28 **Micronutrient deficiencies account for an estimated one million premature deaths**  
29 **annually, and for some nations can reduce GDP by up to 11%<sup>1,2</sup>, highlighting the need**  
30 **for food policies focused on improving nutrition rather than simply increasing volumes**  
31 **of food produced<sup>3</sup>. People gain nutrients from a varied diet but fish, a rich source of**  
32 **bioavailable micronutrients essential to human health<sup>4</sup>, are often overlooked. A lack of**  
33 **understanding of the nutritional composition of most fish<sup>5</sup> and how nutrient yields vary**  
34 **among fisheries has hindered policy shifts needed to effectively harness the potential of**  
35 **fisheries for food and nutrition security<sup>6</sup>. Here, using the concentration of seven nutrients**  
36 **in more than 350 species of marine fish, we estimate how environmental and ecological**  
37 **traits predict nutrient content among marine finfish species. We use this predictive model**  
38 **to quantify spatial patterns of nutrient concentration from marine fisheries yields**  
39 **globally and compare nutrient yields to the prevalence of micronutrient deficiencies in**  
40 **human populations. We find that species from tropical thermal regimes contain higher**  
41 **concentrations of calcium, iron, and zinc; smaller species contain higher concentrations**  
42 **of calcium, iron, and omega-3; and, species from cold thermal regimes or those with a**  
43 **pelagic feeding pathway contain higher concentrations of omega-3. There is no**  
44 **relationship between nutrient concentrations and total fisheries yield, highlighting that**  
45 **nutrient quality of a fishery is determined by species composition. For a number of**  
46 **countries where nutrient intakes are inadequate, nutrients available in marine finfish**  
47 **catches exceed the dietary requirements for coastal (within 100km) populations, and a**  
48 **fraction of current landings could be particularly impactful for children under five years.**  
49 **Our analyses show that fish-based food strategies have the potential to substantially**  
50 **contribute to food and nutrition security globally.**

51

52

53 Uneven progress in tackling malnutrition has kept food and nutrition security high on the  
54 development agenda globally<sup>1,3</sup>. Micronutrients, such as iron and zinc, are a particular focus;  
55 it is estimated that nearly two billion people lack key micronutrients<sup>7</sup>, underlying nearly half  
56 of all deaths in children under the age of five years<sup>1</sup>, and reducing GDP in Africa by estimates  
57 of up to 11%<sup>2,3,7</sup>. Consequently, efforts to tackle malnutrition have shifted from a focus on  
58 increasing energy and macronutrients (e.g. protein) towards ensuring sufficient consumption  
59 of micronutrients<sup>3</sup>. People gain nutrients from a mix of locally produced and imported food  
60 products. Fish, harvested widely and traded both domestically and internationally, are a rich  
61 source of bioavailable micronutrients, which are often deficient in diets that rely heavily on  
62 plant-based sources<sup>6,8</sup>. Fish could therefore help address nutritional deficiencies if there are  
63 sufficient quantities of fishery-derived nutrients accessible in places where deficiencies exist.  
64 However, addressing this major food policy frontier has been elusive, in part because the  
65 nutrient composition of fish varies significantly among species, and data remain sparse for most  
66 species<sup>5</sup>.

67

68 Here we determine the contribution marine fisheries can make to addressing micronutrient  
69 deficiencies. First, using strict inclusion protocols (methods), we developed a database of 2,267  
70 measures of nutritional composition, from 367 fish species, spanning 43 countries, for seven  
71 nutrients essential to human health: calcium, iron, selenium, zinc, vitamin A, omega-3 (n-3  
72 fatty acids), and protein. We then gathered species-level environmental and ecological traits  
73 that capture elements of diet, thermal regime, and energetic demand in fish<sup>9,10</sup> to develop a  
74 series of Bayesian hierarchical models that determine drivers of nutrient content (Methods).

