Running title: Molecular Diversity of Libraries from Libraries

Abbreviations: CDF, cumulative distribution function; DOS, diversity-oriented synthesis; GpiDAPH3, graph-based three point pharmacophores; HBA, hydrogen bond acceptors; HBD, hydrogen bond donors; LoL, library from library; MLSMR, Molecular Libraries Small Molecule Repository; MOE, Molecular Operating Environment; MW, molecular weight; LTM, Latent Trait Model; PCA, principal component analysis; PC, principal components; RB, rotatable bonds; TGD, typed graph distances; TPSA, topological polar surface area; DVMS, Data Visualization and Modeling System

ABSTRACT

Combinatorial libraries continue to play a key role in drug discovery. To increase structural diversity, several experimental methods have been developed. However, limited efforts have been performed so far to quantify the diversity of the broadly used diversity-oriented synthetic (DOS) libraries. Herein we report a comprehensive characterization of 15 bis-diazacyclic combinatorial libraries obtained through *libraries from libraries*, which is a DOS approach. Using MACCS keys, radial and different pharmacophoric fingerprints as well as six molecular properties, it was demonstrated the increased structural and property diversity of the libraries from libraries over the individual libraries. Comparison of the libraries to existing drugs, NCI Diversity and the Molecular Libraries Small Molecule Repository revealed the structural uniqueness of the combinatorial libraries (mean similarity < 0.5 for any fingerprint representation). In particular, bis-cyclic thiourea libraries were the most structurally dissimilar to drugs retaining drug-like character in property space. This study represents the first comprehensive quantification of the diversity of *libraries from libraries* providing a solid quantitative approach to compare and contrast the diversity of DOS libraries with existing drugs or any other compound collection.

INTRODUCTION

Synthetic combinatorial methods have advanced the ability to synthesize and screen large numbers of compounds because of improvements made in technology, instrumentation, and library design strategies (1). Combinatorial chemistry combined with high throughput and other screening methodologies continues to play a key role in drug discovery (1-3). A very successful synthetic method is the *'Libraries from Libraries'* (LoL) approach (4). This concept is based on the use of well-established solid-phase synthesis methods for the generation of combinatorial libraries combined with the chemical transformation of such libraries. The chemical libraries that are generated by this process have very different physical, chemical, and biological properties compared to the libraries from which they were

derived (4). As such, LoLs can be regarded as a diversity-oriented synthetic (DOS) approach (5, 6), where multiple scaffolds are generated from the same starting material. Increasing skeletal diversity is known to be a very efficient way to increase structural diversity (7). As opposed to high-throughput screening, where often a large number of compounds with different scaffolds are screened, LoL explores the bioactivity space around each scaffold of interest in much more detail, by using a large number of diversity appendages on every scaffold.

A number of small molecule libraries have been prepared in our group using the LoL approach. These libraries have been used successfully to identify novel compounds across a wide range of therapeutic applications (4, 8). Figure 1 shows the LoLs considered in this study. Each LoL includes five individual combinatorial libraries containing the same number of diversity positions, identical side chain functionalities at each diversity position, and the same number of compounds. Libraries within each LoL differ only in the chemical nature of the central scaffold.

It is well accepted that the structural diversity of LoLs improves upon the diversity of other combinatorial libraries, where the 'multidimensional diversity' regarding both scaffold and appendages is often one of the key contributing factors. However, characterizing the diversity is not an easy task, and efforts have been pursued in this regard. One example is in the work of Spandl et al.(7) in which the importance of skeletal diversity was stressed. Previously, circular fingerprints have been used to assess diversity of compound collections (9). While in this work overall good discrimination between DOS and target-oriented synthesis (TOS) libraries could be observed, the question of how to normalize for library size could not be answered completely – smaller libraries often assessed were more diverse, since larger libraries nearly necessarily contain repetitive chemical motives. Also, Rolfe et al. recently addressed the structural diversity of a number of 17 compounds obtained via a "click, click, cyclize" DOS strategy using principal component analysis (PCA) based on BCUT descriptors and principal moment of inertia. The 17 compounds covered different regions of chemical space (10).

The goal of this study was to characterize the structural diversity of 15 combinatorial libraries organized into three LoLs (Figure 1A-C). The analysis is based on two criteria: structural fingerprints and

molecular properties. Thus, the LoL concept reported previously and perceived by chemists as giving rise to diverse compounds, is now assessed quantitatively for the first time. It is demonstrated that LoL generates molecules truly diverse in both structural and molecular property space.

This work is organized into four sections. The first section describes the fingerprint-based diversity of each combinatorial library and LoL. The second section shows the cross-comparison of the three LoLs and the 15 libraries. The third section describes the structural comparison of the 15 libraries with external compound collections. Section four compares the compound datasets in terms of molecular properties. The approaches presented here are general and can be used to characterize the diversity of other LoLs or DOS libraries.

