Background: This randomized controlled trial (RCT) evaluated a 6-month peer-led community education and mentorship program to improve the diagnosis and management of osteoporosis.

Methods: Ten seniors (74–90 years of age) were trained to become peer educators and mentors and deliver the intervention. In the subsequent RCT, 105 seniors (mean age =80.5±6.9; 89% female) were randomly assigned to the peer-led education and mentorship program (n=53) or control group (n=52). Knowledge was assessed at baseline and 6 months. Success was defined as discussing osteoporosis risk with their family physician, obtaining a bone mineral density assessment, and returning to review their risk profile and receive advice and/or treatment.

Results: Knowledge of osteoporosis did not change significantly. There was no difference in knowledge change between the two groups (mean difference =1.3, 95% confidence interval [CI] of difference –0.76 to 3.36). More participants in the intervention group achieved a successful outcome (odds ratio 0.16, 95% CI 0.06–0.42, $P<0.001$).

Conclusion: Peer-led education and mentorship can promote positive health behavior in seniors. This model was effective for improving osteoporosis risk assessment, diagnosis, and treatment in a community setting.

Keywords: prevention, seniors, mentor, bone mineral density, capacity building, community knowledge translation

Background

The sequelae resulting from osteoporosis and osteoporotic fractures are significant and include functional impairment,¹ institutionalization,² and death.³ Despite the adverse outcomes, osteoporosis is largely underdiagnosed, with as few as 13%–25% of patients who experience a fragility fracture being investigated for osteoporosis by bone mineral density (BMD) assessment.^{4,5} Similarly, the management of osteoporosis is less than optimal, with those at high risk for fractures often remaining untreated.^{6–8} It is a challenge to improve the management of osteoporosis since, in the absence of an osteoporotic fracture, osteoporosis is symptomless and is dependent on risk assessment and screening for diagnosis. Successful risk screening not only depends on educating physicians but also relies on increasing public awareness of osteoporosis.

Self-management approaches to prevention and management of health conditions have been lauded as effective ways to improve health outcomes in adults and to reduce health care costs.^{9–11} Although self-management may be an effective strategy for younger

age groups, it poses a challenge for seniors in advanced age who have multiple problems and reduced physical and mental capacity. Well-documented barriers include a large number of care recommendations,¹² limited knowledge of medical conditions,¹³ cultural and communication factors and transportation issues,¹⁴ poor recall,¹⁵ and comorbidity and compounding effects of conditions.¹⁶ It has been suggested that self-help models of community development, in which some of the responsibility for health care planning and provision is placed not just in the hands of individuals but also on the community as a whole, may provide the greatest benefit.^{17,18} In particular, building community capacity using a peer support model (neighbors helping neighbors) may expand the potential pool of health and supportive services within a local setting.^{19,20} In the context of seniors, younger-old age groups may assist in supporting the oldest-old and friends and neighbors helping each other may extend the reach of the health system and assist the frail elderly to successfully age in place.^{19–21} The use of knowledgeable and skilled senior volunteers trained to educate their peers on health-related topics, although not new, is gaining popularity and support as an effective method of health promotion.^{22–24}

This paper reports results from a pragmatic randomized controlled trial (RCT) of a participatory community development approach that actively engaged seniors in providing peer-led osteoporosis education and mentoring within a naturally occurring retirement community (NORC) in Ontario, Canada. Findings are reported in accordance with the Consolidated Standards of Reporting Trials (CONSORT) checklist for the reporting of pragmatic trials.²⁵

Study context

This study consisted of two phases: 1) the recruitment and training of 10 osteoporosis peer educators and mentors to deliver the intervention and 2) an RCT to test the efficacy of the peer-led community osteoporosis education and mentoring program. Participants were recruited from a NORC in a major urban center in Ontario. This community consists of 12 privately owned apartment buildings housing over 2,500 seniors (mean age =79, standard deviation [SD]=9.53) and 64 local businesses housed in a public mall adjacent to the apartment buildings. A previous survey showed that 54% of the population in this community were >80 years of age.

