## Superfamily PROCTOTRUPOIDEA<sup>19</sup>

This is a large superfamily, the members of which exhibit striking differences in structure and in habits. It is, moreover, comparatively poorly known, with most of the North American species still undescribed. Except for the small families Evanidae and Gasteruptiidae, which have been critically studied by Bradley and more recently by Townes, and for the scelionid subfamily Platygasterinae, which has been reviewed by Fouts, the Proctotrupoidea of North America have received little attention from systematists. We have as yet only suggestions or bits of actual evidence here and there concerning the habits of the forms comprising this superfamily. It offers attractive opportunities to students of Hymenoptera.

No comprehensive study of the North American species has been published since Ashmead's revision of 1893, although these species were included by Kieffer in his monograph of the world forms published in several volumes between 1914 and 1926. The majority of American species were known by Kieffer only from generally inadequate descriptions and his treatment is for that reason often faulty. Like most of the workers in this group during the past thirty years Kieffer used the name Serphoidea, based on *Serphus* Schrank, for the superfamily. *Serphus* Schrank, however, was set aside by the International Commission of Zoological Nomenclature in 1946 in Opinion No. 178 under suspension of the Rules, and *Proctotrupes* Latr. was established in its place and added to the Official List of Generic Names in Zoology. Thus it has unfortunately become necessary to return to the all but forgotten name Proctotrupoidea.

## Family EVANIIDAE<sup>20</sup>

The evaniids are parasitic in the egg capsules of Blattidae. The family is best represented in the tropics. Two introduced species (*Evania appendigaster* and *Prosevania punctata*) are common in the larger cities of the Atlantic States, where they parasitize *Periplaneta* and *Blatta*. Our common native species of *Hyptia* are presumed to be parasites of *Parcoblatta*.

Type: (*Ichneumon polycerator* Fabricius) = *Ichneumon polyturator* Drury. Monob.

*Epiceuastes* Gistel, 1848. Naturgesch. Thierr. f. höh. Schul., p. X, col. 1.  
Unnecessarily proposed for *Pelecinus* Latreille.

Biology: Clausen, 1940. Entomophagous Insects, pp. 270-271.—Hammond, 1944.  
Canad. Ent. 74: 130.

Taxonomy: Brues, 1928. Psyche 35: 205-209.

This genus, which comprises the family Pelecinidae, is a peculiar genus, conspicuously distinct from all other families of the Proctotrupoidea although apparently belonging in this group, and with the two sexes strikingly dimorphic. It appears to be represented in North America by a single extremely variable species, but no really critical study of the large accumulations of specimens that are to be found in the principal insect collections has ever been attempted. Such a study, supplemented by more information on biology, may prove this segregate to be a complex of several distinct species. The present meager records pertaining to biology and host relations indicate that *Pelecinus* parasitizes the larvae of soil-inhabiting Scarabaeidae.

## Superfamily CHRYSIDOIDEA<sup>24</sup>

### Family CHRYSIDIDAE

The North American forms of these brilliantly metallic blue and green wasps, popularly known as gold- or cuckoo-wasps, occur as inquilines or parasites in the nests of solitary bees and wasps. The group is of little economic importance although an unsuccessful attempt was made to establish a Chinese parasite (*Chrysis shanghaiensis* Smith) of the oriental moth in Massachusetts.

Taxonomic work in this family is complicated by lack of information on the biology of the group since a knowledge of host relationships is essential for the proper understanding of the various species complexes. It is anticipated that many changes will be made in the synonymy as biological data become available.

## Superfamily BETHYLOIDEA<sup>25</sup>

### Family BETHYLIDAE

This family, and even its North American representation, is by no means as small as is suggested by the following record of described species.

<sup>25</sup>By C. F. W. Muesebeck and Luella M. Walkley, U. S. Bureau of Entomology and Plant Quarantine.

