#### Abstract

In this paper, graph multiset transformation is introduced and studied as a novel type of parallel graph transformation. The basic idea is that graph transformation rules may be applied to all or at least some members of a multiset of graphs simultaneously providing a computational step with the possibility of massive parallelism in this way. As a consequence, graph problems in the class $N P$ can be solved by a single computation of polynomial length for each input graph.

Keywords Graph multiset transformation • DNA computing • Transformation units • NP problems • Massive parallelism

## 1 Introduction

In this paper, a new type of graph transformation, called graph multiset transformation, is introduced that is inspired by the concepts of genetic algorithms and DNA computing (see, e.g., Adleman 1994; Fogel 2006; Goldberg 2002; Holland 1975; Păun et al. 1998). Adleman's seminal experiment demonstrates how combinatorial problems may be solved using DNA. Roughly speaking, a tube is filled with certain quantities of properly chosen DNA strands. Then their reactions according to the Watson-Crick complementarity produces DNA molecules, a suitable selection of which represents solutions. Similarly, a genetic algorithm transforms a "population of individuals" step by step into one of "fitter" individuals by means of "mutation," "cross-over," and "selection." If, for example, the individuals are solutions of an optimization problem that differ from the optimum, then the genetic algorithm may yield solutions that are closer to the optimum or even meet it. If one replaces tubes of molecules and populations of individuals by multisets of graphs and

[^0]chemical reactions and genetic operations by rule applications, one gets the concept of graph multiset transformation.

The basic idea is that graph transformation rules may be applied to all or at least some members of a multiset of graphs simultaneously providing a computational step with the possibility of massive parallelism in this way. As a consequence, graph problems in the class $N P$ can be solved by a single computation of polynomial length for each input graph.

The paper is organized in the following way. The next section provides the preliminaries concerning graphs and rule-based graph transformation. In Sect. 3, simple graph transformation units are recalled as devices to model and compute graph algorithms and processes. Section 4 introduces a way to solve decision problems on graphs by means of terminating units. In particular, a graph-transformational variant of the class $N P$ is defined. Based on simple and terminating units, graph multiset transformation is proposed as a computational framework with massive parallelism in Sects. 5 and 7. As a consequence, $N P$-problems can be solved in a polynomial number of computational steps. In Sect. 6, we simulate Adleman's experiment by means of graph multiset transformation. The Appendix recalls multisets together with some basic definitions used in this paper. Throughout the paper, the well-known $N P$-complete Hamiltonian path problem is discussed as a running example. It may be noted that the basic ideas of graph multiset transformation have been sketched in Kreowski (2002) in a draft way and that a short and less complete version of this paper appeared in Kreowski and Kuske (2008) without proofs.

## 2 Graphs and rule-based graph transformation

In this section, we recall the basic notions and notations of graphs and rule-based graph transformation as far as they are needed in this paper. We use directed and edge-labeled graphs with binary edges.

Let $\Sigma$ be a set of labels. A graph over $\Sigma$ is a system $G=(V, E, s, t, l)$ where $V$ is a finite set of nodes, $E$ is a finite set of edges, s,t:E $\rightarrow V$ are mappings assigning a source $s(e)$ and a target $t(e)$ to every edge in $E$, and $l: E \rightarrow \Sigma$ is a mapping assigning a label to every edge in $E$. An edge $e$ with $s(e)=t(e)$ is called a loop. The components $V, E, s, t$, and $l$ of $G$ are also denoted by $V_{G}, E_{G}, s_{G}, t_{G}$, and $l_{G}$, respectively. The set of all graphs over $\Sigma$ is denoted by $\mathcal{G}_{\Sigma}$. We reserve a specific label $*$ which is omitted in drawings of graphs. In this way, graphs where all edges are labeled with $*$ may be seen as unlabeled graphs. The sum of the number of nodes and the number of edges is the size of $G$, denoted by size $(G)$.

For graphs $G, H \in \mathcal{G}_{\Sigma}$, a graph morphism $g: G \rightarrow H$ is a pair of mappings $g_{V}: V_{G} \rightarrow V_{H}$ and $g_{E}: E_{G} \rightarrow E_{H}$ that are structure-preserving, i.e., $g_{V}\left(s_{G}(e)\right)=s_{H}\left(g_{E}(e)\right), \quad g_{V}\left(t_{G}(e)\right)=$ $t_{H}\left(g_{E}(e)\right)$, and $l_{H}\left(g_{E}(e)\right)=l_{G}(e)$ for all $e \in E_{G}$. If the mappings $g_{V}$ and $g_{E}$ are bijective, then $g$ is an isomorphism, and $G$ and $H$ are called isomorphic. If the mappings $g_{V}$ and $g_{E}$ are inclusions, then $G$ is called a subgraph of $H$, denoted by $G \subseteq H$. For a graph morphism $g: G \rightarrow H$, the image $g(G) \subseteq H$ of $G$ in $H$ is called a match of $G$ in $H$.

Example 1 The graph $G_{0}$ in Fig. 1 has four Hamiltonian paths which are represented by the graphs $H_{1}, H_{2}, H_{3}$, and $H_{4} .{ }^{1}$ A box $\square$ represents a node with an unlabeled loop. Therefore, $G_{0}$ has four nodes, four loops and five additional unlabeled edges. The other graphs are variants of $G_{0}$. We use $\odot$ to represent a begin-node which is a node with a loop labeled with begin. Analogously, O represents an end-node. If one starts in the begin-node and follows the $p$-labeled edges, one reaches the end-node in the graphs $H_{1}, H_{2}, H_{3}$, and

[^1]

Fig. $1 G_{0}$ with all its Hamiltonian paths

Fig. 2 Two graphs with a common subgraph

$H_{4}$. In each case, the sequence of $p$-edges defines a Hamiltonian path of $G_{0}$, where the intermediate nodes have no loops.

If one removes the right vertical edge and the loops at the source and the target of this edge in the graph $G_{12}$ in Fig. 2, then one gets the subgraph $Z_{0}$. One may extend the graph $Z_{0}$ by a $p$-edge and an end-loop to get $G_{123}$.

There are two graph morphisms from the graph $L_{r u n}=0 \longrightarrow \square$ into $G_{12}$ which map to the subgraphs of the same form. The construction in Fig. 2 is an example of a rule application in the following sense.

A rule $r=(L \supseteq K \subseteq R)$ consists of three graphs $L, K, R \in \mathcal{G}_{\Sigma}$ such that $K$ is a subgraph of $L$ and $R$. The components $L, K$, and $R$ of $r$ are called left-hand side, gluing graph, and righthand side, respectively. The application of $r=(L \supseteq K \subseteq R)$ to a graph $G=(V, E, s, t, l)$ yields a directly derived graph $H$ and consists of the following three steps.

1. A match $g(L)$ of $L$ in $G$ is chosen subject to the following conditions.

- dangling condition: $v \in g_{V}\left(V_{L}\right)$ with $s_{G}(e)=v$ or $t_{G}(e)=v$ for some $e \in E_{G}-g_{E}\left(E_{L}\right)$ implies $v \in g_{V}\left(V_{K}\right)$.
- identification condition: $g_{V}(v)=g_{V}\left(v^{\prime}\right)$ for $v, v^{\prime} \in V_{L}$ implies $v=v^{\prime}$ or $v, v^{\prime} \in V_{K}$ as well as $g_{E}(e)=g_{E}\left(e^{\prime}\right)$ for $e, e^{\prime} \in E_{L}$ implies $e=e^{\prime}$ or $e, e^{\prime} \in E_{K}$.

2. Now the nodes of $g_{V}\left(V_{L}-V_{K}\right)$ and the edges of $g_{E}\left(E_{L}-E_{K}\right)$ are removed yielding the intermediate graph $Z \subseteq G$.
3. Let $d: K \rightarrow Z$ be the restriction of $g$ to $K$ and $Z$. Then $H$ is constructed as the disjoint union of $Z$ and $R-K$ where all edges $e \in E_{Z}+\left(E_{R}-E_{K}\right)$ keep their labels and their sources and targets except for $s_{R}(e)=v \in V_{K}$ or $t_{R}(e)=v \in V_{K}$ which is replaced by $d_{V}(v)$.

The application of a rule $r$ to a graph $G$ is denoted by $G \Longrightarrow H$, and called a direct derivation. The subscript $r$ may be omitted if it is clear from the context.

The dangling condition requires that nodes to be removed are only incident to edges to be removed, and guarantees that the removal of $L-K$ from $G$ yields a graph and that the restriction $d$ of $g$ to $K$ and $Z$ is a graph morphism. One possibility to construct the disjoint union of $Z$ and $R-K$ is to rename $R-K$ to $h(R-K)$ such that $Z \cap h(R-K)=\emptyset$ and, therefore, their union is a disjoint one. In this case, we have $Z \subseteq H$, and the renaming can be extended to a graph morphism $h: R \rightarrow H$ by defining $h$ on $K$ by $d$. The identification condition concerns the match only and makes sure that $G$ can be constructed from $d: K \rightarrow Z$ and $R-K$ as $H$ from $d$ and $L-K$. These constructions are known as so-called pushouts so that, altogether, a direct derivation is given by a double pushout (cf. Fig. 3).

As the pushouts and hence the rule applications are only unique up to isomorphism, it makes sense to assume from now on that $\mathcal{G}_{\Sigma}$ contains the corresponding equivalence

Fig. 3 Diagram of a double pushout

classes of graphs and, in this way, abstract graphs rather than concrete ones. However, each concrete graph is a meaningful representative of its class so that we can go on to deal with graphs in a concrete way.

The sequential composition of direct derivations $d=G_{0} \underset{r_{1}}{\Longrightarrow} G_{1} \underset{r_{2}}{\Longrightarrow} \cdots \underset{r_{n}}{\Longrightarrow} G_{n}(n \in \mathbb{N})$ is called a derivation from $G_{0}$ to $G_{n}$. As usual, the derivation from $G_{0}$ to $G_{n}$ can also be denoted by $G_{0} \xlongequal[P]{n} G_{n}$ where $\left\{r_{1}, \ldots, r_{n}\right\} \subseteq P$, or just by $G_{0} \xlongequal[P]{*} G_{n}$. The subscript $P$ may be omitted if it is clear from the context. The string $r_{1}, \ldots, r_{n}$ is the application sequence of the derivation $d$.

