37 interactions, viral hepatitis

38 Abstract

39

40 **Background & Aims:** Human genetic variation is thought to guide the outcome of
41 hepatitis C virus (HCV) infection but model systems within which to dissect these host
42 genetic mechanisms are limited. Norway rat hepacivirus (NrHV), closely related to HCV,
43 causes chronic liver infection in rats but causes acute self-limiting hepatitis in typical
44 strains of laboratory mice, which resolves in two weeks. The Collaborative Cross (CC) is
45 a robust mouse genetics resource comprised of a panel of recombinant inbred strains,
46 which model the complexity of the human genome and provide a system within which to
47 understand diseases driven by complex allelic variation. **Approach & Results:** We
48 infected a panel of CC strains with NrHV and identified several that failed to clear virus
49 after 4 weeks. Strains displayed an array of virologic phenotypes ranging from delayed
50 clearance (CC046) to chronicity (CC071, CC080) with viremia for at least 10 months.
51 Body weight loss, hepatocyte infection frequency, viral evolution, T-cell recruitment to the
52 liver, liver inflammation and the capacity to develop liver fibrosis varied among infected
53 CC strains. **Conclusions:** These models recapitulate many aspects of HCV infection in
54 humans and demonstrate that host genetic variation affects a multitude of virus and host
55 phenotypes. These models can be used to better understand the molecular mechanisms
56 that drive hepacivirus clearance and chronicity, the virus and host interactions that
57 promote chronic disease manifestations like liver fibrosis, therapeutic and vaccine
58 performance, and how these factors are affected by host genetic variation.

59

60 Introduction

61 Hepatitis C virus (HCV) causes chronic infection of the liver in a majority of those
62 infected. If untreated, chronic HCV infection can lead to the development of end-stage
63 liver disease including hepatocellular carcinoma (HCC) and cirrhosis and may require
64 liver transplant¹⁻⁴. Curative treatments, although costly, are available yet undiagnosed
65 cases, access to treatment, reinfection, drug resistance development and a lack of an
66 effective vaccine have complicated efforts for global elimination of HCV as a public
67 health threat^{2,5}. In addition, it is not yet clear if cure will prevent the subsequent
68 development of HCC^{1,2,4}. While human genetic variation (e.g. *IL28B* locus) is thought to
69 guide both the kinetics of spontaneous clearance and chronic infection, animal model
70 systems within which to dissect these host genetic mechanisms are not available⁶.
71 Thus, our understanding of how host genetic variation affects HCV pathogenesis, the

72 development of chronicity, immunity and vaccine efficacy is hampered by the lack of
73 robust immune competent small animal models.

74 HCV-related hepaciviruses have been discovered in multiple animal species
75 including horses, non-human primates, wild rodents and bats⁷. In 2014, Norway rat
76 hepacivirus (NrHV) was discovered in rats in New York City to cause chronic liver
77 infection⁸. Many basic aspects of NrHV biology are shared with HCV, including
78 hepatotropism, genome organization, dependence on a liver-specific micro RNA (miR-
79 122) for replication and the use of scavenger receptor B-1 for entry⁹⁻¹¹. In common lab
80 strains of mice, NrHV causes subclinical self-limiting hepatotropic infection that is
81 cleared in 14-21 days but chronic infection can be initiated via transient depletion of
82 CD4 T-cells prior to infection⁹. Models of chronic hepacivirus infection in fully immune
83 competent mice without immune manipulation are not yet available.

84 The Collaborative Cross (CC) is a robust mouse genetics resource created by the
85 systematic breeding of eight founder strains encompassing classic inbred, disease model
86 and wild-derived models resulting in the generation of a panel of recombinant inbred (RI)
87 strains, which together model the complexity of the human genome and provide a system
88 within which to understand disease driven by complex allelic variation¹². The CC contains
89 greater than 90% of the common genetic variation in mouse resources through the
90 presence of uniformly distributed SNPs (>40 million) and indels (>4 million) across the
91 various genomes^{13,14}. When applied to virology, the CC has been a powerful tool to both
92 identify better models of human disease, as shown with Ebola virus¹⁵, severe acute
93 respiratory syndrome associated coronavirus (SARS-CoV)¹⁶, West Nile virus^{17,18}, SARS-

94 CoV-2¹⁹, and influenza A virus²⁰, and also to map the genetic determinants responsible
95 for complex phenotypic traits¹³.

96 Here, we describe multiple CC mouse models of chronic hepatitis C virus
97 pathogenesis. We show that host genetic variation affects hepatitis C virus chronicity, the host
98 response to infection, hepatocyte infection frequency, liver inflammation, liver fibrosis and
99 viral evolution thus recapitulating many aspects of HCV disease biology. This system can
100 be used to better understand the host genes and molecular mechanisms that guide
101 hepatitis C virus pathogenesis, liver fibrosis, therapeutic and vaccine performance.

102

103 **Results**

104 **Host genetics is a determinant of acute hepatitis C virus clearance.** Given the profound
105 impact human genetic variation can have on HCV infection, we aimed to determine if
106 host genetic variation would affect hepatitis C virus pathogenesis and infection kinetics in mice
107 (Fig. 1A). We infected ten different CC mouse strains with a mixture of two sub-
108 populations of mouse derived hepatitis C virus inoculum, hepatitis C virus-A and -B along with a putative
109 mouse adapted hepatitis C virus-B⁹ (B_{SLIS}) at a ratio of 1:1:1 (A:B:B_{SLIS}) (Fig. S1). We utilized this
110 mixture to give the best possible foundation for persistency not knowing which genotype
111 would be optimal in the CC. After infection, we monitored viremia for 4 weeks which is
112 1-2 weeks after WT C57BL/6J (WT) mice typically clear. All strains of mice became
113 infected following hepatitis C virus inoculation (Fig. S2), but most CC strains and WT had cleared
114 the infection by week 4. In contrast, CC040, CC046, CC071 and CC080 remained
115 viremic at week 4 (Fig. 1B) and both CC071 (P = 0.02) and CC080 (P = 0.002) had
116 significance elevated levels of viremia. Concurrently, CC071 (P = <0.0001) and CC080

117 (P = 0.001) intrahepatic viral RNA was significantly elevated over WT (Fig. 1C). Gene
118 expression of Mx1, a typical interferon stimulated gene (ISG), was elevated in the livers
119 of CC strains that remained viremic, a sign that sustained virus replication continued to
120 instigate the host (Fig. 1D). All together, these data demonstrate that host genetic
121 variation influences acute hepacivirus clearance.