The Nearctic Bethylidae have never been intensely collected or critically studied, and comparatively little is known about their biology. The group should prove a very attractive one to an energetic and competent student of Hymenoptera. Apparently its closest affinities are with the Cleptidae in the Chrysidoidea.

#### Family TRIGONALIDAE<sup>26</sup>

The trigonalids are parasites, either of social Vespidae or of the parasites of caterpillars. Their minute and very numerous eggs are laid at random on foliage and subsequently eaten by caterpillars. In the case of secondary parasites of caterpillars the eggs hatch in the gut of the caterpillar and the trigonalid larva enters the body of the caterpillar to attack an ichneumonid, tachinid, or other parasitic larva. Trigonalids parasitic on the larvae of social vespids are presumably brought to the vespid larvae with their caterpillar food.

The genus is rather widely distributed in North America (specimens have been seen from New York, Maryland, Georgia, Florida, Louisiana, Texas, New Mexico, Ohio, Illinois, Iowa, North Dakota and Idaho), and

represented by several distinct species. It is impossible here to elucidate the component forms. The Hawaiian *hospes* Perkins may have been introduced from North America.

## Family MUTILLIDAE

The author is indebted to Prof. C. E. Mickel and Dr. R. M. Schuster for reading over the first draft of this section. Prof. Mickel has suggested some of the new synonymy proposed herein, and he has been recorded as the authority for it after each pertinent citation.

So far as is known, the North American species of this family, some of which are popularly called "velvet ants" or "cow killers," are parasitic on other aculeate Hymenoptera, mostly on ground-nesting forms.

### Subfamily APTEROGYNINAE

#### Tribe CHYPHOTINI

##### Genus CHYPHOTES Blake

*Chyphotes* Blake, 1886. Amer. Ent. Soc. Trans. 13: 276.

Type: *Chyphotes elevatus* Blake. Monob. and orig. desig.

*Blaketa* Pate, 1948. Ent. News 59: 41. N. name.

Revision: Buzicky, 1941. Ent. Amer. 21 (n. s.): 201-243.

Pate states that *Chyphotes* Blake is a homonym of *Cyphotes* Burmeister, 1835, since both have the same etymology (Opin. 147, Internat. Comn. Zool. Nomencl.). Inasmuch as *Chyphotes* is the basis for a tribal name in the Mutillidae and has been used in the modern revision of the group, it would be desirable to conserve it if possible. Since Blake gives no derivation for his name, it is recommended that the name be considered an arbitrary combination of letters (Article 8, Recommendation k, Internat. Rules Zool. Nomencl.), and therefore not of the same derivation as *Cyphotes*. *Chyphotes* and *Cyphotes* are widely separated zoologically as well as alphabetically, so no confusion should arise from having both names in current usage.

#### Family FORMICIDAE<sup>29</sup>

Ants are social insects that live in colonies in diverse situations, more commonly in the ground or in rotting wood. Some are general feeders; others have highly specialized food habits. Although most ants are free-living forms, some are parasites on other species of ants or live as inquilines with them. A number of forms are of concern to man because of their feeding, nesting or stinging habits. A colony is normally composed of one or more reproductive females and workers, and at certain seasons of the year it contains also males and virgin females.

### Subfamily DORYLINAE

The legionary ants are the New World equivalent of the Old World driver or army ants. Highly predaceous, they are known for their foraging expeditions on other arthropods, including ants. They exhibit a number of peculiar developments not common to most ants, such as wasplike males, wingless, termitelike females, and often blind workers. The biology of most of the forms is not well known.

## Subfamily MYRMICINAE

This is the largest subfamily and the most diverse with respect to size, shape, structure, and habits. Moreover, it contains more forms inimical to man than any other group of ants. Nests are constructed in soil, wood, crevices of plants, debris, insect galls, buildings, ships, and in many other situations. The feeding habits are highly varied; and some forms have restricted diets, whereas others are general feeders.