Training of peer educators/mentors to deliver the intervention

A town hall meeting was held to inform the community of the osteoporosis study, the need for peer educators and mentors,

and the role that they would have to perform. Community members interested in the project were invited to establish contact. No specific inclusion or exclusion criteria were applied. After providing informed consent, 10 participants, all female, aged from 74 to 90 years, committed to becoming peer educators and mentors and entered Phase I of the study. All 10 peer educators/mentors participated in the education program presented over a 2-week period, after which four withdrew (two due to health issues, one due to family obligations, and one due to time constraints). The education program for peer educators/mentors consisted of five osteoporosis education modules presented at the level of a lay person and delivered by local experts. A detailed description of the education modules, including objectives, curriculum, and instructors, is provided in Table 1. Each education session was 1 hour in length followed by a question and answer period.

In addition, peer educators/mentors attended an education session focused on enhancing public presentation skills. This presentation was delivered by the project coordinator and focused on 1) confidently speaking in front of audiences, 2) effectively eliciting audience interest, participation, and feedback, 3) beginning your presentation, 4) delivering your presentation (encouraging audience involvement, keys to developing good listening skills, speaker's nonverbal communication, how to handle difficult situations), 5) concluding your presentation, and 6) key attributes of a senior-friendly presentation. Consistent with principles of community capacity building, once trained these peer educators/mentors formed the Community Osteoporosis Advisory Committee. Peer educators/mentors, as a group, took the information they were provided within the five training modules and, with the help of the research team, synthesized and repackaged the information in a way they felt comfortable presenting. This was an iterative process between the peer educators/mentors and the research team that took place over the course of 2 weeks. Once peer educators/mentors were comfortable, the repackaged material was presented to the local osteoporosis experts to check for clarity and accuracy.

The intervention

For the RCT, the intervention involved a 2-hour education program delivered to small groups of participants by pairs of peer educators/mentors (for mutual support), using the educational materials they had developed. The first hour consisted of the peer-led osteoporosis education program where participants learned about osteoporosis, assessment, and treatment using the repackaged presentation of the five education modules. During the second hour, each peer

Table 1 Description of the education modules, including objectives, curriculum, and instructors

Module	Instructor	Objectives (upon completion of this session participants will be able to)	Curriculum (topics included)
1. What is osteoporosis?	Geriatrician	Answer the question "What is osteoporosis?"; recognize causes of bone loss; discuss the relationship between osteoporosis and fractures and the consequences of osteoporotic fractures in terms of one's health and quality of life; assess their own, and others', risk of osteoporosis; outline action plans for individuals at varying levels of osteoporosis risk (ie, suggestions for successful patient-physician interactions); understand the medical assessments used to diagnose osteoporosis, who should be assessed, and what to expect during a BMD or heel ultrasound	1) What is osteoporosis?; 2) bone formation and bone loss; 3) osteoporosis and fractures; assessing your osteoporosis risk factors; 4) action plans for individuals at risk of osteoporosis; 5) diagnosing osteoporosis: what to expect
2. Physical activity and osteoporosis	Physiotherapist	Explain how physical activity affects bone mass (at the level of a lay person); provide practical examples of weight-bearing and resistance exercises; highlight the exercise precautions that should be taken by individuals with osteoporosis	1) Effect of physical activities on bone health; 2) exercise precautions for people with osteoporosis; 3) practical examples of weight-bearing and resistance exercises; 4) maintaining good posture to protect your back
3. Drug therapies for the treatment and prevention of osteoporosis	Endocrinologist	Understand how drug therapies work (at the level of a lay person); provide a brief overview of the primary classes and brands of drug therapies used to prevent and treat osteoporosis (at the level of a lay person); emphasize the significant increase in the incidence of male osteoporosis	1) How drug therapies work; 2) common osteoporosis medications; 3) what about male osteoporosis?; 4) how long should I continue taking my medication?
4. Nutrition and osteoporosis	Registered dietician	Explain the role of calcium and vitamin D in preventing and treating osteoporosis; inform their peers of their required amount of daily calcium; recommend methods of maximizing dietary calcium intake; understand the role of calcium and vitamin D supplements in preventing and treating osteoporosis, when calcium and vitamin D intake should be supplemented, how to choose and how to take a supplement	1) Calcium is essential for healthy bones; 2) using diet to maximize your daily calcium intake; 3) vitamin D's role in preventing osteoporosis; 4) when you cannot get enough calcium and vitamin D from your diet
5. Living with osteoporosis and protecting your back	Occupational therapist	Discuss the physical consequences and challenges of living with osteoporosis; provide practical suggestions to effectively practice safe movements, complete household chores safely, and eliminate fall hazards in one's home; provide contact information for Osteoporosis Canada.	1) Physical consequences of living with osteoporosis; 2) protecting your bones; 3) how to move safely; 4) how to safely complete your household activities; 5) eliminate fall hazards from your home.

