$$y_4^{(k)} \leq a [t^{(k)}]^2, \quad (k = 1, 2), \quad (77)$$

the interior point constraints

$$\begin{aligned} t_f^{(1)} &= 0.01, \\ t_f^{(2)} &= t_f^{(3)}/4, \\ y_i^{(k)} &= y_i^{(k+1)}, \quad (i = 1, \dots, 6, k = 1, 2, 3), \end{aligned} \quad (78)$$

and the boundary conditions

$$\begin{aligned} y_1^{(1)}(0) &= 1.57776, \quad y_2^{(1)}(0) = 8.32, \quad y_3^{(1)}(0) = 0, \\ y_4^{(1)}(0) &= 0, \quad y_5^{(1)}(0) = 0, \quad y_6^{(1)}(0) - p = 0, \\ y_4^{(3)}(t_f^{(3)}) &\leq 1, \end{aligned} \quad (79)$$

where

$$\begin{aligned} k_1 &= \hat{k}_1 \exp(-\beta_1/u_5^{(k)}), \\ k_{-1} &= \hat{k}_{-1} \exp(-\beta_{-1}/u_5^{(k)}), \\ k_2 &= \hat{k}_2 \exp(-\beta_2/u_5^{(k)}), \quad , \quad (k = 1, 2, 3), \\ k_3 &= k_1, \\ k_{-3} &= \frac{1}{2}k_{-1}, \end{aligned} \quad (80)$$

and the values for the parameters \hat{k}_j , β_j , and K_j are given as

$$\begin{aligned} \hat{k}_1 &= 1.3708 \times 10^{12}, \quad \beta_1 = 9.2984 \times 10^3, \quad K_1 = 2.575 \times 10^{-16}, \\ \hat{k}_{-1} &= 1.6215 \times 10^{20}, \quad \beta_{-1} = 1.3108 \times 10^4, \quad K_2 = 4.876 \times 10^{-14}, \\ \hat{k}_2 &= 5.2282 \times 10^{12}, \quad \beta_2 = 9.599 \times 10^3, \quad K_3 = 1.7884 \times 10^{-16}. \end{aligned} \quad (81)$$

The kinetic batch reactor optimal control problem was solved using GPOPS – III using the $ph - (3, 6)$ mesh refinement method with an initial mesh in each phase consisting of ten uniformly spaced mesh intervals with three LGR points per mesh interval, a base derivative perturbation step size of 10^{-5} , and the following linear initial guess (where the superscript represents the phase number):

$$\begin{aligned} y_1^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, y_1(0), 0.5), & y_1^{(2)} &= 0.5, & y_1^{(3)} &= \mathbf{linear}(t_0^{(3)}, t_f^{(3)}, 0.5, 0.1), \\ y_2^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, y_2(0), 6), & y_2^{(2)} &= 6, & y_2^{(3)} &= \mathbf{linear}(t_0^{(3)}, t_f^{(3)}, 6, 5), \\ y_3^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, y_3(0), 0.6), & y_3^{(2)} &= 0.6, & y_3^{(3)} &= 6, \\ y_4^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, y_4(0), 0.5), & y_4^{(2)} &= 0.5, & y_4^{(3)} &= \mathbf{linear}(t_0^{(3)}, t_f^{(3)}, 0.5, 0.9), \\ y_5^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, y_5(0), 0.5), & y_5^{(2)} &= 0.5, & y_5^{(3)} &= \mathbf{linear}(t_0^{(3)}, t_f^{(3)}, 0.5, 0.9), \\ y_6^{(1)} &= 0.013, & y_6^{(2)} &= 0.013, & y_6^{(3)} &= 0.013, \\ u_1^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, 7, 10), & u_1^{(2)} &= 10, & u_1^{(3)} &= 10, \\ u_2^{(1)} &= 0, & u_2^{(2)} &= 0, & u_2^{(3)} &= 0, \\ u_3^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, 0, 10^{-5}), & u_3^{(2)} &= 10^{-5}, & u_3^{(3)} &= 10^{-5}, \\ u_4^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, 0, 10^{-5}), & u_4^{(2)} &= 10^{-5}, & u_4^{(3)} &= 10^{-5}, \\ u_5^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, 373, 393.15), & u_5^{(2)} &= 393.15, & u_5^{(3)} &= 393.15, \\ t_0^{(1)} &= 0, & t_0^{(2)} &= 0.01 \text{ hr}, & t_0^{(3)} &= 2.5 \text{ hr}, \\ t_f^{(1)} &= 0.01 \text{ hr}, & t_f^{(2)} &= 2.5 \text{ hr}, & t_f^{(3)} &= 10 \text{ hr}. \end{aligned}$$