75

76 Our models successfully predicted nutrient concentrations, with posterior predictive  
77 distributions consistently capturing both the observed overall mean and individual values of  
78 each nutrient<sup>11</sup> (Extended Data Figs. 1 and 2; Methods). We found that calcium, iron, and zinc  
79 – nutrients critical in preventing public health conditions such as stunting and anaemia<sup>7,12</sup> –  
80 were in higher concentrations in tropical fishes (Fig. 1). Tropical soils are often zinc and  
81 calcium deficient because these nutrients are easily exported from land to sea during strong  
82 pulse rainfall events common in the tropics; this process may elevate levels of these nutrients  
83 in marine food-webs<sup>13</sup>. Higher concentrations of calcium, zinc and omega-3 were found in  
84 small fish species. Small fish consumption is promoted, particularly in Asia and Africa<sup>14,15</sup>, as  
85 a rich source of micronutrients and, although these high concentrations are often linked to the  
86 practice of consuming fish whole<sup>15</sup>, we also detected elevated levels of these nutrients in  
87 muscle tissue.

88

89 Greater concentrations of omega-3 – which supports neurological function and cardiovascular  
90 health<sup>16</sup> – was found in species that are pelagic feeders, are from cold regions, and approach  
91 their maximum size more slowly (Fig. 1). Pelagic feeders consume plankton, the main source  
92 of omega-3 in aquatic systems<sup>17</sup>, whereas species adapted to a colder thermal regime, have a  
93 greater need for energy storage compounds and fat, including fatty acids<sup>18</sup>. Selenium  
94 concentrations were higher for species found at greater depths and lower for species in tropical  
95 waters, whereas lower concentrations of vitamin A were found in species from cold regions,  
96 with high trophic levels and short, deep body shapes. Concentrations of protein were greater in  
97 higher trophic level species, and those with a pelagic feeding pathway, and lower in species  
98 found in cold regions, and with a flat or elongated body shape (Fig. 1).

99

100 Given the alignment between our posterior predictions and observed data (Extended Data Fig.  
101 2), we used our trait-based models of nutrient concentration, and traits for species within the  
102 landed catch of the world's marine fisheries<sup>19</sup>, to produce the first global estimates for  
103 nutritional concentration (Fig. 2) and nutritional yield (Extended Data Fig. 3) of marine  
104 fisheries (Methods). These data reflect catches from within a country's Economic Exclusive  
105 Zone (EEZ) that are landed and consumed domestically, landed outside the country by foreign  
106 fleets, or traded internationally<sup>19</sup>. We include both officially recorded and reconstructed  
107 unrecorded catches (see Methods for comparisons), but do not include discards. There was no  
108 correlation between the concentration of nutrients per unit catch and either total nutrient yield  
109 or total fishery yield (Extended Data Fig. 4), suggesting the nutrient quality of fishery landings  
110 is influenced by species composition rather than the quantity landed; and thus, fish-based food  
111 policy guidelines <sup>e.g.</sup> <sup>20</sup> should specify for what types of fish consumption is advised.

112

113 High concentrations of iron and zinc ( $>2.5\text{mg } 100^{-1}\text{g}$  and  $>1.8 \text{ mg } 100^{-1}\text{g}$  respectively, of raw,  
114 edible portion) are found in the species caught in a number of African and Asian countries (Fig.  
115 2, Extended Data Table 1), the same regions at greatest risk of deficiencies in these nutrients<sup>7,12</sup>.  
116 This suggests that, in areas of critical public health concern, a single portion (100g) of an  
117 average fish provides approximately half the recommended dietary allowance (RDA) of iron  
118 and zinc for a child under the age of five years. Calcium concentrations are high ( $>200\text{mg}/100\text{g}$   
119 raw, edible portion) in the species caught in the Caribbean region, an area with a high  
120 prevalence of deficiency risk<sup>7</sup>, again highlighting the potential contributions fish can make to  
121 targeted health interventions in these areas. Concentrations of selenium and omega-3 are high  
122 ( $>25\text{ug } 100^{-1}\text{g}$ ,  $>0.5\text{g } 100^{-1}\text{g}$  respectively, of raw, edible portion) in fish species caught from  
123 high latitude regions including parts of Russia, Canada, Northern Europe, and Alaska (Fig. 2,  
124 Extended Data Table 1). This is consistent with omega-3 observed as abundant in marine foods

125 consumed by Arctic indigenous populations such as the Inuit of Nunavik, Canada<sup>21</sup>.  
126 Furthermore, these high selenium concentrations are found in some of the areas where selenium  
127 deficiencies are common<sup>22</sup>, yet a single portion of an average fish (Methods) from these waters  
128 contains enough selenium to meet the daily RDA for a child under the age of five years, and  
129 nearly half that required by adults.

