Abstract: This paper provides a review on pyrolysis technologies, focusing on reactor designs and companies commercializing this technology. The renewed interest on pyrolysis is driven by the potential to convert lignocellulosic materials into bio-oil and biochar and the use of these intermediates for the production bio-fuels, biochemicals and engineered biochars for environmental services. This review presents slow, intermediate, fast and microwave pyrolysis as complementary technologies that share some commonalities in their designs. While slow pyrolysis technologies (traditional carbonization kilns) use wood trunks to produce char chunks for cooking, fast pyrolysis systems process small particles to maximize bio-oil yield. The realization of the environmental issues associated with the use of carbonization technologies and the technical difficulties to operate fast pyrolysis reactors using sand as heating media and large volumes of carrier gas, as well as the problems to refine resulting highly oxygenated oils, are forcing the thermochemical conversion community to rethink the design and use of these reactors. Intermediate pyrolysis reactors (also known as converters) offer opportunities for the large scale balanced production of char and biooil. The capacity of these reactors to process forest and agricultural wastes without much preprocessing is a clear advantage. Microwave pyrolysis is an option for modular small autonomous devices for solid waste management.

1. Introduction

The practice of carbonizing wood to manufacture char has existed for as long as human history has been recorded¹⁻⁵. Initially, producing char was the sole objective of wood carbonization^{2,4,5}. In fact, char is the first synthetic material produced by mankind^{6, 7}. However, new byproducts (tars, acetic acid, methanol, acetone) were obtained from wood as the civilization progressed and new reactors and bio-oil recovery systems were designed. The ancient Egyptians used pyrolytic liquid products such as fluid wood-tar and pyroligneous acid to embalm their deads⁵. According to the writings of Theophrastus, the Macedonians obtained wood tar from burning biomass in pits⁴. At the end of the eighteenth century, technologies to recover and utilize the condensable pyrolysis products were relatively well developed^{3,4,8}. This resulted in brick kilns to recover the condensable gases that were normally lost in the pits. Iron retorts (vessels) followed brick kilns. In the 19th century the “acid-wood industry”, also known as the “wood distillation industry” was established⁹ to produce charcoal and liquid by-products (e.g. acetic acid, methanol and acetone). The historical development of carbonization industry is one of the most fascinating in the annals of the Industrial Chemistry^{1,4}. The hardwood distillation industry is frequently considered the precursor of the modern petrochemical industry¹⁰. The rise of the petroleum industry at the beginning of the twentieth century, with cheaper products, caused the decline of the pyrolysis industry. However, the oil crisis during the 1970’s forced to reconsider biomass pyrolysis as a technology that could contribute to reduce our dependency on fossil oil. The “fast” pyrolysis reactors were introduced at that time, aiming at maximizing liquid products¹¹⁻¹⁹. Recent advances in bio-oil hydrotreatment^{20,21}, bio-oil fractionation²²⁻²⁵ and new bio-oil derived products (e.g., transportation fuels, phenol formaldehyde resins, carbon fibers) are catalyzing the development of bio-oil refineries. Figure 1 shows important developmental milestones of pyrolysis technology.

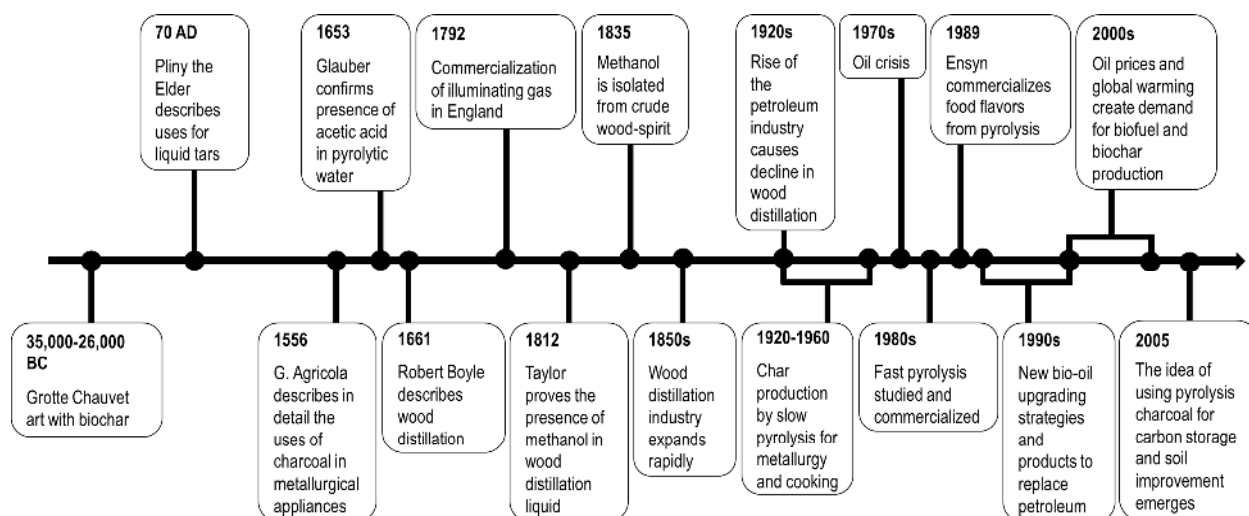

Figure 1. Some important milestones in the development and use of pyrolysis (Adapted from:^{2,4,5})

The social and economic impact of wood carbonization in today's world is significant²⁶. The wood used as fuelwood and charcoal is about half of the wood extracted from forest, generating income for 40 million people worldwide²⁶. The world's top producers of charcoal are (in descendent order): Brazil, Nigeria, Ethiopia, India, the Democratic Republic of Congo, Ghana, Tanzania, China, Madagascar and Thailand²⁶. Today this industry contributes with an estimated \$ 650 million to Tanzania's economy (300 000 people involved in production and trade)²⁶. The Food and Agriculture Organization (FAO) of the United Nations, estimated that 2.4 billion people in developing nations use charcoal as domestic fuel²⁶⁻³¹. Approximately, 3 billion people still lack access to clean fuels and technologies for cooking²⁶. According to the FAO³² more than 52 Mt of charcoal were produced worldwide in 2015 (Africa 62 %, Americas: 19.6 % and Asia: 17 %)²⁶, showing an increase of close to 20 % since 2005. Since current char yields a mere 20 wt. % of the original biomass, it can be estimated that more than 260 Mt of wood are currently processed worldwide to produce charcoal. Between 1 and 2.4 GT CO_{2eq} of greenhouse gases are emitted annually in the production and use of fuelwood and charcoal which represents 2-7 % of global anthropogenic emissions^{26,33}. Charcoal produced using sustainable managed resources and improved pyrolysis technologies has the potential to reduce emissions by 80 %²⁶. Therefore, there are huge opportunities to improve the environmental performance of current carbonization

1
2
3
4 units³⁴⁻³⁶. The potential use of char as a means to fight global warming is also attracting renewed
5 interest on pyrolysis³⁷. Char has the capacity to increase soil fertility and sequester carbon³⁸⁻⁴¹.
6 Sustainable char technology could offset up to 130 Gt CO₂eq emissions during the first century of
7 adoption³⁹. Greening the pyrolysis value supply chain (with sustainable sourcing, production,
8 transport, and distribution) is critical to supporting livelihoods and providing energy security in
9 developing nations²⁶. The International Energy Agency forecasted that by 2030 charcoal will
10 become a \$ 12 billion industry²⁷.

18

19 According to Scopus, the number of research papers with the keyword “carbonization reactors
20 (CR)” and “fast pyrolysis reactors (FP)” have been steadily growing: 1980-1990 (CR:59 and
21 FP:63 papers), 1990-2000 (CR:86 and FP:88 papers), 2000-2010 (CR:306 and FP:371 papers),
22 2010-2017 (CR:340 and FP:840 papers). Despite the growing interest to produce bio-oil and
23 char, the disperse information on pyrolysis technologies and manufacturers hinders the
24 development of this industry. There is a vast diversity of factors affecting the pyrolysis process
25 (different feedstocks, scale, capacity, use of mobile or stationary units) which makes it very
26 difficult to find an exclusive design that is sustainable across all the potential feedstocks and
27 applications.

33
34
35

36 Although there are excellent reviews on fast pyrolysis technologies^{13-19,42}, on conventional
37 carbonization reactors^{5, 6,41,43}, and microwave pyrolysis^{44, 45} there are only few reviews on the
38 converters and retorts^{1,4,9,46}. Lynch and Joseph⁴⁷, published a guideline for the development and
39 testing of pyrolysis plants for char production. Interestingly, some companies are reproducing
40 old concepts to design new pyrolysis reactors. Thus, the main goal for this paper is to provide a
41 comprehensive overview of pyrolysis reactors. Herein, we describe designs, operating
42 conditions, scale, and yields to help those involved in the development of pyrolysis projects
43 identifying robust flexible designs for their business models. This work is an attempt to present
44 all pyrolysis reactors in a single document within a historical perspective intending that the
45 knowledge and experience generated through centuries could serve as inspiration for the
46 development of new designs.

2. Fundamentals of biomass pyrolysis

The main factors on the operation of pyrolysis reactors affecting the yield and composition of products are: (1) Biomass pyrolysis temperature⁴⁸, (2) Particle size⁴⁹⁻⁵¹, (3) Alkali content⁵²⁻⁵⁴, (4) Residence time in vapor phase⁵⁵⁻⁵⁷, (5) Pressure⁵⁸⁻⁶⁰, (6) Pretreatment temperature^{61, 62} and (7) Heating rate^{55,56,63}. Other factors such as feedstock composition, use of additives, and condensation conditions are outside the scope of this review.

