# GUC-Secure Set-Intersection Computation 

Yuan Tian ${ }^{1} \quad$ Ying Wang ${ }^{2}$<br>Software School of Dalian University of Technology, Dalian, Liaoning, 116620<br>${ }^{1}$ tianyuan_ca@sina.com ${ }^{2}$ wangying@dlut.edu.cn

#### Abstract

Secure set-intersection computation is one of important problems in secure multiparty computation with various applications. We propose a general construction for secure 2-party set-intersection computation based-on anonymous IBE (identity-based encryption) scheme and its user private-keys blind generation techniques. Compared with related works, this construction is provably GUC(generalized universally composable) secure in standard model with acceptable efficiency. In addition, an efficient instantiation based-on the anonymous Boyen-Waters IBE scheme is presented which user private-key's blind generation protocol may be of independent values.

Keywords: Secure Multiparty Computation; Secure Set-Intersection Computation; Anonymous Identity-based Encryption; Generalized Universally Composable Security.

## 1 INTRODUCTION

Secure set-intersection computation is one of important problems in the field of secure multiparty computation with valuable applications in, e.g., secure keyword searching, pattern matching, private database processing, etc. In secure set-intersection computation, participants with their own private datasets get the intersection of all their private sets and nothing more(except for each private set's cardinality). In this paper, like most recent works, we focus on the 2-party case and make an efficient GUC-secure, standard model protocol for it.

Much work has been done in designing solutions to secure computation for different cryptographic functions, but only few are about this special problem among which [8,11-12] are most relevant to this paper. They are heuristic and valuable works on secure set-intersection computation published most recently, each using different techniques and security concepts and most of them(except [12]) mainly dealing with the 2-party case. However, none reaches Canetti's UC/GUC security[4-6]. In [8] Freedman et al present provably-secure and efficient protocols for this problem against semi-honest and malicious adversaries respectively based-on polynomial interpolation and homomorphic encryption schemes. The solution against malicious adversaries assumes the random oracle model. [12] solves this problem (and more, e.g., union and element reduction operations) via smartly exploiting mathematical properties of polynomials and has fully-simulatable security [10] so that their solution is securely composable(but the concept of fully-simulatable security is strictly weaker than Canetti's UC/GUC security proposed in [4-5]). In addition, as indicated by [11], [12] executes lots of zero-knowledge proofs of knowledge most of which are known how to efficiently realize but not all. Most recently [11] proposes solutions to this problem via oblivious pseudorandom function evaluation techniques. They work in two relaxed adversary models to achieve security of "half-simulatability" and "full-simulatability
against covert adversaries"[1]. At the price of relaxation in security, the protocols in [11] are highly efficient, so these solutions can be considered as practical and reasonable compromise between security and efficiency.

In this paper we construct a protocol for secure set-intersection computation in standard model which is efficient and GUC-secure. Like most previous works, we focus on the 2-party case, however, there are substantial differences between our solution and the others. Technically, our construction is based-on the anonymous IBE scheme and it's user private-key's blind generation techniques(i.e., to generate the correct user private-key usk $(a)=\operatorname{UKG}(m s k, a)$ for a user without leaking the user-id $a$ to the key-generator). The protocol's high-level description is simple: let $\Pi=($ Setup,UKG,E,D) be an IBE scheme, $\mathrm{M}_{0}$ be a publicly-known plaintext, $\mathrm{P}_{1}$ owns (for example) $\mathrm{X}_{1}=\left\{x_{1}, x_{2}, x_{3}, x_{4}\right\}$ and $\mathrm{P}_{2}$ owns $\mathrm{X}_{2}=\left\{x_{1}, x_{2}, x_{5}, x_{6}\right\}$. Let $\mathrm{P}_{1}$ generate IBE's master public/secret-key ( $m p k, m s k$ ), send $m p k$ and all $y_{i}=\mathrm{E}\left(m p k, x_{i}, M_{0}\right)(\mathrm{i}=1,2,3,4)$ to $\mathrm{P}_{2}$. When $\mathrm{P}_{2}$ tries to decipher each $y_{i}$ by private-keys $\operatorname{usk}\left(x_{1}\right)$, usk $\left(x_{2}\right)$, $u s k\left(x_{5}\right)$ and $u s k\left(x_{6}\right)$ (obtained via $\Pi$ 's user private-keys blind generation protocol), only $u s k\left(x_{1}\right)$ and $\operatorname{usk}\left(x_{2}\right)$ can succeed in obtaining $M_{0}$. As a result, $\mathrm{X}_{1} \cap \mathrm{X}_{2}=\left\{x_{1}, x_{2}\right\}$. In addition, $\Pi$ 's anonymity prevents $P_{2}$ from knowing anything about $X_{1} \backslash X_{2}=\left\{x_{3}, x_{4}\right\}$ through $y_{3}, y_{4}$. (Interestingly, this approach doesn't require IBE's (IND_CPA) data-privacy so its efficiency may be further improved if we can get some "anonymous(key-private) but not data-private" IBE scheme). The same approach can be even further used to solve the conditional intersection computation problem via ABE(attribute-based encryption) scheme recently proposed by Waters et al.

To be GUC-secure, the formal construction is more involved and presented in section 3. It is constant-round in communications and linear-size in message-complexity(close to [8,11]). In computation-complexity, one party is $\mathrm{O}\left(\mathrm{N}_{1}+\mathrm{N}_{2}\right)$ (close to $[8,11]$ ) and the other is $\mathrm{O}\left(\mathrm{N}_{1} \mathrm{~N}_{2}\right)$ ( close to [12]) where $\mathrm{N}_{1}, \mathrm{~N}_{2}$ are each party's private set's cardinality. It is well-modularized, only executing few zero-knowledge proofs of knowledge which can be efficiently instantiated. Most importantly and distinctively, our construction reaches Canetti's GUC-security: it is GUC-secure against malicious adversaries assuming static corruptions in the ACRS(augmented common reference string) model [5]. For this goal we introduce a notion of identity-augmented non-malleable zero-knowledge proofs of knowledge which may be of independent values. In addition, our construction can be also enhanced to be GUC-secure against malicious adversaries assuming adaptive corruptions in erasure model.

## 2 NOTATIONS, DEFINITIONS AND TOOLS

P.P.T. means "probabilistic polynomial-time", $x \| y$ means string $x$ and $y$ in concatenation, $|x|$ means string $x$ 's size(in bits) and $|\mathrm{X}|\left(\mathrm{X}\right.$ is a set) means X 's cardinality, $x \leftarrow^{\$} \mathrm{X}$ means randomly selecting $x$ from the domain $\mathrm{X} . k$ denotes the complexity parameter. $\approx^{\mathrm{PPT}}$ stands for computational indistinguishability and $\approx$ for perfect indistinguishability.

### 2.1 Secure Set-Intersection Computation and Its GUC Security

Briefly speaking, GUC-security means that any adversary attacking the real-world protocol can be efficiently simulated by an adversary attacking the ideal-world functionality, both have the outputs indistinguishable by the (malicious) environment. For space limitations, we assume the reader's
familiarity with the whole theory in [4-6] and only provide necessary descriptions with respect to the secure set-intersection computation problem here.

Similar to most previous works, we only focus on the unidirectional 2-party scenario. Such ideal cryptographic functionality for set-intersection computation is defined as

$$
F_{\mathrm{INT}}:\left(\mathrm{X}_{1}, \mathrm{X}_{2}\right) \rightarrow\left(\left|\mathrm{X}_{2}\right|,\left|\mathrm{X}_{1}\right|| |\left(\mathrm{X}_{1} \cap \mathrm{X}_{2}\right)\right)
$$

The bi-directional functionality is defined as

$$
F^{*}{ }_{\mathrm{INT}}:\left(\mathrm{X}_{1}, \mathrm{X}_{2}\right) \rightarrow\left(\left|\mathrm{X}_{2}\right|| |\left(\mathrm{X}_{1} \cap \mathrm{X}_{2}\right),\left|\mathrm{X}_{1}\right|| |\left(\mathrm{X}_{1} \cap \mathrm{X}_{2}\right)\right)
$$

It's not hard to implement $F^{*}{ }_{\text {INT }}$ as a $F_{\text {INT }}$-hybrid protocol. However, unidirectional set-intersection computation per se is independently useful in practice.

Let $\mathrm{P}_{1}{ }^{*}, \mathrm{P}_{2}{ }^{*}$ be parties in ideal model with private sets $\mathrm{X}_{1}$ and $\mathrm{X}_{2}$ respectively, $\mathrm{N}_{1}=\left|\mathrm{X}_{1}\right|, \mathrm{N}_{2}=\left|\mathrm{X}_{2}\right|$, S be the adversary in ideal model. The ideal model works as follows:

On receiving message (sid,"input", $\mathrm{P}_{1}{ }^{*}, \mathrm{X}_{1}$ ) from $\mathrm{P}_{1} *, F_{\mathrm{INT}}$ records $\mathrm{X}_{1}$ and sends message (sid,"input", $\mathrm{N}_{1}$ ) to $\mathrm{P}_{2}{ }^{*}$ and S ; On receiving message (sid,"input", $\mathrm{P}_{2}{ }^{*}, \mathrm{X}_{2}$ ) from $\mathrm{P}_{2} *, F_{\mathrm{INT}}$ records $\mathrm{X}_{2}$ and sends (sid,"input", $\mathrm{N}_{2}$ ) to $\mathrm{P}_{1} *$ and S .

On receiving message (sid,"intersection", $\mathrm{P}_{2}{ }^{*}$ ) from $\mathrm{P}_{2}, F_{\text {INT }}$ responses $\mathrm{P}_{2} *$ with message (sid,"intersection", $\mathrm{X}_{1} \cap \mathrm{X}_{2}$ ).

At last $\mathrm{P}_{1} *$ outputs $\mathrm{N}_{2}, \mathrm{P}_{2} *$ outputs $\mathrm{N}_{1} \|\left(\mathrm{X}_{1} \cap \mathrm{X}_{2}\right)$.
Let $\psi$ be the real-world protocol, each party $\mathrm{P}_{i}$ of $\psi$ corresponds to an ideal-world party $\mathrm{P}_{i}{ }^{*} . A$ is the real-world adversary attacking $\psi, Z$ is the environment in which the real protocol/ideal functionality executes. According to [4-5], $Z$ is a P.P.T. machine modeling all malicious behaviors against the protocol's execution. $Z$ is empowered to provide inputs to parties and interacts with $A$ and $S$, e.g., $Z$ gives special inputs or instructions to $A / S$, collects outputs from $A / S$ to make some analysis, etc. In UC theory[4], $Z$ cannot access parties' shared functionality(such shared functionality is specified in specific protocol) while in the improved GUC theory[5] $Z$ is enhanced to do this, i.e., to provide inputs to and get outputs from the shared functionality. As a result, in GUC theory $Z$ is strictly stronger and more realistic than in UC theory.

Let output ${ }_{\mathrm{Z}}(\psi, A)$ denote the outputs (as a joint stochastic variable)from $\psi$ 's parties $\mathrm{P}_{1}, \mathrm{P}_{2}$ under Z and $A$, output $\left(F_{\text {INT }}, S\right)$ denote the similar thing under $Z$ and $S$. During the real/ideal protocol's execution, $Z$ (as an active distinguisher) interacts with $\mathrm{A} / \mathrm{S}$ and raises its final output, w.l.o.g., 0 or 1 . Such output is denoted as $Z\left(\right.$ output $\left._{\mathrm{Z}}(\psi, A), u\right)$ and $\mathrm{Z}\left(\right.$ output $\left._{\mathrm{Z}}\left(F_{\mathrm{INT}}, S\right), u\right)$ respectively, where $u$ is the auxiliary information.
Definition 2.1 (GUC security[5]) If for any P.P.T. adversary $A$ in real-world, there exists a P.P.T. adversary $S$ (called $A$ 's simulator) in ideal-world, both corrupt the same set of parties, such that for any environment $Z$ the function $\mid \mathrm{P}\left[Z\left(\operatorname{output}_{\mathrm{Z}}(\psi, A), u\right)=1\right]-\mathrm{P}\left[Z\left(\right.\right.$ output $\left.\left._{\mathrm{Z}}\left(F_{\mathrm{INT}}, S\right), u\right)=1\right] \mid$ is negligible in complexity parameter $k$ (hereafter denote this fact as output $(\psi, A) \approx{ }^{\mathrm{PPT}} \operatorname{output}_{\mathrm{Z}}\left(F_{\mathrm{INT}}, S\right)$ ), then we define that $\psi$ GUC-emulates $F_{\text {INT }}$ or say $\psi$ is GUC-secure, denoted as $\psi \rightarrow{ }^{\text {GUC }} F_{\text {INT }}$.

The most significant property of GUC-security is the universal composition theorem. Briefly speaking, given protocols $\varphi_{2}, \varphi_{1}$ and $\psi\left(\varphi_{1}\right)$ where $\psi\left(\varphi_{1}\right)$ is the so-called $\varphi_{1}$-hybrid protocol, if $\varphi_{2} \rightarrow{ }^{\mathrm{GUC}} \varphi_{1}$ then (under some technical conditions, e.g., subroutine-respecting) $\psi\left(\varphi_{2} / \varphi_{1}\right) \rightarrow{ }^{\mathrm{GUC}} \psi\left(\varphi_{1}\right)$ where $\psi\left(\varphi_{2} / \varphi_{1}\right)$ is a protocol in which every call to the subprotocol $\varphi_{1}$ is replaced with a call to $\varphi_{2}$. This guarantees that a GUC-secure protocol can be composed in any execution context while still
preserving its proved security. A similar consequence is also ture in UC theory but with some serious constraints. All details are presented in [4-5](ACRS model is defined in [5]'s sec.4, or see Appendix A in our paper).

### 2.2 IBE Scheme, Its Anonymity and Blind User-Private Key Generation Protocol

In addition to data-privacy, anonymity(key-privacy) is another valuable property for public-key encryption schemes ${ }^{[2]}$. An IBE scheme $\Pi=$ (Setup, UKG, E, D) is a group of P.P.T. algorithms, where Setup takes as input the complexity parameter $k$ to generate master public/secret-key pair ( $m p k, m s k$ ), UKG takes as input $m s k$ and user's id $a$ to generate $a$ 's user private-key $u s k(a)$; E takes ( $m p k, a, M$ ) as input where $M$ is the message plaintext to generate ciphertext $y, \mathrm{D}$ takes (mpk,usk(a),y) as input to do decryption. Altogether these algorithms satisfy the consistency property: for any $k, a$ and $M$

$$
\mathrm{P}[(m p k, m s k) \leftarrow \operatorname{Setup}(k) ; u s k(a) \leftarrow \mathrm{UKG}(m s k, a) ; y \leftarrow \mathrm{E}(m p k, a, M): \mathrm{D}(m p k, u s k(a), y)=M]=1
$$

Definition 2.2(IBE Scheme's chosen plaintext anonymity[2]) Given an IBE scheme $\Pi=$ (Setup, UKG,E,D), for any P.P.T. attacker $A=\left(A_{1}, A_{2}\right)$ consider the following experiment $\operatorname{Exp}_{\Pi, A}^{A N O}{ }^{C P A}(k)$ :

$$
\begin{aligned}
& (m p k, m s k) \leftarrow \operatorname{Setup}(k) ; \\
& \left(M^{*}, a_{0}^{*}, a_{1}^{*}, S t\right) \leftarrow A_{1}^{\mathrm{UKG}(m s k, .)}(m p k), a_{0}^{*} \neq a_{1}^{*} \\
& b \leftarrow{ }^{\$}\{0,1\} ; \\
& y^{*} \leftarrow \mathrm{E}\left(m p k, a_{b}^{*}, M^{*}\right) ; \\
& d \leftarrow A_{2} \mathrm{UKG}(m s k, .)\left(S t, y^{*}\right) ; \\
& \operatorname{output}(d \oplus b)
\end{aligned}
$$

$A$ is contrained not to query its oracle $\mathrm{UKG}(m s k,$.$) with a_{0}{ }^{*}$ and $a_{1}{ }^{*}$. Define $A d v_{\Pi, A}^{A N O}{ }_{-}^{C P A}$ as $\left|2 P\left[\operatorname{Exp}_{\Pi, A}^{A N O_{-} C P A}(k)=1\right]-1\right|$. If $A d v_{\Pi, A}^{A N O_{-} C P A}$ is negligible in $k$ for any P.P.T. $A$ then $\Pi$ is defined as anonymous against chosen plaintext attack or ANO_CPA for short. In the above, if $M^{*}, a_{0}{ }^{*}, a_{1}{ }^{*}$ are generated independent of $m p k$ then $\Pi$ is called selective ANO_CPA.

Denote $\max _{A \in P . P . T .} A d v_{\Pi, A}^{A N O_{-} C P A}(k)$ as $A d v_{\Pi}^{A N O_{-} C P A}(k)$ or $A d v_{\Pi}^{A N O_{-} C P A}(t, q)$ where $t$ is the adversary's maximum time-complexity and $q$ is the maximum number of queries for the UKG-oracle.

