**Abstract.** Pseudorandom functions are traditionally built upon block ciphers, but with the trend of permutation based cryptography, it is a natural question to investigate the design of pseudorandom functions from random permutations. We present a generic study of how to build beyond birthday bound secure pseudorandom functions from public random permutations. We first show that a pseudorandom function based on a single permutation call cannot be secure beyond the  $2^{n/2}$  birthday bound, where  $n$  is the state size of the function. We next consider the Sum of Even-Mansour (SoEM) construction, that instantiates the sum of permutations with the Even-Mansour construction. We prove that SoEM achieves tight  $2n/3$ -bit security if it is constructed from two independent permutations and two randomly drawn keys. We also demonstrate a birthday bound attack if either the permutations or the keys are identical.

**Keywords:** RP-to-PRF, SoEM, beyond the birthday bound

## 1 Introduction

In the seminal work of Luby and Rackoff [44], a paradigm of constructing a pseudorandom permutation (PRP) from a pseudorandom function (PRF) was introduced. Their work, motivated by the DES block cipher, consists of an  $r$ -round Feistel construction involving independent invocations of a PRF. Soon people realized that they actually needed the opposite construction, i.e., constructing a PRF from a PRP. The reason for this is two-fold: (i) PRPs are easier to design than PRFs and (ii) many cryptographic schemes, such as counter mode, are better off if instantiated with a PRF.

The classical PRP-PRF switch [5, 7, 18, 35, 38], which consists of taking an  $n$ -bit block cipher  $E_K$  as a PRF, is only secure up to the birthday bound: an attacker that can learn around  $2^{n/2}$  evaluations of  $E_K$  can distinguish it from random. Although this bound is acceptable for large enough  $n$ , in light of the rise of lightweight block ciphers [2, 3, 15, 17, 27, 33, 37, 43, 60, 64] this bound is on the

edge for certain applications. For example, for a 64-bit block cipher, breaking security requires approximately  $2^{32} \cdot 64$  bits of data, which is approximately 35GB. Of a similar kind, Bhargavan and Leurent [12] performed practical attacks on TLS and OpenVPN when a 64-bit block cipher is used.

Various approaches of turning a PRP into a PRF with beyond birthday bound security have been introduced. Hall et al. [35] suggested truncation:  $\text{trunc}_m(E_K(M))$ , an approach that was later proven to be secure up to around  $2^{n-m/2}$  queries [4, 32]. Bellare et al. [6] proposed the sum of permutations (SoP),

$$E_{K_1}(M) \oplus E_{K_2}(M), \tag{1}$$

a construction that is known to achieve  $q/2^n$  security [4, 25, 45, 55]. Cogliati and Seurin [22] introduced the Encrypted Davies-Meyer (EDM) construction,  $E_{K_2}(E_{K_1}(M) \oplus M)$ , and proved that it is  $2^{2n/3}$  secure. Mennink and Neves [47] improved the security to be  $2^n$  using Patarin’s mirror theory [50, 53, 55, 56]. They also introduced the dual:  $E_{K_2}(E_{K_1}(M)) \oplus E_{K_1}(M)$ , called Encrypted Davies-Mayer Dual (EDMD), and showed that its security is implied by that of the sum of permutations.

All constructions, however, are yet based on block ciphers. Even stronger, they only evaluate  $E_K$  in the forward direction. As block ciphers are designed to be efficient in both the forward and inverse direction, these are thus over-engineered primitives for this purpose. This is in contrast with the modern trend in cryptography, namely that of permutation based cryptography, where the underlying permutations are particularly developed to be fast in the forward direction, but not necessarily in the inverse direction. Examples of cryptographic permutations include Keccak [11], Gimli [8], and SPONGENT [14].

So what we really need is a PRF designed from public permutations, but the state of the art in this direction is scarce. To our knowledge, the only notable approach in this direction are the keyed sponge [1, 10, 49] and Farfalle [9], however these constructions have been developed with different incentives in mind. Most importantly, they are variable-length, and for small fixed length messages better solutions may be possible.

Acknowledgedly, the state size of a permutation is typically larger than the block size  $n$  of a message: whereas AES has a block size of 128 bits, making the naive birthday bound PRP-PRF switch on the edge, the SHA-3 permutation is of size 1600 bits, and a simple Even-Mansour [29] construction on top of it would give a PRP that behaves like a PRF up to an attack complexity of  $2^{800}$ . However, this example permutation is on the extreme end: lightweight permutations such as SPONGENT [14] and PHOTON [34] go as low as 88 and 100 bits, respectively. For these types of permutations, birthday bound solutions are inadequate.

### 1.1 Towards Birthday Bound Security

Suppose we take the sum of permutations (1), and want to turn it into a PRF conversion function for a public random permutation. Recall that the sum of permutations is secure up to complexity  $2^n$  as long as the underlying block

ciphers are secure. A naive way of proceeding is to plug the Even-Mansour block cipher construction

$$EM_K(M) = \pi(M \oplus K) \oplus K,$$

where  $\pi$  is an  $n$ -bit permutation, into the sum of permutations. However, the Even-Mansour construction is known to be tightly  $2^{n/2}$  birthday bound secure. A simple modular reasoning, in turn, leaves us with an unsatisfiable birthday bound security level.

One way to resolve this is by eschewing the Even-Mansour construction in favor of multiple-round Even-Mansour. For example, 2-round Even-Mansour is secure up to complexity around  $2^{2n/3}$ , and the generic composition of the sum of permutation with this construction guarantees security up to the same level as well. On the other hand, the scheme has become twice as expensive in the number of primitive evaluations: it is based on four permutation calls. Fortunately, the poor bound of the composition of the sum of permutations with Even-Mansour is not inherent to the scheme, but rather, it is due to a lossy composition. A dedicated analysis can render an improved bound.

## 1.2 Our Contribution

We tackle the problem of designing a PRF from a public random permutation from a generalized perspective. First, we consider the general design of a PRF based on one and only one public permutation that is preceded and followed by linear mappings, and demonstrate that such construction cannot be secure beyond the birthday bound. The proof consists of considering different types of linear mappings, and deriving attacks in the birthday bound (or faster) for all variants. The result is given in Section 3.

Our second and main contribution centers around the sum of permutations instantiated with Even-Mansour, a construction which we dub SoEM: (Sum of Even Mansour). It is based on two permutations  $\pi_1, \pi_2$ , and it either takes two keys  $K_1, K_2$  (one before and after each permutation) or it takes a single key  $K$  (added before each permutation, and to the final sum). We derive the following results in Section 4:

- (i) If  $\pi_1 = \pi_2$ , so if both Even-Mansour constructions are instantiated using the same permutation, SoEM can be broken in complexity around  $2^{n/2}$ ;
- (ii) If  $\pi_1$  and  $\pi_2$  are independent, and the construction takes a single key  $K$ , SoEM can again be broken in complexity around  $2^{n/2}$ ;
- (iii) If  $\pi_1$  and  $\pi_2$  are independent, and so are  $K_1$  and  $K_2$ , the resulting construction is tightly secure up to complexity  $2^{2n/3}$ .

The proof of (iii) is performed in the ideal permutation model, using Patarin’s H-coefficient technique [19, 52, 54]. It resembles ideas of the first iteration in Patarin’s mirror theory [55], but difficulties appear in the fact that the permutations  $\pi_1, \pi_2$  can be queried by the distinguisher.

*Is  $2n/3$ -bit security achievable by a construction based on a single key?* An earlier version of this article suggested, as a side result, the SoKAC (Sum of Key Alternating Ciphers) construction

$$\text{SoKAC}(K, M) = \pi_2(\pi_1(M \oplus K) \oplus K) \oplus K \oplus \pi_1(M \oplus K) \oplus K,$$

with a claimed security of  $2^{2n/3}$ . However, Nandi [51] pointed out that SoKAC can be seen as a cascade of two non-injective functions, therewith having twice as many collisions as expected, and can be distinguished from random in about  $2^{n/2}$  queries. Closer inspection of the security proof revealed a very subtle issue in the application of the mirror theory, namely that it cannot readily handle systems of equations with a conditional existence of (in-)equalities, e.g., where two unknowns must be equal if two other unknowns satisfy a certain condition. Broadly speaking, the problem is similar to the issue that appear in the security proof of EWCDMD [47] by Mennink and Neves. As such, we consider it to be a non-trivial exercise to derive a  $2n/3$ -bit secure PRF construction based on public random permutations and using a single key.

### 1.3 Our Contribution in Bigger Perspective

Conversion from public or secret permutations to public or secret functions and vice versa is a fundamental problem in symmetric key cryptography, and our work fills the last remaining notable gap in the picture.

We already discussed the issue of PRF-to-PRP conversion: Luby and Rackoff [44] described the Feistel network, a method still used to design block ciphers. Reversely, PRP-to-PRF conversion was covered by SoP [6], EDM [22], and EDMD [47].

One can consider similar techniques for conversion between public random permutations (RPs) and public random functions (RFs). In this setting, the functions are keyless, and one assumes ideality of the underlying primitives in order to prove security in the indistinguishability framework [46]. The Feistel construction has seen notable indistinguishability analysis [23, 24, 26], and so has the sum of permutation construction [13, 21, 48].