Thermochemical depolymerization reactions are important between 250 and 600 °C⁶³. When biomass is heated, thermal cracking of bonds in biomass constituents (cellulose, hemicellulose and lignin) happens. These primary thermal depolymerization reactions happen in the solid. When biomass macromolecules are heated, some fractions can crosslink and form a solid product^{63, 64} and others can depolymerize into light oxygenates that can be easily evaporated⁶⁵ or into oligomeric products that can form a liquid intermediate⁶⁶⁻⁶⁸. This liquid intermediate is acidic which enhances dehydration and polycondensation reactions⁶⁹. Most of the pyrolytic water is formed in the liquid intermediate⁶⁹. The oligomeric molecules in the liquid intermediate may be removed from the hot reaction environment in the form of aerosols by thermal ejection^{66, 67}.

Biomass particle size has a direct impact on heating rate and the release of aerosols, and ultimately on the product distribution of pyrolysis. Indeed, the evacuation of the aerosols formed during the pyrolysis reaction can proceed in two distinct ways depending on the particle size. When very small particles (mostly formed by cell walls) are used, aerosols formed in the pyrolysis reaction can be easily ejected and pyrolysis vapors can be removed without travelling inside the cell cavities^{50,51}. Mass transfer limitations increase with particle size. The second regime involves aerosol formation inside cell walls. An important part of these aerosols is retained from escaping through the cell walls and will eventually contribute to the formation of extra char through secondary reactions. Volatile pyrolysis products are also formed inside the particles and will react on their way out of the biomass particle and of the reactor^{49,50}. Secondary reactions are typically called intra- and extra- particle homogeneous and heterogeneous reactions^{49,57,70,71}.

1
2
3
4
5 The temperature and hydrodynamics of the gaseous reaction environment, the presence of a
6 secondary heating medium (e.g. sand, steel balls, reactor walls, heating tubes) and the size of the
7 biomass particle determine the total conversion time by controlling internal particle heat transfer
8 and reaction kinetics⁷². External heat transfer is determined by the reactor type and its heating
9 method. These factors together define the traditional distinction between slow and fast pyrolysis
10 reactors. The heat transfer in carbonization units operating with logs is controlled by the heat
11 transfer rate inside the wood pile (bed) and inside the logs (typically low heating rates are
12 achieved: less than 100 °C/min). Fast pyrolysis reactors typically operate with very small
13 particles to achieve high heating rates (>1000°C/s) inside the particles and high bio-oil yields.
14
15
16
17
18
19
20
21

22 Although there are few studies on the effect of these parameters for all the reactors covered in
23 this review, a discussion for the specific case of fluidized bed reactors is instructive to gain
24 insights on their potential impact in other reactors. Fluidized beds are designed to maximize bio-
25 oil yields; thus, in order to obtain an adequate gas-solid heat transfer for this purpose, the
26 biomass particles should be very small. This is due to the poor thermal conductivity of biomass
27 (typically around 0.1 W/mK along the grain and around 0.05 W/mK across the grain). A thin
28 reaction layer may achieve a temperature increase of 10,000 °C/s, but the low thermal
29 conductivity of wood will prevent this heating rate to occur throughout the entire particle. As the
30 size of the particle increases, secondary reactions within the particle become increasingly
31 significant, leading to the reduction of liquid yields¹¹.
32
33
34
35
36
37
38
39
40
41

42 Figure 2 shows the effect of some operational parameters on the yield of pyrolysis products in
43 fluidized beds. These studies clearly show that to achieve high bio-oil yields: (i) the pyrolysis
44 temperature should be between 450 and 550 °C, (ii) very small particle sizes should be used, (iii)
45 the residence time of pyrolysis vapors inside the reactor should be minimized, and (iv) alkaline
46 content in biomass should be low^{48-50, 54, 55, 73, 74}. Data from this figure also suggest that: a) the
47 type of reactor is only one of the several factors controlling product yields, and b) a careful
48 control of the operating conditions (temperature, particle size, ash content) of systems that are
49 not traditionally considered fast pyrolysis reactors could dramatically improve the yield of
50 desirable products. This is especially relevant since most of the literature on fast pyrolysis from
51

60

1
2
3
4 the 1980s and 90s focused on identifying the very stringent operational conditions that maximize
5 bio-oil yields, while assuming that char should be combusted to provide the energy needed for
6 the process. Instead, currently there is a growing research interest towards the design and use of
7 simpler systems for combined production of bio-oil and char, both presently regarded as valuable
8 products ^{20,75}. The design of reactors resulting in oils with lower oxygen content and higher
9 yields of gases by taking advantage of the secondary homogeneous reactions in gas phase
10 warrant further investigation.

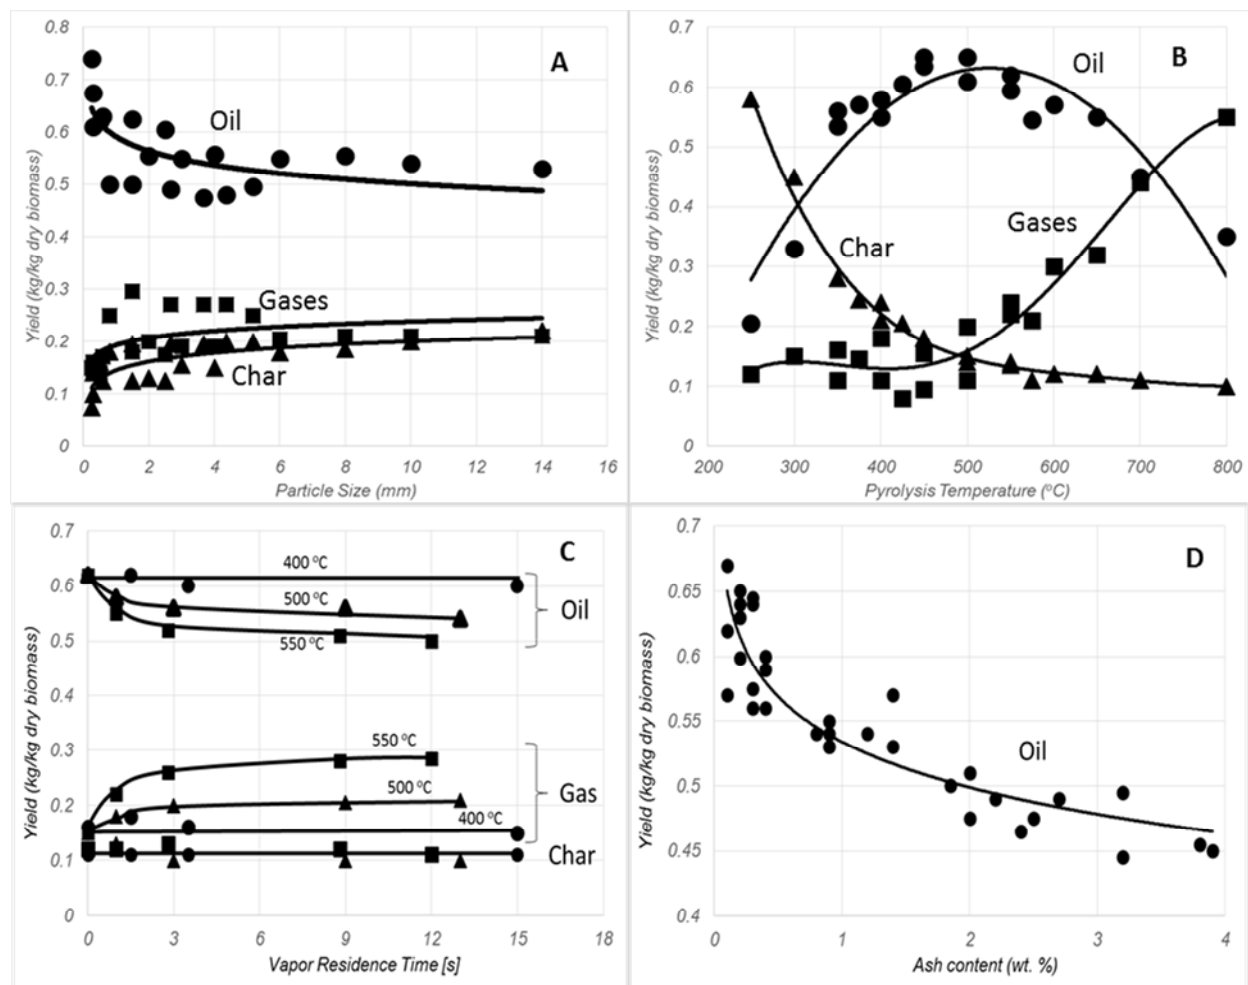

Figure 2. Effect of operational parameters on the yield of products during fast pyrolysis: **A:** Effect of particle size (Adapted from:^{49, 50}) (Feedstock: Mallee wood⁴⁹, Beech wood⁵⁰), **B:** Effect of Pyrolysis temperature (Adapted from ^{48, 74}) (Feedstock: Pine, Beech, Bamboo, Demolition wood⁴⁸, Malee Wood⁷⁴), **C:** Effect of vapor residence time (Adapted from⁵⁵) (Feedstock: Pine wood⁵⁵), **D:** Effect of ash content (Adapted from⁵⁴).

The interest in reactors capable of producing both char and bio-oil, has resulted in a growing number of designs for the balanced production of both products^{76, 77}. Figure 3 shows the effect of the temperature on the yield of products obtained when pellets and small particles are processed in a rotary drum and in an auger pyrolysis reactor respectively^{76, 77}. Although, bio-oil yields in the auger and rotary drum reactors were lower than for fluidized beds (see Figure 2), these

reactors are easier to operate (use less carrier gas and do not use sand) and do not consume the charcoal for their energy needs. The higher gas yields could help to satisfy an important fraction of the energy needs of these systems. Moreover, pyrolysis gas produced in Auger and rotary drums is less diluted in the carrier gas than in bubbling or circulating fluidized beds, making it more plausible their combustion in conventional boilers and gas engines.