Abbreviation: BMD, bone mineral density.

educator/mentor was assigned up to nine participants to mentor. A risk assessment tool and action plan was designed to facilitate participants' discussions with their family physician (Figure 1). Peer educators/mentors worked one-on-one with their assigned participants to complete Part 1 of the tool (Figure 1) that included questions about past fractures, family history, drug use, and other factors known to increase risk of fractures. These risk factors were consistent with those outlined in the Canadian guidelines for the diagnosis and management of osteoporosis at the time of the study.²⁶

Participants who had not had a BMD assessment done were requested to arrange an appointment with their family physician to request a BMD assessment. If, and when, this was obtained, and for those who already had a BMD assessment done but had not discussed results with their physician, a further appointment with their physician was advised to discuss the results.

During this visit, the physician was presented with Part 1 of the risk assessment and action plan tool (Figure 1) and was requested to complete Part 2. If the physician did not complete the risk tool and therefore did not provide the BMD result, the participant subsequently requested, via a release of information form, that the BMD result be faxed to one of the study physicians (RC). Each participant was tutored by their peer educator/mentor on the questions to ask their family physician, the information they should obtain, and to discuss appropriate management based on the information recorded on their risk assessment tool. The objective of the RCT was to test whether a participatory community development approach that actively engages seniors in providing peer-led osteoporosis education and mentoring could be used to improve the diagnosis and management of osteoporosis.

Methods

The study reported in this paper involved a pragmatic two-arm RCT conducted over a 2-year period from 2007 to 2009.

To ensure the study was as inclusive as possible, individuals were eligible to participate if they were ≥ 65 years of age and lived within the NORC. Recruitment was confined to English speaking individuals. Potential participants were recruited by the peer educators/mentors using a number of strategies: word-of-mouth, notices posted in the public shopping mall and in the mail and laundry rooms of the 12 apartment buildings, a mall table display, and advertising on the internal community television channel. Potential participants identified by the peer educators/mentors were provided with an information package containing a letter of information about the study, a consent form, and a baseline

demographic, risk and knowledge questionnaire (further details below). The peer educators/mentors provided potential participants with assistance in completing the forms if it was required. Informed consent was obtained from each participant. The study coordinator reviewed all completed consent forms and questionnaires for completeness prior to enrolling and randomizing the participants to the peer-led education program ($n=53$) or to a control group ($n=52$). Participants were randomized using the sequentially numbered, opaque sealed envelope method of randomization and allocation concealment.²⁷ Three education sessions for 14 participants and one final session for up to 12 participants were planned. To maintain balanced allocation throughout recruitment, a batch approach was used. One batch of 28 envelopes (14 for the intervention and 14 for the control) was created by the study coordinator and used for the first 28 participants enrolled. A second batch of 28 envelopes was used for the second wave of participants recruited, a third batch of 28 for the third wave, and fourth batch of 22 for the final wave (recognizing that one of the allocation envelopes would not be required for a sample of 105 participants). It was not possible to blind the involved parties to their allocation due to the nature of the intervention and the study design.

