The Severe Acute Respiratory Syndrome Coronavirus-type 2 (SARS-Cov-2) infection has caused a global pandemic whose medical consequences in the long term are not yet well known. Although some patients develop pulmonary fibrosis (1), the majority of them recover without sequelae, especially after mild symptoms. The French Pulmonary Society of Respiratory Diseases has proposed guidelines for monitoring patients (2). In case of unexplained persistent respiratory symptoms, it is suggested to look for a cardiac or pulmonary thromboembolic cause or for a hyperventilation syndrome (HVS) (2). HVS is characterized by a wide variety of somatic symptoms induced by inappropriate ventilation and reproduced by voluntary hyperventilation (3,4). HVS is frequently confusing for physicians as the patient may express both cardiorespiratory (dyspnea: thirst for air, difficulty in breathing; sighs; yawning, chest pain; palpitations) and extrapulmonary symptoms (intense asthenia, weakness, confusion, anxiety, dizziness, paresthesia, muscle cramps), that can possibly match to the clinical presentation of COVID (5).

On June 30th, 147 out patients had undergone in our Department a clinical evaluation 3 months after COVID-19 infection with respiratory functional tests and measurement of carbon monoxide diffusing capacity (DLCO), EKG, thoracic computed-tomography (CT)-scan, measurement of blood cells level, D-Dimers and troponin. We dismissed patients with dyspnea and obvious abnormality on one of these tests. Ten out of these 147 patients (7%) complained of persistent dyspnea unexplained by above investigations.

They presented with a stereotypical symptomatology suggesting a diagnosis of HVS: difficulty in inspiration or chest tightness.

The set of complementary explorations we applied to these 10 patients included the Nijmegen score, a voluntary hyperventilation challenge with PET-CO₂ monitoring, a cardiopulmonary exercise testing (CPET), arterial blood gas analysis, a ventilation/perfusion lung scan, and a cardiac magnetic resonance imagery (MRI). A brain MRI was performed on patients with HVS diagnosis. All patients consented to the use of routine care exam-extracted medical data. This study was approved by the research ethical committee of Foch Hospital (IRB No. IRB00012437).

Among the 10 patients, eight were female, two were male. The COVID-19 infection had been confirmed by reverse transcriptase-polymerase chain reaction test on nasopharyngeal swab for all patients. Two patients had been hospitalized, only one had required oxygen and non-invasive ventilation. Initial thoracic CT-scan had disclosed restricted extension of COVID-related lung infiltrates (<25%) and no pulmonary embolism had been diagnosed at the time of COVID-19 diagnosis (all patients underwent a CT-pulmonary angiography at diagnosis). Three patients had been prescribed antibiotics and one had received hydroxychloroquine.

At the time of assessment [median delay from COVID-19 diagnosis, 46 days (IQR 36–60)], all patients complained of dyspnea on both rest and exertion. The major symptoms reported by all patients were difficulties in breathing in or

chest tightness.

We retained the diagnosis of HVS for 6/10 patients, characterized by a Nijmegen score >23/64, hypocapnia on blood gas at rest and a positive hyperventilation challenge (induction of two or more symptoms and delayed PET-CO₂ normalization) (Table 1). All patients with HVS were female, three had a previous diagnosis of mild asthma (2 were receiving inhaled corticosteroids) that was

controlled with normal functional tests. On CPET, aerobic capacities were conserved. Disharmony in the respiratory pattern during exercise (uncoordinated and anarchical evolution of tidal volume and respiratory rate) was noted for 5/6 patients. Brain MRI of patients with HVS were normal.

Among the four patients without diagnosis of HVS, one was diagnosed with deconditioning, one had a slight increase in alveolar-arterial partial oxygen pressure

Table 1 Clinical and functional characteristics of patients

Characteristics	HVS (n=6)	No HVS (n=4)
Sex (M/F)	0/6	2/2
Age (years)	48 [46–54]	55 [45–60]
BMI (kg/m ²)	24 [22–25]	23 [22–24]
Previous asthma	3	0
HAD (/42)	21 [17–23]	
Difficulty in breathing in	5	2
Chest tightness	4	3
Hemoglobin (g/dL)	14.5 [13.6–15]	15 [14,3–15.5]
Lymphocytes (G/L)	2,7 [2–2.8]	2 [1.6–2.3]
PFT		
FEV ₁ (L/min)	2.6 [2.4–2.8]	3.5 [3.2–3.6]
FEV ₁ (%pred)	95 [92–97]	105 [102–111]
FVC (L/min)	3.3 [3–3.4]	4.3 [3.8–4.4]
FVC (%pred)	101 [97–103]	111 [105–116]
FEV ₁ /FVC	81 [78.5–85]	81.5 [78.6–84]
DLCO (%pred)	74 [72–75]	83 [74–85]
DLCO/VA (%pred)	93 [89–93]	93.5 [81–94]
Resting arterial blood gases		
pH	7.45 [7.40–7.49]	7.41 [7.39–7.42]
paO ₂ (mmHg)	84.5 [80.2–94.7]	87.5 [82.2–92.5]
paCO ₂ (mmHg)	31.5 [26.5–37.2]	37.5 [35.5–38.2]
HCO ₃ ⁻ (mmol/L)	22 [19.4–23]	24 [22.8–24.1]
Nijmegen score (/64)	25.5 [24–33]	16 [8–22]
Hyperventilation challenge		
petCO ₂ resting (mmHg)	29 [26–32]	35 [32–36]
petCO ₂ after 2 min VHV	13 [12–15]	13 [13–16]
petCO ₂ recovery (>5 min)	26 [24–30]	36 [32–37]

