Abstract

This research aims to find out whether the synthetic 1, 2, 4-triazine and its derivatives have antifungal effects and can protect humans from infection with *Candida albicans*. Molecular docking and molecular dynamic simulation are widely used in modern drug design to target a We are interested in using molecular docking and molecular dynamics modelling to investigate the interaction between the derivatives of 1, 2, 4-triazine and the resulting Lanosterol 14 - demethylase (CYP51) of *Candida albicans*. The inhibition of *Candida albicans* CYP51 is the main goal of our research. The 1, 2, 4-triazine and its derivatives have been docked to the CYP51 enzyme, which is involved in *Candida albicans* Multidrug Drug Resistance (MDR). Autodock tools were used to identifying the binding affinities of molecules against the target proteins. Compared to conventional fluconazole, the molecular docking results indicated that each drug has a high binding affinity for CYP51 proteins and forms unbound interactions and hydrogen bonds with their active residues and surrounding allosteric residues. The docking contacts were made using a 10 ns MD simulation with nine molecules. RMSD, RMSF, hydrogen bonds, and the Rg all confirm these conclusions. In addition, these compounds were expected to have a favorable pharmacological profile and low toxicity. The compounds are being offered as scaffolds for the development of new antifungal drugs and as candidates for future in vitro testing.

Key Words: 1, 2, 4-Triazine; Lanosterol 14a-demethylase (CYP51); Drug Resistance; Molecular Docking; Molecular Dynamic Simulation.

Introduction

Candida species, the most common of which are *C. albicans*, cause most of the fungal infections in humans. The presence of *Candida albicans* is noteworthy. *Candida albicans* is often found as part of the normal microbiota in the human intestine, but can cause life-threatening infections in immunocompromised people such as HIV patients [1]. *Candida* species can also cause bloodstream infections, and with the increase in candida infections in recent years, multi-drug resistance (MDR) has become a major public health problem [2-3]. MDR is a property in which cells become resistant to multiple chemotherapy drugs that are not chemically related at the same time. Drug efflux pumps from the ATP-Binding Cassette (ABC) or Major Facilitator Superfamily (MFS) families play an important role in establishing and maintaining drug tolerance. Because of their rapid expulsion, induced overexpression of genes that produce these transporter proteins is unable to enable cells to maintain dangerous levels of the drug, rendering it unusable [3-6].

Lanosterol-14-demethylase (CYP51) belongs to the cytochrome P450 superfamily of monooxygenases, which catalyzes the oxidative removal of the 14-methyl group (C-32) from lanosterol to give 14, 15-desaturated intermediates in ergosterol biosynthesis in fungi produce kingdoms, CYP51 is an important enzyme in sterol biosynthesis, which fulfills metabolic functions such as membrane permeability, membrane fluidity, enzyme activity, cell shape and progression of the cell cycle [7-9]. This enzyme occurs in all eukaryotes (including humans) and because azoles also interact with other cytochrome P450-dependent enzymes (CYP3A4), a specific inhibition of the enzyme is decisive for a higher therapeutic index [1013], the hydrophilic H-bond region, and thus the small hydrophobic gap formed. The affinity of azole antifungals for Lanosterol 14a-demethylase is determined not only by the coordinative binding of the nitrogen of the azole ring to the heme iron within the active side (N-4 of triazole and N-3 of imidazole), but also by the affinity of the N1 substituent to the apoprotein, which is part of the remainder of the azole antifungal agent fits into the hydrophobic groove of CYP51 in the same way as Lanosterol [14-19].

1,2,4-Triazine and its derivatives can be a common core structural system found in a variety of physiologically active chemicals, including antifungal and antibacterial activity, and are also known to move pharmacologically [20].

The aim of this work was to use a computer-aided drug discovery strategy to find 1, 2, 4-triazine and its derivatives that have the potential to inhibit the protein *Candida albicans* Lanosterol 14-demethylase (CYP51).

Materials and Methodology

Protein Preparation

The protein database (<https://www.rcsb.org/>) was used to obtain the structure of Lanosterol 14 - Demethylase (CYP51) (PDB ID: 4LXJ) [21]. PDB is a database containing information about experimental proteins and nucleic acid structures. Water molecules were removed with PyMOL (Figure 1). PyMOL is an open source software program that can be used to create molecular graphics [22].

