Time to insulin in the Trial Evaluating Cardiovascular Outomes with Sitagliptin (TECOS)

S.S. Engel[1], M.A. Bethel[2], J. Garg[3], S.R. Stevens[3], Y. Lokhnygina[3], R.G. Josse[4], J.B. Green[3], E.D. Peterson[3], R.R. Holman[2], on behalf of the TECOS Study Group;

[1]Merck & Co., Inc., Rahway, USA, [2]University of Oxford, UK, [3]Duke Clinical Research Institute, Durham, USA, [4]University of Toronto, Canada.

Background and aims: TECOS was a randomized, placebo-controlled trial assessing the impact of sitagliptin on cardiovascular outcomes when added to usual care in patients with type 2 diabetes (T2DM). Among those not using insulin at baseline (n=11,263), we report the risk for progression to insulin during follow-up.

Materials and methods: TECOS enrolled 14,671 participants with HbA1c 6.5-8.0% on monotherapy with metformin (MET), pioglitazone, sulfonylurea (SU) or insulin, or dual combination with two oral agents or insulin with MET. They were randomized double-blind to sitagliptin or placebo, with subsequent diabetes management by the participants' usual care physician. Time to initiation of insulin was estimated using a Cox proportional hazards model.

Results: 5739 and 5472 participants were on mono- (MET 4435 [77%], SU 1246 [22%]) and dual- (SU + MET 5152 [94%]) oral agent therapy, respectively. Monotherapy patients had similar mean age (66 vs 65 years) but shorter median T2DM duration (6 vs 11 years), compared to dual therapy patients. MET monotherapy users were slightly younger (65 vs 68 years), had shorter T2DM duration (6 vs 8 years), similar HbA1c (7.1% vs 7.2%) and higher eGFR (77.4 vs 70.7) compared to SU monotherapy users. Overall, 4.7% of MET monotherapy users, 11.0% of SU monotherapy users and 17.2% of MET + SU users initiated insulin over a median duration of 3.1 years. Randomization to sitagliptin delayed the time to progression to insulin when added to MET monotherapy (1.3 vs 2.0 events per 100 pyrs; HR 0.67 [95% CI 0.51-0.89]) or SU + MET dual therapy (5.1 vs 7.8 events per 100 pyrs; 0.64 [0.56-0.73]), but not to SU monotherapy (4.0 vs 4.2 events per 100 pyrs; 0.96 [0.68-1.34]).

Conclusion: Among a cohort of international clinical trial participants with T2DM well controlled with MET or SU mono- or dual oral agent therapy, the rate of initiation of insulin was higher among SU users (as mono- or dual therapy). Randomization to sitagliptin treatment delayed progression to insulin among MET and MET + SU users.

2

Comparable glycaemic control with once weekly dulaglutide versus insulin glargine, both combined with lispro, in type 2 diabetes and chronic kidney disease (AWARD-7)

K.R. Tuttle[1], M.C. Lakshmanan[2], J.L. Gross[3], B. Rayner[4], R.S. Busch[5], D.B. Woodward[2], A.G. Zimmerman[2], F.T. Botros[2];

[1]Institute of Translational Health Sciences, Providence Health Care, Spokane, [2]Eli Lilly and Company, Indianapolis, USA, [3]Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [4]Division of Hypertension and Nephrology, University of Cape Town, South Africa, [5]Division of Community Endocrinology, Albany Medical Center, Albany, USA.

Background and aims: This phase 3 study compared once weekly dulaglutide (DU) to titrated daily insulin glargine, both combined with insulin lispro, in people with type 2 diabetes (T2D) and moderate to severe chronic kidney disease (CKD) stages 3-4.

Materials and methods: Participants were randomised (1:1:1) to DU 1.5 mg or DU 0.75 mg or titrated insulin glargine. The objective was to demonstrate DU noninferiority for HbA_{1c} change from baseline.

Results: Baseline characteristics (N=576) included: [mean±SD] age 64.6 ±8.6 years, HbA_{1c} 8.6±1.0%, eGFR 38.3±12.8 mL/min/1.73m^2, BMI 32.5±5.2 kg/m^2, daily insulin dose 58.2±31.8 units. DU was non-inferior to insulin glargine for HbA_{1c} change from baseline at both 26 weeks (primary timepoint), and 52 weeks (table). Body weight decreased with DU, whereas it increased with insulin glargine at both timepoints. The hypoglycaemia event rate (glucose ≤3.9 mmol/L) was lower with DU 1.5 mg and 0.75 mg versus insulin glargine at 26 weeks (5.5, 7.8 and 17.1 events/participant/year; p<0.001 for both) and 52 weeks (5.8, 7.6 and 14.4 events/participant/year; p<0.001, p=0.004, respectively). Patients experiencing severe hypoglycaemia were fewer in the DU groups compared to the insulin glargine group (0 in DU 1.5 mg; 5 [2.6%] in DU 0.75 mg; and 13 [6.7%] in insulin glargine). Nausea, vomiting and diarrhoea were more common with DU 1.5 mg (19.8%, 13.5%, 17.2%) and DU 0.75 mg (14.2%, 8.4%, 15.8%) versus insulin glargine (4.6%, 4.6%, 7.2%).

Conclusion: In conclusion, DU produced comparable glycaemic control, greater weight loss, and lower hypoglycaemia rate versus insulin glargine in people with T2D and CKD stage 3-4, with the anticipated gastrointestinal side effects.

Individual HbA_{1c} and weight responses to exenatide QW or placebo added to titrated insulin glargine in type 2 diabetes uncontrolled after insulin optimisation in the DURATION-7 study

E. Hardy[1], J. Rosenstock[2], J.P. Frías[3], A. Somogyi[4], S. Jabbour[5], H. Wang[1], C. Guja[6];

[1]AstraZeneca, Gaithersburg, [2]Dallas Diabetes Research Center at Medical City, Dallas, [3]National Research Institute, Los Angeles, USA, [4]Semmelweis Univeristy, Budapest, Hungary, [5]Endocrinology, Jefferson, Philadelphia, USA, [6]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Background and aims: Results of the DURATION-7 trial showed that, compared to placebo, adding exenatide once weekly (ExQW) to titrated insulin glargine (IG) ± metformin resulted in significant HbA1c-lowering and weight loss in patients with type 2 diabetes (T2D) not achieving glycaemic targets on intensified IG. Since mean values do not provide information on distribution of HbA1c and weight responses, in this analysis we examined the associated HbA1c and body weight individual responses to ExQW or placebo added to titrated IG.

Materials and methods: DURATION-7 included 511 T2D patients with screening HbA1c 7.5-12.0% who underwent an 8-week IG dose optimization period during which any sulphonylurea use was discontinued. Subsequently, 464 patients with continued hyperglycaemia (HbA1c 7.0-10.5%) were randomized to ExQW (n=233) or placebo (n=231) added to IG ± metformin while IG titration continued over 28 weeks.

Results: Of 464 randomized patients, 91% completed 28 weeks. Mean baseline values in patients who received treatment and had at least one post-baseline HbA1c measurement (n=461) were: age 57.7 years; diabetes duration 11.3 years; HbA1c 8.5%; body weight 94.0 kg; BMI 33.7 kg/m^2; IG dose 51 U/day. At 28 weeks, a greater proportion of patients achieved any HbA1c reduction with ExQW + IG vs placebo + IG (165/204, 81% vs 123/206, 60%, respectively), while half the proportion of patients treated with ExQW + IG experienced an increase in HbA1c versus those treated with placebo + IG (39/204, 19% vs 83/206, 40%, respectively; Figure). The proportion of patients experiencing any body weight loss was greater with ExQW + IG vs placebo + IG (127/204, 62% vs 82/206, 40%, respectively), while almost half the proportion of patients treated with EQW + IG experienced body weight gain versus those treated with placebo + IG (77/204, 38% vs 124/206, 60%, respectively; Figure). The proportion of patients achieving both HbA1c and body weight reduction with EQW + IG was more than double that observed with placebo + IG (103/204, 51% vs 47/206, 23%, respectively; Figure).

Conclusion: While patients with inadequately controlled T2D despite optimized IG ± metformin, demonstrated a wide range of HbA1c and body weight responses with ExQW or placebo addition to ongoing titrated IG, patients receiving ExQW were twice as likely to experience an improvement in HbA1c and body weight reductions than those remaining on titrated IG alone.

Figure. Individual HbA1c and Body Weight Responses at 28 Weeks. One ExQW-treated patient with changes in body weight of −34 kg and HbA1c of −4.4% not shown.

Semaglutide provides sustained reductions in body weight over 2 years in subjects with type 2 diabetes (SUSTAIN 6)

A. Consoli[1], S.C. Bain[2], M. Davies[3], I. Lingvay[4], E.Q. Bergan[5], O. Hansen[5], T. Vilsbøll[6];
[1]DMSI and CeSI-MeT, G. d'Annunzio University, Chieti-Pescara, Italy, [2]School of Medicine, Swansea University, Swansea, [3]University of Leicester, UK, [4]University of Texas Southwestern Medical Center, Dallas, USA, [5]Novo Nordisk A/S, Søborg, Denmark, [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark.

Background and aims: Semaglutide, a glucagon-like peptide-1 analogue in development for the treatment of type 2 diabetes (T2D), has demonstrated superior body weight loss vs placebo and active comparators across the SUSTAIN phase 3a clinical trial programme. Excess weight is often a concomitant complication in patients with T2D and is associated with increased cardiovascular risk.

Materials and methods: SUSTAIN 6 was a 2-year cardiovascular outcomes trial that was conducted in 3,297 subjects with T2D at high risk of cardiovascular events. The primary outcome was a composite of the first occurrence of CV death, non-fatal myocardial infarction or non-fatal stroke. Secondary endpoints included glycaemic and weight-related endpoints. Key inclusion criteria were subjects ≥50 years old with established cardiovascular disease (previous cardio-, cerebro-, or peripheral-vascular disease), chronic heart failure (New York Heart Association class II or III), or chronic kidney disease (stage 3 or higher) or ≥60 years old with at least one cardiovascular risk factor. Subjects were randomised to once-weekly, s.c. semaglutide 0.5 or 1.0 mg, or volume-matched placebo, added to standard of care, without any lifestyle intervention, for 104 weeks.

Results: At baseline, overall mean body weight, age, duration of diabetes and HbA_{1c} were 92.1 kg, 65 years, 13.9 years and 8.7%, respectively. Semaglutide significantly reduced the risk of the primary composite outcome vs placebo (hazard ratio, 0.74; 95% CI, 0.58-0.95; p<0.001 for non-inferiority with a margin of 1.8). Treatment with semaglutide, vs placebo, led to significantly reduced body weight, BMI and waist circumference at 2 years vs placebo (p<0.001; Table). BW loss plateaued at Week 44 and was sustained throughout the remainder of the trial until Week 104. The proportion of subjects achieving ≥5% and ≥10% reduction in body weight was more than two-fold greater with semaglutide vs placebo. For semaglutide 0.5 and 1.0 mg, 77% and 81% of subjects, respectively, had no weight gain at 2 years, compared with 52% and 53% of subjects receiving placebo 0.5 and 1.0 mg, respectively. A dose-response effect with semaglutide was observed for body weight reduction.

Conclusion: Semaglutide treatment, added to standard of care, led to clinically meaningful and sustained reductions in body weight, BMI and waist circumference at 2 years in subjects with T2D at high cardiovascular risk.

Table. Body weight-related endpoints: Change from baseline at Week 104

	Overall mean at baseline	Semaglutide 0.5 mg	Semaglutide 1.0 mg	Placebo 0.5 mg	Placebo 1.0 mg

The effects of GIP/GLP-1 receptor co-activation on appetite and food intake in overweight/obese subjects

N.C. Bergmann[1,2], A. Lund[1], L.S. Gasbjerg[1,3], E.C.E. Meessen[4], L. Jessen[2], M. Christensen[1,5], T. Vilsbøll[1,6], F.K. Knop[1,7];

[1]Center for Diabetes Research, Gentofte Hospital, Hellerup, [2]Zealand Pharma A/S, Glostrup, [3]Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark, [4]Department of Endocrinology and Metabolism, Amsterdam Medical Center, University of Amsterdam, Netherlands, [5]Department of Clinical Pharmacology, Bispebjerg Hospital, University of Copenhagen, Copenhagen, [6]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, [7]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

Background and aims: Glucagon-like peptide-1 (GLP-1) is a potent suppressor of appetite and food intake in humans whereas the other incretin hormone, glucose-dependent insulinotropic polypeptide (GIP), does not seem to have independent effects on eating behaviour. Interestingly, rodent data have shown that concomitant activation of the GIP and the GLP-1 receptors may potentiate the satiety-promoting effects of GLP-1. The aim of this study was to delineate the effects of GIP/GLP-1 receptor co-activation on food intake, appetite, and resting energy expenditure (REE) in overweight/obese humans.

Materials and methods: We examined 18 overweight/obese men (age: 38 (25-70) years [median (range)]; BMI: 33 (26-36) kg/m^2) during five experimental days separated by at least 72 hours: 50-g OGTT followed by isoglycaemic i.v. glucose infusion (IIGI)+saline (placebo), IIGI+GIP (4 pmol/kg/min), IIGI+GLP-1 (1 pmol/kg/min) and IIGI+GIP+GLP-1 (4 and 1 pmol/kg/min, respectively) performed in a double-blinded and randomised order. The primary endpoint was food intake measured by an *ad libitum* meal after 240 minutes of infusion. Secondary endpoints included appetite ratings on visual analogue scales (VAS) and REE measured by indirect calorimetry at baseline and after 210 minutes.

Results: Food intake was significantly less on the IIGI+GLP-1 day, compared to placebo (2,736±1,637 kJ vs. 4,391±2,306 kJ [mean±SD], p=0.035) while no significant differences were seen on the IIGI+GIP (4,048±2080 kJ) and the IIGI+GIP+GLP-1 day (3,827±1,815 kJ), compared to placebo. On the IIGI+GLP-1 day participants reported less hunger, compared to placebo (-6.9 [-2.4 to -11.4] (mean difference [95% CI]), p<0.001), a higher degree of satiety (4.6 [8.6 to 0.5], p<0.05) and lower prospective food consumption (-5.9 [-2.4 to -9.5], p<0.0001). The IIGI+GIP day and the IIGI+GIP+GLP-1 day, did not differ from placebo on any of the above ratings. Ratings of comfort and nausea, and measures of REE were similar between all study days.

Conclusion: While GLP-1 receptor activation lowers food intake and appetite in overweight/obese male subjects, simultaneous activation of the GIP receptor did not potentiate these GLP-1-mediated effects.

DURATION-8 randomised controlled trial 1-year results: efficacy and safety of once-weekly exenatide plus once-daily dapagliflozin versus exenatide or dapagliflozin alone

C. Guja[1], J.P. Frías[2], A.A. Ahmed[3], E. Hardy[4], H. Wang[4], P. Öhman[4], S.A. Jabbour[5];

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]National Research Institute, Los Angeles, [3]Apex Medical Research, Chicago, [4]AstraZeneca, Gaithersburg, [5]Thomas Jefferson University, Philadelphia, USA.

Background and aims: In patients with T2D uncontrolled by metformin (baseline HbA1c 8-12%), dual therapy for 28 weeks with once-weekly exenatide (ExQW) plus once-daily dapagliflozin (DAPA) reduced glycaemia, body weight and systolic blood pressure (SBP) significantly more than with ExQW + placebo or DAPA + placebo alone with no unexpected safety signals (DURATION-8 trial). Here, we examined these outcomes after a further 24 weeks of double-blind therapy.

Materials and methods: DURATION-8 was a phase 3, multicentre, double-blind, randomised, 28-week study with a 24-week double-blind extension. Adults with T2D (n=695; 1 not treated) were randomised to ExQW (2-mg subcutaneous injection) plus DAPA (10-mg oral tablet) (n=231), ExQW with oral placebo (n=230), or DAPA with injected placebo (n=233).

Results: Of 695 patients randomized, 525 (75.5%) completed 52 weeks with 3.7% discontinuing due to adverse events (AEs). At Week 52, greater reductions in HbA1c, FPG, 2-h PPG, body weight and SBP were observed with ExQW + DAPA versus ExQW + placebo or DAPA+ placebo. Compared with Week 28, reductions in HbA1c in all treatment groups and treatment differences were maintained at Week 52. AEs occurring in ≥5% of patients were diarrhoea, headache, injection site nodule, nausea, upper respiratory tract infection, and urinary tract infection. Serious AEs occurred in 4.8%, 5.2%, and 5.2%, respectively. Minor hypoglycaemia occurred in 1.3%, 0%, and 0.4%. No major hypoglycaemia was recorded. Reductions in estimated glomerular filtration rate at Week 1 with ExQW + DAPA and DAPA + placebo returned to baseline by Week 52 (Table).

Conclusion: ExQW + DAPA was well tolerated with no unexpected AEs, and the glycaemic, weight, and SBP effects observed at Week 28 were maintained over 52 weeks.

Non-alcoholic fatty liver disease and risk of mortality and cardiovascular disease among people with type 2 diabetes: a national retrospective cohort study

S.H. Wild[1], C.D. Byrne[2], Scottish Diabetes Research Network epidemiology group;
[1]Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, [2]Nutrition and Metabolism, University of Southampton, UK.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) occurs frequently in type 2 diabetes (T2DM), but the association between NAFLD and mortality or cardiovascular disease (CVD) in people with T2DM is unclear. Our aim was to investigate whether clinically significant NAFLD as identified from history of hospital admission with NAFLD is associated with mortality or CVD among people with T2DM.

Materials and methods: We used linked routine data from Scottish population-based diabetes, hospital admissions and death registers for people with type 2 diabetes diagnosed between 2004 and 2013 of 40-89 years of age who had a history of at least one hospital admission and complete data available. NAFLD, cause-specific mortality and CVD were identified using International Classification of Diseases codes. Cox proportional hazards models were adjusted for age, sex, an area-based measure of socio-economic status, smoking status, high blood pressure/ anti-hypertensive use, high cholesterol/statin treatment, HbA1c and prevalent CVD at diagnosis of diabetes.

Results: We included 133,312 people with complete data available (88% of potentially eligible people) of whom 1998 had a hospital admission mentioning NAFLD. At diagnosis of diabetes people with NAFLD compared to those without NAFLD were younger (60.0 vs 62.7 years), had higher BMI (32.9 vs 32.1 kg/m2) and HbA1c (64 vs 62 mmol/l) and were more likely to be women (49% vs 45%) and current smokers (25% vs 22%), p<0.01 for all comparisons. Adjusted hazard ratios (95% CIs) and numbers of events by NAFLD status over mean follow-up of 4.7 years are shown in the table.

Conclusion: NAFLD is an independent risk factor for increased mortality and incident/recurrent CVD events in people with type 2 diabetes. Lifestyle interventions should be emphasised for people with type 2 diabetes to prevent NAFLD and effective, safe treatments are urgently needed for NAFLD.

Outcome	HR (95% CI) for NAFLD vs no NAFLD	Number of events	
		NAFLD	No NAFLD
All-cause mortality	2.11 (1.92, 2.32)	434	16,211
CVD mortality	1.39 (1.10, 1.74)	75	4,432
Hepato-cellular cancer (HCC) mortality	41.9 (27.1, 64.8)	33	59
Cancer mortality (excluding HCC)	1.15 (0.92, 1.42)	85	5,570
Other causes of death	3.16 (2.77, 3.59)	241	6,150
Incident or recurrent CVD event	1.62 (1.47, 1.77)	460	21,892

HRs and number of events by NAFLD status for all-cause and cause-specific mortality and CVD events among study cohort of people with type 2 diabetes.

Association between steatohepatitis and left ventricular diastolic function in type 2 diabetes

K. Huh[1], Y. Cho[2], M. Lee[2], Y.-H. Lee[2], B.-W. Lee[2], E. Kang[2], C. Ahn[3], B.-S. Cha[2];
[1]Huh's Diabetes Center and the 21st Century Diabetes and Vascular Research Institute, [2]Internal Medicine, Yonsei University College of Medicine, [3]Department of Internal Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea.

Background and aims: Association between hepatic steatosis or fibrosis and cardiac dysfunction in relation to insulin resistance has not been fully investigated. We evaluated whether hepatic steatosis or fibrosis is associated with left ventricular (LV) diastolic dysfunction in patients with type 2 diabetes (T2DM).

Materials and methods: 454 patients with T2DM, aged 55 years or older (men 22.0%, mean age 64.9 years old) were enrolled. All subjects had undergone liver ultrasonography, pulsed-wave doppler echocardiography, short insulin tolerance test (SITT), and bioimpedance analysis. Simple hepatic steatosis and steatohepatitis were defined in the presence or absence of fibrosis according to NAFLD fibrosis scores by liver ultrasonography. Diastolic dysfunction was measured by using peak early (E) to late (A) ventricular filling ratio (E/A) and E-wave deceleration time (DT).

Results: Of 454 patients, 284 (62.6%) had hepatic steatosis, and 273 (60.1%) had diastolic dysfunction. The prevalence of diastolic dysfunction showed a positive correlation with the presence of hepatic steatosis or fibrosis (52.9%, 62.0%, and 65.3%; normal, simple steatosis, and steatohepatitis, respectively; P for trend<0.05). Multivariate logistic regression analysis revealed a significant association between diastolic dysfunction and hepatic steatosis (odds ratio [OR]=1.98, 95% confidence interval [CI]=1.02-3.90, P<0.05), after adjusting for glycometabolic parameters, abdominal fat percentages, and SITT. Furthermore, subjects with steatohepatitis presented a significantly higher odds for diastolic dysfunction (OR=2.06, 95% CI=1.04-4.11, P<0.05) compared to subjects with normal or simple steatosis. This statistical significance was attenuated when including SITT in the model though.

Conclusion: In conclusion, hepatic steatosis and steatohepatitis is an independent predictive marker for LV diastolic dysfunction in older adults with T2DM, and insulin resistance may mediate this correlation between steatohepatitis and diastolic dysfunction.

Fatty liver disease determines the progression of coronary artery calcification in a metabolically healthy obese population

W. Lee, Y. Kang, C. Jung, Y. Cho, S. Lee, J. Hwang, E. Kim, J.-Y. Park, H.-K. Kim;
Asan Medical Center, Seoul, Korea, Republic of.

Background and aims: Metabolically healthy obese (MHO) phenotype describes an obese state with a favorable metabolic profile. However, the prognosis of this subpopulation remains controversial. We aimed to examine whether MHO phenotype is associated with progression of atherosclerotic activity, reflected as the changes in coronary artery calcification (CAC) over time. If so, we sought to determine the role of fatty liver disease (FLD), the hallmark of hepatic steatosis, in this progression.

Materials and methods: We enrolled 1,240 asymptomatic subjects who underwent repeated CAC score measurement during routine health examinations. CAC score progression was defined as either incident CAC in a population free of CAC at baseline, or an increase by ≥2.5 units between the baseline and final square root of CAC scores in participants with detectable CAC at baseline. Subjects were stratified by body mass index (cut-off, 25.0 kg/m^2) and metabolic health state using Adult Treatment Panel-III criteria. FLD was assessed via ultrasonography.

Results: Over 2.9 years of follow-up, 25.2% of total subjects exhibited CAC score progression. The MHO phenotype was not significantly

associated with CAC score progression (multivariate adjusted-odds ratio [OR], 1.45; 95% confidence interval [CI], 0.93-2.25), as compared to the metabolically healthy non-obese (MHNO) phenotype. However, subgroup analysis indicated that the MHO/FLD phenotype was significantly associated with CAC score progression (multivariate adjusted-OR, 2.37; 95% CI, 1.34-4.16), as compared to the MHNO/no FLD phenotype, whereas the MHO/no FLD phenotype was not (multivariate adjusted OR, 1.25; 95% CI, 0.71-2.24).

Conclusion: Obese individuals with FLD have an increased risk of atherosclerosis progression, despite their healthy metabolic profile. Preventive interventions targeting cardiometabolic risk factors should be considered in such individuals, regardless of the weight status.

Unravelling the pathogenetic mechanisms of fructose consumption as multiple hit in the pathogenesis and progression of non-alcoholic fatty liver disease

S. Smajis[1], M. Gajdosik[2], M. Krssak[2], L. Pfleger[2], P. Wolf[1], A. Luger[1], M. Trauner[3], M. Krebs[1];

[1]Division of Endocrinology and Metabolism, Medical University Vienna, [2]High field MR-Centre, Medical University Vienna, [3]Division of Gastroenterology and Hepatology, Medical University Vienna, Vienna, Austria.

Background and aims: High dietary fructose consumption is associated with fatty liver disease (NAFLD) and might contribute to the development of insulin resistance, characterized by ectopic lipid deposition and impaired postprandial glycogen synthesis.

Materials and methods: 5 NAFLD patients (age 49.6±2.3 years; BMI 29.1±2.2 kg/m^2) and 10 healthy controls (CON) (age: 27.5±2,1 years; BMI 21.5±0.5 kg/m^2) underwent stepped hyperinsulinemic euglycemic clamp tests and high caloric mixed meal tests (MMT) in combination with ^{1}H and ^{13}C MRS for measurement of glycogen and lipid content in the liver (HCL[%]) and skeletal muscle (IMCL[%]). Glucose infusion rates at low (15mU/m^2) and high dose (40mU/m^2) of insulin infusion was used to calculate the rate of metabolized glucose [M(mg/kg*min)]. These tests were repeated in CON after 8 weeks of dietary fructose challenge (150g/day).

Results: As expected NAFLD were characterized by decreased hepatic (M_{NAFLD} 3,96±0,44 vs. M_{CON} 6,23±0.8; p=0.07) and skeletal muscle insulin sensitivity (IS)(M_{NAFLD} 9,9±2,5 vs. M_{CON} 15,9±1.8; p=0.049) in comparison to CON. Notably, 8 weeks of high caloric fructose consumption did not affect hepatic (M_{CON} 6,23±0.8 vs. M_{CON_POST} 7,4±1,1; p=0,39) or skeletal muscle IS (M_{CON} 15,9±1.8 vs. M_{CON_POST}16,4±1.8; p=0,88) in CON. Ectopic lipids were higher in NAFLD (HCL_{NAFLD} 19.2±8.84 vs HCL_{CON} 1.19±0.21; p=0.004), ($IMCL_{NAFLD}$ 2.18±0.26 vs $IMCL_{CON}$ 1.19±0.21; p=0.007) at baseline. In the postprandial state ectopic lipids increased in NAFLD, but decreased or remained unchanged in CON: (ΔHCL_{NAFLD} 20.6±13.05 vs. ΔHCL_{CON} -19.54±9.2; p=0.039); ($\Delta IMCL_{NAFLD}$ 17.6±16.6 vs. $\Delta IMCL_{CON}$ 0.61±7.72; p=0.3). Also postprandial glycogen storage was impaired in NAFLD ($\Delta GlycogenLiver_{NAFLD}$ 17.76±7.8 vs. $\Delta GlycogenLiver_{CON}$ 72.06±12.03; p=0.02); ($\Delta GlycogenMuscle_{NAFLD}$ 6.62±10.6 vs. $\Delta GlycogenMuscle_{CON}$ 32.29±9.01; p=0.15) but was not affected by fructose challenge in CON: ($\Delta GlycogenLiver_{CON}$ 72.06±12.03 vs. $\Delta GlycogenLiver_{CON\_POST}$ 51,89±9,23 p=0,11); ($\Delta GlycogenMuscle_{CON}$ 32.29±9.01 vs. $\Delta GlycogenMuscle_{CON\_POST}$ 16,57±5,46 p=0,17).

Conclusion: As expected patients with NAFLD were characterized by severely impaired postprandial lipid and glycogen metabolism. Notably, high dose fructose consumption did not affect insulin sensitivity or postprandial lipid and glucose metabolism higlighting the capacity to compensate for high dietary fructose intake in metabolcally healthy subjects.

Effects of 3-week low carbohydrate diet on endothelial function, visceral fat and liver fat in type 2 diabetes patients compared to a low fat diet

R.L. Barbosa Yañez[1], U. Kaiser[1], S. Kabisch[1,2], A.F.H. Pfeiffer[1,2];

[1]Clinical Nutrition, German Institute of Human Nutrition, Potsdam-Rehbrücke, [2]Department of Endocrinology, Diabetes and Nutrition, Charité-University Medicine, Berlin, Germany.

Background and aims: Increasing fat and carbohydrate consumption are suggested to trigger a complex metabolic pathologic network, which links type 2 diabetes (T2DM) with cardiovascular diseases (CVD) and non-alcoholic fatty liver disease (NAFLD) together. Our objective is to compare the effects of a short term low carbohydrate with a low fat dietary intervention, both hypocaloric, on the endothelial function, visceral fat and intrahepatic lipids of T2DM patients.

Materials and methods: Fifty five T2DM patients were randomized to a short term hypocaloric dietary intervention characterized either by a very low carbohydrate (VLC, n=27) (4-10% E) intake or by a low fat (LF, n=28) intake (<30% E) (age: 62 ±7.8 yr, BMI: 32.5 ±4.8 kg/m^2, HbA1c: 6.6 ±1.0 %). Endothelial function was assessed by a partially automated computer assisted flow mediated-dilation (FMD) method (Brachial Analyzer for Research, Version 5.10.6, Medical Imaging Applications LLC, Iowa City, Iowa, USA). Adipose tissue depots and intrahepatic lipids (IHL) were determinate via magnetic resonance imaging (MRI) and magnetic resonance spectroscopy (MRS), respectively. All data was collected before and after 3 weeks dietary intervention.

Results: Both groups experienced significant reductions of body weight (VLC: 93.7 ± 20.4 kg vs 89.6 ± 19.3 kg, p<0.001; LF: 98.5 ± 19.6 kg vs 89.7 ± 23.6 kg, p<0.05), blood lipids (VLC: Total CHO: p<0.05, LDL: p<0.05, TAG p<0.001; LF: Total CHO: p<0.001, LDL: p<0.001, TAG: p<0.001) and HbA1c (VLC: p<0.001; LF: p<0.001). IHL showed a significant reduction also in both groups (VLC: 12.3 ± 8.6 % vs 7.9 ± 7.3 %, p<0.001; LF: 14.4 ± 11.1 % vs 9.4 ± 9.6 %, p<0.001). We did not observe significant alterations on endothelial function nor visceral fat in either group after 3 weeks on respective macronutrient restriction. However, visceral adipose tissue at umbilical level was reduced only in the LF group (p<0.001). Besides the greater improvement of body weight in the LF group compared with the VLC group (p<0.05), no significant difference was found between dietary groups.

Conclusion: Short-term, hypocaloric VLC/LF diets both stimulated significant metabolic improvements inducing reductions of IHL in T2DM patients suggesting that caloric restriction primarily determines the outcomes. Unexpectedly, an effect on endothelial function could not be appreciated after 3 weeks diet, which may be explained by the absence of CVD in the patients.

Disclosure: **R.L. Barbosa Yañez:** None.

Effectiveness of dapagliflozin in nonalcoholic fatty liver disease in type 2 diabetes patients compared to sitagliptin and pioglitazone

A. Koutsovasilis, A. Sotiropoulos, E. Bletsa, A. Antoniou, C. Tamvakos, D. Ntionias, S. Bousboulas, T. Peppas;

3rd Internal Medicine Department & Diabetes Center, General Hospital of Nikaia-Piraeus, Athens, Greece.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) shows a wide disease spectrum ranging from simple steatosis to cirrhosis while it is also associated with the presence and morphology of subclinical coronary atherosclerosis. Dapagliflozin, a selective oral sodium glucose cotransporter 2 (SGLT2) inhibitor lowers blood glucose, significantly reduces body weight and blood pressure and it may also improve high density lipoprotein (HDL) cholesterol and triacylglycerol. Sitagliptin is a widely used DPP-4 inhibitor while pioglitazone already has several clinical evidence in the treatment of NAFLD. The aim of the study was to examine the effectiveness of dapagliflozin in NAFLD patients with type 2 Diabetes Mellitus (T2DM) compared with sitagliptin and pioglitazone.

Materials and methods: 247 T2DM patients with NAFLD were included in the study. 89 patients were under treatment with dapagliflozin, 67 under

treatment with pioglitazone and 91 under treatment with sitagliptin. All patients also received metformin. Mean follow up period was 52 weeks ± 2 weeks. The evaluation of liver fibrosis depended on calculation of aspartase aminotransferase (AST) to platelet counts rAPRI) index. APRI index was calculated as AST level (IU/L) divided by upper limit of AST (37 IU/L) nad platelet counts and finally multiplied bay 102. APRI over 1.5 was considered as bridging fibrosis and over 2.0 as liver cirrhosis. All patients went through an ultrasonography before being included in the study and after the end of the study.

Results: The study's patients were aged 59.6 ± 9.2 years without differences between groups under study and mean duration of T2DM was 6.1±3.4 years without differences between treatment (p=0.312) and with no differences in Body Mass Index (BMI) (p=0.362) and HbA1c (p=0.218) with mean value 7.74±0.89%. HbA1c values improved in all three groups with most patients maintain the therapeutic goal in the dapagliflozin (p=0.036) group after 52 weeks of treatment. APRI index's improvement was significant in the dapagliflozin group (1.12 (0.59-1.22) vs 0.97 (0.32-0.1.01), p=0.016), significant in the pioglitazone group (1.14 (0.49-1.28) vs 0.80 (0.41-1.06), p=0.011) while there was no improvement in the sitagliptin group (1.07 (0.42-1.29) vs 1.05 (0.43-1.27) p=0.455). APRI index's improvement was accompanied by a significant change of fatty liver in ultrasonography. The decrease of body weight in the dapagliflozin group was statistically significant (p<0.001) with most its patients (59 patients) achieving a >3Kg decrease.

Conclusion: Administration of dapagliflozin led not only to good control of T2DM but also improvement of liver inflammation, alteration of liver fibrosis, and reduction of body weight, which are particularly important factors in patients with T2DM. Aggravation of liver fibrosis score might lead to future liver cirrhosis, and body weight gain, observed in the pioglitazone group, could exacerbate liver inflammation and other metabolic disorders. As far as we know, this study is the first to be carried out on the long-term effect of dapagliflozin on liver fibrosis which indicates its positive impact in T2DM with NAFLD. Particularly, body weight reduction was a favorable outcome of applying dapagliflozin in NAFLD patients with T2DM.

OP 03 Genetics and epigenetics of type 2 diabetes

13

Discovery and fine-mapping of type 2 diabetes susceptibility loci across diverse population

H. Kitajima[1], A. Mahajan[1], X. Sim[2], M.C. Ng[3], W. Zhang[4], J.E. Below[5], D. Taliun[6], K.J. Gaulton[7], A.P. Morris[8], on behalf of the DIAMANTE Consortium; [1]Wellcome Trust Centre for Human Genetics, University of Oxford, UK, [2]Saw Swee Hock School of Public Health, National University of Singapore, Singapore, [3]Center for Genomics and Personalized Medicine Research, Wake Forest School of Medicine, Winston-Salem, USA, [4]School of Public Health, Imperial College London, UK, [5]Human Genetics Center, University of Texas Health Science Center at Houston, [6]Center for Statistical Genetics, University of Michigan, Ann Arbor, [7]Department of Pediatrics, University of California San Diego, La Jolla, USA, [8]Department of Biostatistics, University of Liverpool, UK.

Background and aims: To discover and improve fine-mapping resolution of type 2 diabetes (T2D) loci, we conducted the most comprehensive and diverse trans-ethnic meta-analysis of genome-wide association studies (GWAS).

Materials and methods: 99,265 T2D cases and 545,212 controls were included in this interim meta-analysis. Each GWAS was imputed up to optimal reference panels from the 1000 Genomes Project or Haplotype Reference Consortium. We conducted meta-regression analysis to account for heterogeneity in allelic effects between diverse populations. We performed approximate conditional analyses to identify distinct signals in the loci attaining genome-wide significance ($p<5x10^{-8}$). For each signal, we defined credible sets of variants that accounted for 99% of the posterior probability of driving the association. Across signals, we evaluated enrichment in the posterior probability across genomic annotations

Results: We identified 110 loci at genome-wide significance, including 37 mapping outside regions previously implicated in T2D, with the strongest novel associations at/near *INHBB* (rs58884021, $p=2.8x10^{-12}$), *PLEKHA1* (rs2421016, $p=3.2x10^{-12}$), and *EIF5A2* (rs6804915, $p=3.8x10^{-12}$). We identified 156 distinct association signals across the 110 loci, including 11 at *KCNQ1*, 5 at *INS-IGF2*, and 4 each at *CDKN2A-B* and *CCND2*. Whilst allelic effects on T2D risk of index variants were predominantly consistent across populations, for the first time we observed strong evidence of heterogeneity correlated with ancestry at *LEP* (rs7778167, $p_{HET}=8.2x10^{-16}$, East Asian specific), *UBE2E2* (rs35352848, $p_{HET}=4.2x10^{-11}$, effect strongest in East Asians), and *KCNQ1* (rs11819853, $p_{HET}=2x10^{-10}$, varying direction/magnitude of effect between ethnic groups). We substantially improved fine-mapping resolution compared with previous efforts, highlighting 17 signals with a single variant accounting for >99% of the posterior probability of driving the association, including at *JAZF1* (rs10226758), *CDC123-CAMK1D* (rs11257655), *TCF7L2* (rs7903146), and 2 signals at *KCNQ1* (rs2237884 and rs2237895). The posterior probability of association was significantly enriched in coding exons ($p=1.4x10^{-5}$), for the first time including an index variant at the *APOE-TOMM40* locus, *APOE* p.Cys130Arg (rs429358). After accounting for coding variation, the posterior probability was also significantly jointly enriched for transcription factor binding sites for PDX1 ($p=2.6x10^{-6}$) and FOXA2 ($p=1.8x10^{-5}$).

Conclusion: Our study represents the most comprehensive view of the genetic contribution to T2D in terms of sample size and ethnic diversity, and will be enhanced by GWAS in an additional 400,000 individuals in the coming months.

Novel locus discovery through trans-ethnic association analyses of glycaemic traits using densely imputed genetic data

I. Barroso, Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) Investigators;

The Wellcome Trust Genome Campus, The Wellcome Trust Sanger Institute, Cambridge, UK.

Background and aims: To date, genome-wide association studies (GWAS) have identified >120 loci associated with glycaemic traits, most arising from European descent populations. We present the first large-scale trans-ethnic discovery for four glycaemic traits: fasting glucose (FG), fasting insulin (FI), glycated haemoglobin (HbA1c) and 2-hour glucose (2hG). We aimed to identify additional glycaemic trait-associated loci, investigate the portability of signals across ancestries, and leverage linkage disequilibrium differences to conduct fine-mapping.

Materials and methods: Meta-analyses included up to 281,416 individuals without diabetes, from five ancestries (71% Europeans, 13% East Asian, 7% Hispanic, 6% African-American and 3% South Asian) with genetic data imputed to the 1000 Genomes Project (phase 1 v3, March 2012, or later). Genetic association analyses were performed at the cohort level using an additive model, and combined by fixed-effect ancestry-specific meta-analyses, followed by trans-ethnic meta-analyses in MANTRA. A $\log_{10}$ Bayes factor ($\log_{10}$BF) threshold of 6 was used to identify trans-ethnic genome-wide significant signals. HbA1c signals were classified as erythrocytic or glycaemic through hierarchical clustering after lookup in red blood cell traits and glycaemic traits. Lastly, GARFIELD and DEPICT (FDR<5%, unless otherwise stated) were used to perform functional, tissue and pathway enrichment analyses.

Results: We identified 102 trans-ethnic signals associated with FG, of which 48 did not overlap known FG-associated regions. The most significant novel FG signals - not previously known to be involved in diabetes - include those at or close to NFX1 and ZBTB38 genes ($\log_{10}$BF=12.42 and 11.79, respectively). We also identified 62 FI-associated trans-ethnic signals (43 novel), 130 HbA1c-associated trans-ethnic signals (57 novel) and 21 2hG-associated trans-ethnic signals (10 novel). The most significant novel signals for FI, HbA1c and 2hG - not previously known to be involved in diabetes - fall in or near BCL2, LRRC16A and CLEC14A genes ($\log_{10}$BF = 11.66, 18.60 and 9.68, respectively). BCL2 was previously associated with waist-to-hip ratio and body mass index, LRRC16A was shown to be involved in platelet count and volume, and CLEC14A was associated with monoamine metabolite levels in human cerebrospinal fluid. HbA1c signals were mostly classified as influencing HbA1c via erythrocytic pathways (~70%) which was consistent with functional, tissue and pathway enrichment analyses, which identified hemic and immune system signatures, as well as anaemia related pathways. Functional and tissue enrichment analyses also identified a liver signature in all glycaemic traits; pancreas in HbA1c and FG; adipose and fat tissues, as well as, adrenal glands and cortex specific in FI (FDR<20%). Pathway analyses highlighted insulin signalling in HbA1c; insulin and MTOR signalling, maturity onset diabetes of the young, type 2 diabetes and circadian rhythm in FG; and cancer in FI. This large trans-ethnic study, afforded new discoveries including ancestry-specific signals, lower minor allele frequency variants, and common variants of more modest effects.

Conclusion: This large international effort has identified over a hundred novel loci underlying glycaemic traits that pose new hypotheses about the biology and genetic architecture of glucose and insulin related traits.

Poor glycaemic control is associated with altered blood gene expression levels of cell cycle and immune related genes. The Hoorn Diabetes Care System cohort

R.C. Slieker[1,2], A.A.W. van der Heijden[3], N. van Leeuwen[1], G. Nijpels[3], J.W.J. Beulens[2,4], L.M. 't Hart[1,5];
[1]Molecular Cell Biology, LUMC, Leiden, [2]Epidemiology and Biostatistics, VUmc, [3]General Practice and Elderly Care Medicine, VUmc, Amsterdam, [4]Julius Center for Health Sciences and Primary Care, UMCU, Utrecht, [5]Molecular Epidemiology, LUMC, Leiden, Netherlands.

Background and aims: With the global pandemic of obesity, type 2 diabetes is becoming increasingly prevalent. Yet, people with type 2 diabetes are heterogeneous in their disease trajectory. Glycaemic control is tracked by measuring blood HbA1c levels on a regular basis. To predict glycaemic control over a longer period of time, the utility of several molecular measures in blood is increasingly explored, but one of them - gene expression - has been sparsely investigated. To this end, we here investigate the relation between whole blood gene expression and HbA1c at baseline and up to 2-year follow-up in individuals participating in the Hoorn Diabetes Care System cohort.

Materials and methods: Genome-wide gene expression levels in whole blood (15,564 genes, RNA-seq) were measured in 391 individuals with type 2 diabetes. Gene expression levels were compared to baseline (N=391), 1-year (N=372) and 2-year HbA1c levels (N=362), adjusted for age, sex, blood cell composition, BMI, medication use and technical covariates. To investigate the pathways to which identified genes were related with HbA1c at baseline we explored the interrelatedness of genes in a co-expression network. Genes identified at baseline were investigated in external microarray data of target tissues muscle (N=115) and pancreas (N=113).

Results: Gene expression levels were particularly associated with baseline HbA1c (220 genes, 1.4%, fold change (fc): -3.34 - 4.80) and to a lesser extent to one year follow-up HbA1c (25 genes, 0.16%, fc: -2.90 - 3.10) and two-year follow-up HbA1c (9 genes, 0.06%, fc: -3.88 - 2.69). Genes identified at baseline and follow-up overlapped, with 5 genes identified at all time points and 18 additional genes between baseline and 1-year follow-up. After adjustment for baseline HbA1c, the number of genes markedly decreased with 1 gene at 1-year follow-up (NDN, fc:-2.11) and 2 genes at 2-year follow-up (MTND1P23, fc:-3.64, FAM132B, fc:-1.90). Genes associated with baseline HbA1c clustered to three groups of co-expressed genes. Two larger clusters comprised 55 and 42 genes respectively and the third comprised 2 genes. The largest cluster showed strong overrepresentation in cell cycle (checkpoint) pathways ($P_{FDR} < 1{\cdot}10^{-10}$). The second cluster showed overrepresentation in the complement system activation and B-cell signalling pathway ($P_{FDR} < 1{\cdot}10^{-10}$). The third cluster consisted KLF10 and KLF11, that both link to cell cycle regulation. Finally, the association between HbA1c and gene expression was also confirmed for 15 genes (|r|>0.2) in external datasets of target tissues muscle (N=115) and pancreatic islets (N=113).

Conclusion: While gene expression levels are interesting biomarkers for poor glycaemic control, our study suggests that gene expression levels in whole blood are particularly a reflection of the current glycaemic state, rather than predictive of the future glycaemic state. Nonetheless, identified genes provide insight into the relation of glycaemic control with gene expression changes in blood, where some genes also associate with HbA1c levels in target tissues.

Identification of alleles associated with higher body fat percentage but lower risk of type 2 diabetes

H. Yaghootkar, Y. Ji, J. Tyrrell, S.E. Jones, R. Beaumont, M.A. Tuke, K.S. Ruth, R.M. Freathy, A.R. Wood, A. Murray, M.N. Weedon, T.M. Frayling; University of Exeter Medical School, University of Exeter, UK.

Background and aims: Recent studies have identified metabolically "healthy obesity" alleles - those associated with higher body fat % but lower risk of type 2 diabetes, hypertension, and heart disease. By definition, the opposite alleles of the same variants are associated with lower BMI but higher risk of disease - "polygenic lipodystrophy" alleles. We aimed to identify novel "healthy obesity" alleles, and test their protective effects on type 2 diabetes.

Materials and methods: First, we identified alleles associated with higher body fat % (p-value < $5x10^{-8}$) using 220,000 individuals from the initial UK Biobank dataset and published studies. Next, we used a multivariate model that jointly tested the effects of these alleles on biomarkers of "healthy obesity": higher HDL-C (N=99,900), lower Triglycerides (N=96,600), lower fasting insulin (N=51,800), higher adiponectin (N=29,400), higher SHBG (N=21,800) and a marker of lower liver fat, lower ALT (N=55,500). We defined "healthy obesity" alleles as those (i) which had a multivariate p-value of < $5x10^{-4}$ (multiple test corrected) and (ii) which were associated with the multivariate model stronger than body fat % alone. The latter criterion was set to uncouple "healthy obesity" from "unhealthy obesity" alleles. To validate the variants as protective of disease, we calculated the association of "healthy obesity" genetic score with type 2 diabetes using independent published type 2 diabetes GWAS data from the DIAGRAM consortium.

Results: We identified 85 independent genetic variants associated with 1.66%-6.44% standard deviation (SD) per allele differences in body fat % (p-value < $5x10^{-8}$). Fourteen of these genetic variants fitted the definition of "healthy

obesity" including 10 known alleles previously published. All of the previously known variants were more strongly associated with the "healthy obesity" phenotype when we used adiponectin, SHBG and ALT in the multivariate statistical model. The multivariate model was able to uncouple "healthy obesity" (e.g. the *PPARG* allele) from "unhealthy obesity" alleles (e.g. *FTO* allele) among alleles associated with higher body fat %. When analysing all 14 genetic variants together as a genetic score, carrying 5 additional "healthy obesity" alleles was associated with a 0.340 [0.338, 0.341] Kg/m^2 higher BMI (p-value = 2x10^{-62}, using data from GIANT consortium) but lower risk of type 2 diabetes (odds ration: 0.882 [0.876, 0.889]; p-value = 2x10^{-11}, using data from DIAGRAM consortium). These effects were primarily driven by the ten known "healthy obesity" variants.

Conclusion: "Healthy obesity" alleles can be defined using adiposity related phenotypes. Adiponectin, SHBG and ALT add extra accuracy to the identification of "healthy obesity" alleles when used in the model. Our study supports the use of a multivariate analysis approach in identifying variants associated with higher body fat % but lower risk of type 2 diabetes.

DNA Methylome signature in subcutaneous adipose tissue precursor cells identifies individuals with a family history of type 2 diabetes

L. Parrillo[1], G.A. Raciti[1], A. Hammarstedt[2], F. Colaps[1], R. Spinelli[1], F. Zatterale[1], A. Desiderio[1], P. Mirra[1], U. Smith[2], F. Beguinot[1];

[1]URT-GDD, National Council of Research, Department of Translational Medical Sciences, Federico II University of Naples, Naples, Italy, [2]Lundberg Laboratory for Diabetes Research, Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Background and aims: First-degree relatives (FDRs) of individuals with type 2 diabetes (T2D) have dysfunctional subcutaneous adipose tissue (sAT). Indeed, they feature significantly larger sAT cells due to impaired adipogenesis and hypertrophy of pre-existing mature sAT cells, which increases their susceptibility to the detrimental effects of weight gain. Despite clear familiarity of these abnormalities, no genotype convincingly accounting for their increased diabetes risk has so far been identified. Since epigenetics might also have a role, we have explored the DNA Methylome and full transcriptome analyses in sAT pre-adipocytes from FDRs and matched subjects lacking a known family history of T2D.

Materials and methods: Stromal Vascular Fraction cells (SVFs, enriched in pre-adipocytes) were isolated from sAT biopsies of 9 FDR and 12 control individuals. DNA Methylome and transcriptome profiles of SVFs were analyzed using MeDIP- and RNA-seq, respectively. Bisulphite sequencing and qPCR were then performed in SVFs of these individuals.

Results: The clinical characteristics of individuals in the study group are shown in Table 1. MeDIP-seq analysis revealed a uniform distribution of differentially methylated regions (DMRs) throughout the entire SVF genome, with a greater number of hypomethylated regions in FDR subjects (fdr<5%). This different methylation pattern was accompanied by a decreased expression of DNMT1 (p<0.05) and DNMT3A (p<0.05) genes in FDRs. Most DMRs were located within gene bodies. DMRs mapped to 3234 unique differentially methylated genes (DMGs, fdr<5%). Of note, pathway analysis revealed that most DMGs were significantly enriched in key cell growth and differentiation pathways, including FGF, PKA and Wnt/β-catenin signaling pathways. The RNA-Seq analysis identified a total of 84 (fdr<5%) differentially expressed genes. Merging DNA Methylome with RNA-seq data identified 12 genes showing concomitant changes in mRNA expression and DNA methylation. These included genes that are biologically relevant to the adipocyte function and development of T2D. Bisulphite sequencing and qPCR assays were used to validate the MeDIP-seq findings at individual gene level. Moreover, 11 obesity and 12 T2D candidate genes, identified by GWAS, had altered methylation in SVF from FDR individuals.

Conclusion: In FDRs, the DNA Methylome signature of sAT pre-adipocytes includes abnormalities in key genes implicated in adipocyte growth and function and in T2D risk. Persistent epigenetic changes may affect the evolution towards T2D and identify potential therapeutic targets.

Lower DNA methylation of metformin transporter genes in human liver is associated with metformin therapy in type 2 diabetes subjects

S. García-Calzón[1], A. Perfilyev[1], V. Männistö[2], V.D. de Mello[3], E. Nilsson[1], J. Pihlajamäki[4], C. Ling[1];

[1]Lund University, Malmö, Sweden, [2]University of Eastern Finland and Kuopio University Hospital, Kuopio, [3]University of Eastern Finland, Joensuu, [4]University of Eastern Finland and Kuopio University Hospital, Joenssu, Finland.

Background and aims: Given that metformin is the most common pharmacological therapy for type 2 diabetes (T2D), understanding the metabolism of this drug is of great importance. Hepatic metformin transporters are responsible for the pharmacologic action of metformin. Since epigenetics of metformin transporter genes remains uncertain, we wanted to analyze DNA methylation in metformin transporter genes in human liver, and assessed whether epigenetic alterations associate with diabetes medication.

Materials and methods: DNA methylation in metformin transporter genes (OCT1 encoded by *SLC22A1*, OCT3 encoded by *SLC22A3*, MATE1 encoded by *SLC47A1)* was analyzed in human liver of 95 subjects from the Kuopio Obesity Surgery Study using the Infinium HumanMethylation450 BeadChip array. mRNA expression was measured with the HumanHT-12 Expression BeadChip in a subsample of 42 individuals. Thirty T2D patients who were taking metformin or insulin plus metformin were considered for the analyses. A control group of 3 diabetic patients who did not receive any diabetes medication was also included. All analyses were adjusted for age, sex and the presence of nonalcoholic steatohepatitis.

Results: T2D subjects who received just metformin showed lower average and promoter DNA methylation of *SLC22A1*, *SLC22A3* and *SLC47A1* genes compared to patients who received insulin plus metformin or no diabetes medication. There were also 13 individual CpG sites annotated to the hepatic metformin transporter genes with differential DNA methylation according to diabetes medication (FDR<0.05). Notably, multiple regression models showed that DNA methylation was also associated with gene expression of all metformin transporter genes in human liver. In addition, higher methylation levels in these genes were associated with higher fasting glucose levels and higher BMI.

Conclusion: Our study demonstrates that DNA methylation of metformin transporter genes in human liver is different according to diabetes medication and associates with hepatic gene expression, glycaemia and obesity. Importantly, metformin decreases DNA methylation of *SLC22A1*, *SLC22A3* and *SLC47A1* in human liver.

OP 04 Novel regulators of insulin sensitivity

19

The association between insulin resistance and iron overload through the transferrin receptor 1 in human skeletal muscle cells and muscles from patients with type 2 diabetes

K.-W. Lee[1], R. Cui[1], S.-E. Choi[2], T. Kim[3], H. Lee[1], J. Jeon[4], Y. Kang[2], S. Han[1], H. Kim[1], D. Kim[1];

[1]Endocrinology and Metabolism, Ajou University Hospital, [2]Physiology, Ajou University Hospital, Suwon, [3]Department of Internal Medicine, Seoul Medical Center, [4]Endocrinology and Metabolism, Seoul Medical Center, Seoul, Republic of Korea.

Background and aims: Iron plays an important role in many physiological processes, including redox balance, inflammation, and mitochondrial respiratory metabolism. Altered iron homeostasis is associated with insulin resistance (IR) and diabetes. Iron perturbations are well studied in several tissues, such as adipose tissue and the liver in diabetic animal models. However, the relationship between iron metabolism and IR in skeletal muscle has not been well studied. In this study, we investigated the relationship and molecular mechanism between iron overload and IR in human skeletal muscle cells and muscle biopsies from patients with type 2 diabetes (T2DM).

Materials and methods: To clarify the iron homeostatic brake in IR muscle cells and muscle biopsies from patients with T2DM, we measured iron metabolism-related protein levels such as transferrin receptor 1 (TfR1), heavy chain ferritin (FTH), light chain ferritin (FTL) and divalent metal transporter 1 (DMT1).

Results: Immunoblotting analysis showed that treating human skeletal muscle cells with palmitate increased the levels of TfR1 and FTH, but not iron regulatory protein 1. In addition, the levels of TfR1, FTH, FTL and DMT1 increased in muscle biopsies from patients with T2DM compared to those in normal subjects. In addition, the intracellular labile iron pool increased in palmitate-induced IR skeletal muscle cells. Knockdown of TfR1 using siRNA in human skeletal muscle cells protected against palmitate-induced IR and preserved the intracellular iron pool. Treatment with an iron donor ($FeSo_4$ or $FeCl_3$) stimulated phospho-JNK and phospho-p38 and significantly induced mitochondrial dysfunction in human skeletal muscle cells. In particular, the chemical iron chelator deferoxamine recovered mitochondrial dysfunction and palmitate-induced IR in human skeletal muscle cells.

Conclusion: The current study showed that iron overload in skeletal muscle cells induced mitochondrial dysfunction and IR through TfR1, whereas reducing the intracellular iron overload protected against IR. Therefore, attempts to block iron overload might be a strategy for preventing IR and diabetes.

ApoJ is a novel hepatokine regulating muscle glucose metabolism and insulin sensitivity

J. Seo[1,2], M.-C. Kang[2], S. Hong[2], A. Vijyakumar[2], L.P. Moura[2], W. Li[2], Y.-B. Kim[2];

[1]Division of Endocrinology, Korea University College of Medicine, Seoul, Republic of Korea, [2]Division of Endocrinology, Diabetes, and Metabolism, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, USA.

Background and aims: A crosstalk between the liver and skeletal muscles has long been recognized as vital for adequate glucose homeostasis. Critical factors for this interorgan crosstalk are hepatokines, liver-derived proteins that play a pivotal role in regulating glucose metabolism and insulin sensitivity in skeletal muscle. Thus, discovery of a new hepatokine would be of particular interest. The aims of the current study are 1) to determine the physiological role of hepatic ApolipoproteinJ (ApoJ, also called clusterin) in the regulation of glucose homeostasis and insulin sensitivity, and 2) to determine whether the ApoJ → LRP2 signaling pathway is a key component of insulin action in skeletal muscle.