130

131 While recognising challenges of fisheries sustainability, and potential climate-driven declines  
132 in yields<sup>23</sup>, the availability of high concentrations of key nutrients in areas at risk of nutrient  
133 deficiencies suggests that marine fisheries could be critical in helping close nutrient gaps. To  
134 assess this, we calculated nutrient yields (per capita) using the estimated national nutrient yield  
135 in our models and the human population living within 100 km of the coast (which represents  
136 39% of the global population<sup>24</sup>; Methods). We focus on calcium, iron, zinc, and vitamin A,  
137 which constitute a major burden of malnutrition, particularly within low-income countries<sup>1,7,12</sup>.  
138 For each nutrient and country, we compare this to published dietary deficiency risks<sup>12</sup>, seafood  
139 consumption rates<sup>25</sup>, and RDA<sup>26</sup> (Methods). We specify RDA averaged for the population aged  
140 five years and over, and children between six months and four years (Fig. 3). The latter category  
141 represents a vulnerable proportion of the population, in which interventions have the greatest  
142 potential long-term effects on growth, development, and health.

143

144 Fish-derived calcium, iron, zinc, and vitamin A yields of a large number of countries could  
145 contribute a significant proportion of the RDA for their coastal populations. For eight countries,  
146 these yields exceed requirements for at least one of these nutrients (Fig. 3a-d). Of those  
147 countries, only Iceland has mild dietary deficiency risks (<20%)<sup>12,27</sup> (Fig. 3a-d). Very high  
148 nutrient yields and prevalence of dietary deficiency risk coincide for at least two nutrients in

149 Namibia, Mauritania, and Kiribati (Fig. 3a-d). In these countries, a small fraction of available  
150 fisheries production, has the potential to close nutrient gaps. For example, iron dietary  
151 deficiency risk in Namibia is severe (47%)<sup>12</sup>, but just 9% of the fish caught in her EEZ is  
152 equivalent to the dietary iron requirements for her entire coastal population.

153

154 Fisheries clearly have an important place in food and nutrition policy. This contribution could  
155 be particularly significant if targeted towards the most vulnerable groups within society, such  
156 as children under the age of five, capturing the period when most growth-faltering occurs. Over  
157 50% of coastal countries have moderate to severe deficiency risks (>20%)<sup>12,27</sup> and nutritional  
158 yields that exceed the RDA needed for all children under five in the coastal population (Fig.  
159 3e-h). Most notably in Kiribati, calcium dietary deficiency risk is severe (82%)<sup>12</sup>, but just 1%  
160 of fish caught in her EEZ equals the calcium requirements for all children under five years. For  
161 a further 22 countries, predominantly in Asia and west Africa, the dietary requirements for all  
162 children under five years is equivalent to 20% or less of current catches. That targeted  
163 approaches could only require a fraction of current landings, suggests a nutrition-sensitive  
164 fisheries approach could align with environmental efforts to reduce current harvest levels.

165

166 Nutrient surpluses of some coastal countries where nutritional needs are not being met  
167 highlights that large yields do not necessarily lead to food and nutrition security. International  
168 fishing fleets and trade deals<sup>19</sup>, physical, economic, or institutional access to the right food<sup>28</sup>,  
169 food preferences and cultures, waste, and reduction to fish oil for animal feed<sup>29</sup>, can all act as  
170 barriers or avenues to these resources meeting local nutritional needs. For example, trade and  
171 foreign fishing are dominant in countries with large nutrient yields, where high rates of dietary  
172 deficiency risk exist (Methods; Extended Data Table 2). Understanding why, when there is an

173 adequate supply of nutrients, populations are still at risk of dietary deficiency, will require a  
174 multiscale socio-economic research agenda, that situates fish in the broader food system,  
175 accounting for patterns of production, distribution, preparation, and consumption.

