Home Energy Rating System Building Energy Simulation Test (HERS BESTEST)

Volume 1 Tier 1 and Tier 2 Tests User's Manual

Ron Judkoff Joel Neymark

National Renewable Energy Laboratory 1617 Cole Boulevard Golden, Colorado 80401-3393 A national laboratory of the U.S. Department of Energy Managed by Midwest Research Institute for the U.S. Department of Energy under contract No. DE-AC36-83CH10093

Prepared under Task No. BE51.4101

November 1995

This work is divided into two volumes. Volume 1 contains the test cast specifications and is a user's manual for anyone wishing to test a computer program. Volume 2 contains the reference results and suggestions for accrediting agencies on how to use and interpret the results.

Neither the U.S. Department of Energy, the National Renewable Energy Laboratory, nor the authors of this report can be held responsible for any misfortunes caused by the use of the HERS BESTEST example pass/fail criteria in your certification program.

NOTICE

This report was prepared as an account of work sponsored by an agency of the United States government. Neither the United States government nor any agency thereof, nor any of their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, apparatus, product, or process disclosed, or represents that its use would not infringe privately owned rights. Reference herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise does not necessarily constitute or imply its endorsement, recommendation, or favoring by the United States government or any agency thereof. The views and opinions of authors expressed herein do not necessarily state or reflect those of the United States government or any agency thereof.

Available to DOE and DOE contractors from: Office of Scientific and Technical Information (OSTI) P.O. Box 62 Oak Ridge, TN 37831 Prices available by calling 423-576-8401

Available to the public from: National Technical Information Service (NTIS) U.S. Department of Commerce 5285 Port Royal Road Springfield, VA 22161 703-605-6000 or 800-553-6847 or DOE Information Bridge http://www.doe.gov/bridge/home.html

Printed on paper containing at least 50% wastepaper, including 10% postconsumer waste

Acknowledgments

In developing the Home Energy Rating System (HERS) Building Energy Simulation Test (BESTEST) we ran two field tests with early versions. We would like to thank the following people for participating in those field tests, providing us with their results, and providing comments:

Evan Brown, Energy Rated Homes of America Jeanne Byrne, Pacific Gas & Electric Bud Heiss, Columbus Southern Power Jim Neukam, Texas Gas Transmission Corp. Scott Roberts, Architectural Energy Corp. Robert Scott, California Home Energy Efficiency Rating System Charles Segerstrom, Pacific Gas & Electric/CHEERS Dwight Shuler, Owens Corning Fiberglass Corp. Dick Tracey, D&R International.

The authors also wish to thank past and current HERS Council Technical Committee members for providing guidance during this project:

Dick Bahn, Chairman, Honeywell, Inc. Dick Tracey, Co-Chairman, D&R International Cindy Baxter, Oregon Department of Energy Evan Brown, Energy Rated Homes of America Robert Brown, National Conference of States on Building Codes and Standards Matthew Chwalowski, Edison Electric Institute Frank Denney, Alabama Power Co. Robert Egan, Washington Gas Co. Chris Fennel, National Conference of States on Building Codes and Standards Bud Heiss, Columbus Southern Power Michael Holtz, Architectural Energy Corporation Richard Holtz, RRH Associates Bion Howard, The Alliance to Save Energy Jack Laverty, COAD Neil Leslie, Gas Research Institute Duncan Prahl, Western Massachusetts Electric Company/Energy Crafted Home Henry Rutkowski, Air Conditioning Contractors of America Charles Segerstrom, Pacific Gas & Electric Company/CHEERS,

We also thank the following HERS Council Technical Committee Advisory Members:

Harold Crowder Jr., Virginia Power Richard Faesy, Energy Rated Homes of Vermont Jim Neukam, Texas Gas Transmission Martin Petchul, Columbia Gas Transmission Andrew Sinclair, Carrier Corporation Doug Swartz, City of Fort Collins Light & Power

Finally, we appreciate the efforts of current and past Department of Energy (DOE) program managers for this project, including Jean Boulin, Lou Divone, Mary Margaret Jenior, Jake Kaminsky, and Robert Mackie.

.

Background

In 1991, the Department of Energy (DOE), in cooperation with the Department of Housing and Urban Development (HUD), initiated a collaborative process to define a residential energy efficiency rating program linked with energy-efficient mortgage (EEM) financing. During this process, the collaborative, consisting of a broad-based group representing stakeholder organizations, identified the need for quality control procedures to evaluate and verify the energy prediction methods used by Home Energy Rating System (HERS) providers. Such procedures were needed so that a variety of locally developed rating systems would have equal opportunity to qualify under the umbrella of a national HERS/EEM system by meeting minimum technical requirements (National Renewable Energy Laboratory (NREL)).

On October 26, 1992 the Energy Policy Act was signed into law. The section on Residential Energy Efficiency Rating Guidelines called for negotiated voluntary rulemaking with private sector groups having a stake in Residential Energy Rating Systems. The act confirmed the need for technical quality control and called for the creation of a set of guidelines for HERS. The act also called for establishing "protocols and procedures for certification of the technical accuracy of building energy analysis tools used to determine energy efficiency ratings."

In 1994 the HERS Council was incorporated under the laws of Maryland as a 501C nonprofit corporation. The council is a broad-based organization with more than 100 member organizations representing all groups identified in the legislation and other stakeholder groups. NREL was directed by DOE to work closely with the HERS Council and, in accordance with the legislation, to develop the guidelines and the technical basis for software certification. This document is a result of that effort.

NREL had already developed the theoretical basis for this type of building energy software testing in cooperation with the International Energy Agency (IEA) (Judkoff and Neymark). NREL led a group consisting of experts from the IEA Solar Heating and Cooling Program Task 12b and the IEA Buildings and Community Systems Program Task 21c. The 5-year international research effort resulted in a software testing methodology that is being adopted by the American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE), Canada, Britain, Finland, Belgium, France, Italy, Spain, Sweden, the United States, the California Energy Commission, and the HERS Council.

This type of software testing based on intermodel comparisons forms one portion of an overall validation methodology that was first developed at NREL in 1983 and that has been further refined since then by NREL and a number of European researchers (Bloomfield, Bowman and Lomas, Irving, Judkoff, Judkoff and Neymark, Judkoff et al., Lomas). The overall validation methodology consists of three parts:

- Analytical Verification in which the output from a program, subroutine, or algorithm is compared to the result from a known analytical solution for isolated heat transfer mechanisms under very simple boundary conditions
- Empirical Validation in which calculated results from a program, subroutine, or algorithm are compared to monitored data from a real structure, test cell, or laboratory experiment
- Comparative testing in which a program is compared to itself or to other programs. The comparative approach includes "sensitivity testing" and "intermodel comparisons."

Comparative testing as applied in the HERS Building Energy Simulation Test (BESTEST) method includes a set of public domain reference programs that have already been subjected to extensive analytical, empirical, and intermodel testing. In addition to the software testing procedures described in this document, the HERS Council Guidelines, and DOE 10 CFR Part 437 require collection of utility bill

data for further checking and improvement of the building energy prediction tools used by HERS providers. NREL anticipates further development of empirical validation methods appropriate for testing HERS software. NREL also anticipates further development of comparative testing methods appropriate for HERS software.

1.0 Introduction

Home Energy Rating System (HERS) Building Energy Simulation Test (BESTEST) is a method for evaluating the credibility of building energy software used by Home Energy Rating Systems. The method provides the technical foundation for "certification of the technical accuracy of building energy analysis tools used to determine energy efficiency ratings" as called for in the Energy Policy Act of 1992 (Title I, Subtitle A, Section 102, Title II, Part 6, Section 271). Certification is accomplished with a uniform set of test cases that facilitate the comparison of a software tool with several of the best public-domain, state-of-the-art building energy simulation programs available in the United States. This set of test cases represents the Tier 1 and Tier 2 Tests for Certification of Rating Tools as described in DOE 10 CFR Part 437, and the HERS Council *Guidelines for Uniformity* (HERS Council).

The Tier 1 tests consist of a basic house with typical glazing and insulation. Specific cases are designed to test a building energy computer program with respect to the following components of heat and mass transfer:

- Infiltration
- Wall and ceiling R-Value
- Glazing physical properties, area, and orientation
- South overhang
- Internal loads
- Exterior surface color
- Energy inefficient building
- Crawl space
- Uninsulated and insulated slab
- Uninsulated and insulated basement.

The Tier 2 tests consist of the following additional elements related to passive solar design:

- Variation in mass
- Glazing orientation
- East and west shading
- Glazing area
- South overhang.

A third Tier of tests not included in this document is also planned as described in the *HERS Council Guidelines*. These are anticipated to include:

- Domestic water heating
- Utility rate structures including demand
- HVAC simulation
- Solar water heating
- Sunspace
- Thermostat set-back and set-up
- Trombe wall
- Whole house fan

To help avoid user input errors, we have tried to keep the input for the test cases simple, while remaining as close as possible to "typical" constructions and thermal and physical properties. For this reason, we have followed as closely as possible typical building descriptions and physical properties published by sources such as the National Association of Home Builders (NAHB), the U.S. Department of Energy (DOE), American Society of Heating Refrigerating and Air Conditioning Engineers (ASHRAE), and the National Fenestration Rating Council (NFRC).

The theoretical basis for HERS BESTEST is described in detail in the final report of International Energy Agency (IEA) Solar Heating and Cooling Task 12b, and Conservation Task 21c (Judkoff and Neymark).

This work is divided into two volumes. Volume 1 contains the test case specifications and is a user's manual for anyone wishing to test a computer program. Volume 2 contains the reference results and suggestions for accrediting agencies on how to use and interpret the results.

The diskette included with volume 1 contains the following:

- WEATHER.ZIP (compressed TMY weather data for Colorado Springs, Colorado, and Las Vegas, Nevada)
- PKUNZIP.EXE (decompression utility)
- README.TXT (directions for weather data decompression).

1.1 Performing the Tests

1.1.1 Input Requirements

Table 1-1 is a summary of the various parametric cases contained in HERS BESTEST and indicates which tests are Tier 1 (T1) and which tests are Tier 2 (T2). This table is provided only as an overview; use Section 2 to generate input to your HERS tool. We recommend a quick look at Table 1-1 now to briefly get acquainted with the base building and various other cases. Two climates will be used: Colorado Springs, Colorado, which is a clear, cold climate, and Las Vegas, Nevada, which is a hot, dry climate. More detail on weather data is provided in Section 2.1.

1.1.2 Modeling Rules

- Use the most detailed level of modeling your tool will allow.
- In some instances the specification will include input values that do not apply to the input structure of your tool. For example, your tool may calculate window solar transmittance based on input of physical properties of glass or based on shading coefficient. When this occurs either use approximation methods suggested in your users manual, or <u>simply disregard the nonapplicable inputs</u> and continue. Such inputs are in the specification for those programs that may need them.

1.1.3 Output Requirements

For the Tier 1 and Tier 2 Tests, generate output for comparison to the reference results as shown in Table 1-2 and Table 1-3 respectively. Note in Table 1-3 for cases P100A through P150A that the climate for generating cooling load outputs is Colorado Springs, Colorado, rather than the Las Vegas, Nevada, climate required for the other cases. This is because the passive solar design described in Cases P100A and P105A, while appropriate for Colorado Springs is inappropriate for Las Vegas.

			R-VALUE	E (h ft² F/Btu)	T	WINDOW	DAT	A

ABBREVIATIONS

SUBFLOOR = construction below main floor, VC = ventilated crawl space, SLAB = slab on grade, BASEMENT = full basement.

INFILTR (ACH) = infiltration (Air Changes per Hour) R-VALUE, FLOOR: UNINS = slab or basement coupled to ground, EDGE INS = 4 ft. deep perimeter slab insulation. WINDOW DATA: SATB = single pane, clear glass, aluminum frame with thermal break; DLEW = double pane, low-e glass, wood frame, insulated spacer; WINDOW DATA. SATE = single parte, clear glass, auminum mame with thermal break; DLE w = double pane, low-e glass, wood frame, insula DW = double pane, clear glass, wood frame, metal spacer. ORIENT = Orientation; AVG DIST = window area distributed over walls in proportion to total exterior wall area. N/A = not applicable; 1.0 S = all windows on south wall; 0.5E, 0.5W = 50% of window area on east wall and 50% of window area on west wall. SHADE = window shading device; H = horizontal shade (overhang); HV = horizontal and vertical shading (overhang and fins). ASHRAE = American Society of Heating, Refrigerating, and Air-Conditioning Engineers, Atlanta, GA.

NOTES Note1: Changes to Case L100A are highlighted with bold font. Note 2: These are composite R-values including all materials, films, and the presence of the attic for ceiling R-value; see Section 2 for more detail. Note 3: Gross area is the total window area including the frame; net area is the area of just the glass portion of the window. Note 4: Basement below-grade wall R-values including the ground are: L322A = R-8, L324A = R-19.

For software that designates heating and cooling seasons, monthly reference results and instructions for use of these results are provided in Volume 2, Section 3. Heating and cooling seasons may be for the entire year or some other reasonable length as defined by your tool.

1.1.4 Comparing Your Output to the Reference Results

In order to compare your output to the HERS BESTEST reference results, the following annual and monthly load outputs from simulations have been provided (see Volume 2, Section 3): heating loads for Colorado Springs, Colorado; cooling loads for Las Vegas, Nevada, except for the passive solar (P-series) cases where cooling loads are for Colorado Springs, Colorado.

The following programs were used to generate reference results:

- BLAST 3.0 Level 215
- DOE2.1E-W54
- SERIRES/SUNCODE 5.7

BLAST 3.0 is the program used by the U.S. Department of Defense for energy efficiency improvements to their buildings. (*BLAST User Reference*) DOE2.1E is considered to be the most advanced of the programs sponsored by the U.S. Department of Energy, and is the technical basis for setting national building energy codes and standards in the United States. (*DOE2 Reference Manual, DOE2 Supplement*) SUNCODE 5.7 is based on the public domain program SERIRES-1.0 developed by NREL. (Palmiter et al.)

1.2 Advice to Certifying Agency

1.2.1 Example pass/fail criteria

A program may be thought of as having passed successfully through the test series when its results compare favorably with passing ranges based on the reference program outputs on a case-by-case and a sensitivity basis (difference or delta (Δ) between certain cases).

Example pass/fail criteria based on the reference results are included and discussed in Section 4 (Volume 2) to illustrate how a certifying agency may evaluate a HERS tool with HERS BESTEST. The procedure for developing example passing ranges (excluding any application to specific reference results) is provided in Appendix H (Volume 1). The certifying agency using HERS BESTEST may adopt these example pass/fail criteria or develop their own pass/fail criteria. Neither DOE, the National Renewable Energy Laboratory (NREL), nor the authors of this report can be held responsible for any misfortunes caused by the use of the HERS BESTEST example pass/fail criteria in your certification program.