Materials and methods: Mice lacking ApoJ in liver or in muscle and LRP2 in muscle were studied for glucose metabolism and insulin signaling. Cultured muscle C2C12 cells were also studied for the molecular interaction of insulin receptor (IR) with LRP2 and insulin-induced endocytosis. Glucose tolerance (1.0 g/kg) and insulin tolerance test (0.75unit/kg) were performed. Glucose-stimulated insulin secretion (1.0 g/kg) was measured. Glucose uptake into peripheral tissues was determined by ip injection with 2U/kg insulin with 0.33 μCi [^{14}C]2-deoxyglucose. Insulin-stimulated signaling events (10 U/kg) in insulin-sensitive tissues were assessed. In situ proximity-ligation assay were performed. Endocytosis was measured in the presence of an inhibitor of clathrin-mediated endocytosis.

Results: Circulating ApoJ is primarily produced by the liver and transports to metabolically active organs, including muscle. Elevated ApoJ levels in serum but decreased ApoJ levels in muscle are found in mice lacking LRP2 in muscle, indicating that ApoJ is used in muscle via LRP2. Of physiologic significance, selective deletion of hepatic ApoJ or muscle LRP2 leads to systemic insulin resistance and glucose intolerance by suppressing insulin-induced signal transduction and glucose uptake in skeletal muscle. Mechanistically, we found that insulin drives the physical interaction between the IR and LRP2 on the cell surface of muscle and the complex of LRP2 with the IR undergoes co-endocytosis, which is an essential step of insulin signaling in muscle. However, when hepatic ApoJ or muscle LRP2 is absent, insulin-stimulated IR-LRP2 interaction is disrupted.

Conclusion: Our findings identify ApoJ as a novel hepatokine that is required for insulin-mediated glucose metabolism through a LRP2-dependent mechanism, coupled with the IR system. Thus, the ApoJ → LRP2 axis is a novel metabolic signaling pathway that is central for the maintenance of normal glucose homeostasis and insulin sensitivity.

Carnitine supplementation improves metabolic flexibility and skeletal muscle acetylcarnitine formation

Y.M.H. Bruls[1], M. de Ligt[2], L. Lindeboom[1,2], E. Phielix[2], B. Havekes[3], J.E. Wildberger[1], M.K. Hesselink[2], P. Schrauwen[2], V.B. Schrauwen[1];

[1]Department of Radiology, Maastricht University Medical Center+, [2]Department of Human Biology and Human Movement Sciences, Maastricht University Medical Center+, [3]Department of Internal Medicine, Division of Endorinology, Maastricht University Medical Center+, Maastricht, Netherlands.

Background and aims: Insulin resistance and type 2 diabetes are characterized by decreased metabolic flexibility and concomitant disturbances in glucose homeostasis. Recent evidence indicates that low carnitine availability may play a substantial role. When substrate availability is high, accumulation of mitochondrial acetyl-CoA is known to blunt glycolysis. However, acetyl-CoA can also be conjugated to acetylcarnitine, which can leave the mitochondria. Hence, impaired formation of acetylcarnitine formation may underlie compromised metabolic flexibility and therefore impair glucose tolerance (IGT). Here, we investigated whether carnitine supplementation improves acetylcarnitine formation and thereby rescues metabolic flexibility and insulin sensitivity in IGT subjects.

Materials and methods: Eleven IGT subjects followed a 36 day placebo- and L-carnitine treatment (2g/day) in a randomized, placebo-controlled, double blind crossover design. Plasma free carnitine concentrations were determined to check compliance to the intervention. A hyperinsulinemic-euglycemic clamp (40mU/m2/min), combined with indirect calorimetry (ventilated hood) was performed to determine insulin sensitivity and metabolic flexibility. Skeletal muscle acetylcarnitine concentrations were measured in vivo using long echo time proton magnetic resonance spectroscopy (1H-MRS, TE=500ms). To stimulate near maximal acetylcarnitine formation, 1H-MRS was performed before and immediately after a 30-minute cycling exercise

at 70% of the subjects predetermined maximal output (W_{max}). Twelve normal glucose tolerant (NGT) subjects were included without any intervention as control group.

Results: Plasma free carnitine concentrations increased upon carnitine supplementation (from 40.8±1.6 to 50.5±1.7μmol/L, p=<0.01) and did not change after placebo treatment (from 39.4±1.4 to 39.8±1.3 μmol/L, p=0.785) indicating compliance to the carnitine supplementation. Metabolic flexibility (Δ respiratory exchange ratio, ΔRER) was lower in IGT compared to NGT (ΔRER 0.07±0.01 vs. 0.10±0.01 respectively, p=0.022), but was completely restored upon carnitine supplementation (0.10±0.01, p=0.001). Similarly, the insulin stimulated increase in glucose oxidation was higher in IGT after carnitine supplementation compared to placebo (ΔGlucose oxidation 7.08±0.74 vs. 4.84±0.48 μmol/kg/min, p=0.001). No difference in whole-body insulin sensitivity (Δ rate of disappearance, ΔRd) was found upon carnitine supplementation (ΔRd 13.32±3.08 vs. 11.74±1.99 μmol/kg/min after placebo, p=0.513). Finally, carnitine supplementation increased pre-exercise (1.08±0.20 vs. 1.62±0.27 mmol/kgww, p<0.05) as well as post-exercise (3.60±0.49 vs. 4.23±0.53 mmol/kgww, p<0.05) skeletal muscle acetylcarnitine concentrations.

Conclusion: Carnitine supplementation completely restored skeletal muscle acetylcarnitine concentrations and rescued metabolic flexibility in IGT. Why insulin sensitivity was unaffected requires further investigation.

A novel skin-adipose tissue axis regulates pancreatic beta cell function

E. Evans[1], X. Kodji[1], S. Sayers[1], S. Brain[1], M. Philpott[2], R. Hannen[2], P. Caton[1];
[1]Kings College London, [2]Queen Mary University of London, London, UK.

Background and aims: The inflammatory skin disease psoriasis is an independent risk-factor for development of insulin resistance and type 2 diabetes (T2D), and presence of psoriasis is a strong predictor of T2D progression and severity. Moreover, some skin-specific transgenic mouse models display altered whole-body glucose homeostasis. This suggests an important role for skin in regulating whole-body glucose metabolism. We investigated the role of the skin secretome on subcutaneous adipose tissue (sAT) and beta-cell function using human and rodent models.

Materials and methods: Human explant skin, from abdominoplasty surgery, was incubated with the TLR7 agonist immiquimod (IMQ; 50 μg/ml; 24 - 48h) to induce a psoriatic phenotype. Conditioned media (skin-CM) was collected and retained or used to incubate explant human sAT, with sAT-CM also collected. Subsequently, MIN6 beta-cells were incubated with skin-CM and sAT-CM. For treatments, CM was diluted 1:1 with fresh media. All experiments were conducted serum-free. To induce skin inflammation in mice, IMQ (3.125 mg/day) was applied to a shaved dorsal region. After 5 days' treatment, serum, sAT and islets were collected for further analysis. We measured MIN6 glucose-stimulated insulin secretion (RIA), proliferation (BrDU assay) and cell viability (MTT assay) and sAT gene expression changes (qPCR). In the mouse model, sAT gene expression (qPCR), plasma insulin (ELISA) and glucose levels were measured.

Results: IMQ induced an inflammatory phenotype in human and mouse skin, evidenced by elevated pro-inflammatory cytokine gene expression (IL1β, IL6, IL8, IL17). Indicative of a regulatory role for human skin-derived factors, IMQ-skin-CM incubation decreased MIN6 GSIS (IMQ-treated-CM 20mmol/l: 6.1 ± 0.8 ng/ml, vs. CON-skin-CM 20mM: 25.5 ± 3.7 ng/ml, p<0.001, n=1 of 4 observations) as well as MIN6 BrDU incorporation (IMQ-treated CM: 0.2 ± 0.01, vs. CON-skin-CM: 0.8 ± 0.03, p<0.0001, n=1 of 6 observations) and cell viability (IMQ-treated CM: 0.08 ± 0.01,vs. CON-skin-CM: 0.8 ± 0.03, p<0.0001, n=2 of 4 observations), both normalised to fresh media control, which equals 1. Moreover, IMQ-skin-CM increased pro-inflammatory cytokine expression (IL1β, IL6, IL8, TNFα) and reduced markers of insulin sensitivity (GLUT4, adiponectin) in human sAT compared to CON-skin-CM. Incubation with sAT-CM (generated by pre-treatment of sAT with skin-CM) significantly enhanced GSIS (20mmol/l: 26.8 ± 3.1 ng/ml) vs. CON-sAT-CM treated with only fresh media (20mM: 16.9 ± 1.2 ng/ml, p<0.001, n=1 of 4 observations), indicating that skin-derived factors may modulate adipocytokine secretion. These effects were reversed following incubation with IMQ-skin-CM. Similarly, IMQ-treated mice displayed elevated pro-inflammatory cytokine expression (IL1β, IL6, IL17, TNFα) and reduced levels of (GLUT4) in sAT. Moreover, IMQ-mice displayed elevated serum insulin levels. These results are suggestive of insulin resistance in IMQ-mice.

Conclusion: These results support the hypothesis that the skin plays an important role in whole-body glucose homeostasis and that impaired skin health or function may play a direct role in development of insulin resistance and T2D. Skin inflammation impairs insulin secretion, beta-cell proliferation and viability as well as increasing sAT inflammation and potentially modulating adipocytokine secretion. This may constitute a novel pathophysiological pathway mediating T2D development.

Physical inactivity lowers mitochondrial oxidative capacity and predisposes to muscle fat accumulation and lipid-induced insulin resistance

L. Bilet[1], E. Phielix[1], T. van de Weijer[1], A. Gemmink[1], M. Bosma[1], E. Moonen-Kornips[1], J.A. Jorgensen[1], K. Meijer[1], M. Hopman[2], M.K.C. Hesselink[1], D.M. Ouwens[3], V.B. Schrauwen-Hinderling[4], P. Schrauwen[1];
[1]Human Biology and Human Movement Sciences, Maastricht University Medical Center+, Maastricht, [2]Department of physiology, Radbound University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, Germany, [4]Radiology, Maastricht University Medical Center+, Maastricht, Netherlands.

Background and aims: Physical inactivity and associated decline in mitochondrial function, increased myocellular fat deposition and reduced insulin sensitivity are common denominators in chronic metabolic disorders like obesity and T2DM. Here we examined if one-legged physical inactivity for one week would result in a decline in mitochondrial oxidative capacity, increase in muscle fat content and reduced insulin sensitivity.

Materials and methods: Ten male subjects (age 22.4 ± 4.2 years, BMI 21.3 ± 2.0 kg/m^2) underwent a 12-day unilateral lower limb suspension to investigate the effect of one-legged physical inactivity on skeletal muscle mitochondrial oxidative capacity (^{31}P-NMRS), lipid and glucose metabolism (ex vivo ^{14}C lipid and glucose oxidation), intramyocellular lipid content (IMCL by ^{1}H-NMRS and histology) and insulin sensitivity (markers of insulin signalling upon an acute intravenous insulin bolus). The contralateral leg served as an active internal control.

Results: In vivo mitochondrial oxidative capacity was lower upon inactivity, as revealed by a significantly longer PCr-recovery half-time compared to the active leg (PCr-t1/2: 21.4 ± 2.3 sec vs. 16.7 ± 1.8 sec, p=0.02). In skeletal muscle biopsies, palmitate oxidation to $14CO_2$ was significantly lower in the suspended leg compared to the active leg (0.14 ± 0.03 nmol/2h/mg vs. 0.18 ± 0.03 nmol/2h/mg, p=0.013) accompanied by a higher 14C-palmitate incorporation into TAG in the suspended leg (ex vivo assays, 0.019 ± 0.005 nmol/2h/

mg vs. 0.010 ± 0.002 nmol/2h/mg), p=0.075). Further, IMCL in both m. tibialis anterior (0.312 ± 0.045% vs 0.239 ± 0.041, p=0.003) and in m. vastus lateralis (2.09 ± 0.47 % lipid fraction vs 0.91 ± 0.27% lipid fraction, p=0.008) was higher in the suspended leg compared with the active leg. Finally, lipid-induced insulin resistance was more pronounced in the suspended leg (p<0.05).

Conclusion: These results indicate that a short episode of inactivity already blunts in vivo mitochondrial oxidative capacity and ex vivo fat oxidative capacity, redirecting fat into IMCL storage, and finally augmenting lipid-induced insulin resistance. Thus, we demonstrate that a physical inactivity-mediated decline in mitochondrial oxidative capacity directly impacts insulin sensitivity under conditions of high lipid availability.

Gut ghrelin regulates hepatic glucose production and insulin signalling via a gut-brain-liver pathway in rats

T. Wu[1], L. Li[1], G. Yang[2];

[1]Key Laboratory of Diagnostic Medicine of Ministry of Education, School of Laboratory Medicine, Chongqing Medical University, [2]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China.

Background and aims: Ghrelin, a 28-amino acid peptide originally isolated from human and rat stomach, it has been demonstrated to regulate a variety of physiological processes such as stimulating food intake and fat deposition. Although ghrelin's involvement in glucose metabolism in peripheral tissues and the central nervous system (CNS) has been reported, the effects of gut ghrelin on glucose homeostasis and insulin signaling remain unknown. In this study, we clarified a novel role of gut ghrelin in the regulation of hepatic glucose production (HGP) via neuronal network.

Materials and methods: We established the system of intraduodenal infusion and intracerebral micro infusion into the nucleus of the solitary tract (NTS) in normal chow-diet rats. Ghrelin and the local anesthetic tetracaine were co-infused into duodenum. MK-801, a NMDA receptor blocker to inhibited the NMDA receptors-mediated neuronal transmission in the NTS, was administrated into the dorsal vagal complex (DVC) targeting the NTS though bilateral catheters. The hepatic vagus nerve was transected by surgery. And the changes in glucose kinetics and hepatic insulin signaling were evaluated with the pancreatic-euglycemic clamp (PECs) technique combined with [3-^{3}H]glucose as a tracer. Gut nutrition sensing was assessed by co-infused lipid with ghrelin into duodenum during PECs. We further activated duodenal mucosal Adenosine Monophosphate Activated Protein Kinase(AMPK) signaling via intraduodenal co-infusion of ghrelin with the AMPK activator(AICAR) in vivo.

Results: Intraduodenal infusion of ghrelin induced a significant increase of HGP with inhibited hepatic insulin signaling which suppressed phosphorylation of insulin receptors(InsR) and Akt kinase during the clamps. These changes were associated with increased hepatic expression of phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6Pase). The metabolic and molecular signal effects of duodenal ghrelin were negated by co-infusion with tetracaine, MK-801 or hepatic vagotomy in rats. Iintraduodenal infused of lipid with ghrelin attenuated the ability of duodenal lipid to increase the glucose infusion rate(GIR) and lower HGP. In addition, duodenal ghrelin decreased AMPK phosphorylation in the duodenal mucosa and the role of ghrelin to increase HGP was abolished by AMPK activator.

Conclusion: Gut ghrelin plays an important role in glucose homeostasis by the regulation of hepatic glucose metabolism and insulin sensitivity, which is associated with the activation of the Gut-Brain-Liver Pathway.

OP 05 Beta cell development: genetic and epigenetic regulation

25

H3K4 methylation is essential for endocrine progenitor cell specification and migration

S.A. Campbell[1,2], T.L. Stephan[2], B.G. Hoffman[1,2];
[1]Cell and Developmental Biology, University of British Columbia, [2]Surgery, BC Children's Hospital Research Institute, Vancouver, Canada.

Background and aims: Following induction of *Neurog3* in bipotent pancreas progenitors, endocrine progenitors begin specification into the islet cell types through a transcription factor cascade. For example, beta-cell specification requires induction of Pdx1, Nkx6-1, Mafa, and Pax4. However, exactly how these factors are activated during pancreas development is largely unknown. The Trithorax group (TrxG) complexes are chromatin remodelers that promote gene activation by catalyzing histone H3 lysine 4 methylation. We previously observed that loss of the TrxG core protein Dpy30 from pancreas progenitors (*Pdx1*-Cre; *Dpy30* knockout mice) results in decreased H3K4 methylation, which prevents reliable gene induction (e.g. *Neurog3*, *Cpa1*, etc.) and appropriate specification into endocrine and acinar cells. Similarly, we hypothesize that the TrxG complexes are a critical player in the appropriate induction of factors that control Neurog3-induced endocrine cell specification and maturation.

Materials and methods: We generated endocrine-specific Dpy30 knockout mice (*Neurog3*-Cre; $Dpy30^{flox/flox}$; *Dpy30ΔN*) and examined the role of Dpy30 in endocrine progenitor development.

Results: To investigate the formation of $Neurog3^+$ endocrine progenitors, we quantified the number of $Neurog3^+$ cells at embryonic day 14.5 (E14.5), but found no apparent difference between control and *Dpy30ΔN* pancreata. This suggests that endocrine progenitors are formed correctly in Dpy30 knockout mice. To examine loss of H3K4 methylation in *Dpy30ΔN* mice, we stained for trimethylation of histone 3 lysine 4 (H3K4me3). We found that H3K4 methylation was maintained until E18.5, but was lost in $insulin^+$ beta-cells at 4 weeks of age. This data implies that loss of H3K4 methylation is only observed after post-natal expansion of endocrine cells. To determine whether endocrine progenitors specify into the correct proportions of alpha-, beta-, and delta-cells, we quantified the number of $glucagon^+$, $insulin^+$, and $somatostatin^+$ cells relative to the entire pancreas at 4 weeks. Compared to control, we found no difference in the number of delta-cells, a decrease in the number of beta-cells generated and an increase in the number of alpha-cells in *Dpy30ΔN* mice. Our data suggests that H3K4 methylation is required to activate the beta-cell lineage and repress the alpha-cell lineage during endocrine progenitor cell fate decisions. Interestingly, the islets in *Dpy30ΔN* pancreas at 4 weeks are more often found closely associated with the ducts in elongated endocrine cell structures (as observed in embryonic pancreas), rather than throughout the pancreas in adult islet cell clusters. This implies that endocrine cells fail to migrate into islets from the progenitor epithelium during specification in the absence of H3K4 methylation. To assess islet function, we measured random blood glucose and found that *Dpy30ΔN* mice become diabetic (2 blood glucose readings $\geq$ 20 mM) by 4 weeks of age ($n=3$, $p<0.05$), suggesting their islet cells have failed to reach functional maturity. Consistent with this data, we observed a decrease in fraction of $insulin^+$ beta-cells that express the mature beta-cell marker, Nkx2-2, in *Dpy30ΔN* mice ($n=2$, $p<0.01$).

Conclusion: Overall, these results suggest that the core TrxG complex protein Dpy30 is essential for differentiation of endocrine progenitors and islet cell migration.

p300 is an important cofactor for beta cell development and function

C.-K. Wong[1], A. Lee[1], K. Louie[1], F.C. Lynn[1], J.D. Wasserman[2], K. Hussain[3], P.K. Brindle[4], W.T. Gibson[1];
[1]BC Children's Hospital Research Institute, Vancouver, [2]The Hospital for Sick Children, Toronto, Canada, [3]Great Ormond Street Hospital, London, UK, [4]St. Jude Children's Research Hospital, Memphis, USA.

Background and aims: We have previously shown that the expression of p300, a transcriptional coactivator, in pancreatic islets maintains whole body glucose homeostasis in mice due to defects in various islet endocrine cell types. We hypothesized that such glucose metabolism defects are primarily due to the loss of p300 in beta cells.

Materials and methods: To determine the direct cause of the glucose intolerance in mice lacking p300 in pancreatic islets, we generated and studied mice lacking p300 specifically in beta cells using *Ins1*-Cre knockin line ($p300^{BetaKO}$ mice) and inducible *Pdx1*-CreER line ($p300^{PKO}$ mice). We had also acquired a cohort of patients with p300 mutations that also had MODY-like phenotypes.

Results: $p300^{BetaKO}$ mice suffered from glucose intolerance by eight weeks of age with impaired plasma insulin responses resembling our *Neurog3*-Cre model. These mice also had reduced beta cell area but normal alpha cell area. Thus, the expression of p300 specifically in beta cells is required for glucose homeostasis. Interestingly, although islets derived from $p300^{BetaKO}$ mice had lower insulin content in part due to a skewed beta-to-alpha ratio, transmission electron microscopy revealed that p300-null beta cells had significantly smaller mature insulin granules. As insulin granule defect is likely a mature beta cell phenotype, we hypothesized that the postnatal expression of p300 in beta cells is required to maintain beta cell function. Using $p300^{PKO}$ mice, we found that they developed glucose intolerance nine weeks after tamoxifen administration without loss of beta cell area. Archived case reports of Rubinstein-Taybi syndrome (caused by mutations in CBP/p300) and phenotyping of a subset of Rubinstein-Taybi syndrome patients with p300 mutations showed association between p300 mutations and MODY-like phenotypes ranging from early-onset diabetes to neonatal hyperinsulinemic hypoglycaemia.

Conclusion: p300 appeared to be not only required for establishing normal beta cell population but also for insulin granule synthesis. p300 is known to coactivate MODY transcription factors such as HNF4a and HNF1a, and mutations in these proteins had been shown to cause similar phenotypes observed in our cohort of patients with p300 mutations. We argue that p300 is a crucial cofactor for beta cell development and maintenance of beta cell function.

Suppression of Stat3 signalling promotes acinar-to-beta reprogramming

T. Miyatsuka[1,2], M. Miura[1], S. Sasaki[2], T. Katahira[1], Y. Fujitani[1], T.-A. Matsuoka[2], H. Watada[1];
[1]Department of Metabolism & Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, [2]Department of Metabolic Medicine, Osaka University Graduate School of Medicine, Osaka, Japan.

Background and aims: Uncovering pancreas development and β-cell differentiation has helped us to explore efficient methods to generate surrogate β cells to cure diabetes. Since it has been demonstrated that Stat3 plays a role in the plasticity of pancreatic acinar cells, we investigated how Stat3 signaling affects the cellular reprogramming of pancreatic exocrine cells into β cells.

Materials and methods: The combined expression of the defined transcription factors Pdx1, Neurog3, and Mafa was induced in the pancreatic progenitor-like cells *in vitro* and in the mouse models *in vivo*.

Results: Whereas phosphorylation of Stat3 (pStat3) was induced by adenoviral vectors expressing Pdx1 or Mafa, most of the reprogrammed β cells induced by an adenoviral vector carrying Pdx1- Neurog3- Mafa polycistronic cassette (Ad-PNM) were negative for pStat3. Furthermore, suppression of pStat3, using small molecules or dominant-negative form of Stat3, significantly enhanced β-cell neogenesis by Ad-PNM, while a constitutively active form of Stat3 inhibited the reprogramming efficiency into β cells. In order to confirm the role of Stat3 *in vivo* as well as *in vitro*, we generated a transgenic mouse line "*acinar-PNM*", which ectopically expressed Pdx1, Neuro3, and Mafa in acinar cells to induce acinar-to-β reprogramming, and found that Stat3 was activated in the acinar cells surrounding the reprogrammed β cells. In Stat3-deficient *acinar-PNM* mice, the number of newly differentiated β cells was significantly higher than that in control mice. Furthermore, the newborn β cells in *acinar-PNM; Stat3KO* pancreata formed islet-like clusters.

Conclusion: Both *in vitro* and *in vivo* experiments suggest that Stat3 signaling negatively regulates acinar-to-β reprogramming induced by distinct transcription factors, and that Stat3 inhibition promotes the reprogramming efficiency into β cells, which could lead to future cell therapy for cure of diabetes.

Glucokinase- and insulin receptor substrate-2 independent pathway was involved in pancreatic beta cell replication induced by short-term high-fat diet feeding in mice

N. Kitao[1], A. Nakamura[1], H. Miyoshi[1], K. Takahashi[1], K. Yamamoto[1], H. Nomoto[1], K. Cho[1], Y. Terauchi[2], T. Atsumi[1];

[1]Graduate School of Medicine, Hokkaido University, Sapporo, [2]Graduate School of Medicine, Yokohama City University, Yokohama, Japan.

Background and aims: Glucokinase and insulin receptor substrate-2 (Irs2) play an important role in compensatory beta cell hyperplasia in response to insulin resistance induced by longitudinal high-fat (HF) diet feeding. In this study, we investigated whether glucokinase and Irs2 were required for beta cell replication induced by short-term HF diet feeding.

Materials and methods: Eight-week-old C57BL/6J mice were exposed to either standard chow (SC) or a HF diet. After 1 week on the diet, histopathological beta cell proliferation was compared. In addition, 8-week-old beta cell-specific glucokinase haploinsufficient ($Gck^{+/-}$) and Irs2 knockout ($Irs2^{-/-}$) mice were exposed to either a SC or HF diet. To identify key genes involved in beta cell proliferation following short-term HF diet consumption, gene expression in isolated islets from 8-week-old C57BL/6J mice fed either diet for 1 week was analyzed using cDNA microarray and real-time quantitative PCR. Moreover, we orally administered a placebo or glucokinase activator to SC- and HF-fed mice during the final 3 days of the diet and compared beta cell proliferation.

Results: Immunohistochemical analysis revealed that short-term HF diet feeding resulted in a significant increase in the BrdU incorporation rate compared with SC consumption. Western blot analysis demonstrated that Irs2 expression levels did not differ between the two groups. There was a significant increase in the BrdU incorporation rate in the HF diet group compared with the SC group in both $Gck^{+/-}$ and $Irs2^{-/-}$ mice. By cDNA microarray analysis, we identified 62 genes expressed differentially (fold change ≥ 1.5) in HF diet-fed mice compared with SC-fed mice. When we clustered placentas according to the gene expression profiles for those 62 genes, three genes, cyclin A2, cyclin B1 and centromere protein A, were relatively close to each other. These three genes are located downstream of Foxm1. Real-time quantitative PCR revealed that Foxm1, cyclin A2, cyclin B1 and centromere protein A expression levels were significantly increased in HF diet mice compared with those of SC mice. Interestingly, glucokinase activator treatment resulted in an additive effect on proliferation induced by HF diet feeding for 1 week.

Conclusion: The pancreatic beta cell replication mechanism induced by short-term HF diet feeding in mice involved a glucokinase- and Irs2-independent pathway. Our results suggest that the beta cell replication pathways involved in short-term HF diet feeding may differ from those involved in chronic HF diet feeding.

Pancreas heterotopia in Gata4-deficient mice

E. Rodríguez-Seguel[1], A. Rojas[1,2];

[1]Centro Andaluz de Biología Molecular y Medicina Regenerativa-CABIMER, Universidad Pablo de Olavide, [2]Centro de Investigación Biomédica en Red, Diabetes y Enfermedades Metabólicas Asociadas, CIBERDEM, Seville, Spain.

Background and aims: Mutations in *GATA4* have been linked to pancreas agenesis in humans. In mice, while single inactivation of *Gata4* does not have a major impact in pancreas development, simultaneous inactivation of *Gata4* and *Gata6* results in pancreas agenesis, indicating redundancy between the two GATA factors. Adult *Gata4* conditional knockout mice (Gata4 KO) are normoglycemic, fertile and the body weight is similar to control littermates. Interestingly, adult mice lacking GATA4 display heterotopic pancreas, which localizes in the serosa layer of the antrum stomach. The aim of this work is to analyze the molecular mechanism underlying the heterotopic pancreas in Gata4 KO mice.

Materials and methods: To analyze the ectopic pancreas we are using conditional *Gata4* Knockout mice where the Cre recombinase transgene is under the control of the *pancreatic and duodenal homeobox gene* (*Pdx1*). Immunohistochemistry and immunofluorescence analyses of embryonic and adult stomach were performed.

Results: Analysis of *Gata4* KO stomach through embryonic development shows ectopic pancreas from E17.5 onwards. Immnuohistochemical and immunofluorescent analyses of adult heterotopic pancreas reveal complete differentiation of exocrine cells. Moreover, small cluster of insulin and glucagon expressing-cells are also observed. Histological analyses show an ingression of the glandular epithelial cells into the serosa, suggesting a stomach epithelial origin of heterotopic pancreatic cells. In agreement with these results, we found lack expression of glandular stomach differentiation markers, including H^+/K^+ ATPase, in the near proximity of the heterotopic pancreatic cells.

Conclusion: Inactivation of *Gata4* in the glandular stomach leads to changes in the cellular phenotype towards a pancreatic fate. Heterotopic pancreatic cells are able to fully differentiate into acinar and endocrine pancreatic cells.

A novel, highly proliferative population of islet endocrine cells in adolescent and adult human pancreata

J.A. Kushner[1], C.J. Lam[1], D.R. Jacobson[2], M.M. Rankin[2], A.R. Cox[1];

[1]Pediatric Diabetes & Endocrinology, McNair Medical Institute, Baylor College of Medicine, Houston, [2]Division of Endocrinology and Diabetes, Children's Hospital of Philadelphia, Philadelphia, USA.

Background and aims: Although previous studies have focused on turnover of human β-cells from cadaveric pancreata, little is known regarding proliferation of other islet endocrine cell types in control and T1D states.

Materials and methods: We studied a large collection of pancreata from JDRF nPOD across a wide range of ages, quantifying islet endocrine cell turnover by high throughput imaging.

Results: In a previous study we found no evidence of ongoing β-cell regeneration in T1D pancreata compared to controls, regardless of diabetes duration. Surprisingly, we observed plentiful islet endocrine cell proliferation in many of the sample samples derived from adolescent and young adult T1Ds and controls. However, the increased islet endocrine cell proliferation was not within insulin, PP, somatostatin, or ghrelin expressing cells. Glucagon-expressing α-cells accounted for a large fraction (~30%) of islet cell proliferation in those samples from adolescents and young adults that exhibited high proliferation. To further characterize the proliferative cells we tested for a variety of islet endocrine markers in proliferative samples from adolescents and young adults. The highly proliferative cells represent a novel population hormone negative islet endocrine cells, with ARX (known to determine α-cell identity), INSM1 (present in human α- and β-cells), and cytoplasmic Sox9 cytoplasmic-immunoreactivity. These highly proliferative cells represented the majority of islet endocrine Ki67+ cells in adolescent and young adult pancreata with high turnover.

Conclusion: We have identified a novel population of highly proliferative, α-related cells in adolescent and young adult pancreata. These α-related islet endocrine cells suggest the possibility of previously unrecognized ongoing islet development and/or lineage plasticity within adolescent and adult human pancreata.

Remodelling of adipose tissue transcriptome by diurnal distribution of carbohydrates and fat in humans

O. Pivovarova[1,2], K. Kessler[1,3], K. Jürchott[4], S. Hornemann[1], C. Sticht[5], K.J. Petzke[6], M. Kemper[1,3], N. Gretz[5], N. Rudovich[1,7], A. Kramer[8], A.F.H. Pfeiffer[1,3];

[1]Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, [2]German Center for Diabetes Research (DZD), München-Neuherberg, [3]Dept. of Endocrinology, Diabetes and Nutrition, Campus Benjamin Franklin, Charité University Medicine, Berlin, [4]Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Charité University Medicine, Berlin, [5]Center for medical research (ZMF), Faculty of Medicine Mannheim at Heidelberg University, Mannheim, [6]Dept. of Physiology of Energy Metabolism, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany, [7]Division of Endocrinology and Diabetes, Department of Internal Medicine, Spital Bülach, Bülach, Switzerland, [8]Laboratory of Chronobiology, Institute for Medical Immunology, Charité University Medicine, Berlin, Germany.

Background and aims: Time of food consumption and meal composition strongly affect metabolic state and gene expression in metabolically active tissues. Here, we for the first time investigated effects of the diurnal distribution of carbohydrates and fat consumption on the subcutaneous adipose tissue (SAT) transcriptome in humans.

Materials and methods: 29 non-obese men without diabetes (age 45.9 ± 2.5 years, BMI 27.1 ± 0.8 kg/m^2) participated in the cross-over study. They consumed two 4-week isocaloric diets - (1) HC/HF diet consisted of a carbohydrate-rich breakfast and lunch (65 EN% carbohydrates, 20 EN% fat, 15 EN% protein) and a fat-rich snack and dinner (35 EN% carbohydrates, 50 EN% fat, 15 EN% protein) and (2) HF/HC diet consisted of a fat-rich breakfast and lunch and a carbohydrate-rich snack and dinner. At the end of each intervention period, SAT samples were collected three times during the investigation day (at 8.40, 12.20 and 19.00), and saliva samples were collected every 4 h during 24 h. Microarray analysis of SAT samples from 15 subjects was performed using GeneChip® Human Gene 2.0ST Arrays (Affymetrix) and validated by real-time PCR. Parameters of circadian oscillations were estimated by a 24 h rhythm prediction method established previously.

Results: From 2372 oscillating SAT transcripts, 644 (27.2%) transcripts were rhythmic on both HC/HF and HF/HC diets, whereas 531 (22.4%) and 1197 (50.5%) transcripts showed circadian oscillations only on the HC/HF and HF/HC diet, respectively. A number of genes rhythmic in both dietary conditions demonstrated alterations of acrophase (37), amplitude (22) and mesor (52). Different patterns of meal composition did not affect both oscillations of clock genes in SAT and the salivary cortisol rhythm used as a central clock marker. However, we found dietary effects on numerous oscillating and non-oscillating genes involved in glucose (e.g. IRS1, IRS2, PCK1, PDK4) and lipid metabolism (e.g. ACACA, ACAT1, ACOX2, PPARA) as well as inflammatory response (e.g. CCL5, IL1B, ITGAX, CD3E). Mechanisms underlying this remodeling include the change of activity of the insulin signaling, I-kappa B kinase/NF-kappa B and MAPK pathways. Serum leptin rhythm was delayed on the HF/HC diet, whereas levels of adiponectin, visfatin, IL-6 and C-reactive protein were not changed.

Conclusion: Our study revealed that diurnal distribution of carbohydrates and fat consumption induces deep remodeling of adipose tissue transcriptome in humans including the alteration of glucose and lipid metabolism and inflammatory pathways.

The FAT score, a Fibrosis score of Adipose Tissue: predicting weight loss outcome after gastric bypass

P. Bel Lassen[1,2], F. Charlotte[3], Y. Liu[4], P. Bedossa[5], G. Le Naour[3], J. Tordjman[1], C. Poitou[1,2], J.-L. Bouillot[6], L. Genser[1,7], J.-D. Zucker[1], N. Sokolovska[1], J. Aron-Wisnewsky[1,2], K. Clément[1,2];

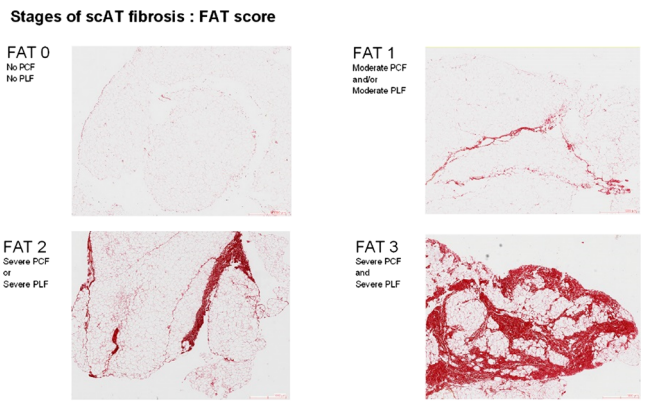
[1]Institute of Cardiometabolism and Nutrition, UMRS INSERM 1166, Paris, [2]Nutrition, Pitié-Salpêtrière Hospital, Assistance Publique - Hôpitaux de Paris, [3]Pathology, Pitié-Salpêtrière Hospital, Assistance Publique - Hôpitaux de Paris, [4]Institute of Cardiometabolism and Nutrition, [5]Beaujon Hospital, Assistance Publique - Hôpitaux de Paris, Paris, [6]Ambroise Paré Hospital, Assistance Publique - Hôpitaux de Paris, Boulogne, [7]Surgery, Pitié-Salpêtrière Hospital, Assistance Publique - Hôpitaux de Paris, Paris, France.

Background and aims: Bariatric surgery (BS) induces major and sustainable weight loss in many but not all patients. Factors predicting poor responders (PR) need to be identified to improve patient care. Quantification of subcutaneous adipose tissue (scAT) fibrosis is negatively associated with post-BS weight loss, but whether it could constitute a predictor applicable in clinical routine remains to be demonstrated. The objective of this work was to create a semi-quantitative score evaluating scAT fibrosis and test its predictive value on weight loss response after Roux-en-Y gastric bypass (RYGB).

Materials and methods: We created a Fibrosis score of Adipose Tissue (FAT score) integrating peri-lobular and peri-cellular fibrosis. Using this score, we characterized 183 peroperative scAT biopsies (stained with picrosirius red) of severely obese patients who underwent RYGB (85 from a training cohort, 98 from a confirmation cohort). Poor Response (PR) to RYGB was defined as < 28% of total weight-loss at one year (lowest tertile). The link between FAT score and PR was tested in univariate and multivariate models.

Results: FAT score was directly associated with increasing scAT fibrosis measured by a standard quantification method (p for trend <0.001). FAT score inter-observer agreement was good (κ =0.76). FAT score ≥2 was significantly associated with PR. The association remained significant after adjustment for age, diabetes status, hypertension, percent fat-mass and IL-6 (adjusted OR =3.6, IC 95% [1.8, 7.2]; p =0.003).

Conclusion: The FAT score is a new simple semi-quantitative evaluation of human scAT fibrosis that may be used to help identifying patients with a potential limited weight loss response to RYGB.



Peroperative scAT biopsies stained with picrosirius red to reveal fibrosis (collagen accumulation)
scAT: subcutaneous adipose tissue; PLF: perilobular fibrosis; PCF: pericellular fibrosis; FAT score: Fibrosis Adipose Tissue score

Characteristics of differentiated small proliferative adipocytes (SPA), a newly identified adipocyte progenitor

K. Kajita[1], Y. Kitada[1], K. Taguchi[1], M. Fuwa[1], T. Ikeda[1], T. Ishizuka[2], H. Morita[1];
[1]General Internal Medicine, Gifu University Graduate School of Medicine, [2]General Internal Medicine and Rheumatology, Gifu Municipal Hospital, Gifu, Japan.

Background and aims: We reported cells expressing adipocyte specific genes and proliferative activity in adipose tissue last year. We considered these cells as a new population of adipocyte progenitors, and named them small proliferative adipocytes (SPA). We found that SPA expressed several neuronal genes, such as synaptic vesicle, GABA-A receptor, serotonin receptor 1F and glutamate receptor 7 (Grm7). Moreover, SPA, as well as stromal vascular cells (SVC), were found to differentiate into adipocytes. In this study, we examined the difference between adipocytes differentiated from SPA (DSPA) and ones from SVC (DSVC).

Materials and methods: Mouse epididymal adipose tissue was digested with collagenase, and centrifuged at 9g for 1 sec. Cells in the sedimentary fraction were regarded as SVC. Floating cell fraction was separated and further centrifuged at 226g for 3 min. The resultant sedimentary cells were regarded as half-floating cells. Half-floating cells were small but expressed adiponectin, fatty acid binding protein 4 and leptin. In addition, incorporation of EdU was detected in these cells. Therefore, they were considered as SPA. Adipogenic differentiation was induced with differentiation medium containing insulin/dexamethasone/IBMX. Gene expression of DSPA was compared with DSVC with microarray.

Results: Incubation of SPA with differentiation medium for 2 days yielded lipid laden cells expressing increased amount of PPARγ2 and adiponectin mRNA (DSPA). Neuronal genes, such as Grm7 were more abundantly expressed in DSPA than in DSVC. Treatment with dexamethasone or pioglitazone alone, but not insulin, led to lipid accumulation to a less extent than differentiation medium in SPA. In contrast, fewer lipid droplets ware detected in SVC treated with differentiation medium (DSVC). To characterize DSPA, microarray was performed comparing with DSVC. Adipocyte genes including adipsin, β3 adrenergic receptor (Adrb3) and perilipin 4, and neuronal genes, neurofilament light (Nefl), synapsin 3 and adenosine A1 receptor, were more abundantly expressed than adiponectin in DSPA compared with DSVC. Immunocytochemical study confirmed these results. In addition, immunohistochemical study detected two populations of adipocytes, (adipocytes positive for Nefl and Adrb3, and negative for Nefl and Adrb3). Recent study demonstrated that stimulation of Adrb3 induces beige remodeling in white adipose tissue. These data suggested that DSPA may functionally differ from DSVC.

Conclusion: Differentiation of SPA and SVC resulted in functionally distinct mature adipocytes.

34

Bone morphogenetic protein 2 is a depot-specific regulator of human adipogenesis

N. Denton;
Radcliffe Department of Medicine, University of Oxford, Oxford, UK.

Background and aims: Body fat distribution is a strong determinant of human metabolic health but the mechanisms underpinning regional deposition of adipose tissue remain poorly understood. Recent genome-wide association studies of body fat distribution suggest that bone morphogenetic protein 2 (BMP2) and Smad signalling regulate this phenotype. The aim of this project was to investigate whether BMP2 modulates adipogenesis in a depot-specific manner.

Materials and methods: BMP2 gene expression was measured in adipose tissue and analysed in combination with genotype data from the Oxford Biobank to identify eQTLs. Depot-specific effects of BMP2 signalling were studied in immortalised human subcutaneous abdominal and gluteal preadipocytes. Smad1/5/8 signalling activity was measured via Western blot; adipogenesis was evaluated via triglyceride (TG) quantification and qPCR. Preadipocytes were treated with BMP2 and/or K02288, an inhibitor of Smad signalling.

Results: BMP2 expression in both male and female abdominal and gluteal adipose tissue was 15% lower in BMP2 rs2145270 CC carriers ($p<0.05$, ANOVA corrected for age and BMI), a recently-identified GWAS locus for body fat distribution. Adipose tissue BMP2 expression did not exhibit any regional variation. Acute treatment with 50ng/ml exogenous BMP2 stimulated the phosphorylation of Smad1/5/8 in preadipocytes from both depots but this was blocked by co-administration of 500nM K02288. Supplementation of differentiation media with BMP2 enhanced adipogenesis specifically in abdominal preadipocytes in a dose-dependent manner: compared to vehicle, 5ng/ml BMP2 stimulated a 2-fold increase in *PPARG* expression ($p<0.05$; post-hoc T-test for ANOVA) and 1.5 fold increase in TG accumulation ($p<0.05$, post-hoc T-test for ANOVA); 50ng/ml BMP2 increased *PPARG* expression 3.5 fold ($p<0.05$, post-hoc T-test for ANOVA) and TAG accumulation 3 fold ($p<0.05$, post-hoc T-test for ANOVA). However BMP2 treatment had no effect on adipogenesis in gluteal cells. The depot-specific, pro-adipogenic action of BMP2 was blocked by co-administration with K02288.

Conclusion: BMP2 represents a novel depot-specific regulator of (subcutaneous) adipogenesis. Its pro-adipogenic effects require activation of Smad1/5/8 signalling but the depot-specific nature of BMP2 action likely manifests through regional variation in Smad1/5/8-regulated gene expression. These functional studies build on recent GWAS meta-analysis results and strongly implicate BMP2-Smad signalling in preadipocyte biology and the determination of human body fat distribution.

Effect of diet-induced obesity on peripancreatic adipose tissue secretion: TIMP-1

S.A. Rebuffat[1], A. Nouvel[1], Y. Esteban[2,3], A. Garcia[2,3], S. Peraldi-Roux[1], R. Gasa[2,3], R. Gomis[2,3], A.-D. Lajoix[1];
[1]EA7288, EA7288, Universite de Montpellier, Montpellier, France, [2]IDIBAPS, [3]CIBERDEM, Barcelona, Spain.

Background and aims: Besides storing energy, adipose tissue integrates a wide array of physiological processes which are coordinated mainly through the synthesis and release of adipokines which can act either locally or through the blood stream. Using a model of obesity and insulin resistance induced by a hypercaloric diet (representative of the unhealthy so-called western diet), we demonstrated that the peripancreatic adipose tissue is able to secrete some proliferative signals involved in the pancreatic beta cell plasticity, suggesting a cross-talk between the adipose tissue and the beta cell. The objective of this study is to investigate signals emanating from the adipose tissue that potentially may contribute to both beta cell compensation and decompensation processes.

Materials and methods: The study has been carried out along the "Principles of laboratory animal care" and according to the national law. Male Wistar rats were exposed to a high caloric cafeteria (CAF) diet (65% of the energy derived from lipids) (n=29) or standard (STD) chow diet (n=15) for 24 weeks. Body weight was measured weekly. Pancreas was removed to perform morphometric studies. Adipose tissues (AT) from epididymal (eWAT) and peri-pancreatic (pWAT) depots, as well as pancreatic islets, were collected. Conditioned medium (CM) was obtained from AT by culturing in serum-free medium for 24 hours. The expression profile of peri-pancreatic fat derived factors was analyzed by antibody-array. TIMP-1 expression was determined by qRT-PCR,

immunoblotting and TIMP-1 concentration was quantified by ELISA. Proliferation in INS1E cells was evaluated by BrdU incorporation.

Results: Administration of CAF diet induced a rapid increase in the animals' body weight. The CAF diet increased the weight of all adipose depots analyzed (eWAT: 27.17g ±5.34 vs. 14.37g ±2.81, pWAT: 5.76g ±1.33 vs. 2.39g ± 0.80; p<0.001). As expected, the obesity induced by the long term CAF diet led to an impairment of glucose tolerance. Although no significant difference were observed in fasting glycaemia, CAF diet fed rats had higher fasted levels of insulin compared with lean ones (3.9ng/mL ±1.1 vs. 1.8ng/mL ±0.7, p<0.001). Changes in cytokine and chemokine secretion profiles of peripancreatic adipose tissue (pWAT) due to diet-induced obesity have been observed. We are particularly interested by tissue inhibitor of metalloproteinase 1 (TIMP-1). TIMP-1 expression was increased after 4 weeks of CAF diet (4-fold, p<0.01), but decreased by half after 24 weeks (p<0.01), suggesting an effect of age and diet. The decrease in the expression of Timp-1 transcript was observed in pWAT relative to lean animals. Western blot analysis confirmed that long-term CAF diet decreased TIMP-1 expression in peripancreatic adipose tissue (pWAT) and in CM from pWAT. TIMP-1 concentration was quantified precisely in CM from pWAT by ELISA (STD: 3.2 ng/mL ±0.1 and CAF: 0.6ng/mL ±0.4, p<0.001) and these concentration was tested on INS1E cells proliferation.

Conclusion: TIMP-1 is known to exhibit a broad range of biological activities, including inhibition of MMP activity, regulation of proliferation and apoptosis of a variety of cell types. Here, we suggested that TIMP-1, secreted by peripancreatic adipose tissue, might have a survival effect on pancreatic β-cells.

The crucial role of Fibrinogen-related protein 1 in obesity

H.-T. Wu[1], H.-Y. Li[2], S.-C. Chen[3], H.-Y. Ou[4], C.-J. Chang[5];
[1]Department of Family Medicine, National Cheng Kung University Hospital, Tainan, [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, [3]Department of Internal Medicine, New Taipei City Hospital, New Taipei City, [4]Department of Internal Medicine, National Cheng Kung University and Hospital, Tainan, [5]Department of Family Medicine, National Cheng Kung University and Hospital, Tainan, Taiwan.

Background and aims: The prevalence of obesity has significantly increased in the past few decades, and the excessive body fat is associated with many metabolic disorders. Changes of adipokines release in obesity were the key mechanism that led to the development of insulin resistance. Fibrinogen-like protein 1 (FGL1) was previously discovered as a novel adipokine that led to insulin resistance. However, the physiological functions in adipogenesis and the role of FGL1 in obesity are still obscure.

Materials and methods: A total of 359 subjects (included 290 women and 129 men) were enrolled in the present study. Among these subjects, 224 participants were normal weight (body mass index <25) and 135 participants were overweight/obesity (body mass index ≥25). Body fat composition was determined using computed tomography. Serum FGL1 concentrations were measured by enzyme-linked immunosorbent assay. Overexpression or knockdown of FGL1 in the adipose tissue of high fat diet- fed mice was achieved by lenti-viral vector transfection to evaluate the effects of FGL1 in fat pad. In addition, 3T3-L1 adipocytes were used to investigate the possible mechanisms in FGL1-induced adipogenesis.

Results: Participants with overweight/obesity had higher fat composition, fasting plasma glucose, HbA1C, blood pressure, triglyceride levels, glutamate oxalate transaminase, glutamate pyruvate transaminase levels, and lower high-density lipoprotein levels. The fasting plasma FGL1 concentration was 689 ng/ml in normal weight group and 743 ng/ml in overweight/obesity group (p=0.003). In univariate analyses, we found that plasma FGL1 level was associated with body mass index (BMI), waist circumference, total fat area, visceral fat area and subcutaneous fat area (p<0.01). In multivariate logistic regression analysis, plasma FGL1 was significantly associated with BMI, waist circumference, log-transformed total fat area, and log transformed subcutaneous fat area (p<0.05) after the adjustment of age. Overexpression of FGL1 in epididymal adipose tissue significantly increased the size of the fat pad in mice. On the other hand, knockdown of FGL1 in the fat pad significantly decreased the size of the fat pad in high fat diet-fed mice. Furthermore, we found FGL1 facilitated 3T3-L1 pre-adipocyte proliferation through an ERK1/2-dependent pathway.

Conclusion: FGL1 increased the proliferation of pre-adipocytes and contributed to the development of obesity. In this study, we clarified the physiological function of FGL1 in adipose tissue and provided a novel mechanism for the development of obesity.

Time to next therapy for patients with type 2 diabetes in the UK: canagliflozin compared with other antihyperglycaemic agents

J. Diels[1], A. Schubert[2], G. Hamilton[3];
[1]Janssen Research & Development, Beerse, Belgium, [2]Janssen-Cilag Poland, Warsaw, Poland, [3]Janssen-Cilag Ltd, High Wycombe, UK.

Background and aims: This study describes the pattern of changes in therapy for patients with type 2 diabetes mellitus (T2DM) treated with canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor (SGLT2i), versus other antihyperglycaemic agents (AHAs) using retrospective data in the UK.

Materials and methods: Patients with T2DM who were initiated on glucagon-like protein-1 receptor agonists (GLP-1 RA), dipeptidyl peptidase-4 inhibitor (DPP-4i), or SGLT2i between 2012 and 2015 were extracted from Clinical Practice Research Datalink (N = 46,349). Time to next therapy was analysed using Kaplan-Meier analysis and multivariate Cox proportional hazards regression, with age, sex, HbA1c, systolic blood pressure, and body mass index (BMI) at baseline, and background therapy as covariates.

Results: Time to next therapy was longer for CANA (n = 1,143) versus GLP-1 RA, DPP-4i, and other SGLT2i (Figure). Adjusted hazard ratios (HRs; 95% confidence interval [CI]) versus CANA ranged from 1.43 [1.20, 1.70] (sitagliptin; n = 17,777) and 1.76 [1.47, 2.11] (saxagliptin; n = 4,531) for DPP-4i (all P <0.001); from 1.43 [1.20, 1.71] (liraglutide; n = 4,933) and 1.84 [1.52, 2.23] (exenatide; n = 1,254) for GLP-1 RA (all P <0.001); and from 1.20 [1.00, 1.44] (P = 0.048; dapagliflozin; n = 5,821) and 1.20 [0.80, 1.81] (P = 0.38; empagliflozin; n = 317) for SGLT2i.

Conclusion: These analyses indicate that patients receiving CANA versus other AHAs had a longer time on treatment before a change in therapy, which may reflect better effectiveness and/or tolerability.

Figure. Adjusted HRs (95% CI) for time to next therapy for selected GLP-1 RA, DPP-4i, and other SGLT2i versus CANA based on the multivariate Cox proportional hazards regression.

Safety and efficacy of ertugliflozin compared to glimepiride in patients with type 2 diabetes inadequately controlled on metformin: the VERTIS SU trial

P. Hollander[1], J. Liu[2], J. Hill[2], J. Johnson[2], Z. Jiang[3], G. Golm[2], S. Huyck[2], S. Terra[4], J.P. Mancuso[5], S. Engel[2], B. Lauring[2];
[1]Baylor Endocrine Center, Dallas, [2]Merck & Co., Inc., Kenilworth, USA, [3]MSD R&D (China) Co., Ltd, Beijing, China, [4]Pfizer, Inc., Andover, [5]Pfizer, Inc., Groton, USA.

Background and aims: Ertugliflozin (ERTU) is an oral sodium/glucose cotransporter 2 (SGLT2) inhibitor in development for treatment of type 2 diabetes mellitus (T2DM). This study assessed the safety and efficacy of once-daily ERTU 15 mg (E15) or 5 mg (E5), compared with glimepiride (G), over 52 weeks in patients with T2DM inadequately controlled on metformin.

Materials and methods: In a double-blind, randomised Phase 3 trial, patients with HbA1c 7.0-9.0% on stable metformin ≥1500 mg/day were randomised 1:1:1 to E15, E5, or G (initiated at 1 mg QD and uptitrated to a maximum of 6 or 8 mg/day according to local label or maximum tolerated dose; appropriateness of up titration was assessed at study visits or more frequently as per investigator discretion, and was guided by an algorithm that considered glycaemic control and hypoglycaemia). Endpoints were analysed at Week 52. Primary hypothesis was that E15 was non-inferior to G in reducing HbA1c; non-inferiority was to be declared if the upper bound of the two-sided 95% CI of the mean treatment difference was <0.3%. Key secondary endpoints included change from baseline in HbA1c (E5 vs G), incidence of symptomatic hypoglycaemia, and change from baseline in body weight and systolic BP (SBP). Efficacy endpoints were analysed with a longitudinal model using a pre-specified testing sequence to control for multiplicity.

Results: In total, 1326 patients were randomised. Baseline characteristics were generally comparable between arms (mean age 58.2 yrs, HbA1c 7.8%, eGFR 87.2 mL/min/1.73m^2, weight 86.8 kg). The mean dose of G was 3.0 mg. After 52 weeks, E15 was non-inferior to G in reducing HbA1c (Table). Significantly less symptomatic hypoglycaemia (p<0.001) and greater reductions in body weight (p<0.001) were observed with E15 vs G. E5 was not non-inferior to G in reducing HbA1c. Less symptomatic hypoglycaemia (nominal p<0.001) and greater reductions in body weight (nominal p<0.001) were observed with E5 vs G. Greater reductions in SBP were observed in the E15 and E5 arms vs G (nominal p<0.001). ERTU was generally well-tolerated. AE incidence was similar across arms, with a low frequency of serious AEs (SAEs), drug-related SAEs and AEs leading to discontinuation. One (0.2%) and 5 (1.1%) patients in the E15 and E5 arms, respectively, died during the treatment period; 1 death occurred in the G group due to an AE that started after the last treatment dose. Higher rates of genital mycotic infections (GMI) were reported in the E15 and E5 arms vs G. Comparable rates of urinary tract infection and hypovolaemia AEs were observed.

Conclusion: E15 was non-inferior to G in reducing HbA1c and resulted in greater reductions in body weight than G. ERTU was well tolerated and resulted in less hypoglycaemia, but more GMI, than G.

Long-term efficacy and safety of canagliflozin in combination with insulin in Japanese type 2 diabetes patients

S. Harashima[1], N. Inagaki[1], K. Kaku[2], K. Kondo[3], N. Maruyama[3], M. Otsuka[3], Y. Kawaguchi[3], Y. Watanabe[3], M. Goda[3], H. Iijima[3];
[1]Graduate School of Medicine, Kyoto University, Kyoto, [2]Department of Internal Medicine, Kawasaki Medical School, Kurashiki, [3]Mitsubishi Tanabe Pharma Corporation, Tokyo, Japan.

Background and aims: This study investigated the efficacy and safety of canagliflozin (CAN) administration in Japanese type 2 diabetes mellitus patients with inadequate glycemic control on insulin monotherapy.

Materials and methods: The study comprised a 16-week double-blind period in which patients were randomized to either CAN 100 mg (N=76) or placebo (P; N=70), followed by a 36-week open-label period in which all patients received CAN 100 mg.