Ligand Preparation

The 1, 2, 4-triazine and its derivatives were selected for their potential pharmacological and therapeutic benefits (Figure S1) [20]. Docking research was conducted against fluconazole, a controlled drug that may be a potent CYP51 inhibitor and is commonly given to mycoses. The structures of the control drug fluconazole were retrieved from the PubChem database. The PubChem database contains data on chemical compounds, including their structure, formula, molecular weight etc. (<https://pubchem.ncbi.nlm.nih.gov/source/15751>) [23]. ChemDraw software was used to create all derived connections in mol file. The structures were first called up in SDF format and then translated into PDB format using PyMOL, an open source system program for molecular visualization [22].

Binding Site Prediction

The Computed Atlas for Surface Topography of Proteins was used to identify the amino acids that are involved in the formation of active pockets (CASTp). CASTp could be a simple and helpful web-based tool for the identification of protein structures and site pockets [24]. Determining the location is crucial for aligning the mesh box before docking.

Molecular Docking

The molecular docking simulations were performed using Auto Dock (The Scripps Research Institute, La Jolla, CA, USA). It is widely used as open software for molecular docking and significantly increases the accuracy of binding mode predictions compared to Auto Dock 4 [25-28] and site residues of the proteins were estimated using the web-based CASTp tool. The size () of the lattice box in lanosterol-14-demethylase (CYP51) was 88.63, 86.49 and 60.53, while the middle (x, y and z) of the lattice box was 22.01, 14.21 and 19.82.

Analysis and Visualization of Docking Results

The docked posture with the best negative score was selected as the best for the appropriate chemical and protein after the docking simulation. PyMOL Molecular Graphics System 2.0 [22] and Discovery Studio 4.5 [29] were used to display and score the best docked posture to study unbound interactions.

Molecular Dynamic (MD) Simulation

Molecular dynamics calculations were used to determine the physical motions of atoms and molecules in a protein-ligand-docked complex. The nine molecules were selected for a 10nsMD simulation. The docked complexes were constructed using the steepest descent minimization module, the YASARA energy minimization module (YASARA Biosciences, GmbH) and the AMBER force field (Assisted Model Building with Energy Refinement) [30-31] before proceeding with the MD simulation Force field, 298 K temperature, 1 bar pressure, Coulomb electrostatics with a cut-off of 7.86, 0.9% NaCl, solvent density 0.997, pH 7.0, 1-fs time steps, periodic boundaries and all mobile atoms were used in the MD simulation [32-33]. The binding energy, the root mean square deviation (RMSD), the root mean square fluctuation (RMSF), the radius of gyration (Rg) and the total number of H-bonds were measured with MD determines simulations in the same way as in previous research [34-36].

MMPBSA Calculations

Molecular mechanics / Poisson-Boltzmann surface (MMPBSA) [37] is one of the most frequently used methods for calculating the binding free energy of a protein-ligand combination. The stable region of the nine molecules with CYP51 complexes was used to construct a 10 ns MD trajectory for MM-PBSA calculations. The MMPBSA method of the YASARA simulator was used to measure the binding energy components (YASARA Biosciences, GmbH). The `g_mmpbsa` tool uses the following equation to calculate the binding energy of the protein-ligand complex-

$$\Delta G_{\text{Binding}} = G_{\text{Complex}} - (G_{\text{Protein}} + G_{\text{Ligand}})$$

Where G_{Complex} denotes the binding complex's total free energy, and G_{Protein} and G_{Ligand} denote the total free energies of the nine molecules bound to Lanosterol 14--demethylase (CYP51), respectively.

Prediction of Pharmacological Properties

The DruLito software was used to predict the drug-like properties of the compounds. To demonstrate their pharmacological integrity, orally active drugs should have certain commonly used drug-like properties the number of rotatable bonds and Lipinski's rule violations of 5 [38]

were determined during this research. In accordance with a previously described method [39], the absorption (% ABS) was calculated using the following formula:

$$\% \text{ ABS} = 109 - (0.345 \times \text{TPSA}).$$

Prediction of Toxicological Properties

Since drug toxicity is an important issue, we used the admetSAR online toolbox (<http://lmmd.ecust.edu.cn:8000/>) to predict toxicological properties of the compounds that were critical and Predictors are helpful in drug development [40]. Table 7 summarizes the data including Ames toxicity, carcinogenic properties, acute oral toxicity, acute rat toxicity, and inhibitory effects on hERG_a.