Example 2 Consider the following two rules

$$
\begin{aligned}
& \text { start }=\square \supseteq \bigcirc \bigcirc \\
& \text { run }=0 \longrightarrow \square \supseteq \bullet \bullet \subseteq{ }^{p} \longrightarrow
\end{aligned}
$$

The rule start describes the removal of an unlabeled loop and the addition of a begin-loop and an end-loop at the same node, which is depicted by ©. The rule run replaces an unlabeled edge by a $p$-edge removing the two loops of the left-hand side and adding an end-loop at the target node of the right-hand side.

Figure 4 shows all derivations that start in the graph $G_{0}$ in Fig. 1 and apply the rule start only once in the beginning (while the rule run is applied repeatedly afterwards). At first,

Fig. 4 The derivations starting in $G_{0}$ with one application of start
the rule start can be applied to $G_{0}$ in four ways deriving the four graphs in the second column from the left of Fig. 4. The graphs in the right-most column of Fig. 4 are $H_{1}, H_{2}, H_{3}$, and $H_{4}$ representing the Hamiltonian paths of $G_{0}$. They are characterized by the property that they do not contain any unlabeled loop.

It is not difficult to prove that the Hamiltonian paths of every unlabeled graph (with a single loop at each node) can be generated in the same way: Apply the rule start once and then the rule run repeatedly. A path in a derived graph is Hamiltonian if and only if the graph has no unlabeled loop left.

Given a finite set of rules and a graph $G$, the number of matches is bounded by a polynomial in the size of $G$ because the sizes of left-hand sides of rules are bounded by a constant. Given a match, the check, whether the dangling and the identification condition hold, and the construction of the directly derived graph is linear in the size of $G$. Therefore, polynomial time is needed to find a match and to construct a direct derivation, and there is a polynomial number of choices at most. Moreover, the size of the resulting graph differs from the size of the host graph by a constant.

## 3 Simple graph transformation units

A rule yields a binary relation on graphs and a set of rules a set of derivations. The example of Hamiltonian paths shows (like many other examples would show) that more features are needed to model algorithms and processes on graphs in a proper way. In particular one needs initial graphs to start the derivation process and terminal graphs to stop it. Initial and terminal graphs may be specified by graph class expressions. Moreover, further control conditions may be helpful to regulate the derivation process. The notion of simple graph transformation units encompasses all these features to model and compute relations between initial and terminal graphs by means of regulated derivations.

### 3.1 Graph class expressions

A graph class expression may be any syntactic entity $X$ that specifies a class of graphs $\operatorname{SEM}(X) \subseteq \mathcal{G}_{\Sigma}$. A typical example is a subset $\Delta \subseteq \Sigma$ with $\operatorname{SEM}(\Delta)=\mathcal{G}_{\Delta} \subseteq \mathcal{G}_{\Sigma}$. Requested, forbidden, and reduced structures are also frequently used. Let $F$ be a graph. Then SEM (requested $(F)$ ) consists of all graphs $G$ containing a subgraph that is isomorphic to $F$. And $\operatorname{SEM}($ forbidden $(F)$ ) consists of all graphs $G$ such that there is no subgraph in $G$ that is isomorphic to $F$. Another useful type of graph class expressions is given by sets of rules $P$ where $\operatorname{SEM}(\operatorname{reduced}(P))$ contains all $P$-reduced graphs, i.e., graphs to which none of the rules in $P$ can be applied. In the examples, we use the constant expression unlabeled graphs denoting the set of unlabeled graphs each node of which is equipped with a single unlabeled loop.

### 3.2 Control conditions

A control condition is any syntactic entity that cuts down the non-determinism of the derivation process. A typical example is a regular expression over a set of rules (or any other string-language-defining device). Let $C$ be a regular expression specifying the language $L(C)$. Then a derivation with application sequence $s$ is permitted by $C$ if $s \in L(C)$. In the following, we consider no other control conditions.

### 3.3 Simple graph transformation units

A simple graph transformation unit is a system $t u=(I, P, C, T)$, where $I$ and $T$ are graph class expressions to specify the initial and the terminal graphs respectively, $P$ is a finite set of rules, and $C$ is a control condition.

Each such transformation unit $t u$ specifies a binary relation

$$
\operatorname{SEM}(t u) \subseteq \operatorname{SEM}(I) \times \operatorname{SEM}(T)
$$

that contains a pair $(G, H)$ of graphs if and only if there is a derivation $G \underset{P}{*} H$ permitted by $C$.

Example 3 The considerations in Examples 1 and 2 can be summarized by the following simple graph transformation unit:

```
HP
    initial : unlabeled graphs
    rules : start, run
    control : start; run*
    terminal : forbidden(\square)
```

The initial graphs are unlabeled graphs with a single unlabeled loop at each node. The rules start and run are given in Example 2, and the control condition is a regular expression over the set of rules with the sequential composition ; and the Kleene star $*$ (specifying that a single application of start can be followed by an arbitrary sequence of applications of run). Graphs derived in this way from initial graphs are accepted as terminal if they do not contain any unlabeled loop.

In Fig. 4, the initial graph is semantically related to the four terminal graphs-the rightmost ones. They represent the four Hamiltonian cycles of the initial graph. All other derived graphs contain some forbidden loop.

### 3.4 Computation and complexity

Using the effective construction of direct derivations, the relation $S E M(t u)$ of a transformation unit $t u=(I, P, C, T)$ is recursively enumerable if $S E M(I)$ is recursively enumerable and $\operatorname{SEM}(T)$ and the control condition are decidable. SEM(tu) can be computed as follows:

- Enumerate the graphs of $\operatorname{SEM}(I)$.
- For each $G \in S E M(I)$, enumerate all derivations starting in $G$ together with their application sequences.
- For each derived graph $\bar{G}$, check whether $\bar{G} \in \operatorname{SEM}(T)$.
- If yes, check whether the respective application sequence belongs to $L(C)$.
- If yes, put $(G, \bar{G})$ into $\operatorname{SEM}(t u)$.

The assumptions apply to all graph class expressions and control conditions that are explicitly introduced above.

The time to check whether a graph $G$ belongs to SEM(unlabeled graphs), $\operatorname{SEM}($ forbidden $(F))$ or SEM(reduced $(P))$ is polynomial in the size of $G$. If $G \stackrel{k}{\Longrightarrow} H$ and $k$ is bounded by a polynomial in the size of $G$, then the size of $H$ is also
bounded by a polynomial in the size of $G$. Therefore, to check whether $H$ belongs to the graph $\operatorname{SEM}(\operatorname{forbidden}(F))$ or $\operatorname{SEM}(\operatorname{reduced}(P))$ takes also time that is polynomial in the size of $G$. Finally, the construction of the application sequence can be done together with the derivation without extra effort and its length coincides with the length of the derivation. The membership problem of regular expressions is linear in this length so that it is polynomial in the size of $G$.

The notion of a transformation unit has been introduced in Kreowski and Kuske (1999a, b) and in Kreowski et al. (1997) as a modeling and structuring concept for graph transformation systems. Here the structuring component is omitted and the computational aspect is emphasized. In addition to the cited papers, one can find more about graph class expressions and control conditions in Kuske (2000a, b). Habel and Plump (2001) have shown that a similar kind of graph transformation approach is computationally complete.

## 4 Solving decision problems

A simple graph transformation unit is terminating if, for every initial graph, the number of derivations starting in this graph is finite. In this case, all these derivations can be constructed effectively, and it can be checked whether any of them is permitted by the control condition and derives a terminal graph. This means that a terminating unit can be re-interpreted as a solution of a decision problem on the initial graphs. If the lengths of derivations are bounded by a polynomial in addition, one gets a graph-transformational variant of the class $N P$ of decision problems with nondeterministic polynomial solutions.

Definition 1 Let $t u=(I, P, C, T)$ be a transformation unit. tu is terminating if, for each initial graph $G \in S E M(I)$, there is an upper bound $b(G) \in \mathbb{N}$ such that $n \leq b(G)$ for each derivation $G \underset{P}{n} G^{\prime}$. The function $b: S E M(I) \longrightarrow \mathbb{N}$ given in this way is called termination bound.

A well-known sufficient condition for termination can be used in the framework of graph transformation units.

Observation 2 Let $t u=(I, P, C, T)$ be a transformation unit. Let val $: \mathcal{G}_{\Sigma} \longrightarrow \mathbb{N}$ be a valuation function with $\operatorname{val}\left(G^{\prime}\right)>\operatorname{val}\left(G^{\prime \prime}\right)$ for each direct derivation $G^{\prime} \underset{P}{\longrightarrow} G^{\prime \prime}$. Then $t u$ is terminating.

Proof Consider a derivation $G_{0} \underset{P}{\Longrightarrow} G_{1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow} G_{n}$ with $G_{0} \in \operatorname{SEM(I)\text {.Duetothe}}$ property of val, this yields $\operatorname{val}\left(G_{0}\right)>\operatorname{val}\left(G_{1}\right)>\cdots>\operatorname{val}\left(G_{n}\right)$ and, therefore, $n \leq \operatorname{val}\left(G_{0}\right)$. In other words, val is a termination bound for $t u$.

Definition 3 Let $t u=(I, P, C, T)$ be a terminating transformation unit with the termination bound $b: \operatorname{SEM}(I) \rightarrow \mathbb{N}$.

1. A function $D: S E M(I) \rightarrow\{$ TRUE, FALSE $\}$ is called a decision problem.
2. tu solves $D$ if the following holds for all $G \in \operatorname{SEM}(I)$ :

$$
D(G)=\operatorname{true} \text { if and only if }(G, \bar{G}) \in S E M(t u) \text { for some } \bar{G} \in S E M(T) .
$$

This is denoted by $\operatorname{COMP}(t u)=D$.
3. $t u$ is called polynomial if there is a polynomial $p$ such that, for all $G \in \operatorname{SEM}(I), b(G) \leq p(\operatorname{size}(G))$ and the membership problems of $\operatorname{SEM}(I)$ as well as of $\operatorname{SEM}(T)$ are polynomial.
4. The class of all decision problems that are solved by polynomial transformation units is denoted by $N P_{G T}$.