2.0 Specific Input Information

This section contains building input data and weather data necessary for running all the cases. Refer to Tables 1-2 (Tier 1) and 1-3 (Tier 2) for a description of which cases are required for each of the two climate locations. Weather data is described in Section 2.1 below.

No two programs require exactly the same input information. Therefore, we have tried to describe the test cases in a fashion that allows many different HERS tools, representing different degrees of modeling complexity, to be tested.

Building input data (beginning in Section 2.2) are organized case by case. The base building description (Case L100A) occupies Section 2.2 with other cases organized as modifications to the base case (other Tier 1 cases in Section 2.3, and Tier 2 cases in Section 2.4). In some instances (e.g., Case L200A), a case developed from modifications to Case L100A will also serve as the base case for other cases. Within this structure, figures and tables are grouped as summary data and supplemental data. The summary data are figures and tables that contain information that should cover most of the input requirements for most users.

The supplemental tables contain more detailed information that was required for generating a consistent set of inputs to the reference programs. Such data include: material properties for modeling thermal mass and modeling the attic as a separate zone, interior solar distribution fractions, combined convective and radiative surface coefficients, hourly internal gains schedules, and detailed window optical properties. We expect that most HERS BESTEST users will only need a small amount of the supplemental data for their input decks, although we do not know exactly which part of it they may need. Again, the modeling rules of Section 1.1 apply in all instances.

Abbreviations used in the tables, figures, and text are defined in the acronyms and abbreviations list on page ix of this document.

2.1 Weather Data

Use the weather diskette supplied in your packet; see Appendix A for details about Typical Meteorological Year (TMY) Weather File format.

Weather data for two locations are supplied for the test:

- Colorado Springs, Colorado (a clear, cold climate)
- Las Vegas, Nevada (a hot, dry climate).

The weather data supplied on the enclosed diskette are TMY files that contain hourly weather data. These files have been compressed so that two weather files will fit on one diskette. Please use the file decompression instructions included under README.TXT on the diskette; file decompression software is included on the diskette. If your program uses some other representation of weather such as degree days, bin method, etc., then you will have to process the TMY weather data with your program's weather processor so that your weather data will be based on the diskette data. The weather properties for Colorado Springs, Colorado, and Las Vegas, Nevada, are summarized in Tables 2-1 and 2-2 below.

Weather Type	Cold Clear Winters
Weather Format	Typical Meteorological Year (TMY)
Latitude	38.8° North
Longitude	104.7° West
Altitude	6145 ft
Time Zone	7
Ground Reflectivity	0.2
Site	flat, unobstructed, located exactly at weather station
Mean Annual Wind Speed	10.7 mph
Mean Annual Ambient Dry-Bulb Temperature (also for ground)	49.43°F
Mean Annual Daily Temperature Range	25.5°F
Minimum Annual Dry-Bulb Temperature	-9.9°F
Maximum Annual Dry-Bulb Temperature	93.9°F
Maximum Annual Wind Speed	36.9 mph
Heating Degree Days (Base 65°F)	6031.0°F-days (Note 2)
Cooling Degree Days (Base 65°F)	489.5°F-days (Note 2)
Mean Annual Dew Point Temperature	27.9°F
Mean Annual Humidity Ratio	0.0047
Global Horizontal Solar Radiation Annual Total	584.33 kBtu/ft²-y
Direct Normal Solar Radiation Annual Total	759.67 kBtu/ft²-y
Direct Horizontal Solar Radiation	430.27 kBtu/ft²-y
Diffuse Horizontal Solar Radiation	154.07 kBtu/ft²-y

Table 2-1. Colorado Springs, Colorado, Climate Summary (Note 1)

Note 1: Unless otherwise noted, values are SERIRES/SUNCODE weather outputs. Note 2: From DOE2.1E weather processor summary.

Weather Type	Hot Dry Summers
Weather Format	Typical Meteorological Year (TMY)
Latitude	36.1° North
Longitude	115.2° West
Altitude	2178 ft
Time Zone	8
Ground Reflectivity	0.2
Site	flat, unobstructed, located exactly at weather station
Mean Annual Wind Speed	9.6 mph
Mean Annual Ambient Dry-Bulb Temperature (also for ground)	66.69°F
Mean Annual Daily Temperature Range	23.6°F
Minimum Annual Dry-Bulb Temperature	23.0°F
Maximum Annual Dry-Bulb Temperature	113.0°F
Maximum Annual Wind Speed	35.8 mph
Heating Degree Days (Base 65°F)	2415.0°F-days (Note 2)
Cooling Degree Days (Base 65°F)	3025.0°F-days (Note 2)
Mean Annual Dew Point Temperature	28.1°F
Mean Annual Humidity Ratio	0.0040
Global Horizontal Solar Radiation Annual Total	687.38 kBtu/ft²-y
Direct Normal Solar Radiation Annual Total	872.62 kBtu/ft²-y
Direct Horizontal Solar Radiation	528.86 kBtu/ft²-y
Diffuse Horizontal Solar Radiation	158.52 kBtu/ft²-y

Table 2-2. Las Vegas, Nevada, Climate Summary (Note 1)

Note 1: Unless otherwise noted, values are SERIRES/SUNCODE weather outputs. Note 2: From DOE2.1E weather processor summary.

2.2 The Base Case Building (Case L100A)

The bulk of the work for implementing HERS BESTEST is assembling an accurate base building. We recommend that you double check your base building inputs before going on to the other cases. As described in the following subsections, the base building is a 1539 ft² single-story house with one conditioned zone (the main floor), an unconditioned attic, and a vented crawl space. The following figures and tables included after the base building discussion contain information that is applicable to most users.

- Figure 2-1. Base Building Axonometric
- Figure 2-2. Floor Plan Case L100A
- Figure 2-3. East Side Elevation Case L100A
- Figure 2-4. Exterior Wall Plan Section Case L100A
- Figure 2-5. Floor Above Vented Crawl Space Section Case L100A
- Figure 2-6. Ceiling/Attic/Roof Section Case L100A
- Figure 2-7. Interior Wall Plan Section Case L100A
- Figure 2-8. Window Detail, Vertical Slider (NFRC AA) with 2-3/4" Wide Frame Case L100A
- Table 2-3. Building Thermal Summary Case L100A
- Table 2-4. Other Building Details Case L100A.

Relevant supplementary tables that include more detailed information are:

- Table 2-5. Component Surface Areas and Solar Fractions Case L100A
- Table 2-6. Material Descriptions, Exterior Wall, Door, and Window Case L100A
- Table 2-7. Material Descriptions, Floor Over Vented Crawl Space Case L100A
- Table 2-8. Material Descriptions, Ceiling, Attic, and Roof Case L100A
- Table 2-9. Material Descriptions, Ceiling/Attic/Roof, Attic as Material Layer Case L100A (for calculating equivalent ceiling/attic/roof composite R-value.)
- Table 2-10. Material Descriptions, Interior Wall Case L100A
- Table 2-11. Internal Loads Schedule Case L100A
- Table 2-12. Gross Window Summary, Single Pane Aluminum Frame with Thermal Break Case L100A
- Table 2-13. Glazing Summary, Single Pane Center of Glass Values Case L100A
- Table 2-14. Optical Properties as a Function of Incidence Angle for Single-Pane Glazing Case L100A.

Other details not described in these figures and tables are discussed topically in the following subsections.

2.2.1 Attic

Many of the HERS tools that we surveyed input an attic by specifying it within a menu of roof types, and then specifying the insulation-only R-value corresponding to the insulation installed on the attic floor. If this is the case for your software, then the information provided in Figure 2-6 will be sufficient.

For programs such as those used for developing the reference results, more detailed information is required. The detailed information for modeling an attic as a separate zone is supplied in Table 2-8. Table 2-9 gives similar information as Table 2-8 except in Table 2-9 the attic space is modelled as a layer of thermal resistance between ceiling and roof materials. Table 2-9 is included to document the calculation of ceiling/attic/roof composite air-air R-value noted in the building thermal summary of Table 2-9. In Table 2-9 the equivalent resistance for the attic is based on values from the *Cooling and Heating Load Calculation Manual* (McQuiston and Spitler, p. 4.12); typical ventilation by natural effects

and roof solar absorptance of 0.6 were assumed. The equivalence of the one-zone model versus the twozone base case was verified with sensitivity tests using BLAST and SERIRES/SUNCODE. However, model the attic as a separate zone if your software allows it.

2.2.2 Vented Crawl Space

No attempt was made to describe the vented crawl space as a separate zone. To simulate a vented crawl space, HERS BESTEST only requires the floor to have an exterior film coefficient for "rough" surface texture and zero windspeed (in addition to the floor materials and interior film coefficient). Consistent with ASHRAE Handbook 1993 Fundamentals, vented crawl space air temperature is assumed to equal outdoor air temperature.

2.2.3 Windows

A great deal of information about the window properties has been provided so that equivalent input for windows will be possible for many programs. The basic properties of the single-pane window, including shading coefficient, solar heat gain coefficient, and thermal resistance, are provided in Table 2-3. Additional information can be found in Figure 2-8, Table 2-6, and Tables 2-12 through 2-14. This information is drawn primarily from the WINDOW 4.1 (WINDOW 4.1, 1994) software for developing detailed glazing properties. For programs that need transmittance or reflectance at other angles of incidence, interpolate between the values of Table 2-14. Where other unspecified data are needed, then values consistent with those quoted will have to be calculated.

For the base case, total glass and frame areas for each wall can be combined into a single large area for that wall. For later cases where shading is used, the specific window geometry will need to be modeled as closely as possible.

2.2.4 Interior Walls

The interior walls within the conditioned zone have been included for the purpose of modeling the effect of their mass. They are not intended to divide the conditioned zone into separately controlled zones. The importance of modeling interior wall mass will be more evident in Tier 2 tests when passive solar cases are added to HERS BESTEST.

2.2.5 Infiltration

Colorado Springs, Colorado, and Las Vegas, Nevada, are at 6145 ft. and 2178 ft. altitude respectively, so the density of air is less than that at sea-level for both locations. If your program does not use barometric pressure from the weather data, or otherwise automatically corrects for the change in air density caused by altitude, then adjust the specified infiltration rates (to yield mass flows equivalent to what would occur at the specified altitude) as shown in **Table 2-4**. Only use the attic infiltration rate if your software allows that input. Attic infiltration is based on the *Cooling and Heating Load Calculation Manual*, (McQuiston and Spitler, P. 4.12) for typical ventilation by natural effects. If you need more information about altitude effects on infiltration, see Appendix B.

2.2.6 Internal Loads

These are non-HVAC related internally generated loads from equipment, lights, people, animals, etc. An hourly internal load schedule for the conditioned zone is specified in Table 2-11. There are no internal loads in the attic. This schedule disaggregates sensible and latent loads. If your software does not analyze latent loads, then leave them out and use only the sensible portion of the internal loads. Aggregate sensible loads are 70% radiative and 30% convective.

Because internal loads are given only for their effect on heating and cooling load, the equipment fuel type and efficiency associated with generating these loads do not matter.

2.2.7 Combined Radiative and Convective Surface Coefficients

Combined surface coefficients are denoted in various section drawings throughout Volume 1 as "Interior Film" and "Exterior Film" (e.g., see Figures 2-4 through 2-7). If your program uses combined surface coefficients, then use the information given in **Table 2-4** (this information is also included with the detailed material descriptions of Tables 2-6 through 2-10). Because the heating season average windspeed for Colorado Springs, Colorado, is nearly equal to the cooling season average windspeed for Las Vegas, Nevada, the listed exterior surface coefficients apply to both climates.

If your program does not allow variation of combined surface coefficients or if your program automatically calculates interior and exterior surface convection and radiation in greater detail, then you may ignore this information. See Appendices C and D if you need more information on surface coefficients.

2.2.8 Surface Radiative Properties

Surface radiative properties are given in Table 2-4. These properties apply to all opaque exterior and interior building surfaces; they are roughly equivalent to medium color paint or a light color roof.

2.2.9 Interior Solar Distribution

Interior solar distribution is the fraction of transmitted solar radiation incident on specific surfaces in a room. This effect can be significant in passive solar applications. If your program does not calculate this effect internally, then use the interior solar fractions from Table 2-5. The calculation of transmitted solar radiation reflected back out through windows (cavity albedo) is presented in Appendix E. If your program does not allow for variations of interior solar distribution, then disregard.

2.2.10 Mechanical System

For the base building, obtain only pure load outputs (i.e., assume all equipment including ducts is 100% efficient). The thermostat settings and equipment descriptions below are sufficient for this purpose. This mechanical system only applies to the conditioned zone; it does not apply to the unconditioned attic. Assume the following:

- 100% Convective Air System
- The thermostat senses only the air temperature
- The thermostat is of the nonproportional type.

2.2.10.1 Thermostat Control Strategies

Annual thermostat control settings are shown below. Because monthly reference results for an entire year are provided in Volume 2, Section 3, your heating and cooling seasons may be for the entire year or some other reasonable length as designated by your tool. Instructions for using monthly reference results are also provided in Volume 2, Section 3.

For Colorado Springs, Colorado (heating only) cases: HEAT = ON IF TEMP < 68°F; COOL = OFF.

For Las Vegas, Nevada (cooling only) cases: COOL = ON IF TEMP > 78°F; HEAT = OFF.

The thermostat is nonproportional in the sense that when the air temperature exceeds the thermostat cooling set-point, the heat extraction rate is assumed to equal the maximum capacity of the cooling equipment. Likewise, when the air temperature drops below the thermostat heating set-point, the heat addition rate equals the maximum capacity of the heating equipment. A proportional thermostat model can be made to approximate a nonproportional thermostat model by setting a very small throttling range (the minimum allowed by your program).

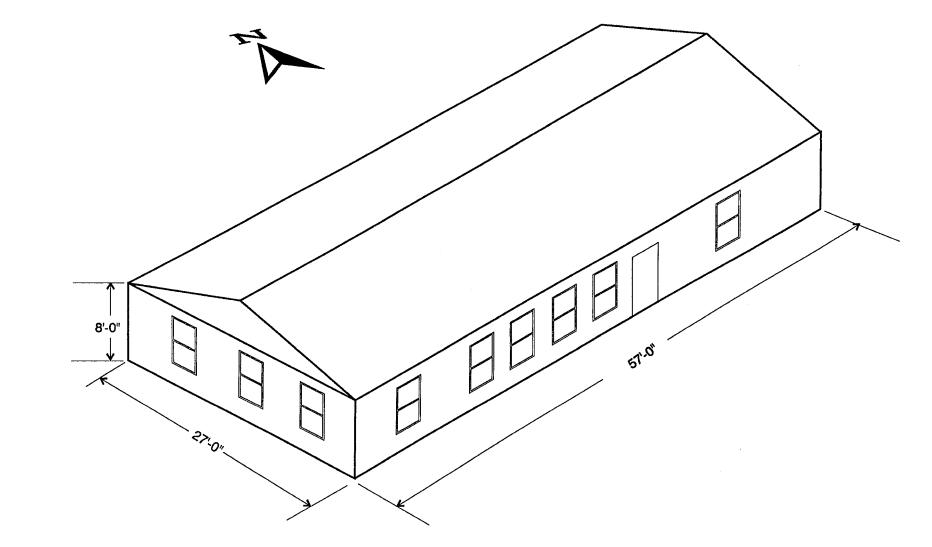

2.2.10.2 Equipment Characteristics

HEATING CAPACITY = 3413 MBtu/h (effectively infinite). EFFECTIVE EFFICIENCY = 100%.