Results: Placebo-adjusted changes (least squares mean, last observation carried forward [LOCF]) in HbA1c, body weight, and homeostatic model assessment (HOMA) 2-%B were −1.10% (95% CI −1.33, −0.87), −2.37% (95% CI −3.09, −1.65), and 9.27% (95% CI 5.35, 13.19), respectively (all p<0.001). These effects were sustained throughout the open-label period: the changes from baseline (LOCF) in the P/CAN (36-week treatment, N=67) and CAN/CAN groups (52-week treatment, N=76), respectively, were −1.09% (95% CI −1.29, −0.88; p<0.001) and −0.88% (95% CI −1.08, −0.68; p<0.001) for HbA1c; −1.40% (95% CI −2.03, −0.77; p<0.001) and −2.14% (95% CI −2.78, −1.51; p<0.001) for body weight; and 7.84% (95% CI 4.25, 11.43 ; p<0.001) and 8.91% (95% CI 6.41, 11.41; p<0.001) for HOMA2-%B. The incidence rates of adverse events were 64.8% and 68.0% in the P and CAN groups, respectively, during the double-blind period, and 85.1% and 92.0% in the P/CAN and CAN/CAN groups, respectively, during all treatment period of CAN (P/CAN:36-week treatment, CAN/CAN:52-week treatment). The incidence rates of hypoglycemia per subject-year exposure were 4.51 and 7.97 in the P and CAN groups, respectively, during the double-blind period, and 4.85 during all treatment period of CAN. Hypoglycemic events in both groups were mild in severity and insulin dose reduction decreased the incidence rate of hypoglycemic events per subject-year exposure (14.76 before dose reduction, 9.30 after dose reduction; N=38). Cumulative logistic model obtained by the number of hypoglycemic events was applied to investigate risk factors for hypoglycemia and suggested that lower baseline plasma C-peptide was the risk factor for hypoglycemia in both the P and CAN groups in the double-blind period as well as in all treatment period of CAN.

Conclusion: This study demonstrates the long-term efficacy and safety of CAN in combination with insulin in Japanese patients.

Dapagliflozin + saxagliptin + metformin triple therapy vs sitagliptin add-on to metformin dual therapy in subgroups of patients with uncontrolled type 2 diabetes

S. Del Prato[1], Y. Handelsman[2], C. Mathieu[3], E. Johnsson[4], R. Kurlyandskaya[4], N. Iqbal[5], R. Garcia-Sanchez[5], J. Rosenstock[6];
[1]University of Pisa, Pisa, Italy, [2]Metabolic Institute of America, Tarzana, USA, [3]University Hospital Gasthuisberg, Leuven, Belgium, [4]AstraZeneca Gothenburg, Mölndal, Sweden, [5]AstraZeneca, Gaithersburg, , [6]Dallas Diabetes Research Center at Medical City, Dallas, USA.

Background and aims: Stepped up therapy adding a single antidiabetes agent often fails to improve glycaemic control meaningfully in patients with significant hyperglycaemia and metformin-treated type 2 diabetes mellitus (T2DM). The efficacy and safety of triple therapy achieved with add-on of saxagliptin (SAXA) plus dapagliflozin (DAPA) to metformin (MET) vs dual therapy with a single addition of sitagliptin (SITA) to MET were evaluated in this randomized, double-blind, double-dummy, 26-week trial in patients with T2DM.

Materials and methods: Patients with T2DM and glycated haemoglobin (HbA_{1c}) levels 8.0%—10.5% on stable MET therapy (≥1500 mg/day) were randomized (1:1) to add-on oral therapy with DAPA 10 mg/day plus SAXA 5 mg/day or SITA 100 mg/day. The primary efficacy end point was change in HbA_{1c} from baseline to week 26; secondary end points were the proportion of patients achieving a therapeutic glycaemic response (HbA_{1c} <7.0%) and changes in body weight and fasting plasma glucose (FPG) at week 26. The primary end point was analysed for predefined subpopulations stratified by baseline HbA_{1c} category, sex, age, race, and region using a longitudinal repeated-measures model. The incidences of adverse events and hypoglycaemia were also assessed.

Results: The analysis included 461 patients (45.6% men; mean±SD age, 55.9±9.2 years; BMI, 33.1±6.2 kg/m^2; duration of T2DM, 8.0±5.4 years; HbA_{1c}, 8.8±0.9%). The reduction from baseline to week 26 in HbA_{1c} was greater with DAPA+SAXA+MET vs SITA+MET (−1.41% vs −1.07%; *P*=0.0008) irrespective of baseline HbA_{1c} (<8.0% vs 8.0%—9.0% vs ≥9.0%), sex, age, race, or region (Table). Reductions in total body weight (−1.9 kg vs −0.5 kg; *P*<0.0001) and FPG (−32 mg/dL [1.8 mmol/L] vs −11 mg/dL [0.6 mmol/L]; *P*<0.0001) were greater, and significantly more patients achieved HbA_{1c} <7.0% (37% vs 25%; *P*=0.0034), with DAPA+SAXA+MET vs SITA+MET. Both treatments were well tolerated, and the incidence of confirmed hypoglycaemia was low (<5%).

Conclusion: Add-on of DAPA+SAXA to MET provided significantly greater improvements in HbA_{1c} and other glycaemic parameters, weight, and the proportion of patients achieving target HbA_{1c} <7.0%, compared with SITA+MET, across diverse predefined subpopulations with poorly controlled T2DM.

Table. Adjusted mean HbA_{1c} change by baseline characteristics

Safety and efficacy of ertugliflozin after 52 weeks in patients with type 2 diabetes inadequately controlled on metformin and sitagliptin: VERTIS SITA2 trial extension

R. Eldor[1], J. Liu[1], S. Dagogo-Jack[2], G. Amorin[3], J. Johnson[1], Y. Liao[4], S. Huyck[1], G. Golm[1], S.G. Terra[5], J.P. Mancuso[6], S.S. Engel[1], B. Lauring[1];
[1]Merck & Co., Inc., Kenilworth, [2]University of Tennessee Health Science Center, Memphis, USA, [3]MSD, Buenos Aires, Argentina, [4]MSD R&D (China) Co., Ltd, Beijing, China, [5]Pfizer, Inc., Andover, [6]Pfizer, Inc., Groton, USA.

Background and aims: Ertugliflozin (ERTU) is an oral sodium/glucose cotransporter 2 (SGLT2) inhibitor in development for treatment of type 2 diabetes mellitus (T2DM). This study assessed the safety and efficacy of adding ERTU 5 mg or 15 mg compared with placebo (PBO) to the dual combination of metformin and sitagliptin over 52 weeks of treatment.

Materials and methods: Patients (n=464) with HbA1c 7.0-10.5% on stable metformin ≥1500 mg/day and sitagliptin 100 mg/day were randomised to ERTU 5 mg, ERTU 15 mg, or PBO in a double-blind Phase 3 trial. The primary outcome was at Week 26 and treatment was continued until Week 52 in a double-blind extension phase.

Results: Baseline characteristics were generally comparable between groups (mean age 59.1 years, mean HbA1c 8.0%, mean body weight 86.9 kg, mean eGFR 87.9 mL/min/1.73m^2). After 52 weeks, greater reductions in HbA1c, fasting plasma glucose (FPG), body weight and systolic BP and a greater proportion of patients with an HbA1c <7.0% were observed in the ERTU groups versus PBO (Table), consistent with previously reported Week 26 findings. Rates of genital mycotic infections were higher in patients receiving ERTU compared with PBO at Week 52 (males: 4.9% [ERTU 5 mg], 3.7% [ERTU 15 mg], 0 [PBO]; females: 12.0% [ERTU 5 mg], 14.1% [ERTU 15 mg], 1.9% [PBO]; all p<0.05 vs PBO except ERTU 15 mg males). The incidences of urinary tract infections, symptomatic hypoglycaemia and hypovolaemia adverse events were not meaningfully different across groups.

Conclusion: Addition of ERTU 5 mg or 15 mg to metformin and sitagliptin provided clinically meaningful glycaemic control over 52 weeks and was well-tolerated.

Table. Summary of key efficacy endpoints at Week 52 (excluding rescue approach)

Empagliflozin (EMPA) reduces mortality in analyses adjusted for control of blood pressure (BP), low density lipoprotein cholesterol (LDL-C) and HbA_{1c} over time

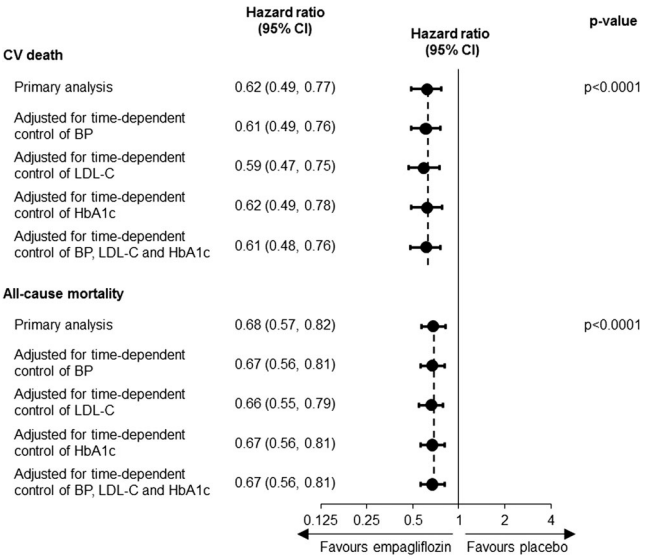
D. Fitchett[1], C. Mathieu[2], S. Kaspers[3], M. Mattheus[3], H.J. Woerle[3], B. Zinman[4];
[1]St Michael's Hospital, Division of Cardiology, University of Toronto, Canada, [2]Department of Clinical and Experimental Medicine, University of Leuven, Leuven, Belgium, [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, [4]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, Division of Endocrinology, University of Toronto, Toronto, Canada.

Background and aims: In EMPA-REG OUTCOME, EMPA given in addition to standard of care significantly reduced the risk of cardiovascular (CV) (HR 0.62 [95% CI 0.49, 0.77]) and all-cause (0.68 [0.57, 0.82]) mortality vs placebo (PBO) in patients with type 2 diabetes (T2DM) and established CV disease. We investigated the effects of controlling BP, LDL-C and HbA1c on the treatment difference in mortality.

Materials and methods: Patients were randomised to EMPA 10 mg, EMPA 25 mg, or PBO. CV and all-cause mortality were assessed in the pooled EMPA group vs PBO adjusting for control of BP, LDL-C and HbA1c at baseline and during the study as time-dependent covariates. Control was defined as systolic BP <140 mmHg and diastolic BP <90 mmHg, LDL-C <100 mg/dL, and HbA1c <7.5%.

Results: Adjusting for control of BP, LDL-C, HbA1c and all these covariates at baseline and during the study, HRs for CV death with EMPA vs PBO were 0.61 (0.49, 0.76), 0.59 (0.47, 0.75), 0.62 (0.49, 0.78) and 0.61 (0.48, 0.76), and for all-cause mortality were 0.67 (0.56, 0.81), 0.66 (0.55, 0.79), 0.67 (0.56, 0.81) and 0.67 (0.56, 0.81), respectively (Figure).

Conclusion: EMPA reduced CV and all-cause mortality to the same extent when analyses were adjusted for control of BP, LDL-C and HbA1c over time, suggesting that the mortality reductions were not driven by controlling or not controlling these CV risk factors during the study.



Cox regression analysis in patients treated with ≥1 dose of study drug.
Control of BP, LDL-C and HbA1c were defined as systolic BP <140 mmHg and diastolic BP <90 mmHg, LDL-C <100 mg/dL, and HbA1c <7.5%.

Longitudinal in vivo imaging of glucose-induced gene transcription in pancreatic beta cells

T. Moede, M. Paschen, B. Leibiger, P.-O. Berggren, I.B. Leibiger;
Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Glucose induced gene-transcription represents an important functional parameter of the pancreatic β-cell. It was successfully analyzed in vitro using microscopic detection of fluorescent protein expression controlled by either the rat insulin 1 or the rat β-cell glucokinase gene promoter. To monitor this process in vivo longitudinally and non-invasively during the development of β-cell dysfunction could provide new insights into the etiology of type 2 diabetes. We therefore created an expression construct that facilitates in vivo imaging of glucose-induced gene transcription with cellular resolution. Furthermore, we wanted to study whether a high-fat high-sucrose diet (HFHSD) affected β-cell specific glucose-induced gene transcription.

Materials and methods: GFP under the control of a -278/+123 bp glucokinase (rβGKGFP) and DsRed2 under a -410 bp insulin promoter (rIns1DsRed) were combined with cerulean under the non-glucose responsive CMV promoter as a reference into a single adenoviral construct to enable expression of all three reporters in transduced β-cells. Transduced C57B/6J islets were transplanted into the anterior chamber of the eye of littermates. Islets were allowed to engraft for 4 weeks. In vivo monitoring of glucose induced reporter gene expression was performed after an overnight fast. Mice were anesthetized and cerulean-, GFP and DsRed2 fluorescence were imaged using confocal microscopy. The awake mouse was then injected with 2g/kg glucose (or saline), followed by a glucose tolerance test. 4h after injection, imaging was repeated with identical settings. GFP and DsRed2 fluorescence were normalized to cerulean fluorescence. The ratio of normalized GFP and DsRed2 fluorescence obtained before and 4 h after glucose stimulation was calculated as increase in normalized fluorescence intensity (INFI) and used as a measurement of glucose-induced gene transcription. Mice were put on either a control diet or on HFHSD (60% calories fat, 32% sucrose in drinking water) for 8 weeks. Imaging was performed after 4 and 8 weeks of diet and following a 4 week refeeding with normal chow. Glucose tolerance and bodyweight were measured during the imaging experiments. Additionally, insulin tolerance was determined during the diet treatment.

Results: Glucose, but not saline injection resulted in a significant increase of both rIns1DsRed (INFI=1.58±0.12, $p<0.001$ vs. saline) and rβGKGFP expression (1.54±0.08, $p<0.001$). Glucose induced gene transcription in control animals was detectable in vivo until the end of the 16 week experiment. Mice receiving the HFHSD for 8 weeks showed increased bodyweight and impaired glucose- and insulin tolerance. These animals also demonstrated reduced glucose-stimulated expression of both rIns1DsRed (HFHSD INFI=0.99 ±0.05 vs control 1.53±0.06, $p<0.001$) and rβGKGFP (HFDHSD 0.94±0.05 vs 1.48±0.05, $p<0.001$). All parameters were restored after 4 weeks of normal diet.

Conclusion: A construct expressing rIns1DsRed2, rβGKGFP and CMVCerulean enables non-invasive longitudinal in vivo monitoring of glucose stimulated gene transcription in pancreatic β-cells. This process is reversibly disturbed when the mice are overweight, glucose- and insulin-intolerant after receiving a high-fat high-sucrose diet for 8 weeks. Thus, using our in vivo imaging approach will allow us to determine key-events in β-cell failure also at the gene transcription level during the progression of type 2 diabetes.

Long-term live-cell imaging of endogenous Ins2 gene activity reveals distinct beta cell states

H. Modi[1], H. Cen[1], S. Skovsø[1], X. Hu[1], D. Dionne[1], M. Huising[2], S. Xuan[3], J.D. Johnson[1];
[1]Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada, [2]Department of Neurobiology, Physiology & Behavior, University of California, Davis, [3]Dept. of Medicine Nephrology, Columbia University, New York, USA.

Background and aims: For regenerative therapies targeting type 1 diabetes (T1D), it is important to understand islet cell heterogeneity and plasticity. To address these questions, we have begun to extend our previous studies using more sophisticated mouse models, including an *Ins2*^{GFP} knock-in/knockout line. Here, we leverage our live-cell imaging tools and expertise, as well as complementary fluorescent reporter technologies, to capture β-cell heterogeneity and transient state-switching events as they happen. Our aim was to catalogue and quantify state transitions of β-cell maturation, differentiation, dedifferentiation *in vitro* and *in vivo* as well as to screen for factors that can modulate these states.

Materials and methods: We have combined *Ins2*^{GFP} knock-in and *Ins1*^{mCherry}:*Ins2*$^{GFP/wt}$ genetically modified mouse alleles such that transcription at the endogenous *Ins2* locus can be recorded using ImageXpress^{MICRO} live-cell, high-throughput imaging systems. Multiple days live cell imaging of dispersed islets were complemented with FACS analysis, histology of pancreatic sections, and functional studies of insulin secretion using a perifusion system. cDNA libraries were prepared from FACS purified GFP-positive β-cells using the SmartSeq2 protocol.

Results: Analysis of pancreatic tissue sections from *Ins2*^{GFP} knock-in mice showed that, at any given time, only about half of all β-cells were robustly GFP-positive, suggesting that not all β-cells have active transcription at the *Ins2* locus. To determine whether states of high versus low *Ins2* gene activity were stable, we conducted long-term robotic imaging studies of dispersed primary islets. We added a transgenic allele wherein H2B-mCherry is driven by an *Ins1* promoter to image virtually all β-cells. In these 3 day long imaging studies, we were surprised to see GFP fluorescence flash on and off in a few individual β-cells, suggesting bursts of transcription at the *Ins2* gene locus. To the best of our knowledge, this represents a previously uncharacterized form of β-cell plasticity/heterogeneity. FACS analysis confirmed *Ins2* mRNA and pre-mRNA were increased in GFP-positive cells compared to negative cells (861.9 ±110.5 vs 97.2±16.3, 2.06±0.45 vs 1.01±0.04 respectively). RNAseq analysis on GFP-positive cells further elucidated the molecular features of this β-cell state. Interestingly, we observed that GFP-positive cells with active transcription at the endogenous *Ins2* locus were more susceptible to apoptosis under a broad range of conditions than islet cells lacking GFP (including both non-β-cells and β-cells without GFP). Expectedly, *in vitro* perifusion of islets isolated from *Ins2*$^{GFP/GFP}$ knock-in/knockout mice showed reduced insulin secretion at 20 mM glucose (AUC = 44.63 ±4.7) compared to heterozygous *Ins2*$^{GFP/Wt}$ knock-in/knockout mice (AUC = 82.5 ±6.3) and control *Ins2*$^{Wt/Wt}$ mice (AUC = 71.7 ±10.2).

Conclusion: Collectively, our results demonstrate the feasibility of long-term imaging of primary islet cells and establish *Ins2*^{GFP} knock-in mice as a new tool for studying β-cell heterogeneity, state transitions and plasticity. We will continue to combine this model with other tools including Gcg-Venus transgenic lines to examine transdifferentiation.

Glucotoxicity-induced upregulation of lincRNA GAS5 in the pancreatic islets of type 2 diabetes donors and in Goto-Kakizaki rats

J.L.S. Esguerra[1], J. Ofori[1], M. Nagao[1], J. Fadista[2], L. Groop[1], L. Eliasson[1];
[1]Department of Clinical Sciences-Malmö, Lund University Diabetes Centre, Lund and Malmö, Sweden, [2]Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark.

Background and aims: We have previously shown Growth Arrest-Specific 5 (GAS5) long intergenic non-coding RNA (lincRNA) to be abundantly expressed in human pancreatic islets. GAS5 is a known tumour-suppressor that is dysregulated in many types of cancer. However, the role of GAS5 in pancreatic islet dysfunction caused by hyperglycaemia is not known. Here, we aimed to determine whether the expression of GAS5 in the pancreatic islets is

regulated under glucotoxic conditions in diabetic donors and in the type-2 diabetes (T2D) model GK rats. We also aimed to dissect the glucose-dependent regulation of GAS5 using the insulin-secreting human beta cell line, EndoC-BH1.

Materials and methods: Human islets RNA-seq data (N=195) were used in global co-expression analysis and correlation of GAS5 expression with donor phenotypes. A separate cohort of 19 human islet preparations from donors with T2D (N=9) or controls (N=10) were used for qPCR validation. Isolated islets from Goto-Kakizaki rats (N=4) or Wistar controls (N=4) were also used. RNA or protein expression levels were determined by qPCR or western blot, respectively. The human beta cell line, EndoC-BH1 was incubated in 5 mM glucose or 20 mM glucose for 1 h, 6 h, or 24 h. An F-test for simple linear regression was employed to determine significant correlations among gene expression levels and versus donor phenotypes, e.g. HbA1c. Significant differences between two samples were determined using the Student's t-test or using ANOVA for multiple testing.

Results: Using RNA-seq data from 175 human islet samples, we found GAS5 expression to be positively correlated with the donor's long-term glycaemic indicator, HbA1c (F-test, $p<0.05$). We validated this result by qPCR using19 human islet samples (F-test, $p<0.001$). Furthermore, we found GAS5 expression to be elevated in the islets from T2D donors (N=9) than those from NGT donors (N=10) (Student's t-test, unpaired, two-sided, $p<0.01$). Co-expression analysis strengthened our previous findings regarding the significant negative correlations of *GAS5* with beta cell transcription factors *PDX1* and *NKX6-1*, and the exocytotic gene *SYT13*. In the GK islets, GAS5 was found to be ~50% upregulated compared to the controls (N=4, $p<0.05$), with profound downregulation of PDX1, NKX6-1 and SYT13 proteins. In the human EndoC-BH1 beta cell line, GAS5 was found to be ~50% more expressed in 20 mM glucose than in 5 mM glucose at 6 hours and 24 hours incubation (N=3, ANOVA, $p<0.05$).

Conclusion: The lincRNA GAS5 is highly upregulated under glucotoxic conditions in the islets from humans with T2D or in the GK rats. Moreover, upregulation of GAS5 in the human EndoC-BH1 cells during exposure to high glucose levels indicate potential involvement of GAS5 lincRNA in beta cell adaptations to hyperglycaemic environment.

A novel method for the background-free purification of age-distinct insulin secretory granules for proteomic and lipidomic analyses

M. Neukam[1,2], K. Ganß[1,2], J. Vasiljevic[1,2], A. Sönmez[1,2], T. Kurth[3], S. Hauck[4], M. Solimena[1,2];

[1]Paul Langerhans Institute Dresden of the Helmholtz Center Munich at Univ. Clinic, TU Dresden, Dresden, [2]German Center for Diabetes Research (DZD e.V.), Neuherberg, [3]Center for Regenerative Therapies Dresden (CRTD), TU Dresden, Dresden, [4]Research Unit Protein Science, Helmholtz Zentrum München, Munich, Germany.

Background and aims: The hormone insulin is stored in dense-core secretory granules (SGs) of pancreatic beta cells and is released in two distinct phases upon glucose stimulation. While the proximity of SGs to the plasma membrane (PM) likely influences their secretion probability, a temporal component is also important. In particular, upon glucose stimulation the beta cell favors the secretion of newly synthesized insulin SGs, or young SGs, over their older counterparts. Based on image analysis, we have previously found that younger SGs are more motile and their luminal pH more acidic relative to their older counterpart. However, the molecular changes accounting for the characteristic of age-distinct SG pools remain unknown. A plausible approach to identify potential mediators for the ageing of SGs is to investigate their proteomic and lipidomic composition. In order to achieve this ambitious goal, we report the development of the first protocol for the purification of age-distinct SGs.

Materials and methods: The SG-specific transmembrane protein phogrin was tagged with a cytosolic CLIP-tag to allow for the age-defined pulse-chase labeling of SGs. Specific antibodies for the CLIP substrates were used to immunopurify the labeled SGs. A protease cleavage site between the CLIP-tag and phogrin allowe the elution of intact SGs from magnetic beads.

Results: A stable INS-1 cell line for expression of phogrin-CLIP was established as a surrogate model of primary beta cells. Super-resolution microscopy validated the restricted localization of TMR-labeled phogrin-CLIP on insulin SGs. The effective immunoisolation of SGs with antibodies specific for the CLIP substrate TMR was confirmed by electron microscopy (EM) on the magnetic beads. EM analysis further validated the elution of intact SGs upon incubation of the beads with a protease specific for the linker region. SDS electrophoresis and silver staining of the SGs immunoisolated from TMR-labelled phogrin-CLIP INS-1 cells revealed a very distinct protein profile, while the corresponding control sample from non-labeled cells was virtually void of proteins, except for the protease. Further evidence for the high purity of the SGs eluted from the beads were obtained by western blotting, which showed the virtual lack of contaminating protein markers of other cellular compartments, such as ER, endosomes, lysosomes or the Golgi complex.

Conclusion: Here we report the first protocol for the immunoisolation of intact insulin SGs of distinct age, without significant contamination by other organelles. This approach shall enable proteomic and lipidomic analyses of age-distinct SG pools.

Glucose but not KCl diminishes submembrane granule turnover in mouse beta cells

D. Brüning[1], K. Reckers[1], P. Drain[2], I. Rustenbeck[1];

[1]University of Braunschweig, Braunschweig, Germany, [2]University of Pittsburgh, Pittsburgh, USA.

Background and aims: The conventional view that insulin granules sequentially approach at the plasma membrane, then bind and finally fuse when the cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) increases has been challenged by the recognition that granules continually arrive at and depart from the submembrane space. Here it was tested whether KCl depolarization elicits the same functional consequences on insulin secretion and granule turnover as high glucose.

Materials and methods: All parameters were measured in perifused single mouse beta-cells. $[Ca^{2+}]_i$ was measured by the Fura technique, the mobility of the granules in the submembrane space and the actin cytoskeleton were imaged by TIRF microscopy. Actin was visualized by mTagRFP-Lifeact, the insulin granules were visualized by two cargo-directed labels, namely insulin-EGFP and C-peptide-emGFP. The granule behavior, common to both, was used to compare the effect of sequential stimulation with 40 mM KCl and 30 mM glucose and sequential stimulation in reversed order. The same protocol was used to measure the insulin secretion of perifused cultured islets.

Results: At 32 °C but not at 37 °C, the control of $[Ca^{2+}]_i$ in single adenovirally transduced beta cells was unimpaired for the entire length (90 min) of continuous perifusion experiments. Thus the measurement of insulin secretion by perifused islets was performed at 37 °C and at 32 °C to ascertain the relevance of the single cell TIRF measurements. The sequential pulse protocol revealed clear differences between glucose and KCl depending on the order of application. KCl produced higher maximal secretion rates and diminished the response to the subsequent glucose stimulus whereas glucose enhanced the response to the subsequent KCl stimulus. The overall secretion rates were lower at 32 °C, but the pattern was the same and the differences between the stimuli were even more marked. To specifically measure the effect of the stimuli on the behaviour of insulin granules by TIRF microscopy net values were calculated by subtracting the values obtained during control perifusions (5 mM glucose throughout) from those of the test perifusions. At the level of granule behaviour a difference between glucose and KCl developed during the first stimulation phase in that the total number of granules, the short term resident granules, and the arriving granules, which are all parameters of granule turnover in the submembrane space, were significantly smaller for glucose. The frequency of exocytotic events

was not increased during the phases of stimulation. Single beta cells, as studied here, had a remarkably thick cortical actin web as compared with beta cells within clusters. Actin was particularly dense in the area on which the perifusion solution impinged.

Conclusion: Glucose and KCl did not only elicit different response patterns at the level of islet secretion but also at the level of insulin granule turnover in the submembrane space. This argues against the hypothesis that KCl elicits the same initial response mechanisms as glucose. Exocytotic rates of single primary beta cells may not reflect the secretion pattern of intact islets, possibly because of cytoskeletal reorganization after dissociation.

Modulation of endoplasmic reticulum/mitochondrial interface and mitochondrial dynamic by glucotoxicity in pancreatic beta cells

F. Dingreville, Y. Gouriou, S. Ducreux, M. Alam, M.-A. Chauvin, F. Van Coppenolle, C. Thivolet, J. Rieusset, A.-M. Madec;
INSERM U1060 CarMeN, Oullins, France.

Background and aims: Mitochondria network plays a pivotal role in insulin release in pancreatic beta cells by its ability to product ATP, and is controlled by calcium, a key regulator of fission/fusion event and oxidative energy production. Alterations of mitochondria and endoplasmic reticulum (ER) have been shown to contribute to metabolic disorders such as type 2 diabetes (TD2). To determine how glucotoxicity alters insulin secretion we focus on mitochondria fusion and fission dynamics and on ER/mitochondria interactions in studying MAMs (Mitochondria Associated endoplasmic reticulum Membrane) in beta cells. MAMs are conserved structures with crucial role for cell survival and death through the transfer of calcium, lipid and metabolite exchange. Increasing evidence in liver tissue indicates that dysfunctional MAMs can be an important precursor of disease in TD2.

Materials and methods: Human islets and INS-1 rat beta cells were exposed during 72h to moderate glucotoxicity (16.5 mM and 22.5mM Glucose). ER stress was measured by qPCR, mitochondrial respiration by oxygraphy and insulin secretion in response to glucose (GSIS) by ELISA. Mitochondrial and reticulum calcium contents were respectively analyzed using 4mtD3CPV and ERGAP1 probes, and mitochondrial dynamic using mitotracker Green. MAMs were quantified using the In situ Proximity Ligation Assay (PLA) between IP3R2 and VDAC1, respectively ER and mitochondria calcium channels implicated in MAM tethering. All statistical tests have been done with unpaired Mann-Whitney test and paired Student t-test.

Results: Chronic exposure of human islets and INS-1 cells to moderate glucotoxicity induced an increase in ATF4 and spliced-XBP1 mRNA expression ($P<0.01$) without modification of CHOP mRNA expression, an ER stress marker of apoptosis way, reflecting a mild ER stress as in TD2, and a decrease in ER calcium content ($P<0.0001$). A decrease in mitochondrial respiration ($p<0.0001$) and insulin secretion ($P<0.001$) was parallely observed. Mitochondria fusion/fission dynamics were disrupted in favor of a fission state ($P<0.0001$), in synergy with a decrease in mitochondrial calcium content ($P<0.0001$) in INS-1 cells. In the same conditions, we showed an up-regulation of the contacts between ER and mitochondria highlighted by the increase of IP3R2-VDAC1 interactions ($P<0.05$) in INS-1 cells.

Conclusion: We confirmed that glucotoxicity induces a metabolic stress in both ER and mitochondria in human islets and rat beta cells. The decrease in mitochondrial calcium content associated with mitochondrial fission were consistent with an alteration of beta cell function as respiration, calcium homeostasis and insulin secretion. Interestingly we observed for the first time an increase in ER/mitochondria tethering in beta cells in response to glucotoxic conditions. The modulation of these interactions could help us to clarify the role of MAMs in pancreatic beta cells and their dysfunction in TD2 and may open a new potential way of treatments in TD2.

OP 09 Genetics of type 1 diabetes and MODY

49

New insights into HLA in type 1 diabetes from population analysis: DR4 homozygosity specifically predisposes to type 1 diabetes after 30 years

N.J.M. Thomas, S.E. Jones, M. Weedon, R. Oram, A. Hattersley;
Exeter University, Exeter, UK.

Background and aims: The major genetic determinants of Type 1 diabetes (TID) are the DR3, DR4 polymorphisms of class II HLA genes encoding DQ and DR. DR3/DR4 carriers show increased risk of T1D relative to DR3/DR3 and DR4/DR4 carriers in children and young adults but it is not known if this relative risk persists in individuals diagnosed with T1D later in life.

Materials and methods: We analysed the development of diabetes (aged 0-60 years) in subjects with highest risk HLA groups DR3/DR3, DR3/DR4 and DR4/DR4 (allele frequencies 2.4%, 2.9% 1.1%) in 120,192 UK individuals from the UK Biobank. We used the Exeter susceptibility-exclusion method with HLA group X/X being assumed to have no T1D.

Results: The highest risk genotypes represent 6.4% (7,676/120,192) of the population but contribute 61% (228/376) of all cases of T1D. In high risk HLA groups DR3/DR3, DR3/DR4 and DR4/DR4 there were marked differences in likelihood of developing T1D (1.2%, 4.2%, 3.5%, $p<0.001$) and in the mean age of diagnosis (17, 28, 38 years $p<0.001$). The majority 71% (32/45) of T1D cases associated with DR4/DR4 are diagnosed over 30 years of age unlike 26%(9/34) DR3/DR3 and 40%(59/149) DR3/DR4 $p<0.001$. (Fig.)

Conclusion: Whilst all three major genotypes greatly increase risk of T1D throughout life, population analysis has shown for the first time that DR4/DR4 specifically predisposes to T1D over 30 years of age and carriers of this genotype have the highest risk for development of late-onset T1D. This result is consistent with heterogeneity in age of diagnosis reflecting heterogeneity in immune mechanisms in T1D.

Figure 1

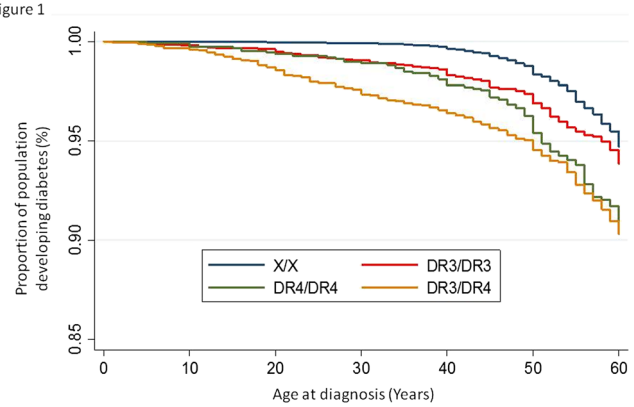

Figure 1:- DR4/DR4 predominately presents after 30 years of age
The majority 71% (32/45) of T1D cases associated with DR4/DR4 are diagnosed over 30 years of age unlike 26%(9/34) DR3/DR3 and 40%(59/149) DR3/DR4 ($p<0.001$).

Whole-exome sequencing in rare families identified novel genetic variants for familial type 1 diabetes

S. Noso[1], K. Hosomichi[2], N. Babaya[1], Y. Hiromine[1], H. Ito[1], Y. Taketomo[1], Y. Kawabata[1], H. Ikegami[1];
[1]Department of Endocrinology, Metabolism and Diabetes, Kindai University Faculty of Medicine, Osaka, [2]Department of Bioinformatics and Genomics, Graduate School of Advanced Preventive Medical Sciences, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Japan.

Background and aims: The prevalence of type 1 diabetes is much lower in Japanese than in populations of European descent (0.014% vs. 0.4%). The prevalence in siblings of proband with type 1 diabetes, however, is comparable between them (Japanese 3.8% vs. European 6.0%). Therefore, markedly high λs in Japanese was observed in comparison with European populations (271 vs. 15), indicating strong familial clustering and the involvement of rare genetic variants for the development of type 1 diabetes in Japanese population. Although very rare in Japan, we have previously reported two rare families clustered with type 1 diabetes. Present study aimed to identify the genetic causality of familial type 1 diabetes and study association of the identified variants with susceptibility to sporadic type 1 diabetes in Japanese population.

Materials and methods: Twenty one individuals from four families (family A to D: twelve patients with type 1 diabetes and nine unaffected individuals) were subjected to whole exome sequencing (Illumina HiSeq). After variants were detected, genome-wide linkage analysis was performed for all families to scan high LOD score region. Linkage was estimated using non-parametric linkage analysis assuming a dominant mode of inheritance. The exome variants were filtered on the basis of variant annotation, functional expectation, allele frequency and LOD score, to narrow down the candidate causal variants as exome variant analysis.

Results: All subjects except an unaffected individual of family B possess at least one of the susceptible HLA haplotypes (DR4, DR8 or DR9). Combined linkage analysis of four families identified maximal LOD score of 3.557 with single peak on chromosome 9, which was not overlapped with *GLIS3* locus on 9p24.2, suggesting a novel risk locus of familial type 1 diabetes specific to Japanese population. Two of non-synonymous variants of a gene X on the locus with high LOD score were shared by families A and B, suggesting the gene as a candidate causal gene for familial type 1 diabetes. To identify alternative causal variants specific to each family, exome variant analysis was also performed. As for family A, 29 rare variants from the total of 9,208 exome variants were co-segregated with affected patients with type 1 diabetes. Among these, a non-synonymous variant (SNV_04) with high damage scores (SIFT: 1.00, PolyPhen2: 0.999) was overlapped with genetic loci with high LOD score (max. LOD score 1.2 on chromosome 6) by linkage analysis for family A alone. Association study of the variant (SNV_04) revealed that the variants were absent in the European population (225 controls and 229 cases), but significantly associated with susceptibility to sporadic type 1 diabetes in the Japanese population (minor allele frequency, control: 0.7% vs. case: 6.1%, odds ratio [95%CI]: 9.6 [3.1-26.9], p<0.0003).

Conclusion: These data indicated that linkage analysis combined with whole exome sequencing is a useful tool to identify genetic variants linked to familial type 1 diabetes, particularly in low incidence populations.

A type 1 diabetes genetic risk score predicts progression of islet autoimmunity and development of type 1 diabetes in individuals at risk

M.J. Redondo[1], S. Geyer[2], A.S. Steck[3], S. Sharp[4], J. Wentworth[5], M. Weedon[4], P. Antinozzi[6], A. Pugliese[7], R. Oram[4], and the Type 1 Diabetes TrialNet Study Group;

[1]Baylor College of Medicine, Houston, [2]University of South Florida, Tampa, [3]Barbara Davis Center for Childhood Diabetes, Aurora, USA, [4]University of Exeter, Exeter, UK, [5]Walter and Eliza Hall Institute, Parkville, Australia, [6]Wake Forest School of Medicine, Winston-Salem, [7]University of Miami, Miami, USA.

Background and aims: Current prediction models for type 1 diabetes (T1D) include immunologic and metabolic markers but these change during disease progression and reflect advanced stages in the autoimmune process. Genetic associations to T1D are strong and time-independent. Genotyping can be affordably measured with single nucleotide polymorphism (SNP) analysis. We recently developed and validated a T1D genetic risk score (T1D GRS) that incorporates HLA and non-HLA T1D-associated SNPs. The T1D GRS is highly discriminative of T1D from controls, T2D and monogenic diabetes. We tested the ability of the T1D GRS to predict progression of islet autoimmunity and development of T1D in non-diabetic, autoantibody-positive (Ab+) individuals in the TrialNet Pathway To Prevention (PTP) study.

Materials and methods: We studied the 1244 Ab+ TrialNet PTP participants who were genotyped using the Illumina Immunochip SNP microarray. Median [range] age at Ab+ determination was 11.1 years [1.22-51.8], median follow up 5.5 years [0.2 to 11.9], 47.7% males, 80.5% non-Hispanic White. Participants were monitored with autoantibody testing, HbA1c and OGTTs at 6- or 12-month intervals depending on risk (e.g. single vs multiple Ab+). Of 291 participants with single Ab+ at screening, 156 progressed to multiple Ab+ and 55 developed T1D. Of 953 participants with multiple Ab+ at screening, 421 developed T1D. Time to progression was defined as time from Ab+ determination to T1D diagnosis (for multiple Ab+ subjects) or to development of new autoantibodies (for single confirmed Ab+ subjects). The T1D GRS was calculated as previously described. All results reflect analyses using multivariable Cox regression models, adjusting for age, sex and impaired OGTT at Ab+ determination. Recursive partitioning analyses were used to identify cutpoints.

Results: The T1D GRS ranged from 0.14 to 0.33 in Ab+ subjects (median=0.27). A score increase of 0.05 (e.g. from 0.225 to 0.275) significantly increased by 40% the risk of progression from single to multiple Ab+ (HR=1.4, 95% CI=1.04-1.88, p=0.028) as well as from multiple Ab+ to T1D (HR=1.4, 95% CI=1.11-1.74, p=0.004). Dichotomization of the T1D GRS also was significant in identifying those at greatest risk of conversion from single to multiple Ab+ (T1D GRS≥0.275, HR=1.68, 95% CI=1.21-2.34, p=0.002). Similarly, multiple Ab+ subjects with T1D GRS ≥0.25 were at significantly higher risk of progression to T1D (HR=1.69, 95% CI=1.2-2.4, p=0.004). A low T1D GRS was also effective at identifying subjects who were significantly less likely to progress to T1D (T1D GRS cutoff<0.226, HR 0.39, 95% CI=0.17-0.87, p=0.02).

Conclusion: The T1D GRS is an independent predictor of the risk and rate of progression of islet autoimmunity and development of T1D in non-diabetic, Ab+ individuals in TrialNet. These findings warrant further investigations on the use of the T1D GRS for early assessment of T1D risk, particularly in longitudinal studies.

A type 1 diabetes genetic risk score discriminates monogenic autoimmune diabetes from polygenic clustering of diabetes and autoimmunity

M.B. Johnson, K.A. Patel, E. De Franco, S.E. Flanagan, S. Ellard, A.T. Hattersley;

Institute of Biomedical and Clinical Science, University of Exeter Medical School, Exeter, UK.

Background and aims: Autoimmune diabetes can occur with other autoimmune disease in a patient as a result of either overlapping polygenic predisposition or due to monogenic autoimmunity**.** Diagnosing monogenic autoimmune diabetes is important as it will determine prognosis and optimal treatment. However differentiating monogenic autoimmune diabetes from polygenic type 1 diabetes (T1D) is difficult due to overlapping clinical features and biomarkers (islet autoantibodies). We aimed to test if a T1D genetic risk score (T1D-GRS) could assist the identification of patients with monogenic autoimmune diabetes.

Materials and methods: We studied 79 patients with young-onset diabetes (diagnosed ≤1 year without non-autoimmune monogenic diabetes) and ≥1 autoimmune disorder diagnosed <5 years. We measured the T1D-GRS (based on the top 10 HLA and non-HLA risk alleles) and sequenced all 7 genes known to cause diabetes and monogenic autoimmunity using targeted capture and next generation sequencing. The T1D-GRS centiles were calculated from 1963 T1D patients from the Wellcome Trust Case Control Consortium.

Results: A mutation in a known autoimmunity gene was identified in 47% (37/79) of individuals (25 FOXP3, 8 LRBA, 2 STAT3 and 2 IL2RA). Patients with known monogenic autoimmunity were diagnosed younger than patients were a monogenic cause was not found (median 5.5 v 36 wks, p<0.001). Other clinical features such as the number of additional autoimmune features, insulin dose and the proportion of islet autoantibody-positive patients (47% v. 48%,

p=1.00) were similar in both groups. In the confirmed monogenic autoimmune patients median T1D-GRS was markedly lower than the patients without a defined monogenic cause; 9th v 50th centile (p<0.001). The T1D-GRS was highly discriminatory for identifying those with monogenic autoimmunity (ROC-AUC 0.82 (95% CI 0.72-0.91)). 64% (29/45) patients with a T1D-GRS in the lowest quartile had monogenic autoimmunity v 0% (n=11) in the highest T1D-GRS quartile (p<0.001). 19% of patients without a monogenic cause of autoimmunity had a T1D-GRS below the 10th centile suggesting there are more causes of monogenic autoimmunity to be discovered.

Conclusion: We have shown that the polygenic predisposition to T1D does not determine if a patient with monogenic autoimmunity develops diabetes. The T1D-GRS is a strong predictor of whether monogenic autoimmune diabetes is likely in patients with young-onset diabetes and autoimmune disease and can be used to guide clinical testing. A low T1D-GRS will be used to prioritise patients with early-onset diabetes and autoimmunity for gene discovery studies.

Targeted next-generation sequencing demonstrates high frequency of monogenic forms in gestational diabetes

N. Zubkova[1], F. Burumkulova[2], V. Petrukhin[2], M. Plechanova[2], A. Panov[2], T. Budyikina[2], V. Ulyatovskaya[2], N. Makretskaya[1], A. Tiulpakov[1];
[1]Department and Laboratory of Inherited Endocrine Disorders, Endocrinology Research Centre, [2]Moscow Regional Research Institute of Obstetrics and Gynecology, Moscow, Russian Federation.

Background and aims: Monogenic forms of diabetes can manifest during pregnancy and misclassified as type 1, type 2 or gestational diabetes (GDM). About 10% of cases of gestational diabetes are shown to be due to the most common forms of monogenic diabetes, such as glucokinase (*GCK*) and hepatocyte nuclear factor 1 alpha (*HNF1A*) defects. We suggest that using a next generation sequencing (NGS) approach may increase the mutation yield in GDM.To define molecular basis of GDM using a targeted NGS.

Materials and methods: 120 patients with GDM were studied according to the inclusion criteria. 'Diabetes panel' genes were sequenced using a custom Ion Ampliseq gene panel and PGM semiconductor sequencer (Ion Torrent). Bioinformatic analysis was carried out using Torrent Suite 4.2.1 and ANNOVAR software packages. Assessment of the pathogenicity of sequence variants was performed according to international guidelines.

Results: In 46 patients (38%) 45 different sequence variants (all heterozygous) were identified that were classified as pathogenic, likely pathogenic or variants of uncertain significance. The majority of variants were detected in *GCK* gene (27%, n=33), including missense mutations (n=27), deletions with frameshifts (n=2), deletions without frameshifts (n=1) and splicing mutations (n=1). Missense variants were also detected in *HNF4A* (n=1), *HNF1A* (n=1), *HNF1B* (n=1), *INSR* (n=3), *GLIS3* (n=2), *KCNJ11* (n=1), *PAX4* (n=1) and *PTF1* (n=2). Digenic or oligogenic variants were detected in 4 patients.

Conclusion: The results demonstrate high frequency of mutations in patients with GDM. The molecular findings were consistent with the phenotype only in the *GCK*/GDM cases. Other mutations/factors may also play a role in development of GDM.

Modelling of RFX6 associated neonatal diabetes disease modelling using CRISPR/Cas9 genome edited patient derived iPSCs

J. Saarimäki-Vire[1], H. Ibrahim[1], D. Balboa[1], V. Chandra[1], H. Grym[1], S. Eurola[1], T. Otonkoski[1,2];
[1]Research Programs Unit, Molecular Neurology and Biomedicum Stem Cell Centre., University of Helsinki, [2]Children's Hospital, Helsinki, Finland.

Background and aims: Neonatal diabetes mellitus is a monogenic disorder caused by mutations affecting genes involved in pancreatic development and β-cell functionality. One of those is the regulatory factor X 6 (*RFX6*), a transcription factor involved in pancreatic development and β-cell function. *Rfx6* knockout mice show intestinal malformations, hypoplastic pancreas and die soon after birth. Homozygous mutations in *RFX6* causes Mitchell-Riley syndrome (MRS), associated with developmental defects of the pancreas, biliary tract and intestine. The aim of this study was to understand early pancreatic developmental defects in this condition through the use of patient-derived iPS cells. iPSC were derived from a neonatal diabetic patient with MRS caused by a homozygous deletion of the *RFX6* gene (c.878_879delAC). The patient is born with neonatal diabetes and a hypoplastic pancreas as well as intestinal and biliary defects. C-peptide levels were not detected at birth. Although normal levels of elastase in stool indicated normal exocrine functions, the patient manifested chronic diarrhea. As a result, total parenteral nutrition (TPN) was started and still ongoing.

Materials and methods: The mutation was heterozygously corrected using CRISPR/Cas9 mediated genome editing. The mutant and corrected cells were differentiated into pancreatic endocrine lineage using a 6-stage protocol in parallel with iPSCs derived from a healthy donor.

Results: Analysis of the differentiation experiments at different time points showed that the *RFX6*$^{-/-}$ cells progressed similar to control cells until definitive endoderm stage. However, they failed to form confluent PDX1+/NKX6.1+ pancreatic epithelial cell layers in the pancreatic progenitor stage, as was observed in the control cells. The expression level of these critical pancreatic progenitor markers was dramatically decreased (*PDX1* 8-fold decrease, p<0.05; *NKX6.1* 10-fold decrease). *NEUROG3* expression decreased 8-fold at endocrine progenitor stage (p<0.01) in RFX6$^{-/-}$ cells. The *RFX6*$^{-/-}$ cells failed to show expression of endocrine hormones at the latest stages, except for scarce INS+ cells. *INS* expression levels were 52000-fold lower than *CTRL* or *corrected* cells (p<0.01). These differentiation defects were rescued by heterozygous correction of the mutation, including differentiation into all pancreatic endocrine cell lineages.

Conclusion: This study suggests a role for RFX6 already during pancreatic specification stage in humans, earlier to what has been reported in mice. Its expression is essential for pancreatic endocrine development. The genetic correction of only one allele was able to rescue the disease phenotype. Further study of the RFX6 mechanisms of action in pancreatic organogenesis and beta-cell function is currently ongoing using this model.

Skeletal muscle-specific mitochondrial OxPhos defect mice are protected from obesity and insulin resistance by inducing GDF15 as a myomitokine

H. Chung;
Chungnam National University School of Medicine, Daejeon, Republic of Korea.

Background and aims: Mitochondria are subject to dynamic processes in order to establish a control system related to survival or cell death and adaptation to changes in the metabolic environment of cells. Reduced mitochondrial OxPhos activity promotes longevity and improves energy homeostasis via cell-autonomous and cell-non-autonomous factors in multiple model systems. This mitohormetic effect is thought to involve the mitochondrial unfolded protein response (UPR^{mt}), an adaptive stress-response pathway activated by mitochondrial proteotoxic stress. To address how tissue-specific activation of the UPR^{mt} in situations of altered mitochondrial proteostasis with reduced OxPhos activity controls systemic energy homeostasis. We developed mice with skeletal muscle-specific Crif1 deficiency, and analyzed skeletal muscle function and metabolic phenotypes

Materials and methods: Skeletal muscle-specific Crif1 knockout (MKO) mice were generated by crossing $Crif1^{f/f}$ mice to transgenic mice expression the Cre under the myosin light chain (MLC) promoter. To identify mitochondrial dysfunction and metabolic phenotypes in MKO and WT mice, we evaluated OxPhos gene and protein expression, mitochondrial activity, mitochondria morphology, metabolic parameters, H&E tissue staining and molecular markers in NCD or HFD conditions.

Results: We show that skeletal muscle-specific deficiency of Crif1, a mitochondrial protein in the large mitoribosomal subunit is sufficient to activate the UPR^{mt} and to produce cell non-autonomous signaling factors, or myomitokines, that regulate systemic energy homeostasis. We identify growth differentiation factor 15 (GDF15), a divergent member of the transforming growth factor family, a critical cell non-autonomous factor enhancing oxidative function in liver and skeletal muscle, and lipolytic action in adipose tissues. Therefore, we propose that increased production of GDF15 in MKO mice was responsible for the marked decrease of fat mass, resistance to obesity, and improved insulin sensitivity. In line with this hypothesis, exogenous administration of GDF15 to ob/ob mice promotes weight loss and enhances insulin sensitivity.

Conclusion: This provides robust evidence for the cell non-autonomous factor GDF15 as a regulator of systemic energy homeostasis, and as a potentially useful therapeutic agent in the treatment of obesity-associated insulin resistance.

Regulation and functional impact of miRNAs in alpha cells during type 2 diabetes

R. Dusaulcy[1], S. Handgraaf[1], F. Visentin[1], C. Vesin[2], J. Philippe[1], Y. Gosmain[1];
[1]Division of Endocrinology, Diabetes, Hypertension and Nutrition, University Hospital/Diabetes Center/University of Geneva Medical School, [2]Department of Cell Physiology and Metabolism, University of Geneva School of Medicine, Geneva, Switzerland.

Background and aims: miRNAs are small non-coding RNAs of 21 to 23 nucleotides regulating the expression of target genes by inhibiting translation or by inducing mRNA degradation. The expression of miRNAs themselves, like mRNAs, is submitted to both transcription factor and epigenetic regulations. miRNAs are found in various genomic locations and are often observed to be clustered. Several studies give evidence of the implication of miRNAs on glucose homeostasis. Although most of the studies on miRNAs have been performed in beta-cells, it was suggested that miRNAs also play a role in alpha-cell. The aim of this study is to identify miRNAs regulated in alpha-cell during type 2 diabetes as well as their function.

Materials and methods: We used mice, expressing the Venus fluorescent protein under the control of the rat glucagon promoter as well as the Cherry fluorescent protein under the control of the rat insulin promoter, fed with a control low (10%) fat diet or a high (60%) fat diet during 16 weeks to generate obesity and hyperglycemia. miRNA profiling was performed through a microarray analysis on FACS-purified alpha and beta-cells of obese hyperglycemic and control mice. Selected dysregulated miRNAs were mimicked or inhibited in primary culture of rat alpha-cells to evaluate their molecular and functional impact in alpha-cells.

Results: We identified 16 miRNAs significantly regulated in alpha-cells and 28 in beta-cells from hyperglycemic obese mice. Among the 16 miRNAs regulated in alpha-cells, 14 are down-regulated and 2 are up-regulated. Interestingly, 8 of the down-regulated miRNAs in alpha cells are localized in a common genomic cluster. Moreover 125 miRNAs were differentially expressed between alpha and beta-cells. The analysis showed a significant interaction between cell type and diet for 14 miRNAs. We focused then our analysis on miR-132-3p, the most regulated miRNA in diabetic alpha-cells with a 2.24 fold decrease (adj P.Val=6.9 10^{-4}), which was also regulated in an opposite manner in corresponding beta-cells (1.67 Fold increase, adj P.Val=1.3 10^{-2}). *In vitro* inhibition of miR-132-3p in primary alpha-cells led to an increase of mRNA levels of specific genes previously identified in diabetic alpha-cells, among which *Gcg*, *Foxa1*, *Cacna1C* and *Pcsk1*. Interestingly, mimicking of miR-132-3p in the same conditions was correlated to decreased expression of these genes, suggesting that part of the diabetic molecular footprint of alpha-cells may be due to the regulation of miR-132-3p expression. We did not observe significant modification of glucagon content and release 48h after transfection with miR-132-3p mimics and inhibitors.

Conclusion: Several miRNAs in pure populations of alpha and beta-cells are regulated by high fat diet and hyperglycemia. As described for beta-cells, miR-132-3p seems to have a functional impact on alpha-cells, at least on their molecular identity. The mechanism implicated in this effect remains to be identified.

Pericentrin regulates insulin secretion and relates closely with the development of impaired glucose tolerance

Y. Gong, L. Wang, C. Li, Y. Zu;
the Geriatric Endocrinology Department, the People's Liberation Army General Hospital, Beijing, China.

Background and aims: Diabetes has become a serious threat to human health, how to make the β cells secreting insulin on-demand becomes a hot spot. Pericentrin (PCNT), a component of the pericentriolar material, was found positively relating with intracellular insulin expression in our former research. This study further investigated the effect and mechanism of PCNT on insulin secretion and its role in the development of impaired glucose tolerance.

Materials and methods: Two kinds of mouse models and MIN-6 cells were used. Mouse model of PCNT reduction specifically in β cells (ΔPCNTβ) was built by Tet-on induction system; impaired glucose tolerance model (IR) was built by high-glucose high-fat feeding (HG-HF). Glucose tolerance, insulin secretion, and the distribution of intracellular insulin granules, pancreas PCNT, insulin and F-actin expressions were compared among control, ΔPCNTβ and IR mice at baseline, 4 weeks, 12 weeks by intraperitoneal glucose injection (IPGTT), WB, IF, IHC, ELISA and transmission electron microscope. MIN-6 cells were divided into control, exenatide group (Exn, 100 nm) and repaglinide group (Reg, 50 nm); control, Si-PCNT group and Si+Exn group. PCNT, Insulin, F-actin expressions were observed at baseline, 15 min, 30 min, 2 h and 6 h.

Results: (1) Compared with control, ΔPCNTβ had similar glucose level, but higher fasting insulin level at baseline. While after IPGTT, ΔPCNTβ showed

higher blood glucose area under the curve ($AUC_{Glu0-15}$) ($P < 0.01$) and lower insulin area under the curve ($AUC_{INS0-15}$) ($P < 0.05$) at 0-15 min. There was no difference at 30-120 min in IGPTT. Lower F-actin level, and reduced insulin granules of rapid release pool and anchoring pool (0-300 nm under the cyto-membrane) were detected in ΔPCNTβ mice ($P < 0.01$). (2) The PCNT expression decreased in IR group with the extension of HG-HF feeding. At 4 weeks, compared with control, PCNT expression of IR mice reduced ($P < 0.05$) and AUCs increased ($P < 0.05$ and $P < 0.01$) significantly; while ΔPCNTβ had further lower PCNT and higher AUCs than IR. At 12 weeks, the PCNT expression of IR mice dropped to that of ΔPCNTβ mice level, and there were no difference in AUCs between these 2 groups. (3) Compared with control, the PCNT, insulin and F-actin expressions of MIN-6 cells in Exn group decreased obviously at 2 h, while dramatically increased after 6 h (Figure). No difference could be found between Rep mice and control. Exenatide could not change the insulin and F-actin expressions of Si-PCNT group.

Conclusion: PCNT could adjust the first phase insulin release by regulating granules of the rapid release and anchor pools through F-actin. Decreased PCNT plays an important role in the process of impaired glucose tolerance induced by HG-HF feeding. GLP-1 has two-way regulating effect on beta cells at early stage (< 2 h) and late stage (> 6 h) through PCNT.

Effects of nocturnal rise in cortisol on gluconeogenesis and glycogenolysis in type 2 diabetes

R. Basu, M.Q. Slama, R.A. Rizza, A. Basu;
Endocrinology, Mayo Clinic College Of Medicine, Rochester, USA.

Background and aims: We have previously shown that nocturnal glucose concentrations and rates of endogenous glucose production (EGP) correlate with higher overnight cortisol concentrations in individuals with type 2 diabetes (T2D). However the contribution of gluconeogenesis (GNG) and glycogenolysis (GGL) to EGP in response to physiological rise in cortisol and the extent to which this is altered in T2D in the overnight fasted state has not been investigated.