Figure 1 here

METHODS

Data sets. Each LoL contains five individual combinatorial libraries reported previously (Figure 1):

LoLA = A1 U A2 U A3 U A4 U A5

LoLB = **B1** U **B2** U **B3** U **B4** U **B5**

$LoLC = C1 \cup C2 \cup C3 \cup C4 \cup C5$

where LoLA-C are the three libraries from libraries considered in this study. Figure 1A shows the bisheterocyclic LoLA that includes bis-cyclic diketopiperazines A1, bis-cyclic piperazines A2, bis-cyclic guanidines A3, bis-cyclic ureas A4 and bis-cyclic thioureas A5 (8, 11, 12). LoLB (Figure 1B) is composed of bis-cyclic diketopiperazines B1, bis-cyclic piperazines B2, bis-cyclic guanidines B3, biscyclic ureas B4 and bis-cyclic thioureas B5 (8, 13). LoLC (Figure 1C) includes different pentaamines and pyrrolidine bis-heterocyclic libraries, such as pyrrolidine bis-diketopiperazine C1, pyrrolidine bispiperazine C2, pyrrolidine bis-cyclic guanidines C3, pentaamine C4 and pyrrolidine bis-cyclic thiourea C5 (14). To note, libraries with the core scaffolds of LoLC and LoLB were screened in a μ -opioid receptor binding assay (1). The most active libraries had the scaffolds of B3 and C3 (1) and several compounds of **C3** had a K_i lower than 100 nM (1). Combinatorial libraries with the core scaffold of LoLC were recently screened for antitubercular activity leading to compounds with 90–100% inhibition against *M. tuberculosis* at concentrations less than 6.25µg/mL (14).

Libraries A1-A5 and B1-B5 have three diversity positions, and C1-C5 have four diversity positions. To enumerate libraries A1-A5 and B1-B5, we used ten amino acids or carboxylic acids as building blocks for each diversity position. Thus, the size of each individual combinatorial library was $10 \times 10 \times 10 =$ 1,000 compounds; hence LoLA and LoLB contained 5,000 structures each. In order to measure the effect of each core template in the diversity, the same set of ten amino acids or carboxylic acids was considered for each library. To enumerate C1-C5, we selected six amino acids and five carboxylic acids from the pool of the ten building blocks used in the libraries above. Thus, the size of each library C1-C5 was 6×6 x 6 x 5 = 1,080 compounds, and LoLC contained 5,400 structures. A complete list of the building blocks used to enumerate the libraries is in Table S1 of the Supporting information. In order to compare the diversity across different libraries, we considered approximately the same library size; i.e., 1,000 - 1,080compounds. In addition, it has been reported that data sets of 1,000 molecules are representative samples to study the structural diversity of combinatorial and other libraries (15, 16). The combinatorial libraries were enumerated using the QuaSAR-CombiDesign module of the Molecular Operating Environment (MOE) program, version 2009.10 (17). The collection of drugs (1,490 compounds) was obtained from DrugBank (18) as collected in the ZINC database (download July 2008) (19). The NCI diversity set (1,832 compounds with unique SMILES as computed with MOE) was obtained from ZINC (download March 2010). The MLSMR collection was obtained from PubChem (20) (347,480 compounds downloaded in May 2010) and processed with MOE by disconnecting group I metals in simple salts and keeping the largest fragment.

Comparison metrics. Compound collections were analyzed based on structural fingerprints and molecular properties. Similarity values were computed using the 2D fingerprints MACCS keys (21) (166 bits), graph-based three point pharmacophores (GpiDAPH3), typed graph distances (TGD) implemented in MOE, and radial fingerprints (equivalent to ECFP4) implemented in Canvas (22). In addition, we used

the 3D fingerprint spatial three-point pharmacophore (piDAPH3) from MOE, calculated from the structures geometrically optimized using the MMFF94x force field implemented in MOE. The Tanimoto coefficient (23, 24) was used as the similarity measure for all fingerprints.

Intra-library similarity. Pairwise similarities were computed for each combinatorial library. The distribution of similarities was analyzed by means of cumulative distribution function (CDF) curves.

Inter-library similarity. LoLs were compared to each other computing the pairwise structural similarity. To this end, we employed random samples of 300 compounds per library so that each LoL contained 1,500 members (25). The pairwise similarities were analyzed using CDF curves and multi-fusion similarity (MFS) maps. The MFS map is a method developed recently for the visual characterization and comparison of compound databases and is based on data-fusion similarity measures. The fusion data are plotted in two dimensions, where the ordinate represents the maximum-fusion values and the abscissa the mean-fusion values. Each point in the map is associated with a specific molecule in the test set, and its position is determined by the corresponding fusion values computed with respect to the molecules in the reference set (26). The MFS maps can be characterized quantitatively by the corresponding distributions of the max- and mean-fusion values (27). This approach has been employed to explore structure-activity relationships of compounds data sets (28) and to compare combinatorial libraries (16, 27, 29).