COOLING CAPACITY = 3413 MBtu/h (effectively infinite). EFFECTIVE EFFICIENCY = 100%.

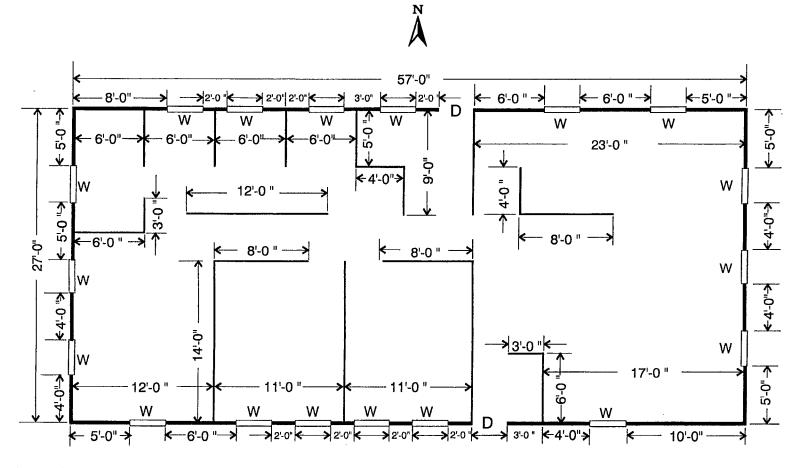

WASTE HEAT FROM FAN = 0.

The 3413 MBtu/h requirement comes from the english equivalent of 1 MW. If your software does not allow this much capacity, then use the largest system that your software will allow.

#### Table 2-3. Building Thermal Summary-Case L100A

Note 1: Includes interior and exterior surface coefficients.

Note 2: Heat capacity includes building mass within the thermal envelope (e.g., insulation and insulation thickness of structural framing are included, exterior siding and roof/attic mass are excluded).

Note 3: Excludes area of windows and doors. ASHRAE framed area fraction of 0.25 is assumed for 2x4 16" O.C. construction.

Note 4: Window area and other properties are for glass and frame combined. The accompanying window summary disaggregates glass and frame properties for a single window unit. North and south walls contain six window units each; east and west walls contain three window units each.

Note 5: ASHRAE roof/ceiling framing area fraction of 0.1 applied to both ceiling and floor.

Note 6: Infiltration UA = (infiltration mass flow)\*(specific heat). Assumes air properties: specific heat = 0.240 Btu/(lb\*F); density = 0.075 lb/ft<sup>3</sup> at sea level, adjusted for altitude per Appendix B. The following values were used to obtain

| infiltration UA: | Location   | ACH  | Volume (ft <sup>3</sup> ) | Altitude (ft) | UAinf (Btu/(h*F)) |  |
|------------------|------------|------|---------------------------|---------------|-------------------|--|
|                  | Colo Sprgs | 0.67 | 12312                     | 6145          | 118.2             |  |
|                  | Las Vegas  | 0.67 | 12312                     | 2178          | 136.9             |  |

Note 7: This data summarizes one complete window unit per detailed description of Figure 2-8 and Tables 2-12 through 2-14. Note 8: SHGC is the Solar Heat Gain Coefficient that includes the inward flowing fraction of absorbed direct normal solar radiation in addition to direct normal transmittance. For more detail, see ASHRAE 1993 Fundamentals, chp. 27. Note 9: "Trans." is the direct normal transmittance.

Note 10: Shading coefficient (SC) is the ratio of direct normal SHGC for a specific glazing unit to direct normal SHGC for the WINDOW 4.1 reference glazing unit.

### Table 2-4. Other Building Details—Case L100A

-

#### 2.2.11 Case L100A: Supplementary Tables

The following data were used for generating reference results. The previous figures and tables summarized, and are based on, the data presented in this section. We expect that many HERS tools will not be able to directly input much of the data in this section (e.g., material densities, specific heats, detailed window optical properties, interior solar fractions, surface coefficients, etc.). However, if your models are capable of receiving this level of detail, then you must use these tables where possible.

| Note 1: Insulated section only, see Figure 2-4 for | section view of v | wall.     |                      |                |                    |                  |           |
| Note 2: Framed section only, see Figure 2-4 for s  |                   |           |                      |                |                    |                  |           |
| Note 3: 10.7 mph wind speed and brick/rough pla    |                   |           | endices C and D f    | or more inform | ation about exter  | rior film coeffi | cients.   |

Note 3: 10.7 mph wind speed and brick/rough plaster roughness assumed; see Appendices C and D for more information about exterior film coefficients. Note 4: Total composite R-values based on 75% insulated section 25% frame area section per ASHRAE. Thermal properties of windows and doors are not included in this composite calculation.

Note 5: Total surf-surf composite R-value is the total air-air composite R-value less the resistances due to the film coefficients.

Note 6: Door has same film coefficients as exterior wall.

Note 7: This section summarizes the detailed window description of Tables 2-12 through 2-14. Areas pertain to one complete window unit only (see Figure 2-8). If your software is capable of modeling windows in greater detail than shown here, then use Tables 2-12 through 2-14. Note 8: SHGC is the Solar Heat Gain Coefficient, which includes the inward flowing fraction of absorbed direct normal solar radiation in addition to

direct normal transmittance. For more detail, see ASHRAE 1993 Fundamentals, chp. 27.

Note 9: "Trans." is the direct normal transmittance.

Note 10: Shading coefficient (SC) is the ratio of direct normal SHGC for a specific glazing unit to direct normal SHGC for the WINDOW 4.1 reference glazing unit.

Note 11: Exterior surface coefficient is the same for both frame and glass; see Appendices C and D for more about exterior film coefficients.

| Note 1: This table is for modeling the attic as a sen |               |                |              |         |                    |          |

Note 1: This table is for modeling the attic as a separate zone.

Note 2: Average of ASHRAE heating and cooling coefficients, horizontal surface.

Note 3: Insulated section only, see Figure 2-6 for section view of ceiling.

Note 4: Framed section only, see Figure 2-6 for section view of ceiling.

Note 5: Based on 10% frame area fraction per ASHRAE; applies to temperature difference between room air and attic air.

The "Composite surf-surf" R-value is the composite air-air R-value less the two interior film coefficient R-values.

Note 6: 10.7 mph wind speed and brick/rough plaster roughness assumed; see Appendix C for more about exterior film coefficients.

Note 7: Average for ASHRAE upward and downward heat flow through sloped surface, interpolated on cosine of roof pitch angle.

Note 8: Area weighted sum of plywood and asphalt shingle or wood siding material layers, does not include film coefficients. This value used for developing Table 2-9.

Note 5: This "material" combines roofing and end gable materials into one hybrid layer of material.

Note 6: Based on total roof/gable UA, surf-surf calculated in Table 2-8.

.

Note 7: (ceiling interior film coefficient) + (ceiling materials) + (attic as material layer) + (scaled roof deck/gable materials)

+ (scaled exterior film coefficient). Based on 90% insulated section and 10% frame section per ASHRAE.

Note 8: Based on total air-air R-value less R-values of interior film coefficient and scaled exterior film coefficient.

## Table 2-14. Optical Properties as a Function of Incidence Angle for Single-Pane Glazing—Case L100A

.

### 2.3 The Tier 1 Test Cases

This section describes revisions to the base building required to model the other Tier 1 cases of HERS BESTEST case by case. In some instances the base building for a case is not Case L100A; cases with non-L100A basis are:

| Case  | Basis for that case |
|-------|---------------------|
| L155A | L150A               |
| L202A | L200A               |
| L304A | L302A               |
| L324A | L322A               |

For convenience, relevant portions of the appropriate base building tables and figures have been reprinted with changes highlighted in bold font. Where applicable, summary figures and tables are listed first with supplementary tables listed afterward.

### 2.3.1 Case L110A: High Infiltration (1.5 ACH)

Case L110A is **exactly as Case L100A except** that infiltration for the conditioned zone is changed as shown in Table 2-15. Discussion of infiltration rate adjustment for altitude can be found in Appendix B. Attic infiltration rate remains unchanged.

| Infiltration Algorithm                                                   | ACH            | CFM            |
|--------------------------------------------------------------------------|----------------|----------------|
| HERS w/ automatic altitude adjustment                                    | 1.5            | 307.8          |
| HERS w/ site fixed at sea level<br>Colorado Springs, CO<br>Las Vegas, NV | 1.194<br>1.383 | 244.9<br>283.9 |

Table 2-15. Conditioned Zone Infiltration for Case L110A

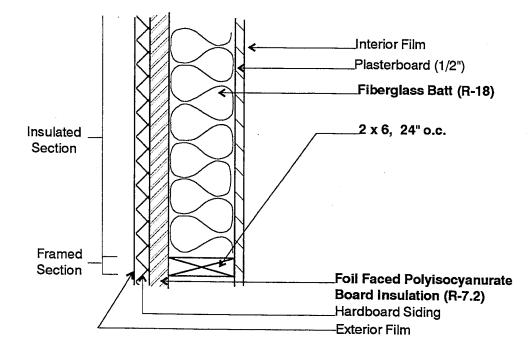

### 2.3.2 Case L120A: Well Insulated Walls and Roof

Case L120A is **exactly as Case L100A except** that an extra layer of R-38 batt insulation has been added to the ceiling, and exterior walls have 2x6 24" O.C. framing and R-18 batt insulation with R-7.2 polyisocyanurate exterior board insulation. The following figures and table highlight information that is expected to be useful to most users.

- Figure 2-9. Exterior Wall Plan Section Case L120A
- Figure 2-10. Ceiling Section Case L120A
- Table 2-16. Building Thermal Summary Case L120A.

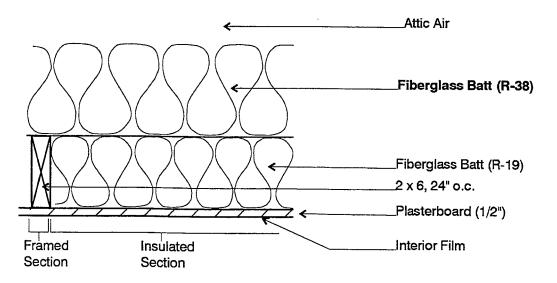

Relevant supplementary tables that include more detailed information are:

- Table 2-17. Component Surface Areas and Solar Fractions Case L120A
- Table 2-18. Material Descriptions, Exterior Wall Case L120A
- Table 2-19. Material Descriptions, Ceiling Case L120A
- Table 2-20. Material Descriptions for Attic as Material Layer Case L120A (for calculation of equivalent ceiling/attic/roof composite R-value, see discussion of the base building attic in Section 2.2).

Note: Changes to Case L100A are highlighted with bold font.

Note: Changes to Case L100A are highlighted with bold font.

## Table 2-16. Building Thermal Summary—Case L120A

### 2.3.2.1 Case L120A: Supplementary Tables

The following data were used for generating reference results. The previous figures and tables summarized, and are based on, the data presented in this section. We expect that many HERS tools will not be able to directly input much of the data in this section (e.g., material densities, specific heats, interior solar fractions, surface coefficients, etc.). However, if your models are capable of receiving this level of detail, then you must use these tables where possible.

### Table 2-17. Component Surface Areas and Solar Fractions—Case L120A

|                                                                                                                 |                           | INSIDE                                |  |  |  |  |  |

### 2.3.3 Case L130A: Double-Pane Low-Emissivity Window with Wood Frame

Case L130A is **exactly as Case L100A except** that all single-pane windows are replaced with double-pane low-emissivity (low-e) windows with wood frames and insulated spacers. The basic properties of the window, including shading coefficient, solar heat gain coefficient, and thermal resistance are provided in:

• Table 2-21. Building Thermal Summary - Case L130A.

Window and frame geometry remain as for Case L100A.

Relevant supplementary tables that include more detailed information are:

- Table 2-22. Advanced Window (Double-Pane, Low-E, Argon Fill, Wood Frame, Insulated Spacer) Case L130A
- Table 2-23. Low-E Glazing System with Argon Gas Fill Glazing Summary (Center of Glass Values) Case L130A
- Table 2-24. Optical Properties as a Function of Incidence Angle for Low-Emissivity Double-Pane Glazing Case L130A
- Table 2-25. Component Solar Fractions Case L130A.

Window properties are drawn from the WINDOW 4.1 (WINDOW 4.1, 1994) software for window thermal analysis. For programs that need transmittance or reflectance at other angles of incidence, interpolate between the values of Table 2-24. Where other unspecified data are needed, then values consistent with those quoted will have to be calculated.

There is a slight change in interior surface solar distribution caused by reduced solar lost (cavity albedo); for those tools that can vary this input, values are included in Table 2-25.

Because of the large number of changes to the glazing for this case, Tables 2-22 through 2-24 have not been highlighted with bold font to show where changes occurred.

| glass and frame properties for a single window unit. North and south walls contain six window units each; east and west walls     |           |                          |                            |             |              |           |  |  |
| contain three window units each.                                                                                                  |           |                          |                            |             |              |           |  |  |
| Note 6: ASHRAE roof/ceiling framing area fraction of 0.1 applied to both ceiling and floor.                                       |           |                          |                            |             |              |           |  |  |
|                                                                                                                                   |           |                          |                            |             | through 2-24 |           |  |  |
| Note 7: This data summarizes one complete detailed window unit per Figure 2-8 and Tables 2-22 through 2-24.                       |           |                          |                            |             |              |           |  |  |

## Table 2-21. Building Thermal Summary—Case L130A

Note 8: SHGC is the Solar Heat Gain Coefficient, which includes the inward flowing fraction of absorbed direct normal solar radiation in addition to direct normal transmittance. For more detail, see ASHRAE 1993 Fundamentals, chp. 27. Note 9: "Trans." is the direct normal transmittance.

Note 10: Shading coefficient (SC) is the ratio of direct normal SHGC for a specific glazing unit to direct normal SHGC for the WINDOW 4.1 reference glazing unit.

### 2.3.4 Case L140A: Zero Window Area

:

Case L140A is exactly as Case L100A except the gross window area (glass and frame) is replaced with the Case L100A solid exterior wall materials of Figure 2-4 (Table 2-6 is the corresponding supplementary table). The following tables summarize the changes:

- Table 2-26. Building Thermal Summary Case L140A ٠
- Table 2-27. Component Surface Areas Case L140A. •

| ELEMENT                                                                                                                                                    | AREA            | R                        | U                          | UA        | HEATCAP |  |  |

### 2.3.5 Case L150A: South-Oriented Windows

This case is **exactly as Case L100A except** that all windows have been moved to the South wall. These changes are summarized in the following:

- Figure 2-11. Exterior Wall and South Window Locations Case L150A
- Figure 2-12. South Wall Elevation Case L150A
- Table 2-28. Building Thermal Summary Case L150A
- Table 2-29. Surface Component Areas and Solar Fractions Case L150A.