Heat-loving forms which usually nest in the soil but sometimes in rotten wood and occasionally in houses. The colonies are usually populous, and the workers are aggressive. They are carnivorous, granivorous, predaceous, and also feed on honeydew. Most of the Nearctic forms are serious pests, stealing seeds from seed beds, killing young quail and poultry or even small game, gnawing into vegetables, fruits, flowers, crops and fabrics, attending or fostering honeydew-excreting insects, damaging telephone equipment, making ugly mounds on lawns, and girdling young nursery trees. The workers of one form have been shown to carry viable dysentery germs for at least 24 hours on their bodies.

### Genus EPOECUS Emery

**Epoecus** Emery, 1892. Soc. Ent. France Bul. 61: CCLXXVI.

Type: *Epoecus pergandei* Emery. Monob.

Revision: Emery, 1895. Zool. Jahrb. Abt. f. System. 8: 272-274.

This genus is represented by a single form, *pergandei*, which was collected from a colony of *Monomorium minimum* (Buckl.). The host colony contained only winged males and winged females. As only males and females of *Epoecus* were noted, the ants of this genus are supposed to be workerless and parasitic.

### Genus ANERGATES Forel

**Anergates** Forel, 1874. Schweiz. Naturf. Gesell. Denkschr. 26: 93.

Type: *Myrmica atratula* Schenck. Monob.

Palaearctic. Presumably introduced into the United States with the host ant. A permanent parasite on colonies of *Tetramorium caespitum* (L.). Parasitized colonies of that ant are rare, and contain only workers of the host species. Workers are entirely lacking in *Anergates*. The virgin females of *Anergates* are winged, the males, wingless, pupoid. As the parasites are entirely dependent on the host for food and care, a colony dies out when all the host workers die.

**atratulus** (Schenck). Conn., Del., Va. Collected on only one occasion in each of the three states.

**Myrmica atratula** Schenck, 1852. Nassau. Ver. f. Naturk. Jahrb. 8: 91. ♀.

*S. (S.) louisianae*, our only Nearctic form of this subgenus, appears to be confined mainly to the southern section of the United States. It nests in the soil beneath objects, in rotting wood such as stumps and logs, in plant cavities, etc. The colonies are small, seldom composed of more than a hundred or so individuals. The ants are thought to feed largely on insects, especially Collembola.

Almost cosmopolitan. The Nearctic forms nest in small colonies in the soil, or humus, usually beneath objects; also in decayed wood,

cavities of plants, and nuts on the ground. Nests are often located near or within colonies of other ants. It has been assumed that members of this group are thief ants. The Wesson brothers have definitely found some of the forms predaceous on collembolans.

Neotropical with a slight extension into the Nearctic Region (Ariz., Calif., Tex.). Our common form, *versicolor versicolor* (Perg.), is apparently largely confined to arroyos in arid areas where the ants nest in the soil. The habits are very similar to those of *Atta texana* Buckl. but colonies are apparently not so large and the leaf-cutting habits are not on so extensive a scale.

Neotropical with an extension into the Nearctic Region (Ariz., La., Tex.). Two forms occur in the United States, *A. mexicana* in southern Arizona and *A. texana* in Louisiana and Texas. Nests, which are deep in the soil and usually have many lateral and vertical entrances, are often extremely large and contain innumerable individuals. Workers defoliate both wild and domesticated plants, including trees. The ants live on a fungus grown from a substratum composed of macerated leaves and other vegetable matter.

##### Genus DOLICHODERUS Lund

###### Subgenus DOLICHODERUS Lund

**Dolichoderus** Lund, 1831. Ann. des Sci. Nat., Zool. 23: 130.

Type: *Formica attelaboides* Fabricius. Monob.

Not known to occur in the Nearctic Region.

###### Subgenus HYPOCLINEA Mayr

Type: *Formica quadripunctata* Linnaeus. Desig. by W. M. Wheeler, 1911.