176

177 Our results identify the current world distribution of nutrients from fisheries catch. In doing so,  
178 we demonstrate that for a number of nutrients essential to human health current production has  
179 the potential to significantly and positively impact the nutritional status of some of the most  
180 nutrient-deficient countries globally, even at reduced catch levels. Given that fish are in many  
181 instances a more affordable animal-source food<sup>4</sup>, with a lower environmental impact<sup>20</sup>, and  
182 nutrient supply from fisheries is comparable to that from other animal-source foods<sup>30</sup>, fisheries  
183 should be a core component of food and nutrition policy. However, current fisheries policy  
184 remains orientated towards maximising profit or yield. Reorienting fisheries policy towards a  
185 more efficient distribution of consumption, aimed at meeting nutritional needs, could close  
186 nutrient gaps in geographies of critical food and nutrition concern such as west and sub-Saharan  
187 Africa. Achieving this will require concerted efforts to understand how existing policies can  
188 be redirected towards desired food and nutrition outcomes. Ultimately, multiple approaches  
189 and actors must work in concert to tackle malnutrition<sup>20</sup>. Fisheries should thus form part of an  
190 integrated approach that is informed from health, production, development, and environmental  
191 sectors.

318

319

## 320 **METHODS**

321

322 **Finfish nutrient content database.** We compiled a database of 4188 measures of nutritional  
323 composition, from 419 finfish species, spanning 45 countries, based on:

- 324 1) Thomson Reuters Web of Science search of the scientific literature published between  
325 the years 1980 and 2015, using the search terms ‘content’ or ‘compos\*’, and  
326 ‘nutrition\* NEAR content NEAR fish\* AND Marine\*’.
- 327 2) FAO/INFOODS food composition for biodiversity database<sup>31-33</sup> produced by the Food  
328 and Agriculture Organisation (FAO) of the United Nations.
- 329 3) Key informant grey literature sources of finfish nutrient composition databases  
330 identified through snowballing of nutrition experts.

331 We extracted quantitative nutrient data from these sources on 14 nutrients essential to human  
332 health<sup>34</sup>; including, protein, minerals (iron, calcium, zinc, phosphorous, magnesium,  
333 selenium), vitamins (Vitamin A and B12), and fatty acids (polyunsaturated fatty acid  
334 (PUFA); the PUFA subsidiaries (omega-6, omega-3), and the omega-3 subsidiaries  
335 (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)). We only included sources  
336 in English, that were fully traceable and accessible, based on wild caught, marine finfish  
337 species, where analyses were conducted on fresh samples, reported nutrient content as a  
338 quantitative measure, and samples were taken from either the muscle, fillet, ‘edible portion’  
339 or whole body.

340

341 Where necessary, nutrient quantities were standardized into g/100g, mg/100g, or µg/100 g.  
342 We followed the FAO-INFOODS guidelines<sup>35</sup> for fatty acid conversions from percentage of  
343 total fatty acids to g/100g. Differences in sampling (e.g., wet weight, dry weight, whole,  
344 whole minus parts, muscle etc) were recorded and controlled for in our analyses (Methods  
345 below, Extended Data Fig. 5.)

346

347 Of the 14 nutrients of interest, seven had sufficient replication for our analyses: calcium, iron,  
348 selenium, zinc, vitamin A, polyunsaturated fatty acids (PUFA), and protein. We focussed our  
349 PUFA on n-3 fatty acids (i.e. omega-3) because fish are known to be the richest source of  
350 these important long chain n-3 fatty acids, and few other sources exist<sup>36</sup>. The final database

351 for the seven nutrients used here was comprised of 2,267 individual samples, from 367  
352 species of finfish, spanning 43 countries.

353

354 **Traits database.** Drawing on a body of theoretical, analytical, and empirical research in fish  
355 ecology<sup>9,10,37-39</sup> we identified a suite of characteristics related to diet, energetic demand, and  
356 thermal regime that are likely to influence nutritional quality of fish. We selected a trait-  
357 based approach to enable mechanisms of nutrient concentrations to be explored. However, we  
358 also allowed for inter-order variation among species in the structure of our hierarchical model  
359 to account for phylogeny<sup>5</sup>.

360

361 We used FishBase<sup>40</sup> to source trait data on the identified characteristics for fish species in our  
362 nutrient database and the Sea Around Us Project landings data. An underlying assumption of  
363 this approach is that trait values are fixed for a species and do not change in time or space.

364 Thus, spatial trends in nutrient concentrations are representative of shifts in the composition  
365 of the catch. Where trait data were missing for a particular species, genus level averages were  
366 calculated (mean for continuous traits and mode for categorical traits). Where genus level  
367 averages were not available due to missing data, family level average values were calculated.  
368 Traits were selected carefully to capture distinct elements of a species diet, energy demand,  
369 and thermal regime.