The knowledge questionnaire (provided as [Supplementary material](#)) included multiple choice and true or false questions related to the five key content areas to be covered by the education modules: what is osteoporosis; physical activity and bone health; drug therapies for the prevention and treatment of osteoporosis; nutrition and bone health; and living with osteoporosis and protecting your bones. The risk questionnaire was derived by the research team based on a review of published material. The knowledge questionnaire was developed by the research team based on the information being delivered in the education modules and subsequently reviewed for face validity by the osteoporosis content experts. The knowledge questionnaire is assumed to have face and content validity as the questionnaire and the correct responses are based on up-to-date expert knowledge reflecting recent guidelines and clinician expertise. The knowledge questionnaire was self-administered and scored by the research coordinator. Test scores were calculated by summing the correct number of responses minus the incorrect responses. To ensure that all scores were positive values, 25 was added to each score for a maximum possible score of 44 points. Participants allocated to the control group received usual care, that is, the care which would normally be provided without this intervention, while the intervention group attended a peer-led

Osteoporosis "Points of Opportunity" Program

TAKE THIS FORM WITH YOU TO YOUR DOCTOR APPOINTMENTS

PEER ADVISORS TO FILL IN WITH PARTICIPANTS

According to the 2002 Clinical Practice Guidelines for the diagnosis & treatment of osteoporosis in Canada, all individuals over age 65 should have a bone mineral density test done. (CMAJ 2002; 167 (10 suppl): S1-S34).

- I am over 65
 I have had a Bone Mineral Density (BMD) test in the last 5 years: Yes No

In addition, I have the following osteoporosis risk factors:

- Prior spine fracture Mother had osteoporosis &/or fractures
 Prior wrist fracture Father had osteoporosis &/or fractures
 Prior upper arm (humerus) fracture I have lost _____ inches in height.
 Prior hip fracture
 Prior rib fracture

ACTION:

- Arrange an appointment with your doctor to schedule a BMD
 Arrange an appointment with your doctor to obtain and discuss the results of your BMD

TAKE TO YOUR DOCTOR & FILL IN WITH YOUR DOCTOR

If no BMD in the last 5 years, schedule a BMD with your doctor. BMD scheduled: Yes No
 If BMD in the last 5 years, or after the above scheduled BMD has been completed:

What is my bone mineral density and what should I be doing?

Total Hip t-score: _____ Spine t-score: _____

On the basis of my BMD results and other osteoporosis risk factors...

- I am at high risk of fracture
 I am NOT at high risk of fracture

What, if any, treatment should I be on?

- No prescription medication
 The following prescription medication _____

What, if any, changes are required to my diet? _____

Should I take any supplements? No Yes (please list dosage)

Calcium: _____
 Vitamin D: _____

What, if any, changes are required to my lifestyle? _____

Should I ever have a BMD done again? If so, when? _____ years

© Sam Katz Community Health and Aging Research Unit

Figure 1 Risk assessment and action plan tool.

osteoporosis education session followed by a 6-month personalized peer mentoring period which involved risk assessment, encouraging participants to visit their family physician, and encouraging compliance with physician recommendations. Following completion of the intervention, all trial participants in both intervention and control groups completed a second knowledge questionnaire.

Data collection

The planned sources of data collection were:

1. Participant submitted data: demographic, risk, and knowledge information were provided by all participants upon recruitment to the study.

Given the tightly-knit composition of this community, potential contamination of the control group was considered to be a significant risk. To determine whether information from the study had an impact upon the control group participants, this cohort was asked to complete a questionnaire at the end of the study to determine whether their behavior or knowledge had changed during the course of the study by assessing whether they had sought out their own information about osteoporosis and BMD testing from their family or friends, had started taking calcium or vitamin D supplements, had started exercising, or had spoken to their friends or neighbors about osteoporosis.

2. Peer educator/mentor collected data: the peer educator/mentor provided their mentees with carbonless duplicate forms (Figure 1) asking participants to confirm their age, whether they had undertaken a BMD assessment in the past 5 years, and whether they had any of eight osteoporosis risk factors prior to the participant scheduling an appointment with their physician. Following the appointment and BMD assessment, participants were instructed to complete the second half of the duplicate form with their doctor. In their next meeting, the peer educator/mentor reviewed the BMD scores; whether or not the participant was at high risk of fracture; what, if any, treatment the participant was recommended by their physician; what, if any, changes to the participants diet had been recommended by their physician; whether calcium or vitamin D supplements had been recommended, and at what dosage; what, if any, lifestyle changes had been recommended; and whether a BMD assessment should be undertaken again in the future, and if so, when. Top copies of the duplicate form were handed back to the participant, and the lower copy was

retained by the peer advisor and returned to the study coordinator.