In the United States the genus ranges from Canada to the Gulf of Mexico and as far west as approximately the 104th degree of longitude. Colonies are small to moderately large. Nests are constructed in the soil, in curled leaves and hollow stems of plants, and in cartons attached to plants. Workers attend honeydew-excreting insects and feed on small arthropods. Some forms emit a fluid from their anal glands which has a peculiar smoky or pungent odor. So far as is known, none of the species is of any economic importance.

### Subfamily FORMICINAE

Second largest subfamily of ants. Although representatives occur in every section, these ants are relatively more abundant in northern areas than elsewhere. Nests are constructed in diverse places, as in the soil, in logs and stumps, in crevices of plants and trees, in insect galls or even in houses. The food includes honeydew, sap, juices of plants and fruits, flesh of arthropods, etc. Some forms even foster mealybugs, plant lice, and possibly other honeydew-excreting insects. Many of them infest houses. One of the most troublesome is the black carpenter ant, *Camponotus herculeanus pennsylvanicus*, which not only infests human foods but may nest in the woodwork and cause appreciable injury. This ant is also known to damage telephone poles.

The Nearctic forms are confined mainly to the southern half of the United States with the most northern extension in the Mississippi Valley region. They nest in wood, branches of trees and shrubs, insect galls, and nuts. Their nests often are polydomous. The soldier uses its subcylindrical, truncate head for blocking the entrance hole to the nest.

Type: (*Paratrechina currens* Motschoulsky)=*Formica longicornis* Latreille. Desig. by W. M. Wheeler, 1911.

The single known species, thought to be a native of India, has been distributed by commerce over the world. In the United States this ant is now well established in towns and cities of the Gulf and Atlantic States; farther inland its distribution is sporadic. In the more northern areas the species lives in greenhouses or apartment buildings.

**longicornis** (Latreille). Introduced into U. S. For distribution see remarks under the subgenus; especially common in Fla. An important house pest.

**Nylanderia** Emery, 1906. Soc. Ent. Belg. Ann. 50: 134.

Type: **Formica vividula** Nylander. Orig. desig.

In the northern sections ants of this subgenus occur in greenhouses; farther south they are capable of living outdoors. The native species nest in soil and rotting wood. Some forms infest human foods, showing an especial fondness for sweets. Although easily recognized generically the ants are difficult to determine specifically. Male genitalia are believed to offer the best characters for separating the species.

These ants usually nest in the soil openly or under cover in small to moderate-sized colonies. Workers feed on honeydew, secretions of floral and extrafloral nectaries, exudates from galls, earthworms and arthropods, and ripened or decaying fruits. The ants often invade houses in search of food, and they sometimes forage even at freezing temperatures. Replete are common. Ants of this genus are among the first to take their nuptial flights in the spring, males and females having overwintered in their nests.

#### Subgenus ACANTHOMYOPS Mayr

**Acanthomyops** Mayr, 1862. Zool.-Bot. Gesell. Wien, Verh. 12: 699.

Type: **Formica clavigera** Roger. Monob.

Revisions: Emery, 1893. Zool. Jahrb., Abt. f. system. 7: 638, 642.—W. M. Wheeler, 1916. Psyche 23: 170-172.—Buren, 1950. Ent. Soc. Wash. Proc. 52: 184-190.

Distributed from Canada to Mexico. The ants nest in the soil, usually beneath objects, and also in rotting logs and stumps, and are

subterranean in habit. The females and workers have a characteristic citronella or lemon-verbena odor which no other forms of *Lasius* possess. Species of *Acanthomyops* are of some economic importance because they foster honeydew-excreting insects and because of their objectionable habit of nesting around foundations of buildings and beneath basement floors. The winged forms are often mistaken for termites.

**claviger claviger** (Roger). Ont. to Fla., west to Wash., Utah, and N. Mex. Unusually common in the Eastern and Central States. Has dimorphic females.