## Remarks

1. If $t u$ is terminating, there is only a finite number of derivations $G \underset{P}{*} G^{\prime}$ for each $G \in \operatorname{SEM}(I)$. Hence, it can be checked effectively whether a terminal graph is derived by a permitted derivation or not.
2. The computational framework given by terminating and polynomial transformation units in particular is still nondeterministic because there may be a derivation $G \stackrel{*}{P} G^{\prime}$ with $G^{\prime} \in \operatorname{SEM}(\operatorname{reduced}(P))$, but $G^{\prime} \notin \operatorname{SEM}(T)$, and also a permitted derivation $G \underset{P}{*} \bar{G}$ with $\bar{G} \in S E M(T)$. In the polynomial case, it takes polynomial time to build up a single derivation and to check whether its derived graph is terminal or not (cf. 3.4). Both points together justify the denotation $N P_{G T}$.

The same reasoning shows that a decision problem $D: S E M(I) \rightarrow\{$ TRUE, FALSE $\}$ which is solved by a polynomial transformation unit belongs to the class of $N P$-problems if one chooses a proper string representation of graphs. Also the converse inclusion holds because one can simulate the computational steps of a Turing machine by the application of graph transformation rules. This consideration yields the following result.

Observation $4 \quad N P_{G T}=N P$.
Proof Let $D \in N P_{G T}$ and $t u$ be a polynomial transformation unit solving $D$. Then each derivation has polynomial length, each step is constructed in polynomial time, and the number of choices per step is polynomially bounded. Moreover, the membership problem of $\operatorname{SEM}(I), \operatorname{SEM}(T)$ and of $L(C)$ is decidable in polynomial time. All facts remain true if one chooses proper string representations of the initial graphs like the sequences of nodes, edges, sources, and targets. This yields $D \in N P$.

Conversely, let $D \in N P$ and $T M=\left(Z, I, d, s_{0}, F\right)$ with $d \subseteq Z \times(I \cup\{\square\}) \times$ $Z \times(I \cup\{\square\}) \times\{n, l, r\}$ be a Turing machine that solves $D$ in a polynomial number of steps. Then $T M$ is simulated by the transformation unit $t u(T M)=(\operatorname{init}(T M), P(T M)$, free, terminal $(T M)$ ) the components of which are defined as follows.

1. The graph class expression $\operatorname{init}(T M)$ describes the class of graphs each member of which is a disjoint union of the two graphs $G\left(T M, s_{0}\right)$ and $w^{\bullet}$ for some $w \in I^{*}$. The graph $G\left(T M, s_{0}\right)$ is the state graph of $T M$ with $s_{0}$ as current state:

$$
G\left(T M, s_{0}\right)=\left(Z, d \cup\left\{s_{0}, c u r r\right\} \cup F, s, t, l\right)
$$

with $\left.\quad s\right|_{d}=\operatorname{proj}_{1},\left.t\right|_{d}=\operatorname{proj}_{3},\left.l\right|_{d}=\left\langle\right.$ proj$\left._{2}, \operatorname{proj}_{4}, \operatorname{proj}_{5}\right\rangle, s\left(s_{0}\right)=t\left(s_{0}\right)=s_{0}=s(c u r r)=$ $t($ curr $), s\left(s^{\prime \prime}\right)=t\left(s^{\prime \prime}\right)=s^{\prime \prime}$ for all $s^{\prime \prime} \in F$, and $l\left(s_{0}\right)=$ init, $l(c u r r)=c u r r$, and $l\left(s^{\prime \prime}\right)=$ fin for all $s^{\prime \prime} \in F$. This means that each state transition $\left(s, x, s^{\prime}, y, m\right)$ is represented by an edge with source $s$, target $s^{\prime}$ and $(x, y, m)$ as label. Moreover, there are some loops indicating the initial state, the current state being initially the initial one, and the terminal states. The graph $w^{\bullet}$ for $w=a_{1} \ldots a_{n} \in I^{*}$ represents the Turing band inscribed initially with $w \neq \lambda$. Moreover, there are two loops indicating the left end and the right end of the band, and there is a further edge that plays the role of the read/write-head:

$$
w^{\bullet}=\left(\{0\} \cup[n],[n] \cup\{ \}, s^{\bullet}, t^{\bullet}, l^{\bullet}\right)
$$

Fig. 5 The rules of $t u(T M)$
with

$$
\begin{aligned}
& -s^{\bullet}(i)=i-1, t^{\bullet}(i)=i \text { and } l^{\bullet}(i)=a_{i} \text { for } i \in[n], \\
& -s^{\bullet}(<)=t^{\bullet}(<)=0, l^{\bullet}(<)=<, s^{\bullet}(>)=t^{\bullet}(>)=n, l^{\bullet}(>)=>, \\
& -s^{\bullet}(h)=0, t^{\bullet}(h)=1 \text { and } l^{\bullet}(h)=\text { head. }
\end{aligned}
$$

For $w=\lambda$ we use the graph $\square^{\bullet}$.
2. $\quad P(T M)$ contains the rules given in Fig. 5. Obviously, an application of a rule mimics a computational step of $T M$ moving from the current state to a follow-up state, reading the symbol $a$ and writing $b$ at the head, and keeping the head or moving to the next symbol to the right or to the left. If one of the end markers is reached the band is extended by the extra symbol $\square$.
3. free is a control condition that does not invoke any restriction. As a regular expression, it may be chosen as the arbitrary iteration of the alternative composition of all rules.
4. The graph class expression terminal $(T M)$ specifies the class of all graphs with some node that is incident with a curr-loop as well as a fin-loop.

If $D(w)=$ true, then $T M$ runs on $w$ as initial inscription of the band from the initial state to some final state in a polynomial number of steps. Starting in $G\left(T M, s_{0}\right)+w^{\bullet}$, each step of $T M$ corresponds to a rule application in $t u(T M)$ reaching a graph where the current-state loop is attached to a terminal state. Conversely, a derivation from $G\left(T M, s_{0}\right)+w^{\bullet \bullet}$ for some
$w \in I^{*}$ to a terminal graph corresponds to a run of $T M$ on $w$ with the same number of steps. As $T M$ is polynomial, $t u(T M)$ is also polynomial. Consequently, one gets $D \in N P_{G T}$ up to the representation of $w$ by $G\left(T M, s_{0}\right)+w^{\bullet}$.

Example 4 The rules start and run (cf. Example 2) decrease the number of unlabeled loops by 1 whenever one of them is applied. Therefore, the unit $H P$ (cf. Example 3 ) is terminating due to Observation 2. Because $H P$ finds all existing Hamiltonian paths of every initial graph as terminal graphs, $H P$ solves the Hamiltonian path problem. Moreover the termination bound is linear so that the problem is explicitly shown to be a member of $N P_{G T}$.

Termination has been studied in the context of graph transformation for example by Plump (1998), Godard et al. (2002), and by Ehrig et al. (2005).

## 5 Graph multiset transformation

In this section, graph multiset transformation is introduced employing ordinary graph transformation as basis. The underlying data structures are finite multisets of graphs. ${ }^{2}$ In each derivation step, some of the graphs of a given actual multiset are directly derived into graphs by applying ordinary rules, yielding a new actual multiset where the deriving graphs are replaced by the derived ones. This idea is formalized in Definition 5. A derivation of multisets of graphs corresponds to a set of simultaneous derivations of graphs (cf. Construction 6). In this sense, graph multiset transformation is a framework for massively parallel computation. In particular, one can show that $N P$-problems can be solved by graph multiset transformation in a polynomial number of steps.

Definition 5 Let $P$ be a set of rules. Let $M: \mathcal{G}_{\Sigma} \rightarrow \mathbb{N}$ be a finite multiset of graphs and $M^{\prime} \leq M$ a sub-multiset of $M$. Let $G_{1} \ldots G_{m} \in \operatorname{Perm}\left(M^{\prime}\right)$ be one of the sequential representations of $M^{\prime}$ and $G_{1}^{\prime} \ldots G_{m}^{\prime} \in \mathcal{G}_{\Sigma}^{*}$ be another sequence of graphs with $G_{i} \underset{p}{\Longrightarrow} G_{i}^{\prime}$ for all $i=1, \ldots, m$. Let $M^{\prime \prime}=\left[G_{1}^{\prime} \ldots G_{m}^{\prime}\right]$ be the multiset of $G_{1}^{\prime} \ldots G_{m}^{\prime}$.

Then $M$ directly derives the graph multiset $\bar{M}=M-M^{\prime}+M^{\prime \prime}$, denoted by $M \underset{P}{\Longrightarrow} \bar{M}$.
A sequence $M_{0} \underset{P}{\Longrightarrow} M_{1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow} M_{n}$ of direct derivations of multisets of graphs defines a (graph multiset) derivation from $M=M_{0}$ to $\bar{M}=M_{n}$ of length $n$ in the usual way. Such derivations are shortly denoted by $M \xlongequal[P]{n} \bar{M}$ or $M \xlongequal[P]{*} \bar{M}$. The subscript $P$ may be omitted if it is clear from the context.