On completing their intervention, the peer educator/mentor also asked members of the intervention group to complete a second self-administered risk and knowledge information questionnaire.

Sample size

The initial RCT sample size calculation was based on achieving a significant improvement in the proportion of participants obtaining a BMD test, reviewing the results and their fracture risk profile with their family physician, and obtaining advice on treatment, if necessary. It was assumed that ~30% would have had a BMD assessment done and have had appropriate follow-up at the start of the study and 40% of the control group may have achieved this by the end of the study, with an increase in the intervention group to about 75%. Without any idea of what to expect for the composite outcome, this seemed both a feasible and clinically meaningful expectation. Using the Kelsey method, the effect size would be 0.725 with a total of 32 participants in each group to have 80% power at the 5% level of significance. Using the Fleiss method with continuity correction gives a required sample size of 36 per group to have 80% power at the 5% level of significance. Given the often frail nature of older subjects, and the potential for loss to follow-up for various reasons in people of this age, the overall recruitment target was increased to 100. On review of the first cohort recruited, the recruitment target was revised to 105 participants as further protection against potential loss to follow-up and to ensure adequate power of the study.

Targeted recruitment by the peer educators/mentors ensured that all potential participants met the eligibility criteria, and recruitment was completed within a 6-month period.

Follow-up

Peer educators/mentors conducted formal follow-up mentoring sessions with intervention group participants monthly and more frequently informally as required. This was face-to-face or by telephone and aimed to encourage compliance with medication and lifestyle recommendations and to problem solve any barriers to compliance. Data were collected on an ongoing basis, as participants reached the goals. There were no specific time points beyond the 6-month termination time, as each participant's trajectory was different. Follow-up with the control group took place at the 6-month point.

Outcome measures

Two outcome measures were identified and analyzed:

1. At the 6-month follow-up, the proportion of participants making a change in behavior related to their osteoporosis risk (obtaining a BMD assessment; returning to their family physician to review their risk profile and to obtain BMD results; and receiving treatment recommendations including calcium, vitamin D, and osteoporosis medication). For this study, appropriateness of the recommendation is not reported as the focus was on completion of the process and not to evaluate the knowledge base of the physicians. All components had to be met to achieve what was a composite outcome. Each participant could have been at different points in the outcome achievement at the start of the study. For example, a participant could have had a BMD done already but have had no follow-up with their family physician. The BMD had to have been done within the previous 2 years. All three of the composite outcomes had to be achieved to meet the endpoint. Participants already on osteoporosis medication were not specifically excluded on the basis that treatment did not necessarily mean that the other outcomes (such as BMD and fracture risk assessment) had been completed.
2. The improvement in participants' knowledge related to osteoporosis, including physical activity, drug therapies for the prevention and treatment of osteoporosis and nutrition.

Analysis

The between-groups difference in the proportion of participants making a change in behavior related to their osteoporosis risk was analyzed using the odds ratio and 95% confidence interval (CI). The between-group difference in knowledge change score was analyzed using an independent group *t*-test and 95% CI of the difference score. McNemar's chi-square was used to analyze the change from baseline to follow-up in the proportion of the treatment group with adequate vitamin D intake. Study outcomes were analyzed on a per protocol basis. All analyses were conducted using OpenEpi 3.03a (www.openepi.com).

Ethics

Ethical approval was obtained from The University of Western Ontario Research Ethics Board for Health Sciences Research Involving Human Subjects, organized and operating according to the Tri-Council Policy Statement on the Ethical Conduct of Research Involving Humans and

the Health Canada International Conference on Harmonization Good Clinical Practices Consolidated Guidelines (reference 12835E).

Results

Recruitment

The CONSORT²⁵ flow chart for the trial is shown in Figure 2. In all, 105 participants were recruited, enrolled, and randomized within the study period.

The mean age of participants was 80.5 years (SD =6.9) and the majority (88.6%) were female. Characteristics of the intervention and control groups are presented in Table 2. The groups were well-balanced on several factors including age, gender, medication, and vitamin/mineral use, although the control group had more fractures than the intervention group and had already had more BMD tests performed. Surprisingly, 61% of participants had already had a BMD assessment performed but of these, only 22% knew what the result was and had discussed the results with their family physician.