Native to Mexico and western United States; especially typical of the arid plains and deserts of the Western States. The ants nest in the soil, usually in small colonies of only a few hundred individuals. Some forms are apparently entirely predaceous or carnivorous; others live on honeydew and nectar obtained from plants or the secretions of galls. Some are diurnal, others nocturnal. Repletes are known to occur in many forms. These ants are called "honey ants" because of the honeylike substance stored in the gasters of the repletes. Owing to the high degree of polymorphism in many forms, these ants are not easily determined specifically without large series of workers, especially major ones.

#### Genus FORMICA Linnaeus

One of the largest genera of ants. The genus includes the three subgenera *Proformica*, *Neoformica*, and *Formica*. For the sake of convenience the subgenus *Formica* has been split into five groups, called the fusca, rufa, microgyna, exsecta, and sanguinea groups. Ants of the genus *Formica* nest in both soil and rotting wood; they have an unusually wide distribution and occur in many diverse habitats. Their food is largely honeydew and small arthropods. Most forms are free living but some are temporary parasites; others are slave makers and still others are slaves.

#### Subgenus PROFORMICA Ruzsky

**Proformica** Ruzsky, 1903. Soc. Ent. Rossica Horae 36: 303.

Type: *Formica nasuta* Nylander. Desig. by W. M. Wheeler, 1911.

Revision: W. M. Wheeler, 1913. Harvard Univ., Mus. Compar. Zool. Bul. 53: 387, 399-400, 401-425.

These ants are distributed from Alaska to at least as far south as the 35th degree of latitude in the United States. The subgenus contains some of our smallest forms of *Formica*. The small colonies are usually constructed in the soil freely or under cover. The ants are timid and are enslaved by *Formica* of the sanguinea group.

Distribution solely Nearctic. In the United States, ants of the pallide-fulva group have been recorded from New Mexico and Wyoming eastward to the Atlantic Ocean and those of the moki group from Arizona, Utah, and Washington. These ants form colonies of small or moderate size in the soil openly or under cover. Some forms nest in rotting wood. Their food is largely honeydew and the flesh of small arthropods. They are docile and are enslaved by ants of the genus *Polyergus* and by various forms of *Formica sanguinea* Latr.

This subgenus is divided into 5 groups, namely, the fusca, sanguinea, exsecta, rufa, and microgyna groups. Members of the fusca group are timid or docile and some are enslaved by certain forms of *Formica (F.) sanguinea* and *Polyergus*; others are hosts of temporary parasites of the rufa, microgyna, and exsecta groups. Most of the forms of *sanguinea* enslave other ants belonging to the fusca group and to the subgenera *Proformica* and *Neoformica*. The best known form of the exsectoides group is the Allegheny mound ant, *Formica exsectoides exsectoides*, whose large mounds attract the attention of the most casual observer. The rufa group contains forms that make conspicuous nests in rotting wood or in soil, which they cover with vegetable detritus. Many are temporary parasites on members of *Neoformica* and of the fusca group of *Formica*. The habits of members of the microgyna group are somewhat similar to those of the rufa group. In these ants the females are exceptionally small; they are usually even smaller than workers.

#### Subfamily POLISTINAE

Nests are formed of a single horizontal comb of hexagonal paper cells, attached to a support by a pedicel. The nests are annual and the queen founders are often difficult to distinguish from workers. In cold climates the queens hibernate. Larvae are fed chiefly on food of animal origin. Common parasites or inquilines are *Chalcoela iphitalis* (Walker), *Polistophaga fulva* (Cresson), and *Dicymolomia pegasalis* (Walker).

The nests are similar to those of *Polistes*, but average somewhat smaller. They consist of a single free comb of hexagonal paper cells and are attached by a short pedicel (in North American forms) to a natural or man-made support usually some distance from the ground. Each colony is generally started by a single fertile female or queen.

The genus is essentially Neotropical but one species extends its range into southern United States. The perennial paper nests are attached to branches of low trees and are begun by small swarms of fertile queens and workers. An average nest is subglobular, is enclosed in a single sheet of papery material, is about 1 foot in diameter, contains about 50,000 cells arranged in layers, has several entrances, and has spiral ramps connecting the tiers of cells. The adults collect and store honey but do not cap the cells.