122

123 **Host genetics is a determinant of hepacivirus chronicity.** We then further
124 characterized a subset of CC strains with sustained NrHV replication at 4 weeks.
125 CC046, CC071 and CC080 are genetically distinct with notably different genomic
126 architectures including at loci likely to be important for the antiviral response such as
127 major histocompatibility complex (MHC), T-cell activation, and type I and III interferons
128 (IFN) (Fig. S3). We infected WT, CC046, CC071 and CC080 mouse strains with NrHV
129 as done above and monitored them for 10 months (Fig. 2A). Interestingly, body weight
130 loss was only observed in CC071 infected mice and only during the first week (Fig. S4
131 and S5). As expected, WT cleared virus within 3 weeks (Fig. 2B). In contrast, CC046
132 had sustained replication during weeks 1-4 but ultimately all mice cleared virus by week
133 7 (Fig. 2B). Notably, the majority of CC071 mice became chronically infected with
134 quantifiable viremia until the termination of the study at week 38-39 (Fig. 2B). CC080
135 mice had a variety of virologic outcomes where some mice cleared virus in middle (4-7
136 weeks) or late (8-22 weeks) times but only a minority became chronically infected (Fig.
137 2B). During the first two weeks of infection, the levels of viremia in CC071 (week 1 P =
138 0.007, week 2 P = 0.001) and CC080 (week 1 P = 0.036, week 2 P = 0.02) were
139 significantly higher than WT and by week 3, viremia in all three CC strains exceeded

140 that in WT mice (CC046 $P = 0.006$, CC071 $P = 0.007$, CC080 $P = 0.04$) (Fig. 2C). While
141 all CC strains had measurable viremia in week 5, only CC071 ($P = 0.01$) remained
142 significantly elevated over WT (Fig. 2C).

143 To assess infectivity in serum, we passively transferred serum from 10-weeks
144 post infection to naïve WT animals and then monitored viremia over time (Fig. S6). As
145 expected, transfer of serum from aviremic mice (WT and CC046) did not transfer
146 infection to recipient animals (Fig. S6B, S6C) but transfer of serum from viremic CC071
147 (Fig. S6D) and CC080 (Fig. S6E) mice resulted in infection in recipient animals. Thus,
148 viral RNA associated with significant viremia is infectious. Interestingly, when examining
149 viremia per animal, chronically infected animals experienced periods of relatively
150 consistent levels of viremia followed by drastic increases or decreases suggesting an
151 interplay among virus and the host response (Fig. S7). Altogether, by varying host
152 genetics, a spectrum of virologic outcomes were observed following NrHV infection
153 where all WT mice clear early (< 3 weeks), most CC046 mice clear between weeks 4-7,
154 the majority of CC071 became chronically infected, and CC080 displayed phenotypes
155 seen in both CC046 and CC071 (Fig. 2D).

156

157 **Host genetics determines infection frequency and viral dynamics in the liver.** To
158 complement our virologic measures in peripheral blood, we next extended our studies to
159 the liver. Labeling viral genomic RNA via *in situ* hybridization (ISH) revealed a variety of
160 phenotypes. First, clearance phenotypes observed in the periphery were similarly
161 observed in WT and CC046 and most CC071 and some CC080 remained viral RNA
162 ISH positive for the duration of the study (Fig. 3A). Second, the amount of viral RNA per

163 cell varied widely especially at 2dpi where the amount of viral RNA per cell was greatest
164 in CC071 (Fig. 3A). Third, the average infection frequency varied greatly among the
165 different strains. On 2dpi, the infection frequency for CC046 was 22%, more than 10-
166 fold greater than other strains (Fig. 3B). By 7dpi, the infection frequency in CC071 mice
167 had increased similar levels, still significantly greater than both WT and CC080 mice. By
168 28dpi, the infection frequency in CC071 mice had increased even further (average
169 frequency = 38.1%) but decreased to levels seen at earlier times by the end of the study
170 (Fig. 3B). In paired tissue samples, we quantitated viral RNA via qRT-PCR. As seen
171 with ISH, CC046 had significantly elevated levels of NrHV RNA at 2dpi ($P = 0.03-0.04$)
172 compared to other CC strains (Fig. 3C). Like the viremia and ISH data, CC071 had
173 elevated levels of intrahepatic viral RNA over WT and CC046 at both 28dpi and 272dpi.
174 Altogether, the intrahepatic virologic data was concordant with that observed in the
175 periphery but also revealed new insights into the impact of host genetic variation on
176 infection frequency and replication dynamics.

177

178 **Immune dysregulation is associated with chronic hepatitis C virus infection.** Given the
179 disparate outcomes we had observed thus far, we next aimed to determine if host
180 genetics differentially affected immune responses. First, we performed completed blood
181 count on longitudinal peripheral blood samples from the studies described above. The
182 numbers of total lymphocytes were largely unaffected over time comparing infected and
183 strain matched mock mice (Fig. S8A and B). In contrast, neutrophils were significantly
184 and consistently elevated in NrHV infected CC071 compared to strain matched mock
185 mice in weeks 1 and 2 (Fig. S8C and D). To better understand intrahepatic responses,

186 we labeled liver tissue sections for CD4 positive cells since CD4 T-cells were previously
187 shown to be important for clearance in WT mice⁹. On 2dpi, clusters of CD4+ cells were
188 observed in the parenchyma and on portal tracts in WT mice, who most rapidly clear
189 virus, whereas the labeling pattern remained unchanged from mock for all infected CC
190 strains (Fig. 4). By 7dpi, periportal CD4+ cells were prominent in WT, CC046 and
191 CC071 mice yet the staining pattern for CC080 remained similar to that in uninfected.
192 By 28dpi, clusters of CD4+ cells in periportal and parenchymal space were readily
193 apparent in all infected CC strains, yet the pattern in WT mice, who had all cleared virus
194 by this time, were like mock. By 39 weeks post infection, WT mice remained
195 unremarkable, but clusters of CD4+ cells around portal tracts remained in all chronically
196 infected CC strains and even in CC046 that had cleared after week 7.