Of the 105 participants, nine subjects from each group were lost to follow-up or chose not to complete the intervention (Figure 2). From the control group, two subjects declined to participate post-survey. Additionally, follow-up was incomplete for five participants in the control group and three in the intervention group. Three participants moved out of the community, one from the control and two from the intervention group. Within the intervention group, four participants withdrew from the study, one as a result of a fractured hip. One participant in the control group died prior to completing the follow-up.

Achievement of outcomes

Outcome 1: change in osteoporosis behavior

Compared with 30 (73%) of the intervention group, only 13 (30%) of the control group achieved a successful outcome (defined as obtaining a BMD assessment; returning to their family physician to review their risk profile and to obtain BMD results; receiving treatment recommendations) with regard to their osteoporosis behavior ($\chi^2[1] = 10.84$, $P < 0.001$) (Table 3).

There was an increase in the number of the intervention group taking adequate vitamin D (800 IU/day) as defined by the Osteoporosis Canada Guidelines.²⁶ The dose was checked by the peer educator/mentor reviewing the actual medication being consumed. Table 4 shows the change in adequacy of vitamin D intake in the intervention group. There was an improvement in the number of subjects taking an adequate

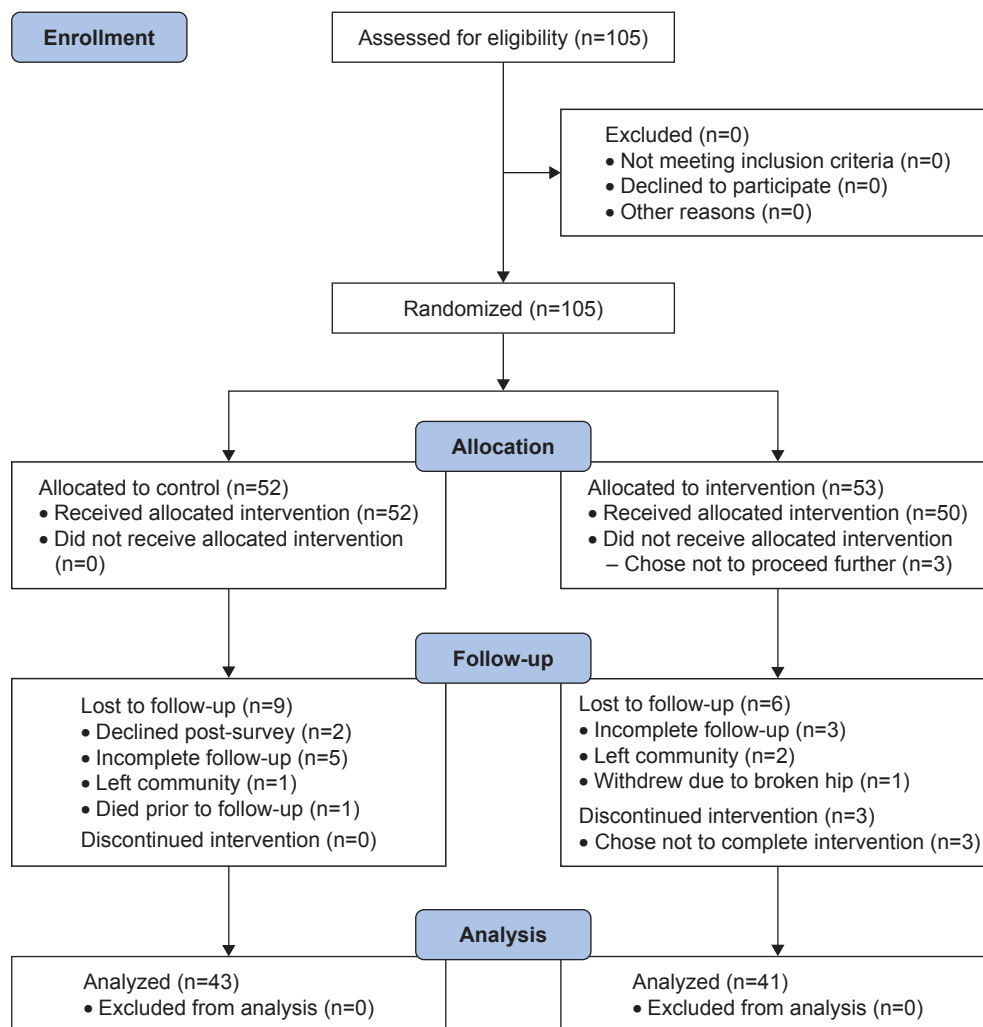

Figure 2 Consolidated Standards of Reporting Trials 2010 flow diagram.