Now we present the ideal functionality $F_{\text {Blind-UKG }}^{\Pi}$ for an IBE scheme $\Pi$ 's user private-key blind generation(note: even IBE scheme is not anonymous such functionality still makes sense. However, in this paper only anonymous IBE's such protocol is needed). In the ideal model, one party generates(just one time) $\Pi$ 's master public/secret-key pair ( $m p k, m s k$ ) and submits it to $F_{\text {Blind-UKG ; }}^{\Pi} F_{\text {Blind-UKG }}$ generates $u s k(a)=\mathrm{UKG}(m s k, a)$ for another party who submits its private input $a$ (this computation can take place any times and each time for a new $a$ ), revealing nothing about $a$ to the party who provides ( $m p k, m s k$ ) except how many private-keys are generated. Formally, let $S$ be the ideal adversary, $\mathrm{P}_{1}{ }^{*}$, $\mathrm{P}_{2}{ }^{*}$ the ideal party, sid and ssid the session-id and subsession-id respectively, the ideal model works as follows:
$\mathrm{P}_{1} *$ selects randomness $\rho$ and computes (mpk,msk) $\leftarrow \operatorname{Setup}(\rho)$, sends the message (sid, $m p k\|m s k\| \rho$ ) to $F_{\text {Blind-UKG }}^{\Pi} ; F_{\text {Blind-UKG }}$ sends message (sid, mpk) to $\mathrm{P}_{2} *$ and $S$;

On receiving a message ( $\operatorname{sid} \| \operatorname{ssid}, a$ ) from $\mathrm{P}_{2}{ }^{*}$ (ssid and a are fresh everytime), in response $F_{\text {Blind-UKG }}^{\Pi}$ computes usk $(a) \leftarrow \mathrm{UKG}(m s k, a)$, sends the message $(\operatorname{sid} \| \operatorname{ssid}$, usk $(a))$ to $\mathrm{P}_{2}{ }^{*}$ and the message $(\operatorname{sid} \| \operatorname{ssid}, n)$ to $\mathrm{P}_{1}{ }^{*}$ and $S$, where $n$ is initialized to be 0 and
increased by 1 everytime the computation takes place.
At last, $\mathrm{P}_{1}{ }^{*}$ outputs its last $n, \mathrm{P}_{2}{ }^{*}$ outputs all its obtained usk $(a)$ 's.

## 2.3 (Identity-Augmented) Non-Malleable Zero-Knowledge Proofs of Knowledge

This subsection presents the concept of zero-knowledge proofs of knowledge following [9,13] with slight symbolic modifications. Let $L$ be a NP language, $R$ is its associated P-class binary relation. i.e., $x \in L$ iff there exists $w$ such that $R(x, w)=1$. Let $A, B$ be two machines, then $A(x ; B)_{[\sigma]}$ represents $A$ 's output due to its interactions with $B$ under a public common input $x$ and common reference string (c.r.s.) $\sigma, \operatorname{tr}_{\mathrm{A}, \mathrm{B}}(x)_{[\sigma]}$ represents the transcripts due to interactions between $A$ and $B$ under a common input $x$ and c.r.s. $\sigma$. When we emphasize $A$ 's private input, say $y$, we also use the expression $A_{y}(x ; B)_{[\sigma]}$ and $\operatorname{tr}_{\mathrm{A}(y), \mathrm{B}}(x)_{[\sigma]}$ respectively. Let $A=\left(A_{1}, A_{2}\right), B$ and $C$ be machines where $A_{1}$ can coordinate with $A_{2}$ by transferring status information to it, then ( $\left\langle B, A_{1}>,<A_{2}, C>\right.$ ) represents the interaction between $A_{1}$ and $B$, (maybe concurrently) $A_{2}$ and $C$. Due to such interactions, let $t r$ be the transcripts between $A_{2}$ and $C, u$ be the final output from $A_{2}$ and $v$ be the final output form $C$, then ( $\left\langle B, A_{1}\right\rangle,\left\langle A_{2}, C\right\rangle$ )'s output is denoted as $(u, t r, v)$.

Two transcripts $t r_{1}$ and $t r_{2}$ are matched each other, if $t r_{1}$ and $t r_{2}$ are the same message sequence(consisted of the same messages in the same order) and the only difference is that any corresponding messages are in the opposite directions.

Let $A$ be a machine, the symbol 4 represents such a machine which accepts two kinds of instructions: the first one is in the form of ("start", $i, x, w$ ) and $A$ in response starts a new instance of $A$, associates it with a unique name $i$ and provides it with public input $x$ and private input $w$; the second is in form of ("message", $, i, m$ ) and $A$ in response sends message $m$ to instance $A_{i}$ and then returns $A_{i}$ 's response to $m$.
Definition 2.3(Zero-Knowldeg Proof and Non-Malleable Zero-Knowledge Proof Protocol[9,13]) $\mathrm{ZPoK}_{\mathrm{R}}=\left(\mathrm{D}_{\text {crs }}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}\right)$ where $\operatorname{Sim}=\left(\operatorname{Sim}_{1}, \mathrm{Sim}_{2}\right)$ is a group of P.P.T. algorithms, $k$ is complexity parameter, $\mathrm{D}_{\text {crs }}$ takes $k$ as input and generates c.r.s. $\sigma$; P is called prover, takes $(\sigma, x, w)$ as input where $R(x, w)=1$ and generates a proof $\pi$; V is called verifier, takes $(\sigma, x)$ as input and generates 0 or 1 ; $\operatorname{Sim}_{1}(k)$ generates $(\sigma, s), \operatorname{Sim}_{2}$ takes $x \in L$ and $(\sigma, s)$ as input and generates the simulation. All algorithms except $\mathrm{D}_{\text {crs }}$ and $\operatorname{Sim}_{1}$ take the c.r.s. $\sigma$ as one of their inputs, so $\sigma$ is no longer explicitly included in all the following expressions unless for emphasis. Now $Z P o K_{R}$ is defined as a zero-knowledge proof protocol for relation $R$, if the following properties are all satisfied:
(1) For any $x \in L$ and $\sigma \leftarrow \mathrm{D}_{\text {crs }}$, it's always true that $\mathrm{P}\left[V(x ; P)_{[\sigma]}=1\right]=1$;
(2) For any P.P.T. algorithm $A, x \notin \mathrm{~L}$ and $\sigma \leftarrow \mathrm{D}_{c r r}$, it's always true that $\mathrm{P}\left[V(x ; A)_{[\sigma]}=1\right]=0^{1}$;
(3) For any P.P.T. algorithm $A$ which outputs 0 or 1 , let $\varepsilon$ be empty string, the function

$$
\left|\mathrm{P}\left[\sigma \leftarrow \mathrm{D}_{c r s} ; b \leftarrow A(\varepsilon ; \mathrm{P})_{[\sigma]}: b=1\right]-\mathrm{P}\left[(\sigma, \mathrm{~s}) \leftarrow \operatorname{Sim}_{1}(k) ; b \leftarrow A\left(\varepsilon ; \operatorname{Sim}_{2}(\mathrm{~s})\right)_{[\sigma]}: b=1\right]\right|
$$

 the same $s$ as one of their inputs.

The non-malleable zero-knowledge proof protocol for relation $R$ is defined as $\mathrm{NMZPo}_{\mathrm{R}}=$ $\left(\mathrm{D}_{\text {crrs }}, \mathrm{P}, \mathrm{V}, \operatorname{Sim}, \mathrm{Ext}\right)$ where $\operatorname{Sim}=\left(\operatorname{Sim}_{1}, \mathrm{Sim}_{2}\right), \mathrm{Ext}=\left(\mathrm{Ext}_{1}, \mathrm{Ext}_{2}\right)$ and $\left(\mathrm{D}_{\text {crs }}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}\right)$ is a zero-knowledge

[^0]proof protocol for relation $R$ as above, P.P.T. algorithm $\operatorname{Ext}_{1}(k)$ generates $(\sigma, s, \tau)$ and the interactive P.P.T. machine $\mathrm{Ext}_{2}$ (named as witness extractor) takes $(\sigma, \tau)$ and protocol's transcripts as its input and extracts $w$, and all the following properties hold:
(4) The distribution of the first output of $\operatorname{Sim}_{1}$ is identical to that of $\operatorname{Ext}_{1}$;
(5) For any $\tau$, the distribution of the output of V is identical to that of Ext ${ }_{2}$ 's restricted output which does not include the extracted value ( $w$ );
(6) There exists a negligible function $\eta(k)$ (named as knowledge-error function) such that for any P.P.T. algorithm $A=\left(A_{1}, A_{2}\right)$ it's true that
$\mathrm{P}\left[(\sigma, s, \tau) \leftarrow \operatorname{Ext}_{1}(k) ;(x, t r,(b, w)) \leftarrow\left(<\operatorname{Sim}_{2}(s), A_{1}>,<A_{2}, \operatorname{Ext}_{2}(\tau)>\right)_{[\sigma]}: b=1 \wedge R(x, w)=1 \wedge\right.$ tr doesn't match any transcript generated by $\operatorname{Sim}_{2}(s)$ ]
$>\mathrm{P}\left[(\sigma, s) \leftarrow \operatorname{Sim}_{1}(k) ; \quad(x, t r, b) \leftarrow\left(<\operatorname{Sim}_{2}(\mathrm{~s}), A_{1}>,<A_{2}, \mathrm{~V}>\right)_{[\sigma]}: \quad b=1 \wedge t r\right.$ doesn't match any transcript generated by $\left.\operatorname{Sim}_{2}(\mathrm{~s})\right]-\eta(k)$.

It's easy to see that $\mathrm{NMZPo}_{\mathrm{R}}$ is a zero-knowledge proof of knowledge. [9,13] developed an efficient method to derive non-malleable zero-knowledge proof protocols based-on simulation-sound tag-based commitment schemes and the so-called $\Omega$-protocols(proposed in [13]). In order to achieve GUC-security in our construction, we need to further enhance NMZPoK to the concept of identity-augmented non-malleable zero-knowldege proof protocol(IA-NMZPoK) as follows.
Definition 2.4(IA-NMZPoK Protocol for Relation $R$ ) The IA-NMZPoK Protocol for relation $R$, IA-NMZPoK ${ }_{R}=(\mathrm{D}, \operatorname{Setup}, \mathrm{UKG}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}, \mathrm{Ext})$ where $\operatorname{Sim}=\left(\operatorname{Sim}_{1}, \operatorname{Sim}_{2}\right)$ and $\mathrm{Ext}=\left(\operatorname{Ext}_{1}, \mathrm{Ext}_{2}\right)$, is a group of P.P.T. algorithms. Setup( $k$ ) generates master public/secret-key pair ( $m p k, m s k$ ), UKG( $m s k, i d$ ) generates id's private-key $u s k(i d)$ where $i d \in\{P, V\}$ (the prover's and verifier's identity). Sim ${ }_{1}$ takes $u s k(V)$ as input, Ext ${ }_{1}$ takes $u s k(P)$ as input. All algorithms except Setup take ( $m p k, \sigma$ ) as one of its inputs(so it no longer explicitly appears). The protocol has the same properties as R's NMZPoK protocol in definition 2.3.

Note that by this definition an IA-NMZPoK protocol works in ACRS model[5] which ACRS is its $m p k$. In addition, only the corrupt verifier can run $\operatorname{Sim}\left(\operatorname{Sim}_{1}\right.$ taking $u s k(V)$ as input) and only the corrupt prover can run $\operatorname{Ext}\left(\operatorname{Ext}_{1}\right.$ taking $u s k(P)$ as input). This is exactly what is required in the ACRS model. Given a relation $R$, a general and efficient construction of IA-NMZPoK protocol for $R$ is presented in Appendix D.

### 2.4 Commitment Scheme

We need the non-interactive identity-based trapdoor commitment sheme [5](IBTC for short) as another important tool in our construction.

Definition 2.5(IBTC scheme[5]) Let $k$ be complexity parameter, the non-interactive identity-based trapdoor commitment sheme $\operatorname{IBTC}=(\mathrm{D}$, Setup, UKG, Cmt , Vf, FakeCmt, FakeDmt) is a group of P.P.T. algorithms, where $\mathrm{D}(k)$ generates $i d$, $\operatorname{Setup}(k)$ generates master public/secret-key pair ( $m p k, m s k$ ), $\mathrm{UKG}(m s k, i d)$ generates $i d$ 's user private-key usk(id), $\operatorname{Cmt}(m p k, i d, M)$ generates message M's commitment/decommitment pair (cmt,dmt), $\operatorname{Vf}(m p k, i d, M, c m t, d m t)$ outputs 0 or 1 , verifying whether $c m t$ is $M$ 's commitment with respect to $i d$. These algorithms are consistant, i.e., for any $M$ :

$$
\mathrm{P}[(m p k, m s k) \leftarrow \operatorname{Setup}(k) ;(c m t, d m t) \leftarrow \operatorname{Cmt}(m p k, i d, M): \operatorname{Vf}(m p k, i d, M, c m t, d m t)=1]=1
$$

FakeCmt $(m p k, i d, u s k(i d))$ generates $(\overline{c m t}, \lambda), \operatorname{FakeDmt}(m p k, M, \lambda, \overline{c m t})$ generates $\bar{d}$ (w.l.o.g. $\lambda$ contains $i d \| u s k(i d)$ as one of its components so FakeDmt doesn't explicitly take $i d$ and $u s k(i d)$ as its input). A secure IBTC scheme has the following properties:
(1)Hiding: for any id and $M_{0}, M_{1},\left(c m t_{\mathrm{i}}, d m t_{\mathrm{i}}\right) \leftarrow \operatorname{Cmt}\left(m p k, i d, M_{\mathrm{i}}\right), \mathrm{i}=0,1$, then $c m t_{0} \approx{ }^{\text {P.P.T. }} \mathrm{cmt}_{1}$;
(2)Binding: for any P.P.T. algorithm $A$, the function $A d v_{I B T C, A}^{\text {binding }}(k) \equiv \mathrm{P}\left[(m p k, m s k) \leftarrow \operatorname{Setup}(k)\right.$; $\left(i d^{*}\right.$, $\left.c m t^{*}, M_{0}{ }^{*}, d_{0}^{*}, M_{1}^{*}, d_{1}{ }^{*}\right) \leftarrow A^{\mathrm{UKG}(m s k, .)}(m p k): A$ doesn't query oracle- $\mathrm{U}(m s k,$.$) with i d^{*} \wedge M_{0}{ }^{*} \neq M_{1}{ }^{*}$ $\left.\wedge \operatorname{Vf}\left(m p k, i d^{*}, M_{0}^{*}, c m t^{*}, d_{0}^{*}\right)=\operatorname{Vf}\left(m p k, i d^{*}, M_{1}^{*}, c m t^{*}, d_{1}^{*}\right)=1\right]$ is always negligible in $k$.
(3)Equivocability: For any P.P.T. algorithm $A=\left(A_{1}, A_{2}\right)$ the following experiment always has $\left|\mathrm{P}\left[b^{*}=b\right]-1 / 2\right|$ upper-bounded by a negligible function in $k$ :

```
\((m p k, m s k) \leftarrow \operatorname{Setup}(k) ;\)
\(\left(S t, i d^{*}, M^{*}\right) \leftarrow A_{1}(m p k, m s k) ;\)
\(u s k\left(i d^{*}\right) \leftarrow \mathrm{UKG}\left(m s k, i d^{*}\right) ;(c m t, \lambda) \leftarrow\) FakeCmt \(\left(m p k, i d^{*}, u s k\left(i d^{*}\right)\right) ;\)
\(d_{1} \leftarrow\) FakeDmt \(\left(m p k, M^{*}, \lambda, \overline{c m t}\right) ; d_{0} \leftarrow^{\$}\{0,1\}^{|d 1|} ;\)
\(b \leftarrow^{\$}\{0,1\}\);
\(b^{*} \leftarrow \mathrm{~A}_{2}\left(S t, d_{\mathrm{b}}\right) ;\)
```

Note that equivocability implies $\operatorname{P}\left[\mathrm{Vf}\left(m p k, i d^{*}, M^{*}, c m t, d_{1}{ }^{*}\right)=1\right]>1-\gamma(k)$ where $\gamma(k)$ is a negligible function in $k$. [5] presented an efficient IBTC construction and proved its security.