## Remarks

1. It should be noted that the derived multiset does not depend on the choice of the sequential representation of $M^{\prime}$ because each permutation of the sequence $G_{1} \ldots G_{n}$ corresponds to the respective permutation of $G_{1}^{\prime} \ldots G_{n}^{\prime}$ and the multisets of sequences are invariant with respect to permutation.
2. The sub-multiset $M^{\prime} \leq M$ in a direct derivation is called left-active and $M^{\prime \prime} \leq \bar{M}$ rightactive respectively.
3. Let $\operatorname{Der}=\left(M_{0} \underset{P}{\Longrightarrow} M_{1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow} M_{n}\right) \quad$ be $\quad$ a graph multiset derivation. For $i=1, \ldots, n-1$, let $M_{i}^{\prime} \leq M_{i}$ be the left-active sub-multiset of the direct derivation $M_{i} \underset{P}{\Longrightarrow} M_{i+1}$ in Der and let $M_{i}^{\prime \prime} \leq M_{i}$ be the right-active sub-multiset of the direct

[^2]

Fig. 6 A graph multiset derivation
derivation $M_{i-1} \underset{P}{\Longrightarrow} M_{i}$ in Der. Then Der is called proactive if $M_{i}^{\prime \prime} \leq M_{i}^{\prime}$ for $i=1, \ldots, n-1$. This means that a graph that is not transformed in some step is kept invariant in all further steps.
4. The left-active sub-multiset $M^{\prime}$ of a direct derivation $M \underset{P}{\Longrightarrow} \bar{M}$ may be empty so that $M^{\prime \prime}=\mathbf{0}$ and $M=\bar{M}$. Such a direct derivation is called inactive. A derivation without inactive steps is called undelayed.

Multiset transformation as introduced is not restricted to graph transformation as underlying computational framework. It would work for any binary relation on some set of configurations where the relation provides computational steps. Nevertheless, we are interested in a graph transformational counterpart to DNA computing. Therefore, we focus on graphs as molecules and rule applications as chemical reactions.

Example 5 The six derivations in Fig. 4 can be turned into the graph multiset derivation in Fig. 6 if one considers the columns of graphs as multisets and adds copies of the second graph and the fourth graph of the last-but-one column to the last column. The derivation is proactive because no graph is kept invariant in the first three steps.

It is not difficult to see that graph multiset derivations correspond to derivations of the graphs in the multisets and that the lengths of graph multiset derivations are bounded if and only if the lengths of graph derivations are bounded. The correspondence is based on two constructions: Each graph multiset derivation induces a multiset of derivations and the other way round.

## Construction 6

1. Let $M \stackrel{k}{\Longrightarrow} \bar{M}$ be a graph multiset derivation and $G_{1} \ldots G_{n}$ be a sequential representation of $M$, ${ }^{P}$ i.e., $G_{1} \ldots G_{n} \in \operatorname{Perm}(M)$. Then there is a multiset of derivations
$\operatorname{MoD}(M \underset{P}{k} \bar{M}):\left[G_{1} \xrightarrow[P]{k_{1}} \bar{G}_{1} \ldots G_{n} \underset{P}{k_{n}} \bar{G}_{n}\right]$ with $k_{i} \leq k$ for each $i=1, \ldots, n$ such that $\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]=\bar{M}$. Moreover, $k \leq \sum_{i=1}^{n} k_{i}$ if $M \underset{P}{k} \bar{M}$ is undelayed. $\operatorname{MoD}(M \underset{P}{k} \bar{M})$ can be constructed inductively as follows.
Induction base: $M \underset{P}{\Longrightarrow} \bar{M}$ implies $\bar{M}=M$ yielding the derivations

$$
G_{i} \underset{P}{\stackrel{0}{\Longrightarrow}} G_{i}=\bar{G}_{i}
$$

for all $i=1, \ldots, n$ with $\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]=\left[G_{1} \ldots G_{n}\right]=M=\bar{M}$.
Induction step: Consider $M \underset{P}{\stackrel{k+1}{\Longrightarrow}} \bar{M}$ which decomposes into $M \xlongequal[P]{k} \hat{M}$ and $\hat{M} \underset{P}{\Longrightarrow} \bar{M}$. By induction hypothesis, one gets derivations $G_{i} \underset{P}{k_{i}} \hat{G}_{i}$ with $k_{i} \leq k$ for all $i=1, \ldots, n$ and $\left[\hat{G}_{1} \ldots \hat{G}_{n}\right]=\hat{M}$. Moreover, there are sub-multisets $M^{\prime} \leq \hat{M}$ and $M^{\prime \prime} \leq \bar{M}$ with $\bar{M}=\hat{M}-M^{\prime}+M^{\prime \prime}$. Without loss of generality, one can assume that $M^{\prime}$ is sequentially represented by $\hat{G}_{1} \ldots \hat{G}_{m}$ for some $m \leq n$. Then there are direct derivations $\hat{G}_{i} \underset{P}{\Longrightarrow} G_{i}^{\prime \prime}$ for $i=1, \ldots, m$ with $\left[G_{1}^{\prime \prime} \ldots G_{m}^{\prime \prime}\right]=M^{\prime \prime}$. Consequently, one can construct the following derivations: $\quad G_{i} \xrightarrow[P]{k_{i}} \hat{G}_{i} \underset{P}{\Longrightarrow} G_{i}^{\prime \prime}=\bar{G}_{i} \quad$ for $i=1, \ldots, m$ and $\quad G_{i} \underset{P}{k_{i}} \hat{G}_{i}=\bar{G}_{i} \quad$ for $i=m+1, \ldots, n$ with lengths not longer than $k+1$ and

$$
\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]=\left[G_{1}^{\prime \prime} \ldots G_{m}^{\prime \prime} \hat{G}_{m+1} \ldots \hat{G}_{n}\right]=\hat{M}-M^{\prime}+M^{\prime \prime}=\bar{M} .
$$

This completes the construction, i.e., the resulting multiset of derivations is equal to

$$
\left[G_{1} \underset{P}{\stackrel{k_{1}^{\prime}}{\Rightarrow}} \bar{G}_{1} \ldots G_{n} \xrightarrow[P]{\stackrel{k_{n}^{\prime}}{\Rightarrow}} \bar{G}_{n}\right]
$$

where $k_{i}^{\prime}=k_{i}+1$ for $i=1, \ldots, m$ and $k_{i}^{\prime}=k_{i}$ for $i=m+1, \ldots, n$.
Moreover, if $M \stackrel{k+1}{\Longrightarrow} \bar{M}$ is undelayed, then $m \geq 1, M \xlongequal{k} \hat{M}$ is undelayed, and by induction hypothesis $k \leq \sum_{i=1}^{n} k_{i}$. Hence, $k+1 \leq \sum_{i=1}^{n} k_{i}+1 \leq \sum_{i=1}^{n} k_{i}+m=$ $\sum_{i=1}^{n} k_{i}^{\prime}$.
2. Let $D E R$ be a multiset of derivations and let

$$
G_{1} \xrightarrow[P]{k_{1}} \bar{G}_{1} \ldots G_{n} \xrightarrow{k_{n}} \bar{G}_{n} \in \operatorname{Perm}(D E R)
$$

be a sequential representation of $D E R$. Then there is a graph multiset derivation $\operatorname{gmd}(D E R):\left[G_{1} \ldots G_{n}\right] \stackrel{k}{\Rightarrow}\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]$ with $k=\max \left\{k_{i} \mid i=1, \ldots, n\right\}$, which can be constructed as follows.
Let $G_{i}=G_{i 0} \Longrightarrow G_{i 1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow}=G_{i k_{i}}=\bar{G}_{i}$ for $i=1, \ldots, n$ be the given derivations. Let $G_{i j}=G_{i k_{i}}$ for $i=1, \ldots, n$ and $j=k_{i}+1, \ldots, k$. Then this induces

$$
\operatorname{gmd}(D E R):\left[G_{10} \ldots G_{n 0}\right] \underset{P}{\Longrightarrow}\left[G_{11} \ldots G_{n 1}\right] \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow}\left[G_{1 k} \ldots G_{n k}\right]
$$

where,
$-\left[G_{10} \ldots G_{n 0}\right]=\left[G_{1} \ldots G_{n}\right]$,
$-\left[G_{1 k} \ldots G_{n k}\right]=\left[G_{1 k_{1}} \ldots G_{n k_{n}}\right]=\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]$, and

- for $j=1, \ldots, k$, the direct graph multiset derivation

Fig. 7 A graph multiset derivation that is not proactive

$$
\left[G_{1(j-1)} \ldots G_{n(j-1)}\right] \underset{P}{\Longrightarrow}\left[G_{1 j} \ldots G_{n j}\right]
$$

is defined by the direct derivations $G_{1(j-1)} \underset{P}{\Longrightarrow} G_{i j}$ for $i=1, \ldots, n$ and $j \leq k_{i}$.

Example 6 Let Der $_{0}$ be the graph multiset derivation in Fig. 6. Then the multiset of derivations $\operatorname{MoD}\left(D e r_{0}\right)$ consists of the six derivations in Fig. 4. Let the (multi-)set of these derivations be denoted by $D E R_{0}$. Then the induced graph multiset derivation $\operatorname{gmd}\left(D E R_{0}\right)$ is the one in Fig. 6. Besides $D e r_{0}$, there are many other graph multiset derivations with the same multiset of derivations. For instance, one may replace the last step in Fig. 6 by the derivation in Fig. 7, which is not proactive, in particular. If the resulting derivation is denoted by $D e r_{1}$, then $\operatorname{MoD}\left(\right.$ Der $\left._{1}\right)=D E R_{0}$.

Observation 7 Let $D E R$ be a multiset of derivations and $\operatorname{Der}$ be a graph multiset derivation. Then the following properties hold.

1. $\operatorname{MoD}(g m d(D E R))=D E R$,
2. in particular, $\operatorname{MoD}(\operatorname{gmd}(\operatorname{MoD}(\operatorname{Der})))=\operatorname{MoD}(\operatorname{Der})$,
3. $\operatorname{gmd}(D E R)$ is proactive,
4. in particular, $\operatorname{gmd}(\operatorname{MoD}(\operatorname{Der}))$ is proactive,
5. if Der is proactive, then $\operatorname{Der}=\operatorname{gmd}(\operatorname{MoD}(\operatorname{Der}))$.