Note that there is little incentive to investigate conversion from PRP/PRF to RP/RF. The Even-Mansour construction [29] transforms an RP to a PRP; it has been generalized in [16, 19, 28, 36, 41, 61]. Gentry and Ramzan [31] proposed the idea of combining the Feistel construction and the Even-Mansour cipher, which was later named the Key Alternating Feistel (KAF) cipher by Lampe and Seurin [42]. In the work of Gazi and Tessaro [30], a construction that turns RFs into PRF has been introduced. Moreover, the Whitened Swap-or-Not construction by Tessaro [62] provides another way of building nearly optimal  $n$ -bits secure PRP from RPs or RFs.

This leaves the problem of RP-to-PRF conversion, i.e. the problem considered in this work. The full picture of example conversion techniques is given in Figure 1.

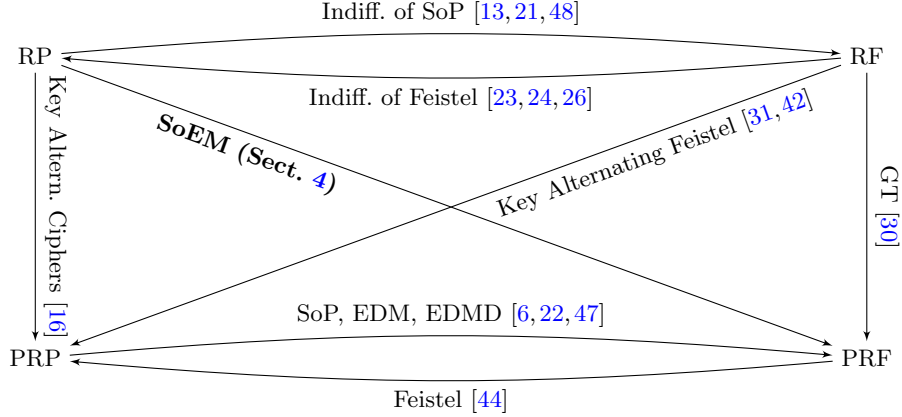

Fig. 1: Conversion among PRP, PRF, RP, and RF. The given example constructions are not exhaustive.

## 2 Preliminaries

For  $n \in \mathbb{N}$ , we denote by  $\{0, 1\}^n$  the set of bit strings of length  $n$ . For two bit strings  $X, Y \in \{0, 1\}^n$ , we denote their bitwise addition as  $X \oplus Y$ . For a value  $Z$ , we denote by  $A \leftarrow Z$  the assignment of  $Z$  to the variable  $A$ . For a finite set  $\mathcal{S}$ , we denote by  $S \xleftarrow{\$} \mathcal{S}$  the uniformly random selection of  $S$  from  $\mathcal{S}$ . We denote by  $\text{Func}(n)$  the set of all functions on  $\{0, 1\}^n$  and by  $\text{Perm}(n)$  the set of all permutations on  $\{0, 1\}^n$ . We denote by  $\langle t \rangle_n$  the encoding of a value  $t \in \{0, \dots, 2^n - 1\}$  as an  $n$ -bit string.

For  $k, n, r \in \mathbb{N}$ , let  $F: \{0, 1\}^k \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be a function that is based on  $r$   $n$ -bit permutations  $\pi_1, \dots, \pi_r$ . We will consider pseudorandom function security of  $F$ , where we assume that  $\pi_1, \dots, \pi_r \xleftarrow{\$} \text{Perm}(n)$ , and where the distinguisher  $\mathcal{D}$  is given access to either  $(F_K^{\pi_1, \dots, \pi_r}, \pi_1^\pm, \dots, \pi_r^\pm)$  for secret key  $K \xleftarrow{\$} \{0, 1\}^k$  or  $(\varphi, \pi_1^\pm, \dots, \pi_r^\pm)$  for  $\varphi \xleftarrow{\$} \text{Func}(n)$ , where the superscript  $\pm$  for the  $\pi_i$ 's indicates that the distinguisher has bi-directional access. Its goal is to determine which oracle it is given access to:

$$\text{Adv}_F^{\text{prf}}(\mathcal{D}) = \left| \Pr \left[ \mathcal{D}^{F_K^{\pi_1, \dots, \pi_r}, \pi_1^\pm, \dots, \pi_r^\pm} = 1 \right] - \Pr \left[ \mathcal{D}^{\varphi, \pi_1^\pm, \dots, \pi_r^\pm} = 1 \right] \right|, \quad (2)$$

for  $K \xleftarrow{\$} \{0, 1\}^k$ ,  $\pi_1, \dots, \pi_r \xleftarrow{\$} \text{Perm}(n)$ , and  $\varphi \xleftarrow{\$} \text{Func}(n)$ .

In the remainder of this work, we will focus on keys of size  $n$  or  $2n$  bits.

## 3 Pseudorandom Functions With One Permutation Call

We will show that any pseudorandom function  $F$  that makes only one permutation call and has linear pre- and post-processing functions cannot achieve

Fig. 2: Function  $F1$  based on two keys  $K_1$  and  $K_2$ , and making one public random permutations evaluation.

security beyond the birthday bound. Let  $n \in \mathbb{N}$ , and let  $\pi \in \text{Perm}(n)$ . Let  $L_1: \{0, 1\}^n \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  and  $L_2: \{0, 1\}^n \times \{0, 1\}^n \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be any two linear mappings (that only consist of modular addition and scalar multiplication). Let  $F1: \{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be the function of Figure 2. We will show that for independent  $K_1, K_2$ , there exists a distinguisher that can distinguish any such function from random using at most  $3 \cdot 2^{n/2}$  construction queries and at most  $3 \cdot 2^{n/2}$  primitive queries. Note that modular addition of the input  $M$  to the output  $C$  does not influence the security of  $F1$ , as the distinguisher knows the exact value of  $M$ .

**Proposition 1.** *Let  $n \in \mathbb{N}$ , and consider the function  $F1: \{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  of Figure 2 based on permutation  $\pi \xleftarrow{\$} \text{Perm}(n)$  and two keys  $K_1, K_2 \xleftarrow{\$} \{0, 1\}^n$ , for any linear  $L_1, L_2$ . There exists a distinguisher  $\mathcal{D}$  making at most  $3 \cdot 2^{n/2}$  construction queries and at most  $3 \cdot 2^{n/2}$  primitive queries such that*

$$\mathbf{Adv}_{F1}^{\text{prf}}(\mathcal{D}) \geq 1 - \frac{1}{e}. \quad (3)$$

*Proof.* As the mixing functions  $L_1, L_2$  are linear, we can represent these as

$$\begin{aligned} L_1 &= (l_{11} \ l_{12}) \\ L_2 &= (l_{21} \ l_{22} \ l_{23}), \end{aligned}$$

where  $L_1, L_2$  are evaluated on  $(K_1, M)$  and  $(K_2, x, y)$ , respectively.

The distinguisher's advantage satisfies

$$\mathbf{Adv}_{F1}^{\text{prf}}(\mathcal{D}) = \left| \Pr \left[ \mathcal{D}^{F1^\pi, \pi^\pm} = 1 \right] - \Pr \left[ \mathcal{D}^{\varphi, \pi^\pm} = 1 \right] \right|.$$

**Subcase  $l_{12} = \mathbf{0} \vee l_{23} = \mathbf{0}$ .** In this case, the input to or the output of the permutation  $\pi$  is not related to  $M$  or  $C$ . When  $l_{12} = \mathbf{0}$ , the distinguisher selects arbitrary  $M, M'$  to obtain  $C, C'$ . If the event  $C = C'$  happens, then output 1; otherwise, output 0. This gives a distinguisher in two construction queries with a success probability of  $1 - 1/2^n$ . Similar for  $l_{23} = \mathbf{0}$ .

**Subcase  $l_{11} = \mathbf{0} \vee l_{21} = \mathbf{0}$ .** In this case, the input to or the output of the permutation  $\pi$  is independent of the keys. When  $l_{11} = 0$ , the distinguisher selects arbitrary  $x, x'$  to obtain  $y, y'$ . Then, it puts  $M = l_{12}^{-1}x$  and  $M' = l_{12}^{-1}x'$  to obtain  $C$  and  $C'$ . If the event  $A$  happens, then output 1; otherwise, output 0:

$$A = \begin{cases} C \oplus C' = l_{23}y \oplus l_{23}y' & \text{if } l_{22} = 0, \\ C \oplus C' = l_{23}y \oplus l_{23}y' \oplus l_{22}x \oplus l_{22}x' & \text{if } l_{22} \neq 0. \end{cases}$$

This gives a distinguisher in two construction and two primitive queries with a success probability of  $1 - 1/2^n$ . Similar for  $l_{21} = 0$ .