Comparison with external compound collections. The 15 libraries, with 1,000 (A1-A5, B1-B5) and 1,080 (C1-C5) molecules each, were compared with a collection of drugs, the NCI Diversity set and the Molecular Libraries Small Molecule Repository (MLSMR) using MACCS keys, GpiDAPH3, TGD and piDAPH3 fingerprints. We employed MFS maps (setting the external compound collections as the reference sets) and Latent Trait Mapping (LTM) plots. LTM is a dimensionality reduction technique that is specially designed to visualize discrete data (30). It defines a function (or mapping) from the original data space to a lower-dimension (usually 2D) visualization space. Because the mapping is non-linear, it often provides a more informative visualization than either plotting pairs of the original variables (such as

MFS maps) or linear maps (such as PCA). The price to pay for the greater insight is that there is no interpretation of the axes on the visualization plot.

Molecular properties and property space. The following properties were computed with MOE molecular weight (MW), number of rotatable bonds (RB), hydrogen bond acceptors (HBA), hydrogen bond donors (HBD), topological polar surface area (TPSA), and the octanol/water partition coefficient (SlogP). To obtain a *visual* representation of the property space (27), PCA was carried out in Spotfire 9.1.2 (31) considering the six molecular properties and plotting the first two principal components.

RESULTS AND DISCUSSION

Intra-library diversity

Figure 2 summarizes the distribution of similarities of LoLA, LoLB and LoLC and the corresponding individual libraries using MACCS keys. Figure 2A shows a comparison of the diversity of LoLA and A1-A5. The CDFs and the corresponding statistics indicate that LoLA is more diverse than each individual library. For example, compare the median and mean of the similarity distribution of LoLA (0.627 and 0.641, respectively) with the corresponding values for the individual libraries (≥ 0.786 and ≥ 0.789 , respectively). Also, compare the standard deviation of LoLA (0.110) with the standard deviation of A1-A5 (≤ 0.08). The CDFs also indicated that A3 and A5 showed slightly higher diversity than A1, A2 and A4. Library A1 showed the lowest diversity.

Figure 2 here

Figure 2B and 2C summarize the distribution of similarities of LoLB and LoLC, respectively, along with their corresponding individual libraries. LoLB and LoLC have higher diversity (lower similarity) than their corresponding libraries. Bis-cyclic diketopiperazine libraries (**B1** and **C1**), had lower diversity as compared to other corresponding individual libraries within the same LoL. To note, a relatively small pre-defined MACCS keys (166 bits) was sufficient to differentiate between the libraries. These results suggest that MACCS keys could focus only on the discriminant features but neglect other relevant

chemistry. However, we obtained similar conclusions using other structural representations including TGD, GpiDAPH, radial and piDAPH3 fingerprints (see below).

Inter-library diversity

Figure 3 shows the heat maps of similarity matrices of the 15 combinatorial libraries calculated with MACCS, TGD, GpiDAPH, radial and piDAPH3 fingerprints. Each map visualizes 1,500 x 1,500 = 2,250,000 pairwise comparisons and is color-coded by similarity value using a continuous scale from green (low similarity value) to red (high similarity value). The name of the individual libraries and LoLs are indicated in the figure. Each map can be divided into $15 \ge 15 = 225$ "minor" regions or squares that correspond to the pairwise comparison of all 15 libraries. The maps can also be divided into $3 \times 3 = 9$ "major" regions that are associated with the cross-comparisons of LoLA, LoLB and LoLC. The minor or major regions along the main diagonals starting from the top-left correspond to the self-library comparisons. The maps help to visually inspect the similarity between individual libraries that belong to the same LoL as well as to different LoLs. In general, in this study most of the similarity values computed with radial fingerprints were close to zero. TGD, piDAPH3 and GpiDAPH3 showed comparable similarity relationships among databases although with different scales; similarity values calculated with TGD were higher than the similarities calculated with piDAPH3 and GpiDAPH3. Noteworthy, the pharmacophoric fingerprints, TGD, piDAPH3 and GpiDAPH3, were unable to distinguish the pair of libraries A4-A5 or B4-B5. This is because the difference in the central scaffold of these libraries is an oxygen (A4-B4) or sulphur atom (A5-B5) that are treated as equal by TGD, piDAPH3 and GpiDAPH3. MACCS keys provided very insightful results and were able to distinguish all libraries; therefore, we will mainly focus on MACCS keys to discuss the inter-library similarity.

Figure 3 here

Along the main diagonal on the heat map based on MACCS keys (Figure 3), there are 15 black-to-red squares indicating a high similarity for the self-individual library comparisons; e.g., comparison of A1-A1, A2-A2, A3-A3, A4-A4, B1-B1. In contrast, the three major regions along the main diagonal (self-

LoL comparisons, LoLA-A, LoLB-B, LoLC-C), contain a number of green and black-to-green squares; in particular, LoLA-A and LoLB-B. This observation suggests a low similarity between the five individual libraries that belong to the same LoL. The visual analysis of the similarity matrix of random samples is in agreement with the increased diversity of each LoL as compared to the individual libraries (see above). A quantitative analysis of each major quadrant is discussed later in this section.