Materials and methods: To do so, we utilized the deuterated water method in combination with isotope dilution technique using [3-^{3}H] glucose to compare EGP in T2D and controls (ND) in the presence vs. absence of a nocturnal rise in cortisol. 17 ND (9M, age 59 ± 8 yr, HbA1c 35 ± 2 mmol/mol) and 16 T2D (9M, age 62 ± 8 yr, HbA1c 59 ± 12 mmol/mol) matched for BMI were studied on two occasions in random order. Subjects were admitted to the Clinical Research Trials Unit at our clinic for overnight stays. Subjects with sleep apnea were excluded from participation. Endogenous cortisol was blocked with metyrapone 500 mg given orally every 4 hours from 1800 to 0600 starting on the evening of each visit. At 1800, 2000 and 2200 subjects ingested 1.7 g/total body weight deuterated water for estimation of fractional GNG. At 2200, hydrocortisone infusion was started at 0.15 μg/kg/min and continued until 0700 on one occasion; on the other occasion infusion rates were sequentially changed (0.3 μg/kg/min from 2200 to 2400,0.6 μg/kg/min from 2400 to 0400,1.0 μg/kg/min from 0400 to 0700) to mimic physiological nocturnal rise in cortisol. [3-^{3}H] glucose was infused starting at 2200 until 0700. Blood was sampled from an arterial catheter.

Results: Data are presented in the table. Fasting glucose, glucagon and insulin concentrations were not different between visits in either group but glucose concentrations were higher in T2D than in ND. Cortisol concentrations by design and rates of EGP at 0700 were higher in the presence than absence of a nocturnal rise in cortisol in both ND and T2D. GNG was significantly higher in ND and T2D at 0700 and higher in the latter irrespective of cortisol concentrations achieved. On the other hand, whereas GGL also was higher in the presence than in the absence of a nocturnal rise in cortisol in T2D, it did not differ in ND.

Conclusion: Higher GNG and GGL in response to high cortisol contribute to the physiological nocturnal rise in EGP observed in T2D; the relative contribution of GNG is higher than that observed for GGL. Further studies are required to test whether medications that block cortisol and/or GNG are clinically relevant in reducing EGP in T2D.

Glucagon secretion in type 2 diabetes: results of the pilot clinical trial "Low dosE GlibENclamide in Diabetes - part A (LEGEND-A)"

I.I. Spiliotis, P. Rorsman, S. Gough;
OCDEM, University of Oxford, Oxford, UK.

Background and aims: Fasting hyperglucagonaemia is a feature of type 2 diabetes (T2DM), though the mechanism by which it occurs and its metabolic consequences are not clear. Previous *in vitro* studies using islets from T2DM donors have recapitulated this phenomenon, and demonstrated that low concentrations of the sulphonylurea tolbutamide could normalise glucagon secretion. We designed a clinical trial to assess the impact low-dose sulphonylureas would have on patients with T2DM.

Materials and methods: In this open-label, dose-titration trial, patients with T2DM (either diet-controlled or on metformin) received increasing doses of an oral suspension of glibenclamide. The dosing schedule ranged from 0.3mg to 6mg per day (split between morning and evening), and the dose was increased every 3-4 days. Two early morning baseline fasting blood samples were taken prior to starting glibenclamide, and further fasting samples were taken prior to each dose change. A subset of participants also agreed to wear a continuous glucose monitor (CGM) throughout the study. The primary objective was to identify the dose of glibenclamide which resulted in a significant decrease in fasting glucagon concentration. Samples were also assayed for c-peptide and glucose. The results were analysed using two-way repeated measures ANOVA, grouped into either normal (N) or high (H) depending on baseline glucagon levels. Statistical significance was set at $p<0.05$.

Results: A total of 16 patients (7 men, 9 women) were recruited, whose characteristics were as follows (median ±interquartile range): age 66 (±17), HbA1c at screening 51mmol/mol (±8), BMI 30 (±7.3), and 10 participants were on metformin (average dose 1g/day). CGM data was collected from 11 patients during the study. Four patients had high fasting (group H) glucagon levels at baseline (mean 25.6 pmol/L, ±SEM 2.1), while 12 had baseline levels (group N) within the normal fasting range (mean 6.1 pmol/L, ±SEM 1.2). There was a significant reduction in fasting glucagon secretion in group H at a glibenclamide dose of 0.3mg/day (17.4 pmol/L ± 2.1), which did not occur at higher doses (0.6mg - 6mg), nor was there a change in glucagon levels in group N. There was no significant difference or change in fasting c-peptide levels between groups at any dose, however there was significant reduction in fasting glucose in group H at 6mg/day (change from baseline = 1.5mmol/L) and in group N at 1.8mg/day (0.9mmol/L), 3mg/day (1.2mmol/L), and 6mg/day (1.5mmol/L). Hypoglycaemia episodes were also reported as adverse events over this dose range. CGM data showed a significant reduction in mean amplitude of glycaemic excursion (MAGE) at 3mg and 6mg glibenclamide (difference of means 2.5 and 1.6 respectively), however this was associated with a 16% increase ($p<0.05$) in hypoglycaemic-range recordings at the highest dose.

Conclusion: This pilot clinical trial is the first to use such low doses of sulphonylurea in patients with T2DM, and indicates that $1/20^{th}$ the normal starting dose of glibenclamide can significantly reduce fasting hyperglucagonaemia by 30%, without having an effect on insulin secretion nor causing hypoglycaemia. Whether this reduction in glucagon has a beneficial impact on glucose control over a longer period of time remains to be investigated.

Membrane estrogen receptor alpha signalling contributes to the prevention of diet-induced obesity and insulin resistance through enhanced energy expenditure

P. Gourdy[1,2], A. Fabre[1], A. Montagner[1], M. Guillaume[1], C. Mouly[1], E. Riant[1], A. Waget[1], C. Fontaine[1], R. Burcelin[1], F. Lenfant[1], J.-F. Arnal[1];
[1]INSERM UMR 1048, [2]Service de Diabétologie, Maladies métaboliques et Nutrition, CHU de Toulouse, Toulouse, France.

Background and aims: Clinical and experimental observations demonstrated that the beneficial influence of estrogens on energy balance and glucose metabolism is mediated by estrogen receptor α (ERα). These metabolic effects absolutely require the transcriptional actions of ERα, mainly mediated by its activation function (AF)-2. However, beside these classical nuclear actions, a palmitoylated ERα sub-population located at the plasma membrane has been shown to elicit Membrane Initiated Steroid Signaling (MISS) which could also contributes to the metabolic influence of estrogens. This study thus aimed to characterize the involvement of ERα MISS in the prevention of obesity and metabolic disorders by estrogens thanks to a recently generated transgenic mouse model harbouring a point mutation at the palmitoylation site of ERα (C451A-ERα) that confers a membrane-specific loss of function of the receptor.

Materials and methods: We analyzed several metabolic parameters (body weight, body composition, glucose tolerance, insulin sensitivity using hyperinsulinemic-euglycemic clamps, energy expenditure, thermoregulation in response to cold exposure) in C451A-ERα and their wild-type littermates (WT-ERα) female mice fed with a normal chow diet (NCD) or a high-fat diet (HFD). In some experiments, mice were ovariectomized and supplemented or not with 17β-estradiol (E2).

Results: Although almost no differences were observed in mice maintained on a NCD, HFD-fed C451A-ERα female mice developed accelerated obesity, adiposity and liver steatosis, and were characterized by a significant insulin resistance (hyperinsulinemic euglycemic clamp) and glucose intolerance, as compared to their wild type littermates (WT-ERα). Physiological E2 supplementation prevented WT-ERα controls from obesity and hyperglycemia but failed to protect C451A-ERα ovariectomized mice. Finally, abrogation of MISS-ERα signaling did not alter food intake and physical activity level but indirect calorimetry revealed a significant decrease in energy expenditure in HFD-fed C451A-ERα females. Accordingly, brown adipose tissue dysfunctions (significant decrease in UCP1 and PGC1a expression) and altered thermogenesis adaptation were observed in HFD-fed C451A-ERα mice.

Conclusion: The present data demonstrate that, in addition to the previously demonstrated role of ERα nuclear actions, MISS ERα is required for the protective effects of estrogens against HFD-induced obesity, insulin resistance and impaired glucose tolerance. This work thus provides important insights into the metabolic actions of estrogens and will open new perspectives to design optimized strategies for ERα selective modulation.

SNogo-B overexpression ameliorates diabetic glomerulopathy

I.P. Hernandez-Diaz[1], C. Ricciardi[1], M. Flaquer-Rife'[1], J. Pan[1], K.E. White[2], J. Ke[1], A.E. Hayward[1], D.A. Long[3], J. Karalliedde[1], L. Gnudi[1];
[1]Cardiovascular Division, King's College London, [2]Electron Microscopy Unit, University of Newcastle, Newcastle, UK, [3]Kidney Development & Disease Unit, University College London, London, UK.

Background and aims: Endothelial dysfunction is a mechanism for chronic vascular complications in diabetes. Diabetic glomerulopathy (DG) is characterized by defects in glomerular capillaries, resulting in altered vascular remodelling, increased vascular permeability and albuminuria. Neurite Outgrowth Inhibitor (Nogo)-B and its soluble form (sNogo-B) have been implicated in the regulation of cell survival, cell migration and vascular remodelling. Both Nogo-B (at the cellular level) and sNogo-B (systemically) bind to NgBR receptor (expressed mainly in endothelial cells), and promote vascular remodelling. Full-length Nogo-B is expressed in glomerular endothelial cells and podocytes and is downregulated in in vitro and in vivo experimental model of diabetic nephropathy. Our aims were to investigate whether overexpression of sNogo-B could ameliorate DG in an experimental animal model of diabetes.

Materials and methods: Eight to ten weeks-old male DBA/2J mice were made diabetic (streptozotocin/low-dose), and administered (12-14 week-old) with an adeno-associated viral vector (AAV) expressing sNogoB or GFP (control vector). Animals were divided into four groups: non-diabetic (ND) and diabetic (D) mice treated with either control vector (GFP-AAV), or vector over expressing sNogo-B (sNogo-B-AAV). Mice were followed for 12-14 weeks of diabetes. Blood pressure was assessed with tail-cuff methodology. Plasma sNogo-B levels were analyzed by ELISA, full-length Nogo-B levels, AKT levels and phosphorylation in kidney cortex lysate with immunoblotting, creatinine by mass spectrometry and albuminuria by fluorescence. Glomerular ultrastructural morphology was assessed with electron microscopy.

Results: Treatment with sNogo-B-AAV allowed a sustained expression of the transgene (sNogoB) in the circulation (GFP vs sNogo-B in both ND and D mice, $p<0.05$). Albuminuria was increased by diabetes in both GFP and sNogo-B AAV mice ($p<0.01$). sNogo-B upregulation ameliorated diabetes-mediated albuminuria (D GFP-AAV vs D sNogo-B-AAV, $p=0.04$). Similarly, diabetes-mediated increase in creatinine clearance was corrected by sNogo-B overexpression to control ND mice levels ($p<0.006$). Preliminary blood pressure determinations showed a similar systolic and diastolic pressure in ND GFP and sNogo-B AAV mice, conversely blood pressure in D animals was lower in sNogo-B mice when compared to GFP ones ($p<0.04$); diabetes was paralleled by a fall in blood pressure observed only in sNogo-B AAV mice ($p<0.04$). Diabetes-mediated increase in mesangial expansion was also ameliorated by sNogo-B overexpression ($p<0.05$). sNogo-B overexpression prevented the diabetes-mediated full-length Nogo-B downregulation ($p=0.02$), and blunted diabetes-mediated Akt-Serine phosphorylation ($p=0.01$). Total Akt protein levels were downregulated in diabetes ($p<0.01$), but not affected by sNogo-B overexpression.

Conclusion: Overexpression of sNogo-B ameliorates DG possibly via amelioration of the diabetes-mediated glomerular haemodynamic perturbations. sNogo-B could represent a potential novel future treatment for DG.

Glyoxalase-1-deficient mice show only mildly enhanced deficits in methylglyoxal detoxification under control or streptozotocin-treated conditions

D. Schumacher[1], X. Tolksdorf[1], C. Matka[1], J. Morgenstern[2], T. Fleming[2], P.P. Nawroth[2], M. Freichel[1];
[1]Institute of Pharmacology, University of Heidelberg, [2]Department of Medicine I and Clinical Chemistry, University Hospital Heidelberg, Heidelberg, Germany.

Background and aims: The pathogenesis of diabetic long-term complications involves the accumulation of reactive metabolites, such as the dicarbonyl methylglyoxal (MG). The rate-limiting enzyme for MG detoxification is glyoxalase1 (Glo1) and it has been shown that Glo1 knockdown mice, generated by injecting shRNA-expressing lentiviral particles in mouse zygotes, exhibit signs of diabetic nephropathy comparable to streptozotocin (STZ)-diabetic wildtype (WT) mice, supporting the hypothesis of MG accumulation as a leading cause of diabetic late complications, in particular nephropathy. In this study, MG metabolism in the kidneys of mice homozygous for a Glo1 null allele were analyzed and the consequences of a complete Glo1 inactivation under STZ-evoked hyperglycemia was studied.

Materials and methods: Glo1-deficient mice were generated using CRISPR/Cas9-mediated genome editing by injecting mRNA encoding Cas9 and a sgRNA targeting exon 1 of the mouse Glo1 gene in C57Bl6/N mouse zygotes. Adult male Glo1-deficient and WT controls (n=12) were injected i.p. with either citrate or streptozotocin (60mg/kg) for five consecutive days. Following the establishment of robust hyperglycemia, the mice were maintained in the diabetic condition for four months. Glomerular filtration rate (GFR) was assessed using FITC-labeled sinistrin as a surrogate parameter for diabetic nephropathy, and MG and MG-H1 was determined by LC-MS/MS.

Results: 17 out of 19 (90%) founder mice showed successful genome editing. Mice with an allele exhibiting a 8 bp deletion ($\Delta 8$) at the 3' end of exon 1 were mated with C57Bl6/N and intercrossed to obtain $Glo1^{\Delta 8/\Delta 8}$ homozygous mice. Western Blot and qPCR analysis together with measurements of Glo1 enzyme activity in several organs verified the $Glo1^{\Delta 8/\Delta 8}$ allele as a *null* allele. $Glo1^{\Delta 8/\Delta 8}$ ($Glo1^{-/-}$) mice appeared normal and were born according to mendelian ratios. STZ-diabetic $Glo1^{-/-}$ mice showed little or no change in either insulin or glucose tolerance and glucose tolerance tests compared to STZ-diabetic WT mice. No differences in hyperfiltration were observed in GFR measurements between the WT and $Glo1^{-/-}$ STZ-diabetic mice. Plasma MG levels were found to be elevated in the STZ-diabetic mice, however no differences were observed between the different genotypes. No differences in the levels of MG-derived hydroimidazolone (MG-H1) were found in total kidney lysates from the mice. The activity of AKR was found to be increased ca.2-fold in the kidney of $Glo1^{-/-}$ mice as compared to WT (p0.001), although this cannot be explained by a corresponding increase in the expression of AKR (AKR1b3, AKR1a1).

Conclusion: In contrast to shRNA-mediated Glo1 knockdown mice, $Glo1^{\Delta 8/\Delta 8}$ KO mice show no elevation of MG-H1 content in kidneys neither in the citrate nor the STZ group. Also hyperglycemia-evoked hyperfiltration was unaltered in Glo1-deficient mice. MG detoxification in the kidney might occur by an increase in AKR activity upon increased MG load, as have been reported in Glo1-deficient Schwann cells.

Adipocyte Fatty Acid Binding Protein (A-FABP) is a pathological mediator of obesity-related renal dysfunction

R.L.C. Hoo[1,2], Y. Pan[1,2], L. Shu[1,2], K.S.L. Lam[1,2], A. Xu[1,2];
[1]Department of Medicine, The University of Hong Kong, [2]State Key Laboratory of Pharmaceutical Biotechnology, Hong Kong, Hong Kong.

Background and aims: Chronic kidney disease (CKD) is an emerging global public health problem which is characterized by irreversible deterioration of kidney function and can gradually progress to end-stage renal disease (ESRD). Obesity is the major risk factor of type 2 diabetes, hypertension and cardiovascular disease which are shown to promote CKD. Obesity is also an independent risk factor for the development and progression of this disease. Adipocyte fatty acid binding protein (A-FABP) is an adipokine expressed in

adipocytes, macrophages and endothelial cells. Its circulating level is increased in obese patients and is closely associated with various obesity-related cardiometabolic diseases. Emerging clinical evidences suggest that A-FABP is implicated in renal dysfunction. Our clinical findings also showed that circulating levels of A-FABP are independently associated with nephropathy staging and macrovascular complications of type 2 diabetic patients. However, the underlying mechanism whereby A-FABP mediates renal dysfunction is so far not explored. Here we investigated the pathological role of A-FABP in the development of renal dysfunction associating with obesity.

Materials and methods: A-FABP knockout (KO) mice and their wildtype (WT) littermates were fed with either standard chow (STC) or high fat high cholesterol (HFHC) diet for 20 weeks. Another batch of WT mice was fed with HFHC diet in the presence of pharmacological inhibitor of A-FABP, BMS309403 (BMS). Various serum and urine biochemical parameters, morphological change and lipid accumulation in kidney were determined.

Results: HFHC-diet feeding increased the circulating and renal expression of A-FABP in WT mice. Pharmacological inhibition of A-FABP by treatment with BMS not only significantly attenuated HFHC diet-induced hyperglycemia and hyperinsulinemia but also alleviated renomegaly in WT mice which was accompanied by reduced glomerulus volume, glycogen deposition and fibrotic area. Treatment of BMS markedly reduced diet-induced urinary albumin level comparing to respective controls. HFHC diet-induced renal lipid accumulation was remarkably attenuated in A-FABP KO mice as indicated by reduced oil droplets and diminished renal triglyceride levels when compared to respective WT controls. A-FABP deficiency also protects against the development of diet-induced hypertension in mice. The expression of A-FABP was significantly increased in the renal sections of HFHC diet-induced WT mice comparing with that of the STC-fed mice and was co-localized with endothelial cell marker CD31. In addition, treatment of palmitate significantly induced the expression of A-FABP in the human umbilical vein endothelial cells (HUVECs) compared to the vehicle-treated control.

Conclusion: Genetically ablation and pharmacological inhibition of A-FABP protect mice against HFHC-diet induced nephropathy. A-FABP as a lipid chaperone, may be a pathological mediator of obesity-related renal dysfunction at least partially through enhancing lipid transportation into the renal tissues.

Adult stem/progenitor cells as a personalised treatment for peripheral vascular disease

M.J. Niven[1], G. Sivak[2,3], E. Kafri[1], M. Moshe[4], O. Galili[5], M. Frogel[6,7], M. Belkin[4,8], Y. Porat[4];
[1]Bildirici Diabetes Center, Sanz Medical Center, Netanya, [2]Vascular Surgery, Sanz Medical Center, Netanya, [3]Vascular Surgery, Rabin Medical Center, Petach Tikva, [4]BiGenCell Ltd, Netanya, [5]Bildirici Diabetes Center, Hadera, Israel, [6]Bildirici Diabetes Center, Brooklyn, USA, [7]BioGenCell Ltd, Netanya, [8]Tel Aviv University, Tel Aviv, Israel.

Background and aims: Peripheral vascular disease in people with diabetes affects principally medium and small caliber vessels which are less amenable to surgical treatment Stem/progenitor cell (SPCs) treatments with bone-marrow-derived cells show promising outcomes in treating vascular diseases, albeit not without adverse events related to cell mobilization and collection. BGC101 is a preparation of enriched endothelial progenitor cells (EnEPCs) generated from peripheral blood using a novel one day technology employing dendritic cells (DCs) to specifically direct potentially therapeutic stem/progenitor cell (SPC) activity in-vitro. Previous animal studies have shown promising results in reversing induced limb ischemia. We describe a "first in man" pilot study of BGC101 for treating patients with severe peripheral vascular disease with no surgical option available.

Materials and methods: We performed a pilot open-label study of treatment with BGC101 in 5 patients, 3 with diabetes, with critical limb ischemia (CLI) characterized by rest pain and/or ulceration, and with no surgical option for revascularization. The primary end-point was assessment of safety, with efficacy as a secondary end-point. BGC101 was prepared from 250ml of peripheral blood. Co-culture of activated DCs for 12-18 hours with SPCs from the same patient sample generated 83.7±7.4×10^6 BGC101 cells with 97% viability, comprising 52.4±2.5% EPCs. Treatment consisted of a single treatment session with 30 intramuscular injections of BGC101 into the gastrocnemius muscle of the diseased leg, with acute safety follow-up during the initial 24±6 hours at the hospital and long-term follow-up at 1 week and at 1, 3, and 6 months.

Results: Preliminary safety data of several months follow-up showed that the therapy was well tolerated. A total of 29 adverse effects (AEs) reported by the 5 patients were typical to CLI disease and happened or could have happen regardless of the therapy. Indeed, 18 of them were judged as being unrelated or unlikely related to therapy, including one episode of hospitalization due to leg infection. Of the remaining 11 AEs, 8 were defined as possibly related, 2 probably related and 1 related. One of these, moderate necrosis of toes, recovered spontaneously without any further treatment. Preliminary efficacy results showed leg and toe salvage and substantial improvements for the patients comprising increased blood flow, enhanced wound healing, reduced pain and recovery of walking ability.

Conclusion: These observations indicate that the cell product BGC101 of EPC-enriched SPCs, generated by a novel culture process taking less than one day, shows promising preliminary results in the treatment of CLI and may also be therapeutic in other vascular conditions.

Liraglutide inhibits vascular smooth muscle cell proliferation by enhancing p-AMPK and cell cycle regulation, and delays atherosclerosis in APO-E deficient mice

T. Iijima[1], T. Jojima[1], K. Uchida[2], K. Akimoto[3], K. Suzuki[1], Y. Aso[1];
[1]Endocrinology and Metabolism, Dokkyo Medical University, [2]Medical Science for Nursing (Phamachology), Dokkyo Medical University, [3]Division of Clinical Science, Research Support Center, Dokkyo Medical University, Tochigi, Japan.

Background and aims: Several studies have demonstrated that both native glucagon-like peptide-1 (GLP-1) and GLP-1 receptor agonists suppress the progression of atherosclerosis in animal models. Recently, the liraglutide Effect and Action in Diabetes: Evaluation of Cardiovascular Outcome Results (LEADER) trial showed a striking reduction in the relative risk of cardiovascular (CV) mortality and all cause death among patients with type 2 diabetes and high CV risk on liraglutide therapy. Then, we investigated whether liraglutide, a GLP-1 analogue, could prevent the development of atherosclerosis in apolipoprotein E knockout mice ($ApoE^{-/-}$) on a high-fat diet. We also examined the influence of liraglutide on angiotensin II-induced proliferation of rat vascular smooth muscle cells (VSMCs) via enhancement of AMP-activated protein kinase (AMPK) signaling and regulation of cell cycle progression.

Materials and methods: $ApoE^{-/-}$ KO mice aged 5weeks and control C57/BL6 mice of the same age were used in this study. We divided total 23 mice into 4 groups ; control, vehicle, liraglutie150ug/day, and liraglutide400ug/day. Control mice were fed with normal chow. $ApoE^{-/-}$ KO mice were fed with high-fat diet for 4 weeks. These isolated aorta and aorta-ring section of each groups were measured for plaque lesion of oil red staining, hematoxylin and eosin staining and immunohistochemistry for AMPK phosphorylation. In an ex-vivo study, we performed the measurement of endothelium-dependent vascular reactivity on each groups. In a vivo study, we used rat vascular smooth muscle cells(VSMCs). Western blot and flow cytometry were performed by standard procedure methods. Measurement of cell proliferation was evaluated by xcelligence systems.

Results: Treatment of Apo-$E^{-/-}$ mice with liraglutide (400 μg/day for 4 weeks) suppressed atherosclerotic lesions and increased AMPK phosphorylation in the aortic wall. liraglutide also improved the endothelial function of thoracic aortas harvested from Apo- $E^{-/-}$ mice in an ex vivo study. Furthermore, liraglutide increased AMPK phosphorylation in rat VSMCs, while liraglutide-induced activation of AMPK was abolished by exendin 9-39, a

GLP-1 antagonist. Moreover, angiotensin (Ang) II-induced proliferation of VSMCs was suppressed by liraglutide in a dose-dependent manner, and flow cytometry of Ang II-stimulated VSMCs showed that liraglutide reduced the percentage of cells in G2/M phase (by arrest in G0/G1 phase).

Conclusion: These findings suggest that liraglutide may inhibit Ang II-induced VSMC proliferation by activating AMPK signaling and inducing cell cycle arrest, thus delaying the progression of atherosclerosis independently of its glucose-lowering effect.

Disclosure: **T. Iijima:** None.

Empagliflozin, an SGLT2 inhibitor, improves survival after myocardial infarction in diabetic rats by up-regulating anti-oxidative stress proteins

H. Oshima, M. Mizuno, T. Miki, A. Kuno, K. Nakata, Y. Kimura, T. Yano, M. Tanno, T. Miura;

Department of Cardiovascular, Renal and Metabolic Medicine, Sapporo Medical University, Sapporo, Japan.

Background and aims: EMPA-REG OUTCOME demonstrated that empagliflozin, an SGLT2 inhibitor, improves cardiovascular outcomes in patients with type 2 diabetes mellitus (T2DM), but its mechanism remains unclear. It has been reported that treatment of T2DM patients with an SGLT2 inhibitor increased serum β-hydroxybutyrate (βOHB) concentration by ~2 fold and that the expression of anti-oxidative stress proteins was increased through inhibition of class I histone deacetylases in βOHB-treated mice. In the present study, we examined whether empagliflozin improves survival rate after myocardial infarction (MI) by suppressing oxidative stress in T2DM rats.

Materials and methods: Coronary artery ligation was performed to induce MI in a rat model of T2DM (25-30-week-old; OLETF) and its control (LETO).. Rats were fasted for 12 hrs before induction of MI, and survival rate at 48 hrs after MI was monitored. Empagliflozin (10 mg/kg/day) or a vehicle was administered for 14 days before MI. In separate groups of rats, myocardial tissue in the non-infarcted region was sampled 12 hrs after MI for biochemical analyses.

Results: Body weight (641±11 vs. 531±7 g), fasting plasma glucose (FPG: 174±10 vs. 122±4 mg/dl) and mean blood pressure (122±2 vs. 111±4 mmHg) were significantly higher in OLETF than in LETO. Treatment with empagliflozin reduced FPG (118±8 mg/dl, $p<0.05$) and increased serum βOHB (1.15±0.09 vs. 0.60±0.04 mmol/L, $p<0.05$) in OLETF, but the effects on body weight and blood pressure were modest. Empagliflozin had no effects on left ventricular function before MI. As in our previous studies, survival rate at 48 hrs after MI was lower in OLETF than in LETO (40% vs. 84%, $p<0.05$) due to exacerbating heart failure. Empagliflozin treatment significantly improved survival rate to 70% in OLETF, although infarct size was unchanged. ATP level in the non-infarcted myocardium was lower in OLETF than in LETO after MI (3571±726 vs. 5692±804 nmol/g, $p<0.05$) and empagliflozin increased ATP to a level similar to that in LETO (5790±1238 nmol/g). Although myocardial βOHB level was significantly higher in empagliflozin-treated OLETF than in LETO and OLETF (1719±670 vs. 189±33 and 184±31 nmol/g), acetyl-CoA level was not changed by empagliflozin in OLETF. Protein levels of βOHB dehydrogenase 1 and succinyl-CoA:3-oxoacid-CoA transferase, key enzymes in ketone oxidation, were also not changed by empagliflozin in OLETF. On the other hand, levels of anti-oxidative proteins, including manganese superoxide dismutase, catalase, and Sirt3, were increased by empagliflozin in OLETF. Empagliflozin also increased the acetylation level of histone H3, suggesting histone deacetylase inhibition. Myocardial levels of Akt and S6 phosphorylation, well-known protective signals, after MI were lower in OLETF than in LETO, regardless of empagliflozin treatment.

Conclusion: Treatment with empagliflozin improved survival after MI in a rat model of T2DM. Empagliflozin up-regulated anti-oxidative proteins presumably via βOHB-induced inhibition of histone deacetylases and preserved ATP in the non-infarcted myocardium. These results suggest that restoration of myocardial energy metabolism by up-regulating anti-oxidant proteins contributes to the beneficial effect of empagliflozin on post-MI outcomes in T2DM.

OP 12 Lipid handling in metabolically active tissues

67

Fatty acid spillover: A signature of a metabolic health?

M.-E. Piche[1,2], S.A. Parry[1], F. Karpe[1], L. Hodson[1];

[1]University of Oxford, Oxford, UK, [2]Quebec Heart and Lung Institute, Quebec, Canada.

Background and aims: Spillover of fatty acids (FAs) into the plasma non-esterified fatty acids (NEFA) pool, due to an inability of adipose tissue to accommodate sufficient fat uptake, has been suggested to be a contributing factor to insulin resistance in obesity. Using specific labelling techniques, we compared the proportion of spillover-derived NEFA in men and women across a range of adiposity.

Materials and methods: Seventy-one healthy adults (55 men, 16 women) aged 22-64 years with a BMI 20-35 kg/m^2 were studied. Participants were fed a mixed meal containing [U^{13}C]palmitate to assess the contribution of dietary-derived spillover FAs to the systemic NEFA pool. To investigate adipose tissue specific spillover, arterio-venous difference and stable-isotope methodologies were used in a sub-study (6 men, 6 women). Dietary FA oxidation was assessed by appearance of ^{13}C into breath CO2 as markers of whole-body FA oxidation.

Results: Dietary FA spillover was higher in individuals with a low BMI (<25kg/m^2, n=18) than in individuals with a high BMI (≥25kg/m^2, n=53, AUC 22.2±1.6% vs. 18.6±0.7%, p=0.02). Women had significantly higher dietary FA spillover than men when matching for BMI (AUC 21.9±1.1% vs. 15.0±1.6%, p=0.001). Assessing spillover across subcutaneous abdominal adipose tissue showed significantly higher proportions in women than in men (28.5±6.1% vs. 9.9±1.3%, p=0.01). The appearance of $^{13}CO_2$ in breath was also greater in women compared with men (p=0.0004).

Conclusion: Our data show that there is a considerable degree of dietary FA spillover into the systemic NEFA pool. This process is greater and more dynamic in lean individuals and in women. Contrary to general perception, dietary spillover of FA into the systemic circulation is a physiologically normal feature most easily observed in people with a high plasma triglyceride clearance capacity and not a pathway providing excess NEFA in people with obesity or insulin resistance.

Effect of gender and metformin on hepatic fat handling in early type 2 diabetes

A. Al-Mrabeh[1], S.V. Zhyzhneuskaya[1], C. Peters[1], A. Barnes[2], K.G. Hollingsworth[1], H. Pilkington[3], M. Lean[4], R. Taylor[1];

[1]Magnetic Resonance Centre, Newcastle University, [2]Human Nutrition Research Centre, Newcastle University, [3]Clinical Ageing Research Unit, Newcastle University, Newcastle upon Tyne, [4]School of Medicine, Dentistry and Nursing, Glasgow University, Glasgow, UK.

Background and aims: Type 2 diabetes and fatty liver disease are more common among men than women, and are associated with lower BMI at diagnosis in men. Liver fat content is now known to be determinant for the onset of type 2 diabetes. We have evaluated fat content and VLDL1-triglyceride (VLDL1-TG) production of the liver in early type 2 diabetes at baseline in a sub-group of the prospective, randomised Diabetes Remission Clinical Trial (DiRECT).

Materials and methods: 95 participants were initially recruited and complete data are available on 89 people (51M/38F; 53.1±7.8 years; weight 99.5±16.2 kg; BMI 34.4± 4.2 kg/m^2; diabetes duration 2.9±1.7 years). Magnetic resonance using 3 point Dixon, and an enzyme competitive blocking methods were used respectively to quantify liver fat content and VLDL1 production rate in vivo. Data are presented as mean ±SD.

Results: Mean liver fat content was elevated at 14.7±9.8%, and VLDL1-TG production rate and TG pool size were 545±179mg/kg/day, and 2291 ±1645mg, respectively. Both VLDL1-TG production rate and pool size were positively correlated with liver fat content (r=0.43, p<0.0001; r=0.31, p=0.003). There was a positive relationship between both liver fat and fasting plasma glucose (r=0.35, p=0.001) and fasting plasma insulin (r=0.52, p<0.0001). Although fasting liver fat and VLDL1-TG production rate were similar in males and females (14.2±9.8 vs. 15.2±9.8%, p=0.63; 531±181 vs. 563±177mg/kg/day, p=0.40), men had a TG pool size 59% larger than that of women (2722±1726 vs. 1712±1346 mg, p=0.003). All physical characteristics of males and females were similar (BMI 33.9±4.1/ 35.1±4.4 kg/m^2, age 54.0 ±6.7/ 51.8±9.0 years, diabetes duration 2.8±1.5/ 2.9±1.8 years) except for body weight (men: 105.6±16.7kg, women: 91.2±11.2kg, p<0.0001). However, the difference in VLDL1-TG pool size remained after normalization for body weight (men: 25.6±15.6mg/kg, women: 18.7±13.9mg/kg, p=0.03).Women had lower fasting TG (0.54±04 vs. 0.73±04 mmol/l) and higher fasting NEFA (0.69±02 vs. 0.56±02 mmol/l) but similar fasting plasma glucose and insulin levels. At the time of the baseline tests, all remained on their usual therapy (38.2% diet alone, 32.6% metformin alone, 29.2% combined oral agents). HOMA-S tended to be higher in Metformin group compared with the combined treatment (89.6±52.4% vs. 62.7±33.1%, p=0.03).There were no differences in liver fat content, metabolic or body characteristics between the groups other than higher fasting plasma glucose in the combined treatment group compared with metformin or diet alone (9.8 vs. 8.1 or 7.6 mmol/l, p<0.05). In the metformin group only, liver fat content positively correlated with VLDL1-TG production rate and TG pool (r=0.61, p<0.0001 and r=0.56, p=0.002, respectively).

Conclusion: These data demonstrate clear gender differences in the dynamics of fat handling in type 2 diabetes. The lower TG pool size together with the raised NEFA and lower plasma TG suggest that adipose tissue clearance of VLDL1-TG is more rapid in women. Regardless of gender, metformin therapy aligned VLDL1-TG production with liver fat content.

Bariatric surgery improves brown adipose tissue lipid metabolism in morbidly obese subjects

P. Dadson[1], J.C. Hannukainen[2], M. U Din[1,2], H.K. Karlsson[1], P. Nuutila[1,3];
[1]Turku PET Centre, University of Turku, [2]Turku PET Centre, Turku University Hospital, [3]Department of Endocrinology, Turku University Hospital, Turku, Finland.

Background and aims: Brown adipose tissue (BAT) plays a role in human energy balance and insulin sensitivity. BAT functional activity is reduced in obese and insulin resistant subjects. Whether BAT metabolism is stimulated with weight loss in humans is unclear. We aimed to investigate BAT free fatty acid uptake and triglyceride content in morbidly obese subjects before and after bariatric surgery.

Materials and methods: We studied 23 morbidly obese women (BMI 41.1 ±4.2 kg/m^2) using [^{18}F]-FTHA-PET/CT imaging after overnight fast before and 6 months after bariatric surgery. 15 age- and sex-matched controls (BMI 22.6±2.8 kg/m^2) were studied once. Fractional uptake rate (FUR) and free fatty acid uptake (FAU) were measured from PET/CT images in the supraclavicular fat depots which is typical location for human BAT. Adipose tissue radiodensity [a marker for intracellular triglyceride content] of supraclavicular fat depots was obtained by voxel-based thresholding using CT images (values from -250 HU to -50 HU). Whole body fat oxidation rate (FOX) was measured using indirect calorimetry and insulin sensitivity was assessed as the insulin sensitivity index (ISI).

Results: Before surgery, FUR (0.0055±0.0034 vs. 0.0016±0.0018 1/min, p=0.001) and FAU (0.39±0.27 vs. 0.57±0.50 μmol/100g/min, p=0.01) were lower in obese compared to lean controls. Adipose tissue radiodensity was lower (-101.24±10.10 vs. -82.48±5.84 HU, p<0.001) and FOX was higher (p<0.001) in obese compared to lean controls. In the whole study group, radiodensity was associated with FUR (r=0.45, p=0.004), and inversely with FOX (r=-0.60, p<0.001) and with FFA levels (r=-0.45, p=0.01). After surgery, BMI decreased by 23% and ISI improved by 79%. FUR and FAU increased (from 0.0055±0.0034 to 0.0074±0.0035, p=0.004, and 0.39±0.27 to 0.56 ±0.50, p<0.01, respectively), and radiodensity increased (from -101.2 ±10.1 to -86.5± 9.6, p<0.001) to levels similar to controls (p=0.135). Lipid oxidation tended to decrease after surgery (p=0.068). The increment in adipose tissue radiodensity correlated with the improvement in insulin sensitivity (r=0.66, p<0.001) and the decrease in BMI (r=-0.72, p<0.001).

Conclusion: BAT lipid metabolism is impaired in obesity and associates with increased adipose triglyceride content. Marked weight loss after bariatric surgery stimulates BAT lipid metabolism and decreases triglyceride content. The improvement in BAT lipid metabolism interrelates with improvements in BMI and whole-body insulin sensitivity.

High protein levels of PLIN2 and low levels of ATGL are associated with insulin resistance and low number of intramyocellular lipid droplets

A. Gemmink, S. Daemen, B. Brouwers, J. Hoeks, E. Kornips, G. Schaart, P. Schrauwen, M.K.C. Hesselink;
Human Biology and Human Movement Sciences, Maastricht University, Maastricht, Netherlands.

Background and aims: Although intramyocellular lipid (IMCL), stored in lipid droplets (LDs) negatively correlates with insulin sensitivity, highly insulin sensitive athletes also present high levels of IMCL. Upon matching for IMCL, we observed that in patients with type 2 diabetes (T2DM), lipid was stored in fewer, but larger LDs than in athletes, suggestive of reduced lipid droplet dynamics (the process of lipid hydrolysis (re-)esterification). Cell and animal studies suggest that ATGL and PLIN2 are players in LD dynamics. Therefore, we examined the hypothesis that LD dynamics in the trained and the T2DM state involves differential regulation of PLIN2 and ATGL.

Materials and methods: Over a wide range of insulin sensitivity (endurance trained athletes, lean sedentary, obese subjects, and T2DM patients), we analyzed muscle biopsies (n=8 per group) for PLIN2 and ATGL protein content (Western blotting). Correlations were performed for these parameters with insulin sensitivity (2-step hyperinsulinemic euglycemic clamp) and LD size and number.

Results: PLIN2 protein content was significantly lower in athletes than T2DM patients (0.54±0.08 vs. 1.36±0.16 AU, p<0.001) who were matched for total IMCL content, with LDs being smaller and more numerous in the athletes. For ATGL it was observed that athletes had higher protein levels than T2DM patients (1.76±0.25 vs. 0.37±0.13 AU, p<0.001). PLIN2 protein content was negatively associated with insulin sensitivity and LD number (insulin sensitivity: r=-0.583, p=0.001; LD number: r=-0.498, p=0.016). In contrast, ATGL protein content was positively associated with insulin sensitivity and LD number (insulin sensitivity: r=0.610, p<0.001; LD number: r=0.706, p<0.001). No associations were observed for PLIN2 or ATGL protein content with LD size (PLIN2: r=0.221, p=0.310; ATGL: r=-0.178, p=0.418).

Conclusion: The high protein levels of PLIN2 and low levels of ATGL may reflect compromised LD dynamics in T2DM patients with larger and fewer LDs as a consequence. Along with the negative association of PLIN2 and positive association of ATGL with insulin sensitivity and LD number, these data indicate that the process of PLIN2- and ATGL mediated LD dynamics (rather than IMCL content per se) plays a role in modulating muscle insulin sensitivity.

Specific hepatic sphingolipids relate to insulin resistance and predict both oxidative stress and inflammation in non-alcoholic fatty liver disease

M. Apostolopoulou[1], R. Gordillo[2], C. Koliaki[1], S. Gancheva[1], T. Jelenik[1], C. Herder[1], D. Markgraf[1], P.E. Scherer[2], M. Roden[1];

[1]German Diabetes Center, Duesseldorf, Germany, [2]Touchstone Diabetes Center, Department of Internal Medicine, The University of Texas Southwestern Medical Center, Dallas, USA.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with obesity and type 2 diabetes. Several lipid metabolites in liver and plasma are related to hepatic steatosis and hepatic insulin resistance in animal models, but their role for human insulin resistance and NAFLD remains unclear.

Materials and methods: To examine the relationship between total and specific sphingolipids with insulin sensitivity and NAFLD progression, we examined 14 obese patients with or without NAFLD and 7 healthy lean individuals (CON), who underwent liver biopsies during bariatric surgery or elective abdominal surgery. Before surgery, hyperinsulinemic-euglycemic clamps with D-[6,6-$^2H_2$] glucose were performed to measure hepatic and peripheral insulin sensitivity. Hepatic oxidative capacity, H_2O_2 and lipid peroxidation were measured to assess mitochondrial function and oxidative stress.

Results: Total liver ceramides were 8% and 19% higher in NAFLD+ compared to NAFLD- and CON. Hepatic dihydroceramides, sphingosine and sphinganine were exclusively increased by 12%, 25% and 40% respectively in NAFLD+. Serum ceramide species 14:0, 16:0 and 20:0, total dihydroceramides, dihydroceramide 16:0, 20:0 and 22:0 correlated negatively with peripheral insulin sensitivity (all $r>0.55$, $p<0.05$). Hepatic maximal respiration correlated positively to total and certain serum dihydroceramides, liver lactosylceramide 16:0 and sphingomyeline 18:0 (all $r>0.50$, $p<0.05$). Liver H_2O_2 (ceramide 16:0, certain hexosyl- and lactosylceramides), lipid peroxides (dihydroceramide 24:1, total ceramides, ceramide 24:1) and pJNK (total dihydroceramides, ceramide 22:0, lactosyl- and hexosylceramides) correlated all positively with the respective hepatic sphingolipids ($r>0.47$, $p<0.05$). Ceramide subsets (total dihydroceramides and specific species) as well as certain sphingomyelins in serum reflected the respective species in the liver, which could be helpful for the future use of certain serum sphingolipids as biomarkers for the detection and progression of NAFLD.

Conclusion: In conclusion, specific sphingolipids are increased in obese people with NAFLD and correlate with higher oxidative capacity and oxidative stress in liver, thus indicating a possible role of sphingolipids in the NAFLD progression.

Tankyrase inhibition ameliorates lipid disorder in diabetic db/db mice

H. Wang[1], S. Kuusela[1], U.A. Ramadan[1], J. Waaler[2], V. Dumont[1], A.-M. Linden[1], N.-W. Chi[3], S. Krauss[2], S. Lehtonen[1];
[1]University of Helsinki, Helsinki, Finland, [2]Oslo University Hospital, Oslo, Norway, [3]Endocrine Service, San Diego, USA.

Background and aims: Tankyrases (TNKSs) catalyze a post-translational modification of proteins by transferring ADP-ribose moiety of NAD^+ to target proteins. TNKSs are associated with metabolic disorders, but the underlying mechanism remains largely unclear. We aimed to dissect the molecular mechanism by which TNKSs regulate energy metabolism in obese and diabetic db/db mice.

Materials and methods: Male C57BLKS/J db/db and db/+ mice served as a diabetes model and its control, respectively. TNKS inhibition was conducted in both db/db and db/+ mice in two parallel groups: regular chow vs chow spiked with G007-LK, a specific TNKS inhibitor, for 15 weeks. The effects on lipid metabolism and molecular mechanisms involved were assessed in white adipose tissue (WAT), muscle and liver.

Results: In diabetic db/db mice, TNKS inhibition with G007-LK reduced body weight gain by 10-12% and abdominal fat mass by 25%, lowered serum LDL cholesterol, and decreased hepatic steatosis. In addition, TNKS inhibition led to a reduction of the fasting insulin level after 8 weeks of treatment and a tendency toward improved insulin response ($p=0.068$). Consistent with a trend of improved insulin sensitivity, G007-LK treatment induced upregulation of GLUT4 in muscle. Furthermore, TNKS inhibition restrained lipolysis in WAT, as demonstrated by downregulation of triglyceride lipase and active (Ser660-phosphorylated) hormone sensitive lipase. In line with restrained lipolysis, low serum glycerol and a tendency for NEFA to decrease appeared in G007-LK-treated mice compared to non-treated controls. Notably, TNKS inhibition augmented NAD^+ content and SIRT1 activity manifested as a decline in PGC-1α acetylation level in WAT. Moreover, the reduction of adiposity was associated with increased fatty acid oxidation and reduction of cholesterol efflux in muscle, as illustrated by the upregulation of transcriptional coactivator PGC-1α and genes involved in fatty acid oxidation, and by the downregulation of ATP-binding cassette transporter A1, a major transporter mediating the efflux of cholesterol and phospholipids. Notably, TNKS inhibition attenuated PARylation of PGC-1α in muscle of db/db mice, likely contributing to PGC-1α stability.

Conclusion: Our findings demonstrate that pharmacological inhibition of TNKSs ameliorates lipid disorder observed in obesity and diabetes via distinct mechanisms in a tissue-specific manner. In addition to supporting SIRT1-dependent effects of TNKS inhibition on metabolism in WAT, our data also provide a novel mechanism whereby TNKS-mediated PARylation directly regulates PGC-1α in muscle. The effects of G007-LK in db/db mice do not occur in nondiabetic db/+ mice. These findings highlight inhibition of TNKSs as a potential pharmacotherapy for obesity and type 2 diabetes mellitus.

What determines treatment satisfaction of type 2 diabetes patients on insulin therapy? An observational study in eight European countries

A. Boels[1], R.C. Vos[1], T.G.T. Hermans[2], N.P.A. Zuithoff[1], N. Müller[3], K. Khunti[4], G.E.H. Rutten[1], GUIDANCE study group;
[1]University Medical Center Utrecht, Julius Center, [2]Utrecht University, Utrecht, Netherlands, [3]University Medical Center Jena, Department of Internal Medicine III, Jena, Germany, [4]Diabetes Research Centre, University of Leicester, Leicester, UK.

Background and aims: Type 2 diabetes (T2DM) patients on insulin therapy are less satisfied with their diabetes treatment than those on oral hypoglycaemic therapies or lifestyle advice only. Determinants of treatment satisfaction in T2DM patients on insulin therapy are not clearly known. The aim of this study was to determine the association of treatment satisfaction with demographic and clinical characteristics of insulin treated T2DM patients.

Materials and methods: For this study we used data from the GUIDANCE study, a cross-sectional study among 7597 T2DM patients from Belgium, France, Germany, Ireland, Italy, Sweden, the Netherlands and the United Kingdom. The majority of patients were recruited from primary care. Treatment satisfaction was assessed with the Diabetes Treatment Satisfaction Questionnaire (DTSQ, score 0-36; higher scores reflecting higher satisfaction). Missing data were handled with multiple imputation. To account for the hierarchical three level structure (i.e. countries-physicians-patients), we used a linear mixed model with random intercepts for country and physician to determine which patient characteristics and laboratory values were independently associated with treatment satisfaction.

Results: In total 1984 T2DM patients on insulin therapy were analysed; the number of included patients per country ranged from 166 (the Netherlands) to 384 (Italy). The mean DTSQ score was 28.50 ±7.52 and ranged from 25.93 ±6.57 (France) to 30.11 ±5.09 (the Netherlands). Higher DTSQ scores were associated with having received diabetes education (β 1.64 for having received diabetes education, versus not having received diabetes education, 95% CI 0.95-2.32), presence of macrovascular complications (β 0.76 for presence versus absence, 95% CI 0.21-1.31) and better health status (β 0.08 for every one unit increase on a 0-100 scale, 95% CI 0.07-0.10). Lower DTSQ scores were associated with more frequently perceived hyperglycaemia (β -0.32 for every one unit increase on a seven-point Likert scale, 95% CI -0.50 - -0.13), and higher HbA1c (β -0.52 for every percentage increase, 95% CI -0.75 - -0.29). No association was found between treatment satisfaction and insulin regimen, nor insulin injection frequency.

Conclusion: These findings underline the importance of diabetes education in insulin-treated T2DM patients. Moreover, health care providers should be attentive to patients with a lower health status, frequently perceived hyperglycaemia and higher HbA1c levels, to discuss and improve their diabetes treatment satisfaction. Patients with macrovascular complications were more satisfied with their treatment; this may be because patients with incident diabetes-related comorbidity are more intensively treated. The lack of an association between treatment satisfaction, and insulin regimen or insulin injection frequency is favourable.

Efficacy and safety of oral basal insulin: eight-week feasibility study in people with type 2 diabetes

L. Plum-Mörschel[1], T. Heise[2], E. Zijlstra[2], K. Lyby[3], K. Wassermann[3], L. Brønsted[3], I.B. Halberg[3];
[1]Profil, Mainz, Germany, [2]Profil, Neuss, Germany, [3]Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Oral insulin 338 formulated into a GIPET® I tablet (OI338GT) is a basal, acylated insulin analog with a half-life of ~70 hours. We investigated efficacy and safety of OI338GT in comparison to subcutaneous insulin glargine U100 (IGlar) in 50 insulin naïve T2DM subjects (mean±SD age 61±7 years, BMI 30.5±3.7 kg/m²) insufficiently controlled (HbA_{1c} 7-10%) on metformin alone or in combination with other oral agents.

Materials and methods: Patients were randomized 1:1 to OI338GT or IGlar once daily for 8 weeks in a double-blind, double-dummy fashion as add-on to existing metformin with or without DPP-4 inhibitor. Insulin doses were uptitrated weekly on an individualized basis aided by a pre-specified algorithm aiming at achieving fasting plasma glucose (FPG) in the target range of 80-126 mg/dL.

Results: Both treatments substantially improved glycemic control as indicated by FPG (primary endpoint), HbA1c and fructosamine with no significant differences between treatments at 8 weeks (table). C-peptide was comparable at end of treatment. The incidence of treatment-emergent hypoglycemia was low (OI338GT: 7 events in 6 subjects, IGlar: 11 events in 6 subjects). No severe hypoglycemia occurred. The rate of adverse events was similar.

Conclusion: In conclusion, this study demonstrated for the first time that an oral basal insulin safely improves glycemic control to a similar extent as does IGlar.

Association of fasting C-peptide levels with glycaemic efficacy and risk of hypoglycaemia in people with type 2 diabetes commencing insulin glargine 100 U/ml

D.R. Owens[1], W. Landgraf[2], M. Zhang[3], L. Traylor[3], B.M. Frier[4], G.B. Bolli[5], P.D. Home[6];
[1]Institute of Life Sciences, Swansea University, Swansea, UK, [2]Sanofi Germany, Frankfurt, Germany, [3]Sanofi US, Bridgewater, USA, [4]The Queen's Medical Research Institute, University of Edinburgh, Edinburgh, UK, [5]University of Perugia School of Medicine, Perugia, Italy, [6]Newcastle University, Newcastle upon Tyne, UK.

Background and aims: To investigate the prognostic value of fasting C-peptide levels for efficacy and safety outcomes when starting insulin glargine 100 U/ml (Gla-100) at bedtime in combination with oral agents.

Materials and methods: Standardized patient-level data were pooled from 16 randomized controlled trials (≥ 24 weeks duration). Outcomes were assessed descriptively up to week 24 stratified according to fasting C-peptide (≤ 0.40, > 0.40-1.20, > 1.20-2.00, >2.00 nmol/l) at start of Gla-100 (baseline).

Results: Overall, 2,165 participants (54% male) were included. Mean ± SD age by baseline C-peptide level (≤ 0.40, > 0.40-1.20, > 1.20-2.00, >2.00 nmol/l) were 58 ± 11, 58 ± 10, 59 ± 9, and 59 ± 10 years. Increasing baseline fasting C-peptide levels were associated with a shorter duration of diabetes (10.4 ± 7.0 vs 10.0 ± 6.6 vs 8.5 ± 5.6 vs 7.6 ± 5.5 years), higher BMI (25.7 ± 3.6 vs 29.5 ± 4.8 vs 31.9 ± 5.2 vs 32.2 ± 5.3 kg/m²), lower baseline fasting plasma glucose (11.5 ± 3.3 vs 10.9 ± 3.0 vs 10.8 ± 2.8 vs 10.3 ± 2.7 mmol/l), and slightly lower baseline HbA_{1c} (9.0 ± 1.1 vs 8.8 ± 1.0 vs 8.7 ± 1.0 vs 8.8 ± 1.0 %). Week 24 outcomes for HbA_{1c}, Gla-100 dose and hypoglycaemia are shown in the Table. From a slightly higher HbA_{1c} level, with smallest titrated and final Gla-100 doses, those in the lowest C-peptide group had a lesser HbA_{1c} reduction (-1.34 vs -1.40 to 1.54%), thus being less likely to achieve the target HbA_{1c} of

<7.0% (26%, 43%, 42%, and 44% in the lowest to highest C-peptide groups, respectively). Lower FPG levels were achieved in the lower C-peptide groups (6.3 ± 2.2 vs 6.5 ± 2.1 vs 6.7 ± 2.1 vs 7.0 ± 2.2 mmol/l). Final Gla-100 insulin dose was least in the lowest C-peptide group (0.34 U/kg), 0.42 U/kg in the >0.40−1.20 C-peptide group, and highest in the upper two C-peptide groups at 0.51, 0.50 U/kg, respectively. For all definitions and time periods of hypoglycaemia, incidence and event rates were higher with lower C-peptide levels (**Table**). The percentage of participants achieving HbA_{1c} <7.0% without hypoglycaemia (confirmed plasma glucose < 3.9 mmol/l) was 9%, 18%, 20%, and 25% in the lowest to highest C-peptide groups, respectively. Body weight change was greater with lower C-peptide levels (3.3 ± 3.7 vs 2.3 ± 3.5 vs 2.0 ± 4.0 vs 1.7 ± 3.2 kg).

Conclusion: This pooled analysis in people with T2D suggests that fasting C-peptide levels may help predict hypoglycaemia, insulin dose, and blood glucose control achieved when commencing Gla-100 therapy.

Table: Clinical outcomes in people with T2D starting Gla-100 stratified by baseline fasting C-peptide levels

		Baseline fasting C-peptide groups (nmol/l)

Contributions of fasting and postprandial hyperglycaemia in type 2 diabetes

Y. Reznik[1], A. Habteab[2], J. Castaneda[2], J. Shin[3], M. Joubert[1];
[1]Diabetes and Endocrinology, Caen University Hospital, CAEN, France, [2]Medtronic Bakken Research Center, Maastricht, Netherlands, [3]Medtronic Diabetes, Northridge, USA.

Background and aims: The Relative contribution of basal and postprandial hyperglycemia (HG) was previously documented in type 2 diabetes subjects treated by oral anti-hyperglycemic agents or basal insulin but not in subjects with an intensified insulin regimen with multiple daily injections (MDI). Our aim was to measure basal and postprandial HG in type 2 diabetes subjects on MDI before randomization in the OPT2MISE study. We also analyzed the predictive value of these variables of the metabolic response to continuous subcutaneous insulin infusion (CSII).

Materials and methods: We performed an analysis of CGM recordings after 8-week run-in period in 259 MDI patients. HG Area under curve (AUC) was calculated in the basal (AUC-B), nocturnal (AUC-N) and postprandial (AUC-PP) periods according baseline HbA1c level (Gr1 :<8, Gr2 :8-8.5, Gr3 :8.5-9, Gr4 :9-9.5, Gr5 :>9.5%). AUC changes were analyzed in 131 subjects switched from MDI to CSII. Non parametric tests were used for comparisons between groups.

Results: AUC-B was 29% to 79% higher in Gr5 vs Gr4 to Gr1 (p=0.002). AUC-N was 18% to 96% higher in Gr5 vs Gr4 to Gr1 (p=0.0001). Conversely, AUC-PP did not differ between groups HbA1c≥9.5% vs <9.5% (p=0.75). Accordingly, HbA1c correlated with AUC-N (R=0.32, p=0.0001) and AUC-B (R=0.183, p=0.003) but not with AUC-PP. After switch from MDI to CSII, both AUC-B and AUC-N decreased significantly (-15% and -19%) while AUC-PP tended to increase by 8% (p=0.087). When comparing responders to non responders to CSII, the latter had higher AUC-B, AUC-N and AUC-PP, but differences did not reach significance.