#### Note: Interior walls are same as for Case L100A

Plan

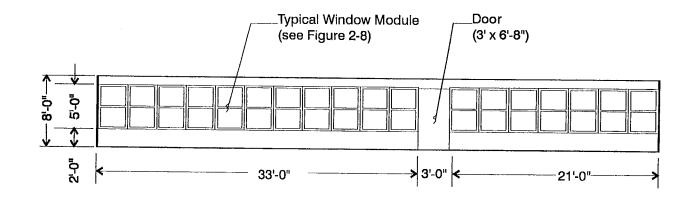

-#W:

W = window (3' wide x 5' high)

# = number of windows along given length of exterior wall

D =Solid-core wood door (3' wide x 6' 8" high)

Figure 2-11. Exterior wall and south window locations—Case L150A

### 2.3.6 Case L155A: South-Oriented Windows with Overhang

Case L155A is exactly as Case L150A except that an opaque overhang has been included at the top of the south exterior wall. The overhang extends outward from this wall 2.5 ft. as shown in Figure 2-13. The overhang traverses the entire length of the south wall.

Depending on the input capabilities of your software, it may not be possible to model the exact geometry of the windows and overhang as shown in Figure 2-13. If this is the case, a simplified model of the south wall may be used such as the conceptual description shown in Figure 2-14. In Figure 2-14, glass and horizontally oriented framing directly above and below the glass are aggregated into long units with all elements located properly in the vertical direction to obtain the nearly equivalent shading of Figure 2-13. Proper dimensions for this example are obtained using Figure 2-8 (Case L100A), Figure 2-13, and Table 2-29 (Case L150A). The vertically oriented framing is similarly aggregated in a separate area so that equivalent shading will also result. While the overhang is not shown in Figure 2-14, it must be included as shown in Figure 2-13.

Recall from Section 1, this test requires that you use the most detailed level of modeling your tool will allow.

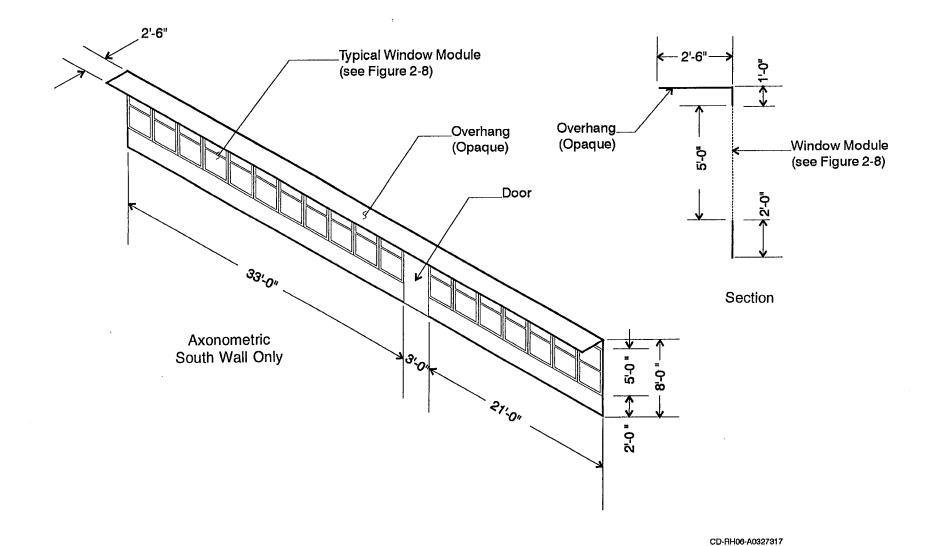

Figure 2-13. South overhang—Case L155A

52

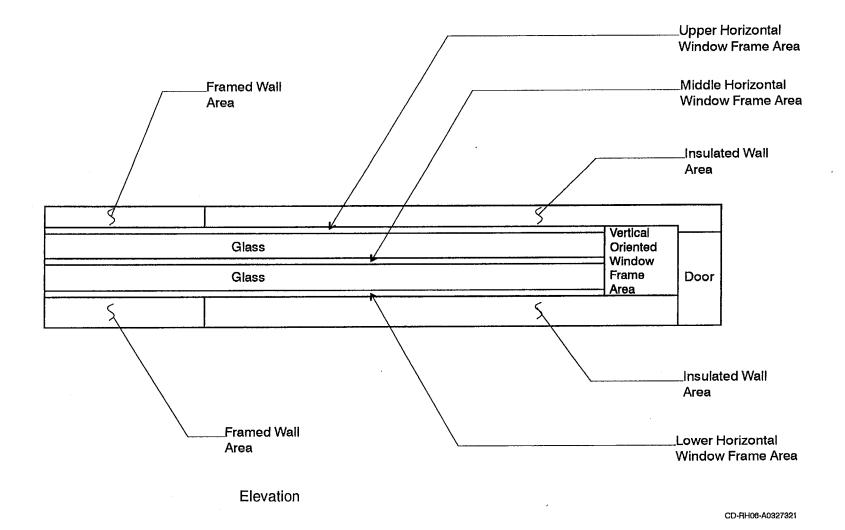

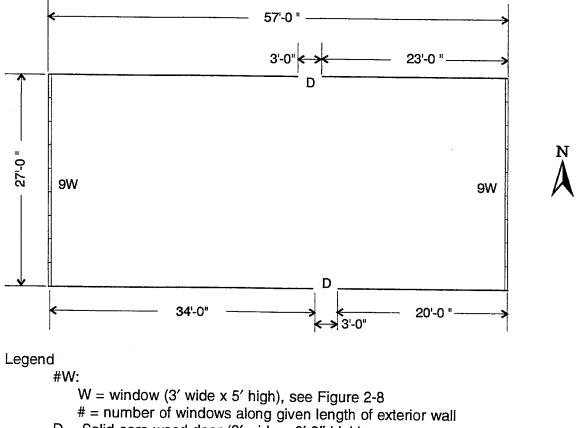

Figure 2-14. Example model of south wall for simulating south overhang effect in Case L155A

### 2.3.7 Case L160A: East- and West-Oriented Windows

This case is **exactly as Case L100A except** that all windows have been moved to the east and west walls. These changes are summarized in the following:

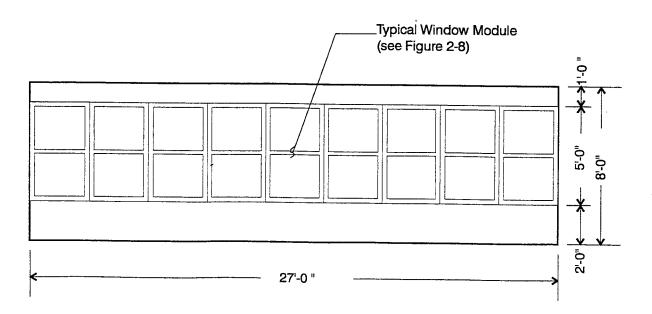

- Figure 2-15. East and West Window Locations, Plan Case L160A
- Figure 2-16. East/West Wall Elevation Case L160A
- Table 2-30. Building Thermal Summary Case L160A
- Table 2-31. Surface Component Areas and Solar Fractions Case L160A.

### Note: Interior walls are same as Case L100A

### 2.3.8 Case L170A: No Internal Loads

Case L170A is exactly as Case L100 except the internal sensible and latent loads in the conditioned zone are set to zero for all hours of the entire year.

### 2.3.9 Case L200A: Energy Inefficient

This case is exactly as Case L100A except for the following changes:

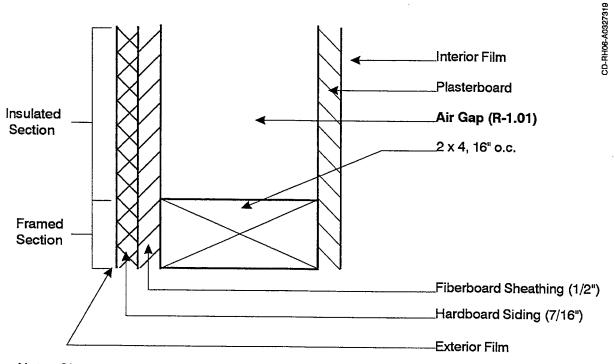

- Infiltration for the conditioned zone is 1.5 ACH
- Exterior wall fiberglass insulation is replaced with an air gap
- Floor fiberglass insulation is eliminated
- Ceiling fiberglass insulation is reduced from 5.5" to 3.5".

The following figures and tables highlight information that is expected to be useful to most users.

- Figure 2-17. Exterior Wall Plan Section Case L200A
- Figure 2-18. Floor Above Vented Crawl Space, Section Case L200A
- Figure 2-19. Ceiling Section Case L200A
- Table 2-15. Conditioned Zone Infiltration for Case L110A (see Case L110A)
- Table 2-32. Building Thermal Summary Case L200A.

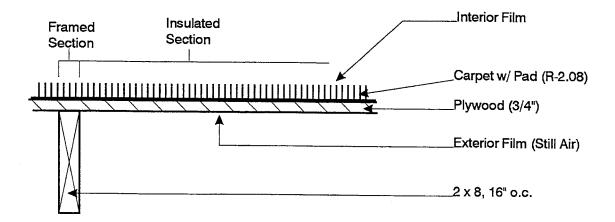

Relevant supplementary tables that include more detailed information are:

- Table 2-33. Material Descriptions, Exterior Wall Case L200A
- Table 2-34. Material Descriptions, Floor Above Vented Crawl Space Case L200A
- Table 2-35. Material Descriptions, Ceiling Case L200A
- Table 2-36. Material Descriptions, Ceiling with Attic as Material Layer Case L200A (for calculation of equivalent ceiling/attic/roof composite R-value, see discussion of the base building attic in Section 2.2).

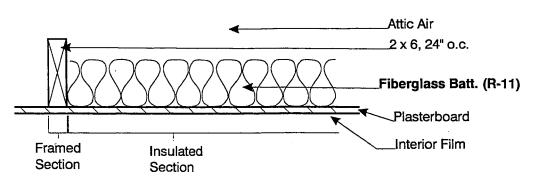

Note: Changes to Case L100A are highlighted with bold font.

Figure 2-17. Exterior wall plan section—Case L200A

Note: R-11 batt insulation of Case L100A has been removed.

Figure 2-18. Floor above vented crawl space, section-Case L200A.

Note: Changes to Case L100A are highlighted with bold font.

# 2.3.9.1 Case L200A: Supplementary Tables

The following data were used for generating reference results. The previous figures and tables summarized, and are based on, the data presented in this section. We expect that many HERS tools will not be able to directly input much of the data in this section (e.g., material densities, specific heats, interior solar fractions, surface coefficients, etc.). However, if your models are capable of receiving this level of detail, then you must use these tables where possible.

| EXTERIOR WALL (inside to outside)             |                   |          |         |        |                    |          |

### Table 2-33. Material Descriptions, Exterior Wall-Case L200A

Note 2: Non-frame (air gap) section only. See Figure 2-17 for section view of wall; airgap replaces fiberglass insulation for this case.

Note 3: Framed section only, see Figure 2-17 for section view of wall.

Note 4: 10.7 mph wind speed and brick/rough plaster roughness; see Appendix C for more on exterior film coefficients.

Note 5: Total composite R-values based on 25% frame area section per ASHRAE.

Note 6: Total surf-surf composite R-value is the total air-air composite R-value less the resistances due to the film coefficients.

### Table 2-35. Material Descriptions, Ceiling-Case L200A

Note 2: Insulated section only. See Figure 2-19 for section view of ceiling.

Note 3: Framed section only, see Figure 2-19 for section view of ceiling. Modeled framing thickness is reduced to that for insulation; remaining length is assumed to be at attic air temperature and is not considered for thermal mass.

Note 4: Based on 90% insulated section and 10% frame section per ASHRAE; applies to temperature difference between room air and

attic air. The "Composite surf-surf" R-value is the composite air-air R-value less the two interior film coefficient R-values.

# 2.3.10 Case L202A: Low Exterior Solar Absorptance Associated with Light Exterior Surface Color

This case is exactly as Case L200A except that exterior shortwave (visible and UV) absorptance ( $\alpha_{ext}$ ) is 0.2 for the following opaque exterior surfaces exposed to solar radiation:

- Exterior walls
- Roof
- End gables
- Doors.

Window frames remain at  $\alpha_{ext} = 0.6$ .

# 2.3.11 Slab-on-Grade Series (Cases L302A and L304A)

Cases L302A and L304A are designed to compare the results of HERS software to reference software results using the steady-state ASHRAE perimeter method for modeling slab-on-grade heat loss (ASHRAE Handbook 1993 Fundamentals, p. 25.12; Wang, 1979). Although this is a simplified method for ground-coupling analysis, we recognize that it is possible a HERS tool could use a more detailed model for slab-on-grade ground coupling, which could have a significant effect on the output. Therefore, we have included the results of more detailed ground-coupling analysis as part of the Volume 2, Section 3 reference results. This serves to widen the range of reference results (and acceptable outputs from HERS tools) for the slab-on-grade cases. Case descriptions for more detailed ground-coupling analysis are given in Appendix G, where Cases L302B and L304B are the more detailed versions of cases L302A and L304A, respectively.

For Cases L302A and L304A, the ASHRAE perimeter method assumes heat loss occurs along the entire 168 ft of full slab perimeter. In both cases an R-2.08 carpet with pad is present at the interior surface of the slab.

For this series Case L302A is the base case for Case L304A.

### **Output Requirements**

Annual or seasonal heating loads for Colorado Springs, Colorado are the only required outputs for these cases.

# 2.3.11.1 Case L302A: Slab-on-Grade, Uninsulated ASHRAE Slab

This case is **exactly as Case L100A except** that the floor above vented crawl space has been changed to an uninsulated slab as shown in:

- Figure 2-20. Uninsulated Slab-on-Grade Section Case L302A
- Table 2-37. Building Thermal Summary Case L302A.

Note that a carpet is present on the interior surface of the slab.

The following supplemental table shows equivalent inputs for modeling the ASHRAE perimeter method with the reference software:

• Table 2-38. Material Descriptions, Slab on Grade Floor - Case L302A.

Because Table 2-38 contains only new information relevant to slab floor construction, it is **not** highlighted with bold font.