**Subcase  $l_{22} = \mathbf{0}$ .** In this case, the construction is a generalization of the Even-Mansour cipher. We will construct a distinguisher  $\mathcal{D}$  distinguishing the real world oracle  $(F1^\pi, \pi)$  from the ideal world oracle  $(\varphi, \pi)$  with significant probability.  $\mathcal{D}$  makes  $2^{n/2}$  construction queries and no primitive queries and operates as follows. For  $j = 1, \dots, 2^{n/2}$ , the distinguisher selects arbitrary  $M^{(j)}$ 's to obtain  $C^{(j)}$ . If we have  $C^{(\bar{j})} \neq C^{(\bar{j}')}$  for all query indices  $\bar{j} \neq \bar{j}'$ , then output 1; otherwise, output 0.

In the real world,  $F1$  behaves as a PRP, and thus  $\Pr \left[ \mathcal{D}^{F1^\pi, \pi^\pm} = 1 \right] = 1$ . For the ideal world, we have

$$\Pr \left[ \mathcal{D}^{\varphi, \pi^\pm} = 1 \right] = \Pr \left[ \bigcap_{j, j'} C^{(j)} \neq C^{(j')} \right] \leq 1 - \left( 1 - e^{-\binom{q}{2} \frac{1}{2^n}} \right) = e^{-\binom{q}{2} \frac{1}{2^n}},$$

where  $q = 2^{n/2}$ .

**Subcase  $l_{11}, l_{12}, l_{21}, l_{22}, l_{23} \neq \mathbf{0}$ .** This is the most general subcase. We will construct a distinguisher  $\mathcal{D}$  distinguishing the real world oracle  $(F1^\pi, \pi)$  from the ideal world oracle  $(\varphi, \pi)$  with significant probability. The distinguisher  $\mathcal{D}$  returns 1 if it guesses that it is interacting with the real world oracle and returns 0 otherwise.  $\mathcal{D}$  makes  $3 \cdot 2^{n/2}$  construction queries, and  $3 \cdot 2^{n/2}$  primitive queries to  $\pi$  in total and operates as follows.

- (i) For  $j = 1, \dots, 2^{n/2}$ , query  $M^{(j)} = l_{12}^{-1}(\langle j \rangle_{n/2} \parallel 0^{n/2})$  to obtain  $C^{(j)}$ , query  $M^{*(j)} = l_{12}^{-1}(\langle j \rangle_{n/2} \parallel 0^{n/2-1}1)$  to obtain  $C^{*(j)}$ , and  $M^{**(j)} = l_{12}^{-1}(\langle j \rangle_{n/2} \parallel 0^{n/2-2}10)$  to obtain  $C^{**(j)}$ ;
- (ii) For  $i = 1, \dots, 2^{n/2}$ , query  $x^{(i)} = 0^{n/2} \parallel \langle i \rangle_{n/2}$  to obtain  $y^{(i)}$ . Define  $(x^{*(i)}, y^{*(i)})$  and  $(x^{**(i)}, y^{**(i)})$  as the tuples that satisfy  $x^{*(i)} = x^{(i)} \oplus 0^{n-1}1$  and  $x^{**(i)} = x^{(i)} \oplus 0^{n-2}10$ , respectively;
- (iii) If there are two query indices  $\bar{j}, \bar{i}$  such that  $C^{(\bar{j})} \oplus C^{*(\bar{j})} = l_{22}(x^{(\bar{i})} \oplus x^{*(\bar{i})}) \oplus l_{23}(y^{(\bar{i})} \oplus y^{*(\bar{i})})$  and  $C^{(\bar{j})} \oplus C^{**(j)} = l_{22}(x^{(\bar{i})} \oplus x^{**(i)}) \oplus l_{23}(y^{(\bar{i})} \oplus y^{**(i)})$ , then output 1; otherwise, output 0.

In the real world, there is exactly one  $(\bar{j}, \bar{i})$  such that  $l_{11}^{-1}(l_{12}M^{(\bar{j})} \oplus x^{(\bar{i})}) = K_1$ , leading to

$$C^{(\bar{j})} = l_{22}x^{(\bar{i})} \oplus l_{23}y^{(\bar{i})} \oplus l_{21}K_2.$$

In addition, also  $l_{11}^{-1}(l_{12}M^{*(\bar{j})} \oplus x^{*(\bar{i})}) = K_1$  and  $l_{11}^{-1}(l_{12}M^{**(\bar{j})} \oplus x^{**(\bar{i})}) = K_1$ , leading to

$$\begin{aligned} C^{*(\bar{j})} &= l_{22}x^{*(\bar{i})} \oplus l_{23}y^{*(\bar{i})} \oplus l_{21}K_2, \\ C^{**(\bar{j})} &= l_{22}x^{**(\bar{i})} \oplus l_{23}y^{**(\bar{i})} \oplus l_{21}K_2. \end{aligned}$$

The equations imply that

$$\begin{aligned} A_{\bar{j},\bar{i}}: C^{(\bar{j})} \oplus C^{*(\bar{j})} &= l_{22}(x^{(\bar{i})} \oplus x^{*(\bar{i})}) \oplus l_{23}(y^{(\bar{i})} \oplus y^{*(\bar{i})}), \\ B_{\bar{j},\bar{i}}: C^{(\bar{j})} \oplus C^{**(\bar{j})} &= l_{22}(x^{(\bar{i})} \oplus x^{**(\bar{i})}) \oplus l_{23}(y^{(\bar{i})} \oplus y^{**(\bar{i})}), \end{aligned}$$

and thus that  $\Pr[\mathcal{D}^{F1^\pi, \pi^\pm} = 1] = 1$ .

For the ideal world, we have

$$\Pr[\mathcal{D}^{\varphi, \pi^\pm} = 1] = \Pr[\cup_{j,i} A_{j,i} \wedge B_{j,i}] \leq \frac{qp}{2^{2n}},$$

where  $q = p = 2^{n/2}$ . □

## 4 Sum of Even-Mansour

We consider the *Sum of Even-Mansour* construction, called SoEM, that combines the sum of permutations of Bellare et al. [6] with the Even-Mansour cipher [29]. Let  $n \in \mathbb{N}$ , and let  $\pi_1, \pi_2 \in \text{Perm}(n)$ . One can consider a generic construction SoEM:  $\{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  as

$$\text{SoEM}(K_1, K_2, M) = \pi_1(M \oplus K_1) \oplus K_1 \oplus \pi_2(M \oplus K_2) \oplus K_2. \quad (4)$$

See also Figure 3. We will consider the construction for three variants: SoEM1 for the case where  $\pi_1$  and  $\pi_2$  are identical in Section 4.1, SoEM21 for the case where  $\pi_1, \pi_2$  are independent but  $K_1$  and  $K_2$  are identical (so the key space is  $n$  bits) in Section 4.2, and SoEM22 for the case where  $\pi_1, \pi_2$  are independent and  $K_1, K_2$  are independent in Section 4.3. Note that for SoEM21, we will have to make a slight adjustment, because by simply putting  $K_1 = K_2$  in above equation, the addition of the keys at the end of the permutation calls will cancel out. We will detail this in Section 4.2.

### 4.1 One Permutation

We show that SoEM1, where  $\pi_1 = \pi_2$  (but no a priori restriction on  $K_1, K_2$  is imposed) cannot achieve security beyond the birthday bound.

**Proposition 2.** *Let  $n \in \mathbb{N}$ , and consider SoEM1:  $\{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  based on permutation  $\pi \xleftarrow{\$} \text{Perm}(n)$  and two keys  $K_1, K_2 \xleftarrow{\$} \{0, 1\}^n$ . There exists a distinguisher  $\mathcal{D}$  making  $4 \cdot 2^{n/2}$  construction queries such that*

$$\text{Adv}_{\text{SoEM1}}^{\text{prf}}(\mathcal{D}) \geq 1 - \frac{1}{2^n}. \quad (5)$$

Fig. 3: Encryption of SoEM based on two keys  $K_1$  and  $K_2$ , and with  $\pi_1$  and  $\pi_2$  two public random permutations.

*Proof.* We will construct a distinguisher  $\mathcal{D}$  distinguishing the real world oracle (SoEM $1^\pi, \pi^\pm$ ) from the ideal world oracle  $(\varphi, \pi^\pm)$  with significant probability. The distinguisher  $\mathcal{D}$  returns 1 if it guesses that it is interacting with the real world oracle and returns 0 otherwise.  $\mathcal{D}$  makes  $4 \cdot 2^{n/2}$  construction queries and no primitive queries and operates as follows.

- (i) For  $j = 1, \dots, 2^{n/2}$ , query  $M^{(j)} = \langle j \rangle_{n/2} \parallel 0^{n/2}$  to obtain  $C^{(j)}$ , and query  $M^{*(j)} = M^{(j)} \oplus 0^{n-1}1$  to obtain  $C^{*(j)}$ ;
- (ii) For  $j' = 1, \dots, 2^{n/2}$ , query  $M^{(j')} = 0^{n/2} \parallel \langle j' \rangle_{n/2}$  to obtain  $C^{(j')}$ . Define  $(M^{*(j')}, C^{*(j')})$  as the tuple that satisfies  $M^{*(j')} = M^{(j')} \oplus 0^{n-1}1$ ;
- (iii) If there are two query indices  $\bar{j}, \bar{j}'$  such that  $C^{(\bar{j})} = C^{(\bar{j}')}$  and  $C^{*(\bar{j})} = C^{*(\bar{j}')}$ , then output 1; otherwise, output 0.