### Subfamily ZETHINAE

#### Genus ZETHUS Fabricius

Revision: Isely, 1917. *Ent. Soc. Amer. Ann.* 10: 364-366.

Nests are of various types and some show an approach to social habits. Wood cavities may be utilized as in many strictly solitary wasps, or several females may construct a colony of cells of vegetable fibers or leaves pasted together with a resinous material. In the latter case each wasp feeds its own larvae, using caterpillars. In still other species abandoned cells of *Polistes* and *Mischocyttarus* are used.

Family POMPILIDAE<sup>31 32</sup>

The taxonomy of the family has been confused, and the literature is consequently hard to use. The classification in many revisionary papers is so different from that presented here that reference to the original descriptions is usually better than consultation of the revisionary literature. The general papers below will often be helpful.

Revisions: Banks, 1911. N. Y. Ent. Soc. Jour. 19: 219-237 (eastern species).—Banks, 1919. Harvard Univ., Mus. Comp. Zool. Bul. 63: 229-248 (western species).—Brimley, 1936. Elisha Mitchell Sci. Soc. Jour. 52: 107-131 (N. C. species).—Dreisbach, 1949. Mich. Acad. Sci., Arts, and Letters Papers 33: 63-71 (American genera).

Members of this family provision their nests with spiders. The nests are usually in the ground, but many of the Macromerini construct mud cells in protected places and at least some species of *Dipogon* nest in holes in wood. *Ceropales* is a social parasite on other members of the family, ovipositing on their prey before it is placed in the nest.

<sup>31</sup>By Howard Evans (Pompilinae), P. D. Hurd, Jr. (*Pepsis*), and Henry Townes (other parts of the family).

<sup>32</sup>There is division of opinion among the contributors to this catalogue regarding the proper name for the family. Evans and Hurd prefer Pompilidae. Townes prefers Psammocharidae.

*Pseudagenia* Kohl, 1884. Zool.-Bot. Gesell. Wien, Verh. 34: 38, 42.

Type: *Sphex carbonarius* Scopoli. Orig. desig.

<sup>36</sup> Pate in 1946 pointed out that the name *Calicurgus* was first published by Brullé in 1833, as a synonym of *Pompilus*. He accepted this mention in synonymy as validating *Calicurgus*, with *Pompilus annulatus*, a species of *Cryptocellus*, the genotype. To replace the, to him, preoccupied *Calicurgus* of Lepeletier and later authors he proposed the name *Caliadurgus*. Though Pate's action was in harmony with some of the Opinions of the International Commission on Zoological Nomenclature I must state (without at present going into details) that the arguments in favor of acceptance of a mention in synonymy as automatically validating a new name seem weak, and the idea itself absurd and harmful to nomenclatorial stability. So, I believe it correct to continue with the traditional application of the name *Calicurgus*.

### Family AMPULICIDAE<sup>40</sup>

Kohl, in 1893 (K. K. Naturhist. Hofmus. Ann. 8: 455-516, 3 pls.), presented generic diagnoses, a key to and descriptions of the species of *Ampulex* known to him, and copies of the original descriptions of the other species of Ampulicidae.

So far as is known, the species of this family nest in twigs, under bark, and under leaf litter on the ground, and provision their nests with immature cockroaches.

#### Genus AMPULEX Jurine

##### Subgenus AMPULEX Jurine

***Ampulex*** Jurine, 1807. Nouv. Meth. Class. Hym. Dipt., p. 132.

Type: *Sphex compressa* Fabricius. Desig. by Audouin, 1822.

The typical subgenus does not occur in North America.

<sup>39</sup> This section is by Karl V. Krombein with the following exceptions: The tribes Larrini and Tachytini by G. E. Bohart; the tribes Philanthini, Bembicini, and Oxybelini by B. D. Burks; the subfamily Sphecinae by W. C. Murray; the tribe Cercerini by H. A. Scullen; and the genus *Astata* by Henry Townes.