## 3 GENERAL CONSTRUCTION

Now we present the formal consctrution of the real-world private set-intersection computation protocol $\Psi . P_{1}$ and $P_{2}$ denote two real-world parties with private set $X_{1}=\left\{x_{1}, \ldots, x_{\mathrm{N} 1}\right\}$ and $X_{2}=\left\{y_{1}, \ldots, y_{\mathrm{N} 2}\right\}$ respectively. $\Pi=($ ESetup,UKG,E,D $)$ is a selective ANO_CPA anonymous IBE scheme, $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ is the real-world protocol for $\Pi$ 's user private-keys blind generation. IA-NMZPoK $(w: R(x, w)=1)$ denotes an IA-NMZPoK protocol for relation $R$ where $w$ is $x$ 's witness. TC $=(\mathrm{D}, \mathrm{TS}$ etup,UKG,Cmt,Vf,FakeCmt, FakeDmt) is an IBTC scheme. $\mathrm{M}_{0}$ is a (fixed) public common plaintext. $\Psi$ 's ACRS is $m p k_{\mathrm{TC}}\left\|m p k_{\Delta}\right\|$ $m p k_{\mathrm{ZK}} \| \mathrm{M}_{0}$ where $m p k_{\mathrm{TC}}, m p k_{\Delta}, m p k_{\mathrm{ZK}}$ are respectively TC 's, $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ 's and an IA-NMZPoK protocol(see below)'s master public key. $\Psi$ works as follows:
(1) $\mathrm{P}_{1}$ computes $\Pi$ 's master public/secret-key $(m p k, m s k) \longleftarrow \operatorname{ESetup}(k)$, for each $x_{i} \in \mathrm{X}_{1}\left(i=1, \ldots, \mathrm{~N}_{1}\right)$ computes ciphertext $\xi_{i} \leftarrow \mathrm{E}\left(m p k, x_{i}, M_{0} ; r_{i}\right)$ where $r_{i}$ is the independent randomness in each encryption, then computes $(c m t, d m t) \leftarrow \operatorname{Cmt}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, \xi_{1}\|\ldots\| \xi_{\mathrm{N} 1}\right)$ and sends $m p k \| c m t$ to $\mathrm{P}_{2}$.
(2) $P_{1}$ and $P_{2}$ run the protocol $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ where $P_{1}$ (as the key-generater) inputs ( $m p k, m s k$ ) and $P_{2}$ (as the key-receiver) inputs $y_{1}, \ldots, y_{\mathrm{N} 2}$ to $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$. On $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ 's completion, $P_{1}$ obtains $N_{2}$ and $P_{2}$ obtains $u s k\left(y_{1}\right), \ldots, u s k\left(y_{\mathrm{N} 2}\right)$ as the output.
(3) $\mathrm{P}_{1}$ sends $\xi_{1}\|\ldots\| \xi_{\mathrm{N} 1} \| d m t$ to $\mathrm{P}_{2}$.
(4) $\mathrm{P}_{2}$ verifies $\operatorname{Vf}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, \xi_{1}\|\ldots\| \xi_{\mathrm{N} 1}, c m t, d m t\right)=1$.
(5) $\mathrm{P}_{1}$ runs the protocol IA-NMZPoK $\left(\left(x_{i}, r_{i}\right): \xi_{i}=\mathrm{E}\left(m p k, x_{i}, M_{0} ; r_{i}\right), i=1, \ldots, \mathrm{~N}_{1}\right)$ as a prover with $\mathrm{P}_{2}$ as a verifier. On this IA-NMZPoK's completion, $\mathrm{P}_{2}$ tries to decrypt each $\xi_{i}$ by $u s k\left(y_{j}\right)$ 's it obtained in step 2 and generates the set $\mathrm{X}_{0} \leftarrow\left\{y_{j} \in \mathrm{X}_{2}\right.$ : there exists $\xi_{i}$ s.t. $\left.\mathrm{D}\left(m p k, u \operatorname{sk}\left(y_{j}\right), \xi_{i}\right)=M_{0}\right\}$.
(6) $\mathrm{P}_{1}$ outputs $\mathrm{N}_{2}$ and $\mathrm{P}_{2}$ outputs $\mathrm{X}_{0}$.

This general construction of $\Psi$ is a $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$-hybrid protocol and we require
$\Delta^{\Pi}{ }_{\text {Blind-UKG }} \rightarrow{ }^{\mathrm{GUC}} F^{\Pi}{ }_{\text {Blind-UKG }}\left(\right.$ definition 2.1). Since for each $\xi_{i}=\mathrm{E}\left(m p k, x_{i}, M_{0} ; r_{i}\right), \mathrm{D}\left(m p k, \operatorname{usk}\left(y_{j}\right), \xi_{i}\right)=M_{0}$ if and only if $x_{i}=y_{j}$ so $\mathrm{X}_{0}=\mathrm{X}_{1} \cap \mathrm{X}_{2}$, i.e., $\mathrm{P}_{2}$ outputs the correct intersection. Regarding security, because the IBE scheme $\Pi$ is (selective) anonymous, i.e., ciphertext $\xi_{i}$ hides $x_{i}$ unless $\mathrm{P}_{2}$ has the correct user private-key $u s k\left(x_{i}\right), \mathrm{P}_{2}$ knows nothing about $\mathrm{X}_{1}$ beyond $\mathrm{X}_{1} \cap \mathrm{X}_{2}$. On the other hand, $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ 's (GUC) security prevents $P_{1}$ from knowing anything about $P_{2}$ 's private set $X_{2}$.

However, merely requiring $\Delta^{\Pi}{ }_{\text {Blind-UKG }} \rightarrow{ }^{\text {GUC }} F_{\text {Blind-UKG }}^{\Pi}$ cannot guarantee $\Psi$ 's GUC-security but only "half GUC-security" instead(i.e., the real adversary $A$ corrupting $\mathrm{P}_{1}$ can be completely simulated by an ideal adversary $S$ but this is not true when $A$ corrupts $\mathrm{P}_{2}$. Only data-privacy can be proved in the latter case). In order to make the real adversary always completely simulatable in ideal-world, some additional property is required for $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$. This leads to definition 3.1 and it is not hard to verify that our concrete construction of $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ in next section really satisfies it.
Definition 3.1(IBE's User Private-keys Blind Generation Protocol with Extractor) Given IBE scheme $\Pi=\left(\right.$ ESetup,UKG,E,D) and $\Delta^{\Pi}{ }_{\text {Blind-UKG }} \rightarrow{ }^{G U C} F_{\text {Blind-UKG }}$, let $P_{1}, P_{2}$ be $\Delta^{\Pi}$ Blind-UKG 's parties where $P_{2}$ provides user-id $a$ and obtains $u \operatorname{sk}(a), \mathrm{P}_{1}$ owns msk and (blindly) gernates usk $(a)$ for $\mathrm{P}_{2}$. This $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ is defined as extractable, if there exists P.P.T. algorithm Setup ${ }_{\Delta}, \mathrm{UKG}_{\Delta}, \operatorname{Ext}_{\Delta}=\left(\operatorname{Ext}_{1}, \operatorname{Ext}_{2}\right)$ and a negligible function $\delta(k)$, called the error function, such that
(1) $\operatorname{Setup}_{\Delta}(k)$ generates the master public/secret-key pair $\left(m p k_{\Delta}, m s k_{\Delta}\right)$.
(2) $\mathrm{UKG}_{\Delta}\left(m s k_{\Delta}, i d\right)$ outputs a trapdoor $u s k_{\Delta}\left(\mathrm{P}_{2}\right)$ when $i d=\mathrm{P}_{2}$ (key-receiver's identity) and outputs nothing otherwise.
(3) for any user-id $a$, honest $\mathrm{P}_{1}$ and any P.P.T. algorithm $A$, it is true that(via notations in subsection 2.3) $\operatorname{Ext}_{1}\left(u s k\left(\mathrm{P}_{2}\right)\right)$ outputs $(\sigma, \tau)$ such that

$$
\mathrm{P}\left[\operatorname{Ext}_{2}(m p k| | \tau ; A(a))_{[\sigma]}=a\right]>\mathrm{P}\left[A_{a}\left(m p k ; P_{1}(m p k, m s k)\right)_{[\sigma]}=\mathrm{UKG}(m s k, a)\right]-\delta(k)
$$

where ( $m p k, m s k$ ) is $\Pi$ 's master public/secret-key owned by $\mathrm{P}_{1}$ ( $m p k$ is published).
We stress that all extractors in definition 2.3 and definition 3.1 are non-rewinding.
Combining all the instantiations of subprotocols in this general construction(some presented in next section and Appendix D), it's easy to see that we can get a $\mathrm{O}(1)$ and $\mathrm{O}\left(\mathrm{N}_{1}+\mathrm{N}_{2}\right)$ message-complexity solution. Furthermore $\mathrm{P}_{1}, \mathrm{P}_{2}$ has computation-complexity of $\mathrm{O}\left(\mathrm{N}_{1}+\mathrm{N}_{2}\right)$ and $\mathrm{O}\left(\mathrm{N}_{1} \mathrm{~N}_{2}\right)$ encryptions/decryptions repectively. The exact efficiency analysis can only be done for specific instantiation (e.g., that presented in next section) which is provided in the full version paper. The formal security consequence is the following theorem which proof is in Appendix B.

Theorem 3.1 Suppose that $\Pi=(E S e t u p, U K G, E, D)$ is a selective ANO_CPA anonymous IBE scheme, $\Delta^{\Pi}{ }_{\text {Blind-UKG }} \rightarrow{ }^{\text {GUC }} F_{\text {Blind-UKG }}^{\Pi}$ with extractor $\operatorname{Ext}_{\Pi}=\left(\operatorname{Ext}_{\Pi, 1}, \operatorname{Ext}_{\Pi, 2}\right)$ and error function $\delta$ as in def.3.1, $\operatorname{IA}-\operatorname{NMZPoK}\left(\left(x_{i}, r_{i}\right): \xi_{i}=\mathrm{E}\left(m p k, x_{i}, M_{0} ; r_{i}\right), i=1, \ldots, \mathrm{~N}_{1}\right)$ is an IA-NMZPoK protocol, $\mathrm{TC}=(\mathrm{D}, \mathrm{TS}$ etup,UKG, Cmt,Vf,FakeCmt,FakeDmt) is an IBTC scheme, then $\Psi \rightarrow{ }^{\text {GUC }} F_{\text {INT }}$ assuming static corruptions.

## 4 AN INSTANTIATION VIA BOYEN-WATERS IBE SCHEME

Theorem 3.1 presents security conditions for the general construction $\Psi$, among which some are available in existing works, e.g., the commitment scheme can be directly borrowed from [5]. The subprotocols which require new efficient constructions are only IBE scheme's user private-keys generation protocol and the protocol IA-NMZPoK $\left((a, r): \xi=\mathrm{E}\left(m p k, a, M_{0} ; r\right)\right)$. In this section we present an efficient instantiation of $\Psi$ via Boyen-Waters IBE scheme. All related zero-knowledge protocols’
constructions are presented in Appendix D.

### 4.1 Boyen-Waters IBE ${ }^{[3]}$

Given an bilinear group pairing ensemble $\mathrm{J}=\left\{\left(\mathrm{p}, \mathrm{G}_{1}, \mathrm{G}_{2}, e\right)\right\}_{k}$ where $\left|\mathrm{G}_{1}\right|=\left|\mathrm{G}_{2}\right|=p, p$ is $k$-bit prime number, $\mathrm{P} \in \mathrm{G}_{1}, e: \mathrm{G}_{1} \times \mathrm{G}_{1} \rightarrow \mathrm{G}_{2}$ is a non-degenerate pairing, Boyen-Waters IBE consists of
$\operatorname{ESetup}(k)$ :

$$
g, g_{0}, g_{1} \leftarrow{ }^{\$} \mathrm{G}_{1} ; \omega, t_{1}, t_{2}, t_{3}, t_{4} \leftarrow{ }^{\$} Z_{\mathrm{p}} ; \Omega \leftarrow e(g, g)^{t_{1} t_{2} \omega} ;
$$

$$
v_{1} \leftarrow g^{t 1} ; v_{2} \leftarrow g^{t 2} ; v_{3} \leftarrow g^{t 3} ; v_{4} \leftarrow g^{t 4}
$$

$$
m p k \leftarrow\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega, g, g_{0}, g_{1}, v_{1}, v_{2}, v_{3}, v_{4}\right)
$$

$$
m s k \leftarrow\left(\omega, t_{1}, t_{2}, t_{3}, t_{4}\right) ;
$$

return ( $m p k, m s k$ );
$\mathrm{UKG}(m s k, a), a \in Z_{\mathrm{p}}$ :
$r_{1}, r_{2} \leftarrow{ }^{\$} Z_{\mathrm{p}} ;$
$u s k(a) \leftarrow\left(g^{r_{1} t_{1} t_{2}+r_{2} t_{3} t_{4}}, g^{-\sigma t_{2}}\left(g_{0} g_{1}^{a}\right)^{-r_{1} t_{2}}, g^{-\sigma t_{1}}\left(g_{0} g_{1}^{a}\right)^{-r_{1} t_{1}},\left(g_{0} g_{1}^{a}\right)^{-r_{2} t_{4}},\left(g_{0} g_{1}^{a}\right)^{-r_{2} t_{3}}\right) ;$ return(usk(a));
The encryption/decryption algorithm is omitted here and completely presented in Appendix D..
[3] has proven that assuming the decisional bilinear Diffie-Hellman problem(D-BDHP)'s hardness on J, this scheme is IND_CPA secure (data-private); assuming the decisional linear problem(D-LP)'s hardness, this scheme is selective ANO_CPA anonymous. Notice that D-BDHP hardness implies D-LP's hardness, all the above consequences can be also obtained only under D-BDHP's hardness.

### 4.2 User Private-Keys Blind Generation Protocol $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ and Its GUC-Security

For simplicity we only present how to blindly generate $\operatorname{usk}(a)$ for a single user-id $a$. The generalization to blindly generating $u \operatorname{sk}\left(a_{1}\right)\|\ldots\| u s k\left(a_{\mathrm{N}}\right)$ for multiple user-id's $a_{1}\|\ldots.\| a_{\mathrm{N}}$ is trival and still constant-round, though the total message-complexity is linearly increased.

The two parties are $\mathrm{P}_{1}$ (with private input $m s k$ ) and $\mathrm{P}_{2}$ (with private input $a$ ). Both parties have the common input $m p k$ where ( $m p k, m s k$ ) are generated by IBE scheme's ESetup( $k$ ) (usually $m s k$ per se is the randomness in ESetup so we use a simplified notation $m p k \leftarrow E \operatorname{Eetup}(m s k)$ hereafter). $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ has two IA-NMZPoK subprotocols (see below) which ACRS's are denoted as $m p k_{\mathrm{ZK}, \mathrm{II}}$ and $m p k_{\mathrm{ZK}, \mathrm{III}}$. $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ is in ACRS model which ACRS is $m p k_{\mathrm{ZK}, \mathrm{II}} \| m p k_{\mathrm{ZK}, \mathrm{III}} . \Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ works as follows: (1) $\mathrm{P}_{1}$ runs a protocol IA-NMZPoK ( $m s k$ : $m p k=\operatorname{ESetup}(m s k)$ ) as a prover with $\mathrm{P}_{2}$ as a verifier, where the meaning of the notation IA-NMZPoK ( $m s k$ : $m p k=\operatorname{ESetup}(m s k)$ ) follows section 3. Denote this protocol as IA-NMZPoK ${ }_{\text {II }}$.
(2) $\mathrm{P}_{2}$ selects $r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}$ at random, computes $U_{i} \leftarrow g^{r_{i}}, V_{i} \leftarrow\left(g_{0} g_{1}^{a}\right)^{-r_{i}}$ for $i=1,2$ and $h_{j} \leftarrow g^{y_{j}} g_{1}^{a}$ for $j=1,2,3,4$, sends $U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4}$ to $\mathrm{P}_{1}$. Then $\mathrm{P}_{2}$ runs the protocol

$$
\operatorname{IA}-\operatorname{NMZPoK}\left(\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{\mathrm{i}}=g^{r_{i}} \wedge_{\mathrm{i}=1,2} V_{\mathrm{i}}=\left(g_{0} g_{1}^{a}\right)^{-r_{i}} \wedge_{\mathrm{j}=1,2,3,4} h_{\mathrm{j}}=g^{y_{j}} g_{1}^{a}\right)
$$

as a prover with $\mathrm{P}_{1}$ as a verifier. Denote this protocol as IA-NMZPoK ${ }_{\text {III }}$.
(3) $\mathrm{P}_{1}$ selects $\sigma, r_{1}^{\prime}, r_{2}^{\prime}$ at random, computes $d_{0} \leftarrow\left(g^{r_{1}^{\prime}} U_{1}^{\sigma}\right)^{t_{1} t_{2}}\left(g^{r_{2}^{\prime}} U_{2}^{\sigma}\right)^{t_{3} t_{4}} ; d_{1}^{\prime} \leftarrow g^{-\sigma t_{2}}\left(h_{1} g_{0}\right)^{-r_{1}^{\prime} t_{2}} V_{1}^{\sigma t_{2}}$; $d_{1} " \leftarrow g^{r_{1} t_{2}} ; \quad d_{2}^{\prime} \leftarrow g^{-\sigma t_{1}}\left(h_{2} g_{0}\right)^{-r_{1}^{\prime} t_{1}} V_{1}^{\sigma t_{1}} ; d_{2} " \leftarrow g^{r_{1} t_{1}} ; d_{3} \leftarrow\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}} V_{2}^{\sigma t_{4}} ; d_{3}{ }^{\prime \prime} \leftarrow g^{r_{2} t_{4}} ;$
$d_{4}{ }^{\prime} \leftarrow\left(h_{4} g_{0}\right)^{-r_{2}^{\prime} t_{3}} V_{2}^{\sigma t_{3}} ; d_{4}{ }^{\prime \prime} \leftarrow g^{r_{2} t_{3}}$ and sends $d_{0}| | d_{1}{ }^{\prime}| | d_{1} "| | d_{2^{\prime}}| | d_{2}{ }^{\prime \prime}| | d_{3}^{\prime}| | d_{3} "| | d_{4}{ }^{\prime}| | d_{4} "$ to $\mathrm{P}_{2}$.
(4) $\mathrm{P}_{2}$ computes $d_{j} \leftarrow d_{j}^{\prime} d_{j}^{" y_{j}}, j=1,2,3,4$ and outputs $\left(d_{0}, d_{1}, d_{2}, d_{3}, d_{4}\right)$.