The distinguisher's advantage satisfies

$$\text{Adv}_{\text{SoEM1}}^{\text{prf}}(\mathcal{D}) = \left| \Pr \left[ \mathcal{D}^{\text{SoEM1}_{K_1, K_2, \pi^\pm}} = 1 \right] - \Pr \left[ \mathcal{D}^{\varphi, \pi^\pm} = 1 \right] \right|.$$

In the real world, there is exactly one  $(\bar{j}, \bar{j}')$  such that  $M^{(\bar{j})} \oplus M^{(\bar{j}')} = K_1 \oplus K_2$ , leading to  $C^{(\bar{j})} = C^{(\bar{j}')}$  in the real world. In addition, also  $M^{*(\bar{j})} \oplus M^{*(\bar{j}')} = K_1 \oplus K_2$ , and  $C^{*(\bar{j})} = C^{*(\bar{j}')}$  as well. Thus,  $\Pr \left[ \mathcal{D}^{\text{SoEM1}_{K_1, K_2, \pi^\pm}} = 1 \right] = 1$ .

For the ideal world, we have

$$\Pr \left[ \mathcal{D}^{\varphi, \pi^\pm} = 1 \right] = \Pr \left[ \cup_{j, j'} C^{(j)} = C^{(j')} \wedge C^{*(j)} = C^{*(j')} \right] \leq \frac{q^2}{2^{2n}},$$

where  $q = 2^{n/2}$ . □

Note that the cost of step (i) in the attack can be reduced by only querying  $M^{*(j)}$  for  $j = \bar{j}$ , but this would complicate the simple description of the distinguisher.

## 4.2 Two Permutations, One Key

Let  $n \in \mathbb{N}$ . Let  $\pi_1, \pi_2 : \{0, 1\}^n \rightarrow \{0, 1\}^n$  be two independent random permutations. We define SoEM construction based on  $\pi_1, \pi_2$  and using a single key  $K$  as follows:

$$\text{SoEM21}^{\pi_1, \pi_2}(K, M) = \pi_1(M \oplus K) \oplus \pi_2(M \oplus K) \oplus K, \quad (6)$$

and we show that SoEM21 cannot achieve beyond the birthday bound security.

**Proposition 3.** *Let  $n \in \mathbb{N}$ , and consider SoEM21:  $\{0, 1\}^n \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  based on two permutations  $\pi_1, \pi_2 \xleftarrow{\$} \text{Perm}(n)$  and one key  $K \xleftarrow{\$} \{0, 1\}^n$ . There exists a distinguisher  $\mathcal{D}$  making  $3 \cdot 2^{n/2}$  construction queries,  $3 \cdot 2^{n/2}$  primitive queries to  $\pi_1$ , and  $3 \cdot 2^{n/2}$  primitive queries to  $\pi_2$  such that*

$$\text{Adv}_{\text{SoEM21}}^{\text{prf}}(\mathcal{D}) \geq 1 - \frac{1}{2^n}. \quad (7)$$

*Proof.* We will construct a distinguisher  $\mathcal{D}$  distinguishing the real world oracle (SoEM21 $_{K}^{\pi_1, \pi_2}, \pi_1^{\pm}, \pi_2^{\pm}$ ) from the ideal world oracle  $(\varphi, \pi_1^{\pm}, \pi_2^{\pm})$  with significant probability. The distinguisher  $\mathcal{D}$  returns 1 if it guesses that it is interacting with the real world oracle and returns 0 otherwise.  $\mathcal{D}$  makes  $3 \cdot 2^{n/2}$  construction queries,  $3 \cdot 2^{n/2}$  primitive queries to  $\pi_1$ , and  $3 \cdot 2^{n/2}$  primitive query to  $\pi_2$  in total and operates as follows.

- (i) For  $j = 1, \dots, 2^{n/2}$ , query  $M^{(j)} = \langle j \rangle_{n/2} \parallel 0^{n/2}$  to obtain  $C^{(j)}$ , query  $M^{*(j)} = \langle j \rangle_{n/2} \parallel 0^{n/2-1}1$  to obtain  $C^{*(j)}$ , and query  $M^{**(j)} = \langle j \rangle_{n/2} \parallel 0^{n/2-2}10$  to obtain  $C^{**(j)}$ ;
- (ii) For  $i = 1, \dots, 2^{n/2}$ , query  $x^{(i)} = 0^{n/2} \parallel \langle i \rangle_{n/2}$  to  $\pi_1$  and  $\pi_2$  to obtain  $y_1^{(i)}$  and  $y_2^{(i)}$ . Define  $(x^{*(i)}, y_1^{*(i)})$  and  $(x^{**(i)}, y_1^{**(i)})$  as the tuples that satisfy  $x^{*(i)} = x^{(i)} \oplus 0^{n-1}1$  and  $x^{**(i)} = x^{(i)} \oplus 0^{n-2}10$ , respectively, and similarly for the queries to  $\pi_2$ ;
- (iii) If there are two query indices  $\bar{j}, \bar{i}$  such that  $C^{(\bar{j})} \oplus C^{*(\bar{j})} = y_1^{(\bar{i})} \oplus y_1^{*(\bar{i})} \oplus y_2^{(\bar{i})} \oplus y_2^{*(\bar{i})}$  and  $C^{(\bar{j})} \oplus C^{**(j)} = y_1^{(\bar{i})} \oplus y_1^{**(i)} \oplus y_2^{(\bar{i})} \oplus y_2^{**(i)}$ , then output 1; otherwise, output 0.

The distinguisher's advantage satisfies

$$\text{Adv}_{\text{SoEM21}}^{\text{prf}}(\mathcal{D}) = \left| \Pr \left[ \mathcal{D}^{\text{SoEM21}^{\pi_1, \pi_2, \pi_1^{\pm}, \pi_2^{\pm}}} = 1 \right] - \Pr \left[ \mathcal{D}^{\varphi, \pi_1^{\pm}, \pi_2^{\pm}} = 1 \right] \right|.$$

In the real world, there is exactly one  $(\bar{j}, \bar{i})$  such that  $M^{(\bar{j})} \oplus x^{(\bar{i})} = K$ , leading to

$$C^{(\bar{j})} = y_1^{(\bar{i})} \oplus y_2^{(\bar{i})} \oplus K.$$

In addition, also  $M^{*(\bar{j})} \oplus x^{*(\bar{i})} = K$  and  $M^{**(j)} \oplus x^{**(i)} = K$ , leading to

$$\begin{aligned} C^{*(\bar{j})} &= y_1^{*(\bar{i})} \oplus y_2^{*(\bar{i})} \oplus K, \\ C^{**(j)} &= y_1^{**(i)} \oplus y_2^{**(i)} \oplus K. \end{aligned}$$

The equations imply that

$$\begin{aligned} A_{\bar{j},\bar{i}}: C^{(\bar{j})} \oplus C^{*(\bar{j})} &= y_1^{(\bar{i})} \oplus y_1^{*(\bar{i})} \oplus y_2^{(\bar{i})} \oplus y_2^{*(\bar{i})}, \\ B_{\bar{j},\bar{i}}: C^{(\bar{j})} \oplus C^{**(\bar{j})} &= y_1^{(\bar{i})} \oplus y_1^{**(\bar{i})} \oplus y_2^{(\bar{i})} \oplus y_2^{**(\bar{i})}, \end{aligned}$$

and thus that  $\Pr \left[ \mathcal{D}^{\text{SoEM22}^{\pi_1, \pi_2, \pi_1^\pm, \pi_2^\pm}} = 1 \right] = 1$ .

For the ideal world, we have

$$\Pr \left[ \mathcal{D}^{\varphi, \pi_1^\pm, \pi_2^\pm} = 1 \right] = \Pr \left[ \bigcup_{j,i} A_{j,i} \wedge B_{j,i} \right] \leq \frac{qp}{2^{2n}},$$

where  $q = p = 2^{n/2}$ . □

### 4.3 Two Permutations, Two Keys

We prove that SoEM22 for independent  $\pi_1, \pi_2$  and independent  $K_1, K_2$  is secure up to attack complexity  $2^{2n/3}$ . We also demonstrate an attack matching this bound.

**Theorem 1.** *Let  $n \in \mathbb{N}$ , and consider SoEM22:  $\{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  based on two permutations  $\pi_1, \pi_2 \xleftarrow{\$} \text{Perm}(n)$  and two keys  $K_1, K_2 \xleftarrow{\$} \{0, 1\}^n$ . For any distinguisher  $\mathcal{D}$  making at most  $q$  construction queries, at most  $p$  primitive queries to  $\pi_1^\pm$  and  $p$  primitive queries to  $\pi_2^\pm$ , we have*

$$\mathbf{Adv}_{\text{SoEM22}}^{\text{prf}}(\mathcal{D}) \leq \frac{4q(p+q)^2}{2^{2n}} + \frac{3qp^2}{2^{2n}}. \quad (8)$$

The proof is given in Section 5.2.