A diagonal of black-to-red squares can be identified in the major region associated with the crosscomparisons of LoLA-B. This diagonal indicates the high similarity between individual libraries that belong to different LoLs; for example, A1-B1, A2-B2, A3-B3, A4-B4 and A5-B5. This is because all these pairs of libraries have a bis-cyclic heterocyclic ring in common, namely, bis-cyclic diketopiperazines (A1, B1), bis-cyclic piperazines (A2, B2), bis-cyclic guanidines (A3, B3), bis-cyclic ureas (A4, B4) and bis-cyclic thioureas (A5, B5). Similar conclusions are obtained from the crosscomparisons LoLA-C and LoLB-C. Note, however, that the A4-C4 and B4-C4 comparisons are green-toblack indicating lower similarity. This observation is associated with the different scaffold of A4 and B4 (bis-cyclic urea), and C4 (pentaamine). To note, the black-to-red square comparing libraries B3-C3 indicates high similarity between these collections. To note, both libraries have a bis-cyclic guanidine moiety in the central scaffold, and libraries with these scaffolds were the most active in a μ -opioid receptor binding assay (1). The heat map calculated using MACCS keys also provides a quick inspection of the more diverse libraries; for example, the green squares corresponding to the pair of libraries A1-B3 and A5-B1 indicate low similarity.

The heat map of similarity matrices is a simple and powerful tool to explore structural relationships between LoLs and the individual libraries. The visual analysis was expanded with a quantitative study of the similarities between LoLs. Figure 4 shows the CDFs and corresponding statistics of the distribution of the MACCS pairwise similarities comparing the LoLs. The CDFs for the self-LoL comparisons with 300 compounds per library are similar to the CDFs for the self-LoL comparisons with 1,000 (LoLA, LoLB) and 1,080 compounds (LoLC) per library. This result suggests that the random samples with 300 compounds per library are representative. The CDF curves indicate that each of the LoL is structurally diverse. Figure 4 shows that LoLA is the most diverse of the three LoLs, whereas LoLC is the least diverse. This result agrees with the conclusions obtained from the heat map in Figure 3 and CDFs in Figure 2A. The CDF for the cross-LoL comparisons (Figure 4) indicate the low similarity between any pair of LoLs. The pair LoLA-B has the highest diversity, whereas the pair LoLB-C has the lowest diversity. Similar conclusions were derived from the heat map (Figure 3).

Figure 4 here

Figure 5 depicts the MFS maps comparing the LoLs with themselves (self-reference) and with other LoL (cross-comparisons) using MACCS keys. The reference sets are designated along the top and the test sets along the left-hand side of the figure. The three maps along the main diagonal are self-referential. In all maps the mean similarity ranges within similar values ($\sim 0.5 <$ mean similarity $< \sim 0.75$) indicating comparable diversity of the reference sets. This result is in agreement with the similarity distributions of the three LoLs (Figure 2 and 4). Concerning the self-referential MFS maps, the maximum values are high (> 0.9 and several > 0.95) indicating that each molecule in the corresponding LoL has a close nearest-neighbor (expected to belong to the same individual library). However, the corresponding mean values are lower than 0.75 indicating the higher diversity of the corresponding LoL.

Figure 5 here

The MFS maps along the left-hand side of Figure 5 show the relationship of LoLB and LoLC to LoLA (reference). LoLB has larger maximum values than LoLC indicating that LoLB has closer neighbors in LoLA. This result is difficult to deduce from the heat maps in Figure 3. The MFS maps along the center of Figure 5 show the relationship of LoLA and LoLC to LoLB (reference) suggesting a similar relationship between the two LoLs and LoLB. The MFS maps along the right-hand side of Figure 5 depict the relationship of LoLA and LoLB with LoLC indicating an overall lower similarity of LoLA (32).

Structural comparison with external data sets

Figure 6 shows the MFS maps and the corresponding CDFs of the maximum- and mean-fusion values comparing the relationship between LoLA-C (test) and drugs (reference) using MACCS keys. The CDF of the maximum-fusion values are reminiscent of the nearest-neighbors curves (33, 34). These maps suggest that there are no identical compounds between any of the combinatorial libraries and drugs; moreover, all the compounds in the combinatorial libraries have a maximum MACCS keys similarity lower than 0.9 to any of the drugs and most of the compounds have maximum similarity lower than 0.85. Note also the larger distribution of the molecules in each of the three MFS maps considering the entire LoLs as compared to the distribution of the molecules of each combinatorial library. This result further supports the increased diversity of LoLs over the individual libraries. Similar conclusions were obtained with other fingerprint representations (see below).

Figure 6 here

Figure 6A shows the MFS maps and CDF for libraries **A1-A5**. **A1** is towards the top right part of the MFS map suggesting a relative increased structural similarity to drugs as compared to **A2-A5**. This observation was further confirmed by the CDFs of the maximum- and mean-fusion values. **A5** is located towards the bottom left part of the MFS map suggesting that this library is the least similar to drugs. A similar conclusion can be derived from the CDFs. Note, however, that the CDF of the mean-fusion value cannot distinguish **A3** and **A5** since these two libraries have the same mean similarity relationship to drugs. **A2** and **A4** are, in general, the second most similar libraries to drugs after **A1** as suggested by the MFS map. To note, the corresponding CDFs of the maximum- and mean-fusion values indicate an opposite order of similarity for **A2** and **A4** with respect to drugs; the CDF of the maximum-fusion values for library **A2** is shifted towards higher values than the corresponding curve for **A4** indicating that the nearest neighbors of **A2** in DrugBank are closer that the nearest neighbors for **A4**. However, the CDF of the mean-fusion values for library **A4** is shifted towards higher values indicating that, on average, **A4** is more similar to drugs than **A2**. These observations highlight the importance of considering more than one metric for a complete assessment of the relationship between compound collections.