197

198 **Dysregulation of the transcriptome in strains susceptible to prolonged infection.**

199 To determine if early defects in the host response were associated with chronic
200 infection, we analyzed the transcriptional responses (Fig. 5) in the liver of WT and CC
201 mouse strains on 7dpi when significant virologic and immunologic differences were
202 observed. Importantly, via principal component analysis (PCA), we confirmed the global
203 responses among mock and infected groups differed and like samples tended to cluster
204 together (Fig. 5A). The numbers of significantly regulated genes varied with host
205 genetics with CC071 regulating more genes than all other strains (Fig. 5B). Pathway
206 analysis of significantly regulated genes (<1.5 Log fold change over mock, P = 0.05)
207 revealed the differential regulation of canonical pathways associated with innate and
208 adaptive immunity among WT and CC strains (Fig. 5C). In Figure 5D, we show the

209 expression fold change data for select canonical pathways including Pathogen Induced
210 Cytokine Storm Signaling, LXR/IL-1 Mediated Inhibition of RXR Function, Th1 Signaling
211 and LXR/RXR Activation. For all affected pathways shown, the gene expression
212 patterns for CC071 are quite different than those in WT and even those of other CC
213 strains with a noted lack of expression in innate immune (e.g. Tlr1, 6, 7, and 13),
214 chemokine (e.g. Ccl6, Cxcl1, Cxcl10), adaptive immune (e.g. *Cd247*, *Cd3*) and Il-
215 1/inflammasome (e.g. Il1b, Il1rn, IL18rap, NLRP3, etc.) related genes. Coupled with the
216 CD4+ cell labeling data above, collectively these data show that CC strains with
217 prolonged and chronic infection are dysregulated in key innate and adaptive immune
218 pathways as compared to WT mice which most rapidly clear virus.

219

220 **Viral evolution is driven by host genetics.** To determine if viral evolutionary patterns
221 varied with host genetics, we deep sequenced the complete viral open reading frame
222 (ORF) in longitudinal serum samples from select mice that either cleared virus or
223 developed chronic infection (Fig. S9). Virus populations from chronically infected
224 animals (CC071 #41, 43, 46; CC080 #58, 63) evolved over time, as evidenced by the
225 continued animal specific branching and increase in branch length in the dendrogram
226 (Fig. S10A). In contrast, virus populations from CC046 who cleared virus the earliest
227 among CC strains evolved the least (Fig. S10A). Proteins/regions of the genome under
228 positive selection accumulate non-synonymous changes at increased frequency
229 compared to synonymous changes. Thus, we then compared the non-synonymous and
230 synonymous changes (dN/dS) per viral ORF. Regardless of host genetic background

231 and unlike other portions of the genome, the dN/dS ratio for structural proteins E1 and
232 E2, as well as p7 was increased at all times suggestive of positive selection (Fig. S10B).

233 We next analyzed the mutational patterns per mouse (Fig. 6). CC071 infected
234 mice (Fig 6A), had more nonsynonymous changes compared to viruses from CC080
235 (Fig. 6B) or CC046 (Fig. 6C) animals no matter infection outcome. In all three CC
236 mouse strains, the mouse adapted NrHV-B_{SLIS} variant was rapidly selected for likely due
237 to its mutations T190S, V353L, F369I and N550S, which appear to adapt the virus to
238 WT mice⁹. In general, viruses from mice that resolved infection had the fewest
239 additional substitutions but several mutations residing in an MHC-I epitope conserved
240 among mice and rats (T184A, S191F, V196A) were observed in viruses from all
241 strains²¹. In addition, either A698V or C715S appeared to be selected in p7 but rarely
242 together. Interestingly, N550S, predicted to disrupt a glycosylation site, reverted in two
243 of three chronically infected CC071 mice concomitantly with the disruption of another
244 predicted glycosylation site at residues 504-506. Substitution of residue 500 (3/3) and
245 570 (2/3) was also observed in chronically infected CC071 mice. Further, unique
246 changes linked to persistence were observed in CC071 (R984H in NS3) and CC080
247 (P1446S/L). Thus, viral evolution, clearance and chronicity were closely linked to host
248 genetics.

249

250 **The pathologic hallmarks of chronic liver infection vary with time and host**

251 **genetics.** To determine the pathological consequences of acute and chronic NrHV
252 infection, we evaluated hematoxylin and eosin-stained liver tissue sections. The hepatic
253 architecture did not vary among mock infected WT, CC046, CC071 and CC080 mice

254 (Fig. 7). For WT mice, the kinetics of liver pathology largely mirrored that of virus
255 replication. On 2dpi, randomly distributed foci of inflammatory cells associated with
256 single cell necrosis of hepatocytes were noted but by 7dpi, inflammation was notably
257 increased with moderate lymphocytic inflammation predominantly focused on portal
258 triads along with focal, random small clusters of inflammatory cells in the parenchyma
259 all of which was largely resolved by 28dpi (Fig. 7 and S11). In infected CC046, a mild
260 lymphocytic periportal inflammation was noted 7dpi, which became moderate by 28dpi
261 and persisted although more mildly to the end of the study, 8 months after mice had
262 cleared virus (Fig. 7 and S12). Although liver tissue sections from CC071 mice were
263 unremarkable on 2dpi, by 7dpi, moderate periportal inflammation was observed in
264 infected CC071 mice with increased lymphocytes in circulation (Fig. 7 and S13). By
265 28dpi, periportal and intraparenchymal inflammation was noted and hepatic nuclear
266 inclusions (Fig. S13 Inset), known to be associated with liver disease such as
267 hepatocellular carcinoma and non-alcoholic fatty liver disease, were observed ^{22,23}. In
268 addition, karyomegaly (i.e. enlargement of nuclei), known to be associated with
269 abnormal liver function, was observed in CC071 infected mice at 28dpi (Fig. S13)²⁴.
270 Unlike WT and CC046, by the end of study, moderate periportal inflammation remained
271 in infected CC071 mice. Like CC071, at 2dpi, liver sections from CC080 infected mice
272 were unremarkable (Fig. 7 and S14). Over time, periportal inflammation and foci of
273 intraparenchymal inflammation increased in frequency and severity which by the end of
274 the study was like that in CC071. Lastly, we performed Masson's Trichrome stain on
275 liver tissue sections from the end of the study (i.e. 272 days post infection) to determine
276 if the chronic infection and inflammation was associated with liver fibrosis (Fig. 8).

277 Remarkably, early bridging fibrosis was observed in chronically infected CC071 mice
278 but not in chronically infected CC080 mice suggesting that genetic factors guide multiple
279 disparate pathologic outcomes.

280

281 **Discussion**

282 Here we describe new mouse models of chronic hepatitis C virus infection that
283 recapitulate multiple aspects of human HCV infection including high titer replication in
284 the liver, persistent infection with virus evolution over time, chronic liver inflammation
285 and liver fibrosis (Fig. S15)^{25,26}. For hepatitis C virus research, the CC provides new models
286 for the mechanistic study of acute and chronic infection, pathogenesis, immunity and
287 vaccination and should provide insights into how host genetics affects acute and chronic
288 infection at an unprecedented resolution.