**Proposition 4.** *Let  $n \in \mathbb{N}$ , and consider SoEM22:  $\{0, 1\}^{2n} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  based on two permutations  $\pi_1, \pi_2 \xleftarrow{\$} \text{Perm}(n)$  and two keys  $K_1, K_2 \xleftarrow{\$} \{0, 1\}^n$ . There exists a distinguisher  $\mathcal{D}$  making  $4 \cdot 2^{2n/3}$  construction queries, and  $4 \cdot 2^{2n/3}$  primitive queries to  $\pi_1$  and  $4 \cdot 2^{2n/3}$  primitive queries to  $\pi_2$  such that*

$$\mathbf{Adv}_{\text{SoEM22}}^{\text{prf}}(\mathcal{D}) \geq 1 - \frac{1}{e} - \frac{1}{2^n}. \quad (9)$$

*Proof.* We will construct a distinguisher  $\mathcal{D}$  distinguishing the real world oracle ( $\text{SoEM22}_{K_1, K_2}^{\pi_1, \pi_2, \pi_1^\pm, \pi_2^\pm}$ ) from the ideal world oracle  $(\varphi, \pi_1^\pm, \pi_2^\pm)$  with significant probability. The distinguisher  $\mathcal{D}$  returns 1 if it guesses that it is interacting with the real world oracle and returns 0 otherwise.  $\mathcal{D}$  makes  $4 \cdot 2^{2n/3}$  construction queries,  $4 \cdot 2^{2n/3}$  primitive queries to  $\pi_1$ , and  $4 \cdot 2^{2n/3}$  primitive query to  $\pi_2$  in total and operates as follows.

- (i) For  $j = 1, \dots, 2^{2n/3}$ , query  $M^{(j)} = \langle j \rangle_{2n/3} \parallel 0^{n/3}$  to obtain  $C^{(j)}$ , query  $M^{*(j)} = \langle j \rangle_{2n/3} \parallel 0^{n/3-1}1$  to obtain  $C^{*(j)}$ , query  $M^{**(j)} = \langle j \rangle_{2n/3} \parallel 0^{n/3-2}10$  to obtain  $C^{**(j)}$ , and query  $M^{***(j)} = \langle j \rangle_{2n/3} \parallel 0^{n/3-2}11$  to obtain  $C^{***(j)}$ ;

- (ii) For  $i = 1, \dots, 2^{2n/3}$ , query  $u^{(i)} = 0^{n/3} \parallel \langle i \rangle_{2n/3}$  to  $\pi_1$  to obtain  $v^{(i)}$ . Define  $(u^{*(i)}, v^{*(i)})$ ,  $(u^{**(i)}, v^{**(i)})$ , and  $(u^{***(\bar{i})}, v^{***(\bar{i})})$  as the tuples that satisfy  $u^{*(i)} = u^{(i)} \oplus 0^{n-1}1$ ,  $u^{**(i)} = u^{(i)} \oplus 0^{n-2}10$ , and  $u^{***(\bar{i})} = u^{(i)} \oplus 0^{n-2}11$ , respectively;
- (iii) For  $i' = 1, \dots, 2^{2n/3}$ , query  $x^{(i')}$  at random to obtain  $y^{(i')}$ , query  $x^{*(i')} = x^{(i')} \oplus 0^{n-1}1$  to obtain  $y^{*(i')}$ , query  $x^{**(i')} = x^{(i')} \oplus 0^{n-2}10$  to obtain  $y^{**(i')}$ , and query  $x^{***(\bar{i}')} = x^{(i')} \oplus 0^{n-2}11$  to obtain  $y^{***(\bar{i}')}$ ;
- (iv) If there are three query indices  $\bar{j}, \bar{i}, \bar{i}'$  such that  $C^{(\bar{j})} \oplus C^{*(\bar{j})} = v^{(\bar{i})} \oplus v^{*(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{*(\bar{i}')}$ ,  $C^{(\bar{j})} \oplus C^{**(\bar{j})} = v^{(\bar{i})} \oplus v^{**(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{**(\bar{i}')}$  and  $C^{(\bar{j})} \oplus C^{***(\bar{j})} = v^{(\bar{i})} \oplus v^{***(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{***(\bar{i}')}$ , then output 1; otherwise, output 0.

The distinguisher's advantage satisfies

$$\mathbf{Adv}_{\text{SoEM22}}^{\text{prf}}(\mathcal{D}) = \left| \Pr \left[ \mathcal{D}^{\text{SoEM22}^{\pi_1, \pi_2, \pi_1^\pm, \pi_2^\pm}} = 1 \right] - \Pr \left[ \mathcal{D}^{\varphi, \pi_1^\pm, \pi_2^\pm} = 1 \right] \right|.$$

Put  $q = p = 2^{2n/3}$ . First consider the real world. Define  $I_{K_1} = \{(j, i) : M^{(j)} \oplus u^{(i)} = K_1\}$ , and note that  $|I_{K_1}| = 2^{n/3}$ . We denote by  $E_{j, i'}$  the event that  $M^{(j)} \oplus x^{(i')} = K_2$ , for fixed  $j, i'$  where  $(j, \cdot) \in I_{K_1}$ . For each  $j, i'$ , we have  $\Pr[E_{j, i'}] = 1/2^n$ , and we obtain from the union bound:

$$\Pr[\cup_{j, i'} E_{j, i'}] \leq \frac{2^{n/3}p}{2^n}. \quad (10)$$

For the lower bound, we denote by  $D_j$  the event that a fixed  $j$  with  $(j, \cdot) \in I_{K_1}$  satisfies  $M^{(j)} \oplus x^{(i')} \neq K_2$  for all  $i'$ . Note that the  $D_j$ 's are mutually independent for different  $j$ , and the probability of any  $D_j$  is

$$\Pr[D_j] = \frac{2^n - p}{2^n} = 1 - \frac{p}{2^n}.$$

The probability of  $M^{(j)} \oplus x^{(i')} \neq K_2$  for all  $j, i'$  can now be computed as

$$1 - \Pr[\cup_{j, i'} E_{j, i'}] = \prod_{j=1}^{2^{n/3}} \Pr[D_j] = \prod_{j=1}^{2^{n/3}} \left( 1 - \frac{p}{2^n} \right).$$

As  $p/2^n \leq 1$ , we can use the inequality  $1 - x \leq e^{-x}$  for each term of above expression, and find an upper bound

$$\prod_{j=1}^{2^{n/3}} e^{-\frac{p}{2^n}} = e^{-\frac{2^{n/3}p}{2^n}}.$$

Putting all this together we get the lower bound

$$\Pr[\cup_{j, i'} E_{j, i'}] \geq 1 - e^{-\frac{2^{n/3}p}{2^n}}. \quad (11)$$

Note that if there exist  $(\bar{j}, \bar{i}) \in I_{K_1}$  and  $\bar{i}'$  such that  $M^{(\bar{j})} \oplus x^{(\bar{i}')} = K_2$ , we also have that

$$C^{(\bar{j})} \oplus v^{(\bar{i})} \oplus y^{(\bar{i}')} = K_1 \oplus K_2. \quad (12)$$

We in addition have that  $(M^{(\bar{j})} \oplus \Delta) \oplus (u^{(\bar{i})} \oplus \Delta) = K_1$  and that  $(M^{(\bar{j})} \oplus \Delta) \oplus (x^{(\bar{i}')} \oplus \Delta) = K_2$  for any  $\Delta \in \{0, 1\}^n$ . Due to our definition of  $M^{**(\bar{j})}$ ,  $M^{***(\bar{j})}$ ,  $u^{**(\bar{j})}$ ,  $u^{***(\bar{j})}$ ,  $x^{**(\bar{j})}$ , and  $x^{***(\bar{j})}$ , we thus obtain that also

$$\begin{aligned} C^{*(\bar{j})} \oplus v^{*(\bar{i})} \oplus y^{*(\bar{i}')} &= K_1 \oplus K_2, \\ C^{**(\bar{j})} \oplus v^{**(\bar{i})} \oplus y^{**(\bar{i}')} &= K_1 \oplus K_2, \\ C^{***(\bar{j})} \oplus v^{***(\bar{i})} \oplus y^{***(\bar{i}')} &= K_1 \oplus K_2. \end{aligned}$$

Combining these three equations with (12), we can conclude that under the premise that (12) holds, the following three events

$$\begin{aligned} A_{\bar{j}, \bar{i}, \bar{i}'} &: C^{(\bar{j})} \oplus C^{*(\bar{j})} = v^{(\bar{i})} \oplus v_1^{*(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{*(\bar{i}')}, \\ B_{\bar{j}, \bar{i}, \bar{i}'} &: C^{(\bar{j})} \oplus C^{**(\bar{j})} = v^{(\bar{i})} \oplus v^{**(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{**(\bar{i}')}, \\ C_{\bar{j}, \bar{i}, \bar{i}'} &: C^{(\bar{j})} \oplus C^{***(\bar{j})} = v^{(\bar{i})} \oplus v^{***(\bar{i})} \oplus y^{(\bar{i}')} \oplus y^{***(\bar{i}')}, \end{aligned}$$

are satisfied in the real world. Therefore, for the real world, we can conclude the following:

$$\begin{aligned} &\Pr \left[ \mathcal{D}^{\text{SoEM22}^{\pi_1, \pi_2, \pi_1^\pm, \pi_2^\pm}} = 1 \right] \\ &= \Pr [\cup_{j, i'} E_{j, i'}] + \Pr [\cup_{j, i, i'} A_{j, i, i'} \wedge B_{j, i, i'} \wedge C_{j, i, i'} \mid \cap_{j, i'} \neg E_{j, i'}] \cdot \Pr [\cap_{j, i'} \neg E_{j, i'}]. \end{aligned}$$

From (10) and (11), we obtain

$$\begin{aligned} \Pr \left[ \mathcal{D}^{\text{SoEM22}^{\pi_1, \pi_2, \pi_1^\pm, \pi_2^\pm}} = 1 \right] &\geq 1 - e^{-\frac{2^{n/3}p}{2^n}} + \frac{qp^2}{2^{3n}} \left( 1 - \frac{2^{n/3}p}{2^n} \right) \\ &= 1 - e^{-\frac{2^{n/3}p}{2^n}}, \end{aligned}$$

where  $p = 2^{2n/3}$ .