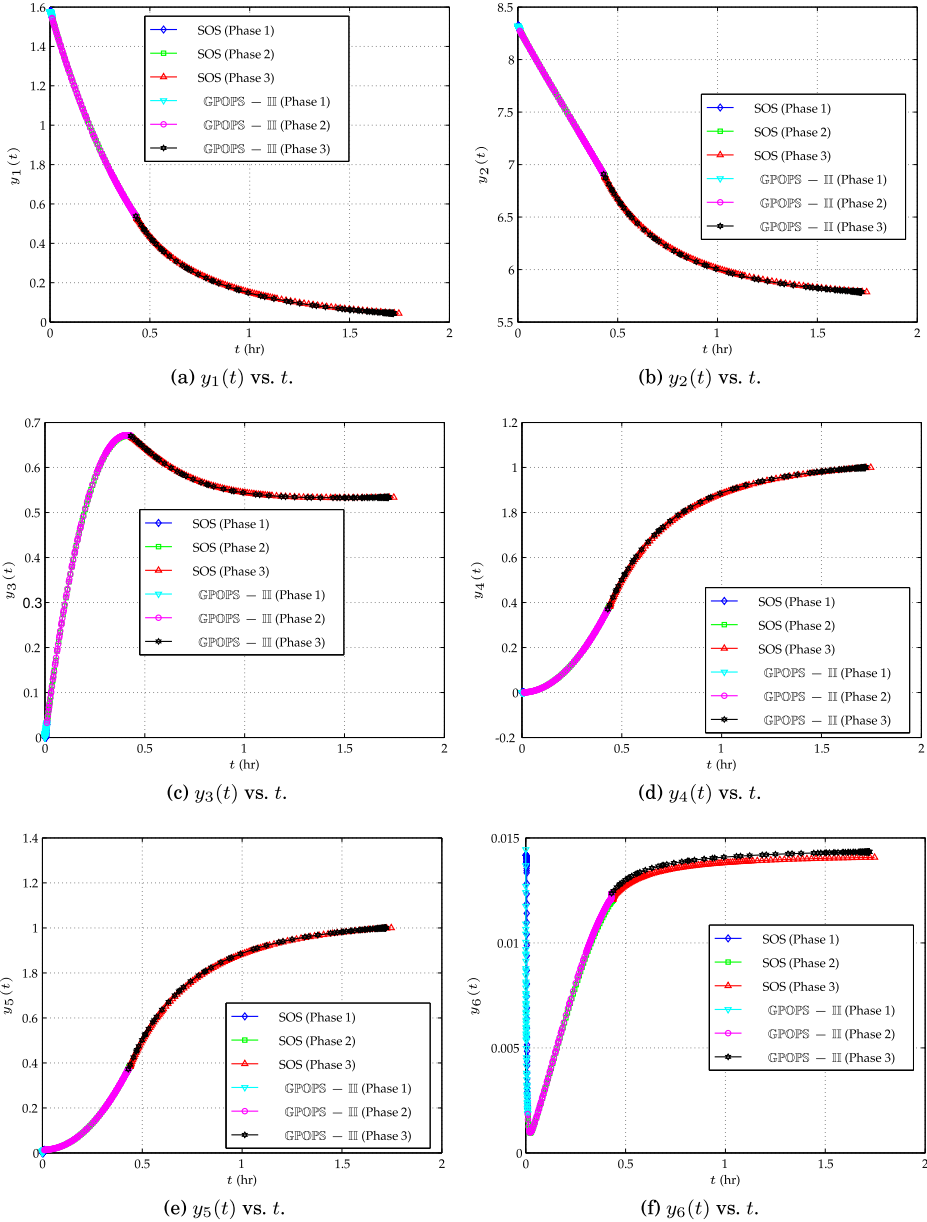

Fig. 14. State solution to kinetic batch reactor optimal control problem using GPOPS – III alongside solution obtained using optimal control software Sparse Optimization Suite.

The state and control solutions obtained using GPOPS – III are shown in Figures 14–17, respectively, alongside the solution obtained using the software Sparse Optimization Suite (SOS) Betts [2013]. It is seen that in the complete three-phase problem the GPOPS – III and SOS solutions have the same trend, the key difference being that the GPOPS – III solution is shorter in duration than the SOS solution. A closer examination, however, of the solution in phase 1 reveals that the two solutions are actually quite different at the start of the problem. The GPOPS – III solution moves away from