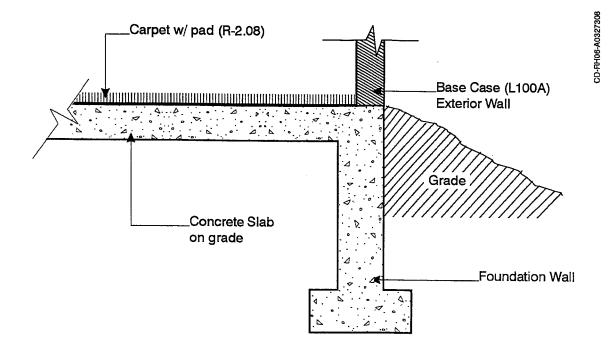

Figure 2-20. Uninsulated slab on grade, section-Case L302A

# 2.3.11.2 Case L304A: Slab on Grade, Insulated ASHRAE Slab

This case is **exactly as Case L302A except** that the slab is insulated with R-5.4 perimeter insulation as shown in:

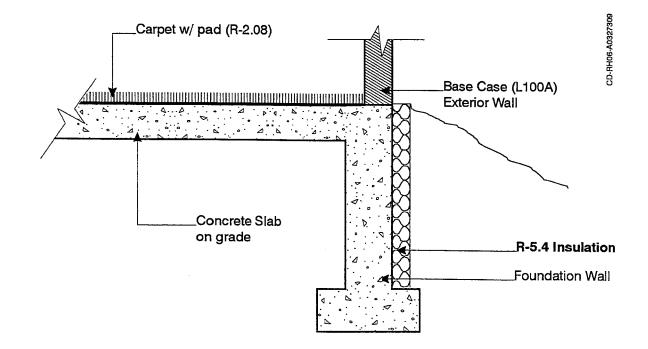

- Figure 2-21. Slab on Grade with Foundation Wall Exterior Insulation, Section Case L304A
- Table 2-39. Building Thermal Summary Case L304A.

The following supplemental table shows equivalent inputs for modeling the ASHRAE perimeter method with the reference software:

• Table 2-40. Material Descriptions, Slab on Grade Floor - Case L304A.

Bold font in the figure and tables for Case L304A highlights changes to Case L302A.

.

Note: Changes to Case L302A are highlighted with bold font.

# 2.3.12 Basement Series (Cases L322A and L324A)

Cases L322A and L324A are designed to compare the results of HERS software to reference software results using the ASHRAE method for modeling basement heat loss from the below-grade basement walls and slab floor (ASHRAE 1993 Fundamentals, pp. 25.10, 25.11, Latta and Boileau 1969; Wang 1979). Although this is a simplified method for ground-coupling analysis, we recognize that it is possible a HERS tool could use a more detailed model for basement ground coupling, which could have a significant effect on the output. Therefore, we have included the results of more detailed ground-coupling analysis as part of the Volume 2, Section 3 reference results. This serves to widen the range of reference results (and acceptable outputs from HERS tools) for the basement cases. Case descriptions for more detailed ground-coupling analysis are given in Appendix G, where Cases L322B and L324B, are the more detailed versions of cases L322A and L324A, respectively.

For this series, Case L322A is the base case for Case L324A.

### **Output Requirements:**

Annual or seasonal heating loads for Colorado Springs, Colorado are the only required outputs for these cases.

### 2.3.12.1 Case L322A: Uninsulated ASHRAE Conditioned Basement

Because this case contains numerous changes to the base building (Case L100A), a "recommended input procedure" is also included in this section.

Case L322A is **exactly as Case L100A except** that a conditioned basement has been added with the following envelope and interior floor modifications:

- Add basement walls
- Add concrete basement floor slab
- Replace the previous main floor (formerly above vented crawl space) with an interior main floor/basement ceiling.

The following figures and table (included after the discussion) contain information that is expected to be useful to most users:

- Figure 2-22. Basement Series Base Building, Section and Plan
- Figure 2-23. Basement Wall and Floor Section Case L322A
- Figure 2-18. Floor Above Vented Crawl Space Case L200A (with change per recommended input procedure, Step 4, below)
- Table 2-41. Building Thermal Summary Case L322A.

Relevant supplementary tables that include more detailed information are listed below. Because these tables contain only new information relevant to the basement construction, they are not highlighted with bold font.

- Table 2-42. Basement Component Surface Areas Case L322A
- Table 2-43. Material Descriptions, Basement Wall Case L322A
- Table 2-44. Material Descriptions, Basement Floor Case L322A
- Table 2-45. Material Descriptions, Interior Main Floor/Basement Ceiling Case L322A.

### Thermostat control and related modeling notes:

Basement air temperature is regulated by the same thermostat as the main floor (see Case L100A), and main floor and basement air are assumed to be well mixed. Therefore, you may model the entire house (main floor and basement) as a single zone, or you may model the main floor and basement as separate zones adjacent to each other with identical thermostat control. In a single-zone model, the main floor/basement ceiling is treated like the main floor interior walls. In a two-zone model, the main floor/basement ceiling is a partition between the main floor and the basement zones.

### **Recommended Input Procedure:**

To develop the input deck for Case L322A, begin with Case L100A and proceed as follows:

- 1. Add the basement with 1539 ft<sup>2</sup> of floor area and 12312 ft<sup>3</sup> of air volume directly below the original conditioned zone as shown in Figure 2-22. The basement wall (effective ceiling) height is 8' as shown in Figures 2-22 and 2-23. Basement envelope and ceiling component surface areas are shown in Table 2-41 (relevant supplemental data is included in Table 2-42). Thermostat control is as described above. No additional infiltration through the basement envelope is assumed (i.e., the sill is caulked Latta and Boileau, 1969). No additional internal gains are present in the basement.
- 2. Construct the basement walls as shown in Figure 2-23 and Table 2-41 (relevant supplementary tables are Table 2-42 and Table 2-43). The walls include a rim joist section, as well as above- and below-grade concrete wall sections. The basement wall construction is the same for all four basement walls. No windows are included in the basement.
- 3. Construct the basement floor as shown in Figures 2-22 and 2-23, and Table 2-41 (relevant supplemental tables are Tables 2-42 and 2-44).
- 4. Replace the base-case main floor (formerly above ventilated crawl space) with the interior main floor/basement ceiling of Table 2-41 (also see supplemental Table 2-45). This floor is based on that of Figure 2-18 (Case L200A) except the exterior film below the floor is replaced by an interior film.

### Table 2-41. Building Thermal Summary-Case L322A

framing are included, exterior siding and roof/attic mass are excluded).

Note 3: Excludes the area of windows and doors. ASHRAE framed area fraction of 0.25 is assumed for 2x4 16" O.C. construction. Note 4: ASHRAE roof/ceiling framing area fraction of 0.1 applied to ceiling.

Note 5: Main floor infiltration is as in Case L100A. The basement zone has no infiltration. If you are modeling the basement and main floor as one combined zone, then use an infiltration rate of 0.335 ACH applied to the entire

conditioned zone air volume of 24624 ft<sup>3</sup>; also see Appendix B for more detail.

Note 6: Basement components are defined in Figures 2-22 and 2-23.

Note 7: For the ASHRAE below-grade wall and basement floor steady-state heat loss models, the effects of thermal mass are incorporated into the steady-state heat loss coefficients.

# 2.3.12.1.1 Case L322A: Supplementary Tables

The following data were used for generating reference results. The previous figures and tables summarized, and are based on, the data presented in this section. We expect that many HERS tools will not be able to directly input much of the data in this section (e.g., material densities, specific heats, interior solar fractions, surface coefficients, etc.). However, if your models are capable of receiving this level of detail, then you must use these tables where possible.

### Table 2-42. Basement Component Surface Areas—Case L322A

Case L100A. The main floor/basement ceiling has been included for the purpose of modeling the effect of its mass; it is not

intended to divide the house into separately controlled zones.

Note 2: Rim joist and sill plate sections are defined in Figure 2-23.

Note 3: Width is the total perimeter length of the exterior walls.

# Table 2-43. Material Descriptions, Basement Wall---Case L322A

Note 1: Rim joist section only. See Figure 2-23 for section view.

Note 2: Sill plate section only. See Figure 2-23 for section view.

Note 3: Total composite R-values based on 7.5" rim joist section and 1.5" sill plate section.

Note 4: Total surf-surf composite R-value is the total air-air composite R-value less the resistances caused by the film coefficients.

Note 5: This R-value is total air-air R-value (based on the ASHRAE overall steady-state heat transfer coefficient for a 6'-7" deep

below-grade concrete wall) less the resistance of the listed interior film coefficient.

### 2.3.12.2 Case L324A: Interior Insulation Applied to Uninsulated ASHRAE Conditioned Basement Wall

This case is exactly as Case L322A except that insulation has been added to the interior side of the basement wall and rim joist. The basement floor slab remains as is in Case L322A.

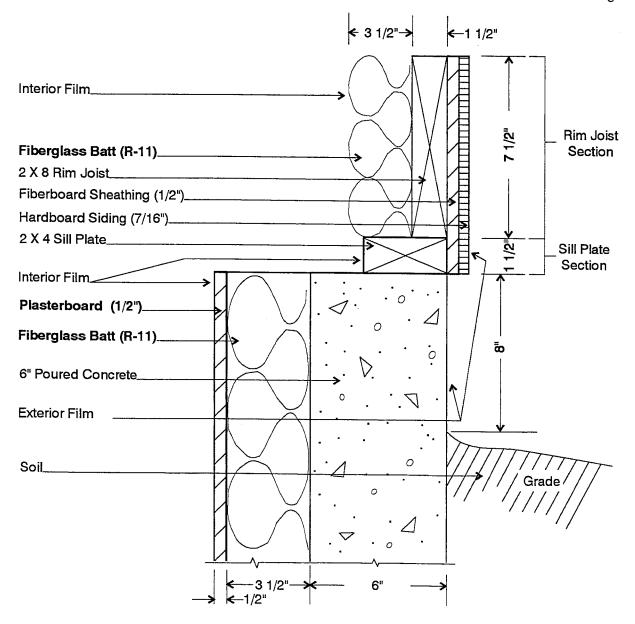

The following figures and table highlight information that will be useful to most users:

- Figure 2-24. Insulated Basement Wall and Rim Joist Section Case L324A
- Figure 2-25. Insulated Basement Wall Plan Section Case L324A
- Table 2-46. Building Thermal Summary Case L324A.

Relevant supplementary tables that include more detailed information are:

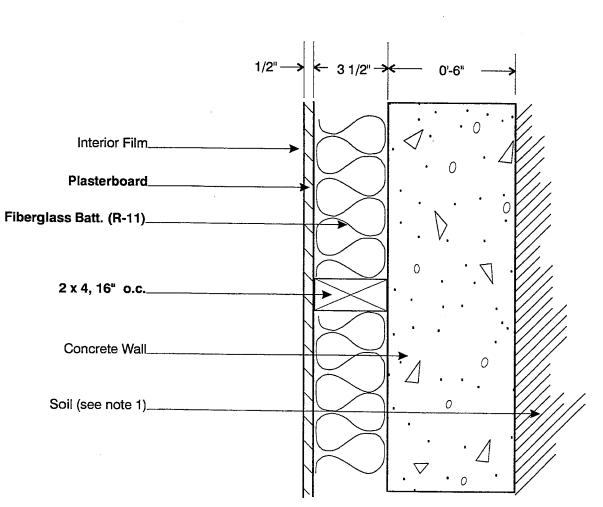

- Table 2-47. Component Surface Areas Case L324A
- Table 2-48. Material Descriptions, Basement Wall Case L324A.

Bold font in figures and tables for Case L324A highlight changes relative to Case L322A.

Notes: (1) Changes to Case L322A are highlighted with bold font. (2) Detail showing floor joist attachment to sill plate and its effect on rim joist insulation is ignored for the purpose of this test. Use the above rim joist section for all walls regardless of orientation.

Plan Section

CD-RH06-A0327306

Notes: (1) Changes to Case L322A are highlighted with bold font. (2) Soil does not apply to above-grade portion of basement wall. Effective soil layer thickness varies with wall depth below grade.

# Table 2-46. Building Thermal Summary-Case L324A

ges to Case L322A are highlighted by bold font. R- and U- values include surface coeff

Note 2: Heat capacity includes building mass within the thermal envelope (e.g., insulation and insulation thickness of structural framing are included, exterior siding and roof/attic mass are excluded).

Note 3: Excludes the area of windows and doors. ASHRAE framed area fraction of 0.25 is assumed for 2x4 16" O.C. construction. Note 4: ASHRAE roof/ceiling framing area fraction of 0.1 applied to ceiling.

Note 5: Basement components are defined in Figure 2-24.

Note 6: Framed area fraction of 0.1 used for insulated basement wall.

Note 7: HEATCAP for below-grade basement wall includes only thermal mass associated with plasterboard, framing, and insulation.

Note 8: For the ASHRAE below-grade wall and basement floor steady-state heat loss models, the effects of thermal mass are incorporated into the steady-state heat loss coefficients.

# 2.4 Tier 2 Test Cases

This section describes revisions to the base building required to model the Tier 2 cases of HERS BESTEST case by case. Recall from Table 1-3 that only the annual cooling output for Case L165A is generated using the Las Vegas, Nevada weather data. Annual heating output for Case L165A and all outputs (annual heating and cooling) for the P-series cases are generated using the Colorado Springs, Colorado, weather data.

Case L165A is based on Tier 1 Case L160A, and Case P100A is based on Tier 1 Case L120A. Case P100A represents the base case for the other P-series cases (P105A, P110A, P140A, P150A). Bold font in tables and figures for the Tier 2 cases denotes changes to their appropriate base cases.

Where applicable, summary figures and tables are listed first with supplementary tables listed afterward.

### 2.4.1 Case L165A: East/West Shaded Windows

Case L165A is exactly as Case L160A except that an opaque overhang and ten opaque fins have been added to the east and west walls as shown in Figure 2-26.

Depending on the input capabilities of your software, it may not be possible to model the exact geometry of the windows and shading devices as shown in Figure 2-26. If this is the case, a nearly equivalent model of the shading devices may be used such as that described in Figure 2-27, where the ten small fins have been replaced with two large fins. It may also be necessary to modify the window geometry. This type of modification process was presented with Figure 2-14 (Case L155A).

Recall from Section 1 that this test requires that you use the most detailed level of modeling your tool will allow.

# 2.4.2 Case P100A: Passive Solar Base Case

Case P100A is the base case for the passive solar series (P-series) cases. This case is representative of good passive solar heating design. However, for the passive base case, a south wall overhang was not included. To prevent summer overheating, good passive-solar design would include an overhang as described in Case P105A. Additionally, an optimized passive solar design would include more glass area (replacing some of the window frame) with a corresponding increase to the mass surface area.

Case P100A is **based on Case L120A** with modifications as described below. Because of the many changes in this case versus Case L120A, we recommend that you double check your inputs before running the remainder of the P-serious cases. A "recommended input procedure" is also included.

In general, the following envelope and interior wall **modifications to Case L120A** were applied to achieve Case P100A:

- · All south window orientation with increased glass area
- Clear double-pane window with wood frame and modified geometry
- R-23 composite floor with brick pavers for thermal mass
- Replacement of three of the 14' lightweight interior walls with three 14' double brick walls for thermal mass.