289 Hepatitis C virus and hepatocyte interactions guide the trajectory of infection likely
290 involving but not limited to the interplay of viral innate immune antagonists, antiviral
291 innate immune sensors, innate (e.g. Kupffer cells) and adaptive immune cells (e.g. T-
292 cells), cytokines and chemokines, hepatocyte turnover, and host genetic variation (e.g.
293 *IL28B* SNPs)²⁷⁻³⁰. Here, we describe three genetically distinct mouse strains with a
294 multitude of different hepatitis C virus infection phenotypes and disease trajectories.
295 Interestingly, CC071 mice also have increased susceptibility to classical flaviviruses
296 such as Zika virus (ZIKV), Powassan virus and West Nile virus but not to the bunyavirus
297 Rift Valley fever virus indicating that this strain is particularly sensitive to the
298 *Flaviviridae*³¹⁻³³. JAK/STAT signaling, a key component of the interferon response,
299 appears to function normally in CC071 as interferon treatment of MEFs from CC071 or

300 WT results in similar levels of STAT1 phosphorylation suggesting that defects in
301 JAK/STAT signaling is not driving increased flavivirus susceptibility³². Neither CC046
302 nor CC071 appear to have a broad immune deficiency as they are not more susceptible
303 to *Salmonella* Typhimurium infection than WT mice (i.e. 129, 129S2/ SvPasCrl)³⁴.

304 There is a dearth of small animal models of chronic hepatitis C virus infection within
305 which to study the virus and host factors that contribute to pathogenesis, mechanisms
306 of viral evolution and evasion of adaptive immunity. Sophisticated transgenic mice,
307 human liver chimeric mice and even mice reconstituted with both human liver and
308 immune cells have been employed to study HCV infection, but species incompatibility
309 complicates the modeling of immunity and chronic disease³⁵. Here, we provide an
310 orthogonal approach with NrHV^{9,10,36}. Although CD4 T-cell depletion prior to NrHV
311 infection of WT mice can facilitate chronic infection⁹, using the CC, we provide a
312 complementary approach demonstrating chronic infection and fibrosis in mice is
313 possible without immune manipulation and that host genetic variation affects viral
314 evolution. Viral evolution was greatest in CC071 mice, with the majority of change
315 occurring in E1 and E2, presumably the main targets of the neutralizing antibody
316 response. The MHC and T-cell related loci of WT, CC046, CC071 and CC080 are
317 different suggesting the potential for differential adaptive immune responses. It is likely
318 that acute resolving and chronic infection are complex processes involving infected cell
319 intrinsic factors, and innate and adaptive immunity. Genetic differences in all these
320 elements could in principle determine the differential outcomes observed between
321 strains. Unfortunately, MHC haplotypes in CC strains remain largely unknown unlike
322 common WT strains of mice.

323 In summary, we provide new small animal models of chronic hepacivirus
324 infection, evidence that host genetic variation can profoundly affect the outcome of
325 infection and a model genetic system within which to map the loci guiding virus
326 clearance and chronicity. These models have the power to provide both basic insights
327 into hepacivirus biology, hepatocyte biology, innate and adaptive immunity, mammalian
328 genetics as well as new immunocompetent systems within which to study hepacivirus
329 therapeutic efficacy and vaccine performance. Thus, these and future studies should be
330 of broad interest to the field of infectious disease biology, hepatology and immunology.

331

332 **Materials and Methods**

333 **Recombinant Virus Production**

334 DNA from consensus clones NrHV-A, NrHV-B and the mouse adapted NrHV-B_{SLIS},
335 carrying the T190S, V353L, F369I and N550S mutations (clones to be published
336 elsewhere), were linearized using *MluI* and purified using DNAClean and concentrator
337 (Zymo). RNA was transcribed from 1 ug of *MluI*-linearized DNA using T7 RiboMAX
338 Express Large Scale RNA Production System (Promega). Template DNA was degraded
339 using RQ1 DNase for 30 min at 4°C and RNA was purified using RNAeasy mini kit
340 (Qiagen). 4-week-old NRG mice were injected intra-hepatically using 10 µg of RNA in a
341 maximum volume of 50 µL of PBS+RNA and one week post injection a terminal bleed
342 was performed, and serum was pooled, titrated by qRT-PCR and stored in -80°C
343 freezer. These passage zero virus stocks were amplified through intravenous infection
344 of new 4-week-old NRG mice (N = 10/virus strain to be amplified) with 10⁴ genomic
345 equivalents (GE) after which serum harboring the new passage #1 stocks were

346 harvested, titrated and stored as above. All experiments were performed using passage
347 #1 of each strain mixed in equal amounts (1:1:1).

348

349 **Mouse Infection Studies**

350 All Collaborative Cross (CC) mice were obtained in 2015-2021 from the Systems
351 Genetics Core Facility at the University of North Carolina at Chapel Hill³⁷. For the initial
352 CC-strain screen, 9–12-week-old female CC004/TauUnc, CC017/Unc, CC021/Unc,
353 CC024/GeniUnc, CC040/TauUnc, CC044/Unc, CC045/GeniUnc, CC046/Unc,
354 CC071/TauUnc and CC080/TauUnc were obtained N = 8/CC strain. Age and sex
355 matched WT C57BL/6J mice were purchased from Jackson Labs. Mice were
356 anesthetized with a mixture of ketamine/xylazine and then infected via retroorbital
357 injection of 100µl containing 1×10^5 genome equivalents (G.E.) of recombinant NrHV
358 diluted in DPBS (Gibco) (N = 5/strain). As a negative control, 3 mice/strain
359 were mock infected with DPBS. Mice were weighed daily for the first week of infection
360 and then weekly thereafter. To measure virus replication in live mice, whole blood was
361 collected via submandibular bleed, was allowed to clot at room temperature in snap cap
362 tubes, centrifuged at 9,600 x g for 10 minutes and then serum was transferred to a new
363 tube and stored at -80°C until analysis. Complete blood count was also performed using
364 a Vetscan HM5c automated veterinary blood analyzer using whole blood collected into
365 EDTA tubes. At the end of week 4, animals were euthanized by isoflurane overdose,
366 whole blood and serum were collected and treated as above. Liver tissue was collected
367 from each animal and stored in RNAlater (Thermo) at -80°C or in 10% formalin prior to
368 processing for histology.

369 For the subsequent two follow up studies, 7–14-week-old female CC046/Unc
370 (CC046) (N = 17 NrHV infected, 13 mock infected), CC071/TauUnc (CC071) (N = 28
371 NrHV infected, 19 mock infected) and CC080/TauUnc (CC080) (N = 15 NrHV infected,
372 14 mock infected) were purchased from the UNC Systems Genetics Core in January
373 through March 2019. Age and sex matched WT C57BL/6J mice were purchased from
374 Jackson Labs (N = 23 NrHV infected, N = 17 mock infected). Mice were infected and
375 followed for the first six weeks as described above. Bleeds and weights then performed
376 every other week for 8 weeks followed then by monthly assessments. These studies
377 were terminated after 37-38 weeks, and blood and tissue were collected as noted
378 above.