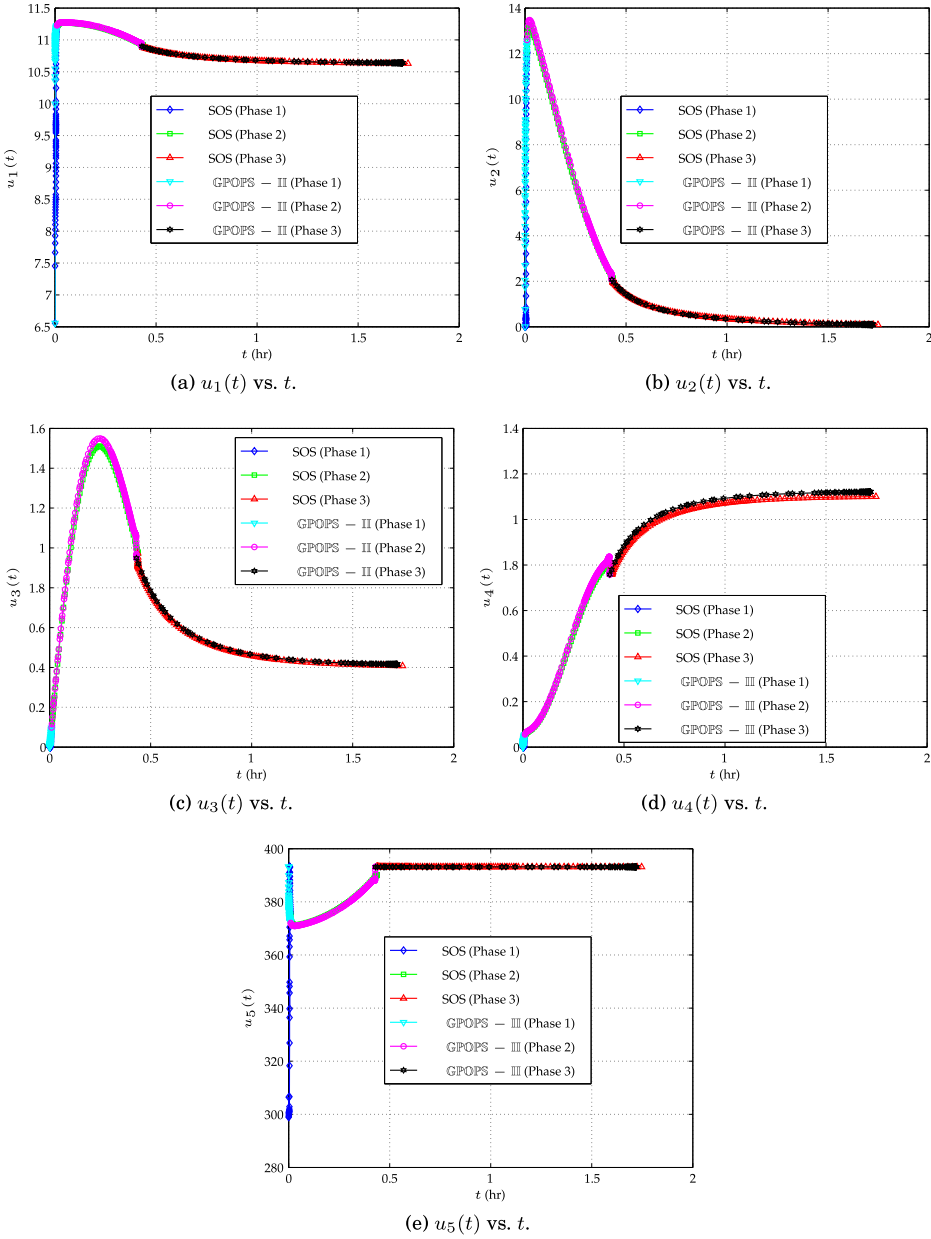

Fig. 15. Control solution to kinetic batch reactor optimal control problem using GPOPS – III alongside solution obtained using optimal control software Sparse Optimization Suite.

the initial condition much more quickly than the SOS solution. Thus, the SOS solution exhibits stiff behavior at the start of the solution while the GPOPS – III solution does not exhibit this stiffness. While the solutions are significantly different in phase 1, the optimal cost obtained using GPOPS – III is 3.1650187 while the optimal cost obtained using SOS is 3.1646696, leading to absolute and relative differences of only 3.4910×10^{-4} and 1.1031×10^{-4} , respectively. Thus, while the solutions obtained by