The sections by B. D. Burks and Karl V. Krombein were to have been done originally by another contributor. A few months prior to the deadline for submission of the manuscript it was learned that he would be unable to participate. Accordingly little time was available for studying specimens for possible new synonymy and for obtaining further distributional data.

There is considerable variation in the nesting sites and prey preferences of the species. Several species nest in soil and provision with nymphs of Oedipodinae (Orthoptera) or Lygaeidae (Hemiptera), whereas other species nest in twigs or deserted galls and provision with nymphs of Lygaeidae. Probably several subgenera should be recognized, but most of the genotypes are not available.

### Subfamily PEMPHREDONINAE<sup>47</sup>

#### Tribe PSENINI<sup>48</sup>

In an excellent revision of the British species Spooner, 1948 (Roy. Ent. Soc., London, Trans. 99: 129-172, 5 figs.) presents biological data which tend to substantiate the generic and subgeneric groupings based

<sup>47,48</sup> By Karl V. Krombein, U. S. Bureau of Entomology and Plant Quarantine.

on structural characters. Thus, in Europe, *Psen* s. str. uses larger Auchenorrhyncha (Cercopidae, Membracidae, and Cicadellidae) and nests in ready-made cavities in wood or sandstone; *Mimesa* s. str. excavates burrows in the soil, and stores smaller Auchenorrhyncha (Cicadellidae) which are carried ventrally with the middle legs; *Mimesa* (*Mimumesa*) also uses smaller Auchenorrhyncha (Delphacidae, Cicadellidae), but carries the prey in the mandibles to nests in cavities in wood and stems; and *Psenulus* [*recte Diodontus*] preys on Sternorrhyncha (Aphidae, Psyllidae), which are carried ventrally by the middle legs to ready-made cavities in wood or plant stems. The scant biological information, published or unpublished, on Nearctic species indicates a similar correlation: Species of *Psen* s. str. prey on Cercopidae and Membracidae, and nest in wood; *Psen* (*Pseneo*) prey on Membracidae and Cicadellidae (*carolina* was reared from soil in a flowerpot and cocoons of reared specimens of *simplicicornis* bear fragments of wood pulp; *Mimesa* s. str. nest in soil and provision with Cicadellidae; nothing is known as to the biology of our native *Mimesa* (*Mimumesa*); *Diodontus* have been reared from lumber and canes of *Rubus*, but the prey is unknown; nothing is known of the biology of *Pluto*, a genus peculiar to the New World, but presumably the species nest in soil.

Subfamily SPHECINAE<sup>50</sup>

## Tribe SPHECINI

There is only one genus, *Sphex*, in this tribe. These wasps store their nests with Acrididae, Tettigoniidae, and Gryllidae. The various subgenera of *Sphex* apparently select certain groups of Orthoptera to the exclusion of others. Odd records in the literature indicate either that these selections are not absolutely fixed or that we are in need of more observations and positive identifications.

Genus SPHEX Linnaeus<sup>51</sup>

Revisions: Kohl, 1890. K. K. Naturhist. Hofmus. Ann. 5: 77-194, 317-462.—Fernald, 1906. U. S. Natl. Mus. Proc. 31: 291-423.

The treatment of *Sphex* has been conservative. It is recognized that some changes will have to be made in the future, but it is believed best to wait until a comprehensive revisional work has been made in order to insure stability.

<sup>50</sup> By William Donald Murray, Visalia, Calif.