379

380 **RNA isolation, qRT-PCR and Illumina Deep Sequencing**

381 For reverse transcription – quantitative polymerase chain reaction (qRT-PCR)
382 quantitation of viral RNA in serum, RNA was isolated from 5µl of mouse serum using
383 the RNA Clean & Concentrator -5 (Zymo) or High Pure Viral Nucleic Acid kit (Roche)
384 kits. qRT-PCR was performed using 5µl of eluted RNA, TaqMan Fast Virus 1-step
385 Master Mix (Applied Biosystems) and primer/probes targeting NS3 primers/probe
386 (IDT)¹¹. The sequence of the NrHV NS3 primers and probes were: Primer 1:
387 AAGCGCAGCACCAATTCC, Primer 2: TACATGGCTAAGCAATACGG, Probe: /56-
388 FAM/CTCACGTAC/ZEN/ATGACGTACGGCATG/3IABkFQ/. NrHV standard curve RNA
389 (MEGAscript, Thermo) was produced by PCR amplification of NS3 downstream of a T7
390 promoter. Reactions were performed in LightCycler 480 Multiwell Plates (Roche) in a
391 LightCycler 480 (Roche) using the following program: 50°C for 30 minutes, 95°C for 5

392 minutes, followed by 40 cycles of 95°C for 15 seconds, 56°C for 30 seconds, and 60°C
393 for 45 seconds, then 40°C for 10 seconds. For qRT-PCR to quantitate NrHV RNA, ISG
394 expression and mRNA sequencing in liver tissue, liver tissue was homogenized in
395 TRIzol reagent (Thermo), and RNA was isolated according to protocol. 500ng total RNA
396 was utilized for each qRT-PCR reaction. ISG MX dynamin-like GTPase 1 (Mx1, Thermo
397 Fisher, Mm00487796_m1) expression was assessed in select samples. Relative
398 expression of Mx1 to housekeeping gene glyceraldehyde-3-phosphate dehydrogenase
399 (GAPDH, Thermo Fisher, Mm99999915_g1) was calculated by $\Delta\Delta\text{CT}$ method³⁸. Illumina
400 total RNA-seq was performed by the UNC High Throughput Sequencing Facility
401 (HTSF). Stranded mRNA libraries were prepared (Kapa mRNA) and read on the
402 Illumina HiSeq4000 platform (single end 1x50 read length). For analysis of raw reads,
403 sequenced reads were mapped to the mouse reference transcriptome (Ensemble; Mus
404 musculus version 108) using Kallisto (version 0.46.0). Transcript quantification data was
405 normalized using the TMM method in EdgeR (version 3.38.4) and differentially
406 expressed genes ($p.\text{Adj.val} < 0.05$; $\log\text{LC} > 1.5$) were identified using linear modeling
407 with limma (version 3.52.2) using R (version 4.2.0) in R Studio (version 2022-04-19).
408 Gene ontology analysis was carried out using the Ingenuity Pathway Analysis (Qiagen).
409 Heat maps were generated using Broad Institute's Morpheus web application
410 (<https://software.broadinstitute.org/morpheus/>). Hierarchical clustering was performed
411 by One Minus Pearson Correlation with Average Linkage clustering by columns and
412 rows. Sequence data is available on the Gene Expression Omnibus (GEO, accession #
413 GSE###).
414

415 **Liver Pathology and Digital Quantitation of Viral RNA in Liver Tissue Sections**

416 To assess liver pathology, we formalin fixed, paraffin embedded liver tissues, generated
417 sections (~5µm) and stained then with hematoxylin/eosin (Richard-Allen Scientific) on
418 an Autostainer XL from Leica Biosystems. To assess liver fibrosis, sections were
419 stained using Masson's Trichrome (Richard-Allen Scientific). For CD4
420 immunohistochemical (IHC) staining, antigen retrieval (20 minutes at 100°C in Leica
421 Bond-Epitope Retrieval Solution 2 pH-9) was performed on dewaxed tissues prior to
422 labeling with CD4 antibody (ab183685, Abcam) at 1:2,000 for 1h followed with Novolink
423 Polymer (RE7260-CE) secondary antibody labeling on a Leica Bond III Autostainer.
424 Antibody labeling was detected using 3,3'-diaminobenzidine (DAB) and the Bond
425 Intense R detection system (DS9263). Tissue sections were evaluated by a Board
426 Certified Veterinary pathologist.

427 NrHV viral RNA was visualized in liver tissue sections by *in situ* hybridization
428 (ISH) using RNAscope probes (Item # V-NrHV-PP) designed by Advanced Cell
429 Diagnostics based on the whole genome sequence of NrHV (Genebank Accession #
430 MF113386.1). ISH on liver tissue sections was performed on a Leica Rx autostainer
431 (Leica Biosystems) with a hematoxylin counterstain. For quantitation, slides were
432 scanned on a Versa slide scanner (Leica Biosystems) with a 40X power objective and a
433 Point Gray camera (8-bit image at 0.137152 microns/pixel) and imported to Definiens
434 Architect XD 2.7 for analysis with Tissue Studio version 4.4.2. Per tissue section per
435 animal, total tissue area was calculated and total numbers of cells per section was
436 calculated using the nuclear counterstain as a guide. Similar numbers of cells were
437 assessed in each tissue section per timepoint. NrHV positive cells were identified by

438 ISH positivity. The spot size threshold was $1.5 \mu\text{m}^2$. Spot areas were ranked as
439 None/Low ($2 \mu\text{m}^2$), Low/Medium ($6 \mu\text{m}^2$), or Medium/High ($10 \mu\text{m}^2$). Resultant data was
440 used to determine the infection frequency per tissue section.