## Proof

1. Let $G_{1} \xrightarrow[P]{\stackrel{k_{1}}{\Longrightarrow}} \bar{G}_{1} \ldots G_{n} \xrightarrow[P]{\stackrel{k_{n}}{\Longrightarrow}} \bar{G}_{n} \in \operatorname{Perm}(D E R)$. Let $\max =\max \left\{k_{i} \mid i=1, \ldots, n\right\}$. The statement is proved by induction on max.
Induction base: $\max =0$ implies $k_{i}=0$ and $G_{i}=\bar{G}_{i}$ for all $i=1, \ldots, n$. Hence, $\operatorname{gmd}(D E R)=\left[G_{1} \ldots G_{n}\right] \underset{P}{\underset{\Longrightarrow}{0}}\left[G_{1} \ldots G_{n}\right]=\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]$ implying

$$
\operatorname{MoD}(\operatorname{gmd}(D E R))=\left[G_{1} \underset{P}{0} G_{1}=\bar{G}_{1} \ldots G_{n} \xrightarrow[P]{0} G_{n}=\bar{G}_{n}\right]
$$

by definition of $g m d$ and $M o D$. This proves $D E R=\operatorname{MoD}(\operatorname{gmd}(D E R))$ for $k_{k_{i}}=0$.
Induction step: Consider $\max =k+1$. For $i=1, \ldots, n$, let $\left(G_{i} \xrightarrow[P]{\Longrightarrow} \bar{G}_{i}\right)=$ $\left(G_{i} \underset{P}{k} G_{i}^{\prime} \underset{P}{\Longrightarrow} \bar{G}_{i}\right)$ for $k_{i}=k+1$ and $k_{i}^{\prime}=k_{i}$ and $G_{i}^{\prime}=\bar{G}_{i}$ for $k_{i} \leq k$. By induction hypothesis, one gets $\operatorname{MoD}\left(\operatorname{gmd}\left(D E R^{\prime}\right)\right)=D E R^{\prime}$ for $D E R^{\prime}=\left[G_{1} \xrightarrow[P]{\stackrel{k_{1}^{\prime}}{\Longrightarrow}} G_{1}^{\prime} \ldots G_{n} \xrightarrow[P]{k_{n}^{\prime}} G_{n}^{\prime}\right]$ with $k_{i}^{\prime}=k$ in the case of $k_{i}=k+1$. The derivation $\operatorname{gmd}\left(D E R^{\prime}\right)=$ $\left(\left[G_{1} \ldots G_{n}\right] \underset{P}{k}\left[G_{1}^{\prime} \ldots G_{n}^{\prime}\right]\right)$ can be extended by

$$
\left[G_{1}^{\prime} \ldots G_{n}^{\prime}\right] \underset{P}{\Longrightarrow}\left[\bar{G}_{1}^{\prime} \ldots \bar{G}_{n}^{\prime}\right]
$$

using the direct derivations $G_{i}^{\prime} \Longrightarrow \bar{G}_{i}$ for $i=1, \ldots, n$ with $k_{i}=k+1$. The resulting derivation is $\operatorname{gmd}(D E R)$ according to the construction of $g m d$, and $\operatorname{MoD}(\operatorname{gmd}(D E R))$ contains the derivations $G_{i} \underset{P}{k} G_{i}^{\prime} \underset{P}{\Longrightarrow} \bar{G}_{i}$ for $k_{i}=k+1$ and $G_{i} \underset{P}{k_{i}} G_{i}^{\prime}=\bar{G}_{i}$ otherwise proving the statement 1 for $k+1$ if it holds for $k$.
2. Statement 2 is a special case of statement 1 .
3. If $D E R$ contains a derivation $G_{i 0} \underset{P}{\Longrightarrow} G_{i 1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow} G_{i k_{i}}$, then $g m d(D E R)$ uses $k_{i}$ rule applications in the first $k_{i}$ steps in this order. If $k_{i}$ is not the maximum length in $D E R$, then $G_{i k_{i}}$ is kept invariant in all further steps. In other words, $\operatorname{gmd}(D E R)$ is proactive.
4. Statement 4 is a special case of statement 3.
5. Consider $\operatorname{Der}=(M \underset{P}{k} \bar{M})$ and $G_{1} \ldots G_{n} \in \operatorname{Perm}(M)$. The statement is proved by induction on $k$.

Induction base: $k=0$ implies $\bar{M}=M$. Therefore,

$$
\operatorname{MoD}(D e r)=\left[G_{1} \underset{P}{0} G_{1} \ldots G_{n} \underset{P}{\stackrel{0}{\Rightarrow}} G_{n}\right]
$$

and $\operatorname{gmd}(\operatorname{MoD}(\operatorname{Der}))=\left(M=\left[G_{1} \ldots G_{n}\right] \underset{P}{0}\left[G_{1} \ldots G_{n}\right]=M=\bar{M}\right)$ proving the statement for $k=0$.
Induction step: $\operatorname{Der}=(M \underset{P}{\stackrel{k+1}{\Longrightarrow}} \bar{M})=(M \underset{P}{k} \hat{M} \underset{P}{\Longrightarrow} \bar{M})$. Because Der is proactive, $M \xlongequal[P]{k} \hat{M}$ is proactive as initial section, too. By induction hypothesis, one gets $\operatorname{gmd}(\operatorname{MoD}(M \underset{P}{k} \hat{M}))=(M \underset{P}{k} \hat{M})$. Let $M^{\prime} \leq \hat{M}$ be left-active and $M^{\prime \prime} \leq \bar{M}$ be rightactive with respect to $\hat{M} \underset{P}{\Longrightarrow} \bar{M}$. Let $G_{1}^{\prime} \ldots G_{m}^{\prime} \in \operatorname{Perm}\left(M^{\prime}\right)$ and $G_{j}^{\prime} \underset{P}{\Longrightarrow} G_{j}^{\prime \prime}$ for $j=1, \ldots, m$ the respective direct derivations. Let $\operatorname{MoD}(M \underset{P}{k} \hat{M})=\left[G_{1} \xrightarrow[P]{k_{1}}\right.$ $\left.\hat{G}_{1} \ldots G_{n} \xrightarrow[P]{k_{n}} \hat{G}_{n}\right]$. Without loss of generality, one may assume that the permutation is chosen in such a way that $G_{1}^{\prime} \ldots G_{m}^{\prime}=\hat{G}_{1} \ldots \hat{G}_{m}$. Then, by construction, $\operatorname{MoD}(\operatorname{Der})$ contains the derivations $G_{i} \underset{P}{k} \hat{G}_{i}=G_{i}^{\prime} \underset{P}{\Longrightarrow} G_{i}^{\prime \prime}=\bar{G}_{i} \quad$ for $\quad i=1, \ldots, m \quad$ and $G_{i} \underset{P}{\stackrel{k_{i}}{\Longrightarrow}} \hat{G}_{i}=\bar{G}_{i}$ for $i=m+1, \ldots, n$. Note that $k_{i}=k$ for $i=1, \ldots, m$ because of
the assumed proactivity. It follows that $\operatorname{gmd}(\operatorname{MoD}(\operatorname{Der}))=\left(M=\left[G_{1} \ldots G_{n}\right]\right.$ $\left.\underset{P}{k+1}\left[\bar{G}_{1} \ldots \bar{G}_{n}\right]=\bar{M}\right)=$ Der proving the statement for $k+1$ if it holds for $k$.

The construction of a multiset of derivations from a derivation of multisets of graphs and vice versa is mainly used to compare the two kinds of computation given by the two kinds of derivations. We do not claim that the multiset of derivations has a DNA analogon of any kind. In particular, the synchronization of the derivation can be done (and is done) step by step without taking any reaction speed into account. Observation 7 means, in particular, that graph multiset transformation is a kind of parallel graph transformation that has the same termination properties as ordinary graph transformation discussed above if one considers proactive derivations. Therefore, graph multiset transformation can be used as a computational framework similarly to graph transformation. In particular, a terminating transformation unit can solve a decision problem on its initial graphs by means of graph multiset transformation. The computation starts with multiple copies of an initial graph and yields true if some terminal graph occurs in one of the derived multisets. Using polynomial transformation units, the lengths of proactive graph multiset derivations are polynomially bounded and TRUE is computed in a single derivation with high probability if the multiplicity of the initial graph is chosen large enough.

Definition 8 Let $t u=(I, P, C, T)$ be a terminating transformation unit. Let $D: \operatorname{SEM}(I) \rightarrow\{$ TRUE, FALSE $\}$ be a decision problem. Then tu computes $D$ by graph multiset transformation (GMST) if the following holds.

For each $G \in \operatorname{SEM}(I)$, there is a proactive graph multiset derivation Der $=(n \cdot[G] \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{M})$ with initial multiplicity $n$ for some $n \in \mathbb{N}$ so that some underlying derivation $G \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{G} \in \operatorname{MoD}(\operatorname{Der})$ is permitted by $C$ with $\bar{G} \in \operatorname{car}(\bar{M}) \cap \operatorname{SEM}(T)$ if and only if $D(G)=$ true.

## Remarks

1. If $t u$ computes $D$ by graph multiset transformation, then this may be denoted by $D=\operatorname{COMP}_{G M S T}(t u)$.
2. PGMST denotes the set of all decision problems that are computed via graph multiset transformation by polynomial transformation units.
3. If $t u$ is polynomial and $G$ an initial graph, then the number of derivations starting in $G$ is bounded by a number exponential in the size of $G$ so that-in general-there is no feasible way to check all of them sequentially.
4. If the initial multiplicity is 1 , then there is no difference between graph transformation and graph multiset transformation because the singleton $x$ and the multiset $[x]$ with the single element $x$ provide the same information-for example the same nondeterminism if $x$ is a derivation.
5. If the multiplicity $n$ of $G$ is chosen large and the multiset derivation

$$
\operatorname{Der}=(n \cdot[G] \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{M})
$$

is long, then the probability is high that some successful derivation starting in graph $G$ is in $\operatorname{MoD}(\mathrm{Der})$. Therefore the probability is high to find the proper value of $D(G)$ in a single graph multiset derivation with a polynomial number of steps. This justifies the denotation PGMST.
6. To make this more precise, let $N$ be the number of derivations $G \xlongequal{*} H$ that cannot be prolonged and $K$ the number of successful derivations. Then the probability that a single derivation out of the $N$ ones is successful is $p_{1}=\frac{K}{N}$. If $\operatorname{Der}$ cannot be prolonged, then $\operatorname{MoD}(\operatorname{Der})$ contains $n$ test derivations that are constructed independently of each other so that one could construct them one after the other and number them from 1 to $n$ without loss of information. Let $p_{i}$ denote the probability that the derivations 1 to $i$ contain a successful derivation. Then the derivation $i+1$ improves the chance to get a successful one by $p_{i}\left(1-p_{i}\right)$ yielding $p_{i+1}=p_{i}+p_{i}\left(1-p_{i}\right)$. By induction, one gets for $1 \leq i \leq n, n \in \mathbb{N}$

$$
p_{i}=\sum_{j=0}^{i-1} \frac{K}{N} \cdot\left(\frac{N-K}{N}\right)^{j}
$$

These are the finite prefixes of a geometric series with the constant ratio $\frac{N-K}{N}$ so that a wellknown fact and a bit of arithmetic leads to

$$
p_{i}=\frac{K}{N} \cdot \frac{1-\left(\frac{N-K}{N}\right)^{i}}{1-\frac{N-K}{N}}=1-\left(\frac{N-K}{N}\right)^{i} .
$$

This means, in particular, that the sequence $\left(p_{i}\right)_{i \geq 1}$ converges against 1 . In other words, a graph multiset derivation finds a successful derivation with arbitrarily high probability that is the better the larger the initial multiplicity is. The case where none of the $N$ possible derivations is successful (i.e. $D(G)=$ FALSE) can be treated similarly.