The following tables and figures highlight information that is expected to be useful to most users.

- Figure 2-9. Exterior Wall Section Case L120A
- Figure 2-28. Window, Door, and Mass Wall Locations Case P100A
- Figure 2-29. Mass Floor Above Vented Crawl Space, Section Case P100A
- Figure 2-30. Interior Mass Wall Section Case P100A
- Figure 2-31. Window Detail, Vertical Slider 30" Wide by 78" High with 2 3/4" Frame Case P100A
- Table 2-49. Building Thermal Summary Case P100A.

Relevant supplementary tables that include more detailed information (presented after the above summary tables) are:

- Table 2-18. Material Descriptions, Exterior Wall Case L120A
- Table 2-50. Component Surface Areas and Solar Fractions Case P100A
- Table 2-51. Material Descriptions, Floor Over Vented Crawl Space Case P100A
- Table 2-52. Material Descriptions, Interior Mass Wall Case P100A
- Table 2-53. Gross Window Summary, Double Pane, Clear, Wood Frame Window Case P100A
- Table 2-54. Glazing Summary Clear Double Pane Center of Glass Values Case P100A
- Table 2-55. Optical Properties as a Function of Incidence Angle for Clear Double-Pane Glazing Case P100A.

Where appropriate, changes to Case L120A have been highlighted in tables and figures with bold font.

#### **Radiative Properties of Massive Surfaces:**

For massive (brick) surfaces, solar absorptance and infrared omittance are 0.6 and 0.9 respectively (same as other surfaces).

### Thermostat Control Strategies:

For the P-series cases, Colorado Springs, Colorado weather data are also used to generate annual (or seasonal) cooling loads and the annual (or seasonal) heating loads. Use the annual thermostat control settings noted below for the P-series cases.

Heating only: HEAT = ON IF TEMP < 68°F; COOL = OFF. Cooling only: COOL = ON IF TEMP > 78°F; HEAT = OFF.

Because this is not deadband thermostat control, separate simulations for heating and cooling outputs were required to generate reference results (just as with the Tier 1 cases when Las Vegas was the cooling climate). Proper comparison with reference results requires separate simulations with your HERS tool/software for generating annual (or seasonal) heating and cooling outputs.

### **Interior Walls:**

As in the Tier 1 tests, interior walls (including massive interior walls) have been included for the purpose of modeling their mass effect. They are not intended to divide the conditioned zone into separately controlled zones.

### Vented Crawl Space:

As in the Tier 1 tests, no attempt was made to describe the vented crawl space as a separate zone, and vented crawl space temperature is assumed to equal outdoor air temperature.

### **Interior Solar Distribution:**

Interior solar distribution is calculated as shown in Appendix F. This represents a more detailed treatment appropriate to passive-solar design.

#### **Recommended Input Procedure:**

To develop the input deck for Case P100A, begin with Case L120A and proceed as follows.

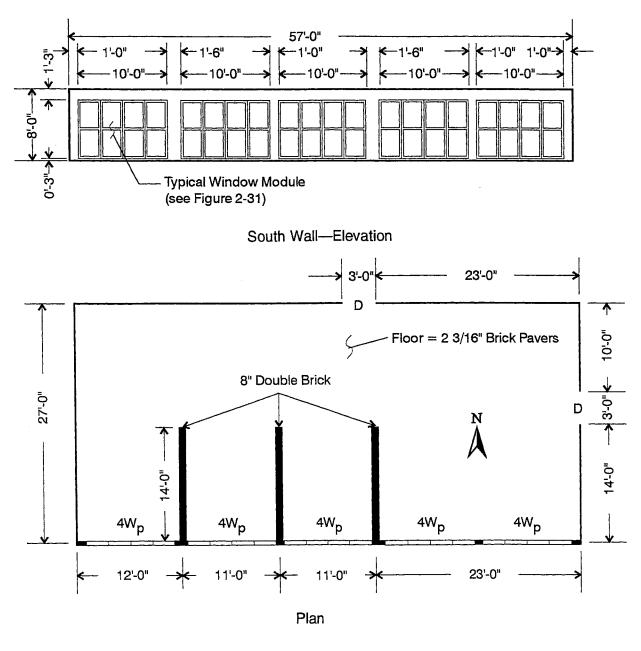

- 1. Remove all window assemblies from the north, east, and west walls and replace them with the Case L120A solid exterior wall material described in Figure 2-9 and Table 2-18 (Case L120A). Resulting component surface areas and solar fractions are shown in Table 2-50.
- Move the door from the south wall to the east wall as shown in Figure 2-28. Material properties of doors are unchanged. Resulting component surface areas and solar fractions are shown in Table 2-50.
- 3. Construct the south wall as shown in Figure 2-28 and Table 2-50. Note that all windows are located on the south wall and that the gross window area (including frames) is 325 ft<sup>2</sup>. While the window remains as clear double-pane with wood frame, the window unit size was modified so that more glazing could be applied to the south wall. The resulting changes in overall (glass plus frame) window properties are described in Figure 2-31 and Table 2-49, and in greater detail in Tables 2-53 through 2-55. Because of the large amount of window area, the only place for batt insulation (see insulated wall section of Figure 2-9 and Table 2-18) is above the window headers, the remaining

portion of the south wall uses only the framed wall section from Figure 2-9 and Table 2-18. Resulting component surface areas and solar fractions are shown in Table 2-50.

- 4. Replace the L120A floor with the floor above vented crawl space described in Figure 2-29 and Table 2-51. For the purpose of this test the floor structure is assumed to be sufficient to support the brick pavers without modification. Resulting component surface areas and solar fractions are shown in Table 2-50.
- 5. Replace the three 14' low-mass interior with the double-brick walls as shown in Figure 2-28. The double-brick interior wall materials are described in Figure 2-30 and Table 2-52. All other lightweight interior walls remain as located in Figure 2-2 (Case L100A). Resulting component surface areas and solar fractions are shown in Table 2-50.

### **Output Requirements:**

Recall from Table 1-3 that for the P-series cases, annual or seasonal cooling loads (as well as heating loads) must be generated using the Colorado Springs, Colorado, weather data. The cooling climate is changed for these cases because the passive solar design described in Cases P100A and P105A, while appropriate for Colorado Springs, Colorado, is inappropriate for Las Vegas, Nevada.

#W:

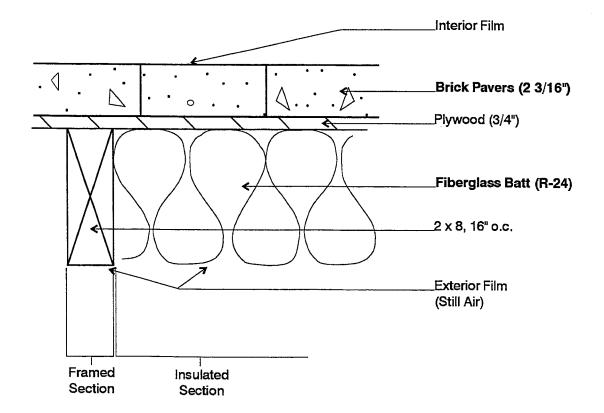

W = window (2'6" wide x 6'6" high), see Figure 2-31 # = number of windows along given length of exterior wall D = Solid-core wood door (3' wide x 6'8" high)

CD-RH06-A0327326

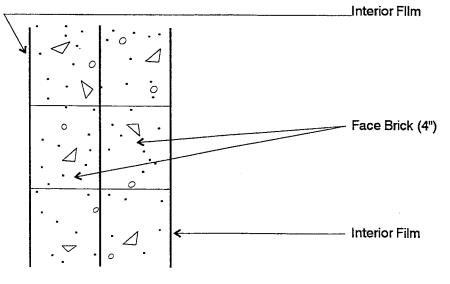

Note: 8" brick interior walls replace low-mass interior walls of Figure 2-2; all other interior walls of Figure 2-2 remain as is.

Note: Changes to Case L120A are highlighted with bold font.

# 2.4.2.1 Case P100A: Supplementary Tables

The following data were used for generating reference results. The previous figures and tables summarized, and are based on, the data presented in this section. We expect that many HERS tools will not be able to directly input much of the data in this section (e.g., material densities, specific heats, detailed window optical properties, interior solar fractions, surface coefficients, etc.). However, if your models are capable of receiving this level of detail, then you must use these tables where possible.

.

Interior walls within the conditioned zone have been included for the purpose of modeling the effect of their mass. They are not inteneded to divide the conditioned zone into separately controlled zones.         Note 7: Total area of just those surfaces to whic                                                                                                                |                                                                                                                                |                                                                                    | TRIBUTIC        | NSUMMARY              |                   | 0.0001              |           |  |  |
| Solar to Air (or low-mass furnishings)       0.1750         Solar Lost (back out through windows)       0.0240       (Note 8)         Note 1: Changes to Case L120A are highlighted with bold font.       0.0240       (Note 8)         Note 2: Calculation of Inside Solar Fractions for Case P100A is described in Appendix F.       0.0240       (Note 8)         Note 3: Because of the large amount of glazing on the south wall (see Figure 2-28), the only place for batt insulation is above the window headers; remaining wall area contains only the framed section of Figure 2-9 (Case L120A).       Note 4: Insulated and framed exterior wall sections are defined in Figure 2-9 (Case L120A). ASHRAE framed area fraction of 0.22 is assumed for 2x6 24" O.C. construction.       Note 5: Insulated and framed floor and ceiling sections are defined in Figures 2-30 and 2-10 (Case L120A) respectively.         ASHRAE roof/ceiling framing area fraction of 0.1 applied to both ceiling and floor.       Note 6: Width is the length of interior walls from Figure 2-2 (Case L100A) and Figure 2-28.         Framed wall area is assumed to be 10% of gross wall area for 2x4 16" O.C. framing. Only one side of the wall is considered for listed area. This area is multiplied by 2 for determining solar fractions. Solar fractions shown are for just one side of the wall. Interior walls within the conditioned zone have been included for the purpose of modeling the effect of their mass. They are not intended to divide the conditioned zone into separately controlled zones.         Note 7: Total area of just those surfaces to which an inside solar fraction is applied.         Note 8: Calculated using the algorithm described in Appendix E. </td <td></td> <td></td> <td></td> <td></td> <td>62327</td> <td>0 8010</td> <td></td> |                                                                                                                                |                                                                                    |                 |                       | 62327             | 0 8010              |           |  |  |

This area is multiplied by 2 for determining solar fractions. Solar fractions shown are for just one side of the wall. Interior walls within the conditioned zone have been included for the purpose of modeling the effect of their mass. They are not inteneded to divide the conditioned zone into separately controlled zones.<br>Note 7: Total area of just those surfaces to which an inside solar fraction is applied.<br>Note 8: Calculated using the algorithm described in Appendix E.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                |                                                                                    |                 | •                     |                   |                     |           |  |  |

# Table 2-55. Optical Properties as a Function of Incidence Angle for Clear Double-Pane Glazing—Case P100A

Hemis = Hemispherically integrated property. Transmittance, reflectance, and SHGC are overall properties for the entire glazing system (excluding the frame).

Note 2: Output is from WINDOW 4.1. SHGC accounts for surface coefficients and is based on windspeed of 10.7 mph.

hspec4.wk3,b:a169..g193

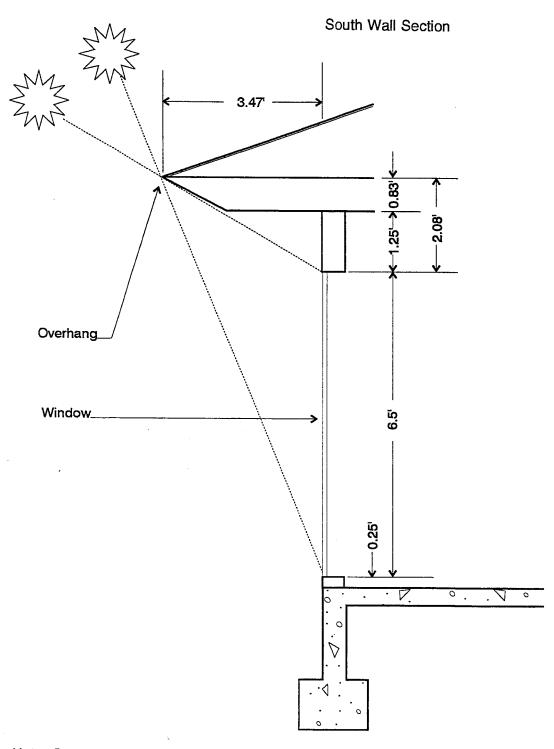

09-Aug-95

#### 2.4.3 Case P105A: Passive Solar with Overhang

Case P105A is **exactly as Case P100A except** that a south wall opaque overhang has been included that extends outward horizontally 3.47 ft. with vertical offset of 2.08 ft. from the top of the window (0.83 ft. from the top of the wall) as shown in Figure 2-32. The overhang traverses the entire length of the south wall. This overhang is representative of appropriate passive solar design for Denver. Overhang width and offset are based on full shading for a summer noon solar altitude angle of 68°, and no shading for a winter noon solar altitude angle of 31°. Window locations remain as shown in Figure 2-28.

Depending on the input capabilities of your software it may not be possible to model the exact geometries of the windows and overhang as shown in Figures 2-28 and 2-32. If this is the case, a simplified model of the south wall may be used such as the conceptual description shown in Figure 2-33. Proper dimensions for this example would be obtained using Figure 2-28, Figure 2-31, and Table 2-50. While the overhang is not shown in Figure 2-33, it must be included as shown in Figure 2-32.

Recall from Section 1, this test requires that you use the most detailed level of modeling your tool will allow.

Note: Overhang traverses entire length of south wall.

CD-RH06-A0327330

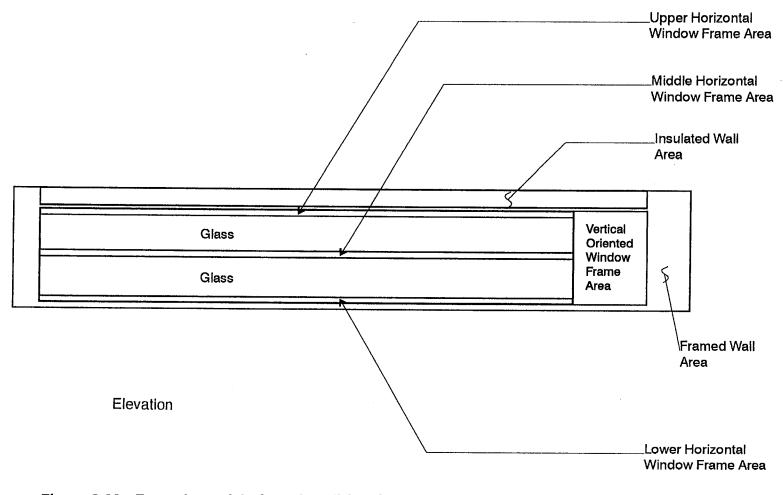

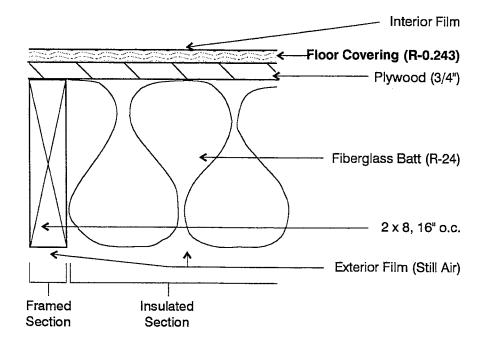

Figure 2-33. Example model of south wall for simulating south overhang effect in CD-RH06-A0327328 Case P105A

#### 2.4.4 Case P110A: Low-Mass Version of Case P100A

Case P110A is **exactly as Case P100A except** for the following changes. The brick pavers have been removed from the floor and replaced with an equivalent resistance massless floor covering. Also, the three massive interior walls have been replaced with low-mass interior walls such that all interior walls are now configured as in Case L100A (Tier 1 base case).