<sup>51</sup> The editors are not in agreement with the generic nomenclature employed by Dr. Murray for *Sphex* and *Ammophila*. It is our conviction that Opinion 180 (Internat'l. Commn. Zool. Nomencl., 1946) constitutes a reversal of Opinion 32 which established *sabulosa* L. as the type of *Sphex*. The reversal of a previous opinion requires an affirmative vote by three-fourths of all the Commissioners (By-Laws, Internat'l. Commn. Zool. Nomencl.). Since only 12 Commissioners out of 17 voted on Opinion 180, the opinion has no legality and we do not feel bound by it. Those who agree with this interpretation of the facts, and who wish to use the names as established by Opinion 32 and confirmed by usage in such major revisionary papers as Fernald's and Murray's on the North American fauna and Arnold's on the African fauna, will have to make the following changes in this catalog:

Tribe Sphecini, p. 971, becomes Chlorionini

Genus *Sphex*, p. 971, becomes Genus *Chlorion*

Subgenus *Ammobia* will replace Subgenus *Sphex*, p. 971.

Tribe Ammophilini, p. 974, becomes Sphecini

Genus *Ammophila*, p. 974, becomes *Sphex*

## Family DRYINIDAE<sup>63</sup>

Comparatively few North American specimens of this family that are collected can be identified at present since the group is virtually unstudied. Most Nearctic species appear to be still undescribed; and many of the species listed here are probably not referred to the genera in which they really belong. A large proportion of them are known only from the unique types. Moreover, the sexes are so strongly dimorphic, except in the subfamily Aphelopinae, that they can be positively associated only by rearing. Apparently most species of the family are parasites of Homoptera, especially Cicadellidae and Fulgoroidea; but definite rearing records are few.

#### Unplaced Species in Genus *Bombus*

**Apis pennsylvanica** Degeer, 1773. Mém. Serv. Hist. des Ins., v. 3, p. 575. Possibly this is the species now being called *Bombus fervidus* (Fabricius); the name *pennsylvanicus* commonly has been used for the species here called *Bombus americanorum* (Fabricius).

**Bombus praticola** Kirby, 1837. Fauna Bor.-Amer., v. 4, p. 274. This may be the species now being called *Bombus pleuralis* Nylander.

**Bombus bruneri** Swenk, 1938. Pan-Pacific Ent. 14: 29. ♀. Said to be allied to *Bombus dahliomii* Guérin, a South American species; *bruneri* was described from Texas.

**Apis marylandica** Fabricius, 1798. Sup. Ent. System., p. 273. This evidently is a *Bombus*, but is not recognizable specifically; it may not be a Nearctic species.

#### Genus *PSITHYRUS* Lepeletier

The genus *Psithyrus* contains a few species of obligate social parasites on the members of the genus *Bombus*. They closely resemble the species of *Bombus*, but lack the worker caste, and the queens lack pollen-collecting baskets on the hind legs.

Biology: Plath, 1922. Biol. Bul. 43: 23-44.

#### Subgenus *PSITHYRUS* Lepeletier

**Psithyrus** Lepeletier, 1832. Soc. Ent. France Ann. 1: 372.

Type: *Apis rupestris* Fabricius. Desig. by Curtis, 1833.

**Apathus** Newman, 1835. Ent. Mag. 2: 404, footnote.

Type: *Apis rupestris* Fabricius. Autobasic with *Psithyrus*; name proposed to replace *Psithyrus*, thought to be preoccupied by *Psithyros* Hübner, 1819.

The typical subgenus does not occur in North America.

### Unplaced Species in Genus Psithyrus

*Apis alata* Fabricius, 1798. *Sup. Ent. System.*, p. 274.

*Bombus elatus* Fabricius, 1804. *Systema Piezatorum*, p. 352. These two names refer to the same Fabrician species, *alata* evidently having been a misprint for *elata* in the 1798 edition. *Psithyrus laboriosus* (Fabricius), 1804, possibly is the same.

### Tribe APIN<sup>194</sup>

#### Genus APIS Linnaeus

*mellifera* Linnaeus. Worldwide. Introduced in Western Hemisphere. Represented in the Old World by numerous subspecies, several of which have been introduced into North America with the result that much interbreeding has occurred among them. The escaped bees of the woodlands are largely *A. mellifera mellifera* (German bee) while the beekeepers' bees are largely *A. mellifera ligustica* (Italian bee). *A. mellifera remipes* (Caucasian bee) is also utilized by some beekeepers.