Conclusion: Fasting and nocturnal HG are the major determinants of HG in type 2 diabetes with MDI failure. Both significantly correlated with baseline HbA1c level. In contrast, postprandial HG accounts for 20-30% overall hyperglycemia only, whatever the HbA1c level. Pump therapy reduces mainly the fasting component of overall hyperglycemic exposure across a large range of A1c levels above 8%.

Clinical Trial Registration Number: NCT01182493

Real-world titration of insulin glargine in type 2 diabetes patients poorly controlled on oral antidiabetic drugs: an analysis in 2308 patients in primary care in Germany

J. Seufert[1], H. Anderten[2], A. Borck[3], A. Fritsche[4], K. Pegelow[3], S. Pscherer[5], M. Pfohl[6];
[1]Division of Endocrinology and Diabetology, Department of Internal Medicine II, University Hospital of Freiburg, Medical Faculty, University of Freiburg, Freiburg, [2]Gemeinschaftspraxis Anderten-Krok & Partner, Hildesheim, [3]Sanofi Aventis Deutschland GmbH, Berlin, [4]Medizinische Klinik IV, Universität Tübingen, Tübingen, [5]Klinik für Innere Medizin I, Sophien- und Hufeland-Klinikum gGmbH, Weimar, [6]Medizinische Klinik I, Evangelisches Krankenhaus Bethesda, Duisburg, Germany.

Background and aims: Addition of insulin glargine 100 U/mL (Gla-100) improves glycemic control in patients (pts) not controlled on oral antidiabetic drugs (OADs). While a number of titration schemes for basal insulin exist, actual titration behavior in daily clinical practice remains unclear.

Materials and methods: TOP-1 is a prospective, observational study in T2DM patients attending primary care offices in Germany. Patients with an HbA1c of 7.5-10% despite being treated by ≥1 OAD (with/without a non-Gla-100 basal insulin) and a physician decision to start Gla-100 therapy were included. The primary endpoint (PE) was achievement of FBG ≤110 mg/dL or individual HbA1c target at 12 months.

Results: In the analysis (n = 2308), patients were grouped by the magnitude of insulin titration during the first month (no titration [+0 U: 39.2%], +1-4 U [31.0%], +5-8 U [17.7%], or +>8 U [12.1%]). At baseline, +>8 U patients were younger (64 vs. 66 years), more often female (58% vs. 50%), and had a higher mean BMI (33 vs. 31 kg/m^2), FBG (201 vs. 179 mg/dl) and HbA1c (8.8% vs. 8.4%) as compared to the +0 U group (all p<0.05). At 12 months, the PE was met by a comparable proportion of patients in each group (65.0%, 68.4%, 66.7%, and 62.9% for +0 U, +1-4 U, +5-8 U and +>8 U, respectively [p = NS]). As expected mean reductions in HbA1c and FBG were greater for +>8 U than +0 U pts (-1.6% vs. -1.2% and -75.1 vs. - 51.2 mg/dl, respectively, all p<0.05). Furthermore, compared to the +0 U group, the proportion of pts who achieved FBG ≤110 mg/dL and their HbA1c target at 12 months was higher in the +5-8 U (27.2% vs. 20.1%; p=0.03) and +>8 U groups (26.2% vs. 20.1%; p=0.02). Confirmed, symptomatic hypoglycemia was documented in 1.5%, 2.4%, 1.2%, and 2.2% of pts in ascending order of titration with no difference between groups.

Conclusion: The majority of patients were not titrated or were titrated slowly in a real word primary care setting. More aggressive titration had only minor effects on the improvement of glycemic control at 12 months.

Glycaemic variability and risk for hypoglycaemia on insulin glargine 300 U/ml versus insulin glargine 100 U/ml in people with type 2 diabetes

B. Kovatchev[1], Z. Meng[2], M. Breton[1], B. Leroy[3], A. Cali[3], R. Perfetti[2];

[1]Center for Diabetes Technology, University of Virginia, Charlottesville, [2]Sanofi, Bridgewater, USA, [3]Sanofi, Paris, France.

Background and aims: It has been observed that the new insulin glargine 300 U/ml (Gla-300) has a smoother 24-hour pharmacokinetic (PK) and pharmacodynamics (PD) profile when compared to insulin glargine 100 U/ml (Gla-100). Here we assess whether these PK/PD differences translate into differences between the daily profiles of glycaemic variability (GV) and risk for hypoglycaemia on Gla-300 vs. Gla-100.

Materials and methods: Edition 2 and Edition 3 are 12-month multicentre trials comparing Gla-300 with Gla-100, both administered in the evening in type 2 diabetes. These trials collected self-monitoring (SMBG) daily profiles and records of documented symptomatic hypoglycaemia (DSH) confirmed by SMBG below 3mmol/l from N=796 insulin users (Edition 2) and N=839 insulin naive patients (Edition 3). The data included 39,388 SMBG readings and 693 DSH episodes (Edition 2), and 41,548 SMBG readings and 235 DSH episodes (Edition 3). GV metrics were computed from SMBG data, including the Low Blood Glucose Index (LBGI) - a GV measure of the risk for hypoglycaemia.

Results: The LBGI and the Night-time LBGI were lower on Gla-300 compared to Gla-100 (P-values <0.001 for both indexes in Edition 2 and P-values =0.09 and =0.02 in Edition 3). These differences were evident throughout the study, and more apparent during the titration phase (mean LBGI Gla-300 vs Gla-100 = 0.333 vs 0.507 in titration and 0.410 vs 0.498 in maintenance in Edition 2; 0.241 vs 0.300 in titration and 0.376 vs 0.410 in maintenance in Edition 3). Figure 1 presents the LBGI daily profiles for Edition 2 (Panel A) and Edition 3 (Panel B), indicating that the largest differences in the risk for hypoglycaemia between Gla-300 and Gla-100 occurred in the second half of the night. Further, among the measures of glucose variability (e.g. SD, CV), the LBGI was the only metric significantly correlated with DSH: r=0.35, p<0.001 (Edition 2) and r=0.26, p<0.001 (Edition 3). While Edition 2 and Edition 3 had different frequencies of hypoglycaemia, the LBGI identified patients at risk uniformly well across the two studies. Compared to those who had LBGI≤1.1, subjects who had LBGI>1.1 experienced several-fold more DSH: 0.63 vs. 3.49 DSH episodes per person, p<0.001 (Edition 2), and 0.25 vs. 1.06 DSH episodes per person, p<0.01 (Edition 3).

Conclusion: Smoother PK/PD profile on Gla-300 compared to Gla-100 is associated with reduced daily glycaemic variability and lower risk for hypoglycaemia, particularly in the second half of the night. Thus, while Gla-300 and Gla-100 maintained similar average glycaemia, Gla-300 may be better suited for treatment intensification than Gla-100. This observation was recently supported by continuous monitoring data in type 1 diabetes. Moreover, type 2 diabetes patients experiencing symptomatic hypoglycaemia when treated with basal insulin are identifiable from SMBG data using risk analysis of glycaemic variation.

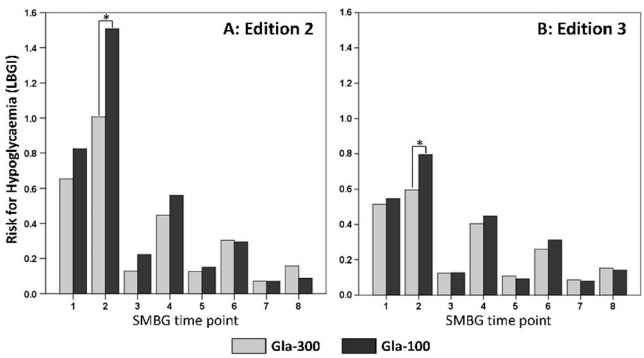

Figure 1: Daily profiles of risk for hypoglycemia on Gla-300 and Gla-100 as measured by the LBGI computed from 8-point SMBG profiles taken at time points: **1**-3AM; **2**-before breakfast; **3**-after breakfast; **4**-before lunch; **5**-after lunch; **6**-before dinner; **7**-after dinner; **8**-at bedtime.

Novel metabolic indices and incident type 2 diabetes among women and men: the Rotterdam study

A. Brahimaj[1], F. Rivadeneira[2], E.J.G. Sijbrands[2], O.H. Franco[1], A. Dehghan[3], M. Kavousi[1];
[1]Department of Epidemiology, Erasmus MC, [2]Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [3]Department of Epidemiology and Biostatistics, Imperial College, London, UK.

Background and aims: Body fat distribution, rather than its magnitude, is increasingly linked to the risk of type 2 diabetes (T2D). Both visceral adipose tissue (VAT); a hormonally active component of total body fat, and truncal fat depot; partitioned into android and gynoid area, have been associated with T2D. While computed tomography (CT) and magnetic resonance imaging (MRI) are the gold standard measures for quantification of VAT, dual energy X-ray absorptiometry (DXA) can measure compartment body compositions; android and gynoid fat. Several easily measured indices, product of combined anthropometric and blood lipid measures, have recently been suggested as indicators of insulin resistance or adiposity. In the large population-based Rotterdam Study, we aimed to investigate the associations of these novel combined metabolic indices with incident type 2 diabetes among women and men and compare them with DXA measurements on body fat.

Materials and methods: Novel combined metabolic indices included visceral adiposity index (VAI), lipid accumulation product (LAP), and the product of triglycerides and glucose (TyG). We used Cox proportional hazard models to investigate associations between VAI, LAP, TyG, the anthropometric [body mass index (BMI) and waist circumference (WC)] and laboratory components [inverse high-density lipoprotein cholesterol (HDL) and triglycerides (TG)] included in their formulas, as well as DXA measurements on body fat (android, gynoid, android to gynoid ratio, total fat mass) with incident type 2 diabetes among women and men in the Rotterdam Study. Associations were adjusted for systolic blood pressure, treatment for hypertension, smoking, prevalent cardiovascular diseases, and serum lipid reducing agents.

Results: We included 9564 subjects (5576 women and 3988 men) free of diabetes at baseline. During a median follow-up time of 6.5 years, 899 incident T2D cases (511 women and 388 men) were identified. In the multivariable adjusted models, VAI (Hazard ratio - HR; 95% confidence interval - CI: 1.49; 1.36, 1.65 in women and 1.37; 1.22, 1.53 in men), LAP (HR; 95% CI: 1.35; 1.16, 1.56 in women and 1.19; 1.01, 1.42 in men), TyG (HR; 95% CI: 1.73; 1.52, 1.98 in women and 1.43; 1.26, 1.62 in men), BMI (HR; 95% CI: 1.37; 1.26, 1.49 in women and 1.45; 1.28, 1.65 in men), and inverse HDL (HR; 95% CI: 1.29; 1.14, 1.46 in women and 1.32; 1.14, 1.52 in men) remained associated with incident T2D in both women and men. WC (HR; 95% CI: 1.24; 1.07, 1.45), TG (HR; 95% CI: 1.24; 1.10, 1.39), gynoid fat mass percentage (HR; 95% CI: 0.64; 0.45, 0.89), and the ratio of android to gynoid fat mass percentage (HR; 95% CI: 1.48; 1.14, 1.94) were associated with incident T2D only in women.

Conclusion: Novel combined metabolic indices including VAI, LAP and TyG were stronger risk markers for incident type 2 diabetes than the traditional anthropometric and laboratory measures included in their formulas. These novel metabolic indices were also comparable to DXA measured body fat compositions. While the association of the combined indices with incident T2D was stronger in women, TyG (the product of triglycerides and glucose) was the best risk marker associated with T2D in both genders.

Spousal diabetes and obesity as risk factors of incident type 2 diabetes: analysis from the English Longitudinal Study of Ageing

A. Hulman[1,2], J. Nielsen[3], D.R. Witte[1,2];
[1]Department of Public Health, Aarhus University, Aarhus C, [2]Danish Diabetes Academy, Odense, [3]Section for Global Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark.

Background and aims: Obesity and family history of diabetes are among the strongest risk factors for type 2 diabetes. Conversely, there is little evidence on the effect of spousal diabetes and obesity as risk factors for type 2 diabetes. Therefore, we investigated the association of spousal diabetes and obesity with incident type 2 diabetes in an elderly population.

Materials and methods: We analysed data from the English Longitudinal Study of Ageing (ELSA), a representative cohort of the English population aged >50 years. We included 3151 men and 3050 women in the study. All participants attended wave 0 of ELSA, serving as baseline. We excluded participants with known diabetes, no follow-up information and missing information on variables of interest. Incidence of diabetes was based on the clinical examinations at waves 2, 4 and 6 (screen-detected: HbA_{1c} >= 6.5% or fasting plasma glucose >= 7 mmol/L) or on the questionnaires at each wave (self-reported diagnosis or medication use). We applied Cox proportional hazards model to obtain hazard ratios (HR) having spousal diabetes status or obesity (BMI and waist circumference) as exposures and diabetes status of the index individual as outcome. The effects of continuous exposures were modelled using splines to reveal potential non-linearity. Model 1 was adjusted for age, ethnicity and socio-economic status, while Model 2 was further adjusted for the index individual's BMI or waist circumference, depending on the exposure.

Results: Women were more likely than men to have a spouse with diabetes at baseline (6.4% vs. 3.3%). Incidence of diabetes was 12.6 and 8.6/1000 person-years among men and women, respectively. There was a tendency that women with a husband with diabetes had higher diabetes risk (HR: 1.45 (95% CI: 0.97,2.19), p=0.07), but this was not seen for men with a wife with diabetes. Non-linear associations between BMI and diabetes risk are shown in the *Figure*. The association between waist circumference and diabetes risk exhibited a similar pattern. After adjustment for a woman's own obesity level, the initial association between the husband's obesity level and the woman's diabetes risk was attenuated and no longer statistically significant. For men, the respective associations were somewhat attenuated but remained statistically significant.

Conclusion: This is the first study investigating the sex-specific effect of spousal diabetes and obesity on diabetes risk. Having an obese wife increases a man's risk of diabetes over and above the effect of his own obesity level, while among women, having an obese husband gives no additional diabetes risk beyond that of her own obesity level. Our results indicate that on finding obesity in a person, screening of their spouse for diabetes may be justified.

Associations of serum fatty acids with insulin resistance and risk of prediabetes and type 2 diabetes

T. Voortman, O.H. Franco, Z. Chen;
Epidemiology, Erasmus MC, Rotterdam, Netherlands.

Background and aims: Few studies have examined the associations between serum fatty acids with insulin resistance and risk of type 2 diabetes (T2D), with conflicting results. Whether and how serum fatty acids are related to risk of prediabetes is still unknown. Therefore, we aimed to investigate the associations between serum fatty acids with insulin resistance and risk of prediabetes and T2D in in a large population-based cohort study.

Materials and methods: Our current study was embedded within the Rotterdam Study (RS), a population-based cohort study in the Ommoord District of Rotterdam, the Netherlands. The study has been approved by the Medical Ethics Committee of Erasmus University Medical Center and all participants gave written informed consent. For the current analyses, we followed 2142 participants aged 65 years and over since 2002-2004 without diabetes, of whom 1653 were without prediabetes, and 1313 had assessments of glucose and insulin, from which we calculated the homeostatic model assessment for insulin resistance (HOMA-IR). Serum phospholipid fatty acids were measured in serum collected from study participants in 2002-2004. Serum fatty acids were categorized into saturated fatty acids (SFA), monounsaturated fatty acids (MUFA), and polyunsaturated fatty acids (PUFA) and were expressed individual serum fatty acid in percentages of total serum fatty acids. We used multivariable cox proportional hazard regression models to analyze the associations between serum fatty acids and risk of prediabetes and T2D. We used multivariable linear mixed models to analyze the associations between serum fatty acids and insulin resistance.

Results: Serum SFA, MUFA and PUFA comprised 38% (SD 1.6%), 23% (SD 3.2%) and 38% (SD 3.3%) of the total phospholipid fatty acids at baseline. During a median follow-up of 8.1 (SD 2.4) years, we documented 193 cases of T2D; during a median follow-up of 8.0 (SD 2.3) years, we documented 232 cases with prediabetes. In multivariable models including age, sex, BMI, physical activity, diet quality score, smoking, education level, total energy intake and family history of diabetes; serum SFA was positively associated with insulin resistance (β=0.07 in HOMA-IR; 95%CI: 0.04-0.10; per 1 SD difference) and risk of prediabetes (HR=1.17; 95%CI: 1.02-1.35; per 1 SD difference) and T2D (HR=1.15; 95%CI: 1.00-1.32; per 1 SD difference). Serum PUFA was inversely associated with insulin resistance (β=-0.11 in HOMA-IR; 95%CI: -0.14- -0.07; per 1 SD difference) and risk of prediabetes (HR=0.34; 95%CI 0.16-0.71; per 1 SD difference) and T2D (HR=0.79; 95%CI: 0.64-0.97; per 1SD difference), which was mainly driven by serum n-6 PUFA. Serum MUFA or n-3 PUFA was not associated with insulin resistance or risk of prediabetes or T2D.

Conclusion: Our findings suggest that serum SFA is associated with a higher risk of developing type 2 diabetes; and that PUFAs, particularly n-6 PUFAs, are associated with less insulin resistance and a lower risk of prediabetes and T2D.

Clinical profile of post-load glucose curves and their association with cardiometabolic risk factors over time

M. Obura[1], F. Rutters[1], R. Slieker[1], T. Hoekstra[1], G. Nijpels[2], E. Pearson[3], P. Franks[4], L. T'Hart[5], J. Beulens[1], The DIRECT consortium;
[1]Epidemiology and Biostatistics, VU Medical Center (VUmc), [2]General Practice and Elderly Care Medicine, VU Medical Center (VUmc),

Amsterdam, Netherlands, [3]Molecular and Clinical Medicine, University of Dundee, Dundee, UK, [4]Clinical Sciences, Genetic and Molecular Epidemiology Unit, Lund University, Malmö, Sweden, [5]Molecular Cell Biology and Dept. of Molecular Epidemiology, Leiden University Medical Center, Leiden, Netherlands.

Background and aims: Subclasses of different glycaemic disturbances could explain the variation in characteristics of people with prediabetes and type II diabetes (T2DM). We aimed to identify subgroups with distinct glucose curves following an oral glucose tolerance test (OGTT) or a mixed meal test (MMT), describe their baseline clinical characteristics and explore associations with cardiometabolic risk factors at follow-up.

Materials and methods: The study included 2179 people with prediabetes and 819 newly diagnosed T2DM patients within the Diabetes Research on Patient Stratification (DIRECT) Study. Latent class trajectory analysis was used to identify subgroups with distinct glucose curves from OGTT for those with prediabetes and MMT for T2DM patients at baseline. Using general linear models, these subgroups were associated with clinical characteristics at baseline and with insulin resistance (HOMA-IR) or HbA1c at 18 months, adjusted for adjusted for potential confounders.

Results: We identified five subgroups from OGTT and three from MMT, labelled in order of increasing peak values as C1 to C5 (OGTT) and T1 to T3 (MMT). At baseline, C4 and C5 had similar fasting glucose (6.0 and 6.2 mmol/l) but different 2-hour glucose (5.5 and 8.4 mmol/l). C5 had higher body mass index (BMI), blood pressure and Hba1c values than C4. C3 compared to C2, had similar fasting glucose (5.7 mmol/l), different 2-hour glucose (5.4 and 7.7 mmol/l), higher BMI and Hba1c. In both analyses, medium (C3 and T2) and highest (C5 and T3) peak curves had the highest BMI, blood pressure and Hba1c. At 18 months, change in HOMA-IR were higher in C5 [beta=1.72; 95%CI=1.28-2.16] , C4 [beta=0.70; 95%CI=0.35-1.06], C3 [beta=1.04; 95%CI=0.73-1.35], C2 [beta=0.38; 95%CI=0.13-0.64] compared to C1. At 18 months, Hba1c (mmol/l) increased across groups with beta=1.88; 95%CI=-0.44-4.20 for T2 and beta=2.93; 95%CI=0.10-5.75 for T3, relative to T1.

Conclusion: Using OGTT and MMT, different glycemic profiles can be identified with different clinical characteristics and cardiometabolic risk. Subgroups with the highest 2-hour glucose had greater cardiometabolic risk than those with high fasting levels only.

Sex-gender differences in diabetes associated risk of cardiovascular events in a young population

G. Seghieri, L. Policardo, P. Francesconi;
Epidemiology, Agenzia Regionale Sanità, Toscana, Florence, Italy.

Background and aims: Excess risk of cardiovascular diseases linked to diabetes is higher in women compared to men, mostly in peri-post-menopausal age. What happens in a younger population (aged lesser than 40yr) is however more uncertain. To answer this question we carried out an observational study concerning the whole population living in Tuscany, a region of centre of Italy, retrospectively followed up along a period of five years (from January1st, 2007 to December 31st, 2012) comparing, by gender, the effect of diabetes on the risk of first hospitalizations for cardiovascular diseases (CVD).

Materials and methods: Using the regional hospital database, first hospitalizations due to any CVD: (acute myocardial infarction, ischemic stroke, lower limbs amputations or chronic heart failure) were recorded during period January 1st, 2007 to December 31st,2012 in the population with age ranging between 16 and 40yr. Presence of baseline diabetes was identified by a regional diabetes registry in year 2006, and current insulin therapy in year 2006 was considered as a proxy for type 1 diabetes (T1D), compared with those with no insulin therapy considered as affected by type 2 diabetes (T2D). Analysis of proportional incident risk of incident hospitalizations, adjusting for confounders, was carried out by Cox-regression analysis model.

Results: Population without diabetes was composed by 514,732 males and 515,799 females while those with diabetes were 2,052 males and 2,598 females of mean age:32±7yr, [934 T1D/1,664 T2D, among females and 1,256 T1D/796 T2D among males]. Hospitalization rates for CVD (p-yr per 100,000) were much higher in those with diabetes in both sexes [32p-yr in people without diabetes vs. 209p-yr for T1D and vs. 510p-yr in T2D among males, and 14p-yr vs. 194p-yr in T1D and vs. 48p-yr for T2D among females]. In T1D the hazard ratio (HR) of hospitalizations for CVD, adjusted for age and co-morbidities, as compared with those without diabetes, was significantly higher in women [HR:6.04 (95%CI: 1.74-16.17); p=0.0012], not in men [HR: 1.47 (95%CI: 0.53-4.05); p=NS], even if CVD incidence rate in diabetic people was similar in both sexes. On the contrary in T2D the excess risk was significantly higher in men [HR:6.32 (95%CI: 4.01-9.95); p=0.0001]but not in women [HR:1.99 (0.74-5.37);p=NS].

Conclusion: In this young population (with age between 16 and 40yr) followed up for 6 years, diabetes associated excess risk of first hospitalizations due to CVD shows an opposite sex-gender dimorphism, according to diabetes type. The incident risk of hospitalization for CVD in patients with T1D, compared to those without diabetes, was six fold significantly higher among females, while on the contrary the excess risk of CVD in patients with T2D was to the same extent higher only among males.

Long-term risk of aortic aneurysm and aortic dissection among individuals with type 2 diabetes: a nationwide observational study

T. Avdic[1], S. Franzén[1], A. Gottsäter[2], M. Zarrouk[2], S. Acosta[2], P.M. Nilsson[3], A.-M. Svensson[1], S. Gudbjörnsdottir[1], B. Eliasson[1,4];
[1]The Swedish National Diabetes Register, Gothenburg, [2]Department of Vascular Diseases, Skåne University Hospital, Lund University, [3]Department of Clinical Sciences, Skåne University Hospital, Lund Univeristy, Malmö, [4]Department of Molecular and Clinical Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden.

Background and aims: Decreased short-term risk for aortic aneurysm (AA) and aortic dissection (AD) has been suggested among individuals with type 2 diabetes (T2DM). No studies have examined long-term risks, or mortality after an AA and AD event in T2DM patients.

Materials and methods: In this nationwide, longitudinal, observational cohort study we linked data for individuals with T2DM in the Swedish National Diabetes Register, and 5 individually matched population-based control subjects (CS) without diabetes (based on sex, age and county), to other national databases to capture hospitalisations and death. We examined the risk of AA and AD in individuals with T2DM and mortality risk after an event with AA or AD using Kaplan-Meier curves and Cox-regression hazards models.

Results: Data on 448,319 individuals with T2DM and 2,251,015 CS was obtained between 1998 and 2015. Mean follow-up time was 7.0 years for T2DM and 7.2 years for CS. In total, there were 2,878 cases of AA in T2DM patients and 16,740 in CS, and 200 cases of AD among T2DM and 2,020 cases among CS.Patients with T2DM had a relative risk reduction (RRR) of 28% (hazard ratio [HR]: 0.72, 95% CI 0.68-0.77, p<0.001) for AA and a 47% RRR (HR 0.53, 0.42-0.66) for AD compared to CS.Adjusted survival rates after an event with AA after 3 months, 1 year and 2 years among T2DM patients were: 84.2, (82.9-85.4), 74.7 (73.2-76.2), and 66.7, (65.1-68.3), respectively. Corresponding rates for CS were: 80. 9 (80.3-81.4), 71. 7 (71.0-72.3) and 64.2 (63.5-64.9). For AD, survival rates were non-significantly higher among T2DM patients.

Conclusion: Among T2DM patients there were significantly decreased risks of AA and AD as well as decreased risk of mortality after an event of AA. Data may suggest that glycated cross-links in aortic tissue may play a protective role in progression of aortic diseases in diabetic patients.

Background and aims: In type 2 diabetes mellitus, congestive heart failure is a frequent, fatal and often forgotten complication and both antidiabetic agents as well as adjuvant therapies modify the risk of developing heart failure. The aetiology of heart failure in patients with diabetes is multifactorial, with both metabolic dysregulation and atherosclerotic disease as risk factors and heart failure might be classified as primary (metabolic/diabetic) or secondary (ischaemic). We have recently reported that 7.8 years of multifactorial intensified intervention in patients with type 2 diabetes and microalbuminuria in the Steno-2 study reduced the risk of atherosclerotic cardiovascular disease. Here, in a post hoc analysis, we examine the impact of intensified multifactorial intervention in patients with type 2 diabetes and microalbuminuria on the risk for hospitalization for heart failure with up to 21.9 years of follow up.

Materials and methods: 160 patients with type 2 diabetes and microalbuminuria were randomized to conventional or intensified, multifactorial, target-driven intervention involving both behavioral and pharmacologic approaches including RAS-inhibition. After 7.8 years, all patients were recommended treatment similar to the intensive-therapy group and the study continued as an observational follow-up study. Heart failure hospitalizations were identified from nationwide registries and supported by mining of patient records. Event-rates were compared using Log-rank test and time to event was analysed using a Cox-regression adjusted for age and sex.

Results: Ten intensive-therapy group patients were hospitalized for heart failure during follow up vs 19 patients in the conventional-therapy group. Cumulative incidence curves are shown in figure 1.The unadjusted hazard ratio was 0.39 [0.18; 0.84], p = 0.017 in the intensive group compared to the conventional group. Adjusted for age and sex, the HR was 0.37 [0.17; 0.81], p = 0.013. Including death in the end-point kept signal stable with HR 0.50 [0.33; 0.75], p = 0.001 after adjustment. In the conventional group, co-existing atherosclerotic coronary disease was more frequent (n = 1 vs. n = 10; p = 0.009).

Conclusion: Intensified, multifactorial intervention in type 2 diabetes with microalbuminuria reduced the risk of hospitalization for heart failure. Heart failure was more frequently associated with ischaemic heart disease in the conventional group, suggesting that intensified multifactorial intervention most importantly reduces secondary (ischaemic) heart failure.

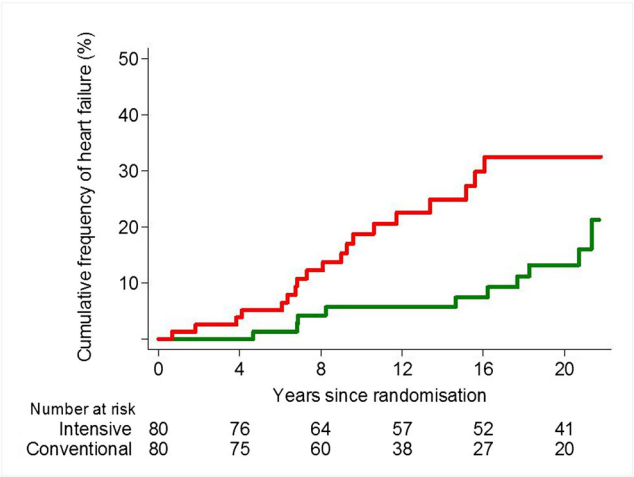

Figure 1: Cumulative incidence of hospitalization for heart failure. Red: conventional therapy. Green: Intensive therapy. HR 0.39 [0.18; 0.84], p = 0.017.

Novel biomarkers predicting heart failure hospitalisation in people with dysglycaemia in the ORIGIN trial

H.C. Gerstein[1], G. Pare[1], M. McQueen[2], S. Lee[2], S. Hess[3];

[1]Population Health Research Institute, McMaster University & Hamilton Health Sciences, [2]Population Health Research Institute, Hamilton Health Sciences, Hamilton, Canada, [3]Research and Development Diabetes, Sanofi Aventis Deutschland GmbH, Frankfurt, Germany.

Background and aims: Heart failure (HF) develops in 1 to 2% of middle aged or older people with diabetes per year and increases with age and HbA1c levels. Adding novel serum biomarkers covering multiple pathways to routine clinical risk factors may identify people at high risk for HF.

Materials and methods: One ml of stored serum from 8018 ORIGIN participants was assayed for multiple novel biomarkers using Myriad RBM's customized Human Discovery Multi-Analyte Profile 250+ panel (N=237) as well as for high sensitivity Troponin I. During a median follow-up of 6.2 years, 449 had at least 1 hospitalization for HF. A Cox regression model using a forward selection approach was used to identify the subset of assayed biomarkers that independently predicted this outcome after accounting for 8 commonly measured clinical CV risk factors (sex, age group, prior CV event, albuminuria, smoking, established diabetes, LDL/HDL ratio, and hypertension).

Results: A Bonferroni-corrected P value for inclusion in the model of less than 0.00021 (i.e. 0.05/238) identified 6 significant biomarkers that included: a) hsTroponin I (HR 1.37); b) NTproBNP (HR 1.69); c) growth differentiation factor 15 (HR1.28); d) angiopoietin- 2 (HR 1.17); e) chromogranin A (HR 0.72); and f) cystatin C (HR 1.26), where angiopoietin-2 was calculated at 5 years to account a significant time-by-covariate interaction. When the model was rerun after also accounting for baseline serum creatinine as a 9th clinical risk factor for heart failure hospitalization, cystatin C was no longer significant and a new biomarker, YKL-40 (HR1.20) became significant. Inclusion of HbA1c or baseline use of statins, or ACE inhibitor/ARB use did not change the list of identified biomarkers. Troponin I, NTproBNP, growth differentiation factor 15, angiopoietin-2 and chromogranin A were previously shown to be independently associated with CV outcomes.

Conclusion: Novel biomarkers can help identify dysglycemic people who are at risk for future heart failure and are potential therapeutic targets.

Endoplasmic reticulum stress and autophagy are impaired in epicardial adipose tissue from heart failure subjects

D. Espinoza[1], A. Burgeiro[1], A. Fonseca[1], L. Carvalho[2], M. Loureiro[3], M. Patrício[3], M. Antunes[4], E. Carvalho[1,5];

[1]Center for Neurosciences and Cell Biology, [2]Institute of Pathology, Faculty of Medicine, University of Coimbra, [3]Laboratory of Biostatistics and Medical Informatics, IBILI – Faculty of Medicine, University of Coimbra, [4]Cardiothroracic Surgery Unit at the University Hospital of Coimbra, Coimbra, Portugal, [5]Department of Geriatrics, University of Arkansas for Medical Sciences, Little Rock, USA.

Background and aims: Cardiovascular disease (CVD) is a primary cause of morbidity and mortality among diabetics. Epicardial adipose tissue (EAT) thickness appears to be correlated with the risk of CVD and the metabolic syndrome. Proper protein turnover is essential for cardiac homeostasis.

Endoplasmic reticulum (ER) stress and dysregulated autophagy are associated with CVD and heart failure. ER stress may induce autophagy in the diabetic heart, in addition to playing a crucial role in adipose tissue dysfunction. Similarly, autophagy is impaired in obesity. However, little is know regarding either of these pathways in EAT. We sought therefore to evaluate ER stress and autophagy in EAT from heart failure patients with and without diabetes (DM).

Materials and methods: Paired subcutaneous adipose tissue (SAT) and EAT biopsies were obtained from 64 (48 male) subjects, (39 non-diabetic (NDM), 65±2 years and 25 DM, 69±2 years), with and without coronary artery disease (CAD) during elective heart surgery. Gene and protein expression was evaluated for markers of ER stress and autophagy by conventional methods.

Results: *GRP94* gene levels were increased in EAT (median=0.3285) compared to SAT (median=02679), with an F ratio of F(1,70) = 10.378, p=0.002, while *GRP78* gene expression was not altered. On the other hand, the protein expression of both of these key chaperones in the ER unfolded protein response, was increased ($p \leq 0.01$) in EAT compared to SAT, but no differences were observed when comparing diabetic versus non-diabetic subjects. Moreover, *BECN1* gene levels were significantly increased in EAT (median=0.0415) compared to SAT (median=0.0312), with and F ratio of F(1,70) = 11.226, p=001. In addition, Beclin1 protein levels were also significantly increased in EAT (median=0.8917) compared to SAT (median=0.3984), F ratio of F(1,16) = 6.180, p=0024. Furthermore, autophagy markers LC3-I (p=0.011) and LC3-II (p=0.002) were significantly increased in EAT compared to SAT. No diferences were observed when comparing diabetic versus non-diabetic subjects.

Conclusion: This study unravels significant metabolic differences between the EAT and SAT depots from heart failure subjects with and without diabetes, in regard to the ER stress and autophagy pathways. However, EAT remains to be investigated in healthy subjects in order to understand whether these differences are characteristic of EAT as a special fat depot or whether these differences are due to heart failure, suggesting that EAT might be a possible therapeutic target.

Hospitalisation for heart failure and death in new users of SGLT-2 inhibitors in patients with and without cardiovascular disease: the CVD-REAL study

M.A. Cavender[1], A. Norhammar[2], K.I. Birkeland[3], M.E. Jørgensen[4], J.P. Wilding[5], K. Khunti[6], A.Z. Fu[7], J. Bodegård[8], B. Blak[9], E.T. Wittbrodt[10], M. Thuresson[11], P. Fenici[12], N. Hammar[13,2], M. Kosiborod[14], on behalf of the CVD-REAL Investigators and StudyGroup;

[1]University of North Carolina, Chapel Hill, USA, [2]Karolinska Institutet, Stockholm, Sweden, [3]University of Oslo and Oslo University Hospital, Oslo, Norway, [4]Steno Diabetes Center Copenhagen, Gentofte, Denmark, [5]Institute of Ageing & Chronic Disease, Liverpool, [6]University of Leicester, Leicester, UK, [7]Georgetown University Medical Center, Washington, USA, [8]AstraZeneca, Oslo, Norway, [9]AstraZeneca, Luton, UK, [10]AstraZeneca, Wilmington, USA, [11]Statisticon AB, Uppsala, Sweden, [12]AstraZeneca, Cambridge, UK, [13]AstraZeneca Gothenburg, Mölndal, Sweden, [14]Saint Luke's Mid America Heart Institute and University of Missouri-Kansas City, Kansas City, USA.

Background and aims: A reduction in cardiovascular death and hospitalization for heart failure (HHF) has been reported with a sodium-glucose co-transporter-2 inhibitor (SGLT-2i) in patients with type 2 diabetes and established cardiovascular disease (CVD). Using observational data from clinical practice (2012-2016), we compared HHF and death in patients with/without prior CVD or heart failure in new users of SGLT-2i vs other glucose lowering drugs (oGLD) in the US, UK, Sweden, Norway and Denmark.

Materials and methods: Both cohorts were matched 1:1 by propensity score. HHF and death were collected via medical records (UK), medical claims, electronic health and death records (US), and national registers (Sweden, Norway, Denmark). Hazard ratios (HR) for HHF, death and the composite endpoint (HHF or death) were estimated by country and pooled as a weighted average.

Results: After matching, baseline characteristics were balanced between groups. In total, 306,156 patients with >150,000 person years (PY) (100,947 PY for SGLT-2i; 89,208 PY for oGLD) and 950 new HHF events were analyzed. SGLT-2i, when compared with oGLD, was associated with significantly lower rates of HHF in patients with and without prior CVD (HR 0.69; 95% CI 0.59-0.80; HR 0.55 95% CI 0.34-0.88, respectively) and with and without prior heart failure (Figure). Similar results were seen for death and the composite endpoint (HHF or death), irrespective of prior history of CVD or heart failure. Findings were consistent across countries with varying proportions of SGLT-2i use by individual agents.

Conclusion: In this large cohort of patients, both with and without CVD or heart failure, SGLT-2i were associated with a significant reduction in HHF and death vs oGLD. This suggests that the benefit of SGLT-2i applies to a broad population of patients with Type 2 diabetes.

Figure: Pooled hazard ratios from meta-analyses for 'hospitalization for heart failure in patients with and without established CVD* and heart failure respectively at initiation of the index drug in five countries: US, UK, Sweden, Norway and Denmark. Analyses of first events on treatment.

Total events of hospitalisation for heart failure in new users of SGLT-2 inhibitors: real world data from 5 countries and more than 298,000 patients: the CVD-REAL study

M. Kosiborod[1], M.A. Cavender[2], A.Z. Fu[3], A. Norhammar[4], K.I. Birkeland[5], M. Jørgensen[6], R.W. Holl[7], N. Hammar[8,4], E.T. Wittbrodt[9], J. Bodegård[10], M. Scheerer[11], M. Thuresson[12], P. Fenici[13], on behalf of the CVD-REAL Investigators and StudyGroup;

[1]Saint Luke's Mid America Heart Institute and University of Missouri-Kansas City, Kansas City, [2]University of North Carolina, Chapel Hill, [3]Georgetown University Medical Center, Washington, USA, [4]Karolinska Institutet, Stockholm, Sweden, [5]University of Oslo and Oslo University Hospital, Oslo, Norway, [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark, [7]University of Ulm, Ulm, Germany, [8]AstraZeneca Gothenburg, Mölndal, Sweden, [9]AstraZeneca, Wilmington, USA, [10]AstraZeneca, Oslo, Norway, [11]AstraZeneca, Wedel, Germany, [12]Statisticon AB, Uppsala, Sweden, [13]AstraZeneca, Cambridge, UK.

Background and aims: A reduction in hospitalization for heart failure (HHF) was recently reported with a sodium-glucose co-transporter-2 inhibitor (SGLT-2i) in patients with type 2 diabetes and established cardiovascular disease. Whether similar results are seen in clinical practice, and across the SGLT-2i class, is unknown. We compared occurrence of all HHF events in new users of SGLT-2i vs other glucose lowering drugs (oGLD) in the US, Norway, Denmark, Sweden and Germany, while still on drug.

Materials and methods: We used medical claims, electronic health and death records (US), prescription data from national registers (Norway, Denmark, Sweden) and electronic health data (Germany) to identify new users of SGLT-2i and oGLD. Non parsimonious propensity scores for SGLT-2i initiation were developed and used to match patients in the two treatment groups 1:1. Incident and recurrent HHF were collected. The relative risk for HHF was estimated by country/database and pooled to provide an overall weighted average.

Results: After matching, baseline characteristics were balanced between the two groups. The percentage of exposure time to individual agents in the SGLT-2i group was 54.2% canagliflozin, 40.1% dapagliflozin and 5.6% empagliflozin. There were 1569 HHF cases among 298,594 patients with 183,732 person-years follow up (incidence rate: 0.85 per 100 person-years). The average follow-up time was 0.54 years in the US, 1.01 years in Norway, 0.93 years in Denmark, 0.75 years in Sweden and 0.49 years in Germany. Initiation of SGLT-2i was associated with significant reduction in the risk of all HHF events (relative risk for SGLT-2i vs oGLD was 0.55 [95% CI: 0.45-0.69]; p-value <0.001).

Conclusion: Treatment with SGLT-2i vs oGLD in this large multi-country cohort was associated with marked reduction in total events of HHF suggesting a class effect applicable to real world practice.

Dapagliflozin is associated with lower risk of major adverse cardiovascular events compared to DPP-4i in type 2 diabetes patients. Results from CVD-REAL Nordic

A. Norhammar[1], M. Kosiborod[2], H. Gulseth[3], J.W. Eriksson[4], P. Fenici[5], D. Nathanson[6], J. Bodegard[7], M. Thuresson[8], T. Nyström[6], K.I. Birkeland[9];
[1]Unit of Cardiology, Karolinska University Hospital, Stockholm, Sweden, [2]2. Saint Luke's Mid America Heart Institute and University, Kansas City, USA, [3]Oslo University Hospital, Oslo, Norway, [4]Uppsala Akademiska Sjukhus, Uppsala, Sweden, [5]AstraZeneca, Cambridge, UK, [6]Södersjukhuset, Stockholm, [7]AstraZeneca Nordic-Baltic, Södertälje, [8]Statisticon AB, Uppsala, Sweden, [9]University of Oslo, Oslo University Hospital, Oslo, Norway.

Background and aims: Despite advances in management, patients with type 2 diabetes (T2D) continue to experience a 2-fold increased risk of cardiovascular (CV) complications, highlighting the need for treatments that improve CV outcomes in addition to lowering HbA1c We aimed to investigate the effects of a SGLT2i dapagliflozin compared to DPP-4i on the risks for MACE (time to first non-fatal stroke, non-fatal myocardial infarction [MI] or CV death), MACE+ (MACE plus unstable angina) and MACE++ (MACE plus unstable angina and hospitalization for heart failure) in using national registers from Sweden and Norway.

Materials and methods: All T2D patients dispensed GLD during 2013—2015 (2014 in Norway) were identified in nationwide mandatory registries in Norway and Sweden. Patients were divided in two groups; new users of dapagliflozin and new users DPP-4i, matched 1:3 by propensity score, calculated using 90 variables covering patient characteristics (age, sex, time since first GLD, frailty), co-morbidities (CV-, kidney-, microvascular complications, cancer, major bleedings, amputations, and respiratory diseases) and drug treatments (antihypertensives, statins, GLD, anticoagulants/platelets). Hazard ratios estimated by Cox survival models were calculated separately for each country, and meta-analyzed using weighted averages.

Results: A total of 60,108 T2D patients were identified as new users of DPP-4i or dapaglifozin. Following matching 25,448 remained and were diveded into the dapagliflozin (n=6362) or DPP-4i group (n=19,086). The groups were well balanced at baseline; mean-age was 61 years, 40% were women, 21% had established CVD, and 17% microvascular complications. Mean follow-up time was 0.75 years, with a total of 19,006 patient-years. Dapagliflozin was associated with 30%, 28% and 31% lower risk of MACE, MACE+ and MACE++ compared to DPP-4i, respectively (Table; p <0.01 for all comparisons).

Conclusion: Treatment with dapagliflozin vs. DPP-4i was associated with significantly lower risk of all three defined MACE outcomes in a broad population of T2D patients from a real-world clinical practice. As CVD is the leading cause of death in T2D, treatments that reduce morbid CV complications should be prioritized.

Socs2$^{-/-}$ mouse as a potential model of macrosomia and gestational diabetes

Y. Brito-Casillas, H. Aranda-Tavío, L. Rodrigo-González, A.B. Expósito-Montesdeoca, P. Martín-Rodríguez, B. Guerra, A.M. Wägner, L. Fernández-Pérez;

Instituto Universitario de Investigaciones Biomédicas y Sanitarias (IUIBS-ULPGC), Las Palmas de Gran Canaria, Spain.

Background and aims: Foetal macrosomia, the predominant complication of gestational diabetes mellitus (GDM), is associated with negative maternal and neonatal outcomes. Macrosomic newborns have increased risk of respiratory distress and neonatal hypoglycemia, and high risk for obesity and DM. The etiopathogenic factors associated with macrosomia are maternal obesity/overweight, high lipid and glucose levels, and older maternal age. Its prevalence is increasing worldwide simultaneously to obesity and DM, but its lifelong impact is not fully understood. Animal models of GDM and macrosomia are necessary to study both conditions, but most are induced, only very few transgenic strains mimic GDM and only *db*$^{-/+}$ shows the poor foetal outcome of macrosomia. We have observed apparent macrosomia in the offspring of the cytokine signalling 2 knockout mice. SOCS2, through the Janus kinases and signal transducers and activators of transcription (JAK/STAT) pathway, acts mediating cytokine responses to control growth, development, metabolism/DM and immunity. Due to its valuable importance as a possible model, we aimed to analyze observational data of the *Socs2*$^{-/-}$ mice as a potential model for foetal macrosomia.

Materials and methods: During routine colony management all pregnant females were followed up. If inability to give birth was detected, they were humanely euthanized. Mothers' age and body weight (BW) were obtained. BW; head length, lateral height and dorsolateral diameter; abdomen width (ventral view) and body length were determined in undelivered and delivered (healthy control) neonates. A retrospective analysis was also assessed in the mouse colony archive (Jan-Dec 2016) to identify related data. To compare groups, Mann-Whitney's U & Student's test were used. A two-tailed $p<0.05$ was considered significant.

Results: Eight pregnant females were euthanized and their 39 non-delivered neonates and six new-born littermates were analyzed. Undelivered neonates were 40% heavier (1.59 ± 0.15 vs 1.14 ± 0.08 g, $p<0.001$), had a 16% increase in dorsolateral head diameter (1.33 [0.7-1.2] vs 0.7 [0.6-0.75] cm, $p<0.045$) and 22% in abdomen width (1.14 [0.75-1.4] vs 0.93 [0.75-1.1] cm, $p<0.025$) than their new-born littermates, but had similar body length. Teratomes were identified in 13% of the necropsied mothers. Retrospective analysis showed high rates of infertility or neonatal mortalities in 60% of all mated females (77 females; 83 mating). Mean age of *Socs2*$^{-/-}$ females with infertility or delivery problems was 175 days (±14.52). No incidences were seen in younger females.

Conclusion: Undelivered neonates were much larger and heavier than the delivered littermates. This macrosomia seemed to cause the inability to deliver in all cases. This condition was seen in mature-old females, along with high rates of infertility. Thus, we hypothesised that macrosomia, mothers' maturity and infertility could be all associated with subsequent GDM or pre-gestational DM. Since same-mother-offspring differences are seen, a placental role or other regulatory mechanisms can be present. Besides, previous insulin resistance in *Socs2*$^{-/-}$ males has been described. Further studies will be performed to evaluate the presence of DM and the role of *Socs2*$^{-/-}$ influence on foetal development. The potential role of pregnant *Socs2*$^{-/-}$ as a spontaneous model of GDM and macrosomia will be established.

Disclosure: **Y. Brito-Casillas:** None.

Role of peroxisome proliferator-activated receptor gamma in the energy homeostasis and metabolic adaptations of pancreas during late pregnancy

P. Corrales-Cordón[1], A. Izquierdo-Lahuerta[1], D. Horrillo[1], I. Velasco[1], L. Torres[1], C. Martinez[1], M. Ros[1], M. Ricote[2], G. Medina-Gomez[1];

[1]Universidad Rey Juan Carlos, [2]Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain.

Background and aims: Reversible β-cell adaptations occur during pregnancy due to the increased maternal insulin resistance, with compensation of β-cell through hyperplasia and hyper-functionality for optimal glucose homeostasis. A defective maternal β-cell adaptation can lead to gestational diabetes mellitus (GDM) and could lead to derived metabolic complications in the offspring. Peroxisome proliferator-activated receptor γ (PPARγ) plays an important role in β-cell proliferation in other pathologic situations such as obesity. Our aim was to study the role of PPARγ in β-cell adaptation during gestation and its consequences in the offspring at later stages.

Materials and methods: We have generated a specific PPARγ knockout mouse in pancreatic β-cell (βγKO). Groups of mice were fed with high fat diet (HFD) or control diet for 3 weeks before pregnancy. At day 15 (D15) of gestation GTT (glucose 1 g/kg BW) and/or ITT (insulin 0.75 U/kg BW) were performed and at D18 animals were sacrificed. Serum concentration values of glucose, insulin and different cytokines were quantified by Bio-plex ProTM Diabetes Assays. Metabolomic analysis in placenta was performed. Immunohistochemistry of insulin and immunofluorescence of insulin/glucagon were performed in pancreas. Indirect calorimetry, locomotor activity, food and drink intake were measure in metabolic cages in adult offspring.

Results: Although our data did not showed differences in body weight in the different experimental groups, βγKO mice fed with HFD showed certain insulin resistance (IR) at late stages of pregnancy and showed higher glucose intolerance than the other experimental groups. Of note, under conditions of HFD, insulin serum concentrations in pregnant βγKO mice were higer (4.8 ± 0.3 *vs* 3.8 ± 0.2 ng/ml) than in WT mice. Furthermore, the adaptation in the expansion of β-cell mass during pregnancy and specific diet was defective (lower β-cell mass in βγKO mice than WT). On the other hand, there were also differences in placental morphology and metabolites between pregnant βγKO and WT mice. Metabolic differences were present in adult offspring depending on the sex, genotype and diet of the mother such as substrate utilization, energy expenditure, activity and drink/food intake.

Conclusion: These data indicated that an appropriate expression of PPARγ in β-cell is necessary to ensure normal pancreas metabolism during the late phase of pregnancy, when a state of insulin resistance is established, contributing to lead normal gestation to term and correct metabolic homeostasis in adult offspring.

Study of the maternal-foetal interface in women with obesity and gestational diabetes as a potential mirror of foetal programming

S. Parrettini[1], P. Montanucci[1], T. Pescara[1], G. Basta[1], R. Calafiore[1], E. Torlone[2];

[1]Department of Medicine, Section of Cardiovascular, Endocrine and Metabolic Clinical Physiology, University of Perugia, [2]Section of Internal Medicine, Endocrine and Metabolic Sciences, Interdepartmental School of Medicine, University of Perugia, Perugia, Italy.

Background and aims: Pre-gestational obesity and GDM impair fetal development and enhance adverse outcomes for both, mothers and newborns, by affecting the uterine milieu and fetal programming. hUCMS, located at the maternal-fetal interface, hold immunomodulatory properties by production of humoral factors (TGFβ, IDO, NO, IL6, PGE2, HGF, VEGF) and expression of immune molecules (HLA E-F-G), and may mirror fetal effects induced by maternal metabolic alterations. We assessed how pre-gestational obesity and GDM, in accurately and intensively managed patients, may influence hUCMS at the maternal-fetal interface.

Materials and methods: We studied 628 pregnant women, that were classified by pre-gestational BMI (normal b.w, overweight, obesity), and presence

of GDM or overt diabetes (OGTT 75 g. at 16-18th or 24-28th week of gestation), and monitored throughout the third trimester of pregnancy. Glycometabolic control (by HbA1c, fasting and 1 hr post-prandial BG, plasma total/HDL cholesterol, triglycerides) and anthropometric parameters (gestational weight gain) including nutritional or drug (ie, insulin) prescriptions were assessed at third trimester. Fetal parameters (metabolic, birth weight, birth complications or hypoglycemia) were assayed and, in a representative sample, maternal systemic inflammatory parameters (plasma cytokines) were tested. We also compared hUCMS stemness and immunoregulatory properties of diabetic and obese vs. normal weight and euglycemic mothers, well monitored during pregnancy. In particular, mesenchymal (CD90, SCF, CD117, vimentin E/N-cadherins, nestin), and stemness (Oct4A, Oct4B, Sox2, Nanog, ABCG2) markers, as well as hUCMS capability to differentiate into osteogenic (osteopontin), adipogenic (FABP4, PPARγ), neural (Map2ab, TUBβ3, Nestin), endocrine (MAFB/A, NEUROD, PDX1, NKX6.1), and definitive endoderm (SOX17, CXCR4, FOXA2) cell phenotypes were evaluated. Immunomodulatory molecules (IDO, iNOS, HLAG1, IL6, IL10, PGE2, TGFβ1 - in basal and after exposure to peripheral blood mononuclear cells in alginate beads) were also examined. Cytokines from isolated hUCMS were evaluated.

Results: The mothers ranked by pre-gestational b.w. and of GDM or T2D under intensive monitoring, terminated pregnancy under optimal metabolic conditions, with final incremental body weight on target (compared to pre-gestational b.w.) and glucose control similar between BMI classes. An optimized metabolic control during pregnancy translates into tangible benefits of neonatal outcomes. However, hUCMS plasticity was different in obese/diabetic vs. normal glucose tolerant mothers, in terms of differentiation potential, expression of pro-inflammatory cytokines and immunoregulatory markers, all these reflecting an inflammatory "milieu", in obese/diabetic vs. normal mothers.

Conclusion: We preliminarily showed that the obesity/DM-induced inflammatory environment, at the maternal/fetal interface, is mirrored by hUCMS, as a possible marker for fetal programming.

Apelinergic system in placenta of women with gestational diabetes

L. Stirm[1,2], L. Fritsche[1,2], A. Fritsche[1,2], H.-U. Häring[1,2], H. Staiger[1,2];
[1]DZD HelmholtzZentrumMünchen, Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Zentrum Munich at the Eberhard Karls University of Tuebingen, [2]German Center for Diabetes Research (DZD), Tübingen, Germany.

Background and aims: With respect to the finding that maternal insulin resistance and GDM are associated with fetal brain insulin resistance, placental Apelin (APL) could be one key player in the establishment of fetal brain insulin resistance and transgenerational diabetes. APL is a protein discussed to improve insulin sensitivity at physiological concentrations. By contrast, high cerebral APL concentrations associate with increased hypothalamic inflammation and development of insulin resistance. Usually, APL plasma levels are markedly elevated in pregnancy due to its strong expression and release by the placenta. Gestational diabetes mellitus (GDM) increases APL plasma levels even more. Additionally, maternal overnutrition was shown to increase maternal and fetal APL plasma levels and placental APL and APL receptor (APJ) expression, in animal models. However, GDM-specific effects on placental and trophoblastic APL and APJ expression awaits further investigation. As high levels of saturated fatty acids (SFA) are found in placental tissue of GDM women, we also focused on trophoblastic APL release and APJ expression after stimulation with SFA.

Materials and methods: Placental tissue from normal glucose-tolerant (NGT) and GDM women was collected in the Tübingen PREG study. RNA was isolated from homogenized placental tissue (N=30). Quantitative PCR (qPCR) was conducted for relative quantification of APL and APJ. Additionally, immunohistochemical staining of paraffin-embedded, serial sections of placental tissue was conducted with antibodies against APL and APJ. Furthermore, primary human trophoblasts (N=6) were stimulated with palmitic and oleic acid (100μM each) and with insulin (10nM and 100nM), lysed, and subjected to APL and APJ gene expression analysis by qPCR

Results: As expected, placental APL (P=0.01) and APJ (P=0.06) mRNA expression was elevated in GDM compared to NGT women after adjustment for pregnancy week at birth, maternal BMI, fetal sex, and maternal smoking behavior. Immunohistochemical studies revealed that trophoblasts express both APL and APJ. Stimulation of primary trophoblasts with palmitic acid (100μM) triggered increased APL release into the cell culture supernatant (P=0.003). No changes in concentrations of APL in cell culture supernatants were seen upon oleic acid (100μM) and insulin (10nM and 100nM) treatment. Furthermore, stimulation of primary trophoblasts with palmitic acid, but not oleic acid or insulin, was associated with increased APJ mRNA expression (P=0.04).

Conclusion: We identified the saturated fatty acid palmitate as a novel and potent inducer of trophoblastic APL and APJ expression. Thus, saturated fatty acids, e.g., derived from insulin-resistant maternal adipose tissue and/or from the lipid-laden placenta itself, may contribute to the GDM-induced increase in APL release from the placenta and may trigger, via the apelinergic system, fetal brain insulin resistance.

High incidence of foetal macrosomia in cohort of pregnant women with type 1 diabetes on continuous subcutaneous insulin infusion despite excellent glycaemic control

M.R. Talla[1], F. Hendry[2], J. Gibson[2], D. McGrane[1];
[1]Department of Diabetes & Endocrinology, Queen Elizabeth University Hospital, [2]Department of Obstetrics & Gynaecology, Queen Elizabeth University Hospital, Glasgow, UK.

Background and aims: Type 1 diabetes mellitus (T1DM) in pregnancy may lead to adverse outcomes. Poor glycaemic control at around the time of conception is associated with congenital anomalies, while persistent hyperglycaemia during pregnancy may result in increased rates of stillbirths, neonatal death, preterm delivery and fetal macrosomia. Achieving good glycaemic control is therefore essential. Our objective was to characterize the relationship between the use of continuous subcutaneous insulin infusion (CSII) use in pregnant women with T1DM and their obstetric outcomes.