Figure 6B shows the MFS maps and CDFs for libraries **B1-B5**. According to the MFS map **B1**, a biscyclic diketopiperazine library (related to **A1**), is structurally more similar to drugs as compared to other libraries within LoLB. Library **B5**, a bis-cyclic thiourea (related to **A5**), is the less similar to drugs. Similar conclusions can be derived from the CDFs. The CDFs of the maximum- and mean-fusion values for **B2** and **B4**, respectively, indicate that while **B2** has closer nearest neighbors in the collections of drugs, **B4** is on average more similar to drugs. Figure 6C shows the MFS maps and CDFs for **C1-C5** indicating that the pyrrolidine bis-cyclic thioureas **C5** are the less structurally similar to drugs. According to the MFS map and CDF of the mean-fusion values, pyrrolidine bis-cyclic diketopiperazines **C1** are more similar to drugs as compared to other libraries within LoLC. To note, the CDF for the maximumfusion values indicates that **C1** and **C2** have a similar nearest-neighbor relationships to drugs; however, **C1** is on average structurally more similar to drugs than **C2**.

Figure 7 depicts a *visualization* of the chemical space comparing LoLs and drugs using the LTM algorithm with MACCS keys (166 bits) as the molecular descriptors (35). The binary (0-1) data is well suited to this algorithm. Figure 7A shows LoLA, LoLB, LoLC and drugs in the same space. For clarity, Figure 7B-D show a comparison of the chemical space of drugs with each LoL, respectively, within the same coordinates as Figure 7A. The LTM plots on the left-hand side of Figure 7B-D shows the LoL as one color, whereas the chemical space on the right-hand side shows each individual combinatorial library with different colors (color scheme as in Figure 1). Visualization of the chemical space in Figure 7B-D shows that LoLA-C cover a larger area of the chemical space than the space covered by each combinatorial library. This result supports the increased structural diversity of the LoLs over the individual libraries.

Figure 7 here

Visualization of the chemical space with the LTM plots shows different relationships of A1-A5, B1-B5 and C1-C5 with drugs. As such, libraries with a bis-cyclic guanidine moiety in the core scaffold A3, B3, C3 (in black), and with a bis-cyclic urea moiety A5, B5 and C5 (in yellow) are the most dissimilar to drugs. In contrast, libraries containing a diketopiperazine moiety A1, B1 and C1 (in blue) are the most

structurally similar to drugs. Measuring the mean distance of drugs to each library in the LTM space further confirmed these conclusions (Table S3 of the Supporting information). Note, however, that there are no overlaps in the structural MACCS keys space between the combinatorial libraries and drugs. These results are in agreement with the MFS maps and CDF curves discussed above (Figure 6). In contrast to MFS maps, LTM plots enable the visualization of the reference set (i.e., drugs) in chemical space. It is also noteworthy that the LTM plots show the separation between different classes much better than the MFS maps (and the PCA visualizations discussed below and shown in Figure 8). In addition, the relationships between different libraries (as measured by distance in the LTM space) are better defined, and there is more information about the groupings of compounds within each library. Further interactive exploration of these visualizations can be carried out using the Data Visualization and Modeling System (DVMS) tool (35, 36).

We also analyzed the structural relationship between LoLs and NCI diversity using the MFS maps and CDFs using MACCS keys (plots not shown). Similar to the comparison with drugs, the combinatorial libraries showed a different structural relationship to NCI diversity. It was also concluded that there are no identical molecules between NCI Diversity and any combinatorial library. Moreover, most of the compounds in any combinatorial library have maximum MACCS keys similarity of 0.80. Lower similarity values were computed with other fingerprint representations (see below).

Since the chemical space depends on the molecular representation (37), we investigated the structural relationship of the LoLs to drugs, NCI diversity and MLSMR using TGD, GpiDAPH3 and piDAPH3 fingerprints. For MLSMR, a subset of 3,000 compounds was selected at random. The maximum- and mean-fusion values (Table S4 of the Supporting information), confirmed that the combinatorial libraries are structurally different from drugs, NCI diversity and MLSMR regardless of the structural representation.

Property Diversity

Table 1 summarizes the median, mean and standard deviation of the distribution of the six molecular properties described in Methods for the 15 libraries, three LoLs and external data sets. Additional statistics of the distributions (e.g., maximum, minimum, first and third quartile and U95 and L95 values) are presented in Table S2 of the Supporting information. The three important molecular properties of size, flexibility and molecular polarity are described by MW; RB; and SlogP, TPSA, HBA and HBD, respectively. The six descriptors used here have been used to compare the property space covered by a virtual collection and reference databases (38) and other combinatorial libraries (16). According to Table 1 and Table S2 of the Supporting information, each LoL has a wider distribution of molecular properties than their corresponding individual libraries as reflected by the larger standard deviation and range for most of the properties. Since all of the combinatorial libraries within a LoL contain the same number of compounds with the library (see above), the variation in the properties within a LoL is due to the central scaffold. These results further demonstrate the observation that increasing skeletal diversity is a very efficient way to increase not only the structural diversity (7), but also property diversity.