370

371 *Diet.* Diet directly influences the nutritional content of organisms through the concentration  
372 of bioavailable nutrients in their food<sup>9,41</sup>. Two diet variables were sourced for each species:  
373 feeding pathway, and trophic level. For feeding pathway, each species was first categorised  
374 based on their food source, as listed under “ecology”, “diet”, and “food items” in FishBase<sup>40</sup>.  
375 These food sources were then classified as either from a predominantly pelagic pathway (e.g.  
376 planktonic feeding) or benthic pathway (e.g. benthic algae, crustaceans). For carnivores, the  
377 prey items needed to be assessed in the same way to see if they reflect pelagic or benthic  
378 pathways. This represents the two dominant energy pathways for fish feeding in the marine  
379 environment, which are likely to influence the accumulation of nutrients<sup>42</sup>. Trophic level,  
380 directly extracted from FishBase<sup>40</sup>, indicates how high in the foodweb a species is feeding,  
381 which can be important for the bioaccumulation or bioaccumulation of some nutrients<sup>43</sup>.

382

383 *Thermal Regime.* The thermal regimes of water depth and the major geographic zones of the  
384 world influence a range of processes that may determine the assimilation or availability of

385 nutrients, for example metabolism of organisms<sup>44</sup>, and precipitation driven run-off of  
386 terrestrial nutrient sources<sup>45</sup>. We capture maximum depth and geographic zone for each  
387 species. Because temperature declines with depth, the maximum depth trait is correlated with  
388 temperature requirements<sup>46</sup>. Geographic zone was captured with four thermal regimes;  
389 tropical, subtropical, temperate, and cold. The ‘cold’ category includes polar and deep-water  
390 specialist species that are adapted to very cold water.

391

392 *Energetic Demand.* The allocation of energy and resources, including nutrients, to different  
393 aspects of life history, for example growth, reproduction, or somatic storage, is fundamental  
394 in animals<sup>47</sup>. Four variables were included to represent energetic demand: maximum length  
395 which is allometric with a range of characteristics such as home range and metabolism; age at  
396 maturity which captures the point at which resources are allocated to reproduction; K which  
397 captures the rate at which maximum size is approached and thus how energy is dedicated to  
398 body mass accumulation; and body shape which influences how a fish moves through its  
399 environment. All variables were extracted from FishBase<sup>40</sup>. Four categories of body shape  
400 were used; flat, elongate, short-deep, and fusiform. Eel-like shaped species (n=5 in our data)  
401 were grouped with elongate. Natural mortality (M) and reproductive guild were not included  
402 due to limited data on these life history traits across species.

403

404 **Control variables.** While fish trait covariates were of substantive interest, other covariates  
405 related to sampling were not; however we included these ‘nuisance parameters’ because they  
406 could have potentially biased our results due purely to sampling (Extended Data Fig. 5).  
407 Therefore we controlled for variability in reported preparation (wet weight or dry weight) and  
408 sampling (whole, whole minus parts, muscle), source (Web of Science, key informant grey  
409 literature, FAO-INFOODS), by representing these conditions as covariates in our model.  
410 Finally, while multiple habitat categories are recorded in FishBase, it was unclear how this  
411 covariate would determine nutritional yield within a given ecosystem; we did however  
412 believe it might affect sampling and therefore chose to include it as a nuisance parameter..

413

414 **Predictive model of nutrient concentrations.** We developed a series of Bayesian  
415 hierarchical models to predict the nutritional quality of marine finfish species, based on their  
416 environmental and ecological traits. None of the traits were sufficiently collinear to be  
417 problematic for the model. Where nutrient data were recorded at the genus level, these data  
418 were retained in the analysis if there were no species data for that genus within the dataset. If