Figure 3. Yield of products in (A) rotary drum (Feedstock: Arbor Pellet⁷⁶) and (B) an auger pyrolysis reactor (Feedstock: Douglas Fir Wood⁷⁷)

3. Types of pyrolysis reactors

There are hundreds of pyrolysis reactors designs⁷⁸. Reviewing all of them is out of the scope of this review. Therefore, in this paper we will focus on the reactors most commonly employed. Bridgwater¹⁶ classified the pyrolysis reactors based on the vapors residence time (VRT) inside the reactor and the time the biomass particle takes to reach final temperature (or heating rate) into: fast (final temperature: 500 °C, particle diameter below 2 mm, VRT: 1 s), Intermediate (final temperature: 500 °C, small particles, VRT: 1 s), Slow (final temperature: 500 °C, logs or chips, VRT: days). The term “*fast pyrolysis reactors*” refers to reactors designed to maximize the yields of bio-oil and typically use powdery biomass as feedstock. Emrich⁵ sub-classified the slow pyrolysis (carbonization) reactors as: kilns, retorts, and converters. The term “*kiln*” is used to

1
2
3
4 describe traditional char making equipment, solely employed to produce char from wood logs.
5
6 Industrial reactors capable of recovering char and products from volatile fractions (liquid
7
8 condensates and syngas) are herein referred to as “retorts or converters.” The term “retort”
9
10 refers to a reactor able to pyrolyze pile-wood, or wood logs over 30 cm long and over 18 cm in
11
12 diameter⁵. “Converters” produce char by carbonizing small particles of biomass such as chipped
13
14 or pelletized wood. The converters using small particles, operate at conditions comparable to the
15
16 intermediate pyrolysis reactors described by Bridgwater¹⁶. In this review we use the heating
17
18 mechanism to group the pyrolysis reactors into: Slow pyrolysis (Kiln, retort), intermediate
19
20 pyrolysis (converters), fast pyrolysis and microwave pyrolysis reactors^{5, 16, 44, 45}. Classification of
21
22 reactors can also be based on: (1) the final products targeted (oil, char, heat, electricity, gases),
23
24 (2) the reactor’s mode of operation (batch or continuous), (3) the manner in which it is heated
25
26 (direct or indirect heating, auto-thermal, microwave), (4) the heat source used (electric, gas
27
28 heater, biomass combustion), (5) the method used to load the reactor (by hand, mechanical), (6)
29
30 the pressure at which the unit operates (vacuum, atmospheric, pressurized), (7) the material used
31
32 for the construction of the reactor (soil, brick, concrete, steel), (8) reactor portability (stationary,
33
34 mobile) and (9) the reactor’s position. More information on the classification of pyrolysis
35
36 reactors can be found elsewhere⁷⁹.

37
38 Although the type of pyrolysis reactor and its operating conditions greatly determine the quality
39
40 of the final targeted products, there is limited information on the open literature linking reactor
41
42 type, operating conditions and product quality. For charcoal, proximate analysis gives a good
43
44 indication of its quality. According to Antal and Gronli⁶, fixed carbon content of charcoal for
45
46 domestic cooking should have volatile matter contents of less than 30%, whereas those of
47
48 metallurgical charcoal should be <15%. Ash contents should be between 0.5 and 5%. These
49
50 values correspond to calorific values between 28 and 33 MJ/kg. For the use of charcoal as
51
52 biochar (soil amendment), the International Biochar Initiative provides a standardized definition
53
54 of its characteristics⁸⁰. A common issue in carbonization reactors, especially in batch systems, is
55
56 the inhomogeneous quality of charcoal due to temperature gradients inside the reactor, uneven
57
58 gas circulation, partial combustion and heterogeneous wood particle sizes. Thus, in terms of
59
60 product quality, a good temperature control is a key factor for well-designed retorts or

converters⁵. The type of reactor is also one of the factors that define bio-oil quality, together with biomass feedstock composition, particle size and condensation system⁸¹. The desired bio-oil characteristics will differ depending on the targeted final use, i.e, use as a fuel, further upgrading, or use as a product source. From the point of view of bio-oil as a fuel, the multiphase nature of bio-oil is a critical issue⁸¹. The bio-oil obtained by the fast pyrolysis of relatively dry materials is a homogeneous single-phase oil. The liquid obtained from intermediate, slow and microwave pyrolysis processes is typically formed by a decanted oil and an aqueous phase¹⁶. The formation of separated phases depends on the relative quantities of the polar compounds (water, sugars, pyrolytic humins), the non-polar compounds (pyrolytic lignin) and the solvents (organic compounds of low molecular weight, such as: methanol, hydroxyacetaldehyde and acetol)^{54, 81}. Most of the research on bio-oil properties has focused on fast pyrolysis. Thus, more studies are needed to understand how the type of intermediate and slow pyrolysis reactor and their operational conditions affect bio-oil composition⁸¹⁻⁸⁵ and its multiphase behavior^{54, 81, 86}.

4. Kilns (Carbonization methods)

This section covers examples of the main groups of “kilns”: earth (mound, pit) and brick/concrete/metal (Brazilian, Argentine, Missouri, TPI) (Figure 4). There are excellent reviews and books covering these reactors^{5,87, 88}. Therefore, this section will focus on the generalities and recent publications related with these reactors. Since, the number of recent publications on these reactors is limited, the information herein reported relates mostly with operating conditions of reactors in real settings.

Earth kilns (mound pit) have been used for centuries; and are still very popular in some developing countries⁴¹. Soil is used as a barrier for oxygen attack to prevent high levels of oxidation. The liquids (condensates) released during carbonization on the soil and the vapors released to the atmosphere are important sources of pollution. Two types of earth kilns are distinguished: pit kilns and mound kilns (sometimes referred to as earth-mound kiln) (Figure 4). When the soil is well drained, deep and easy to excavate pit kilns are preferred⁸⁹. The main advantage of these kilns is their low capital investment. However, the circulation of air is

1
2
3
4
5 difficult to control and are harmful to the environment with the emission of vapors to the
6 atmosphere and the condensation of oils in soils⁸⁹.
7
8
9

10 *Mound kilns* can be classified into three types: vertical mound kiln, horizontal mound kiln, and
11 improved mound kiln designs (the Casamance mound kiln)⁹⁰. Casamance-type kilns, which use
12 oil drums as chimneys, are the result of improvements made during the 1970's and 1980's. The
13 Casamance kiln can typically produce up to 1.7 times more charcoal than a traditional earth kiln
14 (i.e., reaching efficiencies from 20 wt. % in pit kilns to 34 wt. %)^{27, 29, 90, 91}. A number of factors,
15 such as location of kilns, conditions and type of wood, as well as qualification of operators,
16 greatly affect the carbonization efficiency of earth mound kilns. This explains why some
17 publications present different yields for similar types of kilns operating in different places. For
18 example, Mangue²⁷ reports efficiencies from 12 to 16 % in Mozambique. Schenkel et al.⁹⁰ show
19 tables comparing efficiencies of similar kilns operated in other latitudes, with efficiencies
20 varying from 12 to 34%. Kammen and Lew²⁹ show the charcoal energy yield as a function of the
21 kiln size for traditional kilns and the Casamance kiln, noticing a better efficiency of the latter.
22 The average energy efficiency is around 18 % for the traditional kiln and 32% for the Casamance
23 kiln²⁹. Menemencioglu⁹² reported data on wood charcoal production in Turkey. The author
24 collected data from 44 kilns ranging from 25 to 45 m³, which were built by 23 adults. Typically,
25 1 kg of charcoal was obtained from every 5 to 6 kg of biomass, using 1350 tons oak and having
26 255 tons of charcoal. The average productivity was 11 t of charcoal per adult for the 7 month
27 production season. The wholesale price was \$0.7 kg⁻¹ resulting in an average income of \$7,761
28 per season (7 months)⁹².

41
42
43
44

45 The main advantage of earth mound kilns is that they are simple, made of earth and can be built
46 in the same area that the biomass is available. This technology is well suited to operate with logs.
47 Its final product (charcoal chunks) can be easily commercialized as domestic fuel in some
48 developing nations. No special equipment is required and the initial investment is low (\$ 27/t⁸⁷).
49 This kiln is easy to operate and very flexible with regards to capacity⁸⁹. Its main disadvantages
50 are: high labor demand, char is dirtied by the covering, sensitiveness to weather conditions, very
51 poor control of carbonization, low efficiency, difficulty to carbonize small size agricultural
52

wastes and the release of very large quantities of organic pollutants⁸⁹. A detailed description on the construction and operation of earth kilns can be found elsewhere^{10, 88, 89}. Some of the main characteristics of these kilns are presented in Table 1.

Figure 4. Schematic representation of typical kilns. Dimensions are presented for reference only (Adapted from^{5, 88, 89}).

Brick/concrete/metal: The four main kilns reviewed in this section are: Brazilian, Argentine, Missouri and the TPI kilns (Figure 4). In the US, during the 19th century, earth kilns were replaced by the so called “beehive kilns”^{8, 94}. The basic difference between earth kilns and cinder block and brick kilns is the construction material (Table 1). These kilns have a long lifespan and several types have proved their economic viability. Cinder block and brick kilns can be differentiated by their shape: hangar kilns, with rectangular or square shape, and round brick kilns⁵. The main advantages of brick kilns are the use of local materials, higher yields than mound and pit kilns, good quality charcoal, good thermal isolation, easy operation, lifespan of 6 to 10 years and they are not sensitive to climate conditions⁸⁹. These kilns can operate with logs and the final products (charcoal chunks) can be easily commercialized as domestic fuel. The

main disadvantages of brick kilns are associated with the need of skilled workers for their construction, fixed location, long production cycle (on average 15 days, the cooling process is slow), and higher construction and operating costs than mound and pit kilns. These kilns are also responsible for important air pollution⁵. The most commonly used round brick kilns are: the Argentinean half-orange kiln and the Brazilian beehive kiln (see Figure 4). The most commonly used hangar kilns is the Missouri kiln (See Figure 4). All these kilns are auto-thermal and operate by burning part of the charge within the kiln.