It's easy to show by direct calculation that $\mathrm{P}_{2}$ outputs the correct $u s k(a)=\left(d_{0}, d_{1}, d_{2}, d_{3}, d_{4}\right)$ where $d_{0}$ $=g^{\left(r_{1}{ }^{\prime}+r_{1} \sigma\right) t_{1} t_{2}+\left(r_{2}{ }^{\prime}+r_{2} \sigma\right) t_{3} t_{4}}, \quad d_{1}=g^{-\sigma t_{2}}\left(g_{0} g_{1}^{a}\right)^{-\left(r_{1}{ }^{\prime}+r_{1} \sigma\right) t_{2}}, \quad d_{2}=g^{-\sigma t_{1}}\left(g_{0} g_{1}^{a}\right)^{-\left(r_{1}{ }^{\prime}+r_{1} \sigma\right) t_{1}}, \quad d_{3}=$ $\left(g_{0} g_{1}{ }^{a}\right)^{-\left(r_{2}{ }^{\prime}+r_{2} \sigma\right) t_{4}}, d_{4}=\left(g_{0} g_{1}{ }^{a}\right)^{-\left(r_{2}^{\prime}{ }^{\prime}+r_{2} \sigma\right) t_{3}}$. Regarding security, we have

Theorem 4.1 Suppose the bilinear group pairing J has D-BDHP hardness, both IA-NMZPoK ${ }_{\text {II }}$ and $I A-N M Z P o K_{\text {III }}$ are identity-augmented non-malleable zero-knowledge proof protocols for specific relations described in the above, then $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }} \rightarrow{ }^{\text {GUC }} F_{\text {Blind-UKG }}^{\text {Boyn-Wats }}$ assuming static corruptions and $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }} \quad$ satisfies def. 3.1.

Appendix C includes detailed proof and Appendix D contains all related IA-NMZPoK protocols' constructions.

## APPENDIX.A ACRS MODEL

Recently [5] improves and generalizes the early UC-theory proposed in [4] to make a more general, realistic and strictly stronger security notion. The universal composition theorem is still true in this paradigm, however, the pre-setup needs to be strictly enhanced. In GUC paradigm the CRS model is insufficient to implement general cryptographic functionalities, instead we need a new pre-setup model called ACRS(augmented common reference string) model. This pre-setup can be performed via a shared functionality $\bar{G}_{\text {acrs }}^{\text {Setu }, U K G}$ with two parameter functions Setup and UKG similar to IBE scheme's master public/secret-key generator and its user private-key generator. $\bar{G}_{\text {acrs }}^{\text {Setup,UKG }}$,s program is [5]:

Initialization Phase: compute $(m p k, m s k) \leftarrow \operatorname{Setup}(k)$ and store $(m p k, m s k)$;
Running Phase: on receiving message ("CRS request", $\mathrm{P}_{i}$ ) from any party $\mathrm{P}_{i}$, response ("ACRS", mpk) to $\mathrm{P}_{i}$ and the adversary $S$;

On receiving message ("Retrieve",sid, $\mathrm{P}_{i}$ ) from a corrupt party $\mathrm{P}_{i}$, compute usk $\left(\mathrm{P}_{i}\right) \leftarrow \mathrm{UKG}\left(m s k, \mathrm{P}_{i}\right)$ and return the message ("Private-key", sid, usk $\left(\mathrm{P}_{i}\right)$ ) to $\mathrm{P}_{i}$; if $\mathrm{P}_{i}$ is not a corrupt party, response nothing.

## APPENDIX.B PROOF OF THEOREM 3.1

For intuition the protocol $\Psi$ is presented in a figure below. The IA-NMZPoK protocol's arrow points from the zero-knowledge proof's prover to itsverifier.

Now we present the proof sketch. At first it's easy to verify that $\Psi$ produces the correct intersection $\mathrm{X}_{1} \cap \mathrm{X}_{2}$ at $\mathrm{P}_{2}$. Now we prove its GUC-security in two cases that the real-world adversary $A$ corrupts $\mathrm{P}_{1}$ or $P_{2}$ respectively. Below $P_{1} *$ and $P_{2} *$ stand for $P_{1}$ and $P_{2}$ 's respective counterparts in ideal-world.

All parties are assumed to be initialized with a copy of the common reference string $A C R S$, i.e., the concatenation of TC's master public-key $m p k_{\mathrm{TC}}, \Delta^{\Pi}{ }_{\text {Blind-UKG }}$ 's $m p k_{\Delta}$, the IA-NMZPoK protocol's $m p k_{\mathrm{ZK}}$ and $M_{0}$, generated by the pre-setup $\mathrm{G}_{\text {ACRS }}$. For this $A C R S$, its $m s k=m s k_{\mathrm{TC}}\left\|m s k_{\Delta}\right\| m s k_{\mathrm{ZK}}$ and $\mathrm{UKG}(m s k, i d)$ responses with $u s k(i d)=u s k_{\mathrm{TC}}(i d)\left|u s k_{\Delta}(i d)\right| u s k_{Z K}(i d)$ where $u s k_{\mathrm{TC}}(i d), u s k_{\Delta}(i d)$ and $u^{\prime} k_{\text {ZK }}(i d)$ are respectively TC's, $\Delta^{\Pi}{ }_{\text {Blind-UKG's }}$ and the IA-NMZPoK protocol's user private-keys corresponding to $i d \in\left\{\mathrm{P}_{1}, \mathrm{P}_{2}\right\}$.
(1) $A$ corrupts $\mathrm{P}_{1}$ : for simplicity we first make the proof in $F^{\mathrm{\Pi}}{ }_{\text {Blind-UKG }}$-hybrid model and then complete the proof by generalized universal composition theorem. Let $\mathrm{X}_{1}=\left\{x_{1}{ }^{*}, \ldots, x_{\mathrm{N} 1}{ }^{*}\right\}$ be $A$ 's(i.e., $\mathrm{P}_{1}$ 's) own set, $\mathrm{X}_{2}=\left\{y_{1}{ }^{*}, \ldots, y_{\mathrm{N} 2} *\right\}$ be $\mathrm{P}_{2} *$ 's own set. We need to construct an ideal adversary $S_{1}$ who corrupts $\mathrm{P}_{1}{ }^{*}$, runs $A$ as a black-box and simulates the real-world honest party $\mathrm{P}_{2}$ to interact with $A$ :

On receiving the message (sid,"input", $\mathrm{N}_{2}$ ) from $F_{\mathrm{INT}}, S_{1}$ gets $u s k\left(\mathrm{P}_{1}\right)$ by querying the shared functionality $\mathrm{G}_{\text {ACRS }}$ with ("retrieve", $\mathrm{sid}_{\mathrm{P}} \mathrm{P}_{1}$ ) where $u s k\left(\mathrm{P}_{1}\right)=u s k_{\mathrm{TC}}\left(\mathrm{P}_{1}\right)\left\|u s k_{\Delta}\left(\mathrm{P}_{1}\right)\right\| u s k_{\mathrm{ZK}}\left(\mathrm{P}_{1}\right)$ ), computes $(\sigma, s, \tau) \leftarrow \mathrm{IA}-\mathrm{NMZPoK}:: \operatorname{Ext}_{1}\left(u s k_{Z K}\left(\mathrm{P}_{1}\right)\right)($ to avoid ambiguity, we use $\Gamma:: f$ to represent a protocol $\Gamma$ 's algorithm $f$ ), generates $\mathrm{N}_{2}$ data-items $y_{1}, \ldots, y_{\mathrm{N} 2}$ at random and then starts $A$;

After $A$ sends the first message ( $m p k \| c m t$ ), $S_{1}$ interacts with $A$ as an honest key-receiver in model of $F^{\Pi}{ }_{\text {Blind-UKG }}$ and obtains $u s k\left(y_{1}\right), \ldots, u s k\left(y_{\mathrm{N} 2}\right)$;
$S_{1}$ intercepts the message $\xi_{1}\|\ldots\| \xi_{\mathrm{N} 1} \| d m t$ sent from $A$,verifys whether $\operatorname{Vf}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, \xi_{1}\|\ldots\| \xi_{\mathrm{N} 1}\right.$, $c m t, d m t)=1$ and then participates in protocol IA-NMZPoK $\left(\left(x^{*}{ }_{i}, r_{i}\right): \xi_{i}=\mathrm{E}\left(m p k, x_{i}{ }^{*}, M_{0} ; r_{i}\right), i=1, \ldots, \mathrm{~N}_{1}\right.$ as a verifier calling the knowledge extractor IA-NMZPoK:: $\operatorname{Ext}_{2}(\tau)$ to extract the witness $\left(x_{i}{ }^{*}, r_{i}\right)$, $\mathrm{i}=1, \ldots, \mathrm{~N}_{1}$ (in fact only $x_{i}{ }^{*}$ 's are needed in this proof);
$S_{1}$ sends the message (sid,"input", $\left\{x_{1}{ }^{*}, \ldots, x^{*}{ }_{\mathrm{N} 1}\right\}$ ) to $F_{\text {INT }}$, then outputs whatever $A$ outputs to the environment.

Let $\operatorname{tr}\left(A, S_{1}\right)$ denote the transcripts due to the interaction between $S_{1}$ and $A, \operatorname{tr}^{\mu}\left(A, \mathrm{P}_{2}\left(\mathrm{X}_{2}\right)\right)$ denote the transcripts due to the interaction between $A$ and $\mathrm{P}_{2}\left(\mathrm{X}_{2}\right)$ in the real-world protocol $\Psi\left(\mathrm{P}_{2}\left(\mathrm{X}_{2}\right)\right.$ means the real-world party possessing the same private set $\mathrm{X}_{2}$ as $\mathrm{P}_{2}{ }^{*}$ ). From $A$ 's perspective, the difference between $\operatorname{tr}\left(A, S_{1}\right)$ and $\operatorname{tr}^{\mu}\left(A, \mathrm{P}_{2}\left(\mathrm{X}_{2}\right)\right)$ is that the former provides $F^{\mathrm{\Pi}}$ Blind-UKG with $\left\{y_{1}, \ldots, y_{\mathrm{N} 2}\right\}$ as the input, the latter provides $F_{\text {Blind-UKG }}$ with $\left\{y^{*}{ }_{1}, \ldots, y^{*}{ }_{\mathrm{N} 2}\right\}$, but according to $F_{\text {Blind-UKG }}$ 's specification $A$ knows nothing about what data-items are provided to $F_{\text {Blind-UKG }}$ by the other party except the number $\mathrm{N}_{2}$, as a result, $\operatorname{tr}\left(A, \mathrm{~S}_{1}\right) \approx \operatorname{tr}^{\mu}\left(A, \mathrm{P}_{2}\left(\mathrm{X}_{2}\right)\right)($ perfectly indistinguishable) from $A$ 's perspective. In particular, the distribution of $A$ 's output due to interactions with $S_{1}$ is the same as that (in real-world protocol $\Psi$ ) due to interactions with $\mathrm{P}_{2}\left(\mathrm{X}_{2}\right)$. Let $\eta$ be IA-NMZPoK protocol's error function, $A d v_{T C}^{\text {binding }}$ be attacker's advantage against TC's binding property, all are negligible functions in $k$. It's not hard to show(by contradiction) that the probability with which $S_{1}$ correctly extracts all $A$ 's data-items $x^{*}, \ldots, x^{*}{ }_{\mathrm{N} 1}$ is greater than $\mathrm{P}\left[\mathrm{P}_{2}\left(m p k\left\|\xi_{1}\right\| \ldots \| \xi_{\mathrm{N}} ; A\right)=1\right]-\mathrm{N}_{1}\left(\eta+A d v_{T C}^{\text {binding }}\right) \geq \mathrm{P}\left[\mathrm{X}_{0}=\mathrm{X}_{1} \cap \mathrm{X}_{2}\right]-\mathrm{N}_{1}\left(\eta+A d v_{T C}^{\text {binding }}\right)$, therefore, the difference between the probability with which $\mathrm{P}_{2} *\left(\mathrm{X}_{2}\right)$ outputs $\mathrm{X}_{1} \cap \mathrm{X}_{2}$ under the ideal-world adversary $S_{1}$ 's attacks and the probability with which $\mathrm{P}_{2}\left(\mathrm{X}_{2}\right)$ outputs $\mathrm{X}_{1} \cap \mathrm{X}_{2}$ under the real-world adversay $A$ 's attacks against $\Psi$ is upper-bounded by $\mathrm{N}_{1}\left(\mathfrak{\eta}^{+}+A d v_{T C}^{\text {binding }}\right)$, also a negligible function in $k$. Combining all the above facts, for any P.P.T. environment $Z$ we have output ${ }_{\mathrm{Z}}(\psi, A) \approx^{\mathrm{PPT}}$ output $_{\mathrm{Z}}\left(F_{\mathrm{INT}}\right.$,
$S_{1}$ ），i．e．，$\Psi \rightarrow{ }^{\text {GUC }} F_{\text {INT }}$ in $F_{\text {Blind－UKG }}$－hybrid model．
Now replace the ideal functionality $F_{\text {Blind－UKG }}^{\Pi}$ with $\Delta^{\Pi}{ }_{\text {Blind－UKG }}$ in $\Psi$ ．By what is just proved，the assumption $\Delta^{\Pi}{ }_{\text {Blind－UKG }} \rightarrow{ }^{\text {GUC }} F^{\Pi}{ }_{\text {Blind－UKG }}$ and the GUC－theorem，we still have the GUC－emulation consequence．In addition，it＇s not hard to estimate $S_{1}$＇s time complexity $\mathrm{T}_{S 1}=\mathrm{T}_{A}+\mathrm{O}\left(\mathrm{N}_{2}+\mathrm{N}_{1} \mathrm{~T}_{e}\right)$ where $\mathrm{T}_{A}$ and $\mathrm{T}_{e}$ are $A$＇s and the knowledge extractor＇s computation time．
（2）$A$ corrupts $\mathrm{P}_{2}$ ：Denote $A$＇s（i．e．， $\mathrm{P}_{2}$＇s）own set as $\mathrm{X}_{2}=\left\{y^{*}{ }_{1}, \ldots, y^{*}{ }_{\mathrm{N} 2}\right\}, \mathrm{P}_{1}{ }^{*}$＇s own set as $\mathrm{X}_{1}=$ $\left\{x^{*}, \ldots, x^{*}{ }_{\mathrm{N} 1}\right\}$ ，we need to construct an ideal adversary $S_{2} . S_{2}$ corrupts $\mathrm{P}_{2}{ }^{*}$ ，gets $u s k\left(\mathrm{P}_{2}\right)$ by querying the pre－setup $\mathrm{G}_{\text {ACRS }}$ with（＂retrieve＂，sid， $\mathrm{P}_{2}$ ）where $u s k\left(\mathrm{P}_{2}\right)=u s k_{\mathrm{TC}}\left(\mathrm{P}_{2}\right)\left\|u s k_{\Delta}\left(\mathrm{P}_{2}\right)\right\| u s k_{\mathrm{ZK}}\left(\mathrm{P}_{2}\right)$ ，generates $(\sigma, s) \leftarrow \mathrm{IA}-\mathrm{NMZPoK}:: \operatorname{Sim}_{1}\left(u s k_{\mathrm{ZK}}\left(\mathrm{P}_{2}\right)\right)$ ，runs $A$ as a black－box and simulates the real－world honest party $\mathrm{P}_{1}$ to interact with $A$ ：