Materials and methods: We performed a retrospective analysis of fifteen patients from three hospitals in South Glasgow who were on CSII during pregnancy over a three-year period from 2013 to 2016. Data was obtained from maternity records and the electronic Scottish Care Information Diabetes Collaboration (SCI-DC) database.

Results: This cohort had a mean age of 32.3 years (range 27-40 years) and a mean BMI of 26.7 pre-pregnancy. All were on CSII pre-pregnancy. Twelve of the women were of white European descent, and three were white American. Mean duration of diabetes was 15.8 years (range 3.1-24.0 years). Ten women had retinopathy, one had microalbuminuria and one had peripheral neuropathy. Mean HbA1c was 59 mmol/mol pre-pregnancy and 49 mmol/mol at the end of pregnancy. Twelve of the fifteen women underwent structured education. Twelve were planned pregnancies on pre-conceptual folic acid, and twelve were commenced on low dose aspirin from 12 weeks gestation. Five women underwent induction of labour as per National Institute for Health and Care Excellence (NICE) guidance for women with diabetes on insulin therapy. Ten women required pre-term delivery, and two suffered from pre-eclampsia. Ten were delivered by caesarian section. Thirteen women had a fetus with an abdominal circumference (AC) of over the 95th centile. One had polyhydramnios. No patient sustained a third degree tear at delivery, and two women suffered from postpartum haemorrhage.

Conclusion: This cohort demonstrated a marked improvement in HbA1c during pregnancy. Thirteen of fifteen patients had a fetus with an AC over the 95th centile. The reasons for this high rate of fetal macrosomia are unclear and require further exploration. The possibilities include better placental function as a result of CSII use in early pregnancy leading to improved fetal blood

supply and consequential greater exposure to glucose and insulin, over insulinisation, or marked glucose variability not identified on random capillary blood glucose monitoring.

Disclosure: **M.R. Talla:** None.

Higher odds for initiation of insulin therapy in MTRN1B rs10830963 G allele carriers with gestational diabetes and pre-pregnancy BMI above 29 kg/m^2

G. Firneisz[1], K. Rosta[2], Z. Al-Aissa[3], O. Hadarits[4], J. Harreiter[5], Á. Nádasdi[6], D. Bancher-Todesca[2], L. Németh[7], J. Rigó Jr[4], I. Sziller[8], A. Kautzky-Willer[5], A. Somogyi[3];

[1]2nd Department of Internal Medicine, Hungarian Academy of Sciences - Semmelweis University, Budapest, Hungary, [2]Department of Obstetrics and Gynecology, Medical University of Vienna, Vienna, Austria, [3]2nd Department of Internal Medicine, Semmelweis University, [4]1st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary, [5]Gender Medicine Unit, Division of Endocrinology and Metabolism, Department of Internal Medicine III,, Medical University of Vienna, Vienna, Austria, [6]Doctoral School of Clinical Medicine, School of Ph.D. Studies, Semmelweis University, [7]Department of Probability Theory and Statistics, Eötvös Loránd University, [8]Department of Obstetrics and Gynecology, Szent Imre Teaching Hospital, Budapest, Hungary.

Background and aims: Gestational diabetes mellitus (GDM) has a high prevalence, which highlights the importance of factors predicting the need for pharmacological treatment, including antenatal insulin therapy (AIT). The rs10830963/G allele, a common variant of the Melatonin receptor 1 B (MTNR1B) gene is associated with GDM development and glycemic traits. We hypothesized that carrying the rs10830963/G risk allele may have an effect on AIT initiation in GDM in a BMI dependent manner.

Materials and methods: Clinical and MTNR1B genotype data of 211 Hungarian and 87 Austrian GDM cases were assessed in a post-hoc analysis of a recently completed Austro-Hungarian case-control genetic association study. The genetic effect on the initiation of AIT was studied in different body mass index (BMI) subgroups and a BMI threshold was determined with a stepwise increase where the genetic effect became the most significant using logistic regression. The odds were calculated using a chi-square test for both countries.

Results: Although the glycemic targets were the same, we recorded different AIT rates between the two countries (74% vs. 14.7%, p=1x10^{-4} in Austria vs. Hungary, respectively). The pre-pregnancy BMI threshold of 29 kg/m^2 was identified where the genetic effect on the initiation of AIT was the most significant. The mean weight gain of Hungarian patients with pre-pregnancy BMI≥29 kg/m^2 was lower (5.2 kg) compared to all other study subgroups (9.36-10.56 kg, p<0.007). We detected a significant genetic effect on AIT initiation in Hungary (real-life AIT OR=5.2, p=0.02) in patients with GDM and pre-pregnancy BMI≥29 kg/m^2, which even remained significant after adjusting the data to macrosomia (OR=3.29, p=0.05). In addition, there was a NS trend for higher odds of AIT initiation in Austrian MTNR1B rs10830963 G allele carrier GDM patients with pre-pregnancy BMI≥29 kg/m^2 (real-life OR=2.7, NS), however this could not reach the level of statistical significance due to the higher AIT use rate (81%) and the lower number of cases in Austria.

Conclusion: To our knowledge this is the first report that carrying a common gene variant (MTNR1B rs10830963/G allele) increases the odds of AIT initiation in patients with GDM and pre-pregnancy BMI≥29 kg/m^2. This observation might serve as a basis for future studies about the effect - of reporting MTNR1B rs10830963 genotype (or more complex prediction scores) - on GDM management strategies and outcomes, however the results should be first confirmed in replication studies with larger sample sizes.

MANF is required for the postnatal expansion of the pancreatic beta cell mass and for adult beta cell maintenance in mice

T. Danilova[1], T. Otonkoski[2,3], M. Saarma[1], M. Lindahl[1];

[1]University of Helsinki, [2]Research Programs Unit, Biomedicum Stem Cell Center, University of Helsinki, [3]Children's Hospital, Helsinki University Central Hospital, Helsinki, Finland.

Background and aims: Mesencephalic astrocyte neurotrophic factor (MANF) is an endoplasmic reticulum (ER) located, but also secreted protein that is essential for the β cell proliferation and survival in vivo since conventional MANF knockout mice (Manf$^{-/-}$) show progressive postnatal reduction of β cell mass resulting in severe insulin-deficient diabetes. MANF absence in mouse pancreatic islets in vivo caused ER stress and chronic activation of UPR signalling pathways. In this study we aimed 1) to verify that diabetic phenotype of the conventional Manf$^{-/-}$ mice is caused by the lack of MANF from β cells and not from other organs, and 2) to investigate whether MANF-removal in postnatal/adult mouse β cells affects the survival and proliferation of β cells using conditional Pdx1Cre and inducible β cell specific Manf$^{-/-}$ mice.

Materials and methods: We generated pancreas-specific conditional MANF-deficient mice by crossing Manf$^{fl/fl}$ mice with transgenic Pdx1Cre^{Tuv} mice. Inducible β cell specific Manf$^{-/-}$ mice were created by crossing of Manf$^{fl/fl}$ mice to MIP1-CreERT mice. At 8 weeks of age MIP1-CreERT:: Manf$^{fl/fl}$ were injected with 33 mg/kg of Tamoxifen for 5 consecutive days and control mice with corn oil. Mice were analysed four weeks post injection. β cell mass, β cell proliferation and death analysis were quantified from pancreatic sections. RNA was extracted from isolated islets and cDNA was assessed by quantitative real-time PCR for β cell specific- and ER stress markers.

Results: We found that pancreas-specific Pdx-1$^{Cre/+}$::Manf$^{fl/fl}$ mice similarly to Manf$^{-/-}$ mice, developed insulin deficient diabetes due progressively reduced β cell mass after birth. However, the severe growth defect found in Manf$^{-/-}$ mice was absent. We found mosaic MANF expression in the postnatal pancreases of conditional Pdx-1$^{Cre/+}$::Manf$^{fl/fl}$ mice, which probably was due to incomplete and individually variable recombination efficiency, reported previously using Pdx1Cre mice. Importantly, we found that the number of MANF-positive β cells significantly correlates with the β cell mass in individual mice, demonstrating the importance of MANF expression in restoring the β cell mass. Histological analysis of MIP1-CreERT::Manf$^{fl/fl}$ pancreases revealed decreased insulin staining and loss of β cells in the Tmx-injected mice compared to controls. β cell mass was quantified and a significant reduction was seen in the Tmx injected MIP1-CreERT::Manf$^{fl/fl}$ mice compared to oil injected mice. The reduction of the β cell mass was accompanied by enhanced β cell apoptosis and diminished β cell proliferation. Additionally, we observed reduced intensity of immunofluorescent GLUT2 and PDX1 staining in β-cells lacking MANF. Accordingly, decreased mRNA expression of β cell markers and increased expression of ER stress markers was detected in islets isolated from adult Tmx-injected MIP1-CreERT::Manf$^{fl/fl}$ compared to control islets.

Conclusion: Our results show that 1) Embryonic MANF removal specifically from pancreas leads to progressive β cell loss and diabetes in mice 2) MANF is needed for the expansion of β cell mass postnatally 3) MANF is needed for maintaining the adult β cell phenotype and for the survival of adult β cells in mice. Our results makes MANF a promising candidate for regenerative β cell therapy in diabetes.

MicroRNA miR-184 islet expression is regulated by NKX6.1 and is involved in beta cell dedifferentiation and protection from cytokine- and palmitate-induced apoptosis

G.E. Grieco[1,2], N. Brusco[1,2], F. Mancarella[1,2], P. Marchetti[3], G. Sebastiani[1,2], F. Dotta[1,2];
[1]Diabetes Unit-Dept. of Medicine, Surgery and Neuroscience, University of Siena, [2]Umberto Di Mario Foundation ONLUS, Toscana Life Sciences, Siena, [3]University of Pisa, Pisa, Italy.

Background and aims: Beta-cell dysfunction in Type 2 diabetes (T2D) involves several molecular mechanisms, including microRNAs deregulation. A new proposed mechanism of beta-cell dysfunction in T2D is the loss of the mature phenotype or dedifferentiation. We recently demonstrated that miR-184 is reduced both in T2D donors and in in vitro dedifferentiated human islets, and that its downregulation leads to overexpression of CRTC1, protecting from palmitate- and cytokine-induced apoptosis. However, the mechanism leading to miR-184 downregulation is not known. Therefore, the aim of this study is to shed light onto the regulatory pathway of miR-184 expression to better understand whether the dedifferentiation process is a protective mechanism against β cell stress and apoptosis, occurring in T2D.

Materials and methods: The algorithm MatInspector was used to identify the predicted TFBS (transcriptional factor binding sites) for miR-184, and allowed to putatively identify NKX6.1 as regulator gene on miR-184 promoter. Consequently, NKX6.1 expression was evaluated by Taqman qRT Real-time PCR in purified human islets from 7 T2D and 10 non-diabetic multiorgan donors, as well as in 5 in vitro dedifferentiated and 5 native human islet preparations. NKX6.1 nucleus-cytoplasm translocation was induced through H_2O_2 in MIN6 cell line, and miR-184 expression was evaluated in treated vs non-treated samples by Taqman qRT Real-time PCR. Moreover, the binding of NKX6.1 to miR-184 promoter was analyzed by Chromatin Immunoprecipitation (ChIP). Statistical analyses were performed using Mann-Whitney U test and Spearman test; p values <0,05 were considered statistically significant.

Results: We identified 3 binding sites for NKX6.1 on human promoter and 1 binding site on mouse promoter of the miR-184 gene. Results obtained by qRT Real-time PCR demonstrated that NKX6.1 is downregulated in human islets of T2D vs non-diabetic donors (p=0,0004) and in in vitro dedifferentiated vs native human islets (p=0,0079), in line with reduced expression of miR-184. Moreover, NKX6.1 expression positively correlated with miR-184 expression in human pancreatic islets (r=0,68; p=0,0023). Immunofluorescence analysis on MIN6 cells, in which oxidative stress was induced, showed the translocation of NKX6.1 from the nucleus to the cytoplasm and, as hypothesized, a decrease in miR-184 expression (p=0,01). Finally, ChIP data revealed the actual binding of NKX6.1 on miR-184 promoter, suggesting that this gene is indeed one of miR-184 regulators and acts on the expression and function of this miRNA, pivotal for the protection against β-cell death.

Conclusion: In summary, we found that NKX6.1 is a regulator of miR-184 expression in β-cells. Given the pivotal function of NKX6.1 in the maintenance of β-cell identity, we speculate that its downregulation, and the consequent reduction of miR-184 expression, is involved in β-cell dedifferentiation process. We hypothesize that the reduced expression of NKX6.1 and of miR-184, and the consequent increased expression of CRTC1, is a dedifferentiation-induced protection (DiP) pathway, suggesting a new concept of β-cell dedifferentiation as a protection mechanism against apoptosis in T2D.

Disclosure: **G.E. Grieco:** None.

Overexpression of eukaryotic translation initiation factor 2A (eIF2A) in pancreatic beta cells attenuates diabetes in Akita mouse model

E. Panzhinskiy[1], G. Soukhatcheva[2], S. Skovsø[1], D.A. Dionne[1], J.S. Wildi[1], X. Hu[1], F. Taghizadeh[1], C.B. Verchere[2], E. Jan[3], J.D. Johnson[1];
[1]Department of Cellular and Physiological Sciences, University of British Columbia, [2]Department of Surgery, University of British Columbia, [3]Department of Biochemistry and Molecular Biology, University of British Columbia, Vancouver, Canada.

Background and aims: Endoplasmic reticulum (ER) stress-induced unfolded protein response (UPR) is a major mechanism mediating beta-cell apoptosis in diabetes. Inhibition of general protein translation via phosphorylation of eIF2α is a key event during the UPR. Previously, we have demonstrated that overexpression of an alternative translation initiation factor eIF2A, that can deliver initiator tRNA to the ribosome during inhibition of general translation, protects MIN6 cells, primary mouse and human islets from ER stress-induced apoptosis. Therefore, we investigated the potential protective effect of eIF2A in beta cells *in vivo* using Akita mice, which carry a mutated *Ins2* gene leading to spontaneous diabetes due to ER stress-induced apoptosis in beta cells.

Materials and methods: For beta-cell specific overexpression we designed adeno-associated virus 6 (AAV6), encoding either eIF2A-GFP or control GFP and driven by an insulin promoter. 1.5 x 10^11 particles of either virus were injected into the pancreatic duct of 6-week old $Ins2^{Akita/WT}$ female mice randomized into two groups (n=5). Body weight and 4h fasting blood glucose levels were monitored weekly. A glucose tolerance test (GTT) (1 g/kg, i. p.) and a glucose stimulated insulin secretion test (1 g/kg, i. p.) were performed 3 weeks after AAV injection. Plasma insulin and proinsulin levels were measured with commercially available ELISA kit. Pancreatic islets were collected for RNA and protein extraction 4 weeks post AAV injection.

Results: $Ins2^{Akita/WT}$ mice with beta-cell specific eIF2A overexpression had lower fasting blood glucose levels compared to GFP control mice at 2 weeks (11.3±0.8 vs 17.1±1.0 mmol/l, p=0.0022) and 3 weeks (12.8±1.0 vs 19.2±0.4 mmol/l, p=0.0003) after AAV6 ductal injections. As expected GFP control $Ins2^{Akita/WT}$ mice showed increased fasting blood glucose levels with age, but this increase was attenuated by eIF2A overexpression in beta cells. No significant difference in body weight gain was observed between groups at any time point. Three weeks after viral injection, $Ins2^{Akita/WT}$ mice overexpressing beta-cell specific eIF2A showed significantly improved glucose tolerance in comparison to GFP overexpressing $Ins2^{Akita/WT}$ mice (AUC 2646±97 vs 3208 ±85 respectively, n=5, p=0.0024). Overexpression of eIF2A in $Ins2^{Akita/WT}$ was associated with increased insulin secretion at 15 min post glucose challenge (0.73±0.09 vs 0.47±0.07 ng/ml, n=4, p=0.04) when compared with controls infected with GFP alone. In fed state, no significant difference in plasma insulin (0.20±0.06 vs 0.23±0.04 ng/ml, n=5, p=0.7) or proinsulin levels (13.7±5.2 vs 10.9±4.7 pmol/l, n=5, p=0.7) were detected between eIF2A-GFP and control GFP expressing $Ins2^{Akita/WT}$ mice. The evidence of the specific molecular mechanisms involved in this remarkable beta-cell protection was further provided using qPCR and Western Blotting analysis of pancreatic islets.

Conclusion: We conclude that overexpression of eIF2A in pancreatic beta cells prevents progression of diabetes and potentiates glucose stimulated insulin secretion in $Ins2^{Akita/WT}$ mice under the conditions of our study.

Human pancreatic beta cell dedifferentiation

F. Chimienti[1], M. Diedisheim[2], M. Oshima[2], O. Albagli-Curiel[2], C. Wennberg-Huldt[1], I. Ahlstedt[1], M. Clausen[3], S. Menon[4], M. Hammar[1], A.-C. Andréasson[1], P. Marchetti[5], L. Marselli[5], M. Armanet[6], R. Scharfmann[2];
[1]Cardiovascular and Metabolic Diseases, Innovative Medicines and Early Development Biotech Unit, AstraZeneca R&D, Mölndal, Sweden, [2]INSERM U1016, Institut Cochin, Université Paris Descartes, Paris, France, [3]Discovery Sciences, Innovative Medicines and Early Development Biotech Unit, AstraZeneca R&D, Mölndal, Sweden, [4]RDI Operations, AstraZeneca R&D, Cambridge, UK, [5]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [6]Cell Therapy Unit, Hôpital Saint Louis, AP-HP, and University Paris-Diderot, Paris, France.

Background and aims: Clinical and experimental evidences indicate a reduced functional β-cell mass in type 2 diabetes. A recent hypothesis implicates β-cell dedifferentiation in this reduction of functional β-cell mass. Majority of

data related to β-cell dedifferentiation derive from rodent models, and only indirect evidences are available in human. Our goal was to study human β-cell dedifferentiation using the functional human pancreatic β-cell line, EndoC-βH1, and primary human pancreatic islets.

Materials and methods: We first screened for molecules that decrease insulin and MAFA gene expression in EndoC-βH1 cells. We next searched for additional markers of dedifferentiation both in EndoC-βH1 cells and in primary human islets, and studied whether dedifferentiated cells could be protected from extra-cellular signals.

Results: By screening a number of molecules, we first found that FGF2 treatment dramatically reduces insulin production and MAFA expression, a beta cell specific transcriptional activator in EndoC-βH1 cells. RNASeq of EndoC-βH1 cells treated with FGF2 revealed the down-regulation of additional β-cell specific markers, including MAFB, SLC2A2, SLC30A8, GCK. In parallel, FGF2 treatment activated the expression of β-cell disallowed genes. This is the case for transcription factors such as MYC, HES1, SOX9 and NEUROG3. This is also the case for hormones such as GASTRIN and PYY. Such data were further confirmed by qPCR and immunostaining on primary human islets, attesting that dedifferentiation process occurs in human beta cells. We also showed that FGF2-induced dedifferentiation is time- and dose-dependent, and is reversible upon wash-out. Furthermore, transcriptomic analysis revealed an increase of TNFRSF11B (osteoprotegerin) expression upon FGF2 treatment. TNFRSF11B is a decoy receptor for the receptor activator of nuclear factor kappa B ligand (RANKL). Our experimental data on EndoC-βH1 demonstrated that FGF2-induced TNFRSF11B and protected beta cells against TNFSF11 (RANKL) signaling by preventing P38 phosphorylation.

Conclusion: We developed a robust model to study β-cell dedifferentiation in a human context. We discovered SOX9, HES1 and MYC as positive markers of human β-cell dedifferentiation, demonstrating for the first time direct evidence for dedifferentiation process in human beta cell. Finally, we observed that beta-cell dedifferentiation prevents against activation of the RANKL pathway.

Metformin restores insulin secretion from palmitate-treated human islets by normalising mitochondrial metabolism and reducing ER stress and apoptosis

J. Cen, E. Sargsyan, P. Bergsten;
Department of Medical Cell Biology, Uppsala University, Uppsala, Sweden.

Background and aims: Insulin levels in the blood of obese individuals are elevated, which has been related to high concentrations of free fatty acids (FFAs). In long-term, hyperinsulinemia causes exhaustion of beta cells, insufficient insulin secretion and development of type 2 diabetes mellitus (T2DM). In line with this, experiments on isolated human islets showed that palmitate treatment accentuated glucose-stimulated insulin secretion (GSIS) at earlier time points and caused beta cell dysfunction after prolonged palmitate exposure. Metformin is the first-line drug for the treatment of T2DM, in particular, in overweight and obese individuals. However, it remains controversial whether metformin has a beneficial effect on FFA-treated beta cells. Here, we investigated if metformin prevents beta cell dysfunction induced by chronically elevated palmitate levels.

Materials and methods: Study was performed on isolated human pancreatic islets. Human islets were cultured in CMRL medium containing 5.5 mM glucose. For treatments, human islets were exposed to 0.5 mM palmitate with 0.5% BSA in the absence or presence of 25 μM metformin for 0, 2, and 7 days. After treatments, GSIS, intracellular insulin content, mitochondrial function (Extracellular Flux Analyzer XF96e), ER stress (pEIF2α and CHOP), and apoptosis (active caspase 3) were determined.

Results: GSIS from 2-day palmitate treatment was almost doubled compared with the control islets and this was accompanied by a 65% rise in oxygen consumption rate (OCR). After exposing the islets to palmitate for 7 days, GSIS was significantly lowered to 50% of the control islets but there was no difference in OCR compared with control islets. The introduction of metformin restored insulin secretion and OCR in islets exposed to palmitate for 2 days. After 7-day treatment with metformin palmitate-exposed islets showed restored GSIS but exerted no effect on OCR. Insulin content was decreasing during palmitate culture, from 70% of the control level after 2 days to 30% after culture for 7 days. The inclusion of metformin during palmitate culture had no effect on insulin content after 2 days, but almost doubled it after 7 days. Markers of ER stress (pEIF2α and CHOP) and apoptosis (active caspase 3) were not affected after 2 days but significantly increased after 7-day palmitate treatment. They were reduced to the control level in palmitate-exposed islets treated with metformin.

Conclusion: Metformin prevents palmitate-induced increase of GSIS from human islets after 2 days and decrease of GSIS after 7 days. These effects are associated with decreased mitochondrial metabolism at earlier time points and reduced ER stress and apoptosis at later time points.

ER stress induces diabetes by impairing early postnatal beta cell proliferation

G. Leibowitz, Y. Riahi, S. Jimenez, I. Alter, R. Yerosleviz, N. Polin, E. Cerasi;
Hebrew University-Hadassah Medical School, Jerusalem, Israel.

Background and aims: ER stress plays an important role in the pathophysiology of type 1 and type 2 diabetes (T1D and T2D); it is widely believed that chronic ER stress contributes to reduced beta cell mass in diabetes, but the underlying mechanisms remain largely unknown. Akita diabetes is a genetic form of ER stress-induced diabetes resulting from a mutation in the proinsulin gene, leading to its irreparable misfolding. We studied the life-long changes in β-cell mass in Akita mice and the role of apoptosis, altered proliferation, or dedifferentiation in mediating β-cell dysfunction.

Materials and methods: Pancreatic sections were immunostained for islet hormones, transcription factors (PDX-1 and NKx6.1), proliferation markers (Ki67, PCNA and phospho-histone H3) and apoptosis (TUNEL). β-cell lineage tracing was performed using Cre-mediated labeling of differentiated beta cells. Mice metabolic tests included IPGTT and measurement of glucose-stimulated insulin secretion.

Results: In 2-3 months old diabetic Akita mice, β-cell mass was decreased by ~70% compared to age-matched controls. TUNEL labeling was rare and proliferation was observed in <1% of beta cells in both Akita and controls, indicating that altered beta cell mass at this stage reflects earlier events. Genetic lineage tracing showed that <2% of lineage-labeled β-cells were completely degranulated or mis-expressed somatostatin or glucagon without insulin, indicating minimal contribution of reprogramming to loss of beta cell mass. We therefore studied early postnatal β-cell dynamics. In control mice, during the first 3 weeks of life β-cell proliferation was ~10-fold higher than in adult animals, leading to a 3-fold increase in β-cell mass. In Akita mice, β-cell proliferation and the expression of Nkx6.1 and PDX-1 were decreased by ~50% and β-cell mass was reduced by 60% compared with controls at day 21. At this stage, mice were normoglycemic despite marked depletion of pancreatic insulin content, attenuation of insulin secretion, and glucose intolerance. Treatment of wildtype mouse islets with a low concentration of the SERCA inhibitor thapsigargin decreased the expression of cyclin D2, Pdx-1, Nkx6/1 and proinsulin.

Conclusion: ER stress during early postnatal life inhibits β-cell proliferation, possibly by reducing the expression of transcription factors required for β-cell proliferation and maturation, resulting in reduced beta cell mass and silent impairment of beta cell function. Later in life, these early postnatal defects give rise to overt diabetes. These findings may have important implications for the pathophysiology and treatment of T1D and T2D.

OP 18 Impact of exercise on metabolism

103

Mini-dose glucagon as a novel approach to prevent exercise-induced hypoglycaemia in type 1 diabetes

M. Rickels[1], S.N. DuBose[2], H. Wolper[3], E. Toschi[3], R. Beck[2], M. Cummins[4], B. Newswanger[4], M. Riddell[5];
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, [2]Jaeb Center for Health Research, Tampa, [3]Joslin Diabetes Center, Boston, [4]Xeris Pharmaceuticals, Austin, USA, [5]School of Kinesiology and Health Science, Muscle Health Research Center, York University, Toronto, Canada.

Background and aims: Patients with type 1 diabetes (T1D) who do aerobic exercise have a drop in blood glucose concentration that can result in hypoglycemia. Current approaches to prevent exercise-induced hypoglycemia include reduction in insulin delivery or ingestion of carbohydrates, but these strategies may still result in hypo- or hyperglycemia. We sought to determine whether mini-dose glucagon (MDG) given s.c. before exercise could prevent subsequent glucose lowering, and to compare the glycemic response to current approaches.

Materials and methods: We conducted a randomized, 4-period crossover trial involving 15 adults with T1D who exercised at ~55% VO_{2max} for 45 min with no intervention (control), 50% basal insulin reduction, 40 g oral glucose tabs, or 150 μg glucagon, all administered 5 min before exercise.

Results: During exercise, mean plasma glucose increased slightly with MDG compared to a decrease with control and insulin reduction, and with a greater increase with glucose tabs. Insulin levels were not different, while glucagon increased with MDG. Six subjects experienced hypoglycemia (< 70 mg/dl) during control and 5 during insulin reduction and none with glucose tabs or MDG; 5 subjects experienced hyperglycemia (≥250 mg/dl) with glucose tabs and 1 with MDG.

Conclusion: MDG may be more effective than insulin reduction for preventing exercise-induced hypoglycemia, and may result in less post-intervention hyperglycemia than ingestion of carbohydrate.

Evaluation of changes in cerebral oxyhaemoglobin during and after a 20-minute moderate-intensity cycling exercise: a near-infrared spectroscopy study

A. Tsubaki[1], S. Morishita[1], Y. Tokunaga[2], D. Sato[1], H. Tamaki[1], H. Onishi[1];
[1]Institute for Human Movement and Medical Science, Niigata University of Health and Welfare, [2]Department of Rehabilitation, Niigata Rehabilitation Hospital, Niigata, Japan.

Background and aims: Aerobic exercise is highly recommended for patients with type 2 diabetes mellitus to reduce or control their blood glucose level and body weight. During aerobic exercise, cortical activities change, and these changes can be measured noninvasively using near-infrared spectroscopy. Increased oxygenation (O_2Hb) of the cerebral prefrontal cortex during exercise and improved cognitive function following exercise have been observed. However, aftereffects of exercise on cerebral O_2Hb have not been well established. This study aimed to investigate changes in oxygenation during and after a 20-minute moderate-intensity cycling exercise.

Materials and methods: Twelve healthy volunteers (9 women, 3 men) participated in this study. After an incremental exercise test was performed on a cycle ergometer to determine the maximal oxygen consumption (VO_2peak), subjects performed a cycle ergometer exercise on a separate day. After a 3-minute pre-exercise rest, exercise was initiated at workloads corresponding to 50% VO_2peak for 20 minutes followed by a 15-minute post-exercise rest. O_2Hb levels in the right prefrontal cortex (R-PFC) and left prefrontal cortex (L-PFC) were measured using a near-infrared spectrometry system. O_2Hb levels of each area were expressed as changes from the mean pre-exercise rest phase values, and averaged values of the last 5 minutes during the exercise and post-exercise rest phases were calculated. One-way ANOVA was performed to compare these variables according to the factor of time.

Results: The O_2Hb level increased during the exercise and remained following exercise. However, the O_2Hb level changed throughout the experiment significantly in both areas (ANOVA, $p<0.01$). The O_2Hb level significantly increased from the pre-exercise rest phase to 6.60 ± 4.56 (a.u.) in the R-PFC (post-hoc test, $p < 0.01$) and to 8.50 ± 5.23 (a.u.) in the L-PFC (post-hoc test, $p < 0.01$) during the last 5 minutes of exercise. After the exercise, the O_2Hb level did not return to the pre-exercise value during the 15-minute post-exercise rest phase in both areas. The O_2Hb level in the L-PFC during the last 5 minutes of the post-exercise rest phase was 5.94 ± 4.65 (a.u.), which was significantly higher than that during the pre-exercise rest phase (post-hoc test, $p < 0.01$), and there was no difference in O_2Hb levels during exercise (post-hoc test, $p = 0.25$).

Conclusion: Oxygenation of the L-PFC persists at least 15 minutes after a 20-minute moderate-intensity aerobic exercise. The L-PFC plays an important role in improving cognitive task after moderate-intensity exercise. Our results suggest that improvement of cognitive function following exercise is based on increased oxygenation of the prefrontal cortex.

Effects of short-term exercise training on intestinal metabolism and gut microbiota in subjects with insulin resistance

K.K. Motiani[1], M.C. Collado[2], J.-J. Eskelinen[1], K.A. Virtanen[1], E. Löyttyniemi[3], S. Salminen[4], P. Nuutila[1], K.K. Kalliokoski[1], J.C. Hannukainen[1];
[1]Turku PET Center, University of Turku, Turku, Finland, [2]Turku PET Center, IATA-CSIC, Valencia, Spain, [3]Department of Biostatistics, University of Turku, Turku, [4]Functional Food Forum, University of Turku, Turku, Finland.

Background and aims: Insulin-stimulated intestinal glucose uptake is impaired in obese and insulin resistant subjects but ameliorates after weight loss. We have previously shown in healthy sedentary men that already short-term exercise training improves insulin-stimulated intestinal glucose uptake. Whether training improves intestinal metabolism also in insulin resistance is unclear. Here we studied the effects of two different exercise training methods (moderate intensity continuous training (MICT)) and high intensity interval training (HIIT)) on intestinal metabolism in insulin resistant subjects. We also studied the effects of training on gut microbiota.

Materials and methods: Twenty six, sedentary subjects (IFG/IGT n=9, T2D n=17; males/females 16/10, age 49[SD 4] years; BMI 30.5[SD 3]) were randomized into HIIT and MICT for two weeks including six training sessions. Of T2D subjects 13 used glucose lowering medication. Intestinal (duodenum, jejunum, colon) insulin-stimulated glucose uptake (GU) and fasting free fatty acid uptake (FAU) from circulation were measured using PET and [^{18}F]FDG and [^{18}F]FTHA respectively. Fecal samples were successfully collected from eighteen subjects before and after the exercise intervention 16S rRNA gene sequencing (MiSeq). The medication (metformin/no-metformin) and gender were used as additional factors in statistical analyses.

Results: Body adiposity associated positively with intestinal FAU and inversely with aerobic capacity. In the whole study group whole-body insulin

sensitivity associated inversely with *Ruminococcus (r= -0.49, p= 0.054)* and *Blautia (r= -0.53, p= 0.04)* genus. Intestinal GU associated positively with microbiota diversity and Bacteroidetes phyla and inversely with *Dorea* genus. Both HIIT and MICT improved whole-body insulin sensitivity with no group differences (27%,p<0.05) while VO_{2peak} improved only after HIIT (5% p=0.01). FAU decreased in jejunum only after MICT [-34%; p=0.02]. Training had no effect on intestinal insulin stimulated GU. Both training modes increased the Firmicutes/Bacteroidetes ratio at phylum level (p=0.04) and decreased the levels of *Clostridium* and *Blautia* genus (both p=0.04) without group differences. Training also tended to increase the level of Bacteroidetes phyla (decreased in obesity) (p=0.06) and decrease the levels of genus belonging to *Dorea* and *Ruminococcus* (both p≤0.07) previously related to irritable bowel disease.

Conclusion: Two weeks of MICT decreases fasting free fatty acid uptake in jejunum and both HIIT and MICT enhance the gut microbiota profile in insulin resistance.

Effect of aerobic and resistance exercise training on fat derived mesenchymal stromal cells (MSCs) in subjects with prediabetes

E. Nylen[1], N. Kundu[2], C.C. Domingues[2], E. Paal[1], P. Kokkinos[1], S. Sen[2];
[1]Veterans Administration Medical Center, [2]George Washington University, Washington, USA.

Background and aims: The effect of aerobic exercise has been studied extensively using various inflammatory biomarkers. Previously, we have shown endothelial progenitor cells (EPCs) can act as a strong cellular biomarker of endothelial function following aerobic exercise as an intervention. In this study, we are examining the effect of aerobic exercise on adipocyte derived Msenchymal Stem Cells (MSCs) as a cellular surrogate of fat activity and metabolism.

Materials and methods: In this study overweight and obese subjects (n=10) were enrolled in a 12 week exercise intervention study. The bi-weekly exercise sessions were supervised by a trained exercise physiologist and consisted of a 1 hour sessions that included warm-up and cool-down and 30 min of combined aerobic and resistance training at an exercise intensity of 50-80% of heart rate reserve. The patients were also encouraged to be physically active during the rest of the week. Subcutaneous abdominal fat biopsies were obtained and fat derived stromal cells were cultured in vitro for 2-3 weeks. MSCs were analyzed for mRNA gene expression (qRT-PCR) and cellular oxygen consumption rate (OCR) by SeaHorse, pre and post 12 week exercise.

Results: With the intervention, gene expression analysis showed glucose transporter, Glucose Transporter [GLUT1] (p= 0.04), mitochondrial gene Cytochrome C oxidase [COX4] (p= 0.01), antioxidants superoxide dismutase [SOD3] and Glutathione Peroxidase [GPX3] (p values= 0.04, 0.03, respectively) upregulated significantly with a trend of improvement in other antioxidants such as Catalase [CAT] (p values= 0.07) and reduced expression of inflammatory gene Cyclo-oxygenase [COX2] pre vs post exercise. Unexpectedly, oxygen consumption rate of MSCs between pre and post exercise group, however did not showed any significant difference

Conclusion: Preliminary outcome analysis of this on-going study indicates that aerobic exercise modifies gene expression of MSCs. Exercise appears to augment certain mRNA expressions such as, cellular glucose transporters and cellular anti-oxidants with reduction in inflammatory marker gene cyclo-oxygenase expression in spite of no significant change in IL6 or TNF alpha. Though, no significant difference was observed between oxygen consumption rates in the MSCs, significant upregulation of cytochrome C oxidase gene, COX4, gene indicates better mitochondrial function of fat derived mesenchymal stromal cells, post exercise intervention. Our studies elucidates critical genes and pathways that appears to respond in fat derived stem cells post exercise, that may form a basis for pharmaceutical intervention in a population who may be unable to exercise

Coordinated regulation of adipose tissue adrenergic- and non-adrenergic-mediated lipolysis during exercise in lean and obese individuals: the effect of exercise training

R. Stinkens[1], K. Verboven[2,1], D. Hansen[2,3], I. Wens[2], I. Frederix[3,4], B. Op 't Eijnde[2], J.W.E. Jocken[1], G.H. Goossens[1], E.E. Blaak[1];
[1]Dep. of Human Biology and Movement Sciences, Maastricht University Medical Center+, Maastricht, Netherlands, [2]Rehabilitation Research Center, Hasselt University, [3]Heart Center Hasselt, Jessa Hospital, [4]Health Care, Hasselt University, Hasselt, Belgium.

Background and aims: Adipose tissue dysfunction, which includes impairments in (adipose tissue) lipolysis, contributes to insulin resistance. Subcutaneous adipose tissue (SCAT) lipolysis in obesity is characterized by catecholamine resistance and an impaired ANP responsiveness. It remains to be established whether exercise training improves non-adrenergically-mediated lipolysis, next to the adrenergic pathway, in metabolically compromised conditions. The aim of the present study was to investigate the effect of local combined α- and β-adrenergic receptor blockade on SCAT lipolysis in obese insulin sensitive (IS), obese insulin resistant (IR) and age-matched lean IS men. Moreover, obese individuals underwent endurance and resistance exercise training to improve metabolic profile and (non-)adrenergically-mediated SCAT lipolysis.

Materials and methods: Abdominal SCAT lipolysis was investigated in 10 obese IS, 10 obese IR and 10 age-matched lean IS men using microdialysis in the presence or absence of local combined α- and β-adrenergic receptor blockade (100 μmol/l phentolamine and 100 μmol/l propranolol) at rest, during 60 min of low-intense (40% VO_{2max}) endurance-type exercise and recovery. Systemic responses were investigated using venous blood sampling. Obese individuals participated in a supervised, endurance and resistance exercise training intervention for 12 weeks (3 sessions/week) after which the microdialysis measurements were repeated in obese IR men.

Results: The exercise-induced increase in abdominal SCAT glycerol concentrations (expressed as total area under the curve) was more pronounced in obese IS (81%) and IR (34%) as compared to lean individuals (P_{group}=0.012). Abdominal SCAT lipolysis was significantly reduced (by ~40%, P=0.020) following local combined α-/β-adrenoceptor blockade in obese IS individuals only. Despite significant improvements in body composition, physical fitness and exercise-induced changes in circulating free fatty acids, lactate and adrenalin, exercise intervention did not significantly affect (non-)adrenergically-mediated lipolysis in abdominal SCAT of obese IR individuals.

Conclusion: Our findings indicate a major contribution of non-adrenergically-mediated lipolysis during exercise in abdominal SCAT of lean and obese individuals. Furthermore, a 12-week exercise training program improved metabolic profile and body composition in obese individuals, but did not affect abdominal SCAT lipolysis.

Two weeks of exercise training improves bone marrow metabolism

R.A. Ojala[1], K.K. Motiani[1], J.J. Eskelinen[1], E. Löyttyniemi[2], P. Nuutila[1,3], K.K. Kalliokoski[1], J.C. Hannukainen[1];
[1]Turku PET Centre, University of Turku, [2]Department of Biostatistics, University of Turku, [3]Department of Endocrinology, Turku University Hospital, Turku, Finland.

Background and aims: Bone marrow produces blood cells and acts as fat storage. Exercise training improves bone mineral density but little is known about the effects of training on bone marrow metabolism. We studied the effects of short-term high-intensity interval (HIIT) and moderate-intensity continuous training (MICT) on bone marrow metabolism.

Materials and methods: We randomized 54 sedentary subjects of whom 28 were healthy (BMI 26,1 (2,4); age 48 (5)) and 26 had insulin resistance (IR) (8 IGT/IFG and 18 T2D; BMI 30,1 (2,5); age 49(4)) into HIIT and MICT for two weeks. Thoracic vertebral (Th1-Th4), abdominal vertebral (Th12-L3), and femoral bone marrow glucose uptake (GU) were measured during euglycemic hyperinsulinemia and fasting free fatty acid uptake (FFAU) using PET.

Results: At baseline, GU was highest in abdominal vertebral, followed by thoracic vertebral, and lowest in femoral bone marrow (all $p<0.001$). FFAU was higher in abdominal vertebral and thoracic vertebral than in femoral bone marrow (both $p<0.001$). Femoral and abdominal vertebral bone marrow FFAU was higher in healthy compared to IR men ($p=0.02$ and $p=0.002$ respectively) and higher in females than males ($p<0.001$ and $p=0.02$ respectively). Training increased whole-body insulin sensitivity in the whole group and while both training modes increased aerobic capacity in healthy ($p=0.001$) only HIIT improved aerobic capacity in IR men ($p=0.0135$). Training improved femoral bone marrow GU but we found no statistically significant differences between training modes, IR and healthy men, or males and females. MICT decreased FFAU in abdominal bone marrow ($p<0.001$).

Conclusion: Bone marrow substrate uptake differs regarding anatomical region. Short-term training improves bone marrow metabolism in healthy and IR subjects.

OP 19 Novel therapies: future opportunities

109

Potent body weight loss, and therapeutic efficacy in a NASH animal model by a novel long-acting GLP-1/Glucagon/GIP tri-agonist (HM15211)

I. Choi, J. Lee, J. Kim, Y. Park, S. Lee, Y. Kim, S.-C. Kwon;
Hanmi Parmaceutical, Seoul, Republic of Korea.

Background and aims: Obesity and related complications are an increasing public health issue. Existing therapeutic options have limited effectiveness as well as requiring daily injections. Recent clinical and pre-clinical advances indicate that simultaneous targeting more than one GI hormone signaling pathway could lead to improved therapeutic efficacy with fewer adverse events. Thus, we have developed a long-acting GLP-1/glucagon/GIP triple-agonist, HM15211. HM15211 consists of a triple-agonist peptide (TA211) conjugated to the human aglycosylated Fc fragment via a short PEG linker. TA211 is a modified glucagon analog which leads to binding and activation of all three receptors (GLP-1R/glucagonR/GIPR). The human aglycosylated Fc fragment conjugated to TA211 could provide prolonged PK/PD properties. Here, we investigated in vitro properties and therapeutic efficacy of HM15211 for obesity and nonalcoholic steatohepatitis (NASH) in rodent disease models.

Materials and methods: To evaluate triple-agonistic property of HM15211, cAMP accumulation potency was evaluated in CHO cells stably expressing either the human GLP-1 receptor, the glucagon receptor, or the GIP receptor. For the obesity treatment study, diet-induced obesity (DIO) mice were chronically administrated with HM15211 over 4 weeks, and the body weight, food intake, as well as BG were monitored. At the end of treatment, liver TG and blood lipid profiles were determined. For energy expenditure measurement, each mouse was placed in cages for indirect calorimetry, followed by VO_2 and VCO_2 monitoring for 2 days. To evaluate the therapeutic potential treating NASH, methionine choline-deficient (MCD) diet mice, a well-established NASH model was utilized. After 4 weeks treatment, liver TG and the NAFLD activity score (NAS) were determined. Throughout all studies, liraglutide was used as comparative control.

Results: HM15211 induced intracellular cAMP accumulation via all three receptors with a high glucagon activity ratio. The potent glucagon action of HM15211 result in potent weight loss and improved lipid profiles by enhancing energy expenditure and lipid oxidation. In addition, balanced GLP-1/GIP action could neutralize the glucagon-induced hyperglycemic risk. In line with these results, 4 week treatment with HM15211 showed significantly improved BWL (~3.0 fold in DIO mice, ~2.4 fold in DIO rat compared to liraglutide) without hyperglycemia risk with similar food intake. In addition, liver TG and blood CHO level were significantly decreased. Of note, HM15211, but not liraglutide, significantly increased energy expenditure in DIO mice. According to RER (respiratory exchange ratio) value, enhanced energy expenditure by HM15211 primarily resulted from increased fat oxidation, confirming the glucagon action of HM15211 in obesity treatment. As to NASH treatment, HM15211 treatment reduced both liver TG and NAS (1.86 and 0 for liraglutide and HM15211, respectively) in MCD mice.

Conclusion: The unique GLP-1/glucagon/GIP activity of HM15211 could provide a favorable therapeutic profile as well as dosing convenience, compared to existing therapeutics in the treatment of obesity and obesity-related liver disease.

Weight loss unrelated to decrease in calorie intake after a single dose of a bispecific antibody to FGFR1/Klothoβ in obese subjects

P.S. Arora[1], C. Wong[1], A. Baruch[1], L. Chinn[1], A. Vaze[1], N. Lewin-Koh[1], L. Morrow[2], S. Chen[1], R. Boismenu[1];
[1]Early Clinical Development, Genentech, Inc., South San Francisco, [2]ProSciento, Inc., Chula Vista, USA.

Background and aims: BFKB8488A is a humanized, effector-less, bispecific antibody designed to activate the receptor for fibroblast growth factor 21 (FGF21) in adipose tissue, the FGFR1/Klothoβ complex. Preclinical studies demonstrated that BFKB8488A largely recapitulates the metabolic actions of recombinant FGF21 in rodents and non-human primates. This Phase 1, first-in-human study was performed with obese but otherwise healthy subjects. The primary objectives were safety, tolerability, and pharmacokinetics. Additionally, insulin, glucose, lipids, and other metabolic markers were measured.

Materials and methods: Seventy-one subjects were randomized 3:1 to receive a single subcutaneous injection of escalating doses of BFKB8488A or placebo into the abdomen or thigh. All subjects were confined to a Phase 1 unit and provided a weight-adjusted diet between Day -2 and Day 8; BFKB8488A was administered on Day 1.

Results: The mean age of subjects at baseline was 44.6 ± 11.8 years, and mean baseline weight was 99 ± 12.2 kg. Fifty-eight percent of subjects were male and 45% were of Hispanic ethnicity. Over a wide range of dose levels, BFKB8488A was generally well tolerated. The most common adverse event reported was nausea, which was dose-dependent. BFKB8488A exhibited non-linear pharmacokinetics, with greater than dose-proportional increases in exposures. A significant ($p < 0.01$) dose-dependent decrease in body weight was observed during the confinement period with minimal weight change in the placebo group or the lower dose groups (Table 1). Notably, there was no change in calorie consumption by a visual estimation of percent consumption of standardized meals or in appetite as assessed by a visual analogue scale during the confinement period. To further test the mechanism of BFKB8488A-derived weight loss, subjects completed a food preference survey. In line with previously reported preclinical studies with FGF21 mimetics, a trend towards reduced preference for sweet foods was seen. Substantial dose-dependent improvements in cardiometabolic parameters (decreases in insulin, LDL cholesterol, and triglycerides; increases in HDL cholesterol and adiponectin) were observed, with changes peaking between Days 14 and 21 and persisting for up to 8 weeks post dose.

Conclusion: A single subcutaneous dose of BFKB8488A caused weight loss unrelated to loss of appetite or calorie intake and induced long-lasting metabolic effects similar to those seen with FGF21 mimetics. BFKB8488A may have potential utility in the treatment of obesity-related metabolic disorders.

Table 1. Percent change in mean body weight from Days 1–8 by cohort.

	Weight (kg)			
Cohort	Screening Mean (SD)	Day 1 Mean (SD)	Day 8 Mean (SD)	Change (%), Days 1–8 Mean (SD)

REMD-477, a human glucagon receptor (GCGR) antibody, reduces daily insulin requirements and improves glycaemic control in people with type 1 diabetes

J. Pettus[1], D. Reeds[2], T. Santos Cavaiola[1], S. Boeder[1], M. Levin[1], E. Cava[2], D. Thai[3], J. Shi[3], H. Yan[3], E. Bautista[3], J. McMillan[3], R. Henry[1], S. Klein[2];

[1]UCSD, San Diego, [2]Washington University, St. Louis, [3]REMD Biotherapeutics, Camarillo, USA.

Background and aims: Studies conducted in rodent models of T1D have shown that glucagon receptor blockade normalizes plasma glucose concentration without the need for exogenous insulin.

Materials and methods: We conducted a randomized, double-blind, placebo (PBO) controlled trial in 21 subjects with T1D (8 men,13 women) to evaluate the effect of a single 70 mg SC injection of REMD-477, a human monoclonal antibody against the GCGR, on daily insulin requirements and glycemic control. After obtaining baseline insulin use and data from Continuous Glucose Monitoring (CGM), subjects were admitted to the Clinical Research Unit for 5 days. Insulin was provided by continuous IV infusion to maintain postabsorptive and postprandial plasma glucose between 90-120 mg/dl and <180 mg/dl, respectively. Standard meals were provided to ensure the same daily energy and macronutrient contents were consumed during the inpatient study. Drug/PBO was given on the second day of admission. The primary endpoint was the comparison between groups in the change in daily insulin requirements on day 4 from day 1.

Results: An interim analysis of the first 17 subjects found REMD-477 treatment reduced daily insulin use by 32% (4.2%, 60%) vs PBO on Day 4 (p=0.027). Average daily glucose assessed by CGM was 19 mg/dL (6.2, 31; p=0.006), and 26 mg/dL (8.2, 45; p=0.008) lower in the REMD-477 group than in the PBO group at Weeks 2 and 3 after treatment, respectively. Glucose time-in-range (70-180 mg/dL) for REMD-477 was 9.5% (2.7%, 16%; p=0.009) and 13% (1.9%, 25%; 0=0.026) greater in the REMD-477 group than in the PBO group during Weeks 2 and 3 after treatment, respectively. REMD-477 therapy was well tolerated and no episodes of severe hypoglycemia were noted.

Conclusion: These data demonstrate that a single SC injection of REMD-477 reduces daily insulin requirements while simultaneously improving glucose control, as measured by average glucose concentration and glucose time-in-range, without increasing hypoglycemia in subjects with T1D.

Beyond topline results for the oral (non-peptide) GLP-1R agonist TTP273 in type 2 diabetes: How much and when?

J.L.R. Freeman[1], I.M. Dunn[2], C. Valcarce[3];

[1]Clinical Development, vTv Therapeutics LLC, [2]Biometrics and Regulatory Affairs, vTv Therapeutics LLC, [3]vTv Therapeutics LLC, High Point, USA.

Background and aims: The widespread use of GLP-1 analogues/mimetics that provide glycemic control and weight loss may be hindered by the route of administration and by the high incidence of gastrointestinal side effects. TTP273 is an oral, non-peptide, GLP-1R agonist. The aims of this Phase 2 study were to demonstrate 1) competitive HbA_{1c} reduction, 2) weight loss, and 3) negligible GI side effects following 12 weeks of dosing with TTP273.

Materials and methods: Safety and efficacy were evaluated in a 12-week, multi-center Phase 2, double-blind, placebo-controlled study where 174 patients with Type 2 diabetes (T2DM) on stable doses of metformin were randomized to either placebo or TTP273 (150 mg once (QPM) or twice (BID) daily). Statistical analyses for topline results included Placebo (PBO)-subtracted change from baseline (LSM-CFB) for HbA_{1c} (primary endpoint) and body weight (secondary endpoint) as well as a post hoc concentration/effect analysis to evaluate the effect of exposure on efficacy.

Results: Baseline characteristics were well balanced amongst groups with an overall mean age of 56 years, mean HbA_{1c} of 8.6%, and mean BMI of 32 kg/m^2. TTP273 was well tolerated with no severe hypoglycemia Adverse Events

(AEs). The most common Treatment Emergent AEs was diarrhea (2%, 3% and 12% in PBO, 150mg QPM and 150mg BID, respectively), mostly mild in intensity, with only one subject discontinued due to mild diarrhea (150 mg BID). Less nausea was observed in active groups than placebo and the only incidence of vomiting occurred with placebo dosing. The once and twice daily treatment arms of TTP273 demonstrated placebo-subtracted decreases from baseline in HbA_{1c} and weight at 12 weeks of (i) 0.9 ± 0.2 % ($p<0.001$) and 0.7 ± 0.2 % ($p<0.001$), respectively, and (ii) 0.9 ± 0.5 kg ($p=0.08$) and 0.6 ± 0.5 kg, respectively. Subsequent concentration/effect analysis of completers reveals that lower doses demonstrated more pronounced effects for key efficacy endpoints. This observation is confirmed when correlating TTP273 plasma concentration with efficacy. Patients dosed with lower than 1.35mg/kg of TTP273 had greater efficacy with placebo-subtracted reductions from baseline in HbA_{1c} and body weight of 1.7% ($p<0.01$) and 3.7 kg ($p<0.05$), respectively, at 12 weeks.

Conclusion: All three aims of the study were achieved, suggesting that TTP273 can be efficacious without inducing the side effects of nausea and vomiting. Concentration/effect analysis suggests that lower doses showed more pronounced effects for key efficacy endpoints. Similar findings were observed in the Phase 2 study with our predecessor agonist (TTP054). This surprising result may be explained by two significant differences between TTP273 and GLP-1 that may reduce its effect/increase tolerance at higher exposure levels: 1) TTP273 can signal directly in the intestine (a response known to desensitize over time) and 2) TTP273 has a differential signaling pattern that does not signal through β-arrestin and seems to have sustained activation relative to GLP *in vitro*. These results support the conduct of additional clinical investigation using lower doses to evaluate the efficacy of TTP273.

IDegLira improves cardiovascular risk markers in patients with type 2 diabetes uncontrolled on basal insulin: analyses of DUAL II and DUAL V

T. Vilsbøll[1,2], T. Blevins[3], B.W. Bode[4], L.A. Leiter[5], N. Poulter[6], J. Thurman[7], B.F.R. Agner[8], L. Lehmann[8], E. Jaeckel[9];

[1]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, [2]Center for Diabetes Research, Gentofte Hospital, Copenhagen, Denmark, [3]Texas Diabetes and Endocrinology, Austin, [4]Emory University School of Medicine, Atlanta, USA, [5]University of Toronto, Toronto, Canada, [6]Imperial College London, London, UK, [7]SSM Medical Group, St. Charles, USA, [8]Novo Nordisk A/S, Søborg, Denmark, [9]Hannover Medical School, Hannover, Germany.

Background and aims: The efficacy and safety of insulin degludec/liraglutide (IDegLira) has been demonstrated in patients with type 2 diabetes (T2D) uncontrolled on basal insulin, with superior HbA_{1c} reductions vs. basal insulin. The cardiovascular (CV) benefit of liraglutide vs. placebo has also been shown in the LEADER CVoutcomes trial. This post-hoc analysis examined the effect of IDegLira vs. insulin degludec (IDeg; DUAL II) and vs. insulin glargine U100 (IGlar U100; DUAL V), both with metformin for 26 weeks, on CV risk markers.

Materials and methods: DUAL II was a 26-week, randomised, double-blind, treat-to-target trial; 413 patients with T2D (HbA_{1c} 7.5-10.0%) on basal insulin (20-40 U) and metformin with or without sulfonylurea/glinides were randomised 1:1 to once-daily IDegLira or IDeg (maximum dose 50 U). DUAL V was a 26-week, randomised, open-label, treat-to-target trial; 557 patients with T2D (HbA_{1c} 7.0-10.0%) treated with IGlar U100 (20-50 U) and metformin were randomised 1:1 to once-daily IDegLira or IGlar U100.

Results: In both trials, there was a greater decrease in systolic blood pressure with IDegLira (Table), and small but statistically significant increases in mean heart rate were observed with IDegLira vs. insulin comparators (both $p<0.001$; Table). IDegLira was associated with weight loss vs. weight gain with insulin comparators (estimated treatment difference [ETD] -2.5kg [-3.2; -1.8]$_{95\%CI}$ $p<0.0001$ and ETD: -3.2kg [-3.8; -2.6]$_{95\%CI}$ $p<0.05$ for DUAL II and DUAL V respectively). Lipid profile improved with IDegLira in both trials; total cholesterol and low-density lipoprotein (LDL) cholesterol were significantly lower vs. insulin comparators (Table). In DUAL II, apolipoprotein B (Apo-B) and brain natriuretic peptide (BNP) were significantly lower with IDegLira vs. IDeg (estimated treatment ratio [ETR] 0.92 [0.88; 0.95]$_{95\%CI}$ $p<0.0001$ and 0.66 [0.55; 0.79]$_{95\%CI}$ $p<0.0001$ respectively), while high-sensitivity C-reactive protein (hsCRP) was similar after 26 weeks of treatment (ETR 0.90 [0.78; 1.04]$_{95\%CI}$ p = non-significant [NS]).

Conclusion: In conclusion, IDegLira is associated with a general improvement in CV risk markers vs. basal insulin therapy after 26 weeks of treatment, which is likely attributable to the liraglutide component.

MEDI4166, a novel antibody (PCSK9)-peptide (GLP-1) fusion molecule: single-ascending-dose study in patients with type 2 diabetes

M. Jain[1], W. Cook[2], L. Morrow[3], M. Petrone[1], W. Pu[2], P. Ambery[1], B. Hirshberg[2], G. Carlson[4];

[1]MedImmune, Cambridge, UK, [2]MedImmune, Gaithersburg, [3]ProSciento, Inc., Chula Vista, [4]AstraZeneca, Gaithersburg, USA.