The *Brazilian brick* kiln is an internally heated, fixed, batch-type kiln widely operated in Brazil, especially in the state of Minas Gerais and in the Amazonian region, with a typical capacity of 45 m³⁴³. Thousands of them are used to produce charcoal for the Brazilian iron and steel industry⁵,⁹⁵. A detailed description of the methods to build and operate these kilns can be found elsewhere^{88,96}. A typical operational cycle consists of 8 hours for loading/discharging, 80 hours for carbonization and 70 hours for cooling⁴³. Some of the most advanced modifications to the Brazilian kilns are the attachment of an external heating chamber and the reduction of the number of smoke stacks⁵. Branches, brushwood, and other residual materials, which are not suitable for charcoal production and would be otherwise wasted, are used to heat the kiln. The raw material used for carbonization is typically cordwood, obtained from dedicated plantations or from forest clear cutting^{5,96}. These kilns can be modified to recover pyroligneous water and decanted oil. Only few research papers describe the operation and yield of products from Brazilian kilns⁹⁷.

The *Argentine kiln* is also generally referred to as the “half-orange-kiln” due to its hemispherical shape. This kiln, like many others, can be built in various sizes. Unlike the Brazilian kiln, Argentine kilns are built completely out of bricks with no iron parts⁵. A detailed description on how to build and operate a half-orange kiln can be found elsewhere⁸⁸.

Missouri-type kilns are sometimes referred to as concrete kilns³⁸ or batch-type charcoal kilns⁹⁸. They can be built with volumes up to 350 m³ (typically between 150 and 200 m³)^{27,31,43,98}, thus, requiring mechanized loading and unloading^{10,31}. The operational cycle consists of 4 days of

1
2
3
4 loading/discharging, 6 days of carbonization and 20 days of cooling⁴³. The Missouri charcoal
5 kiln, which was developed at the beginnings of the 1950s by V. Wulff in the Ozark County
6 (Missouri)²⁷, is a well proven kiln^{5,10, 38, 99}. Missouri-type kilns are still used in Missouri, United
7 States^{41, 98, 99} and are responsible for an important fraction of the charcoal produced in the USA^{98,}
8 ^{100, 101}. Several improvements have been made to the original design. For instance, using
9 thermocouples within the kiln contributes to the identification of cold ports and controlling
10 airflow³⁸. Additionally, the environmental impact of these kilns can be reduced by using
11 afterburners^{78, 98, 100, 102}. More information on the design and operation of this kiln can be found
12 elsewhere^{5, 10, 31}.

22 The *TPI kiln* is a small size kiln developed by the Tropical Products Institute (TPI) (Figure 4).
23 This kiln is built with two interlocking cylindrical sections and a conical cover with ports to
24 release vapors^{38, 88}. Eight channels located at the perimeter of the base section support the kilns
25 and serve as air inlets or smoke stacks. Compared to earth kilns, air inlet and gas outlet are easy
26 to control, with less supervision needed. All the carbon produced can be recovered. These
27 reactors can be transported to the place the feedstock is collected. They produce high charcoal
28 yields with relatively short carbonization times (around three days). These kilns can be easily
29 operated in high rainfall regions. However, they have important air pollution issues^{38,88}. Other
30 disadvantages include: higher capital costs compared with earth kilns, the need to cut and split
31 biomass to fit inside the kiln, difficult transportation in hilly terrain, and a relatively short
32 lifespan (only 2-3 years)⁸⁹.

43 The emission of gases and particulates from charcoal production in rural areas using medium-
44 sized traditional and improved kilns has been studied by Sparrevik et al¹⁰³. They reported the
45 following average emission levels: 1,950 g CO₂/kg charcoal, 157 g CO/kg charcoal, 6.1 g non-
46 methane organic volatile compounds/kg charcoal, 24 g CH₄/kg charcoal, 24 g solid particles/kg
47 charcoal and 1.8 g NO_x/kg charcoal¹⁰³.

Other important kilns reported in the literature not discussed in this section include: *New Hampshire kiln*^{104,105}, *Connecticut kiln*^{10,104,106;107}, *Black Rock Forest kiln*,^{5,10,106,107}, *Rima Contained kiln (RCK)*⁹³, the *Adam retort*^{103, 108, 109}, and the *European Schwartz kiln*⁵.

5. Retorts

While kilns are typically closed containers releasing gas and vapor to the atmosphere, the retorts condense the vapors and make good use of the energy content of gases^{89, 110}. The main reactors discussed in this section are: the wagon reactor, Lambiotte French SIFIC (<http://www.lambiotte.com/>), the Lurgi Process¹¹¹ and the Carbon Twin Retort¹¹² (Figure 5). All these systems operate with logs. Their main characteristics are listed in Table 2. The main advantages of these systems are associated with the high charcoal yield and high charcoal quality. Additionally, the by-products from the vapors can be recovered. The main disadvantages are related with the high capital costs, attrition problems, the need of external sources of energy and the fact that most of these systems are not portable and require a concentrated supply of raw materials⁸⁹.

The Wagon Retort: These retorts consist of the following components: (a) a steel horizontal carbonizing chamber fitted with either a fixed cover at one end and a door at the other, or doors at both ends⁴. One or two vapor outlets provided on the side, top, or at one end of the chamber and a rail-track for running retort cars through, (b) a furnace for the heating process, (c) a condenser connected to the retort, (d) a steel chamber with a door at each end for cooling char placed in front of the retort and fitted with a similar rail-track, (e) a section of rail that connects the retort with the char cooler that can be moved as needed, (f) mechanical equipment for moving the cars, and (g) retort-cars. A length of 8 to 9 m with a diameter up to 2.5 m is standard for retorts¹¹³. Retorts usually require gradual cooling of the carbonization products, generally by heat release to the surroundings at room temperature². Compared to other methods, the wagon retort required a substantial amount of manpower^{5,114}. This retort commonly used raw material made up of round wood and split round wood with an average length between 1.0 and 1.2 m. A limited quantity of shorter pieces was also charged^{5, 114}. These reactors were able to produce charcoal with efficiencies up to 36%, tar and oils with efficiency varying from 5 to 20%, crude pyroligneous water varying from 30 to 50%, and non-condensable gases varying from 20 to 30%, depending on the composition of wood^{4,8}. According to Klar⁴, these units were able to obtain between 2.3 and 10.5 wt. % of acetate of lime (80 % purity), between 0.6 and 2.5 wt. % crude naphtha, between 5 and 20 wt. % tars, and between 0.4 and 8 wt. % pine-oil. Charcoal was mainly used in the iron industry. Burning of gases and tar in boilers was a common practice⁸.

A wagon retort system was recently in operation by Impianti Trattamento Biomasse (an Italian company). In 2010, this company had plants in Milazzo and Mortera (Italy) producing up to 6,000 t/y of charcoal¹¹⁵. The process was called O.E.T. Calusco (former Carbolisi) but it does not seem in operation currently¹¹⁵. Alterna Biocarbon, a company with head office in Prince George, BC, Canada, recently commercialized an upgraded design of the wagon retort⁸⁷ (the company is not currently in operation). The main products targeted by this company were energy pellets, activated carbon, products for mercury recovery and chars for soil applications.

The Lambiotte Retort has proven to be a successful technology for the production of char. As a result of several attempts to simplify the SIFIC process, the CISR Lambiotte Retort was

1
2
3
4 developed (See Figure 6)⁴³. The pre-dried wood enters by the top of the retort through a lock
5 controlled electronically to keep the retort always full. The retort has four zones (cooling zone,
6 carbonization, drying and torch)¹¹⁰. The charring wood section is where the wood decomposes
7 into char, vapors and gases. Carbonization usually proceeds at a narrow temperature range (547-
8 560 °C). The gases released from this section are drawn upward by a fan. The energy needed for
9 carbonization is provided by the hot flue gases coming from combustion of part of the pyrolysis
10 vapors in an external chamber^{5, 93}. Once the char is discharged, it is loaded on the converter
11 plenum and carried away for storing. Since the lower segment of the retort acts as the first step in
12 the cooling process, there is no need for separating char in the cooler⁵. The surplus combustible
13 vapors can easily be used for steam or electricity generation (Table 2). These plants have been
14 running commercially for several years. Balt Carbon Ltd. is the supplier of Lambiotte retorts for
15 Russia and other East European and Central Asian Countries. The company has built a 2,000 t
16 charcoal per year unit in Kaplava (Eastern Latvia) and an 8,000 t charcoal per year in Ugale
17 (Western Latvia)²⁷. Char Solutions Inc (<http://www.biocharsolutions.com/>), from Colorado, has
18 built a reactor using similar principles (continuous downdraft pyrolysis reactor) but using chips
19 or pellets. This system is a mobile downdraft auto-thermal gasifier able to convert up to 225 kg/h
20 of biomass into synthesis gas and char. The main advantages of the Lambiotte system compared
21 with other retorts are: (1) high labor efficiency due to high level of automation, (2) higher
22 charcoal yield, (3) good product quality, (4) it is possible to use the vapors produced for co-
23 generation²⁷. A disadvantage of the system is its sensitivity to biomass moisture content.
24 Biomass with high moisture content reduces the capacity and in some cases may it require
25 burning auxiliary (oil) fuel. Attrition with the consequent production of fines happens due to the
26 vertical movement of the load. These retorts are also prone to corrosion by acetic acid²⁷.