On receiving message（sid，＂input＂， $\mathrm{N}_{1}$ ）from $F_{\text {INT }}, \mathrm{S}_{2}$ generates $x_{1}, \ldots, x_{\mathrm{N} 1}$ at random，computes $(m p k, m s k) \leftarrow \operatorname{Setup}(k)$ and $\xi_{\mathrm{i}} \leftarrow \mathrm{E}\left(m p k, x_{\mathrm{i}}, \mathrm{M}_{0} ; r_{\mathrm{i}}\right)$ for each $x_{\mathrm{i}}$ where $r_{\mathrm{i}}$ is the independent randomness in each encryption，computes $\left(c m t^{0}, \lambda\right) \leftarrow \operatorname{FakeCmt}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, u s k_{\mathrm{TC}}\left(\mathrm{P}_{2}\right)\right)$ ，starts $A$ and sends the message $m p k \| c m t^{0}$ to $A$ ；
$S_{2}$ interacts with $A$ as the user private－key generator in $\Delta^{\Pi}{ }_{\text {Blind－UKG }}$ and calls the extractor $\Delta^{\Pi}{ }_{\text {Blind－UKG }}: \operatorname{Ext}_{\Delta}\left(u s k_{\Delta}\left(\mathrm{P}_{2}\right)\right)$ to extract $y^{*}, \ldots, y^{*}{ }_{\mathrm{N} 2}$ ，sends the message（sid，＂input＂， $\mathrm{P}_{2}{ }^{*},\left\{y^{*}, \ldots, y^{*}{ }_{\mathrm{N} 2}\right\}$ ） to $F_{\text {INT }}$ ；
$S_{2}$ sends the message（sid，＂intersection＂， $\left.\mathrm{P}_{2}{ }^{*}\right)$ to $F_{\mathrm{INT}}$ and gets the response $\left\{y^{*}{ }_{j 1}, \ldots, y^{*}{ }_{j t}\right\}$（i．e．，the set－intersection）．To simplify the symbol，denote this response set as $\left\{y^{*}{ }_{1}, \ldots, y^{*} t\right.$ ．
$\mathrm{S}_{2}$ computes $\xi^{*}{ }_{\mathrm{i}} \leftarrow \mathrm{E}\left(m p k, y^{*}, M_{0} ; r^{*}{ }_{\mathrm{i}}\right)\left(r^{*}{ }_{\mathrm{i}}\right.$＇s are selected at random）for $\mathrm{i}=1, \ldots, t$ ，replaces arbitrary $t \xi_{\mathrm{i}}$＇s with $\xi_{\mathrm{i}}{ }^{*}$＇s and keeps other $\mathrm{N}_{1}-\mathrm{t} \xi_{\mathrm{i}}$＇s unchanged，making a new sequence denoted as $\xi^{\prime}{ }_{1}\|\ldots ..\| \xi{ }_{\mathrm{N} 1}$ ， computes $d m t^{0} \leftarrow \operatorname{FakeDmt}\left(m p k_{\mathrm{TC}}, \xi^{‘}{ }_{1}\|\ldots\| \xi^{〔}{ }_{\mathrm{N} 1}, \lambda, c m t^{0}\right) . S_{2}$ sends the message $\xi^{‘}{ }_{1}\left\|\ldots \xi^{〔}{ }_{\mathrm{N} 1}\right\| d m t^{0}$ to $A$ ， interacts with $A$ by calling IA－NMZPoK：$: \operatorname{Sim}_{2}\left(\xi^{‘}{ }_{1}\|\ldots\| \xi^{\prime}{ }_{\mathrm{N} 1}, s\right)$ where $\xi^{〔}=\mathrm{E}\left(m p k, x^{0}{ }_{\mathrm{i}}, M_{0} ; r^{\iota}{ }_{\mathrm{i}}\right)$ ， $\left.\mathrm{i}=1, \ldots, \mathrm{~N}_{1}\right), x^{0}{ }_{\mathrm{i}}=y^{*}{ }_{\mathrm{i}}$ for $t$ of $\mathrm{N}_{1} \mathrm{i}$＇s and $x_{\mathrm{i}}^{0}=x_{\mathrm{i}}$ for other i ＇s．

Finally $S_{2}$ outputs whatever $A$ outputs to the environment．
Let $\operatorname{tr}\left(S_{2}, A\right)$ denote the transcripts due to the interaction between $A$ and $S_{2}, \operatorname{tr}^{\Psi}\left(\mathrm{P}_{1}\left(\mathrm{X}_{1}\right), A\right)$ denote the transcripts due to the interaction between $A$ and the real－world party $\mathrm{P}_{1}\left(\mathrm{X}_{1}\right)$（possessing the same set $\mathrm{X}_{1}=\left\{x_{1}{ }^{*}, \ldots, x^{*}{ }_{\mathrm{N} 1}\right\}$ as the ideal－world party $\left.\mathrm{P}_{1}{ }^{*}\right)$ ．From $A$＇s perspective，the differences between these two transcripts are：a）cmt in these two transcripts are respectively $c m t^{0}$ output by FakeCmt and cmt output by $\left.\operatorname{Cmt}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, \mathrm{E}\left(m p k, x_{1}{ }^{*}, M_{0} ; r_{1}\right)\|\ldots\| \mathrm{E}\left(m p k, x^{*}{ }_{\mathrm{N} 1}, M_{0} ; r_{\mathrm{N} 1}\right)\right) ; b\right) d m t$ in these two transcripts are $d m t^{0}$ output by FakeDmt and $d m t$ output by $\operatorname{Cmt}\left(m p k_{\mathrm{TC}}, \mathrm{P}_{2}, \mathrm{E}\left(m p k, x_{1}{ }^{*}, M_{0} ; r_{1}\right)\right.$ $\left.\|\ldots\| \mathrm{E}\left(m p k, x^{*}{ }_{\mathrm{N} 1}, M_{0} ; r_{\mathrm{N} 1}\right)\right)$ respectively $\left.c\right)$ Among the ciphertext sequence $\xi_{1} \| \ldots \xi_{\mathrm{N} 1}$ in these two transcripts，there are $t$ ciphertexts $\xi_{\mathrm{i}}$ having the same identity public－key（i．e．，$\left.x^{*}{ }_{\mathrm{i}}\right)$ but the remaining $\mathrm{N}_{1}-\mathrm{t}$ ciphertexts having different identity public－keys；$d$ ）there are $t$ IA－NMZPoK－witness＇with the same $x^{0}$ ．

By TC＇s equivocation property，$(c m t, d m t)$＇s are P．P．T．－indistinguishable in both cases；because of IBE scheme＇s selective ANO＿CPA anonymity，$\xi_{1}\|\ldots\| \xi_{\mathrm{N} 1} \| d m t$ in both cases are P．P．T．－indistinguishable （otherwise suppose they are P．P．T．－distinguishable with the difference $\delta \geq 1 / p o l y(k)$ ，it＇s easy to construct a selective ANO＿CPA attacker against $\Pi$ with an advantage at least $\delta / \mathrm{N}_{1}$ ，contradicting with $\Pi$＇s selective ANO＿CPA anonymity）．Now denote the ciphertext sequence $\xi_{1} \| \ldots \xi_{\mathrm{N} 1}$ in two cases as $\xi_{1}{ }^{(1)}\|\ldots\| \xi_{\mathrm{N} 1}{ }^{(1)}$ and $\xi_{1}{ }^{(2)}\|\ldots\| \xi_{\mathrm{N} 1}{ }^{(2)}$ respectively，denote the transcripts in session of IA－NMZPoK as

IA-NMZPoK ${ }^{(1)}\left(=\operatorname{tr}_{\mathrm{S} 2(\mathrm{x} 1, \ldots, \mathrm{xN} 1), \mathrm{A}}\left(m p k\left\|M_{0}\right\| \xi_{1}{ }^{(1)}\|\ldots\| \xi_{\mathrm{N} 1}{ }^{(1)}\right)\right)$ and IA-NMZPoK ${ }^{(2)}\left(=\operatorname{tr}_{\mathrm{P} 1\left(\mathrm{x}^{*} 1, \ldots, \mathrm{x}^{*} \mathrm{~N} 1\right), \mathrm{A}}\left(m p k \| M_{0}\right.\right.$ $\left.\left.\left\|\xi_{1}{ }^{(2)}\right\| \ldots \| \xi_{\mathrm{N} 1}{ }^{(2)}\right)\right)$ ) respectively, by the above analysis we have $\xi_{1}{ }^{(1)}\|\ldots\| \xi_{\mathrm{N} 1}{ }^{(1)} \approx^{\text {PPT }} \xi_{1}{ }^{(2)}\|\ldots\|_{\mathrm{N} 1}{ }^{(2)}$; furthermore, by IA-NMZPoK's zero-knowledge property we have

$$
\text { IA-NMZPoK }{ }^{(2)} \approx^{\text {PPT }} \text { IA-NMZPoK }:: \operatorname{Sim}_{2}\left(\xi_{1}{ }^{(2)}\|\ldots\| \xi_{\mathrm{N} 1}{ }^{(2)}, s\right)
$$

and by $S_{2}$ 's construction we also have

$$
\text { IA-NMZPoK }{ }^{(1)}=\text { IA-NMZPoK }:: \operatorname{Sim}_{2}\left(\xi_{1}^{(1)}\|\ldots\| \xi_{\mathrm{N} 1}^{(1)}, s\right)
$$

so IA-NMZPoK ${ }^{(1)} \approx^{\text {PPT }}$ IA-NMZPoK ${ }^{(2)}$.
As a result, the transcripts received by $A$ in both cases are P.P.T.-indistinguishable.
Let $\delta$ be $\Delta^{\Pi}{ }_{\text {Blind-UKG }}$ 's extractor's error function(negligible in $k$ ), then the probability with which $S_{2}$ correctly extracts $A$ 's one data-item $y^{*}{ }_{\mathrm{i}}$ is at least $\mathrm{P}\left[A\left(m p k ; P_{1}(m p k, m s k)\right)=\mathrm{UKG}\left(m s k, y^{*}{ }_{\mathrm{i}}\right)\right]-\delta$, so the probability with which $S_{2}$ correctly extracts $A$ 's all data-items $y^{*}{ }_{1}, \ldots, y^{*}{ }_{\mathrm{N} 2}$ is at least $\mathrm{P}\left[A\left(m p k ; P_{1}(m p k\right.\right.$, $\left.m s k))=\mathrm{UKG}\left(m s k, y^{*} \mathrm{i}_{\mathrm{i}}\right): \quad \mathrm{i}=1, \ldots, \mathrm{~N}_{2}\right]-\mathrm{N}_{2} \delta \geq \mathrm{P}\left[\mathrm{X}_{0}=\mathrm{X}_{1} \cap \mathrm{X}_{2}\right]-\mathrm{N}_{2} \delta$. As a result, $S_{2}$ 's output is P.P.T.indistinguishable from $A$ 's output in $\Psi$ with respect to the GUC-environment $Z$ with an error upper-bounded by $\mathrm{N}_{1}(k) A d v_{\Pi}^{A N O}{ }_{-}^{C P A}(k)+\mathrm{N}_{2} \delta$, which is also negligible in $k$. Note that in both cases the other party $\mathrm{P}_{1} *\left(\mathrm{X}_{1}\right)$ and $\mathrm{P}_{1}\left(\mathrm{X}_{1}\right)$ always output the same $\mathrm{N}_{2}$, so we have the consequence that output $_{\mathrm{Z}}(\psi, A) \approx^{\mathrm{PPT}}$ output $_{\mathrm{Z}}\left(F_{\mathrm{INT}}, \mathrm{S}_{2}\right)$ and it's easy to estimate $S_{2}$ 's time-complexity $\mathrm{T}_{S 2}=\mathrm{T}_{A}+\mathrm{O}\left(\mathrm{N}_{1}+\mathrm{N}_{2} \mathrm{~T}_{\text {ext }}\right)$ where $\mathrm{T}_{A}$ and $\mathrm{T}_{\text {ext }}$ are $A$ 's and the extractor's computation-time.

By all the facts, we have $\Psi \rightarrow{ }^{\text {GUC }} F_{\mathrm{INT}}$.

## APPENDIX.C PROOF OF THEOREM 4.1

For intuition the protocol $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ is presented in the figure below, in which IA-NMZPoK's arrows point from zero-knowledge's prover to its verifier.
$\mathrm{P}_{1}(m p k, m s k) \quad A C R S=m p k_{\mathrm{ZK}, \mathrm{II}} \| m p k_{\mathrm{ZK}, \mathrm{III}} \quad \mathrm{P}_{2}(m p k, a)$
$\operatorname{IA}-\mathrm{NMZPoK} \mathrm{III}_{\mathrm{II}}(m s k: m p k=\operatorname{Setup}(m s k)) \quad$ select $r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}$ at random;

$$
U_{i} \leftarrow g^{r_{i}}, V_{i} \leftarrow\left(g_{0} g_{1}^{a}\right)^{-r_{i}}, i=1,2
$$

$$
h_{j} \leftarrow g^{y_{j}} g_{1}^{a} \quad, j=1,2,3,4
$$

$$
\text { IA-NMZPoK } \frac{U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4}}{\longleftarrow}\left(\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{i}=g^{r_{i}} \wedge_{\mathrm{i}=1,2} V_{i}=\left(g_{0} g_{1}^{a}\right)^{-r_{i}} \wedge_{j=1,2,3,4} h_{\mathrm{j}}=g^{y_{j}} g_{1}^{a}\right)
$$

select $\sigma, r_{1}{ }^{\prime}, r_{2}{ }^{\prime}$ at random;

$$
\begin{aligned}
& d_{0} \leftarrow\left(g^{r_{1}} U_{1}^{\sigma}\right)^{t_{1} t_{2}}\left(g^{r_{2}} U_{2}^{\sigma}\right)^{t_{3} t_{4}} ; \\
& d_{1}^{\prime} \leftarrow g^{-\sigma t_{2}}\left(h_{1} g_{0}\right)^{-r_{1}^{\prime} t_{2}} V_{1}^{\sigma t_{2}} ; d_{1}{ }^{\prime \prime} \leftarrow g^{r_{1}^{\prime} t_{2}} \text {; } \\
& d_{2}{ }^{\prime} \leftarrow g^{-\sigma t_{1}}\left(h_{2} g_{0}\right)^{-r_{1}^{\prime} t_{1}} V_{1}^{\sigma t_{1}} ; d_{2}{ }^{\prime \prime} \leftarrow g^{r_{1} t_{1}} ; \\
& d_{3}{ }^{\prime} \leftarrow\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}} V_{2}^{\sigma t_{4}} ; d_{3}{ }^{\prime \prime} \leftarrow g^{r_{2} t_{4}} ; \\
& d_{4} \leftarrow\left(h_{4} g_{0}\right)^{-r_{2}^{\prime} t_{3}} V_{2}^{\sigma t_{3}} ; d_{4}{ }^{\prime \prime} \leftarrow g^{r_{2} t_{3}} ; \\
& d_{0}| | d_{1}{ }^{\prime}| | d_{1}{ }^{\prime \prime}| | d_{2}{ }^{\prime}| | d_{2}{ }^{\prime \prime}| | d_{3}{ }^{\prime}| | d_{3}{ }^{\prime \prime}| | d_{4}{ }^{\prime}| | d_{4}{ }^{\prime \prime} \\
& d_{\mathrm{j}} \leftarrow d_{j}^{\prime} d_{j}^{\prime \prime} y_{j}, j=1,2,3,4 \\
& \operatorname{output}\left(d_{0}, d_{1}, d_{2}, d_{3}, d_{4}\right)
\end{aligned}
$$

By direct calculation it's easy to show the protocol's output's correctness. Now we present the GUC-security proof sketch. All parties are assumed to be initialized with a copy of the common reference string $A C R S$, i.e., the concatenation of the two IA-NMZPoK protocol's $m p k_{\mathrm{ZK}, I I}$ and $m p k_{\mathrm{ZK}, I I I}$. For this $A C R S, m s k=m s k_{\mathrm{ZK}, \mathrm{II}} \| m s k_{\mathrm{ZK}, \mathrm{III}}$ and $\operatorname{UKG}(m s k, i d)$ outputs $u s k(i d)=u s k_{\mathrm{ZK}, \mathrm{II}}(i d) \| u s k_{\mathrm{ZK}, \mathrm{III}}(i d)$ where $u s k_{\mathrm{ZK}, \mathrm{II}}(i d)$ and $u s k_{\mathrm{ZK}, \mathrm{III}}(i d)$ are respectively two IA-NMZPoK protocol's user private-keys corresponding to $i d \in\left\{\mathrm{P}_{1}, \mathrm{P}_{2}\right\}$.

At first it's easy to show there exists an identity extractor for $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ to satisfy definition 3.1. In fact it is IA-NMZPoK $\operatorname{III}\left(\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{\mathrm{i}}=g^{r_{i}} \wedge_{\mathrm{i}=1,2} V_{\mathrm{i}}=\left(g_{0} g_{1}^{a}\right)^{-r_{i}} \wedge_{\mathrm{j}=1,2,3,4} h_{\mathrm{j}}=\right.$ $g^{y_{j}} g_{1}^{a}$ )'s knowledge extractor for which the to-be-extracted witness is $a$.