Table 1 here

According to Table 1 and S2, LoLA and the corresponding individual libraries have, in general, more HBA, HBD, and larger TPSA values than drugs. The number of rotatable bonds in any of the libraries in LoLA is quite similar to the number of RB in drugs. Also, LoLA has a distribution of SlogP values comparable to drugs; in particular **A4** and **A5**. In general, LoLB and the corresponding individual libraries have larger SlogP, MW and RB values than drugs. **B4**, **B3** and **B5** have a distribution of HBA and HBD comparable to drugs (B3 also has a similar distribution of TPSA values). LoLC has, in general, larger values of HBA, RB and MW than drugs. **C1**, **C2** and **C5** have a distribution of HBD comparable to drugs (C1 also has similar distribution of SlogP values and **C4** a similar distribution of TPSA values).

In order to generate a *visual* representation of the property space, the six molecular properties were subjected to PCA after Z-scaling. Figure 8 depicts an *approximation* of the property space as defined by these properties. The first two principal components (PC) with eigenvalues 2.172 and 2.071, respectively,

account for 70.71% of the variance. (Components with eigenvalues less than 1.0 were not considered). Figure 8A shows LoLA, LoLB and LoLC, drugs and NCI Diversity sets in the same space. From this figure and the property distributions (Tables 1 and S2), it can be concluded that NCI diversity covers a similar region of the property space occupied by drugs. For the sake of clarity, Figures 8B-D show a comparison of the property space of drugs with each LoL, respectively, within the same coordinates as Figure 8A. The property space on the left-hand side of Figures 8B-D show the LoL is one color, whereas the property space on the right-hand side shows each individual combinatorial library with different colors (color scheme as in Figure 1). Table 2 summarizes the corresponding loadings and eigenvalues for the six PCs. For the first PC, the larger loadings correspond to MW followed by RB. For the second PC, the largest loading corresponds to TPSA followed by HBA. Figures 8B-D reveal that LoLA, LoLB and LoLC cover a larger area of the property space than the space covered by each individual library. This observation further demonstrates the increased property diversity of the LoLs over the individual combinatorial libraries.

Figure 8 here

Table 2 here

Figures 8B-D also show a different degree of overlap between LoLs and drugs. LoLA has a significant overlap with drugs (Figure 8B). Noteworthy, LoLA is *structurally dissimilar* to drugs (see above). In other words, the chemical structures of LoLA are different from the structures of drugs; however, the molecular properties of LoLA are similar to the properties of drugs. This observation illustrates the dependence of chemical space with the structural representation (37) and further emphasizes the importance of considering multiple criteria when comparing compound data sets (39, 40).

LoLB and LoLC cover regions of the property space sparsely populated by drugs (Figures 8C and 8D, respectively). A major difference in the distribution of LoLB, LoLC and drugs occurs along the coordinates of the first PC that is mainly associated with MW and RB. These results are in agreement with the conclusions derived from the property distributions in Tables 1 and S2. The areas in the property space with few drugs represent areas that are biologically relevant as revealed by the presence of some

drugs but may not have been sufficiently explored (16). In addition, LoLB and LoLC sample unexplored regions of the drug space. Coverage of regions unexplored by drugs has been reported for other DOS and combinatorial libraries (16, 41). Molecules in these areas, while potentially unlikely to make drugs by themselves, are valuable as chemical probes in order to better understand the structure-activity relationships associated with unknown targets (9, 16). Although the LTM (Figure 7) and PCA plots (Figure 8) represent *visual approximations* of the property space, they provide a useful idea of the molecules' distribution in the space. The non-linear nature of the LTM means that it provides greater discrimination between libraries and also within each library.

We also compared the property space of the LoLs with MLSMR using the same random subset employed in the structural study (42). A visualization of the property space is depicted in Figure S2. (The corresponding loadings and eigenvalues are summarized in Table S5 of the Supporting information). We concluded that LoLA, LoLB and LoLC not only occupy part of the property space of MLSMR but also sparse regions.

The major focus of this study was to demonstrate quantitatively the increased diversity of the combinatorial libraries generated with the LoL approach. To this end, we considered a standard set of building blocks for each LoL enumerating ~1000 compounds per library. Note, however, that the actual size of the libraries can be much larger. For example, libraries with the pyrrolidine bis-cyclic scaffolds have been synthesized and screened with 738,192 compounds per library. Similarly, libraries with the bis-cyclic scaffolds have been synthesized and screened with 45,864 compounds per library (1).