47 The operation of the *Lurgi reactor* is similar to the Lambiotte reactor. The Lurgi reactor (Figure
48 5) also has an upper carbonization zone and a lower cooling zone, each one with its own re-
49 cycling gases^{43, 111}. The reactor has an air-lock hopper fed with a skip hoist that elevates dry
50 wood blocks to the top of the reactor¹¹¹. The combustion of pyrolytic vapors and gases in a
51 staged external incinerator provides the heat for carbonization. In the first stage, the retort gas is
52 burnt at near stoichiometric conditions. In the second stage, more air is added to ensure complete

combustion before releasing to the atmosphere. Up to 6,000 Nm³/h of gas at 600 °C is used for heating the retort¹¹¹. The largest Lurgi charcoal plant forms part of the Silicon Metal Complex (SIMCOA) in Bunbury, (<http://simcoa.com.au>), Western Australia, and produces 27,000 t of charcoal every year in two retorts from local hardwood^{43, 111}.

The *Carbo Twin Retort* was initially developed in the 1990's in the Netherlands. The twin system was formed by two retorts placed in an insulated oven, with a monorail and overhead crane that enables the placement of retort vessels into and out the carbonization unit. The pyrolysis vapors released by the pyrolysis reactions taking place inside the vessel are combusted outside to provide the heat supply needed for heating up the system¹¹². The system is equipped with an internal afterburner furnace with an excess of air to burn all the organic compounds²⁷. One of the main advantages of this system is the low labor requirements: one worker per shift can operate (load and discharge) and supervise a battery of ten twin retorts²⁷. Other advantages of this system are: high energy efficiency, high char yield, superior product quality, straight forward operation, easy scaling up with modular designs, low emissions, flexible operation and control, and continuous operation¹¹². Carbo Twin Retorts have been installed in Almelo (The Netherlands), Parnu (Estonia), Manso Amenfi (Ghana) and Hailin (China)²⁷. Similar twin reactor concepts have been developed also in The Netherlands by VMR Systems⁴³, Charbon Engineering and Clean Fuels BV and also in Portugal by Ibero Massa Florestal.

Other important retorts not reviewed in detail in this section are: *the Reichert Converter*^{5,114}, *the Rima Container Kiln (RCK)*⁹³, and the *CML France Batteries*^{43,93}. Although not commercialized, the innovative concept of the Flash Carbonization process developed by Antal⁷ (*in situ* partial burning of the pyrolysis vapors inside the reactor with air at high pressure) is worth mentioning.

6. Converters (also known as intermediary pyrolysis reactors)

The carbonization techniques described in the previous section are used for logs and are not suitable for the small particles and chips found in agricultural and forest logging residues. If one of the large kilns is charged with small waste particles such as sawdust, the particles will tend to

1
2
3
4
5 pack much more tightly, thus promoting insufficient penetration of gases unless the cargo is
6 continuously rotated or moved^{4,5}. This section reviews reactors able to handle chips and pellets,
7 as well as deliberately crushed or chopped material such as sugarcane bagasse, bark, twiglets,
8 olive stones or coconut shells. The reactors herein reviewed are: *the Herreshoff furnaces, rotary*
9 *drums, auger reactors, paddle kiln* and *moving beds* (Figure 6). The main operational features of
10 these reactors are shown in Table 3.

Pretreatment needed	Ground in chips/ fine particles				

The *Herreshoff multiple* hearth furnace was patented in 1921 by R.D. Pike. It consists of 4-10 circular hearths or plates located one above another inside a refractory lined steel shell²⁷. A vertical rotating shaft (1-2 rpm) with radial arms located in the center of the shell moves the feed from the top of the hearth to the bottom using a spiral of teeth across each hearth. The shaft in the center rotates at 1-2 rpm. This converter was designed for converting raw materials in the form of sawdust, shavings, or milled wood and bark into charcoal. The system is typically heated up to 500-600 °C using external gas or oil burners²⁷. The yield of dry char for this process is about 25 wt.%. Automatic oxygen monitoring is used to minimize power draw and fuel demand. The first carbonization Herreshoff furnace was used in 1984, and by 1985 there were about 16 Herreshoff furnaces in use in the South of US, producing over half of the total char produced

1
2
3
4 from wood and bark²⁷. This type of reactor has also been used in vacuum conditions^{117, 118}.
5
6 Currently, a mobile Herreshoff pyrolysis reactor is commercialized by BIG Char, a company
7
8 with headquarters in Queensland, Australia. This company is commercializing a patented mobile
9
10 multiple heart furnace, producing char and heat with capacities up to 1 t/h of biomass. The char
11
12 produced is available in a briquetted form (<http://www.bigchar.com.au>). The major advantage of
13
14 a Herreshoff furnace is its ability to efficiently and flexibly use fine-grained materials of little
15
16 economic value. One disadvantage is the need for briquetting of charcoal powder before it can be
17
18 commercialized. The capital cost is high.

19
20 The *rotary drum* reactor is a very reliable system for carbonizing biomass. Figure 6 presents the
21
22 two main types of rotary drum designs (directly heated and indirectly heated). The residence
23
24 time of the biomass particles in these systems are controlled by the angle of the drum and the
25
26 rotation speed. A converter of this type consists of: (1) an internal concentric steel tube and a
27
28 cylindrical internally insulated mantle that makes up the rotary part. A sequence of radial steel
29
30 fins is supported by the mantle which has a solid connection to the steel tube, (2) the solid and
31
32 gaseous products are charged and discharged by two fixed parts at the end of the rotary. This
33
34 furnace provides the heat required for the carbonization process by burning gases and pyrolysis
35
36 vapors. Table 4 shows the yield of liquid, char and gases reported for tests with rotary drums.
37
38 This type of reactor is able to achieve a good balance between oil (between 37 and 62 wt. % of
39
40 liquid product) and char yield (19-38 wt. %).

The European Union¹¹⁹ and Japan¹²⁰ have extensively used these reactors for tires, sewage sludge, municipal solid waste, and plastics. Examples of these systems are: a 2.2 MW_{el} pyrolysis plant operating since 1983 in Burgau-Unterknöringen, Germany, a 100,000 t/year pyrolysis plant at the VEW Energie AG (VEW) power station Westfalen in Hamm-Uentrop, Germany, and other systems that combine gasification with pyrolysis or pyrolysis with combustion¹¹⁹. Specific concepts of interest are: the ConTherm® technology by RWE Energie AG (RWE), the Serpac technology, the EDDITH process, The PYROPLEQ® process, Gibros PEC Process or PKA technology, SIEMENS Schwel-Brenn technology, THERMOSELECT process¹¹⁹. Most of those reactors could be easily adapted to work with biomass.

In 2009 Amaron Energy designed, constructed and began testing a unique indirectly-heated rotary kiln for pyrolysis of biomass to produce bio-oil and char^{121, 122}. Amaron has achieved char yields and bio oil yields close to those from fast pyrolysis fluid beds (Figure 6). The Amaron rotary reactor consists of: (1) a cylindrical reaction section heated by multiple high intensity gaseous fueled burners located and controlled to optimize heat transfer into the materials being heated, (2) a feed section with an auger arrangement that suppresses heating of the material until the particles reach the area where optimized heat transfer begins, (3) a withdrawal section with a char outlet below the end of the rotating reaction section, (4) a stationary end closure supporting a withdrawal pipe for vapors and gases. The vapors are condensed in multiple units designed to operate without problems caused by condensation of tars in the interconnecting piping.

Table 4. Yield of products obtained from rotary kilns

Biomass specie and reactor	Capacity	T (°C)	Char (wt. %)	Bio-oil (wt. %)	Gas (wt. %)	References

3
4 The *auger reactor* is typically fed at one end through a hopper or a feeding screw^{116, 124}. A screw
5 then gradually carries the biomass to the hot zone of the reactor where it is carbonized, and the
6 gases and vapors are extracted and led to a condenser⁴⁶. The residence time of the hot vapors in
7 these reactors can vary, in average from 5 to 30 s¹⁶. These reactors can be operated with and
8 without using hot sand, steel or ceramic balls as heat carriers^{124, 42}. The discharging of char and
9 heat carriers happen by gravity⁹⁴. Table 5 shows the yield of products obtained under different
10 operational conditions using auger pyrolysis reactors. Experimental studies with woody biomass
11 show yields of char between 17 and 30 wt. % and yields of oil between 48 and 62 wt. %⁴². The
12 bio-oil yield is slightly lower than that of fluidized bed reactors and contains more water 30-55
13 %⁴². As expected, the oil yield of agricultural residues was much lower due to the high ash
14 content of this feedstock. Although difficult to compare, it seems that the yields obtained with
15 sand heat carrier is slightly higher than those obtained without. ABRI-Tech in Canada has sold
16 several 1 t/day units⁴². Auburn University (USA), KIT (FZK) (Germany), Mississippi State
17 University (USA), Michigan State University (USA), Texas A&M (USA) and Washington State
18 University (USA)⁶¹ have active research programs on this technology¹⁶.

In *moving agitated bed* reactors biomass is conveyed by patented mixers over a horizontal surface heated by molten salts. These reactors have been used in vacuum conditions^{134, 135}. The molten salt used is a mixture of potassium nitrate, sodium nitrate, and sodium nitrite¹³⁶. The size (height) of an industrial moving bed (few cm) is comparable with the height of fixed bed of most of the laboratory tests (also few cm). In fact, the scaling up of this reactor was typically conducted with the aid of fixed bed reactors operating in vacuum. In this section, we report results obtained with fixed bed at laboratory scale (Table 6). Bio-oil yields over 50 wt. % are obtained with woody biomass in most vacuum tests.

Table 6. Fixed bed reactor

Biomass specie and reactor	Capacity	T (°C)	Char (wt. %)	Bio-oil (wt. %)	Gas (wt. %)	References
Rice husk and fixed bed	180 g	100 - 500 °C/min	42-48	28-35		[137]

The *Paddle Pyrolysis reactor* (See Figure 6)¹⁴⁵ are characterized by the use of internal mechanisms to move and mix the biomass and thus to increase heat transfer. This kind of reactors have been used by companies such as BEST Energies, currently part of Pacific Pyrolysis Inc., (<http://pacificpyrolysis.com/technology.html>), and was also part of the design of Choren¹⁴⁶.