As a first result on polynomial graph multiset transformation and as the main result of this section, one can show that the classes $N P_{G T}$ and $P G M S T$ coincide. Unfortunately, this is not a solution of the $P=N P$-problem because the class $P G M S T$ relies on massive parallelism. The equality of the classes $N P_{G T}$ and $P G M S T$ is based on the following observation.

Observation 9 Let $t u$ be a polynomial transformation unit. Then $\operatorname{COMP}(t u)$ $=\operatorname{COMP}_{\text {GMST }}(t u)$.
Proof Let $t u=(I, P, C, T)$ be a polynomial graph transformation unit and let $G \in S E M(I)$ such that $\operatorname{COMP}(t u)(G)=$ TRUE. Then by definition there is a derivation $\operatorname{der}=\left(G=G_{0} \underset{P}{\Longrightarrow} G_{1} \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow} G_{n}\right)$ with $G_{n} \in \operatorname{SEM}(T)$ that is permitted by C. This induces the graph multiset derivation $\operatorname{Der}=\left([G]=\left[G_{0}\right] \underset{P}{\Longrightarrow}\left[G_{1}\right] \underset{P}{\Longrightarrow} \cdots \underset{P}{\Longrightarrow}\left[G_{n}\right]\right)$ with der $\in \operatorname{MoD}(\mathrm{Der})=[\mathrm{der}]$ such that $\operatorname{COMP}_{G M S T}(\mathrm{tu})(G)=$ true. If, conversely, $\operatorname{COMP}_{\text {GMST }}(\mathrm{tu})(G)=$ TRUE, then by definition there are a graph multiset derivation $\operatorname{Der}=(n \cdot[G] \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{M})$ and a derivation $\operatorname{der}=(G \underset{P}{*} \bar{G}) \in \operatorname{MoD}(\operatorname{Der})$ which is permitted by $C$ with $\bar{G} \in \operatorname{car}(\bar{M}) \cap \operatorname{SEM}(T)$. The derivation der yields $\operatorname{COMP}(t u)(G)=$ true such that, all together, $\operatorname{COMP}(t u)=\operatorname{COMP}_{G M S T}(t u)$.

From this observation it follows that the decision problems in $N P_{G T}$ are the same as those in PGMST.

## Corollary $10 \quad N P_{G T}=P G M S T$.

Proof $D \in N P_{G T}$ if and only if there is a polynomial graph transformation unit $t u=(I, P, C, T)$ with $D=\operatorname{COMP}(t u)$. By Observation $9 D=\operatorname{COMP}_{G M S T}(t u)$. This is in turn the case if and only if $D \in P G M S T$. Hence, $N P_{G T}=P G M S T$.

Fig. 8 A graph multiset derivation with terminal graphs

Fig. 9 A graph multiset derivation without terminal graphs

Example 7 Based on the unit HP in Example 3 of Sect. 3, Figure 8 shows a graph multiset derivation that starts with two copies of $G_{0}$. In the first step, the rule start is applied to the left upper node of both copies. There is only one possible match in each case exept for the third step where run is applied to the right vertical edge in the upper graph and to the diagonal edge in the lower graph. In the following steps, run is applied as long as possible. The horizontal rows of graphs represent the underlying derivations which are both permitted. The derived (multi-)set contains two graphs of which one graph is terminal proving that $\operatorname{COMP}_{G M S T}(H P)\left(G_{0}\right)=$ tRUE.

The derivation in Fig. 6 yields the same result as it covers the one in Fig. 8. In contrast to that, the derivation in Fig. 9 fails because both derived graphs are not terminal.

The section is closed by a more explicit construction of the computations that solve decision problems by graph multiset transformation. To keep track of underlying derivations that are permitted by the control condition, a finite automaton is used. Moreover, we assume that terminal graphs are reduced. Therefore, the check for terminality can be postponed until a derivation cannot be prolonged.

Construction 11 Let $t u=(I, P, C, T)$ be a terminating transformation unit with $\operatorname{SEM}(T) \subseteq \operatorname{reduced}(P)$. Let $A=\left(S, P, d, s_{0}, F\right)$ be a finite automaton with $L(A)=L(C)$ where $P$ is the input alphabet.

As underlying data structures, configurations of the form $(M \underset{P}{*} \bar{M}, W, w)$ with $W \in \operatorname{Perm}(\bar{M})$ and $w \in S^{*}$ are used. In addition, one may assume length $(W)=$ length $(w)$ so that each copy of each graph in $\bar{M}$ is associated with a state of A. Given an initial graph $G$, a computation can be constructed inductively in the following way.
Induction base: Choose $n$, and consider $\left(n \cdot[G] \underset{P}{0} n \cdot[G], G^{n}, s_{0}^{n}\right)$ as start configuration. Induction hypothesis: Assume that a configuration

$$
\left(n \cdot[G] \underset{P}{k} \hat{M}, \hat{G}_{1} \ldots \hat{G}_{n}, s_{1} \ldots s_{n}\right)
$$

is already constructed.

Induction step: If possible, then choose for $i=1, \ldots, n, \hat{G}_{i} \Longrightarrow \bar{G}_{i}$ with some $\bar{s}_{i} \in d\left(s_{i}, r\right)$. Otherwise, let $\bar{G}_{i}=\hat{G}_{i}$ and $\bar{s}_{i}=s_{i}$. Then $\left[\hat{G}_{1} \ldots \hat{G}_{n}\right] \stackrel{r}{r}\left[\bar{G}_{i} \ldots \bar{G}_{n}\right]$ is a direct derivation giving rise to the follow-up configuration

$$
\left(n \cdot[G] \underset{P}{\stackrel{k}{\Longrightarrow}} \hat{M} \underset{P}{\Longrightarrow}\left[\bar{G}_{1} \ldots \bar{G}_{n}\right], \bar{G}_{1} \ldots \bar{G}_{n}, \bar{s}_{1} \ldots \bar{s}_{n}\right) .
$$

The construction can be terminated if a configuration

$$
\left(n \cdot[G] \underset{P}{l} \bar{M}, \bar{G}_{1} \ldots \bar{G}_{n}, \bar{s}_{1} \ldots \bar{s}_{n}\right)
$$

is reached such that there is no $\bar{G}_{i} \Longrightarrow \overline{\bar{G}}_{i}$. Consequently, all follow-up configurations remain unchanged. Such a configuration is reached eventually because the transformation unit $t u$ is terminating.

Observation 12 Let $t u=(I, P, C, T)$ be a terminating transformation unit with $S E M(T) \subseteq \operatorname{reduced}(P)$. Let $A=\left(S, P, d, s_{0}, F\right)$ be a finite automaton with $L(A)=L(C)$. Let $D=\operatorname{COMP}_{G M S T}(t u)$. Then the following statements hold.

1. Let $\left(n \cdot[G] \underset{P}{k} \bar{M}, \bar{G}_{1} \ldots \bar{G}_{n}, s_{1} \ldots s_{n}\right)$ be a configuration constructed inductively according to Construction 11. Let, for $i=1, \ldots, n, u_{i}$ be the application sequence of the underlying derivation $G \underset{P}{k_{i}} \bar{G}_{i}$. Then $s_{i} \in d^{*}\left(s_{0}, u_{i}\right)$.
2. Let $\left(n \cdot[G] \underset{P}{*} \bar{M}, \bar{G}_{1} \ldots \bar{G}_{n}, s_{1} \ldots s_{n}\right)$ be a terminated configuration for some graph $G \in \operatorname{SEM}$ (I) with $\bar{G}_{i} \in \operatorname{SEM}(T)$ and $s_{i} \in F$ for some $i=1, \ldots, n$. Then $D(G)=$ true.
3. If $D(G)=$ true, then there is a terminated configuration of the form $(1 \cdot[G] \stackrel{*}{\Longrightarrow}(1 \cdot[\bar{G}], \bar{G}, s)$ for some $\bar{G} \in \operatorname{SEM}(T)$ and $s \in F$.

## Proof

1. Statement 1 is proved by induction on $k$.

Induction base: $\left(n \cdot[G] \underset{P}{0} \bar{M}, \bar{G}_{1} \ldots \bar{G}_{n}, s_{1} \ldots s_{n}\right)$ implies

$$
\bar{M}=M, \bar{G}_{1}=\cdots=\bar{G}_{n}=G, \text { and } s_{1}=\cdots=s_{n}=s_{0} .
$$

Then $(G \underset{P}{\stackrel{0}{\Longrightarrow}} G)$ is the only derivation in $\operatorname{MoD}(n \cdot[G] \underset{P}{\stackrel{0}{\Longrightarrow}} \bar{M})$ with application sequence $\lambda$ such that $s_{0} \in d^{*}\left(s_{0}, \lambda\right)=\left\{s_{0}\right\}$.