Now we prove $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$,s GUC-security in two cases that the real-world adversary $A$ corrupts $\mathrm{P}_{1}$ or $\mathrm{P}_{2}$ respectively. Below $\mathrm{P}_{1} *$ and $\mathrm{P}_{2} *$ stand for $\mathrm{P}_{1}$ and $\mathrm{P}_{2}$ 's respective counterparts in ideal-world. (1) $A$ corrupts $\mathrm{P}_{1}$ : Suppose $A$ 's(i.e., $\mathrm{P}_{1}$ 's) private input is ( $m p k, m s k$ ), $\mathrm{P}_{2}{ }^{*}$ 's private input is $a^{*}$. we need to construct an ideal adversary $S_{1} . S_{1}$ corrupts the ideal-world party $\mathrm{P}_{1}{ }^{*}$, gets $u s k\left(\mathrm{P}_{1}\right)$ by querying $\mathrm{G}_{\text {ACRS }}$ with the message ("retrieve", sid, $\mathrm{P}_{1}$ ) where $u s k\left(\mathrm{P}_{1}\right)=u s k_{\mathrm{ZK}, \mathrm{II}}\left(\mathrm{P}_{1}\right) \| u s k_{\mathrm{ZK}, \mathrm{III}}\left(\mathrm{P}_{1}\right)$, computes $\left(\sigma_{\mathrm{II}}, S_{\mathrm{II},}, \tau\right) \leftarrow \mathrm{IA}-\mathrm{NMZPoK} \mathrm{II}: \operatorname{Ext}_{1}\left(u s k_{\mathrm{ZK}, \mathrm{II}}\left(\mathrm{P}_{1}\right)\right)\left(\right.$ notice that $\mathrm{P}_{1}$ is the prover in protocol IA-NMZPoK $\left.{ }_{\mathrm{II}}\right)$, runs $A$ as a black-box. $S_{1}$ simulates the real-world honest party $\mathrm{P}_{2}$ to interact with $A$ :

In session of IA-NMZPoK ${ }_{\mathrm{II}}(m s k: m p k=\operatorname{ESetup}(m s k)), S_{1}$ interacts with $A$ as a verifier extracting $m s k$ via running IA-NMZPoK $\mathrm{II}_{\mathrm{II}}: \operatorname{Ext}_{2}(\tau)$, sends message (sid, $m p k \| m s k$ ) to $F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$;
$S_{1}$ generates an user-id $a$ at random, follows $\mathrm{P}_{2}$ 's specification in section 4.2 to compute $U_{1}, U_{2}, V_{1}$, $V_{2}, h_{1}, h_{2}, h_{3}, h_{4}, \quad$ sends $\quad U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4} \quad$ to $\quad A, \quad$ computes $\quad\left(\sigma_{\text {III }}, s_{\text {III }}\right) \leftarrow$ IA-NMZPoK $\operatorname{Sim}_{1}\left(u s k_{\mathrm{ZK}, \mathrm{III}}\left(\mathrm{P}_{1}\right)\right)\left(\right.$ notice that $\mathrm{P}_{1}$ is the verifier in protocol IA-NMZPoK ${ }_{\text {III }}$ ) and sends IA-NMZPoK ${ }_{\text {III }}$ : $\operatorname{Sim}_{2}\left(U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4}, S_{\text {III }}\right)$ to $A$.
$S_{1}$ outputs whatever $A$ outputs to the environment.
Denote the second-round message in $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ 's specification (i.e., $U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4}$ ) as $W$. From $A$ 's perspective, the transcripts due to its interactions with $S_{1}$ and the transcripts due to its interactions with the real-world party $\mathrm{P}_{2}\left(a^{*}\right)\left(\mathrm{P}_{2}\left(a^{*}\right)\right.$ stands for party $\mathrm{P}_{2}$ possessing $a^{*}$, the same private input as the ideal-world party $\mathrm{P}_{2}{ }^{*}$ ) differs in: $a$ ) $W$ depends on $a$ in the former case, denoted as $W(a)$, while it depends on $a^{*}$ in the latter case and denoted as $\left.W\left(a^{*}\right) ; b\right) \mathrm{IA}-\mathrm{NMZPoK}_{\text {III }}$ 's witness depends on $a$ in the former case while it depends on $a^{*}$ in the latter. The messages of subprotocol IA-NMZPoK in these two cases are respectively denoted as IA-NMZPoK ${ }_{\mathrm{III}}(a)$ and IA-NMZPoK $\mathrm{III}^{( }\left(a^{*}\right)$.

Let $\mathrm{g}_{0} \equiv g^{\alpha}, \mathrm{g}_{1} \equiv g^{\alpha^{*}}$. Explicitly expand $W(a)$ 's expression to $g^{r_{1}}\left\|g^{r_{2}}\right\| g^{-(\alpha+a \beta) r_{1}} \| g^{-(\alpha+a \beta) r_{2}}$ $\left\|g^{y_{1}+a \beta}\right\| \ldots \| g^{y_{4}+a \beta}$ and $W\left(a^{*}\right)$ to a similar expression where $a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}, \alpha$ and $a^{*}, r_{1}{ }^{*}, r_{2}^{*}$, $y_{1}{ }^{*}, y_{2}{ }^{*}, y_{3}{ }^{*}, y_{4}^{*}, \alpha^{*}$ are probabilistically independent and all are unknown to $A$, so $W(a) \approx W\left(a^{*}\right)$ (perfectly indistinguishable). Furthuremore, by IA-NMZPoK ${ }_{\text {III }}$ 's zero-knowledge property we have

$$
\text { IA-NMZPoK }{ }_{I I I}: \operatorname{Sim}_{2}\left(W\left(a^{*}\right), s_{\mathrm{III}}\right) \approx^{\mathrm{PPT}} \text { IA-NMZPoK } \mathrm{NII}\left(a^{*}\right)
$$

and by $S_{1}$ 's construction we also have
IA-NMZPoK
so $\operatorname{IA}-\operatorname{NMZPoK}_{\mathrm{III}}(a)=\operatorname{IA}-\mathrm{NMZPoK}_{\mathrm{III}}:: \operatorname{Sim}_{2}\left(W(a), \mathrm{s}_{\mathrm{III}}\right) \approx \operatorname{IA}-\mathrm{NMZPoK}_{\mathrm{III}}:: \operatorname{Sim}_{2}\left(W\left(a^{*}\right), \mathrm{s}_{\mathrm{III}}\right) \quad \approx^{\mathrm{PPT}}$

IA-NMZPoK ${ }_{\text {III }}\left(a^{*}\right)$. As a result, from $A$ 's perspective the transcripts due to its interactions with $S_{1}$ is P.P.T.-indistinguishable from that due to its interactions with $\mathrm{P}_{2}\left(a^{*}\right)$, in particular, the output of $A$ due to its interactions with $S_{1}$ is P.P.T.-indistinguishable from its output due to its interactions with $\mathrm{P}_{2}\left(a^{*}\right)$ in $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$.

Let $\eta_{\text {II }}$ denote IA-NMZPoK ${ }_{\text {II }}$ 's knowledge extractor's error function(a negligible function in $k$ ), then the probability with which $\mathrm{P}^{*}{ }_{2}\left(a^{*}\right)$ outputs $\Pi:: \mathrm{UKG}\left(m s k, a^{*}\right)$ under $S_{1}$ 's attacks is at least $P\left[\mathrm{P}_{2}\right.$ accepts $m p k$ as a valid master public-key]- $\eta_{\mathrm{II}}$, i.e., except for an probability upper-bounded by $\eta_{\mathrm{II}}$, $\mathrm{P}^{*}\left(a^{*}\right)$ 's output under $S_{1}$ 's attacks is the same as $\mathrm{P}_{2}\left(a^{*}\right)$ 's output under $A$ 's attacks, in other words, for any P.P.T. environment $Z$ we have output $\left(\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}, A_{1}\right) \approx{ }^{\text {PPT }} \operatorname{output}_{\mathrm{Z}}\left(F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}, S_{1}\right)$ and it's easy to estimate $S_{1}$ 's time-complexity $\mathrm{T}_{S 1}=\mathrm{T}_{A}+\mathrm{T}_{e I I}+\mathrm{O}(1)$ where $\mathrm{T}_{A}$ and $\mathrm{T}_{e \mathrm{II}}$ are $A$ 's and Ext ${ }_{\mathrm{II}, 2}$ 's computation-time.
(2) $A$ corrupts $\mathrm{P}_{2}$ : Let $a$ denote $A$ 's (i.e., $\mathrm{P}_{2}$ 's) private input, ( $m p k^{*}, m s k^{*}$ ) denote the ideal-world party $\mathrm{P}_{1}{ }^{*}$ 's input where $m p k^{*}=\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega^{*}, g, g_{0}, g_{1}, v_{1}{ }^{*}, v_{2}{ }^{*}, v_{3}{ }^{*}, v_{4}{ }^{*}\right)$ and $m s k^{*}=\left(\omega^{*}, t_{1}{ }^{*}, t_{2}{ }^{*}, t_{3}^{*}, t_{4}{ }^{*}\right)$. We need to construct an ideal-world adversary $S_{2}$ which corrupts $\mathrm{P}_{2}{ }^{*}$, gets $u s k\left(\mathrm{P}_{2}\right)$ by querying $\mathrm{G}_{\text {ACRS }}$ with the message ("retrieve",sid, $\mathrm{P}_{2}$ ) where $u s k\left(\mathrm{P}_{2}\right)=u s k_{\mathrm{ZK}, \mathrm{II}}\left(\mathrm{P}_{2}\right) \| u s k_{\mathrm{ZK}, \mathrm{III}}\left(\mathrm{P}_{2}\right)$, runs $A$ as a black-box and simulates the honest real-world party $\mathrm{P}_{1}$ to interact with $A$ :

On receiving the message $\left(\operatorname{sid}, m p k^{*}\right)$ from $F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}, S_{2}$ generates $\omega, t_{1}, t_{2}, t_{3}, t_{4}$ at random and computes

```
\(\Omega \leftarrow e(g, g)^{t_{1} t_{2} \omega} ; v_{1} \leftarrow g^{t 1} ; v_{2} \leftarrow g^{t 2} ; v_{3} \leftarrow g^{t 3} ; v_{4} \leftarrow g^{t 4} ;\)
\(m p k \leftarrow\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega, g, g_{0}, g_{1}, v_{1}, v_{2}, v_{3}, v_{4}\right) ;\)
\(m s k \leftarrow\left(\omega, t_{1}, t_{2}, t_{3}, t_{4}\right)\);
\(\left(\sigma_{\text {II }}, s_{\text {II }}\right) \leftarrow \mathrm{IA}-\mathrm{NMZPoK} \mathrm{II}: \operatorname{Sim}_{1}\left(u s k_{\mathrm{ZK}, \mathrm{II}}\left(\mathrm{P}_{2}\right)\right) ;\)
\(\left(\sigma_{\text {III }}, s_{\text {III }}, \tau\right) \leftarrow \mathrm{IA}-\mathrm{NMZPoK} \mathrm{III} \because \operatorname{Ext}_{1}\left(u s k_{\mathrm{ZK}, \mathrm{III}}\left(\mathrm{P}_{2}\right)\right)\);
```

Note that $\mathrm{P}_{2}$ is the verifier in protocol IA-NMZPoK ${ }_{\text {II }}$ and prover in IA-NMZPoK ${ }_{\text {III }}$.
$S_{2}$ starts $A$ and interacts with it by running IA-NMZPoK
When $A$ sends $U_{1}\left\|U_{2}\right\| V_{1}\left\|V_{2}\right\| h_{1}\left\|h_{2}\right\| h_{3} \| h_{4}$ and then launches IA-NMZPoK ${ }_{\text {III }}\left(\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}\right.\right.$, $\left.\left.y_{4}\right): \ldots\right), S_{2}$ participates the session as an verifier by running IA-NMZPoK ${ }_{\text {III }}: \because \operatorname{Ext}_{2}(\tau)$ to extract $\left(a, r_{1}, r_{2}\right.$, $y_{1}, y_{2}, y_{3}, y_{4}$ )(in fact only $a$ is used below);
$S_{2}$ sends the message ( $\left.\operatorname{sid} \| 1, a\right)$ to $F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$ and gets the response $\left(\operatorname{sid} \| 1, \mathrm{UKG}\left(m s k^{*}, a\right)\right)$ where $\operatorname{UKG}\left(m s k^{*}, a\right) \equiv\left(d_{0}{ }^{*}, d_{1}{ }^{*}, d_{2}{ }^{*}, d_{3}{ }^{*}, d_{4}{ }^{*}\right)$;
$S_{2}$ generates $d_{j}^{\prime "}$ at random, computes $d_{j}{ }^{*} \leftarrow d_{j}^{*} / d_{j}^{\prime \prime y_{j}}, j=1,2,3,4$, sends $d^{*}{ }_{0}\left\|d_{1}{ }^{\prime}\right\| d_{1}{ }^{\prime \prime}\left\|d_{2}{ }^{\prime}\right\| d_{2}{ }^{\prime \prime} \| d_{3}{ }^{\prime}$ $\left\|d_{3}{ }^{\prime \prime}| | d_{4}{ }^{\prime}\right\| d_{4}$ " to $A$.

Now we prove that from $A$ 's perspective the transcripts due to its interactions with $S_{2}$ and that due to its interactions with $\mathrm{P}_{1}\left(m p k^{*}, m s k^{*}\right)$ (a real-world party possessing the same input as the ideal-world party $\mathrm{P}_{1}{ }^{*}$ ) are P.P.T.-indistinguishable.

At first, consider the transcripts in IA-NMZPoK ${ }_{\text {II }}$ 's session. Let IA-NMZPoK ${ }_{\text {II }}\left({ }^{*}\right)$ and IA-NMZPoK ${ }_{\text {II }}()$ denote the messages generated by $\mathrm{P}_{1}\left(m p k^{*}, m s k^{*}\right)$ and $S_{2}$ in this session respectively. By IA-NMZPoK ${ }_{I I}$ 's zero-knowledge property we have

$$
\mathrm{IA}^{-N M Z P o K_{I I}}:: \operatorname{Sim}_{2}\left(m p k^{*}, s_{\mathrm{II}}\right) \approx^{\mathrm{PPT}} \mathrm{IA}-\mathrm{NM} \mathrm{ZPoK} \mathrm{ZI}(*)
$$

and by $S_{2}$ 's construction we have

$$
\left.\mathrm{IA}-\mathrm{NMZPoK}_{\mathrm{II}}:: \operatorname{Sim}_{2}\left(m p k, s_{\mathrm{II}}\right)=\mathrm{IA}-\mathrm{NMZPoK}_{\mathrm{II}}\right)
$$

Let $\Omega_{\mathrm{R}}$ denote a random element on group $\mathrm{G}_{2}$. Since $\omega^{*}, \omega, t_{i}{ }^{*}, t_{i}(i=1,2,3,4)$ are probabilistically independent and all are unknown to $A$, from $A$ 's perspectiove we have

$$
\begin{aligned}
& m p k^{*} \equiv\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega^{*}, g, g_{0}, g_{1}, v_{1}^{*}, v_{2}^{*}, v^{*}{ }_{3}, v^{*}{ }_{4}\right) \\
\approx & \approx^{\text {PPT }} \quad\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega_{\mathrm{R}}, g, g_{0}, g_{1}, v^{*}{ }_{1}, v^{*}{ }_{2}, v^{*}{ }_{3}, v^{*}{ }_{4}\right) \quad \text { (D-BDHP's hardness) } \\
\approx & \left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega_{\mathrm{R}}, g, g_{0}, g_{1}, v_{1}, v_{2}, v_{3}, v_{4}\right) \quad \text { (trivial) } \\
\approx & \approx^{\text {PPT }}\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega, g, g_{0}, g_{1}, v_{1}, v_{2}, v_{3}, v_{4}\right) \quad \text { (D-BDHP's hardness) } \\
\equiv & m p k
\end{aligned}
$$

So IA-NMZPoK ${ }_{\text {II }}\left({ }^{*}\right) \approx^{\text {PPT }} \operatorname{IA}-\mathrm{NMZPoK}_{\mathrm{II}}:: \operatorname{Sim}_{2}\left(m p k^{*}, \mathrm{~S}_{\mathrm{II}}\right) \quad \approx^{\mathrm{PPT}} \operatorname{IA}-\mathrm{NMZPoK}_{\mathrm{II}}:: \operatorname{Sim}_{2}\left(m p k, s_{\mathrm{II}}\right)=$ IA-NMZPoK ${ }_{\text {II }}$ ).