For the ideal world, we have

$$\Pr \left[ \mathcal{D}^{\varphi, \pi_1^\pm, \pi_2^\pm} = 1 \right] = \Pr [\cup_{j, i, i'} A_{j, i, i'} \wedge B_{j, i, i'} \wedge C_{j, i, i'}] \leq \frac{qp^2}{2^{3n}},$$

where  $q = p = 2^{2n/3}$ . □

## 5 Security Proofs

The security proof of SoEM22 is given in Section 5.2. The proof is performed using Patarin's H-coefficient technique, which we will recap in Section 5.1. The analysis for good transcripts resembles ideas of the first iteration in Patarin's mirror theory, but difficulties appear in the fact that the distinguisher can make direct queries to the permutations  $\pi_1$  and  $\pi_2$ .

## 5.1 Patarin’s H-Coefficient Technique

In this work, we use the H-coefficient technique by Patarin [52, 54], but we will follow the modernization of Chen and Steinberger [19].

Let  $\pi_1, \pi_2, \dots, \pi_r \xleftarrow{\$} \text{Perm}(n)$ , and  $\varphi \xleftarrow{\$} \text{Func}(n)$ . Let  $K \xleftarrow{\$} \{0, 1\}^k$ , and  $F: \{0, 1\}^k \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be a pseudorandom function based on public random permutations  $\pi_1, \pi_2, \dots, \pi_r$ . We consider a deterministic distinguisher  $\mathcal{D}$  that has query access to either the real world oracle  $\mathcal{O} = (F_K^{\pi_1, \dots, \pi_r}, \pi_1^\pm, \dots, \pi_r^\pm)$  or the ideal world oracle  $\mathcal{P} = (\varphi, \pi_1^\pm, \dots, \pi_r^\pm)$ . The distinguisher’s goal is to distinguish both worlds and we denote by

$$\mathbf{Adv}(\mathcal{D}) = |\Pr[\mathcal{D}^{\mathcal{O}} = 1] - \Pr[\mathcal{D}^{\mathcal{P}} = 1]|$$

its advantage. We summarize all query-response tuples learned by  $\mathcal{D}$  during its interaction with its oracle  $\mathcal{O}$  or  $\mathcal{P}$  in a transcript  $\tau$ . We denote by  $X_{\mathcal{O}}$  (resp.  $X_{\mathcal{P}}$ ) the probability distribution of transcripts when interacting with  $\mathcal{O}$  (resp.  $\mathcal{P}$ ). We call a transcript  $\tau \in \mathcal{T}$  attainable if  $\Pr[X_{\mathcal{P}} = \tau] > 0$ , or in other words if the transcript  $\tau$  can be obtained from an interaction with  $\mathcal{P}$ .

**Lemma 1 (H-coefficient Technique).** *Consider a deterministic distinguisher  $\mathcal{D}$ . Define a partition  $\mathcal{T} = \mathcal{T}_{\text{good}} \cup \mathcal{T}_{\text{bad}}$ , where  $\mathcal{T}_{\text{good}}$  is the subset of  $\mathcal{T}$  which contains all the “good” transcripts and  $\mathcal{T}_{\text{bad}}$  is the subset with all the “bad” transcripts. Let  $0 \leq \epsilon \leq 1$  be such that for all  $\tau \in \mathcal{T}_{\text{good}}$ :*

$$\frac{\Pr(X_{\mathcal{O}} = \tau)}{\Pr(X_{\mathcal{P}} = \tau)} \geq 1 - \epsilon. \quad (13)$$

Then, we have  $\mathbf{Adv}(\mathcal{D}) \leq \epsilon + \Pr[X_{\mathcal{P}} \in \mathcal{T}_{\text{bad}}]$ .

## 5.2 Proof of Theorem 1 on SoEM22

Let  $K = (K_1, K_2) \xleftarrow{\$} \{0, 1\}^{2n}$ ,  $\pi_1, \pi_2 \xleftarrow{\$} \text{Perm}(n)$ , and  $\varphi \xleftarrow{\$} \text{Func}(n)$ . Consider any distinguisher  $\mathcal{D}$  that has access to three oracles:  $(\text{SoEM22}_K^{\pi_1, \pi_2}, \pi_1^\pm, \pi_2^\pm)$  in the real world or  $(\varphi, \pi_1^\pm, \pi_2^\pm)$  in the ideal world. We assume  $\mathcal{D}$  is computational unbounded and deterministic. The distinguisher makes  $q$  construction queries to  $\mathcal{O}_0 \in \{\text{SoEM22}_K^{\pi_1, \pi_2}, \varphi\}$ , and these are summarized in a transcript of the form  $\tau_0 = \{(M^{(1)}, C^{(1)}), \dots, (M^{(q)}, C^{(q)})\}$ . It also makes  $p$  primitive queries to  $\mathcal{O}_1 = \pi_1^\pm$  and  $p$  primitive queries to  $\mathcal{O}_2 = \pi_2^\pm$ , and like before, these are respectively summarized in transcripts  $\tau_1 = \{(u^{(1)}, v^{(1)}), \dots, (u^{(p)}, v^{(p)})\}$  and  $\tau_2 = \{(x^{(1)}, y^{(1)}), \dots, (x^{(p)}, y^{(p)})\}$ . We assume that  $\tau_0$ ,  $\tau_1$ , and  $\tau_2$  do not contain duplicate elements. After  $\mathcal{D}$ ’s interaction with the oracles, but before it outputs its decision, we disclose the keys  $K_1, K_2$  to the distinguisher. In real world, these are the keys used in the construction. In the ideal world  $K_1, K_2$  are dummy keys that are drawn uniformly at random. The complete view is denoted  $\tau = (\tau_0, \tau_1, \tau_2, K_1, K_2)$ .

**Bad Events.** We say that  $\tau \in \mathcal{T}_{\text{bad}}$  if and only if there exists a construction query  $(M^{(j)}, C^{(j)}) \in \tau_0$  and primitive queries  $(u^{(i)}, v^{(i)}) \in \tau_1$  and  $(x^{(i')}, y^{(i')}) \in \tau_2$

$\tau_2$  such that one of the following conditions holds:

$$\text{bad}_1: M^{(j)} \oplus u^{(i)} = K_1 \wedge M^{(j)} \oplus x^{(i')} = K_2, \quad (14)$$

$$\text{bad}_2: M^{(j)} \oplus u^{(i)} = K_1 \wedge C^{(j)} \oplus v^{(i)} \oplus y^{(i')} = K_1 \oplus K_2, \quad (15)$$

$$\text{bad}_3: M^{(j)} \oplus x^{(i')} = K_2 \wedge C^{(j)} \oplus v^{(i)} \oplus y^{(i')} = K_1 \oplus K_2. \quad (16)$$

Note that any attainable transcript  $\tau$  for which  $\tau \notin \mathcal{T}_{\text{bad}}$ , implies that  $\tau$  is a good transcript.

We give an informal explanation of the definition of the bad event. In the real world, every construction query  $j$  induces *exactly one* evaluation  $(u^{(j)}, v^{(j)})$  of the underlying public permutation  $\pi_1$ , and *exactly one* evaluation  $(x^{(j)}, y^{(j)})$  of the underlying public permutation  $\pi_2$ . These two queries naturally satisfy

$$\begin{aligned} M^{(j)} \oplus u^{(j)} &= K_1, \\ M^{(j)} \oplus x^{(j)} &= K_2, \\ C^{(j)} \oplus v^{(j)} \oplus y^{(j)} &= K_1 \oplus K_2. \end{aligned}$$

Clearly,  $u^{(j)}$  and  $x^{(j)}$  are fixed by  $M^{(j)}$ ,  $K_1$ , and  $K_2$ , but there is “freedom” in the value  $v^{(j)} \oplus y^{(j)}$ . If it happens to be that the distinguisher queried  $u^{(j)}$ , i.e., that  $(u^{(j)}, v^{(j)}) \in \tau_1$ , it consequently fixes the tuple  $(x^{(j)}, y^{(j)})$  for  $\pi_2$ . However, in the ideal world, there is no such dependency. This means that if the adversary had queried  $u^{(j)} = M^{(j)} \oplus K_1$  to  $\pi_1$  and  $x^{(j)} = M^{(j)} \oplus K_2$  to  $\pi_2$ , with high probability the third equation would not hold. An identical reasoning applies for the case where the distinguisher happened to have set any other two out of three equations.