Result and Discussion

Binding Site Analysis

CASTp was used to identify the active site pockets in lanosterol-14-demethylase (CYP51). CASTp could be a web-based tool for determining the aminoalkanoic acid residues in the active site of a protein. For CYP51, the CASTp results are shown in Figures S1 and S3. Only the amino acids within the site and their positions are given in Table 1 for CYP51 based on the CASTp findings.

Dock score of 1, 2, 4- Triazine and its derivatives against CYP51

The crystal structure of CYP51 from *Candida albicans* (PDB id-4LXJ) was used for docking. The enhanced precision (XP) mode of lattice-based ligand docking with energetics was used to achieve the blind docking of molecules. For the docking we used 1, 2, 4-triazine and its derivatives (molecule 19) (Figure S2). Here we showed that molecules that systematically docked to lanosterol-14-demethylase (Table 2) have the separation energy (CYP51). Figures 1 to 3 provide a three-dimensional representation of docked complexes.

We observed that all compounds had the best binding affinities, as indicated in Table 2, compared to the control inhibitor fluconazole (-8.1 for CYP51). For lanosterol 14 - demethylase (CYP51) they showed promising binding affinities with variable binding free energies in the range from -8.2 to -11.9. Based on the binding affinities, the molecules could be classified as Molecule 6 > Molecule 4 > Molecule 9 > Molecule 5 > Molecule 7 > Molecule 8 > Molecule 1 > Molecule 3 > Molecule 2 for CYP51.

Protein ligand interactions of 1, 2, 4- Triazine and its derivatives against CYP51

Protein-ligand interactions are highlighted by hydrophobic interactions, hydrogen bonds, electrophoresis, and van der Waals interactions, all of which are essential for predicting ligand binding affinities with proteins. All compounds exhibited a variety of unbound and bound

interactions with multiple site residues or at the edge of the site. With the ligand atoms given in Table 3, Thr A: 507, Arg A: 98, Phe A: 506, Ser A: 508, Met A: 509 and His A: 468 mainly formed conventional chemical bonds and a carbon-hydrogen. All molecules showed hydrophobic interactions with various amino acids via the formation of π - π stacked, or π -alkyl bonds (Figures 1 to 3). It has been discovered that many amino acids are involved in hydrophobic interactions, van der Waals interactions, and hydrogen bonds. In addition, the ligands bind with the CYP51 site or the near site mainly through hydrophobic interactions. Hydrophobic interactions have effectively identified certain functional groups that are responsible for the hydrophobically producing effect of compounds with high binding affinity for target proteins and that should have a significant impact on *Candida albicans* infection.

MD simulations can be used to explain hydrogen bonds and hydrophobic properties as well as molecular processes of ligand-protein interactions depending on the flexibility of ligands or proteins. Today this method is often used in the development of biomolecules and active substances [41-42]. After molecular docking, we performed an MD simulation with targeted enzymes for all nine molecules, since all nine molecules have good dock scores compared to the standard inhibitor fluconazole.

Molecular Dynamic Simulation

The MD simulation was performed for 10 ns on nine molecules in conjunction with lanosterol 14 - demethylase (CYP51) in solute and solvent. The aim was to study the dynamic properties of lanosterol-14-demethylase (CYP51) with the nine compounds to see if structural changes related to the inhibition mechanism were observed. Conformational changes in simulated solute molecules cause density fluctuations in 10 ns. If the simulation box is always the same size, density fluctuations lead to changes in pressure. As a result, the cell is rescaled during the simulation to maintain constant cell pressure. In our study, the simulation lengths of all nine molecules with complex lanosterol-14-demethylase (CYP51) are between 128.34 and 128.52 (Figure S4).

The total potential energy of Lanosterol 14-demethylase (CYP51) with the nine molecules was measured to determine the equilibrium and stability of the systems. Figure S5 shows the total potential energy of Lanosterol 14 - demethylase (CYP51) with the nine-molecule complex in 10 ns. Binding energies (Bond), binding angle energies (Angle), dihedral energies (Dihedral), planarity or false dihedral energies (planarity), van der Waals energies (VdW), electrostatic energies (Coulomb) and distribution energies are all potential energy components of all protein-ligand complexes in KJ / mol versus time intervals. Figure S6 shows the surface of the dissolved

Lanosterol 14 demethylase (CYP51) vs. the time interval of all complexes Vander Waals surface (SurfVdW), molecular surface (SurMol) and surface accessible to solvents (SurfAcc). Figure S7 shows the surface area of the dissolved lanosterol 14 - demethylase (CYP51) calculated using nine molecules.