Now consider the last-round message, which are $d^{*}{ }_{0}| | d_{1}{ }^{\prime}| | d_{1}{ }^{\prime \prime}| | d_{2}{ }^{\prime}| | d_{2}{ }^{\prime \prime}| | d_{3}{ }^{\prime}| | d_{3}{ }^{\prime \prime}| | d_{4}{ }^{\prime}| | d_{4}{ }^{\prime \prime}$ and $d^{*}{ }_{0}| | d^{*}{ }_{1}{ }^{\prime}$ $\| d^{*}{ }_{1} "| | d^{*}{ }^{\prime}| |\left|d^{*}{ }_{2}{ }^{\prime \prime}\right|\left|d^{*}{ }_{3}{ }^{\prime}\right|\left|d^{*}{ }_{3} "\right|\left|d^{*}{ }_{4}{ }^{\prime}\right| \mid d^{*}{ }_{4}$ " in these two cases( interacting with $S_{2}$ and with $\left.\mathrm{P}_{1}\left(m p k^{*}, m s k^{*}\right)\right)$ respectively. Both messages have the same component $d^{*}$, all other components are denoted as $D$ and $D^{*}$ respectively. Expanding $D$ we get

$$
D \equiv d_{1}^{*} / d_{1}^{" y_{1}}\left\|d_{1}^{"}\right\| d_{2}^{*} / d_{2}^{" y_{2}}\left\|d_{2}^{" \|}\right\| d_{3}^{*} / d_{3}^{" y_{3}}\left\|d_{3}^{"}\right\| d_{4}^{*} / d_{4}^{" y_{4}} \| d_{4}^{"}
$$

where $d^{*}{ }_{1}, \quad d^{*}{ }_{2}, \quad d^{*}{ }_{3}, \quad d^{*}{ }_{4}$ come from $\operatorname{UKG}\left(m s k^{*}, a\right)$, i.e., $d^{*_{1}}=g^{-\omega^{*} t_{2}{ }^{*}}\left(g_{0} g_{1}^{a}\right)^{-\tilde{r}_{1} t_{2}{ }^{*}}$, $d^{*}{ }_{2}=g^{-\sigma^{*} t_{1}{ }^{*}}\left(g_{0} g_{1}^{a}\right)^{-\tilde{r}_{t_{1}}{ }^{*}}, d^{*}{ }_{3}=\left(g_{0} g_{1}{ }^{a}\right)^{-\widetilde{r}_{2} t_{4}{ }^{*}}, d^{*}{ }_{4}=\left(g_{0} g_{1}^{a}\right)^{-\widetilde{r}_{2} t_{3}{ }^{*}}$.

Expanding $D^{*}$ we get

$$
\begin{aligned}
& D^{*} \equiv g^{-\sigma^{*} t_{2}{ }^{*}}\left(h_{1} g_{0}\right)^{-r_{1}^{\prime} t_{2}^{*}} V_{1}^{\sigma t_{2}{ }^{*}}\left\|g^{r_{1} t_{2}{ }^{*}}\right\| g^{-\sigma t_{1}{ }^{*}}\left(h_{2} g_{0}\right)^{-r_{1}^{\prime} t_{1}^{*}} V_{1}^{\sigma t_{1}{ }^{*}}\left\|g^{r_{1} t_{1}{ }^{*}}\right\|\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4} t^{*}} V_{2}^{\sigma t_{4}{ }^{*}} \| \\
& \left\|g^{r_{2}^{\prime} t_{4}{ }^{*}}\right\|\left(h_{4} g_{0}\right)^{-r_{2}^{\prime} t_{3}^{*}} V_{2}^{\sigma t_{3}^{*}} \| g^{r_{2} t_{3}{ }^{*}}
\end{aligned}
$$

where $\sigma, \widetilde{r}_{i}, r_{i}{ }^{\prime}$ and $d_{j}{ }^{\prime \prime}$ are probabilistically independent each other and unkown to $A, \sigma, r_{i}{ }^{\prime}$ are generated by $\mathrm{P}_{1}, d_{j}$ " by $S_{2}, \widetilde{r}_{i}$ by $F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$.

Since $r_{1}{ }^{\prime}$ and $r_{2}{ }^{\prime}$ are probabilistically independent each other, $D^{* \prime s} 4$ leftmost-components are probabilistically independent of those 4 rightmost-ones; note that $t^{*}{ }_{1}, t^{*}{ }_{2}, t^{*}{ }_{3}, t^{*}{ }_{4}$ are also probabilistically independent each other, we finally partition $D^{*}$ into 4 independent components $D_{i}{ }^{*}$ as:

$$
\begin{array}{ll}
D_{1}^{*} \equiv g^{-\sigma^{*} t_{2}{ }^{*}}\left(h_{1} g_{0}\right)^{-r^{\prime} t_{2}^{*} *} V_{1}^{\sigma t_{2}^{*}} \| g^{r_{1}^{\prime} t_{2}^{*}} & D_{2}{ }^{*} \equiv g^{-\sigma t_{1}^{*}{ }^{*}}\left(h_{2} g_{0}-r_{1}^{-r_{1}^{\prime} t_{4}^{*}} V_{1}^{\sigma t_{1}^{*}} \| g^{r_{1} t_{1}^{*}}\right. \\
D_{3}{ }^{*} \equiv\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}^{*}} V_{2}^{\sigma t_{4}{ }^{*}} \| g^{r_{2} t_{4}{ }^{*}} & D_{4}{ }^{*} \equiv\left(h_{4} g_{0}\right)^{-r_{2}^{\prime} t_{3}^{*}} V_{2}^{\sigma t_{3}^{*}} \| g^{r_{2}^{\prime} t_{3}^{*}}
\end{array}
$$

Similarly partition $D$ into 4 independent components $D_{i}$ as:

$$
D_{1} \equiv d_{1}^{*} / d_{1}^{" y_{1}}\left\|d_{1}^{\prime \prime} \quad D_{2} \equiv d_{2}^{*} / d_{2}^{" y_{2}}\right\| d_{2}^{\prime \prime} \quad D_{3} \equiv d_{3}^{*} / d_{3}^{* y_{3}}\left\|d_{3}^{\prime \prime} \quad D_{4} \equiv d_{4}^{*} / d_{4}^{" y_{4}}\right\| d_{4}^{"}
$$

The problem is now reduced to analysis on relationship between $D_{i}$ and $D^{*}$. Consider $D_{3}{ }^{*}$ $\equiv\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}^{*}} V_{2}^{\sigma t_{4}{ }^{*}} \| g^{r_{2}^{r_{2}^{\prime} t_{4} *}}$ and $D_{3} \equiv d_{3}^{*} / d_{3}^{\prime \prime y_{3}} \| d_{3}^{\prime \prime}:$ obviously $D_{3} \approx\left(h_{3} g_{0}\right)^{-\widetilde{r}_{2} t_{4}{ }^{*}} / g^{v_{3} b_{2}^{\prime} t_{4}^{*}} \| g^{r r_{2}^{\prime} t_{4} *^{*}}$ so it's adequate to analyze the relationship between $\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}{ }^{*}} V_{2}^{\sigma t_{4}{ }^{*}}$ and $\left(g_{0} g_{1}^{a}\right)^{-\widetilde{r}_{2} t_{4} *} / g^{y_{3_{2}} t_{4} *^{*}}$. Further note that $\left(h_{3} g_{0}\right)^{-r_{2}^{\prime} t_{4}^{*}} \approx\left(h_{3} g_{0}\right)^{-\widetilde{\Gamma_{2} t_{4} *}}, V_{2}^{\sigma t_{4}^{*} *} \approx g^{-y_{3}^{\prime} t_{4} t_{4}^{*}},\left(h_{3} g_{0}\right)^{-\widetilde{\tilde{L}_{2} t_{4}^{*}}}$ and $g^{r_{2}^{\prime} t_{4}^{*}}$ are independent each other, so $D_{3}{ }^{*} \approx D_{3}$. For the same reason $D_{4} * \approx D_{4}$.

Consider $D_{1}^{*} \equiv g^{-\omega^{*} t_{2}{ }^{*}}\left(h_{1} g_{0}\right)^{-r_{1}^{\prime} t_{2}{ }^{*}} V_{1}^{\sigma t_{2}{ }^{*}} \| g^{r_{1} t_{2}^{*}}$ and $D_{1} \equiv d_{1}^{*} / d_{1}^{\prime y_{1}} \| d_{1}^{\prime \prime}$ : obviously $D_{1} \approx g^{-\sigma^{*} t_{2}{ }^{*}}\left(g_{0} g_{1}^{a}\right)^{-\tilde{r}_{t_{2}} t^{*}} / g^{r t_{2} t_{2}^{*} y_{1}} \| g^{r_{1} t_{2}{ }^{*}}$, by similar analysis as before we have $D_{1} * \approx D_{1}$. For the same reason $D_{2}{ }^{*} \approx D_{2}$. Therefore:

$$
d^{*}{ }_{0}| | d_{1}^{\prime}| | d_{1} "| | d_{2}^{\prime}| | d_{2} "| | d_{3}^{\prime}| | d_{3}{ }^{\prime \prime}| | d_{4}^{\prime}| | d_{4}{ }^{\prime \prime} \approx d^{*}{ }^{*}| | d^{*} 1^{\prime}| | d^{*}{ }^{*} "| | d^{*}{ }_{2}^{\prime}| | d^{*}{ }_{2}{ }^{\prime \prime}| | d^{*} 3^{\prime}| | d_{3}^{*}{ }^{\prime \prime}| | d_{4}^{*}{ }^{\prime}| | d^{*}{ }_{4} "
$$

In consequence, under the assumption of D-BDHP's hardness on J , from $A$ 's perspective the
transcripts due to its interactions with $S_{2}$ and that due to its interactions with $\mathrm{P}_{1}\left(m p k^{*}, m s k^{*}\right)$ are P.P.T.-indistinguishable. In particular, $A$ 's output in the former case is P.P.T.-indistinguishable from its output in the latter, the error is (by some straightforward calculation) upper-bounded by $\eta_{\text {III }}$ $+2 A d v_{J}^{D-B D H P}(k)$ where $\eta_{\text {III }}$ is IA-NMZPoK ${ }_{\text {III }}$ 's knowledge extractor's error function. As a result, for any P.P.T. environment $Z$ we have output $\left(\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}, A\right) \approx^{\text {PPT }} \operatorname{output}_{Z}\left(F_{\text {Blind-UKG }}^{\text {Boyen-Waters }}, S_{2}\right)$ and it's easy to estimate $S_{2}$ 's time-complexity $\mathrm{T}_{S 2}=\mathrm{T}_{A}+\mathrm{T}_{\text {eIII }}+\mathrm{O}(1)$ where $\mathrm{T}_{A}$ and $\mathrm{T}_{\text {eIII }}$ are $A$ 's and IA-NMZPoK ${ }_{\text {III }}$ 's extractor's computation-time.

Combining all consequences in the above, the theorem is finally proved.

## APPENDIX.D IA-NMZPoK PROTOCOL'S CONSTRUCTION AND INSTANTIATION

D. 1 (Dense) $\boldsymbol{\Omega}$-Protocol ${ }^{[6,13]}$

A $\Omega$-protocol for a given relation $R$ is a 3-move protocol in CRS model consisted of P.P.T. algorithms $\mathrm{D}, \mathrm{A}, \mathrm{Z}, \Phi, \operatorname{Sim}$ and $\mathrm{Ext}=\left(\mathrm{Ext}_{1}, \mathrm{Ext}_{2}\right)$. D is the CRS generating algorithm. All algorithms except D takes a CRS $\omega$ as one of its inputs. For some $(x, w)$ s.t. $R(x, w)=1$ the common input for both the prover P and the verifier V is $x$ and witness $w$ is P 's private input. In the first move P generates a randomness $r$, computes $a \leftarrow \mathrm{~A}(\omega, x, w, r)$ and sends $a$ to V ; in the second move, V selects a challenge $c$ at random and sends it back to P ; then P computes $\mathrm{Z} \leftarrow \mathrm{Z}(\omega, x, w, r, c)$ and sends $z$ to V in the last move; on receiving $z, \mathrm{~V}$ outputs "accept" or "refuse" depending on whether $\Phi(\omega, x, a, c, \mathrm{z})=1$ or 0 . In addition, a $\Omega$-protocol has the following properties [13]:
(1) For the honest P which behaves under the above specification, $\Phi(\omega, x, a, c, \mathrm{z})=1$ is always true.
(2) Given $c$ and $x \in L_{\mathrm{R}}$ the simulator $\operatorname{Sim}(\omega, x, c)$ can generate accepting transcripts with a distribution that is P.P.T.-indistinguishable from those when P and V execute the protocol on common input $x$ while V selects $c$ as the challenge.
(3) $(\sigma, \tau) \leftarrow \operatorname{Ext}_{1}(k)$ where $\sigma$ is P.P.T.-indistinguishable from $\omega \leftarrow \mathrm{D}(k)$; in addition, if there exists two accepting transcripts $(a, c, z)$ and $\left(a, c^{\prime}, z^{\prime}\right)$ where $c \neq c^{\prime}$ for some given $x \in L_{\mathrm{R}}$, then $\operatorname{Ext}_{2}(x, \tau,(a, c, z))$ outputs $w$ such that $\mathrm{R}(x, w)=1$.

A dense $\Omega$-protocol has the additional property as follows [6]:
(4) The CRS-domain D is a subset of a larger domain, $\mathrm{D}^{*}$ (named extended CRS-domain), which is an Abelian group and its group operations are all efficient. Furthermore, the element of D and $\mathrm{D}^{*}$ is P.P.T.-indistinguishable from each other.

## D. 2 A General Construction of IA-NMZPoK Protocol

Now we present a general construction for IA-NMZPoK protocol(definition 2.3-2.4) for given relation $R$. It uses a secure (strong existential-unforgeable) one-time signature scheme, a secure IBTC sheme(definition 2.5) and a dense $\Omega$-protocol as its components. Note that among these components the secure one-time signature scheme and IBTC scheme can all be efficiently constructed, only the
$\Omega$-protocol is related with the specific relation $R$, therefore the construction can be regarded as a general transformation from the (comparatively weak) $\Omega$-protocol to the (strong) IA-NMZPoK protocol.

This construction is similar as that in [13] and borrows the coin-tossing technique used in [5-6]. Given a binary relation R and its dense $\Omega$-protocol $\Omega_{\mathrm{R}}=\left(\mathrm{D}, \mathrm{A}, \mathrm{Z}, \Phi, \mathrm{Sim}, \mathrm{Ext}=\left(\mathrm{Ext}_{1}, \mathrm{Ext}_{2}\right)\right)$ with its CRS denoted as $\omega$; SIG=(KGen,Sign,Vf) is a strong existential-unforgeable one-time signature scheme; IBTC $=\left(\mathrm{D}_{\mathrm{TC}}\right.$, Setup,UKG,Cmt,Vf,FakeCmt, FakeDmt) is a secure IBTC scheme with its master public/secret-key pair denoted as $\left(m p k_{\mathrm{TC}}, m s k_{\mathrm{TC}}\right.$ ). The constructed protocol IA-NMZPoK $\mathrm{K}_{\mathrm{R}}$ (see Figure D.1) is in the ACRS model and its ACRS is the IBTC scheme's master public-key $m p k_{\mathrm{TC}}$.

For clearity, we use IBTC::Cmt to stand for IBTC scheme's commitment algorithm Cmt, SIG::Sign to stand for SIG scheme's signing algorithm Sign, etc. $P$ and $V$ denote the prover(P)'s and verifier(V)'s identities respectively. $\xi$ denotes the protocol's transcripts excluding the signature, i.e., $\xi \equiv k_{1}\left\|\omega_{2}| | \omega_{1}| | d_{1}| | s i g_{-} v k\right\| c m t| | c| | a \||d m t| \mid \mathrm{z}$. Actually the first 3-move session is an IBTC-based coin-tossing [5-6] to generate a CRS $\omega$ for the following protocol $\Omega_{\mathrm{R}}$ and the second 3-move session is similar as the construction of NMZPoK protocol in [13].

Figure D. 1 IA-NMZPoK protocol IA-NMZPoK ${ }_{R}$ for relation R.

Theorem D. 1 IA-NMZPoK ${ }_{R}$ is an IA-NMZPoK protocol for relation R.
Proof sketch The proof is similar as that of [13]'s theorem 4.1-4.2, the most difference is the simulation algorithm $\operatorname{Sim}=\left(\operatorname{Sim}_{1}, \mathrm{Sim}_{2}\right)$ and the extraction algorithm $\mathrm{Ext}=\left(\mathrm{Ext}_{1}, \mathrm{Ext}_{2}\right)$ which are presented here.