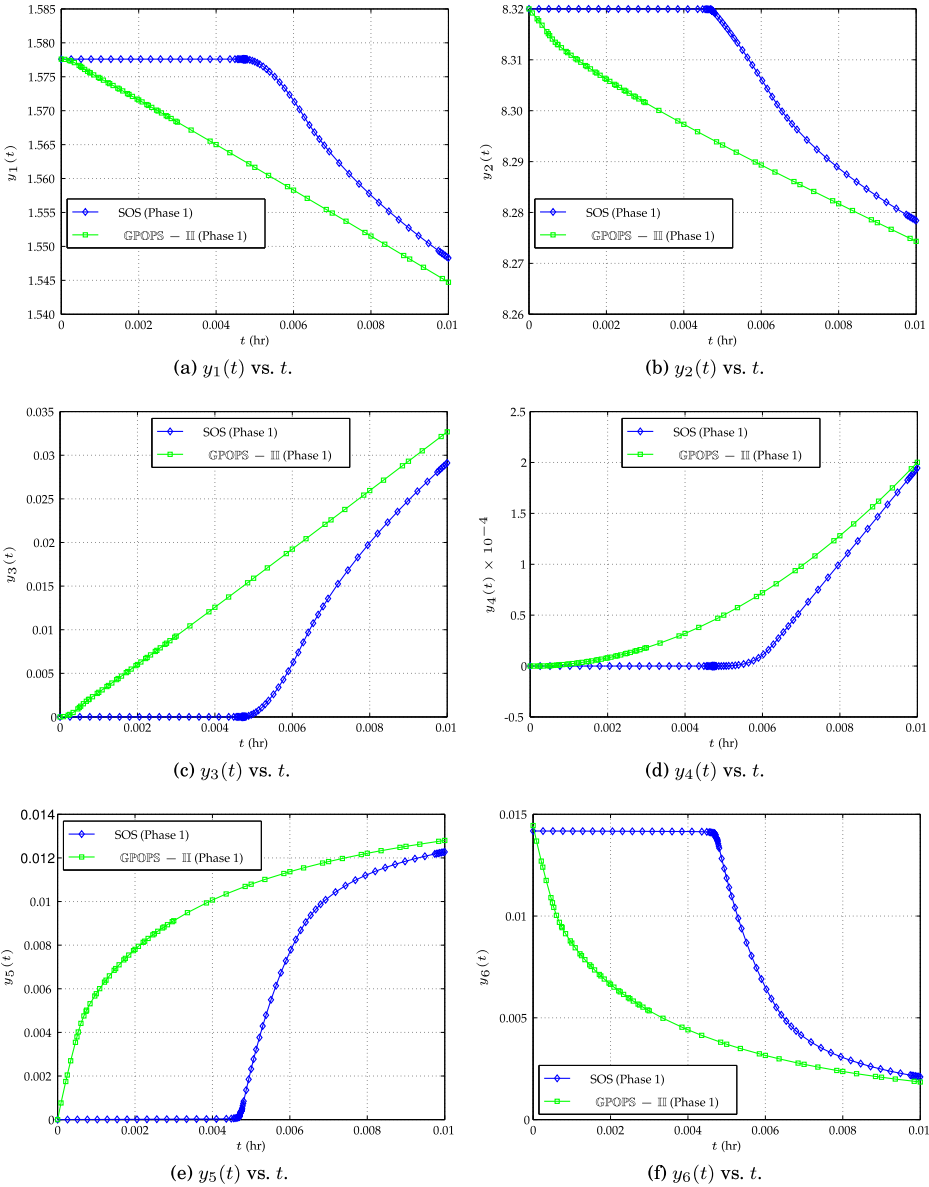

Fig. 16. Phase 1 state solution to kinetic batch reactor optimal control problem using GPOPS – II alongside solution obtained using optimal control software Sparse Optimization Suite.

each software program differ in the first (transient) phase, the overall performance of GPOPS – II is similar to that obtained using SOS (particularly given the computational challenge of this example).

5.5. Multiple-Stage Launch Vehicle Ascent Problem

The problem considered in this section is the ascent of a multiple-stage launch vehicle. The objective is to maneuver the launch vehicle from the ground to the target orbit while maximizing the remaining fuel in the upper stage. It is noted that this example