**Pr** $[\mathbf{X}_{\mathcal{P}} \in \mathcal{T}_{\text{bad}}]$ . We want to bound the probability that an ideal world transcript  $\tau$  satisfies either of (14)-(16). Therefore, the probability that  $\tau \in \mathcal{T}_{\text{bad}}$  is given by

$$\Pr[\tau \in \mathcal{T}_{\text{bad}}] \leq \Pr[\text{bad}_1] + \Pr[\text{bad}_2] + \Pr[\text{bad}_3].$$

We consider the first bad event  $\text{bad}_1$ . For any possible construction query  $(M^{(j)}, C^{(j)}) \in \tau_0$ , any possible  $\pi_1$  primitive query  $(u^{(i)}, v^{(i)})$ , and any possible  $\pi_2$  primitive query  $(x^{(i')}, y^{(i')})$ , the only randomness in the first equation is  $K_1$  and the only randomness in the second equation is  $K_2$ . This means that the probabilities that each of the equation holds in  $\text{bad}_1$  are independent of each other. By the fact that the keys  $K = (K_1, K_2) \xleftarrow{\$} \{0, 1\}^{2n}$  are dummy keys generated independently of  $\tau_0$ ,  $\tau_1$  and  $\tau_2$ , the probability that  $\text{bad}_1$  holds for fixed  $j, i, i'$  is  $1/2^{2n}$ . Summed over all  $q$  possible construction queries,  $p$  possible  $\pi_1$  primitive queries, and  $p$  possible  $\pi_2$  primitive queries, we have

$$\Pr[\text{bad}_1] \leq \frac{qp^2}{2^{2n}}.$$

For the second bad event  $\text{bad}_2$ , note that we can replace  $K_1$  in the second equation by  $M^{(j)} \oplus u^{(i)}$ . Hereby, the only randomness in the first equation is

$K_1$  and the only randomness in the second equation is  $K_2$ . The probabilities that each of the equation holds in  $\text{bad}_2$  are independent of each other. Again, summing over all the construction and the primitive queries, we have

$$\Pr[\text{bad}_2] \leq \frac{qp^2}{2^{2n}}.$$

The same reasoning applies for  $\text{bad}_3$ . Summing the three probabilities, we get

$$\Pr[\tau \in \mathcal{T}_{\text{bad}}] \leq \frac{3qp^2}{2^{2n}}. \quad (17)$$

$\Pr[X_{\mathcal{O}} = \tau] / \Pr[X_{\mathcal{P}} = \tau]$ . Consider an attainable transcript  $\tau \in \mathcal{T}_{\text{good}}$ . To compute  $\Pr[X_{\mathcal{O}} = \tau]$  and  $\Pr[X_{\mathcal{P}} = \tau]$ , it suffices to compute the probability of oracles that could result in view  $\tau$ . Denote by  $\text{all}_{\mathcal{O}}$  the set of all oracles in the real world, and by  $\text{comp}_{\mathcal{O}}(\tau)$  the fraction of them compatible with  $\tau$ , we see that  $\Pr[X_{\mathcal{O}} = \tau] = |\text{comp}_{\mathcal{O}}(\tau)| / |\text{all}_{\mathcal{O}}|$ . Similarly we have  $\text{all}_{\mathcal{P}}$  and  $\text{comp}_{\mathcal{P}}(\tau)$  for the ideal world. We obtain

$$\frac{\Pr[X_{\mathcal{O}} = \tau]}{\Pr[X_{\mathcal{P}} = \tau]} = \frac{|\text{comp}_{\mathcal{O}}(\tau)| \cdot |\text{all}_{\mathcal{P}}|}{|\text{all}_{\mathcal{O}}| \cdot |\text{comp}_{\mathcal{P}}(\tau)|}. \quad (18)$$

For the real world  $\mathcal{O}$ , we have  $|\text{all}_{\mathcal{O}}| = 2^{2n} \cdot (2^n!)^2$ , which is equal to the number of possible keys  $K = (K_1, K_2)$  times the number of possible public random permutations  $\pi_1$  and  $\pi_2$ . Similarly, for the ideal world  $\mathcal{P}$ , we have  $|\text{all}_{\mathcal{P}}| = 2^{2n} \cdot 2^{n^2} (2^n!)^2$ . The first term corresponds to the number of randomly drawn keys, the second term is the number of possible random functions  $\varphi \in \text{Func}(n)$ , and the last term the number of possible public random permutations  $\pi_1$  and  $\pi_2$ . For the computation of the number of oracles compatible with  $\tau$  in the ideal world, we see that there are  $2^{n(2^n - q)}$  random functions  $\varphi \in \text{Func}(n)$  compliant with  $\tau_0$ ,  $(2^n - p)!$  public random permutations  $\pi_1$  compliant with  $\tau_1$ , and  $(2^n - p)!$  public random permutations  $\pi_2$  compliant with  $\tau_2$ . We find

$$|\text{comp}_{\mathcal{P}}(\tau)| = 2^{n(2^n - q)} \cdot (2^n - p)!^2.$$

From (18), we have

$$\frac{\Pr[X_{\mathcal{O}} = \tau]}{\Pr[X_{\mathcal{P}} = \tau]} = \frac{|\text{comp}_{\mathcal{O}}(\tau)| \cdot 2^{2n} 2^{n^2} (2^n!)^2}{2^{2n} (2^n!)^2 \cdot (2^{n(2^n - q)}) (2^n - p)!^2} = \frac{|\text{comp}_{\mathcal{O}}(\tau)| \cdot 2^{nq}}{(2^n - p)!^2}. \quad (19)$$

What remains is the computation of the number of oracles compatible with  $\tau$  in the real world. As defined by the bad events, a transcript  $\tau$  is bad if we get both the same input or output to  $\pi_1$ , and the same input or output to  $\pi_2$ . This means that for any  $\tau \in \mathcal{T}_{\text{good}}$ , a construction query collides with at most one query in  $\tau_1 \cup \tau_2$ . We conclude this fact in the following claim:

*Claim.* For  $\tau \in \mathcal{T}_{\text{good}}$ , any construction query  $(M^{(j)}, C^{(j)}) \in \tau_0$  collides with at most one primitive query  $(u^{(i)}, v^{(i)}) \in \tau_1$  and at most one primitive query  $(x^{(i')}, y^{(i')}) \in \tau_2$ , but never with both a  $\tau_1$  and  $\tau_2$  query.

We will use this claim to re-group the transcripts  $\tau_0$ ,  $\tau_1$ , and  $\tau_2$  into three new transcripts  $\tau_0^{\text{new}}$ ,  $\tau_1^{\text{new}}$ , and  $\tau_2^{\text{new}}$ . We initially define  $\tau_0^{\text{new}} = \tau_0$ ,  $\tau_1^{\text{new}} = \tau_1$  and  $\tau_2^{\text{new}} = \tau_2$ . The trick will be to consider each individual construction query  $(M^{(j)}, C^{(j)})$ , and to operate as follows:

- if  $M^{(j)} \oplus K_1 = u^{(i)}$  for some  $i$ , then remove  $(M^{(j)}, C^{(j)})$  from  $\tau_0^{\text{new}}$ , and add  $(x, y) = (M^{(j)} \oplus K_2, C^{(j)} \oplus v^{(i)} \oplus K_1 \oplus K_2)$  to  $\tau_2^{\text{new}}$ ;
- if  $M^{(j)} \oplus K_2 = x^{(i')}$  for some  $i'$ , then remove  $(M^{(j)}, C^{(j)})$  from  $\tau_0^{\text{new}}$ , and add  $(u, v) = (M^{(j)} \oplus K_1, C^{(j)} \oplus y^{(i')} \oplus K_1 \oplus K_2)$  to  $\tau_1^{\text{new}}$ .

Note that any good transcript will have to meet  $\neg\text{bad}_1 \wedge \neg\text{bad}_2 \wedge \neg\text{bad}_3$ . We know that if a construction query  $(M^{(j)}, C^{(j)})$  collides with  $(u^{(i)}, v^{(i)}) \in \tau_1$ , then  $M^{(j)} \oplus K_2$  cannot be a valid  $x^{(i')}$  value because of  $\neg\text{bad}_1$ , and  $C^{(j)} \oplus v^{(i)} \oplus K_1 \oplus K_2$  cannot be a valid  $y^{(i')}$  value because of  $\neg\text{bad}_2$ , for any  $(x^{(i')}, y^{(i')}) \in \tau_2$ . Similarly for  $\tau_1^{\text{new}}$ . This way, we will end up with soundly defined  $\tau_1^{\text{new}}$  and  $\tau_2^{\text{new}}$  for  $\pi_1$  and  $\pi_2$ , and a set of construction queries  $\tau_0^{\text{new}}$  that does not collide with any tuple in  $\tau_1^{\text{new}}$  or  $\tau_2^{\text{new}}$ . Let  $s_2, s_1 \leq p$  be the number of construction queries that collides with  $(u^{(i)}, v^{(i)}) \in \tau_1$  resp.  $(x^{(i')}, y^{(i')}) \in \tau_2$ . The number of elements in the new transcripts  $\tau_1^{\text{new}}$  and  $\tau_2^{\text{new}}$  are equal to  $p + s_2$  resp.  $p + s_1$ , and the number of construction queries that remains in  $\tau_0^{\text{new}}$  is equal to  $q' = q - s_1 - s_2$ .