419 species-level data were available from a given genus, any genus-level data was removed due  
 420 to non-independence among data points. We ran two sets of models, one where covariates  
 421 were unstandardized and a second set where continuous explanatory variables were  
 422 standardised by subtracting their mean and dividing by two standard deviations. The  
 423 dependent variables, and maximum depth, maximum length, and growth rate were log-  
 424 transformed to normalize the spread of these highly-skewed distributions. Our statistical  
 425 models were hierarchically-structured, allowing for inter-order differences that were  
 426 otherwise unaccounted for in our trait-focused models; this also provided posterior predictive  
 427 distributions for unobserved species that represented the full uncertainty underlying their  
 428 estimation. For each nutrient, our basic linear model structure was:

$$429$$

$$430 \quad \mu = \beta_{0,ORD} + \beta_{1,HAB} + \beta_{2,TR} + \beta_3MAD + \beta_4TL + \beta_5PEL + \beta_6LMX + \beta_{7,BOD} + \beta_8K$$

$$431 \quad \quad \quad + \beta_9AM + \beta_{10,HAB} + \beta_{11,FOS} + \beta_{12,SPM} + \beta_{13,SEA}$$

$$432$$

433 where the  $\beta_x$  values represent covariate parameters for taxonomic order (ORD), thermal  
 434 regime (TR), maximum depth (MAD), total length (TL), pelagic (PEL), maximum length  
 435 (LMX), body type (BOD), growth parameter (K), and age at maturity (AM). It also included  
 436 nuisance parameters for habitat category (HAB), the form of sample (FOS), sample  
 437 preparation method (SPM), and the database used to acquire the data (SEA). This linear  
 438 model was itself hierarchical, with the order-level intercepts ( $\beta_0$ ) allowing for phylogenetic  
 439 variation among groups.

440

441 Depending on assessed levels of fit to the model for each nutrient (see posterior checks  
 442 below), we used this linear model in combination with one of three data likelihoods, either  
 443 Normal ( $Y_i \sim N(\mu, \sigma)$  for calcium, omega-3 fatty acids, and selenium), non-central t  
 444 ( $Y_i \sim T(\nu, \mu, \sigma)$  for protein and vitamin A), or Gamma ( $Y_i \sim \Gamma(\alpha, \alpha/e^\mu)$  for zinc and iron). The  
 445 priors and hyperpriors for the various parameters were:

$$446$$

$$447 \quad \beta_0 \sim N(\gamma_0, \sigma_\gamma)$$

$$448 \quad \gamma_0, \beta_{1...13} \sim N(0, 1000)$$

$$449 \quad \sigma_\gamma, \sigma, \alpha \sim U(0, 1000)$$

$$450 \quad \nu \sim U(0, 4)$$

$$451$$

452 Models were all run in PyMC3 (ref 48) for 5000 iterations of the automatically-assigned No-  
453 U-Turn sampler. We examined posterior traces and Gelman-Rubin statistics<sup>49</sup> for evidence of  
454 model convergence and used posterior predictive distributions to check for model fit.  
455 Beginning with an assumed Normal data likelihood, if we found evidence for lack of  
456 convergence or poor model fit, we tried the alternative non-central t and Gamma likelihoods  
457 instead. Final models all had stable traces and Gelman-Rubin statistics very near one,  
458 supporting convergence, and posterior predictive distributions consistent with the observed  
459 data, supporting accurate predictions under each model (Extended Data Figs. 1 and 2).

460

461 **Mapping nutrient yields from global fisheries.** Using the Sea Around Us (SAU) catch  
462 reconstruction database<sup>19</sup>, we extracted catches from each country's exclusive economic zone  
463 (EEZ) in tonnes and by species group for the period 2010-2014. Reported and unreported  
464 catches are generally available for consumption, but discards are not. We therefore extracted  
465 data on reported and unreported catches from each country's EEZ, and excluded discards  
466 from this data. Insufficient trait data exist for crustaceans<sup>50</sup>, and the majority of landed catch  
467 are finfish. Therefore, all crustaceans, freshwater species, and cephalopods were removed  
468 from the database. We used the top 20 remaining species in our SAU database, which  
469 represent 100% of the catch of 31% of EEZs, over 90% of 74% of EEZs, and 75% of 95% of  
470 EEZs, to calculate the nutrient concentration of the catch from each EEZ over the 5-year  
471 period. The same procedure as used for the nutrient database, was used to assign the  
472 environmental and ecological traits to the species in the landed catch. Where Sea Around Us  
473 data were reported at family or genus level, we used the average trait value for that family or  
474 genus. All higher-level groupings (e.g. order and mixed categories), representing 18% of the  
475 finfish catch, were removed for the purpose of calculating EEZ nutrient concentrations.  
476 Higher level groupings were then reintroduced to calculate the EEZ nutrient yields. Our  
477 nutrient database included 17% of the species in the landed catch and we utilised the  
478 predictive capability of the trait-based model (Extended Data Figs. 1 and 2) for the remaining  
479 catch. Using the trait covariates from our predictive model, we calculated expected nutrient  
480 concentrations (per 100g raw, edible portion) based on the top 20 caught taxon grouping in  
481 the SAU database and the posterior distributions from our model. We then multiplied these  
482 values by total catch to estimate total nutritional yield per EEZ, based on reported SAU  
483 catches. There is some debate around the validity of the reconstructed unreported portion of  
484 these data, we therefore repeated all the analysis using only the reported catch and used  
485 correlation analyses to establish whether any bias was introduced. The spatial patterns in