441

442 **Deep sequencing NrHV genomes**

443 Serum from NrHV infected mice was diluted in PBS ($25 \mu\text{L}$ in $225 \mu\text{L}$ PBS), added to a
444 2 mL Phasemaker tube (Thermo Fisher Scientific), mixed with $750 \mu\text{L}$ TRIzol LS
445 Reagent (Thermo Fisher Scientific) after which $200 \mu\text{L}$ chloroform was added, shaken for
446 15 seconds, incubated for 3 min at room temperature, and centrifuged at $12,000g$ for
447 15 min at 4°C . The aqueous phase was removed and mixed with $450 \mu\text{L}$ ethanol and
448 transferred to an RNA Clean & Concentrator-5 column (Zymo Research) for
449 downstream RNA purification and concentration. Reverse-transcription (RT) was
450 performed with Maxima H Minus Reverse Transcriptase (Thermo Fisher Scientific).
451 Samples were pre-incubated in the presence of RNase inhibitors (Promega) at 65°C for
452 2 min prior to addition of the RT enzyme, followed by incubation at 50°C for 2 h using 0.1
453 μM primer TS-O-00319 (GCTTCCTGGAGCGGGCTAGATACTG). Amplification of the
454 complete ORF was performed using Q5 Hot Start High-Fidelity DNA Polymerase (New
455 England Biolabs), including high GC Enhancer, and the primer pair Reverse TS-O-
456 00318 (CCAAGCCCCAATGCCGTCCGGCACCGCTGCCCTTTTCGG) and Forward
457 TS-O-00361 (AGGTGAAGGGGGCATCGATG) ($0.5 \mu\text{M}$ each). The PCR cycling
458 parameters were 98°C for 30 s , followed by 37 cycles of 98°C for 10 s , 65°C for 10 s
459 and 72°C for 8 min , with a final extension at 72°C for 10 min . Amplified DNA was
460 purified using DNA Clean & Concentrator-25 columns (Zymo Research), and libraries

461 for deep sequencing were prepared using the NEBNext Ultra II FS DNA Library Prep Kit
462 for Illumina (New England Biolabs). Quality of DNA libraries was validated using a 2100
463 Bioanalyzer Instrument (Agilent). DNA libraries were quantitated via Qubit dsDNA High-
464 Sensitivity Assay Kit (Thermo Fisher Scientific) and libraries were pooled in equimolar
465 concentrations prior to denaturation. Pooled libraries were loaded on a MiSeq v3 150
466 cycle flow-cell, and sequencing performed on a MiSeq benchtop sequencer (Illumina).
467 Analysis was performed as previously described^{10,39}. In short, pair-end reads were
468 trimmed and filtered by Sickle and subsequently mapped by BWA onto the NrHV-B
469 reference (GenBank: ON758386) using the MEM algorithm. Samtools were used to
470 process the alignment files and Lofreq were applied to call SNPs that were translated by
471 SNPEffect. Multiple mutations in the same specific codons were subsequently resolved
472 by LinkGE. Pairwise distance and dN/dS ratios were calculated from the vcf files by
473 SNPGenie.

474

475 **Author Contributions:** TPS, MTF, CMR, JB and TKHS designed the studies. AJB, JW,
476 RW, UF, NC, AW, FRM, MTF, CLL, SRL, CN, GDLC, BRM, YX, SAM, and TPS
477 performed the studies. EB, MNB and CMR provided recombinant NrHV for these
478 studies. TPS, RW, UF, EB, SAM, TKHS, JB and CMR wrote and edited the manuscript.
479 All authors read and approved this manuscript.

480

481 **Acknowledgements:** This work was funded by R01 grant from the National Institute of
482 Allergy and Infectious Disease (NIAID, AI131688 to C.M.R.), a U19 grant from NIAID
483 (U19AI100625 to Ralph Baric and Mark Heise), the Independent Research Fund

484 Denmark (1030-00426 to Troels K. H. Scheel), Advanced Grant 4004-00598 to Jens
485 Bukh), the Danish Cancer Society (R204-A12639 to Jens Bukh and Troels K. H.
486 Scheel), the Novo Nordisk Foundation (Distinguished Investigator Grant
487 NNF19OC0054518 and Tandem NNF19OC0055462 to Jens Bukh), and the European
488 Research Council (Starting Grant 802899 to Troels K. H. Scheel). Raphael Wolfisberg.

490 doc Mobility Fellowship (P400PB-183952) from the Swiss National Science Foundation.
491 We gratefully acknowledge the technical support from the UNC High Throughput
492 Sequencing Facility. This facility is supported by the University Cancer Research Fund,
493 Comprehensive Cancer Center Core Support grant (P30-CA016086), and UNC Center
494 for Mental Health and Susceptibility grant (P30-ES010126). We would like to thank
495 Louise B. Christensen (Department of Clinical Microbiology, University of Copenhagen)
496 for laboratory assistance and the Department of Clinical Microbiology, Hvidovre Hospital
497 for access to Illumina miSeq equipment. Collaborative Cross (CC)³⁷ mice were obtained
498 in 2017-2021 from the Systems Genetics Core Facility at the University of North
499 Carolina at Chapel Hill. We would also like to thank Dr. Amit Kapoor from the University
500 of Ohio and Dr. Brad Rosenberg from Mt. Sinai Medical School for helpful and insightful
501 discussion of this work.

502

503 **Figure Legends**

504

505 **Figure 1. Host genetics is a determinant of acute hepatitis C virus clearance. (A)** Study
506 design. Ten Collaborative Cross (CC) strains and control C57BL/6J female mice 9-13

507 weeks in age were infected with 1×10^5 genome equivalents of recombinant NrHV or
508 negative control PBS via retroorbital injection and bled weekly to monitor viremia.
509 Mouse numbers per strain were: C57BL/6J N = 8, CC004 N = 4, CC017 N = 4, CC021
510 N = 4, CC024 N = 5, CC040 N = 5, CC044 N = 5, CC045 N = 5, CC046 N = 6. CC071 N
511 = 5, CC080 N = 4. For all strains PBS mock infected N = 3. **(B)** Week 4 viremia as
512 determined by qRT-PCR of viral RNA isolated from serum. The dotted line indicates the
513 limit of quantitation. **(C)** Intrahepatic viral load 4 weeks post infection by qRT-PCR using
514 500 ng total liver RNA. Numbers of mice per group: C57BL/6J (8 NrHV, 4 Mock),
515 CC040 (4 NrHV, 3 mock), CC046 (6 NrHV, 3 mock), CC071 (5 infected, 3 mock),
516 CC080 (4 infected, 3 mock). **(D)** *Mx1* intrahepatic gene expression 4 weeks by qRT-
517 PCR using 500ng total RNA. Data is expressed as fold change over mock infected by
518 $\Delta\Delta$ CT method. For B and D, asterisks indicate statistical significance as determined by
519 Kruskal-Wallis test. For C, asterisks indicate statistical significance by Two-Way
520 ANOVA with a Dunnett's multiple comparison test.