dose of vitamin D (at least 800 IU/day) from 24.4% to 46.3% at follow-up (McNemar's chi-square $P=0.02$). As the same level of certainty could not be assured for the control group, a similar analysis is not possible. However, there was a change in the behavior of the control group in that 31 (73%) reported starting taking vitamin D supplements although the dosage could not be verified.

Outcome 2: change in osteoporosis knowledge

There was minimal improvement in knowledge in the intervention group (Table 3) and a minimal decline in the control group at the end of the 6-month intervention for a net between-group change of 1.3 points (95% CI of difference -0.76 to 3.36). This difference was not statistically significant.

Discussion

In this study, providing peer-led instruction, support, and guidance had a beneficial effect. Peer mentoring was

successful in increasing the participant's willingness to approach the family physician to review their risk and treatment. It may be that the provision of the "cue" card (risk assessment tool) containing the relevant information, rather than expecting the patient to remember the salient information when face-to-face with the family doctor, made the appointment discussion both easier and more productive.

There was no statistically significant change in the participants' knowledge of osteoporosis prevention and management suggesting that change in knowledge was not the driving force behind the change in behavior. This observation raises doubts about the feasibility of using an awareness or educational model to change behavior and it does question the value of such an approach alone in the attempt to improve self-management of chronic conditions. Although the self-management model has gained widespread popularity, numerous limitations with this approach, particularly for frailer, older individuals, have

Table 2 Baseline characteristics of participants

been identified.^{11,28-30} In particular, the short-term focus of current education programs and the difficulty in maintaining positive change after program completion when supportive resources are no longer available have been identified as major shortcomings.²⁸ This approach, using peer educators and mentors, does however present some challenges as the pool of volunteers needs replenishment given the age, and sometimes the level of frailty, of senior peer leaders.

Table 3 Change in osteoporosis behavior and knowledge

Variables	Intervention group (n=41)	Control group (n=43)	Odds ratio (95% CI)	Mean difference*** (95% CI)	P-value
Frequency of successful outcome* (outcome 1) n (% yes)	30 (73)	13 (30)	0.16 (0.06-0.42)		<0.001

Notes: *Defined as obtaining a BMD assessment; returning to their family physician to review their risk profile and to obtain BMD results; receiving treatment recommendations. **Test scores were calculated by summing correct responses minus the incorrect responses and adding 25; maximum total score =44. ***Two-sample independent t-test of difference in knowledge change scores; $t_{82,df} = 1.25$. ****The baseline score is for all participants whereas the change score represents the participants who completed both tests.

Abbreviations: SD, standard deviation; BMD, bone mineral density; CI, confidence interval.

Green and Kreuter's³¹ model of health promotion outlines enabling factors (conditions and resources that allow or enable behavior change) and reinforcing factors (those that cue, remind, or reinforce behavior change), which are critical to facilitating changes in health-related behaviors. In this intervention, the peer mentorship component along with the risk assessment and action form served as the enabling and reinforcing factors that improved participants' behaviors targeted at osteoporosis assessment, prevention, and management. It is well-documented in the literature that education programs for health professionals that incorporate enabling and reinforcing factors are more effective in creating behavior change than those only aimed at disseminating information and increasing knowledge.³²⁻³⁴ It is also possible that providing the family physician with the information, as well as a summary of the risk factors highlighted in the guidelines, facilitated their response.