CONCLUSIONS AND PERSPECTIVES

Herein we report a comprehensive characterization of the diversity of 15 combinatorial libraries obtained with the libraries from libraries (LoLs) approach. The 15 libraries are grouped in three bis-diazacyclic LoLs. Previous studies showed that several of the central scaffolds considered in this study are biologically relevant. Structural fingerprints, including MACCS keys, GpiDAPH3, TGD, radial and piDAPH3 fingerprints, as well as molecular properties, were considered to assess the diversity. Analysis

of the structural diversity of the libraries showed that the LoLs are more diverse than the corresponding individual libraries. Distributions of pairwise structural similarities and heat maps of similarity matrices revealed that libraries within the same LoL are structurally diverse, mainly combinatorial libraries in LoLA followed by libraries in LoLB. All these results provide quantitative measures of the different chemical and physical properties of the libraries generated by the LoL approach. Fingerprints-based comparisons indicated that the 15 libraries are structurally different from drugs, NCI Diversity and MLSMR. MFS maps and LTM plots revealed that libraries containing a bis-cyclic thiourea moiety in the central scaffold (A5, B5 and C5) are the most structurally dissimilar to drugs. In contrast, libraries with a bis-cyclic diketopiperazine moiety in the central scaffold (A1, B1 and C1) are more structurally similar to drugs. Comparison of the libraries with drugs using molecular properties showed that combinatorial libraries have a different degree of overlap with the property space of drugs. In particular, despite the fact that LoLA is structurally dissimilar to drugs, their properties are similar.

Focused and targeted combinatorial libraries have gained an increased interest in recent years (43-45). The core scaffolds presented here represent potential starting points of focused or targeted combinatorial libraries. The most suitable core scaffold(s) for a particular target family can be explored using computer-aided target fishing approaches (46, 47) and in-silico "scaffold ranking" (1) to identify the most promising core scaffolds for a particular target or target family before synthesis.

ACKNOWLEDGEMENT

We are very grateful to Karen Gottwald for proofreading the manuscript. We also acknowledge Kyle Kryak for his assistance. This work was supported by the State of Florida, Executive Office of the Governor's Office of Tourism, Trade, and Economic Development, NIH (1R03DA025850-01A1, Nefzi), and NIH (5P41GM081261-03, Houghten). JRO is supported by a BBSRC/Pfizer CASE studentship.

If molecule "m" in a compound collection "M" is the nearest neighbor of molecule "n" in a second compound collection "N", this does not necessarily mean that molecule "n" is the nearest neighbor of "m". This is schematically illustrated in Figure S1 in the Supporting information

Supporting information: Non-symmetry in nearest neighbor relationships (Figure S1); property space of LoL, drugs, NCI diversity, and MLSMR (Figure S2); building blocks used to enumerate the combinatorial libraries (Table S1); molecular properties profile of combinatorial libraries and other data sets considered in the study (Table S2); mean relative Tanimoto distance of drugs to combinatorial libraries in LTM plots (Table S3); distribution of maximum and mean Tanimoto similarities of LoL to drugs, NCI diversity, and MLSMR using different structural representations (Table S4); loadings for the six principal components of the property space of drugs, NCI diversity, and MLSMR (Table S5). The scripts to generate the LTM plots are available upon request.

Figure 1 Fifteen combinatorial libraries organized into three libraries from libraries (LoL) analyzed in this study. Each library within a LoL shares the same number of diversity positions, identical building block side chain functionalities, and the same number of compounds within each library

Figure 2 Intra-libraries similarities using MACCS keys. Figure shows the cumulative distribution function (CDF) of pair-wise similarities for each library and LoL. CDF for each library indicates the distribution of 499500 pairwise-comparisons taken from the similarity matrix. The CDF for the LoLs also contains 499500 points taken at random from the entire similarity matrix. (See also Figure 3 and text for discussion)

Figure 3 Heat maps of similarity matrices comparing 15 libraries (300 compounds at random per library) using different fingerprints, 2D (MACCS, TGD, GpiDAPH3 and radial) and 3D (piDAPH3). Similarity is colored using a continuous color scale from red (high similarity) to green (low similarity)

Figure 4 Cumulative distribution functions of the MACCS keys pairwise similarities between the LoLs

Figure 5 Multi-fusion similarity maps comparing the relationship of the LoLs. The reference LoLs are designated along the top and the test LoLs along the left-hand side of the figure. The three plots along the principal diagonal (upper left to lower right in the figure) correspond to self-referencing MFS maps. LoLA is in brown squares, LoLB in orange circles and LoLC in violet triangles

Figure 6 Relationship between a collection of drugs (reference) with the following test compounds: (A) libraries **A1-A5**, (B) libraries **B1-B5** and (C) libraries **C1-C5**. MFS maps and the corresponding CDF of the maximum and mean values distributions are shown

Figure 7 LTM plots of three LoLs, 15 combinatorial libraries and drugs. (A) Drugs (gray), LoLA (brown), LoLB (orange) and LoLC (purple); (B) drugs and LoLA (left), drugs and A1-A5 (right); (C) drugs and LoLB (left), drugs and B1-B5 (right); (D) drugs and LoLC (left), drugs and C1-C5 (right). A1-A5, B1-B5, C1-C5 are color- and shape-coded as in Figures 1, 5 and 6