Structural deviations and Compactness

A tiny chemical can produce wide-ranging conformational changes in a protein once it has been bound. One of the most important features for analyzing protein structure changes and dynamic activity is the root mean square deviation (RMSD) [26]. Complex remained stable. The calculated RMSD values of lanosterol-14-demethylase (CYP51) are 2.35, 5.00, 5.00, 5.00, 7.00, 6.00, 4.00 and 4.5 (Figure 4) . RMSD data show no significant change in the RMSD values of the CYP51 complex with nine molecules. These results show that the overall system remained stable during the MD simulation.

The mean fluctuation of each residue was quantified as the root mean square fluctuation (RMSF) to study the residual vibrations in lanosterol 14-demethylase (CYP51) before and after the binding of the nine substances (Figure 5). Random residual fluctuations were detected in CYP51 from the N-terminal to the C-terminal regions. These variations were shown in solute and solvent for each CYP51 backbone residue beyond nine. The residual fluctuations of CYP51 with nine molecular complexes were found to be 2.96, 1.93, 8.54, 2.66, 2.31, 1.44, 1.42, 2.45 and 1.26 inches. According to the RMSF map, residual fluctuations in the area where nine molecules bind show slight variations. After the nine molecules have attached, however, CYP51 shows less increased fluctuations, which is probably due to conformational changes in the binding pocket of the protein. The radius of gyration (Rg) is a measure of the compactness and folding behavior of a protein, linked to its tertiary structure and the general state of conformation. By estimating the Rg of both Lanosterol 14 - demethylase (CYP51) and the nine-molecule complex, we were able to determine their stability. For nine molecules the Rg stayed between 26.3-27.4, 25.2-27.0, 25.8-26.7, 25.4-27.6, 25.8-26.8, 25 , 8-26.9, 25.4-27.4, 25.3-26.6 and 25.8-27.1 during the simulation period (Figure 6). No structural change was detected in lanosterol-14-demethylase (CYP51) in the presence of the nine compounds, and it reached a stable Rg equilibrium, which indicates a complex stability across the simulation track.

A complicated cross-correlation matrix represents the correlative movements of various bag remnants. Figure 7 shows the correlated residual movement of all simulated protein-ligand complexes. Heat maps with high color intensity were used to depict these linked movements

between the remains of the bag. Colors ranging from blue (-1, fully anti-correlated) to yellow (+1, fully correlated) are used to visualize DCCM, with blue and red lines separating high, anti, and correlated pairings.

Dynamics of CYP51 Interactions: Hydrogen bond analysis

The stability of the three-dimensional structure of a protein is determined by intramolecular hydrogen bonds within the molecule. By studying the stability of the protein-ligand complex, hydrogen bond analysis can be used to assess molecular recognition, directionality, and specificity of interactions [26]. We calculated the kinetics of intramolecular hydrogen bond pairs within 10 ns to determine the stability of CYP51 to validate Lanosterol 14 - demethylase with nine molecules docked complex. The solute-solvent hydrogen bonds for all nine molecules with lanosterol-14-demethylase (CYP51) complexes are shown in Figure 8 at 10 ns intervals.

Analysis Secondary Structure Dynamics of CYP51

Conformational changes are caused by varying degrees of secondary structural dynamics remaining in a protein structure. Observing variations in the secondary structure composition of a polypeptide chain could help researchers better understand its conformational behavior and its folding process. We looked at the dynamics of CYP51 secondary structure content before and after all nine molecules were bound to see how stable it was. The helix, leaflet, and convolutions comprising the secondary structure of Lanosterol 14 demethylase (CYP51) were broken down into individual residues at each time point and the average number of residues making up the secondary structure was shown as a function of the total fraction of alpha helices, beta sheets, turns, coils, 3-10 helices, and pi helices in all nine molecular complexes ranged from 0.0 to 50% at 10 ns time intervals for all nine molecular complexes (Figure 9). Figure 10 shows the secondary structure of protein per residue for protein-ligand complexes from 00 to 550 at time intervals of 10 ns. After all nine molecules were attached, no changes in the secondary structure composition of CYP51 were found over a period of 10 ns, suggesting that the complexes are very stable.

MPBSA Analysis –

The MM / PBSA method was used to calculate the binding energy of the complex structure using ensembles derived from the MD simulation. The binding energy values for lanosterol-14-demethylase (CYP51) with nine molecules are shown in Figure 11 and Table S1.