Let usk( $P$ ) $\equiv \mathrm{IBTC}:: \mathrm{UKG}\left(m s k_{\mathrm{TC}}, P\right), \quad u s k(V) \equiv \mathrm{IBTC}:: \mathrm{UKG}\left(m s k_{\mathrm{TC}}, V\right) . \quad \operatorname{Sim}_{1}(u s k(V)) \quad$ normally simulates the coin-tossing (the first 3-move session in IA-NMZPoK ${ }_{R}$ ) as specified in the constrcution
and its simulated transcript is denoted as $k_{1}\left\|\omega_{2}\right\| \omega_{1} \| d_{1}$, then it outputs $k_{1}\left\|\omega_{2}\right\| \omega_{1}\left\|d_{1}\right\| u s k(V)$. $\operatorname{Sim}_{2}\left(m p k_{\mathrm{TC}}, x, \omega, k_{1}\left\|\omega_{2}\right\| \omega_{1}\left\|d_{1}\right\| u s k(V)\right)\left(\right.$ where $\left.\omega=\omega_{1} \omega_{2}\right)$ computes $(\overline{c m t}, \lambda) \leftarrow \operatorname{IBTC}::$ FakeCmt $\left(m p k_{\mathrm{TC}}\right.$, $V, u s k(V))$ and $\left(\operatorname{sig}_{-} v k, s i g_{-} s k\right) \leftarrow \operatorname{SIG}:: \operatorname{KGen}(k)$, selects $c$ at random, computes $(a, \mathrm{z}) \leftarrow \Omega_{\mathrm{R}}:: \operatorname{Sim}(\omega, x, c)$, $\bar{d} \leftarrow$ FakeDmt $\left(m p k_{\mathrm{TC}}, a \| \operatorname{sig} \_v k, \lambda, \overline{c m t}\right), \mathrm{s} \leftarrow \operatorname{SIG}:: \operatorname{Sign}\left(\operatorname{sig}{ }_{-} s k, \xi\right)$ where $\xi$ is the whole transcript (as specified in the construction) excluding the signature s. Finally $\operatorname{Sim}_{2}$ outputs

$$
k_{1}\left\|\omega_{2}\right\| \omega_{1}\left\|d_{1}\right\| \overline{c m t}\|c\| s i g_{-} v k\|a\| \dot{\bar{d}}\|z\| s
$$

For the extractor $\operatorname{Ext}=\left(\operatorname{Ext}_{1}, \operatorname{Ext}_{2}\right), \operatorname{Ext}_{1}(u s k(P))$ computes $(\omega, \tau) \leftarrow \Omega_{\mathrm{R}}:: \operatorname{Ext}_{1}(k)$ and outputs $(\omega$, $u s k(P) \| \tau) . \operatorname{Ext}_{2}\left(m p k_{\mathrm{TC}}, \omega, \operatorname{usk}(P) \| \tau\right)$ computes $\left(\overline{k_{1}}, \lambda_{1}\right) \leftarrow \mathrm{IBTC}:$ FakeCmt $\left(m p k_{\mathrm{TC}}, P, u s k(P)\right)$ and sends $\overline{k_{1}}$ out; on receiving $\omega_{2}$, it computes $\omega_{1} \leftarrow \omega / \omega_{2}, \overline{d_{1}} \leftarrow \operatorname{FakeDmt}\left(m p k_{\mathrm{TC}}, \omega_{1}, \lambda_{1}, \overline{k_{1}}\right)$ and responses with $\omega_{1} \| \overline{d_{1}}$; then it randomly generates a challenge $c$ on receiving $c m t$. When it gets the last message sig_ $v k\|a\| d m t\|z\| s$, it checks all the required conditions and call $\Omega_{\mathrm{R}}: \because \operatorname{Ext}_{2}(\omega, x, \tau, a\|c\| z)$.

Now it can be shown that $\operatorname{Sim}=\left(\operatorname{Sim}_{1}, \operatorname{Sim}_{2}\right)$ and $\operatorname{Ext}=\left(\operatorname{Ext}_{1}, \mathrm{Ext}_{2}\right)$ indeed satisfy the properties in definition 2.3-2.4, the analysis is almost the same as in the proof of [13]'s theorem 4.1-4.2.

## D. 3 An Efficient Instantiation

Now we can present how to efficiently construct all the related IA-NMZPoK protocols in case of Boyen-Waters scheme for our protocol $\Psi$ and $\Delta_{\text {Blind-UKG }}^{\text {Boyen-Waters }}$. By the construction in last subsection, it's adequate to construct the related dense $\Omega$-protocols for those specific relations deduced from Boyen-Waters IBE scheme [3]. So below we only focus on these $\Omega$-protocols' construction.

For reading convenience let's completely present the Boyen-Waters IBE scheme here which is truncated in sec.4.1 for space limitation: Given an bilinear group pairing ensemble $\mathrm{J}=\left\{\left(\mathrm{p}, \mathrm{G}_{1}, \mathrm{G}_{2}, e\right)\right\}_{k}$ where $\left|\mathrm{G}_{1}\right|=\left|\mathrm{G}_{2}\right|=p, p$ is $k$-bit prime number, $\mathrm{P} \in \mathrm{G}_{1}, e: \mathrm{G}_{1} \times \mathrm{G}_{1} \rightarrow \mathrm{G}_{2}$ is a non-degenerate pairing, Boyen-Waters IBE consists of
$\operatorname{ESetup}(k)$ :

```
\(g, g_{0}, g_{1} \leftarrow{ }^{\$} \mathrm{G}_{1} ; \omega, t_{1}, t_{2}, t_{3}, t_{4} \leftarrow{ }^{\$} Z_{\mathrm{p}} ; \Omega \leftarrow e(g, g)^{t_{1} t_{2} \omega} ;\)
\(v_{1} \leftarrow g^{t 1} ; v_{2} \leftarrow g^{t 2} ; v_{3} \leftarrow g^{t 3} ; v_{4} \leftarrow g^{t 4} ;\)
\(m p k \leftarrow\left(\mathrm{G}_{1}, \mathrm{G}_{2}, p, e, \Omega, g, g_{0}, g_{1}, v_{1}, v_{2}, v_{3}, v_{4}\right)\);
\(m s k \leftarrow\left(\omega, t_{1}, t_{2}, t_{3}, t_{4}\right) ;\)
return (mpk,msk);
```

$\mathrm{UKG}(m s k, a), a \in Z_{\mathrm{p}}$ :
$r_{1}, r_{2} \leftarrow{ }^{\$} Z_{\mathrm{p}} ;$
$u s k(a) \leftarrow\left(g^{r_{1} t_{1} t_{2}+r_{2} t_{3} t_{4}}, g^{-\sigma t_{2}}\left(g_{0} g_{1}^{a}\right)^{-r_{1} t_{2}}, g^{-\sigma t_{1}}\left(g_{0} g_{1}^{a}\right)^{-r_{1} t_{1}},\left(g_{0} g_{1}^{a}\right)^{-r_{2} t_{4}},\left(g_{0} g_{1}^{a}\right)^{-r_{2} t_{3}}\right) ;$
return $(u s k(a))$;
$\mathrm{E}(m p k, a, M), M \in \mathrm{G}_{2}:$

$$
s, s_{1}, s_{2} \leftarrow^{\$} \mathrm{Z}_{\mathrm{p}} ; \xi \leftarrow\left(\Omega^{\mathrm{s}} M, \quad\left(g_{0} g_{1}^{a}\right)^{s}, v_{1}^{\mathrm{s-s} 1}, v_{2}^{\mathrm{s} 1}, v_{3}^{\mathrm{s}-\mathrm{s} 2}, v_{4}^{\mathrm{s} 2}\right) ; \text { return }(\xi)
$$

$\mathrm{D}\left(m p k, u s k(a),\left(\xi_{00}, \xi_{0}, \xi_{1}, \xi_{2}, \xi_{3}, \xi_{4}\right)\right)$ where $\operatorname{usk}(a) \equiv\left(d_{0}, d_{1}, d_{2}, d_{3}, d_{4}\right)$ :
$T \longleftarrow e\left(d_{0}, \xi_{0}\right) e\left(d_{1}, \xi_{1}\right) e\left(d_{2}, \xi_{2}\right) e\left(d_{3}, \xi_{3}\right) e\left(d_{4}, \xi_{4}\right) ;$ return $\left(\xi_{00} T\right)$.
At first, we note that the relationship in IA-NMZPoK ${ }_{\text {II }}(m s k: m p k=\operatorname{Setup}(m s k))$ is

$$
\left(\omega, \mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}, \mathrm{t}_{4}\right): \Omega=e(g, g)^{t_{1} t_{2} \omega} \wedge v_{1}=\mathrm{g}^{\mathrm{t} 1} \wedge v_{2}=\mathrm{g}^{\mathrm{t} 2} \wedge v_{3}=\mathrm{g}^{\mathrm{t} 3} \wedge v_{4}=\mathrm{g}^{\mathrm{t} 4}
$$

Note that $\Omega=e(g, g)^{t_{1} t_{2} \omega}=e\left(v_{1}, v_{2}\right)^{\omega}$ so the desired relation is equivalent to

$$
\begin{equation*}
\left(\omega, \mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}, \mathrm{t}_{4}\right): \Omega=e\left(v_{1}, v_{2}\right)^{\omega} \wedge v_{1}=\mathrm{g}^{\mathrm{t} 1} \wedge v_{2}=\mathrm{g}^{\mathrm{t} 2} \wedge v_{3}=\mathrm{g}^{\mathrm{t} 3} \wedge v_{4}=\mathrm{g}^{\mathrm{t} 4} \tag{D.1}
\end{equation*}
$$

Now we analyze how to construct
IA-NMZPoK $\operatorname{\text {III}}\left(\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{\mathrm{i}}=g^{r_{i}} \wedge_{\mathrm{i}=1,2} V_{\mathrm{i}}=\left(g_{0} g_{1}^{a}\right)^{-r_{i}} \wedge_{\mathrm{j}=1,2,3,4} h_{\mathrm{j}}=g^{y_{j}} g_{1}^{a}\right)$ Observe that (the pairing $e$ is non-degenerate and $\mathrm{G}_{1}, \mathrm{G}_{2}$ are both prime-order) $V_{\mathrm{i}}=\left(g_{0} g_{1}^{a}\right)^{-r_{i}}$ iff $e\left(g, V_{i}\right)=e\left(g^{r_{i}}, g_{0} g_{1}^{a}\right)^{-1}=e\left(U_{i}, g_{0} g_{1}^{a}\right)^{-1}=e\left(U_{i}, g_{0}\right)^{-1} e\left(U_{i}, g_{1}\right)^{-a}$, i.e., $e\left(g, V_{i}\right) e\left(U_{i}, g_{0}\right)=e\left(U_{i}, g_{1}\right)^{-a} \quad i=1,2$ $h_{\mathrm{j}}=g^{y_{j}} g_{1}^{a}$ iff $e\left(U_{1}, g_{0} h_{j}\right)=e\left(U_{1}, g_{0} g_{1}^{a}\right) e\left(U_{1}, g\right)^{y_{j}}=e\left(g, V_{1}\right)^{-1} e\left(U_{1}, g\right)^{y_{j}}$, i.e., $e\left(U_{1}, g_{0} h_{j}\right) e\left(g, V_{1}\right)=e\left(U_{1}, g\right)^{y_{j}} \quad j=1,2,3,4$
The above expression is also true if $U_{2}$ replaces $U_{1}$. Denote publicly-computable items $F_{\mathrm{i}} \equiv e\left(g, V_{i}\right) e\left(U_{i}, g_{0}\right), f_{\mathrm{i}} \equiv e\left(U_{i}, g_{1}\right)^{-1}, H_{\mathrm{j}} \equiv e\left(U_{1}, g_{0} h_{j}\right) e\left(g, V_{1}\right), h \equiv e\left(U_{1}, g\right)$, then IA-NMZPoK ${ }_{\text {III }}$ becomes an IA-NMZPoK protocol for the relation

$$
\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{\mathrm{i}}=g^{r_{\mathrm{i}}} \wedge_{\mathrm{i}=1,2} F_{\mathrm{i}}=f_{\mathrm{i}}^{a} \wedge_{\mathrm{j}=1,2,3,4} H_{\mathrm{j}}=h^{y_{j}}
$$

A further observation tells that $F_{1}=f_{1}{ }^{a}$ and $F_{2}=f_{2}^{a}$ are not independent: in fact, let $F_{1}=f_{1}^{a_{1}}$ and $F_{2}=f_{2}^{a_{2}}$ then via bilinear pairing we have $e\left(f_{1}, F_{2}\right)=e\left(f_{1}, f_{2}\right)^{a_{2}}$ and $e\left(F_{1}, f_{2}\right)=e\left(f_{1}, f_{2}\right)^{a_{1}}$, i.e., $e\left(f_{1}, F_{2}\right)=e\left(F_{1}, f_{2}\right)$ iff $a_{1}=a_{2}$ so one statement of $F_{1}=f_{1}{ }^{a}$ or $F_{2}=f_{2}^{a}$ can imply another one by publicly checking $e\left(f_{1}, F_{2}\right)=e\left(F_{1}, f_{2}\right)$. Therefore the desired IA-NMZPoK ${ }_{\text {III }}$ is equivalent to an IA-NMZPoK protocol for the relation

$$
\begin{equation*}
\left(a, r_{1}, r_{2}, y_{1}, y_{2}, y_{3}, y_{4}\right): \wedge_{\mathrm{i}=1,2} U_{\mathrm{i}}=g^{r_{i}} \wedge F_{1}=f_{1}{ }^{a} \wedge_{\mathrm{j}=1,2,3,4} H_{\mathrm{j}}=h^{y_{j}} \tag{D-2}
\end{equation*}
$$

Now analyze IA-NMZPoK ( $\left.(a, \mathrm{r}): \xi=\mathrm{E}\left(m p k, a, M_{0} ; r\right)\right)$. In case of Boyen-Waters scheme, denote the public common plaintext as $M_{0}$ and the scheme's ciphertext as $\xi \equiv\left(\xi_{00}, \xi_{0}, \xi_{1}, \xi_{2}, \xi_{3}, \xi_{4}\right)$, then IA-NMZPoK ( $\left.(a, \mathrm{r}): ~ \xi=\mathrm{E}\left(m p k, a, M_{0} ; \mathrm{r}\right)\right)$ becomes IA-NMZPoK $\left(\left(a, \mathrm{~s}, \mathrm{~s}_{1}, \mathrm{~s}_{2}\right): \xi_{00}=\Omega^{\mathrm{s}} M_{0} \wedge \xi_{0}=\left(g_{0} g_{1}{ }^{a}\right)^{s}\right.$ $\left.\wedge \xi_{1}=\mathrm{v}_{1}{ }^{\mathrm{s}-\mathrm{s} 1} \wedge \xi_{2}=\mathrm{v}_{2}{ }^{\mathrm{s} 1} \wedge \xi_{3}=\mathrm{v}_{3}{ }^{\mathrm{s} s}{ }^{2} \wedge \xi_{4}=\mathrm{v}_{4}{ }^{\mathrm{s} 2}\right)$. Because in theorem 3.1's proof what is needed is just the witness $a$, with respect to protocol $\Psi$ it's adequate to construct IA-NMZPoK $((a, \mathrm{~s})$ : $\left.\xi_{00}=\Omega^{\mathrm{s}} M_{0} \wedge \xi_{0}=\left(g_{0} g_{1}{ }^{a}\right)^{s}\right)$.

In general $\mathrm{G}_{1}$ and $\mathrm{G}_{2}$ are not the same group, e.g., $\mathrm{G}_{1}$ is usually a prime-order subgroup on elliptic curve while $\mathrm{G}_{2}$ is a multiplicative subgroup in some finite field. Denote $\chi_{00}=\xi_{00} M_{0}{ }^{-1}, t \equiv a s$, then $\chi_{00}=\Omega^{\mathrm{s}}$, $\xi_{0}=\left(g_{0} g_{1}^{a}\right)^{s}=g_{0}^{s} g_{1}^{t}$ and it's easy to see that IA-NMZPoK $\left((a, \mathrm{~s}): \xi_{00}=\Omega^{s} M_{0} \wedge \xi_{0}=\left(g_{0} g_{1}{ }^{a}\right)^{s}\right)\left(a=t s^{-1}\right.$ $\bmod q)$ is equivalent to an IA-NMZPoK protocol for relation

$$
\begin{equation*}
(s, t): \chi_{00}=\Omega^{\mathrm{s}} \wedge \xi_{0}=g_{0}^{s} g_{1}^{t} \tag{D-3}
\end{equation*}
$$

So far all desired IA-NMZPoK protocols' relations are explicitly presented and can be unified to a group of linear exponent equations on prime-order group $G$ in (D-4)(more generally each equation in (D-4) can be on a different group, but this case can be processed by a trivial generalization of the uniform case in which all equations are on the same group, so we only deal with the latter):

$$
\begin{equation*}
\prod_{j=1}^{n} B_{i j}^{x_{j}}=h_{i} \quad i=1, \ldots, m \tag{D-4}
\end{equation*}
$$

where $B_{i j}$ and $h_{i}$ are in G and $x_{i}$ 's are integer witness. [6](see its Appendix.I) presents an efficient construction for relation (D-4)'s dense $\Omega$-protocol which can be directly applied in our work.

[^0]:    ${ }^{1}$ Strictly this protocol should be called "zero-knowledge argument", however, such difference is not essential in this paper so we harmlessly abuse the terminology.