521
522 **Figure 2. Host genetics is a determinant of hepacivirus chronicity. (A)** Study
523 Design. C57BL/6J, CC046, CC071 and CC080 mice were infected with 1×10^5 genome
524 equivalents of recombinant NrHV or negative control PBS via retroorbital injection and
525 viremia was monitored weekly or monthly. **(B)** NrHV viremia for weeks 1-39 determined
526 by qRT-PCR of RNA from serum. See Table S2 for the numbers of animals per strain
527 per time. **(C)** NrHV Viremia for weeks 1-5. Levels of viral RNA in serum were measured
528 by qRT-PCR. C57BL/6J Time (N): week 1 (19), week 2 (15), week 3 (15), week 4 (15),
529 week 5 (15). CC046 Time (N): week 1 (13), week 2 (10), week 3 (10), week 4 (10),

530 week 5 (10). CC071 Time (N): week 1 (22), week 2 (20), week 3 (18), week 4 (19),
531 week 5 (19). CC080 Time (N): week 1 (13), week 2 (10), week 3 (10), week 4 (10),
532 week 5 (10). Asterisks indicate statistically significant differences by Two-Way ANOVA
533 Tukey's multiple comparisons test. **(D)** Proportion of mice per strain that clear virus
534 early (< 3 weeks), middle (week 4-7), late (week 8-22) or do not clear (viremic week 23
535 to end of study). Only mice that survived to the end of the study were considered for
536 this analysis. For B and C, the dotted line indicates the average limit of quantitation. All
537 data for B-D, was compiled from two independent experiments.

545 7dpi (3), 28dpi (6), 272dpi (5). CC071 Time (N): Mock (7), 2dpi (4), 7dpi (2), 28dpi (5),
546 272dpi (15). CC080 Time (N): Mock (6), 2dpi (4), 7dpi (3), 28dpi (4), 272dpi (8). **(C)**
547 NrHV genome copy number in 500ng total liver RNA by qRT-PCR. C57BL/6J Time (N):
548 Mock (4), 2dpi (4), 7dpi (4), 28dpi (5), 272dpi (7). CC046 Time (N): Mock (4), 2dpi (4),
549 7dpi (3), 28dpi (6), 272dpi (5). CC071 Time (N): Mock (4), 2dpi (4), 7dpi (2), 28dpi (5),
550 272dpi (15). CC080 Time (N): Mock (4), 2dpi (4), 7dpi (3), 28dpi (4), 272dpi (8).
551 Asterisks in B and C indicate statistical significance by Two-Way ANOVA Tukey's
552 multiple comparisons test.

553

554 **Figure 4. CD4 cell recruitment is delayed in CC mouse strains.** CD4 cell labeling in
555 liver tissue sections from mock and NrHV infected animals at 2, 7, 28, and 272dpi with
556 CD4 cells (brown) and nuclei (blue). Representative images of mouse strains and
557 timepoints are shown.

558

559 **Figure 5. Dysregulation of the transcriptome in strains susceptible to chronic**
560 **infection.** Total RNA from mock and NrHV infected liver tissue was deep sequenced by
561 Illumina HiSeq 4000. For all groups, N = 3 except for CC071 NrHV infected N =2. **(A)**
562 Principal component analysis of expression data for mock and infected groups. **(B)** Top
563 40 Regulated Canonical Pathways by Ingenuity IPA. The significance (-log(p-value) and
564 predicted regulation (Z-score) for each pathway is indicated by the scale bar. **(C)**
565 Expression of significantly regulated genes (>1.5 Log fold change P < 0.05) over mock
566 in select Canonical pathways. Heat maps were generated in Morpheus.

567

568 **Figure 6. Host genetics drives differential viral evolution.** Amino acid changes
569 observed in the NrHV ORF for **(A)** CC071 animals that clear (#42, 44, 47) and become
570 chronically infected (#41, 43, 46), **(B)** CC080 animals that clear (#57, 60, 61, 62) and
571 become chronically infected (#58 and 63) and **(C)** CC046 animals that clear (#28, 29,
572 30). The heat map color intensity indicates mutation frequencies (%). Mouse adaptive
573 mutations present in the inoculum (T190S, V353L, F369I, and N550S) are highlighted in
574 hot pink. Changes shared by more than one CC strain are in bold.

575

576 **Figure 7. The pathologic hallmarks of chronic liver infection vary with time and**
577 **host genetics.** Liver tissue sections from mock or NrHV infected WT, CC046, CC071
578 and CC080 mice at 2, 7, 28 and 272 dpi were stained with hematoxylin and eosin.
579 Hallmark features of normal liver architecture including portal vein, bile duct, hepatic
580 artery, central vein and hepatocytes are noted in each mock panel.

581
582 **Figure 8. Liver fibrosis is associated with chronic liver infection.** Liver tissue
583 sections from mock or NrHV infected WT, CC046, CC071 and CC080 mice at 272 dpi
584 were stained with Masson's Trichrome which stains collagen blue. Inflammatory cells
585 and early bridging fibrosis are noted.

586
587 Supplemental Figures

588 **Figure S1. Deep sequencing of recombinant virus populations utilized for *in vivo***
589 **studies.** . Associated with main Figure 1. **(A)** The amino acid sequence differences for
590 NrHV-A (Genbank: MF113386), NrHV-B (Genbank ON758386) and B_{SLIS} (NrHV-B with
591 the additional changes T190S, V353L, F369I and N550S) as compared to the RHV-rn1
592 reference isolate (Genbank: KX905133) virus strain. **(B)** Deep sequencing of the input
593 virus pool which revealed a stoichiometry of 42% A, 19% B, 39% B_{SLIS}. Three additional
594 mutations (207T, 1221P and 1590G) were noted in all B virus sequences likely acquired
595 during stock generation *in vivo*.

596
597 **Figure S2. NrHV week 1 viremia for 10-strain Collaborative Cross screen.**

598 Associated with main Figure 1. Ten CC strains and control C57BL/6J female mice 9-13

599 weeks in age were infected with 1×10^5 G.E. of recombinant NrHV or negative control
600 PBS via retroorbital injection and bled weekly to monitor viremia. Infected mouse
601 numbers per strain were: C57BL/6J N = 8, CC004 N = 4, CC017 N = 4, CC021 N = 4,
602 CC024 N = 5, CC040 N = 5, CC044 N = 5, CC045 N = 5, CC046 N = 6. CC071 N = 5,
603 CC080 N = 4. For all strains PBS mock infected N = 3. Levels of viral RNA in 1 μ l serum
604 as measured by qRT-PCR is shown.

605

606 **Figure S3. The genetic architecture of Collaborative Cross strains CC046, CC071,**
607 **and CC080.** Associated with main Figure 2. Figure adapted from Leist et al.⁴⁰ **(A)** The
608 CC is a recombinant inbred mouse reference population generated by breeding five
609 classic inbred strains (A/J, C57BL/6, 129, NOD and NZO) with three wild strains (CAST,
610 PWK and WSB). **(B)** The proportion of each founder strain comprising each CC strain of
611 interest. **(C)** The genomic architecture of CC046, CC071 and CC080. The color
612 segments of each chromosome pair correspond to loci donated by founder strains. **(D)**
613 The genotype of CC046, CC071 and CC080 at the MHC locus, genes related to T-cell
614 activation and type I and III interferon. The colors in the grid correspond to the genotype
615 at each region.