Other important reactors in this category not included in this review are the *Shelf reactors*^{4, 46} and the *Stafford-Badger retort*¹⁰. The converters are the reactors with more potential for the balanced production of char and oil. However, more research is needed to understand the potential of these reactors.

7. Fast pyrolysis reactors for high yields of bio-oil production

This section reviews the most common fast pyrolysis reactors (rotating cone, ablative, conical spouted bed, bubbling fluidized bed and circulating bed) (Figure 7) that have been developed intending to optimize the yields of bio-oil. There are very good literature reviews in fast pyrolysis reactors^{15, 16, 19, 136, 147}. Thus, this section will only focus on recent developments. The main characteristics of the reactors studied in this section are discussed in Table 7.

Figure 7. Schemes of Fast Pyrolysis Reactors (Adapted from¹³⁶)

Table 7. Characteristics of some fast pyrolysis reactors

	Bubbling fluidized bed reactor	Circulating bed reactor	Ablative pyrolysis	Rotating cone
Final product targeted	Bio-oil		Bio-oil/char	Bio-oil
Heat transfer rate achieved	Fast pyrolysis			
Mode of operation	Continuous			
Heating method	Direct and indirect heat/sand		Indirect heating	Direct and Indirect heating
Construction materials	Metal			
Portability	Stationary			
Reactor Position	Vertical		Horizontal	Vertical
Raw material used	Fine particles (less than 2 mm)		Chips	Fine Particles
Loading and discharge methods	Mechanical			
Ind. reactor capacity built	0.5-200 t/day ¹⁶	9.6-96 t/day ¹⁶	6 t/day ¹⁶	50 t/day ¹⁶
Charge ignition method	External combustion chamber to heat the carrier gases			
Process control	Direct measurement of temperature			
Complexity*	Medium		High	High
Status*	Demonstration	Commercial	Pilot	Demonstration
Industrial companies	Agritherm Canada ¹⁶ , Biomass Engineering Ltd ¹⁶ , UK, Dynamotive, Canada ¹⁶ , RTI, Canada ¹⁶ , Avello Bioenergy, USA	Ensyn, Canada ¹⁶ , Metso/UPM Finland ¹⁶	PyTec, Germany ¹⁶	BTG, Netherland ¹⁶
Pressure	Atmospheric			
Pretreatment needed	Particle milling and pre-drying		None	Particle milling
Yields reported (wt. %)	Up to 70% of bio-oil ¹⁴⁷			

The bubbling fluidized bed reactors use a mixture of convection and conduction to transfer heat from a heat source (hot sand) to the biomass particle. Although most of the literature suggest that fast pyrolysis should be operated with particles with diameters 2-3 mm¹⁶ to obtain high liquid yields (over 65 %), the particles must be smaller (typically below 0.5 mm)^{49, 50} to avoid the retention of aerosols inside the particle and to achieve high heat transfer rates. One of the best-known examples of using a fluidized bed reactor was Dynamotive, company that was a result of the pioneering job conducted by the University of Waterloo^{11, 12, 148}. In the design of most fluidized bed reactors in operation the char is entrained by carefully controlling the difference between the sizes and densities between biomass particles and the sand. Char particles obtained

1
2
3
4
5 from the pyrolysis of raw materials with very high ash content such as, sewage sludge, usually
6 abandons the bubbling fluidized beds by overflow. The heat used in bubbling fluidized beds is
7 generated from the combustion of pyrolysis gases and chars and is typically transferred to the
8 fluidized bed by heating coils and by heating the carrier gas (in industrial conditions typically a
9 recirculated pyrolytic gas). Given the low heat transfer rates between combustion gases and the
10 bed (100-200 W/m²K) at least 10 to 20 m² of surface area is required to transfer the heat required
11 to pyrolyze 1 t/h of biomass. These heat transfer surfaces are very susceptible to attrition from
12 the sand¹³⁶. Several main features of this type of reactors are: the ability to accurately control
13 temperature, the use of entrainment for the separation of the char, the use of cyclone separation,
14 the easy scaling, the technology is well known and understood, small particles are required, and
15 there must be a large scale heat transfer to the bed. Dynamotive developed bench-scale plants, a
16 15 t/day pilot plant, a 130 t/day plant in West Lorne, and a 200 t/day plant in Guelph, Ontario,
17 Canada¹⁴⁹ that are currently not operating. Tables 8-10 show the yield of products obtained from
18 the pyrolysis of grass and agricultural residues, softwood, and hardwood species in fluidized
19 beds. When processing grasses and other agricultural wastes the conversion yield to liquid bio-
20 oil, solid char and non-condensable gas are in the ranges of 35-68.7 wt. %, 12.9-45.7 wt. % and
21 3-25.7 wt. %, respectively, on an as fed basis (Table 8). This broad range of values is mostly due
22 to the wide range of ash contents in these materials. When processing of softwoods result in 59-
23 78.1 wt. % bio-oil, 10-15.7 wt. % char and 7.8-28 wt. % non-condensable gas. Comparable
24 yields were also obtained for hardwood species (char: 9.8-20.7 wt. %, bio-oil: 59-77 wt. %,
25 gases: 9.3-24.6 wt. %). Lower oil yields (35-73 wt. %) and higher char yields (13.4-45.7 wt. %)
26 are obtained with some grasses, likely due to higher ash content in some of these materials.

10 t/day mobile pyrolysis units with a fluidized bed reactor have been developed by Agritherm at the University of Western Ontario (<http://agri-therm.com>)^{16, 42}. An important feature of the design proposed by this company is a compact design in which the pyrolysis reactor is built using an annulus with a burner at the core providing the energy needed for the pyrolysis process. Avello Bioenergy in the State of Iowa (US) is another company commercializing fast pyrolysis technologies (<http://www.avellobioenergy.com>). This company specializes in the development of fractionation strategies to obtain different products from bio-oils. Bioware is a Brazilian company commercializing auto-thermal fluidized bed reactors¹⁷² to produce bio-oil, char and phenolic resins (<https://www.bioware.com.br>). Nettenergy BV is a private company from the Netherlands (<http://www.nettenergy.com/index.php/en/>) that built a 100 kg/h mobile unit with a unique multi-stage compact separation design⁴².

Circulating fluidized beds: Research performed by the University of Western Ontario in the late 1970s and early 1980s spawned the Rapid Thermal Processing (RTP)TM technology commercialized and developed by Ensyn. Before feeding this system's reactor, the biomass is comminuted to approximately 6 mm, and then dried to a moisture content of 10% or less. The hot recirculated biomass and sand enter in an up-flowing transported bed reactor. Once the

products have passed through two cyclones that separate both solids from the produced vapors, they experience a rapid cooling and quenching in multiple stages¹⁴. The residence time of the solids and vapors in these reactors is almost the same¹⁶. The recirculation of gases from secondary char combustion is the main heat source¹⁶. RTP is the only pyrolysis technology in the world that has operated on a long-term commercial basis (<http://www.ensyn.com>, <https://www.envergenttech.com>). Larger scale units include: ENEL plant build by Ensyn in Italy (15.6 t/day), several 40 t/day units at Red Arrow (USA) operating for the production of smoke aromas and the Ensyn 50 t/day unit at their R&D center in Renfrew Canada¹⁶. Some features of the transported bed reactor include: precise temperature control within the reactor, the ability to use large size particles, suitability for very large throughputs, and well understood technology¹⁶. Some of the main disadvantages of these technologies are: (1) use of large volumes of inert carrier gases causes a dilution of the pyrolytic gases making bio-oil recovery very difficult (2) many fast pyrolysis reactors use sand as a heat carrier, (3) complex hydrodynamics, (4) high velocities lead to higher levels of attrition, and the separation of the char and the sand from the vapors with a “cyclone”, (5) careful control is needed for the closely integrated combustion, and a large scale heat transfer to the bed is required (6) Char and sand attrition is an important issue. Table 11 shows the yield of bio-oil reported in the literature for different feedstocks. Bio-oil yields between 54 and 71 wt. % have been reported.

Table 11. Pyrolysis of biomass using circulating fluidized bed reactors.

Biomass specie	Capacity	T (°C)	Bio-oil (wt. %)	References
Timothy	20 kg/h	520	54	[155]
Rapeseed straw	20 kg/h	520	60	[155]
Pine saw dust	20 kg/h	520	74	[155]
Green forest residue (86% spruce, 9% pine, 5% birch)	20 kg/h	520	64	[155]
Brown forest residue (80% spruce, 10% pine, 10% birch)	20 kg/h	520	58	[155]
Eucalyptus chips	20 kg/h	520	71	[155]

A similar technology, with the use of catalysts instead of inert sand is being developed by KIOR, now Inaeris Tech (<http://www.inaeristech.com/>), a company located in Houston, Texas. The company uses a proprietary catalyst system to produce a deoxygenated bio-oil in a Fluid Catalytic Cracking (FCC) reactor. Metso, UPM and Fortum constructed and has operated since

1
2
3
4
5 2013 a 400 kg/h circulating bed pyrolysis reactor coupled with a condensation system in Joensuu
6 (Finland). The bio-oil produced is combusted in a fluidized bed power boiler¹⁶. CPERI (Greece),
7
8 Guangzhou Inst. Energy Conversion (China), U. Birmingham and U. Nottingham (UK) and VTT
9 (Finland) have active research programs on this technology¹⁶.
10
11