Pharmacokinetics and Toxicological Properties analysis

The ADME / T properties of ligands must be known in order to determine their drug similarity. The DruLito software was used to evaluate the pharmacological properties of 1, 2, 4-triazine and its derivatives (Figure 12). It can detect molecules using drug similarity rules like Lipinski's rule, MDDR-like rule, Ghose filter, BBB similarity, CMC-50-like rule, unweighted QED, Veber filter, and weighted QED calculate and filter. Table 4 summarizes the results. Table 5 shows the expected uptake, distribution and metabolism of 1, 2, 4-triazine and its derivatives using the admetSAR server. All compounds were found to be non-substrate for P-glycoprotein (P-gp) substrate, yes for Caco-2 permeability, yes for Blood Brain Barrier (BBB) and non-substrate for CYP450C9, CYP450D6 substrate. With the exception of molecule 2, all compounds are non-substrates for CYP450A4. Table No. 6 shows that all compounds have significant CYP inhibitory promiscuity.

SWISS ADME boiled egg diagram (Figure 13) enables the evaluation of HIA as a function of the position of the ten molecules within the WLOGP-Versus-TPSA reference. Molecule 1 (control), molecules 8 are predicted to be absorbed by the gastrointestinal tract (white region) but not penetrate the brain (egg yolk). Molecules 1 to 10 are not subject to any active efflux (red point). The admet website was used to predict the toxicological properties of all compounds (Table 7). The results indicated that, with the exception of molecule 3, none of the compounds posed an AMES toxicity problem and that all of the molecules are non-carcinogenic. On the other hand, all compounds were found to be weak inhibitors of the human ether-a-go-go-related gene (HERG_a) and have a low risk of acute toxicity. In accordance with the expected acute oral toxicity, all compounds are classified in Class III based on their expected acute oral toxicity (Table 7). It is possible that the combination of these chemicals can be predicted, and it is a good idea to stop the mycosis.

In the overall studies, the PDB was used to find the crystal structure of lanosterol-14-demethylase (CYP5). Antifungal and antibacterial activities against strains of 1, 2, 4-triazine and its derivatives were carried out by Aarfah Majid et al., 2020 [20], and these compounds showed good antifungal activity compared to control fluconazole. Our research shows that all 1, 2, 4-triazines and its derivatives have potent inhibitory effects against lanosterol-14-demethylase (CYP51) from *Candida albicans*.

Computational engineering can filter the best ligands from a wide variety of compounds, simplifying the drug development process. After that, further clinical research with experimental animals and further in vivo studies are required. All of the basic information needed to develop

novel antifungal treatments to block Ergosterol biosynthesis will be included in the study. Diseases caused by eukaryotic organisms such as fungi are more difficult to treat than infections caused by bacteria. Antifungal drugs that can discover unique targets that are not shared with human hosts are few and far between. Due to the lack of chitin structure in human cells, the fungal cell wall remains an untapped therapeutic target for selective antimycotics [43-44]. Most treatments are aimed at treating fungal infections and target the Ergosterol production route or its end product Ergosterol, a membrane sterol found only in fungi. It is the primary sterol and is therefore needed for fungal cell development and proper membrane function. It contributes to the correct activity of membrane-bound enzymes and also acts as a bio regulator of membrane fluidity, asymmetry and integrity [45]. As a result, efficient antifungal drugs and the discovery of a potential target to treat them will become possible. Diseases are urgently needed. One of the most important proteins in mycoses is lanosterol-14-demethylase (CYP51). As a result of this discovery, this protein has been identified as a potential therapeutic target.

CONCLUSION

With Lanosterol 14 - demethylase (CYP51) we were able to show for the first time that derivatives of 1, 2, 4-triazine can play a decisive role in the prevention of mycoses in in-silico research. Compared to the conventional inhibitor fluconazole, all derivatives of 1, 2, 4-triazine showed stronger binding affinities to the target protein. We discovered that all compounds can act as inhibitors against a specific protein of *Candida albicans*, based on molecular docking and chemical bonding, hydrophobic interactions and van der Waals interactions nine molecules with the protein Lanosterol 14 - demethylase (CYP51). Their drug-like properties have been demonstrated through physicochemical, pharmacokinetic, and toxicological characteristics, which have proven them to be safe sources of drugs. Overall, we conclude that 1, 2, 4-triazine and its derivatives, either alone or in combination with the different compounds, can target CYP51 or may be beneficial for future antifungal drug development.