Induction step: $\left(n \cdot[G] \underset{P}{k+1} \bar{M}, \bar{G}_{1} \ldots \bar{G}_{n}, \bar{s}_{1} \ldots \bar{s}_{n}\right)$ is obtained from

$$
\left(n \cdot[G] \underset{P}{k} \hat{M}, \hat{G}_{1} \ldots \hat{G}_{n}, s_{1} \ldots s_{n}\right) \text { and } \hat{M} \underset{P}{\Longrightarrow} \bar{M}
$$

where $\hat{G}_{i} \underset{r_{i}}{\Longrightarrow} \bar{G}_{i}$ is used with $\bar{s}_{i} \in d\left(s_{i}, r_{i}\right)$ if possible, and $G_{i}=\bar{G}_{i}$ and $s_{i}=\bar{s}_{i}$ otherwise. By induction hypothesis, one knows that $s_{i} \in d^{*}\left(s_{0}, u_{i}\right)$ where $u_{i}$ is the application sequence of the derivation $G \underset{P}{\stackrel{k_{i}}{\Longrightarrow}} \hat{G}_{i} \in \operatorname{MoD}(n \cdot[G] \underset{P}{\stackrel{k}{\Longrightarrow}} \hat{M})$ for each $i=1, \ldots, n$. Then the derivation of $\operatorname{MoD}(n \cdot[G] \stackrel{k+1}{\underset{P}{M}} \bar{M})$ has the following form for each $i=1, \ldots, n$ : $G_{i} \xrightarrow[P]{k_{i}} \hat{G}_{i} \Longrightarrow \bar{r}_{i} \bar{G}_{i}$ with application sequence $u_{i} r_{i}$ or $G_{i} \xrightarrow[P]{\stackrel{k_{i}}{\longrightarrow}} \hat{G}_{i}=\bar{G}_{i}$ with application
sequence $u_{i}$. In the first case, one gets $\bar{s}_{i} \in d\left(s_{i}, r_{i}\right)$ and $s_{i} \in d^{*}\left(s_{0}, u_{i}\right)$ which implies $\bar{s}_{i} \in d^{*}\left(s_{0}, u_{i} r_{i}\right)$. And in the second case, one gets $\bar{s}_{i}=s_{i} \in d^{*}\left(s_{0}, u_{i}\right)$. Both together prove statement 1 for $k+1$ if it holds for $k$.
2. Let $G \underset{P}{k_{i}} \bar{G}_{i}$ with $G \in \operatorname{SEM}(I), \bar{G}_{i} \in \operatorname{SEM}(T)$ and $s_{i} \in F$ be a derivation of $\operatorname{MoD}(n \cdot[G] \underset{P}{*} \bar{M})$. If the given configuration is terminated, then $\bar{G}_{i} \in \operatorname{reduced}(P)$ for all $i=1, \ldots, n$. Due to statement $1, s_{i} \in d^{*}\left(s_{0}, u_{i}\right)$ for the application sequence of $G \xrightarrow[P]{k_{i}} \bar{G}_{i}$ meaning that $u_{i} \in L(A)=L(C)$ and that, therefore, the derivation is permitted by $C$. Consequently, $D(G)=$ true.
3. By assumption and Corollary $10, D \in P_{G M S T}=N P_{G T}$. Hence, $D(G)=$ true for some $G \in \operatorname{SEM}(I)$ implies the existence of a derivation $G \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{G}$ with

$$
\bar{G} \in \operatorname{reduced}(P) \cap S E M(T)
$$

permitted by $C$. The latter means that $d^{*}\left(s_{0}, u\right) \cap F \neq \emptyset$ if $u$ is the application sequence of $G \underset{P}{\stackrel{*}{\Longrightarrow}} \bar{G}$. It remains to show the following: Let $G \underset{P}{*} G^{\prime}$ be a derivation with application sequence $u$ and $G \in \operatorname{SEM}(I)$ such that $s \in d^{*}\left(s_{0}, u\right)$ for some $s \in S$. Then there is a configuration $\left(1 \cdot[G] \underset{P}{*} 1 \cdot\left[G^{\prime}\right], G^{\prime}, s\right)$. This is proved by induction on the length of $G \underset{P}{\stackrel{*}{\Longrightarrow}} G^{\prime}$.
Induction base: $G \underset{P}{P} G^{\prime}$ implies $G^{\prime}=G$ such that $\left(1 \cdot[G] \underset{P}{0} 1 \cdot[G]=1 \cdot\left[G^{\prime}\right], G^{\prime}, s_{0}\right)$ proves the statement for this case.

Induction step: $G \underset{P}{k+1} G^{\prime}$ with application sequence $u$ decomposes into

$$
G \underset{P}{\stackrel{k}{\Longrightarrow}} G^{\prime \prime} \underset{r}{\Longrightarrow} G^{\prime}
$$

with $u=u^{\prime} r$ where $u^{\prime}$ is the application sequence of $G \underset{P}{k} G^{\prime \prime}$. As $s \in d^{*}\left(s_{0}, u^{\prime} r\right)$ for some $s \in S$ there must be a state $s^{\prime} \in d^{*}\left(s_{0}, u^{\prime}\right)$ such that ${ }_{S}^{P} \in d\left(s^{\prime}, r\right)$. Hence, by induction hypothesis, one gets $\left(1 \cdot[G] \underset{P}{\stackrel{k}{\longrightarrow}} 1 \cdot\left[G^{\prime \prime}\right], G^{\prime \prime}, s^{\prime}\right)$, and by Construction 11 , this yields the configuration $\left(1 \cdot[G] \underset{P}{k} 1 \cdot\left[G^{\prime \prime}\right] \underset{P}{\Longrightarrow} 1 \cdot\left[G^{\prime}\right], G^{\prime}, s\right)$.

## 6 Adleman's experiment

Adleman's famous and seminal experiment (Adleman 1994) can be mimicked by means of graph multiset transformation illustrating how the experiment inspired the presented approach.

Consider some simple directed graph $G=(V, E)$ with a finite set of nodes $V$ and a set of edges $E \subseteq V \times V$ as well as two distinguished nodes begin and end.

Let $s(v)=l(v) r(v) \in\{A, T, C, G\}^{*}$ be a single-stranded DNA sequence for each $v \in V$ so that the lengths of all $l(v)$ and $r(v)$ are equal and the left and right sections identify the nodes, i.e., $v \neq v^{\prime}$ implies $l(v) \neq l\left(v^{\prime}\right)$ and $r(v) \neq r\left(v^{\prime}\right)$. Moreover, let $X(v)$ and $\overline{X(v)}$ be two extra symbols for each $v \in V$ so that all of them are pairwise different.

rules:

Fig. 10 The graph transformation unit $H P(G)$

Then $G$ induces a graph transformation unit $H P(G)$ that computes the Hamiltonian paths from begin to end in $G$ by graph multiset transformation (see Fig. 10)

If $w \in\{A, T, C, G\}^{*}$, then $\bar{w}$ denotes the Watson-Crick complement. A graph of the form

represents the double strand $\left[\begin{array}{l}w \\ \bar{w}\end{array}\right]$. Starting with the initial graph, the rules of type edge and type node can be applied alternatively provided that there is a proper edge in $E$ in the case of edge-rules. Every graph derived in this way, contains exactly one edge with an extra symbol which guides the choice of applicable rules. If this extra symbol is $X($ end $)$, then the stop-rule may be applied. A derivation of this kind is depicted in Fig. 11.

The edge-rules are applicable if $\left(\right.$ begin,$\left.v_{1}\right),\left(v_{i}, v_{i+1}\right),\left(v_{n}\right.$, end $) \in E$ for $i=1, \ldots, n-1$ meaning that the derived graph represents the path beginv $v_{1} \ldots v_{n} e n d$ in $G$. This is a Hamiltonian path if the label $l(v)$ occurs exactly once in the derived graph for each $v \in V$. In other words, the derived graph represents a Hamiltonian path from begin to end in $G$ if and only if it is terminal.

Consequently, starting with a large number of initial graphs, one can detect Hamiltonian paths in $G$ with high probability employing graph multiset transformation.

Fig. 11 A derivation of $H P(G)$
Each graph in Fig. 11 except the last graph contains a single edge labeled with an extra symbol which forms a triangle with an overhanging sticky end:

Each rule application removes the diagonal edge and completes the sticky end into a double strand according to the Watson-Crick-complementarity. The resulting graph corresponds to the double-stranded DNA molecule

$$
\left[\begin{array}{lllll}
\frac{s(\text { begin })}{s(\text { begin })} & \frac{s\left(v_{1}\right)}{s\left(v_{1}\right)} & \cdots & \frac{s\left(v_{n}\right)}{s\left(v_{n}\right)} & \frac{s(\text { end })}{s(\text { end })}
\end{array}\right]
$$

In his experiment, Adleman created very similar molecules out of small pieces that correspond to right-hand sides of the rules above. Then he selected those molecules that contained the strands $s(v)$ for each $v \in V$ and had the proper lengths so that no $s(v)$ could occur twice. Therefore, the selection of the molecules that represent Hamiltonian paths in the experiment is quite similar to the termination condition above.

## 7 Exhaustive computations

A polynomial graph transformation unit $t u=(I, P, C, T)$ solves a decision problem by means of graph multiset transformation in a polynomial number of steps with a high probability if the multiplicity of the initial graph is large. It does not provide an exact solution because there is no guarantee that an existing permitted derivation $G \stackrel{*}{\Longrightarrow} \bar{G}$ with $G \in \operatorname{SEM}(I)$ and $\bar{G} \in \operatorname{SEM}(T)$ belongs to the derivations underlying a computation $n \cdot[G] \stackrel{*}{\Longrightarrow} \bar{M}$. This may be seen as a drawback which can be resolved by means of exhaustive computations that cover all derivations and all their prefixes up to a given length.
Definition 13 A graph multiset derivation $n \cdot[G] \stackrel{k}{\Longrightarrow} \bar{M}$ for some $k, n \in \mathbb{N}$ is exhaustive if each derivation $G \stackrel{l}{\Longrightarrow} \hat{G}$ with $l \leq k$ is an initial section of an underlying derivation, meaning that there is a derivation $\hat{G} \xlongequal{*} \bar{G}$ with $G \stackrel{l}{\Longrightarrow} \hat{G} \stackrel{*}{\Longrightarrow} \bar{G} \in \operatorname{MoD}(n \cdot[G] \stackrel{k}{\Longrightarrow} \bar{M})$.