Background and aims: Glucagon-like peptide-1 (GLP-1) agonists are an attractive therapy for type 2 diabetes mellitus (T2DM), having proven effects on glycemic control and, for some, showing positive effects on cardiovascular (CV) outcomes. High-intensity statin therapy is recommended in T2DM patients with established CV disease (CVD) and those at increased CV risk (eg, LDL cholesterol [LDL-c] ≥100 mg/dL, family history of premature CVD). However, some T2DM patients at high CV risk may require additional lowering of LDL-c or may be intolerant to high-intensity statin therapy. Blockade of antiproprotein convertase subtilisin/kexin type 9 (PCSK9) has emerged as an effective method to lower LDL-c and to decrease risk of CV events by decreasing degradation of the LDL receptor. MEDI4166 is a novel antibody-peptide genetic fusion molecule comprising a PCSK9 antibody and a GLP-1 analogue linked to the *N* terminus of the antibody light chain by a peptide linker, and therefore has the potential to effectively lower glucose and LDL-c with a single molecule. This first-in-human study investigated the safety and pharmacokinetics (PK) of single ascending-doses of MEDI4166 in patients with T2DM.

Materials and methods: In this multicenter, double-blind, placebo-controlled, single-ascending-dose study, 40 adult T2DM subjects receiving metformin monotherapy and LDL-c ≥70 mg/dL were randomized to 1 of 5 cohorts receiving SC MEDI4166 or placebo (MEDI4166, $n = 6$; placebo, $n = 2$ in each cohort). MEDI4166 dose was increased by approximately 0.5 log fold increments between cohorts. After dosing on Day 1, subjects were followed for 6 weeks for safety, including immunogenicity (ADA) and PK. Pharmacodynamic (PD) measures (free PCSK9 levels and GLP-1 activity measured by GLP-1 receptor activation assay) were also assessed throughout the study.

Results: Of 40 randomized subjects, 39 completed the study. MEDI4166 was well tolerated; AEs occurred in 20 (66.7%) MEDI4166 subjects and 5 (50%) placebo subjects. GI symptoms were the most common treatment-related AE in both groups (MEDI4166: n = 5 [16.7%]; placebo: n = 3 [30%]); no dose-dependent relationship was observed. No significant laboratory, vital sign, or ECG abnormalities were identified. PK were nonlinear across the dose range and allowed for weekly dosing. Of 30 subjects, 8 (27.6%) receiving MEDI4166 showed treatment-induced or treatment-boosted ADA response. No significant change in PK or PD was observed between ADA-positive and ADA-negative subjects. Free PCSK9 levels declined in a dose-dependent manner (Figure). GLP-1 activity was confirmed at the higher doses by GLP-1 receptor activation bioassay.

Conclusion: In this single-ascending-dose study in patients with T2DM, MEDI4166 had an acceptable safety profile, and dual target engagement was observed. Further investigation of this molecule in a multiple-ascending-dose study is ongoing.

Understanding of the mechanisms involved in vascular leakage in diabetic retinas with glial activation: a proteomic approach

O. Simo-Servat[1], J. Sundstrom[2], C. Hernández[1], M. García-Ramírez[1], T.W. Gardner[3], R. Simó[1];
[1]Vall d'Hebron Reserach Institute and CIBERDEM, Barcelona, Spain, [2]Penn State Hersey Medical Center, Hersey, [3]Kellogg Eye Center. University of Michigan, Ann Arbor, USA.

Background and aims: Glial activation (GA) or reactive gliosis is an early event in the pathogenesis of diabetic retinopathy (DR), which participates in early events of microvascular impairment. One of the most important features in the early stages of DR is the disruption of the blood-retinal barrier (BRB), which results in vascular leakage. BRB is maintained by cell-cell adhesions and cell-matrix adhesion, with the support of glial cells. Most of the cellular and molecular knowledge on the mechanisms of BRB breakdown comes from experimental models and little is known regarding the underlying mechanisms linking GA and vascular leakage by examining the retinas from diabetic patients. In the setting of a general study aimed at identifying new therapeutic targets for early stages of DR by means of a proteomic approach using human retinas, we have herein focused on proteins that are involved in the maintenance of BRB.

Materials and methods: Human retinal samples were obtained from 10 type 2 diabetic donors without (n=5) and with (n=5) GA, and 5 non-diabetic donors (control group). All groups were matched by age. Diabetic donors did not presented microcirculatory abnormalities in the ophthalmoscopic examinations performed during the two years before death. Retinal lysates from each group were pooled and run on an SDS-PAGE gel. Bands were analyzed sequentially by LC/MS using an Orbitrap Mass Spectrometer.

Results: The retinas with GA presented a significant increase of ERM (ezrin, radixin moesin) proteins and fragments of Rho GDP dissociation inhibitor (RhoGDI) compared with those without GA or the control group ($p<0.01$). ERM proteins regulate cytoskeleton conformation directly (by binding actin filaments) and indirectly (binding RhoGDI, which allows Rho GTPases activation). These pathways when activated induce endothelial contractility, favouring intercellular junction opening and paracellular permeability, which is one of the mechanisms implicated in vascular leakage. On the other hand, isoform A2 of the tight junction protein ZO-2 and the proteins talin-1 and talin-2 (which participate in focal adhesions between the endothelial cells and the extracellular matrix) were significantly reduced in retinas with GA compared with those without GA or controls ($p<0.01$). These findings were associated with a significant increase in albumin and immunoglobulins ($p<0.01$), thus indicating the presence vascular leakage.

Conclusion: ERM proteins and RhoGDI are increased in early stages of DR and could be implicated in vascular leakage by inducing changes in the cytoskeleton conformation of endothelial cells. The reduction in ZO-2, talin-1 and talin-2 proteins observed in retinas from patients with GA could contribute to vascular leakage by means of loss of tight junction and focal adhesions. However, further studies are required for elucidating the mechanisms involved in the regulation of these proteins, as well as their role in the crosstalk between GA and vascular leakage.

The evaluation of ocular changes in prediabetic individuals

A. Sokolowska-Oracz, P. Piatkiewicz;
Medical University of Warsaw, Warsaw, Poland.

Background and aims: Prediabetes is the major risk factor for type 2 diabetes, but the prediabetic state itself is also associated with classical macrovascular

and microvascular complications. Studies indicate that other ophthalmic abnormalities can develop during the stage of prediabetes, however data on the occurrence of ocular changes are limited. The aim of our study was to evaluate ocular changes in prediabetic individuals.

Materials and methods: 60 subjects (40 women, 20 men) aged 37-78, with impaired fasting glucose and/or impaired glucose tolerance, were enrolled in the study and compared to 30 volunteers (20 women, 10 men) without prediabetes, aged 39-75. Both groups underwent a complete physical examination, biochemical tests and ophthalmic examination: visual acuity testing, colour vision and letter contrast sensitivity tests, anterior and posterior segment evaluation, intraocular pressure measurement, fundus photographs and optical coherence tomography. Prediabetic patients underwent examinations twice: on the 1st visit and on the 2nd visit after 9 months period.

Results: The prediabetic group was characterised by statistically higher level of HbA1c, HOMA-IR, increased occurrence of BMI≥25 kg/m² and hypertension as compared to healthy controls (table). Patients with IFG and/or IGT had increased prevalence of cataract as compared to control group (31.7% vs 6.7%; p<0.05), significantly higher incidence of corneal surface disorders (21.7% vs 3.3%; p<0.05), posterior vireous detachment (PVD) (76.7% vs 55%; p<0.05), arteries narrowing (81.7% vs 63.3%; p<0.05) and hypertension angiopathy (70% vs 36.7%; p<0.05). There was also difference in prevalence rate of retinopathy between prediabetic and control groups (8.3% vs 3.3%; NS), as well as acquired colour vision impairment (8.3% vs 0%, NS), but results were not statistically significant. We found association between increased rate of arteries narrowing and hypertension. Higher BMI (≥25 kg/m²) was independent factor of PVD in prediabetic patient. There was association between cataract and older age. Comparing visit 1 to visit 2 statistically significant differences were observed in fasting plasma glucose level (106.9 vs 104.1 mg%; p<0.05) and HbA1c (5.80 vs 5.99%; p<0.05). There was no statistically significant difference in ocular changes, however increased prevalence of retinopathy signs were noted on examination after 9 months period (8.3% vs 12.7%; NS).

Conclusion: Prediabetic subjects present increased prevalence of ocular disorders as compared to healthy population. Results of this study indicate that prediabetic state is the independent risk factor of several ophthalmic complications, although many patients with prediabetes have other features of metabolic syndrome. The regular ophthalmic monitoring seems to be essential at the stage of prediabetes in order to detect ocular abnormalities and identify individuals at risk of other diabetic complications.

Parameter	Visit 1 Prediabetic group (n 60)	Visit 1 Control group (n 30)	P value	Visit 2 Prediabetic group (n 55)	P value

Topical administration of Dipeptidyl Peptidase 4 (DPP-4) inhibitors prevents retinal neurodegeneration in experimental diabetes

C. Hernández, P. Bogdanov, C. Solà-Adell, J. Sampedro, O. Simó-Servat, M. García-Ramírez, R. Simó;

Vall d'Hebron Research Institute, Barcelona, Spain.

Background and aims: Glucagon-like peptide 1 (GLP-1) and GLP-1 receptor (GLP-1R) have recently been found in the human retina, and topical administration of GLP-1R agonists prevents retinal neurodegeneration and vascular leakage in experimental diabetes. Since GLP-1 is rapidly degradable by DPP-IV it is possible that DPP-IV inhibitors can enhance the beneficial effects of retinal GLP-1. The main aims of the present study are: a) To determine whether the topical administration (eye drops) of DPP-IV inhibitors is able to reduce GLP-1 degradation, thus preventing retinal neurodegeneration and vascular leakage in db/db mice; b) To investigate whether, as occurs with GLP-1, the reduction of glutamate mediated excitotoxicity is among their mechanisms of action.

Materials and methods: Eye-drops containing sitagliptin, saxagliptin or vehicle were administered for 14 days (twice per day) to db/db mice (n=10 per group). Neurodegeneration was assessed by measuring glial activation (GFAP-IF), the rate of apoptosis (TUNEL) and ERG (Ganzfeld) features. Vascular leakage was examined by assessing the extravasated albumin. The retinal content of GLP-1 and its downstream effector AMPc were assessed before and after the administration of DPP-IV inhibitors. Glutamate and GLAST were determined by HPLC and IF, respectively.

Results: Topical treatment with saxagliptin or sitagliptin prevented glial activation, apoptosis and vascular leakage induced by diabetes. In addition, they also significantly prevented the diabetes induced functional abnormalities in the ERG. A significant increase of GLP-1 was found after treatment with either saxagliptin or sitagliptin. Furthermore, a dramatic prevention of GLAST downregulation induced by diabetes was found, which resulted in a significant reduction of extracellular concentration of glutamate. All these effects were observed without any change in blood glucose levels and, therefore, they cannot be attributed to changes in the diabetic milieu. However, activation of other pathways unrelated to GLP-1R cannot be ruled out.

Conclusion: Topical treatment with DPP-IV inhibitors prevents the neurodegenerative process, as well as vascular leakage, that occur in early stages of diabetic retinopathy (DR). This non-invasive treatment can be contemplated (alone or in combination with GLP-1) as a new strategy for treating DR.

Growth factor gene therapy as a therapeutic approach for diabetic retinopathy

R. Araújo;

CEDOC-Chronic Diseases Research Center, Lisbon, Portugal.

Background and aims: Diabetic retinopathy (DR) is a serious complication of diabetes mellitus (DM) and its prevalence has been increasing worldwide. Early diabetic retinopathy is characterized by a loss of pericytes from retinal capillaries, the appearance of acellular capillaries and microaneurysms, and a breakdown of the blood-retinal barrier. In later stages, this can evolve into the proliferative phase in which there is neovascularization of the retina and vision loss. Aside from pathological damage, treatments such as laser photocoagulation and vitrectomy, applied in advanced disease stages, have severe side effects and further damage the visual field. Additionally, protein-based anti-angiogenic agents used to delay progression of neovascularization require frequent local administration, increasing the risk of retinal detachment, vitreous hemorrhage, and cataract formation. Studies in human diabetic retinas have revealed an imbalance between pro-angiogenic factors such as the vascular endothelial growth factor (VEGF) and placental growth factor (PlGF) and anti-angiogenic factors, like the pigment epithelial-derived factor (PEDF). This imbalance favoring pathological angiogenesis contributes to DR, and can thus constitute a therapeutic target for gene therapy, recently shown to be an adequate intervention for long-term treatment of several retinal pathologies. We have previously described the effectiveness of PEDF gene therapy using the episomal vector pEPito in human RPE cells and in the retina of diabetic mice after a single subretinal injection. PEDF gene therapy reduced DR hallmarks such as microglia reactivity, VEGF expression and the levels of glucose transporter GLUT1, but we have not explored its effect on the retinal vasculature. In this context, our first aim is to evaluate the effect of PEDF gene therapy on DR vasculature, followed by targeting of pathological angiogenesis. For this we have designed a siRNA targeting PlGF due to its role in pathological angiogenesis. In the future, we intend to evaluate the impact of a dual gene therapy approach promoting PEDF overexpression and simultaneously PlGF suppression to treat DR.

Materials and methods: Human retinal pigment epithelial (RPE) cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM). A small interfering RNA (siRNA) corresponding to PlGF mRNA and a scrambled siRNA (scRNA) were used to transfect cells. PlGF, PEDF and VEGF mRNA were quantified by real-time polymerase chain reaction (RT-PCR).

Results: PlGF production is described in the literature as generally occurring in the choroid, but we have analysed the RPE and found these cells to produce and secrete PlGF. To inhibit PlGF, we have tested a range of concentrations of siRNA and our data shows a reduction of PlGF transcripts of up to 50% in RPE cells, after 24 and 48 h of incubation. The maximum inhibition was achieved with a siRNA concentration of 50 pmol/ml. To determine if PlGF inhibition had an effect on the secretion role of RPEs, we analysed the transcript levels of VEGF and PEDF and found that the suppression of PlGF gene *in vitro* had no effect in the production of these factors. Based on these results we have designed an expression system for a shRNA targeting PlGF to assess in vitro and in vivo feasibility of our approach.

Conclusion: Jointly, the previous results from PEDF-pEPito and the efficient knockdown of PlGF in RPE cells, suggest a possible therapeutic potential of gene therapy with a strategy based on simultaneous PEDF overexpression and PlGF inhibition, for the rescue of DR.

Diabetic retinopathy after Roux-en-Y gastric bypass

L.R. Madsen[1,2], T. Bek[3,2], B. Richelsen[4,2];

[1]Department of Endocrinology, Aarhus University Hospital, [2]Department of Clinical Medicine, Aarhus University, [3]Department of Ofthalmology, Aarhus University Hospital, [4]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark.

Background and aims: Roux-en-Y gastric bypass (RYGB) is a effective and durable treatment of obesity. Furthermore, it leads to improvements in or even remission of obesity-related comorbidities such as type 2 diabetes mellitus (T2D). Ophthalmological screening including retinal photo imaging is a cornerstone in preventing eye-threatening complications in individuals with T2D, but there is no consensus on whether or not to end this screening process after surgical remission of T2D. Moreover, rapid deterioration in diabetic retinopathy due to immediate glucose control following RYGB is still a concern. We aimed to evaluate diabetic retinopathy in T2D individuals following RYGB compared to non-operated T2D individuals, and to investigate if there is cause of concern regarding deterioration following RYGB.

Materials and methods: I this clinical trial, 96 RYGB operated obese individuals with T2D were matched on age, gender, and current BMI with 47 non-operated T2D individuals. After induction of cytoplegia and mydriasis fundus photography was performed. We used the Wisconsin Epidemiologic Study of Diabetic Retinopathy (modified by the ETDRS Report 12) to grade retinal lesions from 1-6 (6= most severe). In 49 of the RYGB operated individuals pre-surgical fundus photography were available and assessed as described above. Moreover, HbA_{1c}, BP, anthropometrics, diabetes duration, and smoking were recorded.

Results: Median time since RYGB was 6.1 years (IQR: 5.4; 7.0). Forty-nine of the 96 RYGB operated individuals fulfilled the criteria for T2D remission (HbA_{1c} < 48 mmol/mol and no antidiabetic medication). Group characteristics are presented in table 1. A total of 103 individuals had no detectable retinal changes (grade 1), 25 had grade 2 retinopathy, and 15 had more advanced retinopathy (grade 3-6). The latter were merged due to small numbers in each group. Only 2% of the RYGB individuals with remission displayed severe retinopathy, compared to 11% in the T2D control group and 19% among RYGB individuals still suffering from T2D (p-value <0.001). When adjusting for smoking, gender, and diabetes duration in a multiple regression model the RR of any diabetic retinopathy was 0.67 (0.65; 0.69) and 0.33 (0.14; 0.74) for RYGB individuals with and without remission, respectively. Only one out of 23 RYGB individuals with T2D remission displayed deterioration (from 0 to 1 in grading), while 4 out of 26 RYGB individuals without remission displayed deterioration (p=0.20).

Conclusion: In our cohort RYGB operated both with and without T2D remission have a significant reduced risk of diabetic retinopathy compared to non-RYGB matched controls. RYGB does not seem to provoke deterioration of retinopathy despite rapid improvement in glucose levels.

Clinical characteristics of patient groups (RYGB with diabetes remission, RYGB without diabetes remission and non-RYGB T2D controls)

	n	Age at examination (years)	Women (%)	HbA1c (mmol/mol)	Duration of T2D (years)	Body mass index (kg/m2)	smokers (%)	MAP (mmHg)

Topical administration of somatostatin and brimonidine in the early stages of diabetic retinopathy: results of the EUROCONDOR study

R. Simó[1], F. Bandello[2], C. Egan[3], J. García-Arumí[4], J. Gibson[5], J. Grauslund[6], S.P. Harding[7], G.E. Lang[8], P. Massin[9], E. Midena[10], P. Scanlon[11], B. Ponsati[12], M. Porta[13], C. Hernández[1], J. Cunha-Vaz[14];

[1]Vall d'Hebron Research Institute, Barcelona, Spain, [2]University Vita-Salute, Milano, Italy, [3]University College London, London, UK, [4]Vall d'Hebron University Hospital, Barcelona, Spain, [5]Aston University, Birmingham, UK, [6]University of Southern Denmark, Odense, Denmark, [7]University of Liverpool, Liverpool, UK, [8]University of Ulm, Ulm, Germany, [9]Lariboisière Hospital, Paris, France, [10]University of Padova, Padova, Italy, [11]Gloucestershire Hospitals NHS Foundation Trust, Cheltenham, UK, [12]BCN Peptides, Barcelona, Spain, [13]University of Torino, Torino, Italy, [14]AIBILI, Coimbra, Portugal.

Background and aims: To present the initial results of the first clinical trial using neuroprotective agents (somatostatin 0.1% [SST] and brimonidine tartrate 0.2% [BMN]) administered in eye drops for treating diabetic retinopathy (DR). The primary objective was to assess whether these neuroprotective drugs, administered topically, were able to prevent or arrest neurodegeneration.

Materials and methods: 449 type 2 diabetic patients with either no visible DR (ETDRS level <20; n=193) or only early stages of DR (ETDRS level 20-35; n=256) were enrolled in a prospective (2 years of follow-up), multicenter and randomized clinical trial. Primary outcome: changes in the implicit time assessed by mfERG. Exclusion criteria included retinal diseases associated with neurodegeneration, renal failure, and HbA1c > 10% in the previous 6 months before recruitment. Eye drops were administered twice per day in each eye. Color fundus photography, SD-OCT and mfERG were performed every 6 months and graded by a centralized reading center.

Results: Similar clinical features and degree of metabolic control (HbA1c) were observed among the three arms (placebo, SST and BMN) at baseline and during follow-up. We did not observe differences at the end of follow-up regarding new cases of neurodegeneration among the three arms. However, in those patients in whom neurodegeneration was already detected at baseline (≥6 abnormal hexagons for implicit time in mfERG), SST and BMN arrested the progression of neurodegeneration in comparison with placebo (p<0.01). No effect was observed in the development or progression of microvascular disease assessed by ETDRS scale. The overall drop-out rate was 23%. The

only remarkable secondary effect was the high local side effects reported with BMN, which significantly contributed to the drop-outs.

Conclusion: Topical administration of SST and BMN are useful in arresting the progression of neurodegeneration in early DR. The high rate of local adverse effects observed with BMN seems a limiting factor for using this drug as chronic treatment. Further studies with SST with more longer follow-up in order to determine whether this beneficial neuroprotective effect results in reduction of microvascular disease are needed.

Irisin improves endothelial dysfunction by upregulating haeme oxygenase-1/adiponectin axis in perivascular adipose tissue in obese mice

X. Sun[1], N. Hou[1], F. Han[2];
[1]Department of Endocrinology, Affiliated Hospital of Weifang Medical University, [2]Department of Pathology, Affiliated Hospital of Weifang Medical University, Weifang, China.

Background and aims: Irisin is secreted by myocytes and has been proposed to improve endothelial function in obesity. However, most of the studies about endothelial function are concerned with the conditions of removed perivascular adipose tissue (PVAT). With regard to PVAT that could exacerbate endothelial dysfunction in obese subjects, it is important for us to know whether irisin also has a protective effect on endothelial function by regulating the PVAT function. Therefore, the objective of this study was to determine whether irisin could improve endothelial dysfunction via regulation of the heme oxygenase-1(HO-1)/adiponectin axis in PVAT in obesity.

Materials and methods: C57BL/6 mice were fed with a regular or a high-fat diet (HFD) with or without treatment with irisin. Endothelial function was determined by measuring endothelium-dependent vasodilatation of the thoracic aorta with or without PVAT (PVAT+ or PVAT−). Nitric oxide (NO) in the aorta was determined. Protein levels of HO-1 and adiponectin were detected by western blot. UCP-1, Cidea, and TNF-α gene expression in PVAT were tested by real-time PCR.

Results: Treatment of HFD mice with irisin improved glucose and lipid metabolism (glucose, 98.5 ± 4.6 mg/dl vs. 108.1 ± 4.7 mg/dl; triglycerides, 109.48±11.35 mg/dl vs. 132.13±8.86 mg/dl; NEFA 0.90 ±0.18 mmol/L vs. 1.20 ± 0.20 mmol/L; $P < 0.01$), reduced plasma levels of TNF-α (29.02 ±2.56 pg/ml vs. 40.22±4.87 pg/ml, $P < 0.01$), malondialdehyde (5.14±0.33 ± 0.60 umol/L vs. 6.63±0.76 umol/L, $P < 0.01$) and enhanced plasma adiponectin levels (15.86±1.04 ug/ml vs. 12.60±1.68 ug/ml, $P < 0.01$). The presence of PVAT significantly impaired endothelial function in the HFD mice (maximum vasodilatation rate, 38.3% ± 3.3% vs. 46.3% ± 3.5%, $P < 0.05$). Treatment of HFD mice with irisin restored this impairment with a similar response to both the PVAT+ ring and the PVAT− ring in vivo (60.2% ± 3.9% vs. 65.3% ± 4.0%, $P > 0.05$) or ex vivo (59.1% ± 3.6% vs. 60.7% ± 3.6%, $P > 0.05$). Incubated aortic rings (PVAT-) with PVAT-derived conditioned medium (CM) from HFD mice impaired endothelial function in control mice (40.5% ± 3.4% vs. 86.4% ± 4.3%, $P < 0.05$). This impairment was prevented by incubating the aortic rings (PVAT-) from HFD mice with PVAT-derived CM from irisin (59.1% ± 4.2% vs. 45.6% ± 3.6%, $P < 0.05$). However, the beneficial effects above were partly attenuated in the presence of HO-1 inhibitor (stannous protoporphyrin) and adiponectin receptor blocking peptide (ACRP-30 N-20). Treatment of HFD mice with irisin significantly increased NO levels, protein levels of HO-1 and adiponectin, mRNA expressions of UCP-1 and Cidea, and decreased superoxide production and TNF-α expression in PVAT ($P < 0.05$).

Conclusion: Irisin improved endothelial function by modulating HO-1/adiponectin axis in PVAT in HFD-induced obese mice. These findings suggest that regulating PVAT function may be a potential mechanism by which irisin improves endothelial function in obesity.

Identification of the transcription factors ZBTB7A and MAZ as novel regulators of gene expression in endothelial cells of diabetic origin

H. Rafehi, J. Okabe, M. Ziemann, A. Kaspi, A. El-Osta;
Department of Diabetes, Monash University, Melbourne, Australia.

Background and aims: Endothelial dysfunction is a critical early step in the development of atherosclerotic plaques in type I diabetes (T1D). While protein

level changes in this transition to a pro-inflammatory state have been well characterised, the transcription events involved, including histone modifications, remain poorly defined. Histone deacetylase (HDAC) inhibitors, which paradigmatically activate gene expression via pharmacological inhibition of HDAC enzymes (acetylation writers), are protective against the development of T1D in animal models. Recent evidence shows anti-inflammatory effects of HDAC inhibitors in healthy primary human aortic endothelial cells (HAECs), though the effects in diabetic HAECs have yet to be defined. We compared and contrasted genome-wide trends in transcriptional regulation in HAECs derived from healthy and T1D individuals following HDAC inhibition.

Materials and methods: We studied genome-wide gene expression (RNA-seq) and histone acetylation (chromatin immunoprecipitation, ChIP-seq) profiles of HAECs derived from healthy and T1D individuals, before and after exposure to the HDAC inhibitor suberanilohydroxamic acid (SAHA, n=3, conc. 2 μM, for 12 or 16h).

Results: SAHA induced potent increases in histone acetylation at gene promoters in diabetic HAECs, consistent with the paradigmatic action of HDAC inhibitors. In contrast, SAHA mediated unexpected increased and decreased promoter acetylation in healthy HAECs, which correlated with gene expression. Transcription factor (TF) analysis identified that gene promoters that are deacetylated in healthy cells, but acetylated in diabetic cells by SAHA, were enriched for the TFs ZBTB7A and MAZ, suggesting altered activities of these proteins in diabetic HAECs. Though not previously linked to diabetes, *ZBTB7A* deletion in some cancers is implicated in the expression of glycolytic genes, while MAZ regulates the expression of insulin via its interaction with the IDDM2 locus. Furthermore, analysis of TF binding sites from the ENCODE projects shows that up to 90% of ZBTB7A binding sites intersect with MAZ genome-wide, suggesting that the two proteins work either in synergy or in opposition to regulate gene expression. Validation by RNA-seq of healthy and diabetic HAECs cultured in hyperglycaemic conditions for 15 days identified suppression of multiple genes regulated by ZBTB7A and MAZ, including *TRIB1*, an inflammatory regulator implicated in atherosclerosis and hepatic glucose homeostasis. *TRIB1* expression was reactivated by SAHA in diabetic HAECs. Furthermore, re-analysis of public data identified strong binding of ZBTB7A at the promoter of *TRIB1* that correlated with low gene expression, and reactivation *TRIB1* expression following *ZBTB7A* deletion in human erythroblasts. This implicates suppression of *TRIB1* mediated by increased ZBTB7A binding at the gene promoter in diabetic cells and on exposure to hyperglycemic conditions.

Conclusion: Our data predicts a role for the transcription factors ZBTB7A and MAZ in altered gene expression following chronic hyperglycaemic. Further work, including ZBTB7A and MAZ ChIP and deletion studies in hyperglycaemic cells, are in progress to validate these findings.

Strict glycaemic control improves arterial stiffness, left ventricular myocardial deformation, endothelial glycocalyx and oxidative stress in type 2 diabetic patients

G. Pavlidis[1], I. Ikonomidis[2], F. Kousathana[1], E. Maratou[3], H. Triantafyllidi[2], M. Varoudi[2], J. Lekakis[2], G. Dimitriadis[1], V. Lambadiari[1];

[1]2nd Dpt of Internal Medicine, Research Institute and Diabetes Center, Medical School, National and Kapodistrian University of Athens, Attikon University Hospital, [2]2nd Dpt of Cardiology, National and Kapodistrian University of Athens, [3]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications, Athens, Greece.

Background and aims: Poor glycaemic control affects myocardial function even subclinically. We investigated whether changes in arterial stiffness, left ventricular (LV) myocardial deformation and endothelial glycocalyx, an index of the microvasculature function, relate to changes of oxidative stress in patients with poorly controlled type-2 diabetes before and after strict glycaemic control.

Materials and methods: In 100 poorly controlled diabetic patients (age:51 ±12 years) and 25 controls matched for age and sex and no atherosclerotic risk factors, we measured at baseline and 6 months after strict glycaemic control: a)pulse wave velocity(PWVc-Complior), central systolic blood pressure(cSBP), augmentation index(AI), b) LV longitudinal strain(GLS), systolic(LongSr)and diastolic(LongSrE)strain rate, peak twisting(pTw), peak twisting(pTwVel)and peak untwisting velocity(pUtwVel)using speckle tracking echocardiography. The degree of LV untwisting was calculated as the percentage difference between peak twisting and untwisting at mitral valve opening(MVO) (%dpTw−Utw_{MVO}),at peak(%dpTw-Utw_{PEF})and end of early LV diastolic filling(%dpTw-Utw_{EDF}), c)perfused boundary region(PBR) of the sublingual arterial microvessels(ranged from 5-25μm) (Sideview,Darkfield imaging,Glycocheck). Increased PBR equals reduced endothelial glucocalyx thickness, d)Flow mediated dilatation(FMD) of the brachial artery and percentage difference of FMD(FMD%), e) malondialdehyde(MDA) and protein carbonyls(PCs) plasma levels.

Results: Diabetic patients had higher AI(26±15 vs. 19.4±14.7%), PWV(12±3 vs. 8.8±1.3m/sec), cSBP(133±20 vs. 119±18mmHg), PBR(2.1±0.3 vs 1.89 ±0.1μm)and lower GLS(-15,4±3 vs. -18±3%), LongSr(-0.8±0.1 vs. -0.96 ±0.2 l/sec), LongSrE(0.83±0.3 vs. 1.2±0.3 l/sec)vs. controls ($p<0.05$ for all comparisons). Intensive 6-months antidiabetic treatment reduced HbA1c(8.8 ±2 vs. 7±1.3%, $p<0.05$), PWV(12±3 vs. 11.1±2.7m/sec), PBR(2.1±0.2 vs. 2 ±0.2μm, $p<0.05$), MDA(1.29±0.8 vs. 1.1±0.9nM/L)and PCs(0.015±0.08 vs. 0.012±0.05nmol/mg protein) while increasing pUtwVel(-92±40 vs. -102 ±36deg/sec), %dpTw−Utw_{MVO}(28±9 vs. 37±11), %dpTw-Utw_{PEF}(46±19 vs. 59±18) and FMD%(8.1±5 vs. 12.8±8)($p<0.05$). Post treatment, reduced PWV positively correlated with PBR(r=0.50)and negatively with Longsr E(r=-0.60) and %dpTw-Utw_{EDF}(r=-0.56) respectively. PBR negatively correlated with pUtwVel(r=-0.43)($p<0.05$). PCs levels at baseline were negatively related to the difference of GLS(r=-0.53).MDA difference correlated with the difference of PWV(r=0.52) ($p<0.05$).

Conclusion: Intensified glycaemic control for a six-months period improves arterial stiffness, LV myocardial strain, twisting-untwisting velocity and glycocalyx thickness in previously poorly-controlled diabetic patients, probably by reducing oxidative stress. Strict glycaemic control can reverse early subclinical myocardial and endothelial dysfunction.

Clinical Trial Registraion Number: NCT03010956

Effects of a 6-month liraglutide treatment on arterial stiffness, left ventricular myocardial deformation and oxidative stress in newly diagnosed type 2 diabetic patients

V.A. Lambadiari[1], I. Ikonomidis[2], G. Pavlidis[1], F. Kousathana[1], E. Maratou[3], H. Triantafyllidi[2], M. Varoudi[2], J. Lekakis[2], G. Dimitriadis[1];

[1]2nd Dpt of Internal Medicine, Research Institute and Diabetes Center, Medical School, National and Kapodistrian University of Athens, Attikon University Hospital, [2]2nd Dpt of Cardiology, National and Kapodistrian University of Athens, Attikon University Hospital, [3]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications, Athens, Greece.

Background and aims: Glucagon-like-peptide-1 analogs (GLP-1R) have recently exhibited a beneficial cardioprotective effect in high cardiovascular risk type-2 diabetes patients possibly by reducing the burden of atherosclerosis. We investigated whether liraglutide modifies arterial stiffness and left ventricular (LV) myocardial deformation, in relation to changes in oxidative stress after a short-term 6-month treatment period

Materials and methods: We examined 60 newly diagnosed, treatment-naive patients with type 2 diabetes. 30 patients were randomized to receive liraglutide, and 30 subjects received metformin for 6 months. We measured at baseline and after 6-months of treatment: a) carotid-femoral pulse wave velocity (PWV-Complior ALAM), central systolic blood pressure (cSBP) and augmentation index (AI), b) LV longitudinal strain (GLS), and strain rate (GLSR), peak twisting (pTw), peak twisting velocity (pTwVel) and peak untwisting velocity (pUtwVel) using speckle tracking echocardiography. The degree of LV untwisting was calculated as the percentage difference between peak twisting and untwisting at mitral valve opening (MVO) (%dpTw −UtwMVO), at peak (%dpTw-UtwPEF) and end of early LV diastolic filling

(%dpTw-UtwEDF) c) Flow mediated dilatation (FMD) of the brachial artery and percentage difference of FMD (FMD%) after hyperaemia d) malondialdehyde (MDA) and protein carbonyls (PCs) plasma levels for the assessment of oxidative stress status.

Results: After a short, six-month treatment period, subjects on liraglutide achieved a reduction in PWV (11.8±2.5 vs. 10.3±3.3m/sec) and MDA (1.47 ±0.2 vs. 0.89±0.2nM/L) in parallel with an increase of pUtwVel (-97±49 vs. -112±52deg,), %dpTw-UtwMVO (31±10 vs. 40±14), %dpTw-UtwPEF (43±19 vs. 53±22) and FMD% (8.9±3 vs. 13.2±6), ($p<0.05$ for all comparisons). There were no statistically significant differences in subjects that received metformin. At baseline, reduced GLS related positively to elevated HbA1c (r=0.39), PWV (r=0.47) and negatively to FMD% (r=-0.29). GLSR was inversely related to HbA1c (r=-0.35) and PWV (r=-0.50) while cSBP was associated with %dpTw−UtwMVO (r=0.29) ($p<0.05$ for all associations). In all subjects, PCs levels at baseline were negatively related to the difference of GLS (r=-0.53) post treatment and the difference of MDA was associated with the difference of PWV (r=0.52) ($p<0.05$ for all associations) after 6-month treatment

Conclusion: Six-month treatment with liraglutide improves arterial stiffness, LV myocardial strain, twisting and untwisting likely by reducing oxidative stress in newly diagnosed treatment-naive type-2 diabetic patients

A pilot study of the effect of relaxing and active music on attention and short term memory in patients with type 2 diabetes compared to control

M.I.M. Szabo[1], M. Tilinca[1], T. Szöllősi[2], J.P. Szabo[3], B. Máté[1], O. Erdélyi[4]; [1]Diabetes, medical and Pharmaceutical University Tg Mures, Romania, [2]Diabetes, Emergency County Clinic Tg Mures, [3]Medical and Pharmaceutical University Tg Mures, Romania, [4]Emergency County Clinic Tg Mures, Tg Mures, Romania.

Background and aims: There is emerging evidence, that music, beside its stress lowering effect, has an impact on cognition, memory or attention in healthy subjects, in elderly, and in patients with cardiovascular disease. Diabetes is well known to be associated with lower cognitive performances, higher degree of dementia. Our aim was to study the effects of music in type 2 diabetes patients on short term memory and attention, a field not yet investigated

Materials and methods: We conducted a two-day, interventional, within-subject design study comparing the effect of relaxing and active music on metabolic parameters, attention and short term memory. 89 patients with only Metformin treated type 2 diabetes and 67 age and gender matched control subjects were included. We used Pierrot Toulouse test, and word recognition test (40 words read during music, recognized afterwards from a list of 80 words) to evaluate attention and short term memory. The music listened was 20 minutes allegro part of the K448 sonata, and 20 minutes andante part of the K331 sonata of Mozart. Participants performed the attention and short term memory test in two different days. Cognitive tests, blood pressure and blood glucose measurement were performed before and after each 20 minutes music intervention, having 30 minutes period between the two types of music

Results: Mean age was 62.06 ± 10.96 years in the control group and 63.82 ± 9.716 years in the type 2 diabetes group. Baseline attention performance was better in control group compared to type 2 diabetes (50.45±15.89% vs. 39.48±13.96%, p = .000). There was no difference in short term memory at baseline. Attention performance improved significantly in type 2 diabetes, under both music interventions (active and relaxing music: 46.92 ± 12.65% vs. 39.48 ± 13.96%, p =.042 and 55.04 ± 14.62% vs. 42.77± 13.71%, p = .002). Improvement was the same in the two groups (performance difference 7.44±8.51 % and 12.27 ± 6.75% in type 2 diabetes vs 8.32 ± 12.64% and 10.68 ± 10.81% in control). Female participants had a better attention performance improvement under active music then male (9.9 ± 8.4% vs. 2.5 ± 8.6%, p=.002). Neither of the music interventions had any effect on short term memory, except in the female participants, were under relaxing music remembered word count was better (62.5 ±10.1 vs.57 ±10.2, p=.04). Neither of the music intervention did influence blood glucose levels. Relaxing music lowered systolic blood pressure significantly more in the type 2 diabetes group (-9.06 ± 3.6 vs. 3.44 ± 4.3, p=.000)

Conclusion: In our study attention was improved, but not short term memory, by both type of music in type 2 diabetes group, and female patients were more sensitive to the effect of music.

Altered olfactory-induced brain activation as an early manifestation of cognitive decline in patients with type 2 diabetes

Z. Zhang[1], X. Wang[2], X. Zhang[2], D. Zhu[1], B. Zhang[2], Y. Bi[1]; [1]Department of Endocrinology, Drum Tower Hospital Affiliated to Nanjing University Medical School, [2]Department of Radiology, Drum Tower Hospital Affiliated to Nanjing University Medical School, Nanjing, China.

Background and aims: Although type 2 diabetes mellitus (T2DM) has been reported to be associated with olfactory dysfunction and increased risk of cognitive decline, it is still unknown whether olfactory neural circuit abnormalities involve cognitive impairment in T2DM. This study thus aimed to examine the comprehensive association of olfactory-induced brain activation with cognitive and metabolic parameters in patients with T2DM.

Materials and methods: Seventy-seven subjects with normal cognition including 41 patients with T2DM (24 males, age: 51±9 years, education degree:14±3 years) and 36 non-diabetic control (NC) subjects (18 males, age: 50±7 years, education degree: 14±4 years) were enrolled. Detailed clinical and biochemical information were collected and neuropsychological assessment was performed. Meanwhile, a computerized battery of olfactory function tests assessing odor threshold, identification and memory was investigated. Neural activation intensity in response to lavender odor stimuli was assessed with high-resolution functional magnetic resonance imaging (fMRI) scanning. Regions of interest (ROIs) were extracted from one-sample t-test of NC group in task fMRI for resting-state functional connectivity (RSFC) analysis between two groups.

Results: The olfactory threshold score was significantly lower in patients with T2DM than NC group (8.7±3.2 vs. 11.0±2.5, p=0.001). Task fMRI scanning demonstrated the olfactory-induced bilateral brain activation of the olfactory circuit in all subjects. Between-group analysis revealed the activation in bilateral orbitofrontal cortex (OFC) and the reduced activation in left hippocampus and left parahippocampus in patients with T2DM. Interestingly, we observed decreased RSFC between the OFC and all ROIs of the olfactory circuit including amygdala, entorhinal cortex and hippocampus in patients with T2DM compared to NC group. Further correlation analysis showed the disrupted connectivity in the olfactory circuit was positively associated with impairment in cognitive domains including memory, attention and executive functions accessed by neuropsychological tests in patients with T2DM. Remarkably, patients with poor pancreatic islet function, as measured by fasting and 2h postprandial C-peptide and insulin, had significantly lower olfactory and cognitive test scores. The 2h postprandial insulin of patients also positively correlated with the RSFC between left hippocampus and left OFC (r = 0.378, p = 0.027).

Conclusion: This is the first study to indicate that the alteration of olfactory-induced brain activation is present before clinical symptoms of cognitive decrements in patients with T2DM. Our study also raises the importance that the improvements of pancreatic islet function might also be beneficial for preserving cognition in diabetes.

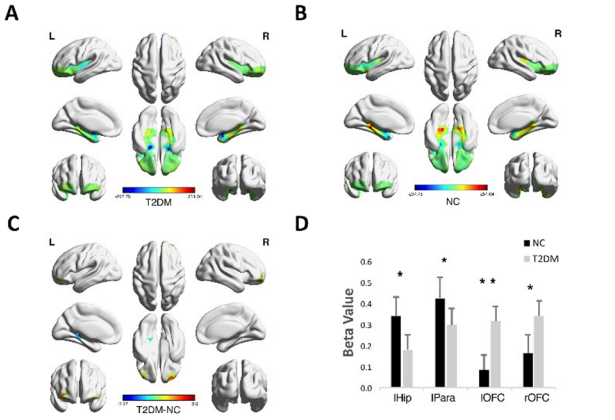

Figure: Olfactory-induced brain responses of patients with T2DM (A) and normal control(B). Independent two-sample T-test result (C) indicating significant altered brain activation in patients with T2DM compared to NC group. (T maps threshold at P<0.05 with AlphaSim corrected). Beta value differences between two groups (D) of the left hippocampus, left parahippocampus, left and right orbitofrontal cortex (lHippo: left hippocampus; lPara: left parahippocampus; lOFC: left orbitofrontal cortex; rOFC: right orbitofrontal cortex).

Clinical Trial Registration Number: NCT02738671

OP 22 Animal models of metabolic disease

127

Genetically modified human Mesenchymal Stromal Cells (MSCs) help improve glucose homeostasis by reducing inflammation and promotes browning of visceral fat

S. Sen, N. Ahmadi, N. Kundu, C.C. Domingues;
George Washington University, Washington, USA.

Background and aims: MSCs are multipotent cells that can home-in to a site of inflammation. Upregulation of specific antioxidants in MSCs reduces intracellular inflammation and ROS formation in a hyperglycemic condition. Hypothesis: Antioxidant over-expressed MSCs will reach fat depots, reduce local & systemic inflammation and improve glucose homeostasis in diet-induced obese (DIO, 60% and 45% fat diet) hyperglycemic mouse models.

Materials and methods: We used GFP-containing adenoviral constructs to upregulate intracellular (SOD1, SOD2, Catalase) and extracellular (SOD3) antioxidants in human adipose-derived MSCs. GFP-Null transduced MSCs were used as control. The modified MSCs were delivered intraperitoneally in 60% and 45% DIO mice.

Results: In-vitro, SOD2 (mitochondrial anti-oxidant) upregulation showed reduced inflammatory markers IL6 and TNFa mRNA while PCG1A mRNA (a gene upstream of UCP1), upregulated. SOD2 upregulated MSC delivery in both DIO models demonstrated improved glucose tolerance test (GTT) at week 4 compared to SOD1-MSC and Null-MSC (control). Catalase-MSC delivery not only improved GTT but also improved insulin tolerance test (ITT) in 60% DIO mice. Interestingly, RT-PCR of pericardial fat showed significant increases in mRNA expression of both UCP1 (25-100,000-fold) and PRDM-16 (2-10-fold) in both DIO mice models that received antioxidants upregulated MSCs, compared to mice receiving Null MSCs. For omental fat, an increase in mRNA expression of UCP1 was observed in 60% fat DIO mice (1,000-6000 fold) for SODs 1-3 and catalase, while for 45% DIO mice only those receiving SOD1 & SOD2 upregulated MSCs presented UCP1 mRNA upregulation (1,000 to 11,000-fold). Omental Fat histology showed less hyperplastic fat with SOD2 and Catalase-MSCs. UCP1 staining of omental fat was also positive with SOD2-MSC. Inflammatory molecules such as IL-6 and TNF alpha levels by ELISA, were reduced with SOD2-MSC in 60% DIO mice model.

Conclusion: We conclude that delivery of antioxidant upregulated MSCs to the inflamed adipocyte depots in diabetic DIO models appear to upregulate UCP1, PGC1 alpha and PRDM-16 in visceral fat while reducing systemic inflammatory markers. This synergestic action via reduction of inflammation and "browning of white fat", may explain improvements noted in GTT and ITT. Delivery of modified MSC is a novel & robust therapeutic tool that may help improve glucose homeostasis in diabetes and obesity.

The novel obesity gene Ifi202b induces Zfp423 and reduces browning and body temperature

M. Stadion[1,2], K. Schwerbel[1,2], A. Graja[3], T.J. Schulz[3,2], H. Vogel[1,2], A. Schürmann[1,2];
[1]Department of Experimental Diabetology, German Institute of Human Nutrition Potsdam-Rehbruecke (DIfE), Nuthetal, [2]German Center for Diabetes Research (DZD e.V.), Neuherberg, [3]Department of Adipocyte Development and Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke (DIfE), Nuthetal, Germany.

Background and aims: Obesity results from a constant and complex interplay between environmental stimuli and predisposing genes. Recently, we identified the transcriptional modulator Ifi202b as putative obesity gene by positional cloning. Ifi202b is expressed in insulin-sensitive tissues of New Zealand

Obese mice - predominantly in white adipose tissue - but is absent in the lean C57BL/6J strain. This study aimed to validate Ifi202b as obesity gene and to clarify how it induces fat mass expansion.

Materials and methods: To investigate the impact of Ifi202b on adipocyte function and metabolism, it was overexpressed in 3T3-L1 preadipocytes and in C57BL/6J mice. B6-Tg(Ifi202b) and B6-wt mice were kept on a high-fat diet and body composition, adipose tissue function and insulin sensitivity were analyzed.

Results: Ifi202b overexpression in 3T3-L1 preadipocytes resulted in accelerated adipogenesis as marked by higher expression levels of Pparg, Fabp4, Glut4 and Plin1 as well as by elevated triglyceride storage capacity. In vivo, Ifi202b expression led to increased body fat mass with hypertrophic adipocytes, reduced isoprenaline-inducible lipolysis, increased expression of the transcription factor Zfp423 and white-selective genes (Tle3, Tcf21), and decreased expression of thermogenic genes (e.g. Prdm16, Cidea, Ucp1). Furthermore, Ifi202b transgenic mice exhibited lower body temperature, elevated liver fat accumulation, and systemic insulin resistance.

Conclusion: In summary, our findings provided direct evidence for the crucial role of Ifi202b as obesity gene, as it induced adipocyte differentiation and hypertrophic adipose tissue expansion accompanied by increased whitening and decreased browning. We hypothesize that Ifi202b determines white adipocyte identity which is at least in part mediated via the induction of Zfp423.

Circulating exosomal miRNAs mediate tissue cross-talk during development of glucose intolerance in mice

C. Castaño[1,2], S. Kalko[2], L. Brugnara[1,2], A. Novials[1,2], M. Parrizas[1,2]; [1]CIBERDEM, [2]IDIBAPS, Barcelona, Spain.

Background and aims: Maintenance of glucose homeostasis is a complex task that requires the coordinated action of many tissues. In addition to hormones and other soluble factors, cells communicate by releasing exosomes, small vesicles enriched in microRNAs (miRNAs) that are detected circulating in blood and other biological fluids. Importantly, these circulating exosomes can be captured by acceptor cells, where the miRNAs they contain induce transcriptomic changes, thus mediating intercellular communication. We hypothesize that the profile of exosomal miRNAs found in blood represents the contribution of many tissues and depends on the physiological context of the organism. Therefore, we focused on determining the changes induced by an obesogenic diet in the profile of exosomal miRNAs, and exploring the role of circulating exosomes in the establishment of glucose intolerance in mice.

Materials and methods: C57BL6/J male mice were fed either standard chow or a high-fat diet (HFD) to render them glucose intolerant. Exosomes were isolated from plasma by centrifugation, and western blotting demonstrated enrichment of the exosomal marker CD63. Exosomal miRNAs were profiled by real-time RT-PCR. Control mice were injected intravenously with exosomes isolated from plasma of control and HFD mice. Glucose tolerance and insulin sensitivity were determined by IGTT and ITT respectively. Blood and tissues were extracted for posterior RNA analysis.

Results: The profiling of 378 miRNAs shows increased levels of liver-enriched microRNAs such as *miR-122* and *miR-192* (19-fold and 7-fold respectively, $p<0.05$) in exosomes isolated from plasma of HFD mice as compared with control mice, thus indicating that development of glucose intolerance is associated with a modification of the population of circulating exosomes. Surprisingly, continued injection of exosomes isolated from HFD mouse plasma into control mice being fed standard chow results in induction of glucose intolerance and insulin resistance. Bioinformatics analyses using IPA software identified the PPAR family of transcription factors and other regulators of lipid metabolism as the main targets of the miRNAs significantly increased in HFD exosomes. We studied gene expression of candidate genes in insulin-sensitive tissues. Accordingly, the liver of exosome-treated mice showed decreased expression of genes associated with *de novo* lipogenesis including *pparg* and *ppara*, as well as the igf-1 signaling pathway. Moreover, the white adipose tissue (WAT) of exosome-treated mice displayed increased expression of adipogenic genes and no changes in the expression of inflammatory mediators, in contrast with the expression profile observed in WAT of HFD mice. Finally, addition of a short-term HFD to exosome-treated mice resulted in an exacerbation of the phenotype of glucose intolerance.

Conclusion: Our data shows that an obesogenic diet causes glucose intolerance and modifies the miRNA content of circulating exosomes. Transmission of the phenotype of glucose intolerance by exosomes suggests that circulating exosomes are not only a reflection of the pathology, but also active players on its development. Therefore, directed manipulation of circulating exosomes and their miRNA content emerges as a novel avenue for the treatment of diabetes.

Increasing GLP-1 levels is a route to improve adipose tissue angiogenesis, contributing to better metabolic outcome

T. Rodrigues[1], D. Marques[1], I. Neves[1], H. Eickhoff[1,2], C. Carrêlo[1,3], D. Ribeiro[1], B. Martins[3], C. Fontes-Ribeiro[3], S. Silva[3], R. Seiça[1], P. Matafome[1,4]; [1]Laboratory of Physiology, Faculty of Medicine, University of Coimbra, Coimbra, [2]Obesity Center, Hospital da Luz, Setúbal, [3]Laboratory of Pharmacology and Experimental Therapeutics, Faculty of Pharmacy, University of Coimbra, [4]Department of Complementary Sciences, Instituto Politécnico de Coimbra, Coimbra, Portugal.

Background and aims: Vascularization is a crucial process in adipose tissue expansion and in its metabolic and secretory functions, improving insulin sensitivity and the metabolic outcome. Incretin-based therapies are known to improve the metabolic homeostasis and we hypothesized that such effect could include the modulation of adipose tissue angiogenesis. Thus, using animal models of increased glucagon-like peptide-1 (GLP-1) levels and the adipose tissue angiogenic assay, our aim was to assess the pro-angiogenic effects of GLP-1 in adipose tissue.

Materials and methods: We used two different animal models of increased GLP-1 levels: rats treated with the GLP-1 mimetic Liraglutide and rats submitted to metabolic surgery. For Liraglutide in vivo studies, 14 week male Wistar and non-obese type 2 diabetic Goto-Kakizaki (GK) rats were injected twice a day with liraglutide (200μg/Kg s.c.) during 14 days. For sleeve metabolic surgery studies Wistar and GK were used as control groups and high-fat diet-fed GK rats divided in 3 groups: GK without surgery intervention (GKHFD), GKHFD with sleeve gastrectomy (GKHFDSl) and GKHFD with sham surgery (GKHFDSh). Besides tested for fasting glycemia (6h) and insulin tolerance [intraperitoneal insulin tolerance test (IPITT)], both animal models were also analysed for the angiogenic mechanisms in the periepididymal adipose tissue. For the adipose tissue angiogenic assay (ex vivo studies), adipose tissue from 4 week old normal Wistar rats was collected and cut into very small pieces (~1mm^3). Explants were then embedded in collagen matrix and incubated for 5 days in EGM- 2 MV, BulletKit (Lonza, Switzerland) with or without liraglutide (50nM) and exendin-3 (GLP-1R antagonist 300nM).

Results: Both animal models showed improved insulin sensitivity and fasting glycemia. Liraglutide treatment upregulated adipose tissue angiogenic pathways in diabetic rats by increasing the levels of VEGFR2, Tie-2 and FGFR, as well as HIF2alpha levels and eNOS, which are involved in the activation of angiogenic pathways and modulation of the vascular function. Moreover, sleeve metabolic surgery also improved adipose tissue angiogenic markers (CD31, FGFR, VEGF and Ang-2) and vascular function (eNOS). In the adipose tissue angiogenic assay, liraglutide did not result in significantly higher area of vascularization, but dramatically increased vessel density in a GLP-1R-independent manner.

Conclusion: Therapies leading to increased GLP-1 levels result in improved metabolic profile, possibly resulting from better adipose tissue vascular remodelling and function. Future studies will reveal the mechanisms of GLP-1-induced angiogenesis and vascular remodelling in adipose tissue.

Reduced insulin secretion in a diet-induced glucose intolerance susceptible mouse model is coupled with increased CD36 and triglycerides in the beta cells

A. Asai[1,2], M. Nagao[1,3], T. Tsuduki[4], T. Miyazawa[2], J.L.S. Esguerra[3], L. Eliasson[3], H. Sugihara[1], S. Oikawa[1];

[1]Endocrinology, Diabetes and Metabolism, Nippon Medical School, Tokyo, [2]Food and Health Science Research Unit, Tohoku University, Sendai, Japan, [3]Islet Cell Exocytosis, Lund University, Malmö, Sweden, [4]Laboratory of Food and Biomolecular Science, Tohoku University, Sendai, Japan.

Background and aims: To study the polygenic etiology and pathophysiology of type 2 diabetes, we recently established two mouse lines with high and low susceptibility to high fat diet (HFD)-induced glucose intolerance by selective breeding; designated *s*electively bred *d*iet-induced *g*lucose intolerance-*p*rone (SDG-P) and -*r*esistant (SDG-R), respectively. We previously demonstrated that the pancreatic islets from SDG-P mice showed lower glucose- and KCl-stimulated insulin secretion (GSIS/KSIS) when compared to those from SDG-R mice. Meanwhile, the islets from SDG-P mice showed higher gene expression of Cd36 than those from SDG-R mice. CD36 (also referred to as fatty acid translocase) is known as a key molecule in fatty acid influx in various types of tissues, while lipid accumulation-induced dysfunction (so-called "lipotoxicity") is known to contribute to the decline of islet insulin secretion in type 2 diabetes. Thus, CD36 is a candidate factor to explain the observed differential GSIS/KSIS response between the islets from SDG-P and SDG-R. We therefore aimed to investigate CD36 expression and lipid accumulation in the islets of SDG-P and SDG-R mice.

Materials and methods: Pancreatic islets were isolated from SDG-P and SDG-R mice by collagenase digestion. Gene and protein expression levels in the islets were evaluated by quantitative PCR and Western blotting, respectively. To determine the intracellular triglyceride (TG) content, total lipid was extracted from the islets and the fatty acid content in the TG fraction was analyzed by gas-liquid chromatography. Values of $p<0.05$ were considered as statistically significant by Student's *t* test.

Results: We found elevated Cd36 mRNA level in the SDG-P mouse islets compared to those from SDG-R (1.7-fold, n=6, p=0.002) even at 5 weeks of age, without HFD feeding. This was confirmed at the protein level, in which CD36 protein was 2.2-fold higher in the islet of SDG-P mice (vs SDG-R, n=6, p<0.001). The higher Cd36 gene expression in SDG-P mouse islets was sustained up to 10 weeks of age, including 5-week HFD feeding in the end of the period. Flow cytometric analysis revealed that CD36 protein was predominantly expressed in the β cells of the islets. Concomitant with the high CD36 expression, intracellular TG content was increased in the islets of SDG-P mice (1.6-fold vs SDG-R, n=6, $p=0.02$).

Conclusion: Our results strongly support the involvement of CD36 in lipid accumulation in islet β cells. Excessive fatty acid influx and the consequent lipid accumulation in pancreatic islets via hereditary higher CD36 expression may play an important role in the lower insulin secretion response and the pathogenesis of impaired glucose tolerance in SDG-P mice.