Pragmatic trials, undertaken in real-world settings, strive to provide evidence on the effectiveness of interventions within usual care settings to make their findings more generalizable. The development and undertaking of these trials is recognized to be more complex, and the 2008 extension of the CONSORT guidelines²⁵ addresses the consistent reporting of many of the issues associated with pragmatic trials. However, it would seem that there are additional issues to consider when conducting a trial within a community setting. It is for these reasons that it could be argued that community-based trials provide an inferior level of evidence. If researchers are aware of the risks associated with conducting community-based trials, and if identified risks are appropriately addressed, these studies can provide high-quality evidence. For example, a recently published pragmatic pilot study³⁵ on telehealth interventions in the UK identified problems with obtaining and maintaining care pathway fidelity. This issue was addressed by clinician education, clear messaging regarding the need to adhere to protocol, and vigilant analysis of care delivery to ensure that protocols were followed.

Table 4 Adequacy of vitamin D intake in the intervention group

	Follow-up		n
	Adequate	Inadequate/none	
Baseline			
Adequate	7	3	10
Inadequate/none	12	19	31
n	19	22	41

Note: There was an increase in the number of participants taking adequate vitamin D from 10/41 (24.4%) to 19/41 (46.3%) (McNemar's chi-square $P=0.02$).

For the current study, the selection of a NORC as the location ensured an adequate number of participants and peer mentors could be recruited perhaps more readily than in a standard community. However, the nature of this community posed a challenge to the researchers as a result of the proximity and frequent interaction between participants; so risk of contamination of the control group could hardly be avoided. While the risk of contamination of the control group could be seen as a methodological weakness, in reality it may have been an asset, as the control group also changed their behavior with regard to osteoporosis. This demonstrated the value of the informal networking and communications that the control group was exposed to, an important finding of the study that could have been lost if strict separation had been achieved.

While the educational component of the intervention may have been inadequate to effect a change in knowledge in the intervention group, behavior change still took place. Furthermore, while the study did not attempt to educate the physicians directly, the present approach allowed seniors to approach the family physician armed with information that could effect a change in physician action. Consequently, it is possible that participant behavior change along with physician education initiatives may have proved more effective than either one alone.

Conclusion

Osteoporosis is undertreated and patients with, or at risk of, fractures are frequently not assessed, let alone treated when appropriate.^{5,8,36,37} The participatory community development initiative reported here may have the potential to reduce the osteoporosis care gap and, importantly, be applicable to improving management of other chronic conditions. There are many clusters of older adults living in high concentrations in urban settings, and while these communities may sometimes challenge health care delivery, they are also an opportunity, appropriately developed, to manage significant health problems such as osteoporosis.

Acknowledgments

This article presents independent research funded by an unrestricted grant from the Alliance for Better Bone Health. The authors acknowledge the contributions of research assistants H Hanson and M van Zandvoort who assisted with subject recruitment and data collection. It is further acknowledged that the abstract for this paper was presented at the 31st Annual Meeting of the American Society for Bone and Mineral, and published online at http://onlinelibrary.wiley.com/doi/10.1002/jbmr.565_0241305/full (abstract MO0263).

One of the authors of this paper (DAF) is supported by the National Institute for Health Research Collaboration for Leadership in Applied Health Research and Care for Yorkshire and The Humber (NIHR CLAHRC YH). The views and opinions expressed are those of the author, and not necessarily those of the National Health Service, the NIHR, or the Department of Health. CLAHRC YH would also like to acknowledge the participation and resources of partner organizations. Further details can be found at <http://clahrc-yh.nihr.ac.uk/>. This trial was registered with Current Controlled Trials on September 11, 2013; registration number ISRCTN44810824.

Author contributions

MK conceived of the study, participated in the design, coordinated the conduct of the study, supervised the research assistants, participated in the data analysis and carried out revisions to the manuscript. DAF was responsible for the design, management and data analysis of the UK Telehealth intervention study, and developed and finalized this manuscript. MS directed the design of the study, contributed towards data analysis and carried out revisions to the manuscript. MYS contributed towards data analysis and provided critical revision of the paper. RGC assisted in the conception and design of the study, participated in the peer mentor's education, participated in the analysis and carried out revisions to the manuscript. All authors read and approved the final manuscript and agree to be accountable for all aspects of the work.

Disclosure

The authors report no conflicts of interest in this work.