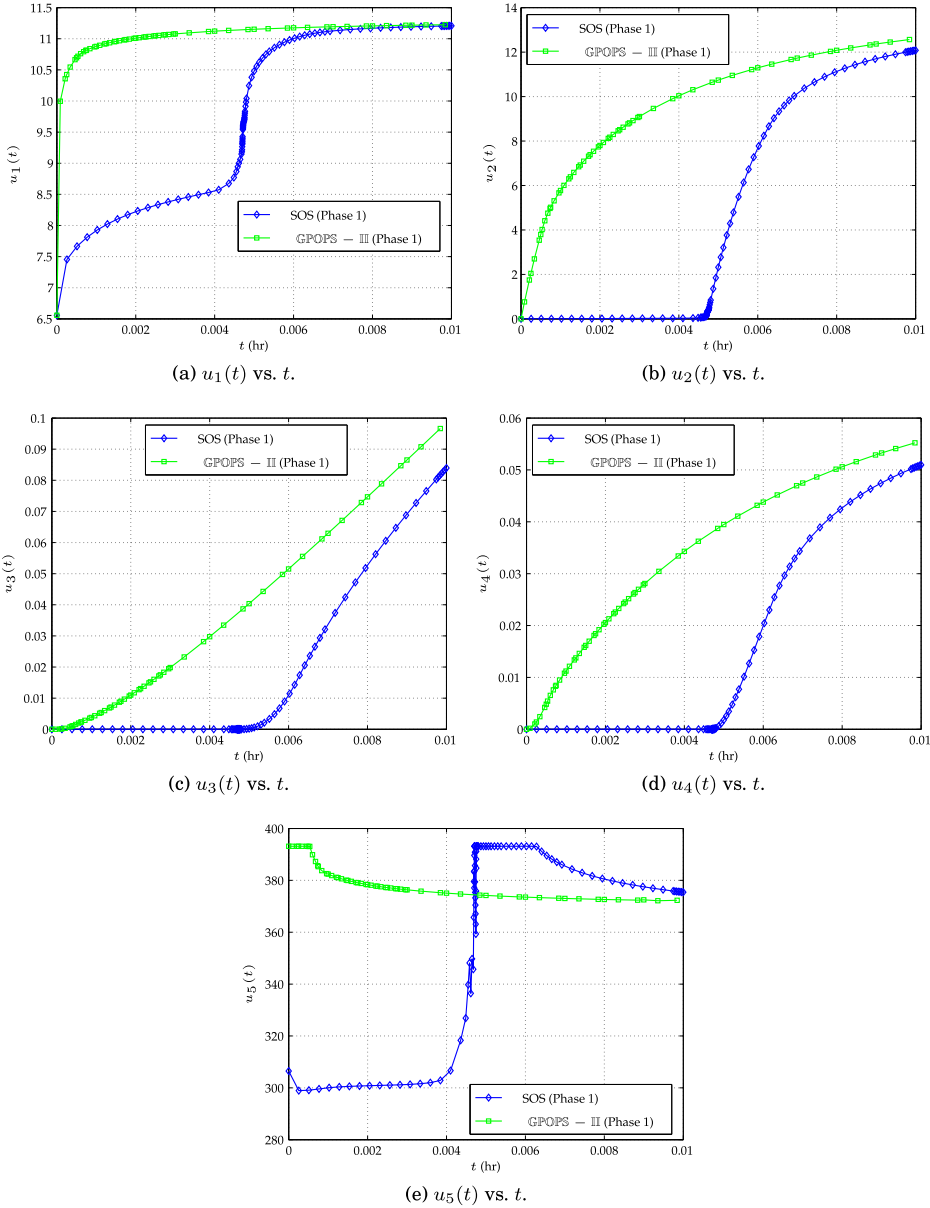

Fig. 17. Phase 1 control solution to kinetic batch reactor optimal control problem using GPOPS – III alongside solution obtained using optimal control software Sparse Optimization Suite.

is is found verbatim in Benson [2004], Rao et al. [2010], and Betts [2010]. The problem is modeled using four phases where the objective is to maximize the mass at the end of the fourth phase, that is maximize

$$J = m(t_f^{(4)}) \tag{82}$$

subject to the dynamic constraints

$$\begin{aligned}\dot{\mathbf{r}}^{(p)} &= \mathbf{v}^{(p)}, \\ \dot{\mathbf{v}}^{(p)} &= -\frac{\mu}{\|\mathbf{r}^{(p)}\|^3}\mathbf{r}^{(p)} + \frac{T^{(p)}}{m^{(p)}}\mathbf{u}^{(p)} + \frac{\mathbf{D}^{(p)}}{m^{(p)}}, \quad (p = 1, \dots, 4), \\ \dot{m}^{(p)} &= -\frac{T^{(p)}}{g_0 I_{sp}},\end{aligned}\quad (83)$$

the initial conditions

$$\begin{aligned}\mathbf{r}(t_0) &= \mathbf{r}_0 = (5605.2, 0, 3043.4) \times 10^3 \text{ m}, \\ \mathbf{v}(t_0) &= \mathbf{v}_0 = (0, 0.4076, 0) \times 10^3 \text{ m/s}, \\ m(t_0) &= m_0 = 301454 \text{ kg}.\end{aligned}\quad (84)$$