Table 1 (continued)

Table 1 (continued)

Characteristics	HVS (n=6)	No HVS (n=4)
CPET		
VO ₂ peak (mL/kg/min)	23,8 [22.5–26.5]	24.2 [23–28]
VO ₂ peak (%pred)	108 [93–110]	90 [84–100]
VE/VO ₂ at VThr	28.5 [26–32]	29 [27–30]
VE/VO ₂ peak	42 [38–44]	42 [39–44]
Vt peak (FVC %)	57 [50–63]	54 [52–55]
RR peak (/min)	39 [36–40]	36 [34–39]
DeltaHR/DeltaVO ₂ peak	61 [57–69]	61 [48–69]
P(Ai-a) O ₂ peak	26 [24–28]	21 [15–26]
Vd/Vt peak	15 [13–17]	20 [16–21]
Delta PetCO ₂ peak-rest	-2.2 (-4.3 to -0.57)	4 (1.5–5.25)
Delta VE/VCO ₂ peak-rest	-0.1 (-0.77 to -5.9)	-4.5 (-5.5 to -2)

Data are expressed in median [interquartile range]. HAD, Hospitality Anxiety and Depression Scale; HVS, Hyperventilation Syndrome; PFT, pulmonary function testing; FEV₁, forced expiratory volume in one second; FVC, forced vital capacity; DLCO, diffusing capacity of the lungs for carbon monoxide, VA, alveolar volume; VHV, voluntary hyperventilation; CPET, cardiopulmonary exercise testing; VO₂, oxygen consumption; VE, minute ventilation; VThr, ventilatory threshold; (PAi-a) O₂, alveolar-arterial PO₂ pressure difference; Vt, tidal volume; RR, respiratory rate; HR, heart rate; Vd/Vt, dead space-to-tidal volume ratio.

difference related to underlying interstitial lung disease. CPET unmasked mild cardiovascular abnormalities in the last two patients: one with ST segment depression but further normal myocardial perfusion scintigraphy and the second one with an early plateau of max consumption of oxygen (VO₂max), leading to the search for defective left ventricle filling on exertion. Cardiac MRIs on rest all showed normal left ventricle ejection fraction and no pericardial nor myocardial abnormalities.

We found a high frequency of post COVID HVS in patients with otherwise unexplained inspiratory dyspnea. As in idiopathic HVS, we observed a female predominance and a high proportion of patients with previous asthma (3).

Although there is no gold standard for the diagnosis of HVS, the combination of Nijmegen score, hyperventilation test and CPET is robust to establish this diagnosis (3).

There were stigmas of cardio-muscular deconditioning for all patients (DeltaHR/DeltaVO₂ >50) that may be due to the lockdown and the reduction of activity secondary to HVS (6).

Ruling out any thrombotic lung disease was essential as COVID-19 is known to cause endothelial damages in various organs (7). This was achieved by normal results of D-dimer values, preserved vascular bed in lung scans,

absence of dead space anomalies in CPET results and a normal DLCO. Moreover, absence of both dead space and arterial alveolar gradient anomalies during exercise eliminated pulmonary arterial hypertension.

Other explorations have been useful to eliminate other diagnoses potentially related to COVID-19. HVS is secondary to an inadequate ventilatory control. The brain MRI data confirmed absence of any central abnormality. Myocarditis which is a complication of COVID-19 infection (8) may mimic the symptoms experienced by our patients but was ruled out by normal biological data, EKG and cardiac MRI.

Although the precise pathophysiology of HVS is unknown, the various symptoms seem related to hypocapnia (9). Anxiety is considered to be a trigger of HVS. Since the current pandemic is a source of anxiety, this may explain the resurgence of HVS as a post-traumatic stress (10). The HVS generates also a high degree of anxiety by itself because of its strong impact on the quality of life of patients.

In conclusion, physicians should be aware that HVS is a frequent manifestation of the post-COVID-19 period and leads to chronic dyspnea. In case of highly suggestive clinical symptoms, diagnosis relies on Nijmegen and

hyperventilation challenge after ruling out pulmonary, vascular and cardiac abnormalities. While the risk factors for developing a severe form of COVID-19 are represented by male sex, age over 65 years, obesity and underlying heart disease, those favoring the appearance of a post-COVID HVS would be the female sex, a mild form of COVID, previous asthma, age under 65 years and the absence of cardiac disorder. Making an HVS diagnosis is of importance because chronic hyperventilation is associated with severe impairment in health-related quality of life while it is accessible to reeducation. The observation of high incidence of HVS after COVID-19 prompted us to create a dedicated respiratory rehabilitation protocol, combining comprehensive physiotherapy and psychological treatment.