616

617 **Figure S4. Body weight for mock and NrHV infected mice.** Associated with main
618 Figure 2. C57BL/6J, CC046, CC071 and CC080 mice were infected with 1×10^5 G.E. of
619 recombinant NrHV or negative control PBS via retroorbital injection. Body weights were
620 measured daily for the first two weeks and then intermittently for the duration of the

621 study to 272 or 273dpi. The percent starting weight is shown for age and strain matched
622 mock PBS infected and NrHV infected over time.

623

624 **Figure S5. Body weight for mock and NrHV infected mice for days 0-14.** Associated
625 with main Figure 2 and Figure S4. C57BL/6J, CC046, CC071 and CC080 mice were
626 infected with 1×10^5 G.E. of recombinant NrHV or negative control PBS via retroorbital
627 injection. Daily body weights are shown for the first 14 days of infection. Asterisks
628 indicate statistical significance by two-way ANOVA with a Sidak's multiple comparison
629 test.

630

631 **Figure S6. Passive transfer to demonstrate the presence of infectious virus.**

632 Associated with main Figure 2. **(A)** To demonstrate the presence of infectious virus in
633 NrHV RNA positive sera, 5 μ l of serum from 12 weeks post infection was diluted in 150 μ l
634 PBS and 100 μ l of this mixture was used to inoculate naïve C57BL/6J mice via the
635 retroorbital route. **(B)** Transfer of serum from previously infected aviremic C57BL/6J
636 mice to recipient naïve C57BL/6J mice. **(C)** Transfer of serum from previously infected
637 but aviremic CC046 mice to recipient naïve C57BL/6J mice. **(D)** Transfer of serum from
638 viremic CC071 mice to recipient naïve C57BL/6J mice. **(E)** Transfer of serum from three
639 aviremic mice and one viremic CC080 mouse to three recipient naïve C57BL/6J mice.

640

641 **Figure S7. Kinetics of viremia in individual mice with different viral clearance**

642 **phenotypes.** Associated with main Figure 2. The levels of viral RNA in serum as
643 measured by qRT-PCR are shown for C57BL/6J, CC046, CC071 and CC080. Four

644 clearance phenotypes were noted: Early Clearance (< 3 weeks), Middle Clearance
645 (Week 4-7), Late Clearance (Week 8-22), No Clearance (viremic at the end of study
646 week 38/39).

647

648 **Figure S8. Total blood lymphocytes and neutrophils for all times post infection.**

649 Associated with main Figure 4. Complete blood count was performed using a Vetscan
650 HM5 automated blood analyzer on whole blood isolated from mock and infected mice
651 for the duration of studies described in Fig. 2. **(A)** Blood lymphocytes are shown for the
652 first five weeks of infection or **(B)** for the duration of the study for each mouse strain. **(C)**
653 Complete blood count for neutrophils for the first five weeks of infection or **(D)** for the
654 duration of the study for each mouse strain. Asterisks indicate statistically significant
655 differences by Two-Way ANOVA Tukey's multiple comparisons test.

656

657 **Figure S9. Viremia phenotypes for mice on which viral ORF sequencing was**

658 **performed.** Associated with main Figure 6 and Figure S12. The levels of viral RNA in
659 serum as measured by qRT-PCR are shown for C57BL/6J, CC046, CC071 and CC080.

660

661 **Figure S10. Chronic infection is associated with increased viral evolution. (A)**

662 Associated with main Figure 6 and Figure S9. The genetic relationships of virus
663 populations isolated from NrHV infected CC046 (N = 3), CC071 (N = 6) or CC080 (N =
664 6) over time are shown in a neighbor joining tree created from whole viral ORF
665 sequences from 1, 4, 7, 13, 27 and 38 weeks post infection. Infected animals and
666 phenotypes are described in Figure 2. The viremia phenotypes per mouse are

667 described in Figure S9. The dendrogram was generated by aligning full ORF sequences
668 by MAFFT and building the phylogeny by maximum likelihood using PhyML using the
669 general time reversible substitution model and rooted the inoculum input of the current
670 study and the rat inoculum used for NRG mouse adaptation (NrHV-A; Genebank
671 MF113386)⁹; NrHV-B (Genebank ON758386) and RHV-rn1 (Genebank KX905133)³⁶ as
672 outgroups. **(B)** Non-synonymous/synonymous (dN/dS) mutation ratios. Using whole
673 ORF sequencing data from (A), dN/dS ratios were generated for each viral protein.
674 Increased dN/dS is associated with increased evolutionary change.

675

676 **Figure S11. Liver pathology in mock and NrHV infected WT C57BL/6J mice.** Liver
677 tissue sections from mock or NrHV infected mice at 2, 7, 28 and 272 dpi were stained
678 with hematoxylin and eosin. Hallmark features of normal liver architecture including
679 portal vein, bile duct, hepatic artery, central vein and hepatocytes are noted in each
680 mock panel. Other pathologic features are noted in the key.

681

682 **Figure S12. Liver pathology in mock and NrHV infected CC046 mice.** Liver tissue
683 sections from mock or NrHV infected mice at 2, 7, 28 and 272 dpi were stained with
684 hematoxylin and eosin. Hallmark features of normal liver architecture including portal
685 vein, bile duct, hepatic artery, central vein and hepatocytes are noted in each mock
686 panel. Other pathologic features are noted in the key.

687

688 **Figure S13. Liver pathology in mock and NrHV infected CC071 mice.** Liver tissue
689 sections from mock or NrHV infected mice at 2, 7, 28 and 272 dpi were stained with

690 hematoxylin and eosin. Hallmark features of normal liver architecture including portal
691 vein, bile duct, hepatic artery, central vein and hepatocytes are noted in each mock
692 panel. Other pathologic features are noted in the key.

693

694 **Figure S14. Liver pathology in mock and NrHV infected CC080 mice.** Liver tissue
695 sections from mock or NrHV infected mice at 2, 7, 28 and 272 dpi were stained with
696 hematoxylin and eosin. Hallmark features of normal liver architecture including portal
697 vein, bile duct, hepatic artery, central vein and hepatocytes are noted in each mock
698 panel. Other pathologic features are noted in the key.

699

700 **Figure S15. Summary of key phenotypic data per mouse strain.** Key phenotypic
701 data per mouse strain is shown to provide an overview of the main pieces of data
702 described in the manuscript.