The following figures and tables highlight these changes:

- Figure 2-7. Interior Wall Section Case L100A
- Figure 2-34. Floor Above Vented Crawl Space, Section Case P110A
- Table 2-10. Material Descriptions, Interior Wall Case L100A
- Table 2-56. Building Thermal Summary Case P110A
- Table 2-57. Component Surface Areas and Solar Fractions Case P110A
- Table 2-58. Material Descriptions, Floor Over Vented Crawl Space Case P110A.

Note: Changes to Case P100A are highlighted with bold font.

# 2.4.5 Case P140A: Zero Window Area Version of Case P100A

Case P140A is **exactly as Case P100A except** the glazing is removed from the south wall such that the entire southwall is now opaque with material properties per Figure 2-9 (Case L120A) and Table 2-18 (Case L120A).

The following tables summarize the changes:

- Table 2-59. Building Thermal Summary Case P140A
- Table 2-60. Component Surface Areas Case P140A.

## Table 2-59. Building Thermal Summary-Case P140A

Note 4: Excludes area of doors. ASHRAE framed area fraction of 0.22 used for 2x6 24" O.C. construction.

Note 5: ASHRAE roof/ceiling framing area fraction of 0.1 used for both ceiling and floor.

#### 2.4.6 Case P150A: Even Window Distribution Version of Case P100A

This case is exactly as Case P100A except that all windows are evenly distributed among the walls. Interior walls are as in Case P100A. These changes are summarized in the following:

- Figure 2-35. Window Locations Case P150A
- Table 2-61. Building Thermal Summary Case P150A
- Table 2-62. Component Surface Areas and Solar Fractions Case P150A.

For calculating interior solar distribution fractions, we have reverted back to assuming that solar energy transmitted through windows, and not absorbed by light weight furnishings or lost due to cavity albedo, is distributed to all interior surfaces in proportion to their areas. Solar lost (cavity albedo) remains as for Case P100A.

Note: Interior wall locations are same as for Case P100A.

Figure 2-35. Window locations—Case P150A

#### Table 2-62. Component Surface Areas and Solar Fractions—Case P150A

Note 1: Changes to Case P100A are highlighted with bold font.

Note 2: Solar energy transmitted through windows is assumed as distributed to interior opaque surfaces in proportion to their areas. Only the radiation not directly absorbed by lightweight furnishings (assumed to exist only for the purpose of calculating inside solar fraction) or lost back out through windows is distributed to interior opaque surfaces.

Note 3: Insulated and framed exterior wall sections are defined in Figure 2-9 (Case L120A). ASHRAE framed area fraction of of 0.22 is assumed for 2x6 24" O.C. construction.

Note 4: Insulated and framed floor and ceiling sections are defined in Figures 2-29 (Case P100A) and 2-10 (Case L120A) respectively. ASHRAE roof/ceiling framing area fraction of 0.1 applied to both ceiling and floor.

Note 5: Width is the length of interior walls from Figure 2-2 (Case L100A) and Figure 2-28 (Case P100A).

Framed wall area is assumed to be 10% of gross wall area for 2x4 16" O.C. framing. Only one side of the wall is considered for listed area. This area is multiplied by 2 for determining solar fractions. Solar fractions shown are for just one side of the wall. Interior walls within the conditioned zone have been included for the purpose of modeling the effect of their mass. They are not intended to divide the conditioned zone into separately controlled zones.

# Typical Meteorological Year (TMY) Weather Data Format Description

For convenience we have reprinted the following discussion from the documentation for DOE2.1A *Reference Manual*, (p. VIII-31), and tables (Table 1-23) from "Typical Meteorological Year" (National Climatic Center 1981). The reprint of tables from "Typical Meteorological Year" also includes some additional notes from our experience with TMY data. If this summary is insufficient for your weather processing needs, the complete documentation on TMY weather data can be obtained from the National Climatic Center (NCC) in Asheville, North Carolina. Their address is Federal Building, Asheville, NC 28801-2733, telephone 704-271-4800.

Solar radiation and surface meteorological data recorded on an hourly<sup>1</sup> basis are maintained at the NCC. These data cover recording periods from January 1953 through December 1975 for 26 data rehabilitation stations, although the recording periods for some stations may differ. The data are available in blocked (compressed) form on magnetic tape (SOLMET) for the entire recording period for the station of interest.

Contractors desiring to use a data base for simulation or system studies for a particular geographic area require a data base that is more tractable than these, and also one that is representative of the area. Sandia National Laboratory has used statistical techniques to develop a method for producing a typical meteorological year (TMY) for each of the 26 rehabilitation stations. This section describes the use of these magnetic tapes.

The TMY tapes comprise specific calendar months selected from the entire recorded span for a given station as the most representative, or typical, for that station and month. For example, a single January is chosen from the 23 Januarys for which data are recorded from 1953 through 1975 on the basis of its being most nearly like the composite of all 23 Januarys. Thus, for a given station, January of 1967 might be selected as the typical meteorological month (TMM) after a statistical comparison with all of the other 22 Januarys. This process is pursued for each of the other calendar months, and the twelve months chosen then constitute the TMY.

Although the data have been rehabilitated by NCC, some recording gaps do occur in the SOLMET tapes. Moreover, there are data gaps because of the change from one-hour to three-hour meteorological data recording in 1965. Consequently, as TMY tapes were being constituted from the SOLMET data, the variables data for barometric pressure, temperature, and wind velocity and direction were scanned on a month-by-month basis, and missing data were replaced by linear interpolation. Missing data in the leading and trailing positions of each monthly segment are replaced with the earliest/latest legitimate observation.

Also, since the TMMs were selected from different calendar years, discontinuities occurred at the month interfaces for the above continuous variables. Hence, after the monthly segments were rearranged in calendar order, the discontinuities at the month interfaces were ameliorated by cubic spline smoothing covering the six-hourly points on either side of the interface.

<sup>&</sup>lt;sup>1</sup>Hourly readings for meteorological data are available through 1964; subsequent readings are on a three-hour basis.

\*Tape positions are the precise column locations of data. Tape Field Numbers are ranges representing topical groups of tape positions.

<sup>b</sup>DRYCOLD.TMY is not defined as a "rehabilitated" station.

"Note for Fields 102-110: Data code indicators are:

0=Observed data, 1=Estimated from model using sunshine and cloud data, 2=Estimated from model using cloud data, 3=Estimated from model using sunshine data, 4=Estimated from model using sky condition data, 5=Estimated from linear interpolation, 6=Reserved for future use, 7=Estimated from other model (see individual station notes in SOLMET: Volume 1), 8=Estimated without use of a model, 9=Missing data follows (See model description in SOLMET: Volume 2).

d"9s" may represent zeros or missing data or the quantity nine depending on the positions in which they occur. Except for tape positions 001-023 in fields 002-101, elements with a tape configuration of 9's indicate missing or unknown data.

### **Appendix B:**

#### Infiltration and Fan Adjustments for Altitude

Infiltration heat loss or gain is a function of ambient air density, which is dependent on altitude. The decline in air density with altitude may be expressed according to the following exponential curve fit:

$$\rho_{\rm air,u} = \rho_{\rm air,0} * e^{a^{*elev}}$$

where:

 $\rho_{air,u}$  = Air density at specified elevation  $\rho_{air,0}$  = Air density at sea level = 0.07500 lb/ft<sup>3</sup> e = Inverse Ln a = -3.71781196 \* 10<sup>-5</sup>/ft elev = elevation in feet (ft)

This results in:

Air density at 6145 ft =  $0.05968 \text{ lb/ft}^3$ Air density at 2178 ft =  $0.06917 \text{ lb/ft}^3$ .

If your software does not allow variation of air density, the specified infiltration rate is adjusted as:

Corrected Infiltration Rate for 6145 ft altitude = (Specified Rate) x (0.05968/0.07500)Corrected Infiltration Rate for 2178 ft altitude = (Specified Rate) x (0.06917/0.07500)

Table B-1 summarizes the appropriate variation of infiltration rates from HERS BESTEST specified values for the base case (Case L100A) and cases where infiltration rates or building air volume have varied. These corrections are only to be used with software that does not automatically account for local variations in air density.

Table B-1 also includes values of equivalent thermal conductance due to infiltration (UAinf) corresponding to altitude-corrected air densities where:

$$UAinf = \rho_{air,u} * V * c_{p}$$

and where:

V = volumetric air flow rate (ft<sup>3</sup>/h) converted from values in Table B-1  $c_p$  = specific heat of air = 0.240 Btu/(lbm F).

## Table B-1. Infiltration Rate Adjustments for Altitude

# Appendix C

#### Exterior Combined Radiative and Convective Surface Coefficients

If your program does not automatically calculate these values internally, then use the information given below.

Exterior Surface Coefficients: ASHRAE and BLAST calculate the exterior combined radiative and convective surface coefficient as a second order polynomial in wind speed of the form:

$$h = a_1 + a_2 V + a_3 V^2$$

where the "a" coefficients are dependent on the surface texture. These coefficients are tabulated below for windspeed in knots (Walton 1983, p. 71).

| Material            | a <sub>1</sub> | a <sub>2</sub> | a <sub>3</sub> |
|---------------------|----------------|----------------|----------------|
| Stucco              | 2.04           | 0.535          | 0.0            |
| Brick/Rough Plaster | 2.20           | 0.369          | 0.001329       |
| Concrete            | 1.90           | 0.380          | 0.0            |
| Clear Pine          | 1.45           | 0.363          | -0.002658      |
| Smooth Plaster      | 1.80           | 0.281          | 0.0            |
| Glass               | 1.45           | 0.302          | -0.001661      |

Assuming a surface texture of brick or rough plaster, and a mean annual wind speed of 10.7 mph (9.304 knots), then:

# Exterior Combined Surface Coefficient for All Walls and Roofs = 5.748 Btu/h-ft<sup>2</sup>-F

For programs requiring a method for disaggregation of infrared and convective surface coefficients from combined surface coefficients, see Appendix D.

# **Appendix D**

#### Infrared Portion of Surface Coefficients

Tables D-1 and D-2 show convective and infrared radiative portions of film coefficients for the various orientations and surfaces of HERS BESTEST. The infrared portion of film coefficients is based on the linearized gray-body radiation equation (J. Duffie and W. Beckman):

$$h_i = 4\varepsilon\sigma T^3$$

Where:

| ε              | = | Infrared emissivity                                                                          |
|----------------|---|----------------------------------------------------------------------------------------------|
| σ              | = | 0.1718 * 10 <sup>-8</sup> Btu/(hft <sup>2</sup> R <sup>4</sup> ) (Stefan/Boltzmann constant) |
| Т              | = | Average temperature of surrounding surfaces                                                  |
|                |   | (assumed 50°F [510°R] for outside, 68°F [528°R] for inside)                                  |
| R              | = | Rankine (absolute zero = $0^{\circ}R = -459.67^{\circ}F$ )                                   |
| h <sub>i</sub> | = | Infrared radiation portion of surface coefficient.                                           |
|                |   |                                                                                              |

Other nomenclature used for Tables D-1 and D-2 are:

 $h_s = Total$  combined interior surface coefficient

 $h_o = Total$  combined outside surface coefficient.

In Table D-1 combined exterior surface coefficients are evaluated using the algorithm of Appendix C; combined interior surface coefficients are based on ASHRAE data. In Table D-2 combined interior and exterior surface coefficients are based on the output of WINDOW 4.1.

| Inside Horizontal Surface (T= 68°F) (528°R) (ε=0.9)                                    |       |  |  |  |  |

#### Detailed Calculation of Solar Lost Due to Cavity Albedo

This section describes the method used to determine "solar lost" for Tables 2-5, 2-25, and 2-50. The assumptions here are useful for the calculation of solar lost, but would result in different inside solar fractions for various opaque surfaces than the area weighting shown in tables that contain solar fractions. A spreadsheet tabulation of the calculation process described below is provided in Table E-1. Note that interior walls have been excluded to simplify the calculation of solar lost.

For single-pane glazing, the solar lost approximations are calculated from:

 $SF_n = B1_n + B2_n + B3_n + BR_n$ 

where:

 $n \equiv a$  particular surface

 $SF \equiv total solar fraction$ 

B1 describes the first "bounce" of incident shortwave radiation assuming all of it initially hits the floor.

 $B1_{floor} = \alpha$ 

 $B1_{all other} = 0$ 

 $\alpha \equiv$  interior shortwave absorptance of opaque surfaces (all interior surfaces have the same absorptance except for the window which is denoted as  $\alpha_w$ ).

B2 describes the second "bounce" such that shortwave radiation diffusely reflected by the floor is distributed over other surfaces in proportion to their view-factor-absorptance product.

$$B2_{floor-floor} = 0$$

$$B2_{floor-other opaque} = (1-\alpha)(FF_i)(\alpha)$$

$$B2_{floor-window lost} = (1-\alpha)(FF_i)(1-(\rho_w+(N)(\alpha_w)))$$

$$B2_{floor-window absorbed} = (1-\alpha)(FF_i)(N)(\alpha_w)$$

where:

FF are view factors from Figures E-1 and E-2 (Kreith & Bohn)

 $i \equiv$  particular surface which the floor "sees." View factors for windows are based on the view factor for the wall where the windows are located, multiplied by the fraction of the area of that wall occupied by the windows. View factors for walls with windows are adjusted similarly. To simplify calculation of solar lost, all windows are assumed located on the south wall (as in Case L150A).

## Table E-1. Calculation of Solar Lost (Cavity Albedo)

 $\rho_w \equiv$  reflectance for specific glazing, hemispherically integrated (diffuse radiation)

 $\alpha_{w} \equiv$  absorptance for specific glazing, hemispherically integrated (diffuse radiation)

 $N \equiv$  inward conducted fraction of cavity reflected absorbed solar radiation. For single-pane glass N is the ratio of the exterior film coefficient R-value to the total air-air center of glass R-value (for single-pane windows this is the sum of the interior and exterior film coefficient R-values).