The two sets of transcripts,  $\tau_1^{\text{new}}$  and  $\tau_2^{\text{new}}$ , define *exactly*  $p + s_2$  input-output tuples for  $\pi_1$  and *exactly*  $p + s_1$  input-output tuples for  $\pi_2$ . What remains is the counting of the number of permutations  $\pi_1, \pi_2$  that satisfy these  $p + s_2$  resp.  $p + s_1$  tuples, and that could give the remaining transcript  $\tau_0^{\text{new}}$ .

For a given transcript  $\tau_0^{\text{new}}$  of  $q'$  elements, our goal is to count the number of  $n$ -bit permutations  $\pi_1: \mathcal{D}_1 \rightarrow \mathcal{R}_1$  with  $|\mathcal{D}_1| = |\mathcal{R}_1| = 2^n - p - s_2$ , and the number of  $n$ -bit permutations  $\pi_2: \mathcal{D}_2 \rightarrow \mathcal{R}_2$  with  $|\mathcal{D}_2| = |\mathcal{R}_2| = 2^n - p - s_1$ . We define  $V_{\text{out}} = \{0, 1\}^n \setminus \mathcal{R}_1$  as the set of range values of  $\pi_1$  that are not permitted (basically these are the  $v$  values from  $\tau_1^{\text{new}}, \tau_2^{\text{new}}$ ) and similarly for  $Y_{\text{out}}$ .

For  $\alpha = 0, \dots, q' - 1$ , define  $\lambda_{\alpha+1}$  as the number of solutions

$$\{v^{(1)}, \dots, v^{(\alpha+1)}; y^{(1)}, \dots, y^{(\alpha+1)}\}$$

that satisfy:

- (1)  $\{v^{(1)}, \dots, v^{(\alpha)}; y^{(1)}, \dots, y^{(\alpha)}\}$  satisfy  $\lambda_\alpha$ ;
- (2)  $v^{(\alpha+1)} \oplus y^{(\alpha+1)} = C^{(\alpha+1)} \oplus K_1 \oplus K_2$ ;
- (3)  $v^{(\alpha+1)} \notin \{v^{(1)}, \dots, v^{(\alpha)}\} \cup V_{\text{out}}$ ;
- (4)  $y^{(\alpha+1)} \notin \{y^{(1)}, \dots, y^{(\alpha)}\} \cup Y_{\text{out}}$ .

Our goal is to derive a recursive formula for  $\lambda_{\alpha+1}$  that depends on  $\lambda_\alpha$ , such that a lower bound can be found for the expression  $\lambda_{\alpha+1}/\lambda_\alpha$ . Note that, by definition,

$$|\text{comp}_{\mathcal{O}}(\tau)| = \lambda_{q'}(2^n - p - s_2 - q')!(2^n - p - s_1 - q')!. \quad (20)$$

Processing from (19), we obtain

$$\frac{\Pr[X_{\mathcal{O}} = \tau]}{\Pr[X_{\mathcal{P}} = \tau]} = \frac{\lambda_{q'}(2^n - p - s_2 - q')!(2^n - p - s_1 - q')! \cdot 2^{nq}}{(2^n - p)!^2}. \quad (21)$$

We will derive a lower bound for  $\lambda_{\alpha+1}/\lambda_\alpha$ . Define by  $B_{(1,2)}$  the set of solutions that only comply with (1) and (2), with no side condition from (3) and (4). Define by  $B_{(3:i)}$  the set of solutions that comply with (1) and (2) of above, and satisfy  $\neg(3:i)$  for  $i = 1, \dots, \alpha + |V_{\text{out}}|$ . It means that any solution in this case satisfies (1) and (2), and  $v^{(\alpha+1)} \in \{v^{(1)}, \dots, v^{(\alpha)}\} \cup V_{\text{out}}$  (nothing is said about  $y^{(\alpha+1)}$  except for property (2)). Similarly for  $B_{(4:i)}$ . By the principle of inclusion-exclusion, we obtain

$$\begin{aligned} \lambda_{\alpha+1} &= |B_{(1,2)}| - \left| \bigcup_{i=1}^{\alpha+|V_{\text{out}}|} B_{(3:i)} \cup \bigcup_{i=1}^{\alpha+|Y_{\text{out}}|} B_{(4:i')} \right| \\ &\geq |B_{(1,2)}| - \sum_{i=1}^{\alpha+|V_{\text{out}}|} |B_{(3:i)}| - \sum_{i=1}^{\alpha+|Y_{\text{out}}|} |B_{(4:i)}| + \sum_{i'=1}^{\alpha+|Y_{\text{out}}|} \sum_{i=1}^{\alpha+|V_{\text{out}}|} |B_{(3:i)} \cap B_{(4:i')}| \\ &\geq 2^n \cdot \lambda_\alpha - \sum_{i=1}^{\alpha+|V_{\text{out}}|} \lambda_\alpha - \sum_{i=1}^{\alpha+|Y_{\text{out}}|} \lambda_\alpha + \sum_{i'=1}^{\alpha+|Y_{\text{out}}|} \sum_{i=1}^{\alpha+|V_{\text{out}}|} |B_{(3:i)} \cap B_{(4:i')}|. \end{aligned}$$

By the fact that

$$\sum_{i'=1}^{\alpha+|Y_{\text{out}}|} \sum_{i=1}^{\alpha+|V_{\text{out}}|} |B_{(3:i)} \cap B_{(4:i')}| \geq 0,$$

we get

$$\lambda_{\alpha+1} \geq 2^n \lambda_\alpha - (\alpha + p + s_2) \lambda_\alpha - (\alpha + p + s_1) \lambda_\alpha.$$

Thus, we have obtained

$$\frac{\lambda_{\alpha+1}}{\lambda_\alpha} \geq 2^n - 2\alpha - 2p - s_1 - s_2, \quad (22)$$

with  $\lambda_0 = 1$ .

Processing from (21), we obtain

$$\begin{aligned} (21) &= \prod_{i=0}^{s_1-1} \frac{2^n}{(2^n - p - i)} \cdot \prod_{i=0}^{s_2-1} \frac{2^n}{(2^n - p - i)} \\ &\quad \cdot \prod_{i=0}^{q'-1} \frac{\lambda_{i+1}}{\lambda_i} \cdot \frac{2^n}{(2^n - p - s_2 - i)(2^n - p - s_1 - i)}. \quad (23) \end{aligned}$$

Using that  $p, s_1, s_2 \leq 2^n$ , and combining (22) with (23), we obtain

$$\begin{aligned}
(23) &\geq \prod_{i=0}^{q'-1} \frac{\lambda_{i+1}}{\lambda_i} \cdot \frac{2^n}{(2^n - p - s_2 - i)(2^n - p - s_1 - i)} \\
&\geq \prod_{i=0}^{q'-1} \frac{(2^n - 2i - 2p - s_1 - s_2)2^n}{(2^n - p - s_2 - i)(2^n - p - s_1 - i)} \\
&= \prod_{i=0}^{q'-1} \left( 1 - \frac{(p + s_2 + p)(p + s_1 + p)}{(2^n - p - s_2 - p)(2^n - p - s_1 - p)} \right) \\
&\geq \prod_{i=0}^{q'-1} \left( 1 - \frac{(p + s_2 + q')(p + s_1 + q')}{(2^n - p - s_2 - q')(2^n - p - s_1 - q')} \right) \\
&\geq \prod_{i=0}^{q'-1} \left( 1 - \frac{4(p + s_2 + q')(p + s_1 + q')}{2^{2n}} \right) \\
&= \left( 1 - \frac{4(p + s_2 + q')(p + s_1 + q')}{2^{2n}} \right)^{q'} \\
&\geq 1 - \frac{4q'(p + s_2 + q')(p + s_1 + q')}{2^{2n}} \\
&\geq 1 - \frac{4q(p + q)^2}{2^{2n}}. \tag{24}
\end{aligned}$$

where we use that  $(1 - x)^y \geq 1 - xy$  and  $q' + s_1 + s_2 = q$ . We conclude from (23) and (24) that

$$\frac{\Pr[X_{\mathcal{O}} = \tau]}{\Pr[X_{\mathcal{P}} = \tau]} \geq 1 - \frac{4q(p + q)^2}{2^{2n}} =: 1 - \epsilon.$$

**Conclusion.** Using Patarin's H-Coefficient technique (Lemma 1), we obtain

$$\mathbf{Adv}_{\text{SoEM22}}^{\text{prf}}(\mathcal{D}) \leq \frac{4q(p + q)^2}{2^{2n}} + \frac{3qp^2}{2^{2n}}.$$