the interior point constraints

$$\begin{aligned}\mathbf{r}^{(p)}(t_f^{(p)}) - \mathbf{r}^{(p+1)}(t_0^{(p+1)}) &= \mathbf{0}, \\ \mathbf{v}^{(p)}(t_f^{(p)}) - \mathbf{v}^{(p+1)}(t_0^{(p+1)}) &= \mathbf{0}, \quad (p = 1, \dots, 3) \\ m^{(p)}(t_f^{(p)}) - m_{\text{dry}}^{(p)} - m^{(p+1)}(t_0^{(p+1)}) &= 0,\end{aligned}\quad (85)$$

the terminal constraints (corresponding to a geosynchronous transfer orbit),

$$\begin{aligned}\alpha(t_f^{(4)}) &= \alpha_f = 24361.14 \text{ km}, & e(t_f^{(4)}) &= e_f = 0.7308, \\ i(t_f^{(4)}) &= i_f = 28.5 \text{ deg}, & \theta(t_f^{(4)}) &= \theta_f = 269.8 \text{ deg}, \\ \phi(t_f^{(4)}) &= \phi_f = 130.5 \text{ deg},\end{aligned}\quad (86)$$

and the path constraints

$$\begin{aligned}\|\mathbf{r}^{(p)}\|_2^2 &\geq R_e, \\ \|\mathbf{u}^{(p)}\|_2^2 &= 1, \quad (p = 1, \dots, 4).\end{aligned}\quad (87)$$

In each phase; $\mathbf{r}(t) = (x(t), y(t), z(t))$ is the position relative to the center of the Earth expressed in ECI coordinates, $\mathbf{v} = (v_x(t), v_y(t), v_z(t))$ is the inertial velocity expressed in ECI coordinates, μ is the gravitational parameter, T is the vacuum thrust, m is the mass, g_0 is the acceleration due to gravity at sea level, I_{sp} is the specific impulse of the engine, $\mathbf{u} = (u_x, u_y, u_z)$ is the thrust direction expressed in ECI coordinates, and $\mathbf{D} = (D_x, D_y, D_z)$ is the drag force expressed ECI coordinates. The drag force is defined as

$$\mathbf{D} = -\frac{1}{2}C_D S \rho \|\mathbf{v}_{\text{rel}}\| \mathbf{v}_{\text{rel}}, \quad (88)$$

where C_D is the drag coefficient, S is the vehicle reference area, $\rho = \rho_0 \exp(-h/H)$ is the atmospheric density, ρ_0 is the sea level density, $h = r - R_e$ is the altitude, $r = \|\mathbf{r}\|_2 = \sqrt{x^2 + y^2 + z^2}$ is the geocentric radius, R_e is the equatorial radius of the Earth, H is the density scale height, and $\mathbf{v}_{\text{rel}} = \mathbf{v} - \boldsymbol{\omega} \times \mathbf{r}$ is the velocity as viewed by an observer fixed to the Earth expressed in ECI coordinates, and $\boldsymbol{\omega} = (0, 0, \Omega)$ is the angular velocity of the Earth as viewed by an observer in the inertial reference frame expressed in ECI coordinates. Furthermore, m_{dry} is the dry mass of phases 1, 2, and 3 and is defined $m_{\text{dry}} = m_{\text{tot}} - m_{\text{prop}}$, where m_{tot} and m_{prop} are, respectively, the total mass and dry mass of phases 1, 2, and 3. Finally, the quantities a , e , i , θ , and ϕ are, respectively, the semi-major axis, eccentricity, inclination, longitude of ascending node, and argument

Table III. Vehicle Properties for Multiple-Stage Launch Vehicle Ascent Problem

Quantity	Solid Boosters	Stage 1	Stage 2
m_{tot} (kg)	19290	104380	19300

μ	$3.986012 \times 10^{14} \text{ m}^3/\text{s}^2$
g_0	9.80665 m/s^2

of periapsis, respectively. The vehicle data for this problem and the numerical values for the physical constants can be found in Tables III and IV, respectively.

The multiple-stage launch vehicle ascent optimal control problem was solved using GPOPS – III with the NLP solver SNOPT and an initial mesh in each phase consisting of ten uniformly spaced mesh intervals with four LGR points per mesh interval, and the following initial guess:

$$\begin{aligned}
\mathbf{r}^{(1)} &= \mathbf{r}^{(0)}, & \mathbf{r}^{(2)} &= \mathbf{r}^{(0)}, \\
\mathbf{v}^{(1)} &= \mathbf{v}^{(0)}, & \mathbf{v}^{(2)} &= \mathbf{v}^{(0)}, \\
m^{(1)} &= \mathbf{linear}(t_0^{(1)}, t_f^{(1)}, 3.01454, 1.71863) \times 10^5 \text{ kg}, & m^{(2)} &= \mathbf{linear}(t_0^{(2)}, t_f^{(2)}, 1.58184, 0.796238) \times 10^5 \text{ kg}, \\
\mathbf{u}^{(1)} &= (0, 1, 0), & \mathbf{u}^{(2)} &= (0, 1, 0), \\
t_0^{(1)} &= 0, & t_0^{(2)} &= 75.2 \text{ s}, \\
t_f^{(1)} &= 75.2 \text{ s}, & t_f^{(2)} &= 150.4 \text{ s}, \\
\\
\mathbf{r}^{(3)} &= \bar{\mathbf{r}}, & \mathbf{r}^{(4)} &= \bar{\mathbf{r}}, \\
\mathbf{v}^{(3)} &= \bar{\mathbf{v}}, & \mathbf{v}^{(4)} &= \bar{\mathbf{v}}, \\
m^{(3)} &= \mathbf{linear}(t_0^{(3)}, t_f^{(3)}, 7.27838, 3.22940) \times 10^4 \text{ kg}, & m^{(4)} &= \mathbf{linear}(t_0^{(4)}, t_f^{(4)}, 2.34640, 0.41640) \times 10^4 \text{ kg}, \\
\mathbf{u}^{(3)} &= (0, 1, 0), & \mathbf{u}^{(4)} &= (0, 1, 0), \\
t_0^{(3)} &= 150.4 \text{ s}, & t_0^{(4)} &= 261 \text{ s}, \\
t_f^{(3)} &= 261 \text{ s}, & t_f^{(4)} &= 961 \text{ s},
\end{aligned}$$

where $(\bar{\mathbf{r}}, \bar{\mathbf{v}})$ are obtained from a conversion of the orbital elements $(a, e, i, \theta, \phi, \nu) = (a_f, e_f, i_f, \theta_f, \phi_f, 0)$ to ECI Cartesian coordinates [Bate et al. 1971] and ν is the true anomaly. The GPOPS – III solution is shown in Figure 18. In this example the mesh refinement accuracy tolerance of 10^{-6} is satisfied on the initial mesh and, thus, no mesh