Figure 8 Property space of three LoLs, 15 combinatorial libraries, drugs (gray) and NCI diversity (pink). The first two PC account for 70.71% of the variance. The loadings are summarized in Table 2. (A) Drugs, LoLA, LoLB, LoLC and NCI Diversity; (B) drugs and LoLA (brown) and drugs and A1-A5; (C) drugs and LoLB (orange) and drugs and B1-B5; (D) drugs and LoLC (purple) and drugs and C1-C5. A1-A5, B1-B5, C1-C5 are color coded as in Figures 1, 5 and 6

 n_1 is the nearest-neighbor (NN) of m_1 however, m_1 is NOT the NN of n_1 : m_2 is the NN of n_1

Figure S1 Non-symmetry in nearest neighbor relationships. If molecule "m" in a compound collection "M" is the nearest neighbor of molecule "n" in a second compound collection "N", this does not necessarily mean that molecule "n" is the nearest neighbor of "m".

Figure S2 Property space of 3 LoLs, 15 combinatorial libraries, drugs (gray), NCI diversity (pink) and 3000 compounds from MLSMR selected at random (light blue). The first two PC account for 70.41% of the variance. The loadings are summarized in Table S5. Figures S2A, S2B and S2C show a comparison of the property space of MLSMR with each LoL. The left hand side of these figures shows the LoLs in one color and on the right hand side show, in different colors, each of the five combinatorial libraries within a LoL. The largest loadings for the first PC correspond to MW followed by RB. In contrast, the largest loadings for the second PC correspond to SlogP followed by TPSA and HBD.

Table S1. Building blocks used to enumerate the coombinatorial libraries. The name of the functionality is also indicated

LoLA	$\mathbf{R}_1 = \mathbf{R}_2 = \mathbf{R}_3$ (10 amino acids)	
$(10^3 = 1000)$	Methyl - Boc-L-Ala	
compounds per	Hydrogen - Boc-Gly	
library)	S-Isobutyl - Boc-L-Leu	
	S-Isopropyl - Boc-L-Val	
	S-4-Hydroxybenzyl - Boc-L-Tyr(BrZ)	
	S-Hydroxymethyl - Boc-D-Ser(Bzl)	
	(S-S)-1-Hydroxyethyl - Boc-D-Thr(Bzl)	
	S-Phenyl - Boc-L-Phenylglycine	
	S-Propyl - Boc-L-Norvaline	
	S-Cyclohexyl - Boc-L-Cyclohexylalanine	

$\mathbf{R}_1 = \mathbf{R}_3$ (10 carboxilic acids)	$R_2 = (10 \text{ amino acids})$
Phenethyl - phenylacetic	S-methyl - Boc-L-Ala
Butyl - butyric	Hydrogen - Boc-Gly
Isobutyl - isobutyric	S-isobutyl - Boc-L-Leu
2-Methylbutyl - 2 -methylbutyric	S-isopropyl - Boc-L-Val
3-Methylpentyl - 3-methylvaleric	S-4-hydroxybenzyl - Boc-L-Tyr(BrZ)
4-Methyl-benzyl - p-toluic	S-hydroxymethyl - Boc-D-Ser(Bzl)
Cyclopently-methyl - cyclopentanecarboxylic	(S-S)-1-hydroxyethyl - Boc-D-Thr(Bzl)
Cyclohexyl-methyl - cyclohexanecarboxylic	S-phenyl - Boc-L-Phenylglycine
(2-Methyl-cyclopropyl)-methyl -	S-propyl - Boc-L-Norvaline
2-methylcyclopropanecarboxylic	
Cyclobutyl-methyl - Cyclobutanecarboxylic	S-cyclohexyl - Boc-L-Cyclohexylalanine
	$R_1 = R_3$ (10 carboxilic acids)Phenethyl - phenylaceticButyl - butyricIsobutyl - isobutyric2-Methylbutyl - 2 -methylbutyric3-Methylpentyl - 3-methylvaleric4-Methyl-benzyl - p-toluicCyclopently-methyl - cyclopentanecarboxylicCyclohexyl-methyl - cyclohexanecarboxylic(2-Methyl-cyclopropyl)-methyl -2-methylcyclopropanecarboxylicCyclobutyl-methyl - Cyclobutanecarboxylic

LoLC	$\mathbf{R}_1 = \mathbf{R}_2 = \mathbf{R}_3$ (6 amino acids)	R ₄ (5 carboxilic acids)
(6 x 6 x 6 x 5 =	S-Methyl - Boc-L-Ala	Butyl - butyric
1080	Hydrogen - Boc-Gly	Isobutyl - Isobutyric
compounds per	S-isobutyl - Boc-L-Leu	2-Methylbutyl - 2-methylbutyric
library)	S-isopropyl - Boc-L-Val	4-Methyl-benzyl - p-toluic
	S-hydroxymethyl - Boc-D-Ser(Bzl)	Cyclopently-ethyl - cyclopentanecarboxylic
	S-phenyl - Boc-L-Phenylglycine	

Table S2. Molecular properties profile of combinatorial libraries and other data sets