As the following construction shows, exhaustive derivations exist for every length, but the initial multiplicity must be chosen large enough to cover all derivations up to the given length. In the construction, the multiplicity grows exponentially with the length if the rule application is not deterministic. If the underlying transformation unit is terminating, then the exhaustive derivation of the length of the termination bound (which can be prolonged by empty steps only) covers all derivations starting in the given initial graph including all successful ones. This is stated in Observation 14 and means that exhaustive derivations compute the corresponding decision problem exactly and not only with high probability.

Construction 14 Exhaustive derivations can be constructed inductively.
Induction base $:[G] \stackrel{0}{\Longrightarrow}[G]$ is an exhaustive derivation of length 0 .
Induction step: Let $n \cdot[G] \Longrightarrow \bar{M}$ be an exhaustive derivation of length $k$ which exists by induction hypothesis. Let max be the maximum number of direct derivations starting in some $\bar{G} \in \operatorname{car}(\bar{M})$. Let $\max \cdot n \cdot[G] \stackrel{k}{\Longrightarrow} \max \cdot \bar{M}$ be obtained from $n \cdot[G] \stackrel{k}{\Longrightarrow} \bar{M}$ by copying every rule application max times. Then there are max copies of $\bar{G}$ in $\max \cdot \bar{M}$ for each $\bar{G} \in \operatorname{car}(\bar{M})$ so that all direct derivations starting in $\bar{G}$ can be constructed. This defines an exhaustive derivation $\max \cdot n \cdot[G] \stackrel{k}{\Longrightarrow} \max \cdot \bar{M} \Longrightarrow \hat{M}$ of length $k+1$.

Observation 15 Let $t u=(I, P, C, T)$ be a terminating transformation unit with termination bound $b: S E M(I) \rightarrow \mathbb{N}$ and $\operatorname{SEM}(T) \subseteq \operatorname{reduced}(P)$. Let $n \cdot[G] \underset{P}{b(G)} \bar{M}$ for some
$n \in \mathbb{N}$ be an exhaustive graph multiset derivation with $\operatorname{car}(\bar{M}) \subseteq \operatorname{reduced}(P)$. Let $G \underset{P}{*} \bar{G}$ with $\bar{G} \in \operatorname{SEM}(T)$ be permitted by $C$. Then $G \underset{P}{*} \bar{G} \in \operatorname{MoD}(n \cdot[G] \underset{P}{\stackrel{b(G)}{\longrightarrow}} \bar{M})$.
Proof Consider $G \underset{P}{l} \bar{G}$ such that $\bar{G} \in \operatorname{SEM}(T)$ and $G \xlongequal{l} \bar{G}$ is permitted by $C$. Then $l \leq b(G)$ and by definition, there is a derivation $\bar{G} \underset{P}{*} G^{\prime}$ such that $G \underset{P}{l}$ $\bar{G} \underset{P}{\stackrel{*}{\Longrightarrow}} G^{\prime} \in \operatorname{MoD}(n \cdot[G] \underset{P}{\stackrel{b(G)}{\Longrightarrow}} \bar{M})$. By assumption one knows that $\bar{G} \in \operatorname{SEM}(T) \subseteq$ $\operatorname{reduced}(P)$ so that $\left(\bar{G} \underset{P}{*} G^{\prime}\right)=\left(\bar{G} \underset{P}{0} G^{\prime}\right)$. Therefore, $G \underset{P}{*} \bar{G} \in \operatorname{MoD}(n \cdot[G] \underset{P}{\stackrel{b(G)}{\Longrightarrow}} \bar{M})$. $\square$

The crucial part of Construction 14 is the copying of graphs which would be awfully inefficient if done in a sequential way. But if one assumes to have some copying mechanism for multisets of graphs that works like the polymerase chain reaction for DNA molecules, then one could duplicate a multiset of graphs in linear time and therefore multiply efficiently. A copying of this kind could be achieved by a DNA simulation of graph multiset transformation, for instance (cf. Point 6 of the conclusion).

Example 8 Figure 6 in Example 5 of Sect. 5 represents the full derivation process starting in $G_{0}$ that obeys the control condition start; run*. The derivation would become exhaustive if all possibilities would be added to apply the rule start more that once. The derivation length is bounded by the number of nodes of the initial graph, and the reduced graphs contain a terminal graph if and only if the initial graph contains a Hamiltonian path. In other words, the exhaustive derivations of maximum lengths solve the Hamiltonian path problem in a linear number of steps.

## 8 Conclusion

In this paper, we have proposed graph multiset transformation as a novel framework for the modeling and computation of graph algorithms and decision problems on graphs in particular. The basic idea is to apply rules to various graphs in a multiset simultaneously in a single computational step. In particular, $N P$-problems can be solved polynomially by graph multiset transformation employing exhaustive derivations. A result like this is typical for and should be expected of a computational model with massive parallelism.

We are convinced that future investigations will emphasize the significance of this approach.

1. Graph multiset transformation may be compared with other types of parallelism within and beyond graph transformation.
2. In particular, one may relate graph multiset transformation with the underlying graph transformation because parallelism is provided in this approach in an elegant way by considering disjoint unions of rules as parallel rules. As they are also ordinary rules, they can be applied in exactly the same way as introduced in Sect. 2 Therefore, a derivation step of a multiset of graphs can be simulated by taking the disjoint union of all graphs in the multiset as host graph and applying the parallel rule of all applied rules to it. But doing this, one is faced with two problems: All known matching algorithms are exponential if the sizes of left-hand sides are not bounded so that one looses the direct correspondence to the class $N P$. Moreover, the relation is not easily conversed because a host graph does not know about its component graphs and a
parallel rule application does not automatically respect that at most one atomic rule is applied to a component graph. One would need some extra information about the component graphs that form the multiset. It may be meaningful to work this out.
3. In the introduction, we refer to genetic algorithms as one of our sources of inspiration for graph multiset transformation. A genetic algorithm transforms "populations of individuals" by means of operations like "mutation" and "crossover". While mutation relates quite nicely to rule application in our approach, there is not yet a proper counterpart of crossover which recombines two individuals (and does not only change one). But this could be achieved by allowing rules that cut graphs into parts on one hand and merge parts together on the other hand. Such rule applications on graph multisets seems to be an interesting topic of future research. It would also yield possibilities to cover further DNA operations such as splicing.
4. Graph multiset transformation may be used like genetic algorithms as a heuristic approach. This would mean to start with a comparatively small multiplicity of initial graphs and to employ more sophisticated control conditions to improve the chances of successful computations.
5. The example of the Hamiltonian path problem indicates that simple graph transformation units and their evaluation by graph multiset transformation provides a quite natural way to model graph problems and their solutions. Further case studies can strengthen this view.
6. As pointed out in the Introduction, graph multiset transformation is inspired by Adleman's experiment, in which he solved the Hamiltonian path problem by means of DNA computing in the proper sense using DNA molecules and their reaction with each other. Similarly, it may be possible to translate graph multiset transformation into DNA computing and implement it by a massively parallel machinery in this way.
7. Because of the close relation to genetic algorithms and DNA computing, graph multiset transformation is potentially applicable wherever these both are useful.

## Appendix

This appendix recalls the notions and notations of multisets used in the paper.

1. Let $X$ be a set. Then a multiset (over $X$ ) is a mapping $M: X \rightarrow \mathbb{N}$, where $M(x)$ is the multiplicity of $x$ in $M$.
2. The carrier of $M$ contains all elements of $X$ with positive multiplicity, i.e.

$$
\operatorname{car}(M)=\{x \in X \mid M(x)>0\} .
$$

3. A multiset is finite if its carrier is a finite set.
4. Let $M$ and $M^{\prime}$ be multisets. Then $M^{\prime}$ is a sub-multiset of $M$, denoted by $M^{\prime} \leq M$, if $M^{\prime}(x) \leq M(x)$ for all $x \in X$.
5. Let $M$ and $M^{\prime}$ be multisets. Then the sum (difference) of $M$ and $M^{\prime}$ is the multiset defined by

$$
\left(M \pm M^{\prime}\right)(x)=M(x) \pm M^{\prime}(x) \text { for all } \mathrm{x} \in \mathrm{X}
$$

Here + and - are the usual sum and difference of non-negative integers with $m-n=0$ if $m \leq n$ in particular.
6. Using the sum of multisets, the multiplication of multisets with non-negative numbers can be defined inductively for all multisets $M$ by
(i) $0 \cdot M=\mathbf{0}$ and
(ii) $\quad(k+1) \cdot M=k \cdot M+M$ for all $k \in \mathbb{N}$
where the multiset $\mathbf{0}$ is the multiset with the constant multiplicity 0 , i.e. $\mathbf{0}(x)=0$ for all $x \in X$.
7. Each sequence $w \in X^{*}$ induces a multiset $[w]$ by counting the number of occurrences of each $x$ in $w$, i.e., for all $x, y \in X$ and $w \in X^{*}$,
$-\quad[\lambda](x)=0$
$-\quad[y w](x)=$ if $x=y$ then $[w](x)+1$ else $[w](x)$.
8. Let $M$ be a finite multiset. Then the set of all sequences $w$ with $[w]=M$ is denoted by $\operatorname{Perm}(M)$. An element of $\operatorname{Perm}(M)$ is called a sequential representation of $M$. Note that $\operatorname{Perm}(M)$ contains all permutations of $w$ if $[w]=M$.
9. The set of multisets over $X$ as well as the set of finite multisets over $X$ give rise to a commutative monoid with the multiset $\mathbf{0}$ as null and the sum as inner composition. Moreover, the set of finite sultisets over $X$ is generated by the singletons $[x]$ for all $x \in X$ so that the finite multisets are characterized as the free commutative monoid over $X$.