B3 describes the third bounce such that the remaining non absorbed shortwave radiation is distributed over each surface in proportion to its area-absorptance product. In this part and the final part of the calculation below, solar radiative exchange between opaque surfaces can be aggregated as shown in Table E-1.

 $B3_{opaque-opaque} = (1 - \alpha - \Sigma(B2_n))(A_n/A_{total})(\alpha)$ 

 $B3_{\text{opaque-window lost}} = (1-\alpha - \Sigma(B2_n))(A_n/A_{\text{total}})(1-(\rho_w + (N)(\alpha_w)))$ 

 $B3_{opaque-window absorbed} = (1 - \alpha - \Sigma(B2_{n}))(A_{n}/A_{total})(N)(\alpha_{w})$ 

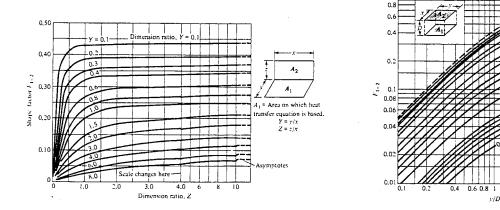

where:

 $A_n \equiv area of surface n$ 

 $A_{total} \equiv total$  area of all surfaces

BR describes the distribution of all remaining bounces based on distribution fractions from calculations for  $B3_n$  above.

 $BR_n = (1 - \alpha - \Sigma(B2_n) - \Sigma(B3_n))(B3_n/\Sigma(B3_n))$ 

Figure E-2: Shape factor for directly opposed rectangles.

Source: F. Kreith and M. Bohn, Principles of Heat Transfer, Fourth Edition, Harper & Row, New York, NY, 1986, pp. 461, 462.

For double-pane glazing, the solar lost calculation is the same as for single-pane glazing except for the following differences.

 $B2_{\text{floor-window lost}} = (1-\alpha)(FF_i)(1-(\rho_w+N_i\alpha_{i+N_o\alpha_o}))$   $B2_{\text{floor-window absorbed}} = (1-\alpha)(FF_i)(N_i\alpha_i+N_o\alpha_o)$   $B3_{\text{opaque-window lost}} = (1-\alpha-\Sigma(B2_n))(A_n/A_{\text{total}})(1-(\rho_w+N_i\alpha_i+N_o\alpha_o))$   $B3_{\text{opaque-window absorbed}} = (1-\alpha-\Sigma(B2_n))(A_n/A_{\text{total}})(N_i\alpha_i+N_o\alpha_o)$ 

where:

 $\alpha_i \equiv$  inner pane absorptance for specific glazing, hemispherically integrated (diffuse radiation),

 $N_i \equiv$  inward conducted fraction of cavity reflected absorbed solar radiation for inner pane,

 $\alpha_{o} \equiv$  outer pane absorptance for specific glazing, hemispherically integrated (diffuse radiation),

 $N_o \equiv$  inward conducted fraction of cavity reflected absorbed solar radiation for outer pane.

For double-pane glazing,  $N_i$  and  $N_o$  are the ratio of total R-value of the components on the exterior side of the pane in question to the total air-air center-of-glass R-value of the double-pane unit (including air gap between panes and interior and exterior film coefficients).

# Appendix F

# Distribution of Solar Radiation in the Passive Solar Base Case (P100A)

Solar energy transmitted through windows is distributed in the following manner.

Solar lost due to cavity albedo and solar directly absorbed by air (lightweight furnishings) are attributed to total (direct plus diffuse) radiation in proportion to the fractions of direct and diffuse solar radiation transmitted through windows. Direct and diffuse transmitted fractions for south windows were calculated using SERIRES/SUNCODE (Kennedy et al.) and Denver TMY weather data.

The portion of direct-beam radiation not absorbed by lightweight furnishings or lost from cavity albedo is assumed to initially hit only the massive surfaces (floor and interior brick walls), and is distributed among these surfaces according to their areas. Direct-beam radiation that is reflected by the massive surfaces is assumed to be diffusely reflected and is distributed among all interior surfaces in proportion to their areas.

Transmitted diffuse radiation not absorbed by lightweight furnishings or lost from cavity albedo is distributed among all interior surfaces in proportion to their areas.

Resulting interior solar distribution fractions are shown in Table F-1.

## Detailed Ground Coupling Analysis Case Descriptions for Cases L302B, L304B, L322B, and L324B

The results for two types of ground coupling models are included in the Volume 2, Section 3 results to effectively widen the range of reference results (i.e., ease the passing criteria) for cases that include ground coupling analysis. This was done in case a HERS provider is using a more sophisticated algorithm than the application of ASHRAE steady-state heat transfer coefficients.

For the more detailed simulations of ground coupling in Cases L302B, L304B, L322B, and L324B, the following case-by-case discussion describes material properties for modeling thermal mass of portions of the building envelope in thermal contact with the ground. While this more detailed method is not well verified, it does serve to incorporate the effects of mass and solar radiation incident on soil directly into the reference simulations, thus reducing loads versus the various steady-state ASHRAE methods.

## Soil modeling and solar effects

In the tables that follow, soil thicknesses may be regarded as curved path lengths for one-dimensional heat conduction between a concrete surface/adjacent soil boundary and a soil/ambient air boundary. Thus, soil is modeled as a large amount of mass in contact with ambient air. Soil conductivity is based on the 9.6 Btu-in/(h-ft<sup>2</sup>-F) cited in *ASHRAE 1993 Fundamentals*.

Solar effects on soil are also important (especially regarding shorter conduction path lengths encountered with a slab on grade or the upper portion of a below-grade wall). Soil adjacent to a house is assumed as shaded by the house on average roughly half the time the sun is present. Exterior solar absorptance of the soil surface is assumed as 0.6. Exterior infrared emittance of soil is assumed as 0.9. The adjacent-soil-to-house-wall view factors are small so that infrared radiative exchange is assumed to occur only between soil and sky.

## Case L302B Uninsulated Slab on Grade

This case is exactly as Case L302A except that Table G-1 is used in place of Table 2-38.

The soil thickness in Table G-1 is based on the ASHRAE perimeter method (ASHRAE 1993 Fundamentals, Chp. 25) for a metal stud wall (normalized for 1539 ft<sup>2</sup> floor area) less listed R-values of surface coefficients and the concrete slab and assuming the listed soil conductivity.

## Case L304B Slab on Grade with Perimeter Insulation

This case is exactly as Case L304A except that Table G-2 replaces Table 2-40.

The perimeter insulation R-value of Table G-2 is based on the ASHRAE perimeter method for a metal stud wall with R-5.4 perimeter insulation from edge to footer normalized for 1539 ft<sup>2</sup> floor area, less the R-values of the listed surface coefficients, concrete slab, and soil layers.

#### Case L322B Uninsulated Conditioned Basement

This case is exactly as Case L322A except that Table G-3 replaces Table 2-43 and just the below-grade concrete wall description of Table 2-42.

For below-grade walls, the associated soil thicknesses are taken directly from ASHRAE 1993 Fundamentals (Table 14, p. 25.11). Note that the listed below-grade soils are for parallel conduction paths, each representing 1' of wall height except for the deepest increment, which represents 7" of wall height.

For the below grade slab floor, soil thickness is based on ASHRAE 1993 Fundamentals (Table 15, p. 25.11) less R-values of surface coefficients and concrete slab, and multiplied by the listed soil conductivity.

| Note 1: Listed thickness is the ASHRAE (1993 Handbook of Fundamentals, Table 14, p.25.11) conduction path length. Also each layer is |                |              |             |        |                    |          |
| only 1' high except for the deepest layer which is only 7" high.                                                                     |                |              |             |        |                    |          |
| Note 2: Although ASHRAE's soil conductivity was applied, overall U-value calculated by summing parallel heat flow through each       |                |              |             |        |                    |          |
| increment of soil depth comes out 7% higher than the value of Table 2-42 which was obtained using just the ASHRAE steady-state       |                |              |             |        |                    |          |
| heat transfer coefficients.                                                                                                          |                |              |             |        |                    |          |
|                                                                                                                                      |                |              |             |        |                    |          |

Note 3: Soil thickness based on ASHRAE 1993 Fundamentals, Table 15, p.25.11 (Heat Loss through Basement Floors) less R-values of surface coefficients and concrete slab assuming the listed soil conductivity. The resulting soil thickness can be thought of as an average curved heat flow path through the soil to ambient air. As a simplification, the layer of sand typically below the concrete slab is assumed to have the same material properties as soil.

Note 4: This is the overall heat loss interpolated from ASHRAE 1993 Fundamentals, Table 15, p. 25.11.

# Case L324B Interior Insulated Conditioned Basement

This case is **exactly as Case L324A except** that Table G-4 replaces just the below-grade concrete wall description of Table 2-48.

# **Appendix H**

### Procedure for Developing Example Pass/Fail Criteria

The certifying agency using HERS BESTEST may adopt this procedure for developing example pass/fail criteria or develop their own procedure. Neither DOE, NREL, or the authors of this report can be held responsible for any misfortunes that occur due to the use of this procedure in your certification program.

#### Passing a Test

A HERS tool may be thought of as having passed successfully through the test series when its results compare favorably with reference program outputs on a case-by-case and a sensitivity basis (difference or delta ( $\Delta$ ) between certain cases).

Example pass/fail ranges based on fictitious reference results used for this appendix were developed according to the procedure described in the following section and are presented in Table H-1. A HERS tool would pass a case if its result for that case falls within the passing range represented by "Example Range Max" and "Example Range Min" shown in Table H-1. A HERS tool would pass HERS BESTEST if its results are passing for all the cases (including the differences in results for certain cases).

#### Procedure for Developing Example Passing Ranges

Example values relevant to the discussion below are included in Table H-1. The example passing ranges for each case were developed as follows:

- 1. Determine the maximum reference result, the minimum reference result, the sample mean (average) of the reference results, and the sample standard deviation (n-1 method) of the reference results. These quantities are shown in Table H-1 as "Ref Max," "Ref Min," "Ref Mean," and "Ref Stds," respectively.
- 2. Calculate the 90% confidence interval for the population mean assuming a Student's "t" distribution based on the reference results (Spiegel). The extremes (confidence limits) of the 90% confidence interval for the population mean are determined from:

$$L_{a} = X + (t_{c})(s)/(N-1)^{1/2}$$
(H-1)

$$L_{b} = X - (t_{c})(s)/(N-1)^{1/2}$$
(H-2)

where:

- $L_a = maximum$  confidence limit for the confidence interval
- $L_b$  = minimum confidence limit for the confidence interval
- X =sample mean
- $t_c = confidence coefficient, see below$
- s = sample standard deviation
- N = number of samples.

The confidence coefficient  $(t_{e})$  is determined from the number of samples and the desired confidence interval. Tables of these coefficients and an explanation of how to use the tables should be available in

|                     |                     |          | Delta     |
|---------------------|---------------------|----------|-----------|
|                     |                     |          | Case #1 - |
|                     | Case #1             | Case #2  | Case #2   |
| Description         | (MBtu/y)            | (MBtu/y) | (MBtu/y)  |
|                     |                     |          |           |
| Reference Result #1 | 73.00               | 46.00    | 27.00     |
| Reference Result #2 | 70.00               | 45.00    | 25.00     |
| Reference Result #3 | 82.00               | 50.00    | 32.00     |
|                     |                     |          |           |
| Ref Max             | 82.00               | 50.00    | 32.00     |

# Table H-1. Example Pass/Fail Criteria Using Fictitious Results

any introductory statistics text book. For this example with three samples and a desired confidence interval of 90%:

$$t_c = 2.92$$
 (H-3)

Equations H-1 and H-2 then reduce to:

$$L_a = X + 2.92(s)/2^{1/2}$$
(H-4)

 $L_{\rm b} = X - 2.92(s)/2^{1/2} \tag{H-5}$ 

The resulting confidence limits are shown in Table H-1 as "Ref 90% Conf Max" and "Ref 90% Conf Min."

3. Calculate:

(Ref Max) + 4 MBtu

and

(Ref Min) - 4 MBtu.

The results of these calculations are shown in Table H-1 as "Ref Max + 4 MBtu" and "Ref Min - 4 MBtu."

4. The example passing range ("Range Max", "Range Min") is then determined by taking the maximum of "Ref 90% Conf Max" and "Ref Max + 4 MBtu" as "Range Max" and the minimum of "Ref 90% Conf Min" and "Ref Min - 4 MBtu" as "Range Min". Therefore, using Table H-1, a HERS tool passes a case if its test result falls within the range for that case. Notice in Table H-1 fictitious sets of results are given such that the confidence interval range setting and the "Ref Max + 4 MBtu" and "Ref Min - 4 MBtu" range setting set the range extremes for Case #1 and Case #2 respectively (it is also possible to have results where one range setting method sets one extreme and the other range setting method sets the other extreme as shown in the "Delta Case #1 - Case #2" result of Table H-1).

# Procedure for Developing Example Passing Ranges for HERS Programs That Designate Heating and Cooling Seasons

The same procedure described in the previous section can be applied to developing passing ranges for HERS programs that designate heating and cooling seasons. In this case, the annual reference results must be replaced by seasonal reference results developed from the monthly output corresponding to the designated heating and cooling seasons. The remainder of the procedure then applies.

## Adjusting Passing Ranges

A certifying agency may prefer to adjust the example range setting criteria to suit its particular needs. To assist with this, some background and other thoughts about range setting are included in the following section.

## Background

In choosing our algorithms for determining passing ranges, we wanted to have some buffer zone around the reference results because:

- The reference results do not represent truth, but rather the state of the art in thermal analysis of buildings.
- A result just outside the range of reference results should pass.
- Where reference results ranges are very narrow, we wanted to have some allowable disagreement based on economic criteria that would still pass.

Determining passing ranges using the widest range created by a 90% confidence interval and by extending reference result extremes by 4 MBtu at each extreme serves this purpose as described below.

Use of confidence intervals provides some theoretical basis for developing passing ranges (Spiegel). The 90% confidence level was chosen because a 95% confidence interval for the population mean widens the range of passing beyond our level of comfort based on allowable fuel cost uncertainty. Similarly, we felt the passing range produced with an 80% confidence interval would be too narrow. To adjust confidence intervals, we would choose a confidence coefficient that corresponds to a confidence interval within the range of 80% to 95%.

Where reference results are very close together, the 4 MBtu factor was used because at typical gas prices it represents roughly \$25/y, which we take as a threshold of economic uncertainty concern. Depending on fuel prices, climate, mortgage lending policy, and other circumstances in specific regions, it may also make sense to adjust this factor.

#### Case Discrimination

Some cases may deserve to have more strict passing criteria than would be generated using the range setting described above. A possible example are cases with higher loads. In these cases where the percentage disagreement between reference results can be roughly consistent with those for lower load cases, the higher loads produce a greater extension of the passing range in terms of estimated fuel cost than is seen for lower load cases.