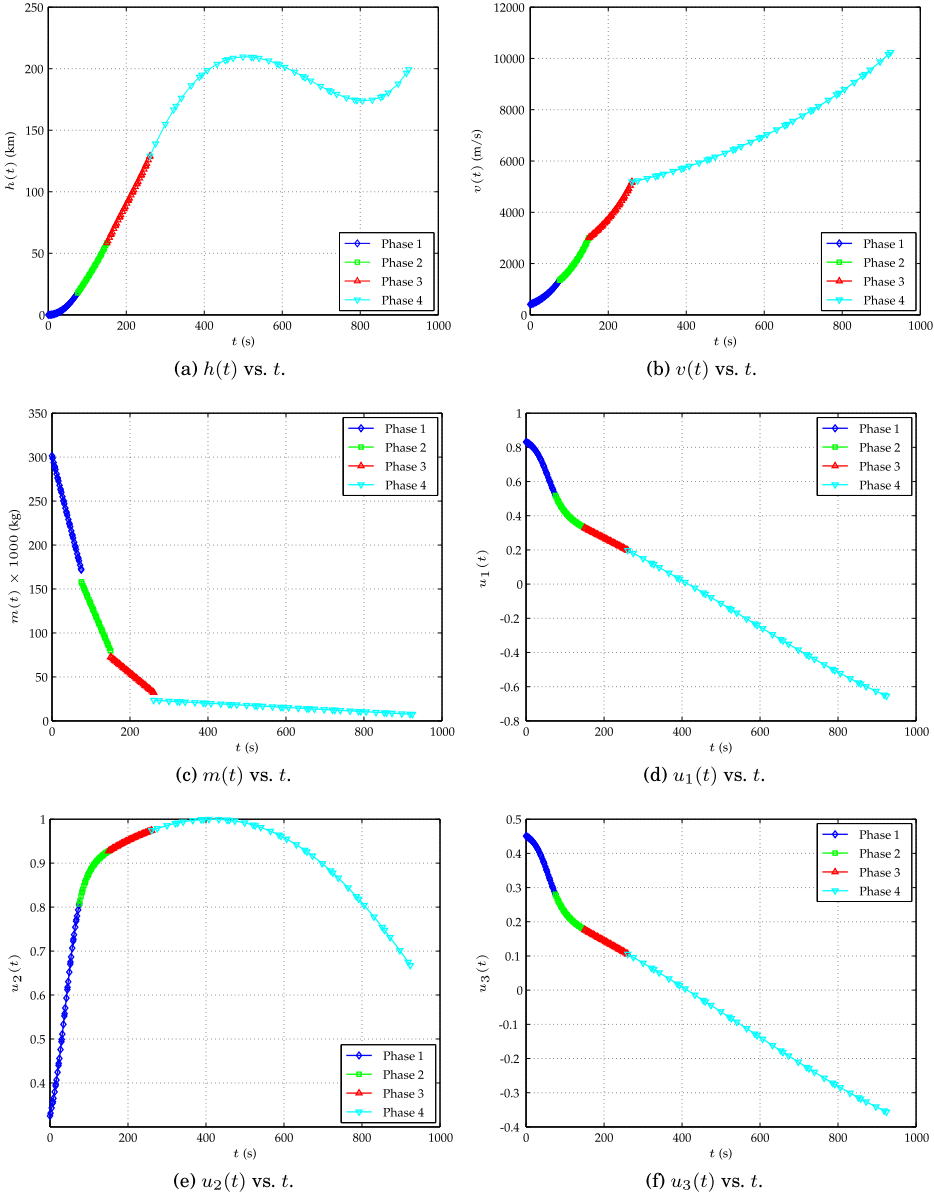

Fig. 18. Solution of multiple-stage launch vehicle ascent problem using GPOPS – III.

refinement is performed. The solution obtained using GPOPS – III matches closely with the solution obtained using the software SOCS [Betts 2010], where it is noted that the optimal objective values obtained using GPOPS – III and SOCS are -7529.712680 and -7529.712412 , respectively.

6. CAPABILITIES OF GPOPS – III

The five examples provide in Section 5 highlight the capability of GPOPS – III to solve a wide variety of problems. First, the hypersensitive example shows the capability of

the ph mesh refinement method in increasing the number of mesh intervals and collocation points in regions where the dynamics are changing more rapidly, while the reusable launch vehicle entry example demonstrates the ability of the ph mesh refinement method to keep the number of collocation points much smaller than might be possible using a fixed low-order collocation method. Second, the space station attitude control and kinetic batch reactor examples demonstrate the flexibility of the software to achieve better performance on an application by modifying the default settings. Third, the launch vehicle ascent problem shows that GPOPS – III has been designed with the ability to employ different NLP solvers. The different examples also demonstrate the wide variety of problems that can be formulated in GPOPS – III. Such problems range from one-phase problems with a Lagrange cost (for example, the hypersensitive and space station attitude control examples), Mayer cost (e.g., the reusable launch vehicle entry and launch vehicle ascent examples), and problems that include static parameters (e.g., the kinetic batch reactor example). Moreover, it was shown that GPOPS – III has the ability to solve challenging multiple-phase problems (e.g., the kinetic batch reactor example). The fact that GPOPS – III is capable of solving the challenging benchmark optimal control problems shown in this article shows the general utility of the software on problems that may arise in different application areas.

7. LIMITATIONS OF GPOPS – III

Like all software, GPOPS – III has limitations. First, it is assumed in the implementation that all functions have continuous first and second derivatives. In some applications, however, the functions themselves may be continuous while the derivatives may be discontinuous. In such problems, GPOPS – III may struggle because the NLP solver is not being provided with accurate approximations to the derivative functions. Furthermore, the ability of any given NLP solver to obtain a solution is always problem dependent. As a result, for some examples, it may be the case that IPOPT will perform better than SNOPT, but in some cases SNOPT may significantly outperform IPOPT (the launch vehicle ascent problem is an example where SNOPT outperforms IPOPT with GPOPS – III). Also, problems with high-index path constraints may result in the constraint qualification conditions not being satisfied on fine meshes. In such cases, unique NLP Lagrange multipliers may not exist. In some cases, these Lagrange multipliers may become unbounded. Finally, as is true for many optimal control software programs, applications whose solutions lie on a singular arc can create problems due to the inability to determine the optimal control along the singular arc. In such cases highly inaccurate solution may be obtained in the region near the singular arc, and mesh refinement may only exacerbate these inaccuracies. The approach for problems whose solutions lie on a singular arc is to modify the problem by including the conditions that define the singular arc (thus removing the singularity).

8. CONCLUSIONS

A general-purpose MATLAB software program called GPOPS – III has been described for solving multiple-phase optimal control problems using variable-order Gaussian quadrature methods. In particular, the software employs a Legendre-Gauss-Radau quadrature orthogonal collocation where the continuous-time control problem is transcribed to a large sparse nonlinear programming problem. The software implements two previously developed adaptive mesh refinement methods that allow for flexibility in the number and placement of the collocation and mesh points in order to achieve a specified accuracy. In addition, the software is designed to compute all derivatives required by the NLP solver using sparse finite-differencing of the optimal control functions. The key components of the software have been described in detail and the utility of the software is demonstrated on five benchmark optimal control problems. The

software described in this article provides researchers a useful platform upon which to solve a wide variety of complex constrained optimal control problems.