486 nutrient yields and nutrient concentrations are extremely similar between the  
487 reported+unreported and only reported data (Extended data Figs. 3 and 5). All nutrient yield  
488 correlation coefficients are  $> 0.98$ ; and nutrient concentration  $> 0.89$  (Extended data Fig. 4); and  
489 reported+unreported nutrient yields are 19-29% greater than just reported nutrient yields.

490

491 There was no correlation between the concentration of nutrients per unit catch and either total  
492 nutrient yield or total fishery yield (Extended Data Fig. 6). This suggests that: first, nutrient  
493 concentrations are independent of total yield, and; second, the nutrient quality of fishery  
494 landings is influenced by species composition rather than the quantity landed. Fish-based  
495 food policy guidelines <sup>e.g.</sup> <sup>20</sup> should thus specify for what types of fish consumption is  
496 advised.

497

501

502

503 **Fishery contributions to meeting nutritional needs.** *Coastal population:* We gathered data  
504 on each country's coastal population within a 100km coastal band and each country's  
505 population age structure in 2015<sup>51</sup>. To calculate coastal proportion, we created a 100km  
506 buffer along each country's coastline based on the Global Administrative Areas database  
507 (GADM v.2.8) and used this to calculate total human population, and population under 5  
508 years, within 100km coastal band for each country in 2015 based on the Socioeconomic Data  
509 and Application Centre gridded population of the world database<sup>52</sup> and each country's  
510 population age structure<sup>51</sup>. In 2010, 39% of the world's population lived within 100km of the  
511 coast<sup>24</sup>, and within our study the coastal population captured on average 74% of each  
512 country's population (ranging from 2% to 100%), or 49% of the population of all countries  
513 considered.

514

515 *Nutrient yields and reference points:* We focused on calcium, iron, zinc, and vitamin A,  
516 which are of great public health concern globally, and especially in low-income countries<sup>7,12</sup>.

517 We calculated each country's per capita nutrient yield for the entire coastal population and  
518 separately for children under 5 years using the calculated fisheries-derived nutrient yields  
519 (methods above) and respective populations within the 100km coastal band. We use  
520 Recommended Dietary Allowance (RDA) for calcium, iron, zinc, and vitamin A as our

521 dietary reference intake values. RDA is the intake level at which the dietary needs of nearly  
522 all (97% to 98 %) of the population will be met. We calculated average RDA for children  
523 under 5 years and for the rest of the population<sup>26</sup>. To calculate average RDA for children  
524 under 5 years, we assumed infants between birth and six months were exclusively breastfed,  
525 and would thus not consume fishery derived nutrients directly. We then calculated the  
526 average RDA for children between 6 months and 4 years (i.e. children <5years), assuming  
527 each country's population was evenly distributed across the first 5 years of life<sup>26</sup>.

528

529 *Prevalence of inadequate intake:* We extracted data on the prevalence of inadequate intake of  
530 calcium, iron, zinc, and vitamin A for each country in 2011 from Beal et al<sup>12</sup>. Beal et al<sup>12</sup>  
531 combined food balance sheets from the FAO, UN population data, and nutrient intakes and  
532 requirements to calculate prevalence of inadequate intake based on the population weighted  
533 estimated average requirement and the distribution of the availability of each micronutrient.

534

535 *Fish consumption rates:* We extracted data on seafood consumption rates<sup>25</sup> as an indicator of  
536 how likely fish-based nutrition strategies were to be locally and culturally acceptable<sup>29</sup>.