12
13 *Rotating Cone:* This technology was developed by the University of Twente and is
14 commercialized by BTG-BTL (Biomass Technology Group-Biomass to Liquid, Netherlands)
15 (<http://www.btgworld.com/en/>)¹⁶. The centrifugal force effectively develops a transported bed
16 without the need for large volumes of carrier gas¹⁶. The hot sand and the biomass are transported
17 up in a conical bed by the centrifugal forces created by rotation of the cone¹⁶. This process has
18 been successfully applied in Malaysia for the conversion of empty fruit bunches from palm oil
19 trees in a demonstration plant of 50 t/day capacity¹⁶⁵. This technology has been also used by
20 Empyro for the construction of a plant that operates from 2015 in Hengelo (The Netherlands).
21 This plant converts 5 t/h of wood residues into pyrolysis oil, process steam and electricity. In
22 both plants, gas and char are burned to heat the sand, which is recycled back to the pyrolysis
23 reactor¹⁶.
24
25
26
27
28
29
30
31
32

33
34
35 *Ablative pyrolysis:* This process entails a heated surface in which wood is pressed against and
36 moved rapidly leaving an oily film that then evaporates¹⁶. Larger particles of wood can be used
37 for this process and the limiting factor is typically the rate of heat supplied to the reactor. These
38 reactors can process large amounts of biomass in a little volume, are compact and do not require
39 carrier gases or recirculation^{70, 71}. The rate of reaction is proportional to the force exerted on the
40 biomass in contact with the wall and the available heat transfer surface¹⁶. An important feature of
41 ablative heat transfer is that when the biomass contacts the hot solid, ablation occurs and
42 subsequently exposes new fresh biomass to the hot surface. This, in theory, allows for no
43 limitations in particle size. NREL (Golden, Colorado, USA) and CNRS laboratories (France)
44 conducted most of the pioneering studies on ablative reactors¹⁶. In the 90s, BBC from Canada
45 built and operated an ablative reactor with a capacity between 10-25 kg/h¹³⁶ (this company is not
46 in operation today). The University of Hamburg built three plants using ablative reactors. The
47 first plant was conceived for research and has a capacity of 20 kg/h; the second one, is a pilot

plant of 250 kg/h and the third is a demonstration unit with capacity of 2 t/h^{16, 136}. Reed and Cowdrey constructed an ablative pyrolysis reactor testing bone dry wood at a feeding rate of 0.2 kg/h¹⁴. Biomass-to-oil (BTO) process was developed by PYTEC, Germany. The process is based on the ablative pyrolysis principle. Biomass wood (including chips of 60x40x5 mm) is put in direct contact with a rotating hot metal surface that melts the wood and produces oil¹⁷³. The crude bio-oil produced is combusted in a CHP unit running on a 300 MW_e diesel engine¹⁷³. Compared with the fluidized bed, the main advantages of ablative reactors are: (1) no milling efforts needed for biomass, (2) compact design because of ideal heat transfer with high heating rates at relatively small contact surfaces, (3) energy and cost efficiency as no heating and cooling of fluidized bed is required, (4) condensation units with small volume can be installed, requiring less space and lower cost¹⁷⁴. The main downsides are that these reactors require a heated surface area control system, operates with moving parts at high temperatures increasing their complexity, and induces an inevitable wear and tear on the moving components¹⁷⁵. Table 12 reports the yields obtained in ablative reactors using wood and wheat straw. The yields of char, oil and gases are comparable with those obtained with similar feedstock with fluidized bed reactors. Aston University (UK), Institute of Engineering Thermophysics (Ukraine), Latvian State Institute (Latvia) and the Technical University of Denmark have active programs on this technology^{16, 42}.

Table 12. Experiences on biomass fast pyrolysis using ablative pyrolysis reactors

Biomass specie	Capacity	T (°C)	Char (wt. %)	Bio-oil (wt. %)	Gas (wt. %)	Reference
Barley or wheat straw	10 kg/h	549	32	50	12	[176]
Wheat straw	Lab-scale pyrolysis centrifuge reactor	525	23-32	40-47	27-30	[177]
Wood	250 kg/h	650	6	60	34	[174]

Spouted fluid bed reactor: The viability of the spouted bed technology for pyrolysis was studied by the Chemical Engineering Department of the University of the Basque Country (Spain). A pilot plant at Ikerlan-IK4 facility with capacity to process up to 25 kg/h of biomass is now operational^{16, 178}. The yield of products shown in Table 13 is comparable and even higher to those reported for fluidized bed reactors for similar feedstocks. The Anhui University of Science & Technology is also developing this technology¹⁶.

Table 13. Biomass pyrolysis results using a conical spouted bed

Biomass specie	Capacity	T (°C)	Char (wt.%)	Biooil (wt.%)	Gas (wt. %)	Reference
Rice husk	60 g/h	450	26	70	4	[179]
50% <i>Cytisus multiflorus</i> and 50% <i>Spartium junceum</i>	200 g/h	500	17	80	4	[180]

<i>Eucalyptus</i>	200 g/h	500	18	75	6	[184]

8. Microwave Pyrolysis

There are excellent reviews on microwave pyrolysis^{44,45, 185, 186}. Von Hippel developed the basic understanding of the macroscopic microwave-matter interactions⁴⁴. Microwave wavelengths falls between infrared and radio regions (from 0.3 to 300 GHz)^{44, 45}. Heating is due to molecular friction during dipolar molecules rotation induced by the electromagnetic radiation. Conversely to conventional heating, microwave heating is a volumetric heating, so an opposite temperature gradient is established⁴⁴. Tech-En Ltd in Hainault (UK) developed microwave pyrolysis in the mid-nineties^{185, 187, 188}. In this process, the feedstock is thoroughly mixed with a highly microwave-adsorbent material (often char), which absorbs enough microwave energy (typically at 915 MHz or 2.45 GHz)¹⁸⁵. Although microwave penetration is typically 1-2 cm, penetration depth varies depending on the properties of the materials and radiation frequency (oil palm fiber: 10.2 cm (at 5.8 GHz), oil palm shell: 5.5 cm (5.8 GHz), biochar: 8.5 cm (5.8 GHz), paper and cardboard: 20-60 cm (2.54 GHz), wood: 8-350 cm (2.54 GHz))⁴⁴. While, microwave heating favors solid phase reactions, or heterogeneous reactions, conventional heating has higher effect on gas-phase reactions⁴⁴. Table 14 shows product yields obtained with these reactors.

Table 14. Results of Biomass microwave pyrolysis.

Biomass specie	Reactor	T (°C)	Char (wt. %)	Bio-oil (wt. %)	Gas (wt. %)	Reference
Wheat straw	Mass: 5-30 g, N ₂ : 3 L/min, 3 kW at 2.45 GHz	400-600			17-22	[189]
Larch (<i>Lalix leptolepis</i> GORDON) Cylindrical blocks (d: 60–300 mm; weight: 80–12000 g)	1.5-3 kW at 2.45 GHz, exposition time: 3-12.5 min		18-50	15-30		[190]
Microalgae (<i>Chlorella vulgaris</i>) particle size < 200µm	Mass:30 g, power: 0.75-2.25 kW at 2.45 GHz, N ₂ : 300 mL/min, catalysts: activated carbon, CaO, SiC	200 600 775	90 30 25	0 36 22	10 34 52	[191]
Douglas fir sawdust pellet (diameter: 6 mm, length: 10 mm)	Mass:400 g, 0.7 kW, reaction time: 10–20 min	350-450	31-61	31-54	8-15	[192]
Sewage sludge	Mass: 100 g, 25 g of graphite (1x1 mm) as microwave absorber, N ₂ : 100 mL/min, Power 0.4-0.6 kW at 2.45 GHz	490-570	39-40	48-50	11-12	[193]
Rice straw	Mass: 3-5 g, N ₂ : 50 mL/min, 0.2-0.5 kW	280-500			< 70	[194]
Oil palm fiber (OPF) (0.3–0.6 mm), and oil palm shell (OPS) (0.001 to 0.1 m)	Ratio sample: microwave absorber (1:0.25, 1:0.5, and 1:1), power 0.45 kW at 2.45 GHz, exposure time: 25 min	400-1300	OPS 45-70 OPF 50-80	OPS 10-20 OPF 5-25	OPS 20-30 OPF 10-28	[195]
Microalgae (<i>Chlorella sp</i>)	Mass: 30 g, 6 g of char as microwave absorber, N ₂ : 500 mL/min, Power 0.5-1.25 kW at 2.45 GHz, exposition time: 20 min	460-630	25-28	Oil 18-28 Water 20-22	24-35	[196]
Sewage sludge	Mass: 3.5 kg, N ₂ : 5-20 L/min, power: 6.4-8.0 kW at 2.45 GHz, time: 120 min	350-500		30.4% of organic fraction		[197]
Rice straw (0.425-0.850 mm)	3-5 g sample, N ₂ flow: 50 mL/min, 0.2-0.5 kW	400	28	23	49	[198]
Oil palm shell (OPS) < 0.850 mm)	Mass: 150 g, ratio sample: microwave absorber (1:0.25, 1:0.5, and 1:1), power 0.45 kW at 2.45 GHz, exposition time: 25 min	450-925	40-65	10-17	25-47	[199]
Corn stover	Mass:50 g, power: 0.3-0.9 kW at 2.45 GHz			30 (0.9 kW)	47 (0.9 kW)	[200]
Rice husk (RH) (0.149–0.297 mm, 0.149–0.074 mm and < 0.074 mm) Sugar cane residues (SCR)	Mass: 7-10 g , 0.15-0.4 kW at 2.45 GHz, exposition time: 4-30 min	280-600	RH: 33-50 SCR:s 25-67			[201]

The main advantages of microwave pyrolysis compared to conventional technologies are: (1) it provides rapid heating¹⁸⁵ (2) it is much cleaner and easier to control¹⁹⁵ (3) it can be easily modularized for small applications (these processes can be developed for on-site processing reducing transportation cost) (4) heat is generated within the material (the particles are heated from the center), allowing the surface of the reactor to operate at lower temperatures, (5) high conversion efficiencies of energy to heat (80-85 %) are obtained and (6) higher power densities are used¹⁸⁵.

The main challenges and barrier for microwave pyrolysis are: (1) limited information is available on waste materials microwave relevant properties¹⁸⁵ (2) uneven heating can lead to poor product quality control, (3) electricity is expensive and often produced from fossil fuels by Rankine cycles (with efficiency typically between 20 and 30 %), (4) electrical hazard that should be contained with an appropriate Faraday cage, (5) the presence of metals generate arcing that may damage the equipment, (6) the microwave heating systems are more expensive than traditional heating systems¹⁸⁵. Some of the institutions with active programs in microwave pyrolysis are: The Chinese Academic of Sciences, the National Institute of Advanced Industrial Science and Technology of Japan, the Shandong University of China, the Technical University of Vienna (Austria), the University of Malaysia Sarawak (Malaysia), the University of Minnesota (USA), Washington State University (Tri-cities), the University of Mississippi (USA), the University of Nottingham (UK), the University of York (UK) and the Ecole Polytechnique de Montreal (Canada)^{16, 42}.

9. Design and scale up of Pyrolysis units

Business models: There are very few reports with information on the development of business models, technical design and techno-economic evaluation of pyrolysis units^{47, 202, 203}. The technical design of the pyrolysis unit will depend on the business model selected²⁰³. The International Biochar Initiative (<http://www.biochar-international.org/commercialization>) has identified a number of business models for bio-char production including the characteristics of the feedstock, sustainability issues, associated production technology, potential co-products,

1
2
3
4
5 economic and social challenges. The main business models discussed by the IBI and the
6 technologies associated were: (1) Restoration site (e.g. forest, wetland) (mobile pyrolysis,
7 charring piles in situ), (2) Managed forest (mobile pyrolysis, hog fuel for co-generation,
8 feedstock for pellets and briquettes), (3) Forest product processing waste (Co-gen pyrolysis or
9 gasification, feedstock for pellet or briquettes), (4) Biomass plantation (Co-gen pyrolysis or
10 gasification, feedstock for pellets or briquettes), (5) Urban forestry and landscaping (Biochar,
11 process heat, electricity, home heat), (6) Agricultural Waste-Industrial (Mobile pyrolysis, co-gen,
12 pyrolysis or gasification), (7) Agricultural waste subsistence (Stoves, kilns feedstock for
13 briquettes), (8) Municipal Solid Waste (MSW) (Co-gen pyrolysis or gasification)²⁰³.

20
21 *Reactor Sizing:* Although companies designing and building pyrolysis reactors may have
22 developed scale up criteria and methodologies for sizing these equipment, the authors were not
23 able to find systematic methodologies for the design of pyrolysis reactors in the open literature.
24 Therefore, the design of pyrolysis reactors is still an art. For this reason, in this section we will
25 briefly present a strategy based on our own experience. The design of pyrolysis reactors can be
26 conducted following these steps: (1) Select throughput capacity, (2) Determine the biomass
27 particle size to be used, (3) In the case of fluidized bed reactors select the appropriate
28 sand/biomass particles size ratio, (4) Select the carrier gas to be used and quantify the carrier gas
29 to be used (for fluidized bed reactors it is recommended 2.75 kg carrier gas/kg dry biomass²⁰⁴);
30 (5) Specify reaction temperature (in the case of fast pyrolysis typically 500 °C) and conduct
31 pyrolysis tests at lab or pilot facilities (6) Conduct a mass balance with the yield of products
32 obtained experimentally (see information in tables 5, 6, 7, 8, 10); (7) Conduct energy balances to
33 calculate how much heat has to be removed or supplied to the reactor. Thermodynamic
34 information for the overall energy balance of pyrolysis reactors can be found elsewhere²⁰⁵⁻²⁰⁸. (8)
35 Calculate the residence time of the biomass particle to achieve a targeted conversion.
36 Information on experimental and modeling strategies (single particle models) to calculate
37 conversion as a function of residence time can be found elsewhere^{72, 75, 209-211}. (9) Calculate the
38 solid hold up in the reactor. The residence time of the solid in the reactor depend on the
39 hydrodynamic and the mechanic design of these reactors. In the case of rotary drums, it depends
40 on the slope of the reactor, kiln rotational speed and the length and diameter of the reactor²¹². For

5 fluidized beds, the retention of the solid is controlled by the terminal velocity of the converted
6 biomass particle in the free board, (10) In the case of fluidized bed calculate or determine
7 experimentally the minimum fluidization velocity (typically use 2 to 3 times the minimum
8 fluidization velocity)^{213, 214}, (11) Calculate the cross sectional area and diameter of the reactor²¹³,
9 (12) In the case of fluidized bed reactors calculate volume of expanded fluidized bed (sand and
10 char particles)^{213, 215}, (13) If designing fluidized bed reactors calculate the length and the
11 diameter of the free board²¹³, (14) Select the heating or cooling method to be used (e.g. indirect,
12 direct or microwave heating) and calculate the heat transfer area needed to supply or remove the
13 heat calculated in the energy balances²¹³, (15) In the case of the fluidized bed reactors size the
14 distribution grate²¹³.

24 **10. Challenges for the implementation of pyrolysis**

25
26
27

28 The development of pyrolysis technologies must overcome two major hurdles. The first one is
29 associated with the lack of markets for pyrolysis oils and the second one with the lack of biochar
30 derived products with well-defined performance characteristics. Consequently, it is imperative to
31 accelerate the development and deployment of bio-oil refineries and the development and
32 commercialization of engineered bio-char for environmental services. Developing flexible
33 designs for pyrolysis units to produce high yields of both bio-oil and char is a technological
34 challenge facing the thermochemical community.
35
36
37
38
39
40
41

42 The selection of pyrolysis technologies, their operational conditions, and the feedstocks to be
43 used will depend mostly on economic tradeoffs²¹⁶. The results presented in this review clearly
44 show that there are multiple operational conditions and designs to obtain a wide range of
45 products yields. Most of fast pyrolysis reactors reviewed are operated at conditions (500 °C,
46 small particles (below than 2 mm), use of heat carrier (sand) and residence time of vapors below
47 2 s (use of a carrier gas)) for maximizing bio-oil yields with little regard for the quality of the
48 product. The use of high volumes of carrier gas and the heat carrier reduce the energy efficiency
49 of these processes, create important sand attrition problems, and makes it very difficult to
50 condense the diluted vapors, requiring very large surface areas and considerable cooling power.
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5 Most of fast pyrolysis designs combust the char to satisfy the energy needs of the process. The
6 difficulties to refine fast pyrolysis oils with high oxygen content is the main reason for the
7 growing interest in catalytic pyrolysis for the production of bio-oils with lower oxygen content.
8
9 The catalytic cracking strategies to reduce bio-oil oxygen content typically result in an increase
10 in gas yield and coke formation. The converters reviewed are flexible enough to operate in
11 conditions where bio-oil and biochar production is possible. More studies are needed to explore
12 designs that take advantage of homogeneous secondary reactions in gas phase for oxygen
13 removal from pyrolysis oils.
14
15
16
17
18
19

20 There is a vast diversity of situations in which pyrolysis can be applied (different feedstocks,
21 scale, capacity, use of mobile or stationary units) as well as the diversity of products that can be
22 obtained. This makes it very difficult to find an exclusive design that is sustainable across all the
23 potential applications. Table 15 is an attempt to summarize the type of reactor suitable for a
24 specific cases. A balanced investment in the creation of new knowledge (i.e., Science), in the
25 design, testing and scale up of new technologies (for pyrolysis reactors and for rural bio-oil
26 refineries) (i.e., Technology) and in the development of new products (from bio-oil and char)
27 (i.e., Market) to build a shared vision that take advantage of existing infrastructure and is
28 achievable in small steps are all critical for the deployment of a viable biomass based economy
29 on pyrolysis technologies.

11. Conclusions

The number of publications on slow and fast pyrolysis reactors has been growing steadily in the last thirty years. The community interested in these reactors is formed by researchers interested on char production and those interested on bio-oil production. This paper reviews slow, intermediate, fast and microwave pyrolysis intending that companies and academic institutions, researching, designing and commercializing pyrolysis/carbonization reactors can take advantage of the technological solutions shown. Very little progress has been made in the last century in the design of kilns. The release of large quantities of pyrolysis vapors to the atmosphere and/or their condensation in soils are major sources of pollution that need to be urgently addressed. Several of the *retorts* used today were developed and commercialized by the “wood distillation industry”. These units were designed for the carbonization of logs. However, deforestation issues and the limited availability of logs for carbonization are major hurdles for their widespread deployment in today’s world. The *converters* are receiving growing attention for their capacity to convert forest and agricultural residues in the form of chips and shredded materials into bio-oil and charcoal. These systems do not require the use of large volumes of carrier gas or a heat carrier (sand). Nevertheless, the lack of commercial interest for fine chars produced by these systems has been a major hurdle for the commercialization of this technology. The growing interest on using char as soil amendments and the development of technologies for the production of char pellets and briquettes from these fines are catalyzing new companies commercializing these designs. The current design and operation of *fast pyrolysis reactors* is based on conditions maximizing bio-oil yields with little regard for the quality of the bio-oil produced. High bio-oil yield is achieved at 500 °C, using small particles (less than 1 mm) a heat carrier (sand) and using high volumes of carrier gas to reduce the residence time of vapors below 2 s. The energy need of these reactors is typically satisfied by char combustion. Consequently, most of these processes do not commercialize char as one of their products. The lack of commercial bio-oil refineries is the main barrier for the commercialization of these reactors. Problems with fast pyrolysis oil refining are catalyzing interest on strategies to produce oils with lower oxygen content. Most of these strategies result in high gas yield, which is an opportunity to explore the use of the gases to satisfy part of the energy needed of the system, without scarifying