537 Countries that do not consume seafood are likely to face social, cultural, or religious barriers  
538 to the introduction of fish as a source of nutrients.

539

#### 540 **Role of trade and foreign fishing**

541 Fish trade could act as an engine of growth<sup>53</sup> enabling the import of large volumes of  
542 nutritious foods. Alternatively, in the absence of fair returns<sup>54</sup>, fish trade could exacerbate  
543 food and nutrition insecurity<sup>55</sup>. Recent global analyses demonstrate the volume of fish  
544 exported from developing countries is equal to the volume imported, with developed  
545 countries importing high-priced seafood in exchange for low-priced seafood<sup>56</sup>. This work  
546 thus suggests developing countries are compensated for the quantities of seafood that they  
547 export with income; but, what remains unclear is whether the income from trade translates to  
548 the consumption of nutrient-rich foods, and how this pattern plays out in different countries.  
549 To address this gap, we analyse the role of trade and foreign fishing in the countries with  
550 potential nutrient supply and high prevalence of deficiencies.

551

552 For the countries whose nutrient yields (from catches in their EEZ's) exceed the RDA for  
553 their coastal populations, and for the same 5-year period (2010-2014), we use the FAO  
554 *fishery statistical collections*<sup>57</sup> (<http://www.fao.org/fishery/statistics/global-commodities->

555 [production/en](#)) to extract data on marine finfish imports and exports to examine the patterns  
556 of marine finfish trade; and the Sea Around Us catch reconstructions data to examine the  
557 prevalence of foreign fishing in their waters, to together establish how trade may affect food  
558 and nutrition security.

559  
560 Domestic fleets account for the greatest volumes of finfish catches (>79%) in Iceland,  
561 Maldives, and Namibia, whereas foreign fleets account for most of the fish caught in Kiribati  
562 and Mauritania (>69%). Namibia and Kiribati subsequently exports most of their fish  
563 landings (>90%), whereas the other nations export approximately half. For all countries, fish  
564 imports amount to a small fraction (<5%) of fish exports. Taken together, Namibia,  
565 Mauritania, and Kiribati, countries with high prevalence of nutritional deficiencies, have the  
566 equivalent of <13% of the fish caught in their waters available for domestic markets, whereas  
567 Iceland and Maldives, countries with low prevalence of nutritional deficiencies, have 68%  
568 and 39% available (Extended Data Table 2). Any income gained from the large quantities of  
569 fish trade and foreign fishing in Namibia, Mauritania, and Kiribati does not appear to  
570 substitute for the nutrients lost. These countries could benefit from policies that seek to divert  
571 a greater portion of fish for local consumption.

572

657 Centre of Excellence for Coral Reef Studies, a Royal Society University Research Fellowship  
658 to N Graham (UF140691), a Tier II NSERC Research Chair awarded to A MacNeil, the  
659 Australian Centre for International Agricultural Research through projects FIS/2017/003 and  
660 FIS/2015/031, and a USAID Feed the Future Innovation Lab for Nutrition – Asia award to A  
661 Thorne-Lyman (award number AIDOAA-1- 10-00005). This work was undertaken as part of  
662 the CGIAR Research Program on Fish Agri-Food Systems (FISH) led by WorldFish,  
663 supported by contributors to the CGIAR Trust Fund. We are very grateful for the support  
664 provided by the FishBase and FAO INFOODs database teams, J. Robinson for help with Fig.  
665 3, N. Swan, J. Silveira, and E. Maire for help sourcing data.

666  
667 **Author Contributions** C.C.H. conceived of the study with P.J.C., N.A.J.G., K.L.N., A.T-L.,  
668 C.D’L., E.H.A., S.H.T., and D.M.; C.C.H., P.J.C., N.A.J.G., K.L.N., C.D’L., and M.R.  
669 collected the data; C.C.H., M.A.M., and K.L.N. developed and implemented the analyses;  
670 C.C.H. led the manuscript with input from all authors.

671  
672 **Author Information**

673 Reprints and permissions information is available at [www.nature.com/reprints](http://www.nature.com/reprints). The authors  
674 declare no competing financial or non-financial interests. Correspondence and request for  
675 materials should be addressed to C.C.H. ([christina.hicks@lancaster.ac.uk](mailto:christina.hicks@lancaster.ac.uk)).