The effect of dicarbonyl stress in the development of kidney dysfunction in metabolic syndrome

H. Malinska[1], M. Hüttl[1], I. Markova[1], O. Oliyarnyk[1], J. Trnovska[1], V. Škop[1], P. Kačer[2], O. Šeda[3], L. Kazdova[1], M. Haluzik[1];

[1]Institute for Clinical and Experimental Medicine, [2]University of Chemistry and Technology, [3]Charles University, First Faculty of Medicine, Prague, Czech Republic.

Background and aims: Dicarbonyl stress plays an important role in the pathogenesis of microvascular diabetic complications through the development of renal dysfunction preceding advanced glycation end products formation. In renal cells, toxic dicarbonyl metabolites like methylglyoxal inhibit electron respiratory chain leading to mitochondrial dysfunction, protein structure modifications which in turn affects their function. Methylglyoxal can also affect different signaling pathways associated with vascular complications in kidney on transcriptomic levels. In our study, we investigated the effect of methylglyoxal on metabolic, transcriptomic and proteomic profile in the context of the development of kidney impairment in an experimental model of metabolic syndrome.

Materials and methods: Dicarbonyl stress was induced by intragastrical administration of methylglyoxal (3x/ week in dose 0.5 mg/kg b.wt.for 4 weeks) in a strain of hereditary hypertriglyceridaemic rats with insulin resistance and fatty liver (HHTg). Transcriptome assessment in kidney cortex was performed using microarray, urine proteome and metabolome were evaluated by mass spectrometry methods.

Results: Methylglyoxal administration aggravated glucose intolerance ($AUC_{0\text{-}120}$ $p<0.05$), increased plasma glucose (8.8±0.2 vs 7.1±0.2 mmol/l, $p<0.01$) and insulin (0.515±0.030 vs 0.246±0.026 μmol/l, $p<0.05$). Compared to controls, methylglyoxal-treated rats exhibited significantly higher levels of microalbuminuria (42.8±7.3 vs 13.8±2.9 mg/g creatinine, $p<0.01$) and urine lactate ($p<0.05$). Targeted proteomic analyses revealed increase in urine secretion of proinflammatory parameters (MCP-1, IL-6, IL-8), specific collagen IV fragments (endostatin), alpha1-antitrypsin and extracellular matrix proteins (heparan sulphate). Urine metabolomic biomarkers in methylglyoxal-treated rats were mainly associated with impairment of membrane phospholipids (MDA, 8-isoprostane, 4-hydroxynonenal). Decreased level of reduced glutathione (-30%, $p<0.01$) together with decreased activity of glutathione-dependent antioxidant enzymes worsened oxidative and dicarbonyl stress and can contribute to the impairment of kidney function. Methylglyoxal administration elevated relative expression of glyoxalase 1 ($p<0.05$), which is involves in methylglyoxal degradation. Comparative transcriptomic analysis in kidney cortex identified 96 genes differentially expressed (FDR < 0.05) after methylglyoxal administration. Network analysis revealed overrepresentation of genes in excessive oxidative stress and proinflammatory signaling pathways and inhibition of angiogenesis suggesting its contribution to renal fibrosis.

Conclusion: Our results support a key role of dicarbonyl stress in the pathogenesis of renal microvascular complications in early phases of development. At transcriptomic level methylglyoxal activated oxidative and proinflammatory pathways and inhibited angiogenesis. Its proinflammatory effects were further supported by urine metabolomic analysis.

Aberrant brain functional connectivity linking insulin resistance to depression

C. He, F. Su, L. Gong, C. Xie;

Neurology, Department of Neurology, Affiliated ZhongDa Hospital, School of Medicine, Southeast University, Nanjing, China.

Background and aims: Type 2 diabetes mellitus (T2DM) often comorbid with major depressive disorder (MDD), but how T2DM and MDD are pathologically connected at the neural network level is poorly understood. A reasonable starting point regarding this field is the common pathophysiological mechanism shared by the two diseases, and brain insulin resistance (IR) reprents a promising target. Wihtin the pathway of IR, the importance of *mTOR* has been demonstrated. Furthermore, ventral striatum (VS), a region which is sensitive to the insulin levels, shows altered function in the context of both IR and depression, thus the VS network represents a promising phonetype to reveal the interactions between T2DM and MDD.

Materials and methods: Forty-nine MDD patients and 37 well-matched healthy control (HC) subjects were recruited and underwent a resting-state functional magnetic resonance imaging (R-fMRI) scan. Whole exome sequencing of *mTOR* gene were conducted, and 56 single nucleotide polymorphisms (SNPs) entered the further gene association analyses after quality control. Socres of Hamilton Depression Rating Scale (HAMD-24) were used as phenotypes to select *mTOR* SNP with behavioral significance, and the selected SNPs were used in the next genetic-imaging analyses. Seed-based connectivity analyses were conducted to construct ventral striatum functional connectivity (VSFC) network. Disease-by-genotype interaction analysis was performed to investigate the influence of *mTOR* on VSFC to illustrate how the genetic variation modified the performance of depression.

Results: Indicated by the gene association analyses, rs2275527 showed significantly influence on the performance of HAMD-24 (P = 0.013). Compared with HC participants, the VSFC network was widely decreased in patients with MDD. The further genetic-imaging analyses suggested the main effect of rs2275527 on VSFC network was located in left orbital frontal cortex, anterior insular and bilateral superior temporal gyrus. The rs2275527-by-disease interactions on VSFC network were mainly detected in regions including medial prefrontal cortex (mPFC) and bilateral caudates. Interesting, the VSFC in *mTOR* GG carriers was similar between HC and MDD group, but the VSFC was significant decreased in MDD compared to HC subject with *mTOR* A+ carriers. Furthermore, left VSFCs in mPFC and left caudate were positively related to the severity of depression in MDD group (mPFC, r = -0.289, P = 0.007, P_{FDR} = 0.042; Caudate, r = -0.5, P = 0.0001, P_{FDR} = 0.0006). The results were similar on the right VSFC network.

Conclusion: The IR risk gene jointed with depression influence the VSFC network. The alteration of VSFC in mPFC and caudates would predict the severity of depression in IR population. These findings extended our understanding about bidirectional associations between T2DM and depression. More importantly, this study provide new insight for further exploration of IR risk on brain function and may become useful for early identification of depression in T2DM patients.

Depressive symptoms and related factors in elderly diabetic patients at a national geriatric hospital

H.T.V. Vu[1], H.T. Nguyen[2], T.X. Nguyen[3], T.A. Le[4];

[1]Hanoi Medical University, [2]Department of Gerontology, Hanoi Medical University, [3]Outpatient Department, National Geriatric Hospital, Hanoi, [4]Department of Endocrinology, Nghe An Endocrinology Hospital, Nghe An, Viet Nam.

Background and aims: Depressive symptoms and diabetes are both increasing and worse in the elderly population. Diabetes complicates depressive symptoms which are conversely harmful to diabetic outcomes. The aim of the study was to evaluate the presence of depressive symptoms and the clinical variables associated with depressive symptoms in elderly diabetic patients.

Materials and methods: A cross-sectional study was conducted among diabetic patients aged ≥60 years old admitted to a National Geriatric Hospital from October 2015 to October 2016. Depressive symptoms were assessed by using the Geriatric Depression Scale (GDS).We obtained information on

socio-demographic, medical history, glycaemic control (fasting plasma glucose and HbA_{1c}), daily activities (Activities of Daily Living - ADL and Instruments Activities of Daily Living - IADL scale) and fall risks (the Time Up and Go test). Chi-square (χ^2) statistics and logistic regression were used to analyse the collected data.

Results: 412 diabetic patients were recruited with ages ranging between 60 and 91 years (average age 71.9 ± 7.63 years). 327 (79.4%) patients were categorized according to having depressive symptoms and the group aged 70 - 80 years old had the highest rate of depressive symptoms (141 patients, 43.1%). The proportion of participants with mild, moderate and severe depression symptoms were 62.9%, 14.6% and 1.9%, respectively. The average age, rates of secondary completion or lower, history of hypertension, and using insulin were higher in the depressive symptom group than those in the non-depressive symptom group ($p < 0.05$). The presence of depressive symptoms in the group with duration of diabetes ≥ 5 years was double in comparision with the group with duration of diabetes < 5 years (OR 2.4, 95% CI 1.27-4.66, p<0.01). The level of HbA_{1c} was significantly different between the depressive symptom group and the non-depressive symptom group (7.74 ± 1.57 % and 6.61±1.21 %, $p < 0.05$, respectively). Depressive symptoms increased risk of falls (OR: 2.93; 95% CI: 1.28-6.72, $p = 0.01$), uncontrolled fasting blood glucose (OR: 4.09, 95% CI: 2.1-7.9, $p < 0.001$) and impairment of IADL (OR: 7.12, 95% CI: 3.4-14.9, $p < 0.001$). Rate of decreased ADL in the depressive symptom group (56.6 %) were higher than that in the non-depressive symptom group (10.6%) (p< 0.05).

Conclusion: The prevalence of depressive symptoms was high and the presence of depressive symptoms was associated with increased poor glycemic control, fall risk and impairments of ADL, IADL among elderly diabetic patients.

Using sense of vitality as an independent marker for predicting risk for MACE in type 2 diabetes

M. Vergara, C. Östgren, T. Länne, F.H. Nyström;

Department of Medical and Health Sciences, Faculty of Medicine and Health Sciences, Linköping University, Linköping, Sweden.

Background and aims: New and clinically useful markers of cardiovascular risk are of essence in type 2 diabetes since ischemic heart disease and stroke are a major causes of morbidity and death in these patients.

Materials and methods: We analyzed baseline data in relation to cardiovascular risk, from 476 men and 244 women who participated in "Cardiovascular Risk factors in Patients with Diabetes -a Prospective study in Primary care" study. All the participants had type 2 diabetes and were 55-66 years old at the recruitment that took place from 2005 to 2008. Except for traditional risk markers such as duration of diabetes, HbA1c, blood pressure and smoking, we also estimated vascular disease non-invasively by carotid-femoral pulse-wave velocity (PWV, with applanation-tonometry) and measured the sagittal abdominal diameter. A questionnaire was used at baseline in which the patients were asked questions about their sense of fatigue, anxiety and physical abilities. The scale for answers were from 1 to 6 in which 1 was "all the time" and then denoted lower frequencies to the figure 6 that corresponded to "never". Patients were followed for morbidity and mortality of ischemic heart disease and stroke (MACE) until December 31 2014, by obtaining data from the national Swedish Cause of Death and Hospitalization Registries.

Results: During the follow-up period of a mean of 7 years 59 patients died or were hospitalized for ischemic heart disease or stroke. To seldom " feel full of pep" predicted increased risk for MACE independently of diabetes duration, age, HbA1c, sagittal abdominal diameter, gender, smoking, systolic blood pressure and PWV (HR 1.321, p= 0.003, CI 1.098-1.589). Correspondingly, a sense of seldom having "lots of energy" related to an independently increased reduced risk with a HR of 1.442 (CI from 1.185 to 1.756, p<0.0001) in the corresponding analysis. In contrast, to feel "tired" or "worn out" were not independent risk markers in the same statistical analyses.

Conclusion: Our data support the use of questions on sense of vitality in type 2 diabetes in order to add prognostic information about risk for subsequent MACE that is independent of traditional risk markers and also of carotid-femoral PWV and sagittal abdominal diameter.

The value-based emotion-cognition-focused educational programme to reduce diabetes distress in adults with type 2 diabetes: a cluster randomised controlled trial

B.-H. Chew[1,2], R.C. Vos[1], R.K. Stellato[1], S. Shariff Ghazali[2], M. Ismail[3], G.E.H. Rutten[1];

[1]Department of General Practice, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, [2]Department of Family Medicine, Universiti Putra Malaysia, UPM Serdang, [3]Health Clinic Seremban 2, Seremban 2, Malaysia.

Background and aims: Type 2 diabetes mellitus (T2DM) patients experience many emotional disorders resulting in decreased self-care, quality of life and disease control. The purpose of this study was to evaluate the effectiveness of a brief value-based emotion-focused educational programme in adults with T2DM on diabetes distress (DD), depressive symptoms, illness perceptions, quality of life, self-efficacy, self-care and clinical outcomes.

Materials and methods: A cluster randomised controlled trial was conducted in 10 public health clinics in Malaysia. Patients' inclusion criteria: Malay, ≥ 18 years with T2DM for at least two years, on regular follow-up and HbA_{1c} or systolic blood pressure (SBP) or LDL sub-optimally controlled, and with a mean 17-item Diabetes Distress Scale (DDS-17) score ≥ 3. Depressive symptoms were measured with the 9-item Patient Health Questionnaire (PHQ-9), and diabetes self-care was measured with the 12-item Summary of Diabetes Self-Care Activities. The intervention (VG) consists of four sessions over a period of six weeks that provide information in proper perceptions of T2DM, managing emotions and goal-setting. The comparator was an attention-control group (AG) with two meetings over a similar period. Primary outcome: between groups difference in proportion of patients achieving a mean DDS-17 score < 3 (non-severe DD) post-intervention. Multilevel mixed-effects modelling were conducted with adjustment for life event (baseline imbalance), age and gender (scientific ground), time and time*group.

Results: A total of 124 participants were included (53 VG and 71 AG). The mean (SD) age in years for VG and AG were 55.6 (10.76) and 55.8 (8.82), respectively. The median diabetes duration was 7.0 and 8.0 years, respectively. At baseline, the mean (SD) DDS-17 score was significantly higher in the VG compared to the AG: 3.4 (0.61) vs. 3.1 (0.98). Reversely, mean (SD) PHQ-9 scores were higher in the AG [6.0 (4.75)] compared to the VG [4.3 (3.30)]. Levels of HbA_{1c} (9.9 vs 9.5%), SBP (137 vs 141 mmHg) and LDL (2.9 vs 3.0

mmol/L) were comparable between groups. Immediately after intervention, VG participants had a three times higher odds of having non-severe DD compared to those in the AG (adjusted OR 3.18 95% CI 1.004 to 10.085). However, VG participants spent on average half a day less to self-care activities per week (adjusted β -0.42 95% CI -0.77 to -0.06). No significant difference was observed between groups [6.2 (4.39) in VG vs 6.7 (5.08) in AG] in depressive symptoms. No differences in other outcomes.

Conclusion: A higher proportion of participants in the intervention group became less distressed but reported less diabetes self-care immediately after the intervention. At short term, our intervention was successful.

Association between improved diabetes-related distress and metabolic control and patient-centered indicators

M. Rossi[1], G. Lucisano[1], A. Bulotta[2], S. Gentile[3], G. Vespasiani[4], A. Nicolucci[1], on behalf of the BENCH-D study group;
[1]CORESEARCH - Center for Outcomes Research and Clinical Epidemiology, Pescara, [2]Novo Nordisk S.p.A., Rome, [3]Department of Clinical and Experimental Medicine, Second University of Naples, Naples, [4]Diabetes Unit, Madonna del Soccorso Hospital, San Benedetto del Tronto (AP), Italy.

Background and aims: New approaches to cope with clinical and psychosocial aspects of type 2 diabetes (T2DM) are needed. We used data from the BENCH-D study to assess impact of changes in diabetes-related distress on clinical and patient-centered outcomes.

Materials and methods: Clinical data was derived from electronic medical records. Diabetes-related distress was measured through the Problem Areas in Diabetes Area-5 (PAID-5). Other nine self-administered validated questionnaires [SF-12 Health Survey; WHO-5 well-being index; Health Care Climate Questionnaire, Patients Assessment of Chronic Illness Care, Diabetes Empowerment Scale (DES-SF), Diabetes Self-care Activities (SDSCA-6), Global Satisfaction for Diabetes Treatment (GSDT), Barriers to Taking Medications (BM), Perceived Social Support (PSS)] were adopted as person-centered outcomes indicators. Association between changes in PAID-5 scores and changes in metabolic control and questionnaire scores (i.e. patient-centered indicators) was assessed by comparing outcomes reached by tertiles of PAID-5 changes (Kruskall-Wallis one-way ANOVA).

Results: Overall, 26 diabetes clinics enrolled 2,390 patients, of whom 1,634 had PAID-5 re-evaluated after 18 months. In the 3 tertiles of PAID-5 changes, PAID-5 score varied from baseline by -40.3±17.0, -8.8±5.9, and +21.0±17.1. Patients in the 3 tertiles did not differ in terms of age (65±10 years) and diabetes duration (13±12 years), but they differed for gender distribution (women represented 44.8%, 35.9%, and 37.0% in the 3 tertiles; p<0.0001). Reduction in PAID-5 score was associated with significant improvements in HbA1c levels, which were reduced by -0.5±1.6%, -0.2±1.3%, and -0.2±1.2% (p=0.003) in the 3 tertiles. Reduction in PAID-5 was also associated with significant improvements in psychological well-being (WHO-5) (score mean changes from baseline to 18 months in the 3 tertiles: +5.4±23.7, -2.2±20.2, -10.4±23.6, p<0.0001), physical well-being (SF-12 PCS) (+2.5±10.2, -0.7 ±8.8, -3.6±10.4, p<0.0001), patients empowerment (DES-SF) (+2.8±17.6, -0.1±16.7, -3.2±17.7, p<0.0001), barriers to medications (BM) (-0.4±11.6, +0.2 ±12.3, +3.2±11.9, p<0.0001), global satisfaction with diabetes treatment (GSDT) (+1.2±15.2, -0.7±12.4,-3.7±13.9, p<0.0001), adherence to pharmacological treatment (SDSCA-6 Drugs) (+0.3±1.8, +0.1±1.6, +0.1±1, p=0.03), perceived social support (PSS) (+0.3±18.3, +0.3±16.0, -2.7±16.3, p<0.0006).

Conclusion: We documented an association between decrease in diabetes related distress and improvement in metabolic control and several quality of life/satisfaction measures in people with T2DM. This suggests that diabetes-related distress might represent a key target of patient-centered diabetes education. Patient-centered outcomes can be regularly monitored with simple, validated questionnaires and should represent an integral component of quality of care evaluation.

Improvements in diabetes distress are associated with improvements in biomedical outcomes in type 1 diabetes

S.K. Shah[1], P. Todd[2,3], P. Choudhary[3];
[1]King's College London, London, [2]University of Edinburgh, Edinburgh, [3]Diabetes Research Group, King's College, London, UK.

Background and aims: Diabetes distress (DD) refers to the emotional distress associated with ongoing worries, burdens and concerns over time when managing diabetes. High DD is associated with impaired self management and resultant high HbA1c and severe hypoglycaemia. This study aims to analyse the relationship between change in DD and change in biomedical outcomes, such as HbA1c and hypoglycaemia risk, over time. The relationship between DD and healthcare utilisation will also be investigated.

Materials and methods: Between September 2015 and March 2016, patients with Type 1 diabetes, attending diabetes specialist clinics at two teaching hospitals, used a tool to assess DD, HbA1c, and hypoglycaemia risk. DD was measured using the brief diabetes distress score (DDS2), and hypoglycaemia risk was measured using the Gold score, for hypoglycaemia awareness, and history of severe hypoglycaemia. Using patient records, patients were followed up for the same parameters a year later, and their use of healthcare services was measured. Wilcoxon signed rank test was used to analyse changes in DD over time. Spearman's rank correlation was used to evaluate the relationship between change in DD, HbA1c, Gold score and overall hypoglycaemia risk, and also baseline DD and healthcare utilisation.

Results: 111 patients were included in the study. The median follow up time was 364 (125) days. At baseline, mean age was 43.9 ± 5.5 years, 61% were female, mean BMI was 26.1 ± 4.8 kgm^{-2}, mean duration of diabetes was 24.8 ± 12.6 years and 75% used an insulin pump. None of these demographic parameters significantly changed over time. There was a significant reduction in overall DD [median DDS2 score 3.5 (2.5) to 2.5 (1.5), p<0.005], and HbA1c [8.3% (1.6) to 7.9% (1.5), p<0.005] over time. On sub analysis, those with high DD (DDS2 ≥ 3) had a significant reduction in DD [4 (1) to 3 (2), p<0.005], those with moderate DD (DDS2 2-2.9) did not significantly change [2 (0.5) to 2 (1), p=0.422], and those with low distress (DDS2 < 2) had a slight increase in DD [1.5 (0.5) to 1.5 (1), p=0.048] but stayed in the low DD category. There was a significant correlation between change in DD and change in HbA1c (r=0.238, p=0.012). There was no statistically significant

correlation between change in DD and change in Gold score (r=0.131, p=0.171) or change in overall hypoglycaemia risk (r=0.123, p=0.198). There was a significant correlation between baseline DD and number of diabetes-related hospital admissions, letters sent out, consultations attended, emails sent out and missed appointments (r=0.223, p=0.019; r=0.392, p<0.005; r=0.237, p=0.012; r=0.289, p=0.002; r=0.193, p=0.042, respectively).

Conclusion: These data demonstrate that reductions in DD are associated with improvements in biomedical control, and high DD is associated with high healthcare utilisation. Acknowledging high diabetes distress in consultations, and addressing it in management plans, may help to reduce DD and improve biomedical outcomes.

Identification of Wisp-1 as a young blood-borne factor that promotes adult pancreatic beta cell proliferation

R. Fernández-Ruiz[1,2], A. García[1,2], Y. Esteban[1,2], B. Serra-Navarro[1], J. Mir-Coll[1], E.G. Ruano[1,2], R. Gomis[1,2], R. Gasa[1,2];
[1]IDIBAPS, [2]CIBERDEM, Barcelona, Spain.

Background and aims: Restoring functional β-cell mass is a current therapeutic goal in diabetes. One of the proposed strategies is to promote replication of remaining β-cells. It is well known that under normal physiological conditions, adult β-cells have a limited capacity to proliferate. The decline in β-cell replicative activity appears to occur around weaning by mechanisms that are still poorly understood. We hypothesize that blood borne factors present in early postnatal life but absent in adulthood have an important role in this age-related decay. Identification of these factors is important to uncover novel switchers of adult β-cell replication.

Materials and methods: In order to test whether circulating factors are important to maintain β-cell replicative activity, we performed transplants of 20-weeks old C57BL/6J mouse islets into the anterior chamber of 16-days and 20-weeks old mouse recipients. To compare serum from 14-days and 20-weeks old mice, we used commercially available antibody arrays (Proteome Profiler, Mouse XL Cytokine Array Kit, R&D Systems). Proliferation (percentage of ki67+insulin+/insulin+ cells) was studied by immunofluorescence staining of transplanted and cultured islets. Gene expression levels were determined by quantitative real time PCR. Wisp-1 serum levels were determined by ELISA (Quantikine ELISA, Mouse/Rat Wisp-1/CCN4 Immunoassay, R&D Systems). Wisp-1 recombinant protein was obtained from R&D (Recombinant Mouse Wisp-1/CCN4, R&D Systems).

Results: Adult β-cells exhibit a significantly higher proliferation rate when transplanted in young than in adult recipients (16-days recipients, 3.5 ±0.38%; 20-weeks recipients, 1.43±0.35%; p<0.005). Antibody arrays revealed Wisp-1/CCN4 (Wnt-1 inducible signaling pathway-1), as one of the circulating factors that are more abundant in young than in adult serum. We corroborated these data by ELISA (14-days old serum, 11613± 977 pg/ml; 20-weeks old serum, 1844±335 pg/ml; p<0.0001). We surveyed Wisp1 gene expression in several tissues in young mice and observed highest expression in bone. In contrast, levels of Wisp1 mRNA in islets were negligible, thus supporting that, if any, the role of Wisp1 on β-cells would be as an extrinsic factor. To directly test whether Wisp-1 impacts β-cell proliferation, we incubated adult islets in the presence of Wisp-1 recombinant protein for 48h and obtained a significant induction of β-cell proliferation (control, 0.38±0.09%; Wisp-1, 1.04±0.13%, p<0.001). Immunoblot analysis showed that Wisp-1 increases Akt/PKB phosphorylation (2.01 ±0.27 fold above control; p<0.05), thus revealing this kinase as a likely intracellular mediator of the pro-proliferative effect of this factor.

Conclusion: In summary, we provide evidence that Wisp-1 promotes proliferation of adult β-cells, hence supporting the idea that young blood borne factors may be a useful strategy to modulate the intrinsic ability of β-cells to proliferate later in life.

miRNAs transferred by exosomes from T lymphocytes to beta cells contribute to type 1 diabetes development

C. Guay[1], J. Kruit[2], S. Rome[3], V. Menoud[1], G. Sebastiani[4], C. Boitard[5], F. Dotta[4], R. Regazzi[1];
[1]University of Lausanne, Lausanne, Switzerland, [2]University Medical Center Groningen, Groningen, Netherlands, [3]University of Lyon, Lyon, France, [4]University of Siena, Siena, Italy, [5]University of Paris Descartes, Paris, France.

Background and aims: During type 1 diabetes development, lymphocytes infiltrating the pancreatic islets cause β-cell dysfunction and death. Beside

cytokines, lymphocytes release small vesicles called exosomes containing miRNAs that can be transferred in active form to recipient cells. Since during insulitis β-cells and T cells are brought in close proximity and miRNAs are important regulators of β-cell functions, we hypothesized that an exosome-mediated transfer of miRNAs from T lymphocytes to β-cells may contribute to the death of the insulin-secreting cells in the initial phases of type 1 diabetes.

Materials and methods: To test this novel concept, exosomes were isolated from the culture media of Jurkat T cells or T effector cells of NOD mice. After analysis of their miRNA content, the exosomes were used to study the transfer of miRNAs from T cells to β-cells and to investigate their functional impact. Blockade of miR-142-3p/-5p and miR-155 in vivo was achieved by injecting an Adeno Associated Virus expressing, under the control of the insulin promoter, a transcript containing multiple binding sites for these miRNAs.

Results: We observed that T-cell specific miRNAs, such as miR-142-3p/-5p and miR-155, are highly upregulated in pancreatic islets of NOD mice during pre-diabetic insulitis. The increase of these miRNAs is not caused by pro-inflammatory cytokines, but results from an exosome-mediated cell-to-cell transfer. Indeed, exposure of islet cells to T-cell exosomes led to a rise in the level of miR-142-3p/-5p and miR-155 and caused apoptosis of β-cells but not of α-cells. This effect could be prevented by inhibiting the action of these miRNAs and was reproduced by direct overexpression of miR-142-3p, miR-142-5p or miR-155 in β-cells. To verify the relevance of this phenomenon in vivo, pre-diabetic NOD mice were injected with a viral construct capable of blocking specifically the miRNAs of interest in β-cells. Inactivation of miR-142-3p, miR-142-5p and miR-155 in β-cells of NOD mice led to a decrease in islet inflammation and T-cell recruitment, combined with an important reduction in the incidence of type 1 diabetes.

Conclusion: Taken together, our results suggest that a subset of miRNAs carried by exosomes released by T cells is transferred in active form to β-cells triggering apoptosis. Our results support the concept that the transfer of miRNAs constitutes a novel cell-to-cell communication mechanism contributing to β-cell failure in type 1 diabetes.

Glucose-stimulated cAMP formation in beta cells involves amplificaton of constitutive from the GLP-1 receptor

H. Shuai, A. Tengholm;
Medical Cell Biology, Medicine, Uppsala, Sweden.

Background and aims: The second messenger cAMP is a key amplifier of Ca^{2+}-triggered exocytosis in insulin-secreting β-cells. Apart from mediating the effects of various Gαs-protein-coupled receptor agonists, like glucagon and glucagon-like peptide-1 (GLP-1), cAMP is important for glucose-induced insulin secretion. Glucose consequently stimulates cAMP generation in β-cells, but the underlying mechanisms are incompletely understood. The aim of this study was to clarify if the GLP-1 receptor and Gαs protein are involved in glucose-stimulated cAMP generation in β-cells.

Materials and methods: Total internal reflection fluorescence microscopy and fluorescent reporters were used to record changes of the intracellular concentration of cAMP ($[cAMP]_i$) and insulin secretion from single MIN6-cells and primary β-cells within intact pancreatic islets.

Results: Elevation of the glucose concentration from 3 to 20 mM induced an increase of $[cAMP]_i$ in both MIN6-cells and mouse and human islet β-cells. $[cAMP]_i$ increased also in response to an elevation of the cytoplasmic Ca2+ concentration induced by membrane depolarization with 30 mM K+ in the presence of 3 mM glucose and the ATP-sensitive K+ channel opener diazoxide. Elevation of the glucose concentration under these conditions induced a further increase of $[cAMP]_i$, reflecting stimulation of cAMP production by cell metabolism. The metabolic component of the glucose-induced cAMP formation was reduced after shRNA-mediated knockdown of Gαs. Both the glucose- and K+-evoked $[cAMP]_i$ increases were inhibited by the GLP-1 receptor antagonist exendin-(9-39). The reduction of $[cAMP]_i$ in glucose-stimulated cells was paralleled by suppression of insulin secretion. The effect of exendin-(9-39) did not involve activation of the inhibitory G-protein Gαi, since pertussis toxin did not affect the $[cAMP]_i$-lowering effect of the antagonist in glucose-stimulated cells, while preventing $[cAMP]_i$-lowering induced by α_2-adrenoceptor activation with 100 nM clonidine. Since no GLP-1 was added to the cells, the findings are taken to reflect that exendin-(9-39) is an inverse agonist of the GLP-1 receptor.

Conclusion: Glucose-stimulated cAMP formation in β-cells involves distinct Ca^{2+}- and metabolism-dependent mechanisms. Glucose metabolism activates cAMP-generating adenylyl cyclases by amplifying constitutive signaling from the GLP-1 receptor via Gαs.

Role of Gs/cAMP-dependent signalling pathway in the establishment of beta cell mass

B. Serra-Navarro[1], A. García[1,2], Y. Esteban[1,2], R. Fernández-Ruiz[1,2], J. Mir-Coll[1], E.G. Ruano[1,2], R. Gomis[1,2], R. Gasa[1,2];
[1]IDIBAPS, [2]CIBERDEM, Barcelona, Spain.

Background and aims: Several signaling pathways have been shown to regulate β-cell proliferation. However, the specific roles of individual pathways, as well as their crosstalk, that participate in the establishment of functional β-cell mass remain less understood. In this study we have investigated the role of the signaling pathway activated by the stimulatory protein Gs - acting through the second messenger cAMP in the regulation of postnatal β-cell mass.

Materials and methods: We generated β-cell Gsα deficient mice (β-GsαKO) by crossing *Ins1*Cre with *Gnas*$^{flox/flox}$ mice. Whole body glucose homeostasis was studied by glucose tolerance tests (IpGTT, OGTT), glucose-induced insulin secretion (GSIS) and insulin tolerance test (ITT). β-cell mass was measured with insulin immunofluorescence followed by morphometry analysis. Apoptosis was determined by TUNEL assay and β-cell proliferation was assessed by Ki67 and phospho-histone H3 staining. Isolated islets were used to study insulin and cAMP content by ELISA, protein levels by western blot and gene expression by real time PCR.

Results: At 4-weeks old (wo) β-Gsα KO mice are hyperglycemic, glucose intolerant, exhibit reduced GSIS and similar insulin sensitivity relative to control littermates. They also show lower islet insulin content and decreased fractional β-cell area and mass. This diminution in β-cell mass is associated with reduced β-cell proliferation (WT: 2.8±0.33%; KO: 1.04±0.22% ki67+ ins+/ins+ $p<0.001$) without signs of enhanced apoptosis. In view of these results, experiments were aimed at deciphering the molecular signatures responsible for the observed decreased β-cell growth. As an initial step, we measured cAMP levels and found an 85% reduction ($p<0.0005$) of this second messenger in 4-wo β-GsαKO as compared to control islets. In agreement with decreased β-cell proliferation, expression of the cell cycle genes *CcnA2* and *Ki67* is downregulated (50% of controls, $p<0.01$), whereas expression of the cell cycle inhibitor *cdkn1a* is upregulated (2.5 fold, $p<0.001$) in β-GsαKO islets relative to controls. We surveyed gene expression of several components of the Gs signaling pathway and found reduced islet mRNA levels for *Glp1r, Gipr, Prkarb1* and *Akap11*. However, genes coding for the cAMP effector transcription factor Creb were unaltered. Further, basal activation levels of the Creb protein were only marginally reduced (20%) in KO relative to control islets. These results led us to study other signaling pathways with established roles in β-cell proliferation and found that the gene encoding the IGF1 receptor (*Igf1r)* was severely downregulated in β-GsαKO islets relative to controls, from as early as postnatal day 7. In accordance to reduced IGF1-dependent signaling, 4-wo β-GsαKO islets present significantly reduced AKT (60% of controls, $p<0.001$) and S6K activation (40 % of controls $p<0.05$).

Conclusion: This study reveals the importance of cAMP-mediated signaling in the establishment of β-cell mass. Furthermore, it supports that the crosstalk between Gs and IGF1/AKT-mediated intracellular signaling in β-cells is

relevant for β-cell mass establishment. Further work is ongoing aiming to identify the molecular determinants of this crosstalk and their specific roles in the regulation of postnatal β-cell proliferation.

Multiple type 2 diabetes genes identified using single-cell RNA-seq of human islets

N. Wierup[1], J.A. Martínez-López[2], R.G. Fred[1], A. Muñoz-Manchado[2], J. Hjerling-Leffler[2];

[1]Dept Experimental Medical Science, Lund University Diabetes Centre, Lund, [2]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.

Background and aims: The pancreatic islets are key regulators of glucose metabolism and deranged islet function is a culprit in type 2 diabetes (T2D). Currently, major focus is on assessing differential expression of genes in T2D vs. non-T2D whole-islet preparations. This strategy does, however, not take into account that the islets are composed of at least five different cell types. If a gene is upregulated in one cell type and downregulated in another, the net outcome may be neutral. Therefore, single-cell information on disease vs. control cells is warranted. Single-cell RNA-sequencing has been successfully performed in human islets, but the available data is contradictory, warranting an additional resource produced at the highest standards.

Materials and methods: Human islets from cadaver donors were provided by The Nordic Network for Clinical Islet Transplantation, Uppsala, Sweden. Islets (100/donor) were handpicked to minimize exocrine content and dissociated into single cell suspensions using an Accutase protocol. Cells were isolated by unbiased FACS and Smart-seq2 single-cell transcriptomics was used to sequence human pancreatic islets cells from 6 human non-diabetic donors and 4 Type 2 diabetic donors (obtaining the transcriptome of 3075 cells). Cell identity was determined using the two way unsupervised clustering algorithm BackSPIN and t-SNE technique. Gene-network analysis was performed using weighted gene co-expression network analysis (WGCNA).

Results: BackSPIN clustering resulted in a model with 12 distinct cell populations, including alpha, beta, delta, PP- and ghrelin cells. The remaining cell populations were exocrine cells, duct cells, stellate cells, endothelial cells, as well as cells from the immune system. Clustering was verified manually by comprehensive analysis of differential expression of established markers for each cell type. Furthermore, we identified subpopulations of beta- and alpha-, and exocrine cells and multiple subpopulation-specific genes. Using reads from 4 T2D donors (1352 cells) and 6 non-diabetic donors (1723 cells), we identified genes that are differentially expressed in T2D specifically in beta cells (972 genes) and alpha cells (857 genes). Most of these genes have not previously been associated with islet function and WGCNA shows that the top listed genes are co-expressed with important T2D associated islet genes, e.g. PDX1, INS, GCGR, and GLP1R. Select genes have been verified by immunohistochemistry in isolated islets, as well as pancreatic sections from the same donors.

Conclusion: We have created a complete roadmap of genes expressed in all islet cell types, as well as subpopulations of alpha and beta cells. We have identified hundreds of genes that are differentially expressed in T2D specifically in human alpha and beta cells. Functional follow up studies will likely generate increased understanding for T2D disease mechanisms and novel drug targets.

Short-chain fatty acids potentiate insulin secretion and protect against apoptosis in mouse and human islets; role of FFAR2

A. Pingitore[1], I. Ruz Maldonado[1], N. Gonzalez Abuin[2], B. Liu[1], G.A. Bewick[1], G. Huang[1], G. Frost[2], S.J. Persaud[1];

[1]Diabetes Research Group, Division of Diabetes&Nutritional Sciences, King's College London, [2]Nutrition and Dietetics Research Group, Imperial College London, London, UK.

Background and aims: Short chain fatty acids (ScFAs) originate from colonic fermentation of fibre and undigested carbohydrates. The main circulating forms are sodium acetate (SA) and sodium propionate (SP), which we have previously shown to increase insulin secretion and protect β-cells from apoptosis. The current study identified whether these beneficial effects are mediated via Gq-dependent signalin through FFAR2

Materials and methods: Islets were isolated from WT and FFAR2KO mice, and human organ donors. Insulin secretion was profiled by perifusion and RIA; real-time changes in [Ca2+]i in islets were determined by microfluorimetry; PLC was inhibited with U73122; PKC was down-regulated by 20h exposure of islets to 200nM PMA; levels of ATP, cAMP and caspases 3/7 (for apoptosis) were quantified by luminescence assays.

Results: Results: In human islets the selective PLC inhibitor U73122 impaired SA-induced potentiation of insulin release at 20mM glucose (20G) (0.1mM SA: 67.2±8.7 pg/islet/min, + 10μM U73122: 34.3±3.3, $p<0.05$). The effects of SA and SP to increase insulin secretion were PKC-dependent (control, 20G + 0.1mM SA: 44.5±12.6 pg/islet/min; PMA-treated: 19.7±1.1, $p<0.01$; control islets, 20G + 0.1mM SP: 18.7±0.8; PMA-treated: 5.6±0.4, $p<0.01$). Deletion of FFAR2 did not affect the peak amplitude of glucose-stimulated insulin secretion (GSIS) (WT: 10.5±0.9 pg/islet/min; KO: 10.2±1.4). However, the effects of SA and SP on GSIS were significantly reduced following FFAR2 knockout (WT, 20G + 1mM SA: 11.2±2.2 pg/islet/min; KO: 6.5±0.7, $p<0.05$; WT, 20G + 1mM SP: 14.8±1.2; KO: 6.6±0.9, $p<0.01$). In agreement with this, SA-induced elevation in [Ca2+]i was lost in islets from FFAR2KO mice (WT, 20G: 0.68 basal to peak ratio, 20G + 1mM SA: 0.74; KO, 20G: 0.72; 20G + 1mM SA: 0.72). Neither SA nor SP affected cAMP levels in islets from WT or FFAR2KO mice (WT, control: 108.6±12.8nM, +1mM SA: 135.0±10.8; +1mM SP: 91.6±32.4; KO, control: 150.3±28.5; +1mM SA: 137.3±7.8; +1mM SP: 117.7±7.0). Deletion of FFAR2 did not influence islet glucose-induced ATP generation (WT, 20G: 148.5±14.0% basal; 20G + 1mM SA: 127.5±6.8; + 1mM SP 154.6±11.9; KO, 20G: 135.1±14.5; + 1mM SA: 143.1±15.3; + 1mM SP: 143.0±12.9, $p>0.2$ FFAR2KO vs WT in all conditions). No differences in basal apoptosis were observed in FFAR2KO islets (caspase 3/7 activity, WT, basal: 0.96±0.04, KO: 1.06±0.08, $p>0.2$), but the ability of SA and SP to protect against cytokine-induced apoptosis was lost in islets from FFAR2KO mice (WT, + cytokines: 2.21±0.12; +1mM SA: 1.72 ±0.09; +1mM SP: 1.51±0.13, $p<0.01$; KO, +cytokines: 2.43±0.19, +1mM SA: 2.29±0.19; +1mM SP: 2.74±0.20, $p>0.2$). Similarly, the ScFAs did not protect islets against apoptosis induced by palmitic acid (PA) following FFAR2 deletion (WT, +0.5mM PA: 1.61±0.10; +1mM SA: 1.24±0.09; +1mM SP: 1.41 ±0.16, $p<0.05$; KO, +0.5mM PA: 1.45±0.16, +1mM SA: 1.38±0.09; +1mM SP: 1.64±0.13, $p>0.2$).

Conclusion: Although FFAR2 is reported to have dual Gi/Gq coupling, we have demonstrated that in islets SA and SP act solely via FFAR2/Gq to elevate [Ca2+]i, potentiate insulin secretion in a PKC-dependent manner and protect islets against cytotoxic and lipotoxic insults. All of these are hallmarks of beneficial effects in the treatment of type 2 diabetes and position FFAR2 as a potential pharmacological target.

Reduction of HbA_{1c} with dulaglutide in type 2 diabetes (T2D) patients negative, low positive or high positive for GAD antibodies (GADA): a post hoc analysis of AWARD -2, -4 and -5

P. Pozzilli[1], R.D. Leslie[2], A. Peters[3], R. Buzzetti[4], S.S. Shankar[5], Z. Milicevic[6], I. Pavo[6], J. Lebrec[7], S. Martin[5], N. Schloot[7];

[1]Department of Endocrinology & Diabetes, University Campus Bio-Medico, Rome, Italy, [2]Blizard Institute, London, UK, [3]Department of Endocrinology & Diabetes, Keck School of Medicine of USC, Los Angeles, USA, [4]Department of Experimental Medicine, "Sapienza" University of Rome, Rome, Italy, [5]Eli Lilly and Company, Indianapolis, USA, [6]Eli Lilly and Company, Vienna, Austria, [7]Lilly Deutschland GmbH, Bad Homburg, Germany.

Background and aims: Dulaglutide is a weekly GLP-1 receptor agonist indicated for T2D. It enhances insulin secretion from β-cells in a glucose-dependent manner. We evaluated the effect of dulaglutide on HbA_{1c} in GADA negative and GADA positive patients with T2D in a post hoc analysis of 3 dulaglutide trials: AWARD-2, -4 and -5.

Materials and methods: GADA positive T2D, termed LADA (latent autoimmune diabetes of the adult), was defined as GADA ≥5 IU/mL (ELISA, Kronus Inc). Changes in HbA_{1c} were estimated using Mixed-Effect Model Repeat Measurement (MMRM) analysis, adjusted for baseline HbA_{1c}, grouped country, study, treatment, GADA status, visit, and treatment-by-visit, study-by-visit, GADA-by-visit, GADA-by-study and GADA-by-treatment interactions.

Results: Results: 2466/2893 patients (85.2%) were tested for GADA: 92.4% (N=2278) were GADA negative (T2D) and 7.6% (N=188) were GADA positive (LADA). Baseline characteristics were generally comparable between patients with T2D and LADA: mean age range across the trials 54.1-59.6 years and 56.4-57.6 years; BMI 31.2-32.6 kg/m^2 and 30.1-31.6 kg/m^2; diabetes duration 7.1-13.0 years and 6.1-10.9 years; HbA_{1c} 8.13-8.44% and 8.14-8.61%. Of all LADA patients, 58 were considered to be GADA high (>200 IU/mL) while 130 were GADA low (≤200 IU/mL). These subgroups were also generally comparable at baseline. Dulaglutide therapy resulted in similar reductions in HbA_{1c} in patients with T2D and LADA, with comparable results across all 3 studies (Table). Pooled analysis showed similar HbA_{1c} reductions at 6 months in dulaglutide-treated T2D (LS mean change [95% CI]: -1.25% [-1.31, -1.20]) vs. LADA patients (-1.12% [-1.31, -0.93]) and at 12 months (-1.09% [-1.15, -1.03] vs. -0.94% [-1.15, -0.72]). Reductions in HbA_{1c} were numerically larger but not statistically significant at 6 months in GADA low (-1.22% [-1.43, -1.01]) vs. GADA high LADA patients (-0.89% [-1.29, -0.48]) and at 12 months (-1.02% [-1.26, -0.78] vs. -0.72% [-1.21, -0.24]).

Conclusion: HbA_{1c} decreased to a similar extent in T2D and LADA at 6 and 12 months of dulaglutide treatment. Our results conflict with a recent study where GLP-1 analogs failed to reduce HbA_{1c} in GADA-positive patients.

Table: Summary of changes in HbA_{1c} levels at 6 and 12 months with dulaglutide in LADA and T2D patients per study (ITT population)

	AWARD-2 (dulaglutide vs. glargine in T2D patients on metformin and glimepiride)		AWARD-4 (dulaglutide vs. bedtime glargine, both in combination with prandial lispro)		AWARD-5 (dulaglutide vs. sitagliptin)	
LS mean (SE) change from baseline in HbA_{1c} (percentage points)	T2D	LADA	T2D	LADA	T2D	LADA
N	432	16	444	54	541	25
At 6 months	-1.00 (0.04)	-1.18 (0.20)	-1.71 (0.05)	-1.32 (0.12)	-1.11 (0.04)	-0.99 (0.17)
N	404	13	415	47	456	21
At 12 months	-0.84 (0.05)	-1.11 (0.24)	-1.48 (0.06)	-1.08 (0.15)	-1.00 (0.05)	-0.76 (0.20)

N = the number of patients with HbA_{1c} data at baseline that were eligible for the 6-month analysis or 12-month analysis.
All data shown are in the dulaglutide arm only, and not in the comparator arms.

Bone turnover in women with prior gestational diabetes after 52 week's treatment with liraglutide

L. Vedtofte[1], E. Hannerup[1], S. Foghsgaard[1], E.R. Mathiesen[2], T. Buhl[3], L.K. Christiansen[1], J.A. Svare[4], T.D. Clausen[5], P. Damm[6], N.R. Jørgensen[7,8], F.K. Knop[1,9], T. Vilsbøll[1,10];

[1]Center for Diabetes Research, Gentofte Hospital, Hellerup, [2]Center for Pregnant Women with Diabetes, Department of Endocrinology, Rigshospitalet, Copenhagen, [3]Department of Nuclear Medicine, Gentofte Hospital, Hellerup, [4]Department of Obstetrics and Gynaecology, Herlev Hospital, Herlev, [5]Department of Gynaecology and Obstetrics, Nordsjællands Hospital, Hillerød, [6]Department of Obstetrics, Rigshospitalet, Copenhagen, [7]Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, [8]OPEN, Odense Patient data Explorative Network, Odense University Hospital/Institute of Clinical Research, Odense, [9]Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, [10]Steno Diabetes Center Copenhagen, Gentofte, Denmark.

Background and aims: Liraglutide induces weight loss and as weight loss is associated with loss of bone mass, we investigated the effect of liraglutide-treatment in women with prior gestational diabetes mellitus (pGDM) on whole-body bone mineral density (BMD), whole-body bone mineral content (BMC), the bone resorption marker C-terminal telopeptide of type 1 collagen (CTX) and the bone formation marker procollagen type-1 amino-terminal propeptide (P1NP).

Materials and methods: Women with pGDM (n=102, age: 38±5 years (mean ±SD), BMI: 32±4 kg/m^2) underwent a 4-hour 75-g OGTT at baseline and after one year's randomised and blinded intervention with placebo (n=54) or liraglutide, 1.8 mg once-daily, (n=48). During the trial, 10 women withdrew from the liraglutide group and 9 from the placebo group leaving 83 women for analysis of the effect of the intervention. Controls matched for age and BMI were studied once (n=15, age: 39±4 years, BMI: 31±5 kg/m^2) with a 4-hour 75-g OGTT. Dual energy X-ray absorptiometry was used to assess whole-body BMD and whole-body BMC in both groups. Comparisons between the control group and the pGDM group at baseline were analysed using Mann-Whitney U test. Changes from baseline to 52 weeks were analysed with a constrained linear mixed model. Changes in BMD and BMC are tabulated as changes in means. CTX and P1NP tAUC data were log-transformed due to lack of normal distribution and changes are therefore expressed as percent change in mean.

Results: At baseline, there were no differences between controls and women with pGDM with respect to whole-body BMD (1.32±0.1 vs. 1.26±0.1 g/cm^2, p=0.149), whole-body BMC (2730±388 vs. 2656±279 g, p=0.492) and the total AUC (tAUC) during the OGTT for CTX (30±16 vs. 27±15 μg/L*min, p=0.548) and P1NP (7355±2243 vs. 8355±3368 μg/L*min, p=0.358). Compared to placebo, liraglutide-treatment induced a significantly greater weight loss after 52 weeks (-4.8 [-6.50; -3.00] vs. -1.5 [-3.13; 0.09] kg (mean [CI]), p=0.009). No changes in whole-body BMD (0.004 vs. 0.005 g/m^2, p=0.883), whole-body BMC (6.7 vs. 9.7 g, p=0.799), tAUC for CTX (9.2 vs. 11.5%, p=0.853) or tAUC for P1NP (-4.5 vs. -11.6%, p=0.254) were observed in the placebo vs. liraglutide group.

Conclusion: Liraglutide-treatment-induced weight loss in women with pGDM does not affect bone turnover, whole-body BMD and whole-body BMC respectively, suggesting that liraglutide treatment from a bone turnover perspective is safe to use in this population.

Site of absorption of an oral formulation of semaglutide

T.A. Bækdal[1], J. Borregaard[1], S.T. Buckley[2], M. Donsmark[1], M.-L. Hartoft-Nielsen[1], S.J. Maarbjerg[1], K.G. Madsen[2], F.L. Søndergaard[1], A. Vegge[2], A. Connor[3], L.B. Knudsen[2];

[1]Novo Nordisk, Søborg, [2]Novo Nordisk, Måløv, Denmark, [3]Quotient Clinical, Nottingham, UK.

Background and aims: Absorption of oral peptide-based drug formulations is challenged by the limited permeability of the gastrointestinal (GI) epithelium and by the fact that peptides are degraded in the stomach due to low pH and proteolytic enzymes. A novel oral tablet formulation of the human glucagon-like peptide-1 analogue, semaglutide, has been developed by co-formulation with the absorption enhancer, sodium N-(8-[2-hydroxybenzoyl] amino) caprylate (SNAC). SNAC facilitates the absorption of semaglutide across the GI epithelium primarily via the transcellular route and protects against proteolytic degradation of semaglutide through a localised increase in pH. The site of absorption of oral semaglutide was investigated in a series of clinical and non-clinical studies.

Materials and methods: In a pharmacoscintigraphic clinical study, 24 healthy males in the fasted state received single-dose oral semaglutide (10 mg/300 mg SNAC) with 50 mL water followed by 4 hrs post-dose fasting. Tablet erosion kinetics were assessed by gamma scintigraphy and systemic absorption of semaglutide was assessed by pharmacokinetic blood sampling. In a food-effect clinical study, the pharmacokinetics of oral semaglutide were investigated in 25 healthy subjects receiving once-daily oral semaglutide in the fed state for 10 days (5 days of 5 mg/300 mg SNAC followed by 5 days of 10 mg/300 mg SNAC). Complementary non-clinical studies were conducted in Beagle dogs. Semaglutide exposure was compared between anaesthetised, pyloric ligated dogs (to prevent the tablet from exiting the stomach) receiving intragastric dosing (10 mg/300 mg SNAC), and awake, non-ligated dogs receiving oral dosing. In another study, semaglutide exposure was compared between the splenic vein (draining the gastric cavity) and the portal vein (draining the GI system) after intragastric dosing in anaesthetised, non-ligated dogs. Finally, using endoscopic technique in anaesthetised dogs, liquid from underneath an oral semaglutide tablet and 3 and 6 cm from the tablet was aspirated and assayed for semaglutide and SNAC.

Results: In the pharmacoscintigraphic study, complete tablet erosion (CTE) occurred in the stomach with an estimated mean time to CTE [95% CI] of 85 min [62;118]. Semaglutide plasma exposure confirmed early systemic absorption with median t_{max} of 90 min and mean $AUC_{0\text{-}24h}$ of 119 nmol·h/L [59;243]. In the food-effect study, when dosed in the fed state, limited (44% of subjects) or no (56%) semaglutide exposure was observed. In dogs, prevention of intestinal absorption by pyloric ligation resulted in semaglutide exposure comparable to that seen in non-ligated dogs (mean±SEM dose-normalised C_{1h} 4174±931 vs. 3764±1066 pmol/L/mg; p=0.83). Moreover, semaglutide exposure ($AUC_{0\text{-}0.5h}$) in non-ligated dogs was higher in the splenic vein than in the portal vein (ratio splenic/portal vein [95% CI] 2.2 [1.2;3.2]). Finally, endoscopy showed that high concentrations of semaglutide and SNAC in the gastric fluid were only observed close to the tablet, indicating that semaglutide absorption occurs in a localised environment and depends on the spatial proximity of semaglutide and SNAC.

Conclusion: Clinical and non-clinical data collectively suggest that orally administered semaglutide is absorbed in the stomach, and clinically relevant exposure requires administration of oral semaglutide in the fasting state.

Evaluation of the effect of food on the pharmacokinetics of oral semaglutide

S.J. Maarbjerg[1], J. Borregaard[1], A. Breitschaft[2], M. Donsmark[1], F.L. Søndergaard[1];

[1]Novo Nordisk, Søborg, Denmark, [2]Parexel International, Berlin, Germany.

Background and aims: Semaglutide, a glucagon-like peptide-1 (GLP-1) analogue, has been co-formulated with the absorption enhancer, sodium N-(8-[2-hydroxybenzoyl] amino) caprylate (SNAC), to allow administration as an oral tablet. Oral semaglutide is absorbed in the stomach, where SNAC facilitates absorption and protects against proteolytic degradation of semaglutide through a localised increase in pH. The aim of this trial was to investigate the effect of food on the pharmacokinetics of oral semaglutide.

Materials and methods: In an open-label, randomised, parallel-group trial design, 78 healthy subjects (39 females/39 males; mean±SD age 55±14 years, body weight 73.5±12.2 kg, body mass index 24.8±2.6 kg/m^2) were allocated 1:1:1 to once-daily treatment (5 mg for 5 days followed by 10 mg for 5 days) using 3 different dosing conditions: 1) Fed (high-caloric, high-fat breakfast ingested during the last 30 minutes pre-dose; 240 mL water taken with dosing; 4 hours post-dose fasting), 2) Fasting (fasting overnight for at least 10 hours; 240 mL water with dosing; 4 hours post-dose fasting) or 3) Reference (fasting overnight for at least 6 hours; 120 mL water with dosing; 30 minutes post-dose fasting). In the Fed and Fasting arms, no further water or liquid was allowed from 2 hours pre-dose until 4 hours post-dose, while there were no restrictions on water, liquid or food intake from 4 hours post-dose. In the Reference arm, no further water or liquid was allowed from 2 hours pre-dose until 30 minutes post-dose, while there were no restrictions on water, liquid or food intake from 30 minutes post-dose. Fed and Fasting arms were designed according to guidelines on the investigation of food effect. The Reference arm reflected the dosing conditions used in the ongoing oral semaglutide clinical development program and was included in order to be able to bridge to the guideline defined dosing conditions.

Results: In the Fed arm, limited semaglutide exposure (11 of 25 subjects) or no semaglutide exposure (14 of 25 subjects) was observed. Semaglutide exposure appeared to be approximately 40% greater for Fasting vs. Reference for both 24-hour exposure ($AUC_{0\text{-}24h,Day\ 10}$; estimated means 383 vs. 272 nmol*h/L; estimated ratio [95% confidence interval] 1.41 [0.96;2.07], p=0.082) and maximum concentration ($C_{max,Day\ 10}$; 20.1 vs. 14.2 nmol/L; 1.41 [0.96;2.08], p=0.080), although not statistically significant. Time to maximum concentration ($t_{max,Day\ 10}$) appeared longer for Fasting vs. Reference (median of 1.75 vs. 1.00 h), while there was no apparent difference in half-life ($t_{½,Day\ 10}$) between Fasting and Reference (geometric mean 160 vs. 152 hours). Overall, the safety profile was as expected for the GLP-1 receptor agonist drug class. In this trial, the most frequently reported adverse events were headache (15%, 38% and 35% of subjects in Fed, Fasting and Reference arms, respectively) and gastrointestinal disorders (19%, 50% and 27%).

Conclusion: Sufficient semaglutide plasma exposure is only achieved when oral semaglutide is administered in the fasting state. Administration with 120 mL water and 30 minutes post-dose fasting is expected to be acceptable to patients and results in clinically relevant semaglutide plasma exposure.

Risk of pancreatic diseases by second-line anti diabetes drug class: real world based evidence

S. Paul[1], J.B. Green[2], J. Atherton[3], O. Montvida[4];

[1]University of Melbourne, Melbourne, Australia, [2]Duke Clinical Research Institute, Durham, USA, [3]Royal Brisbane and Women's Hospital and University of Queensland School of Medicine, [4]Queensland University of Technology, Brisbane, Australia.

Background and aims: Recent clinical observational studies have raised concerns on the possible association of treatment with incretin-based therapies, particularly with DPP-4 inhibitor (DPP-4i), and the risk of acute pancreatitis (AP) or cancer of pancreas (COP) in patients with type 2 diabetes (T2DM). However, a holistic risk analysis in patients receiving different classes of anti-hyperglycaemic agents (AHA) is scarce. The aims of this study were to evaluate the risk of AP, COP, and other disease of pancreas (ODP) in patients with T2DM following the addition of a second-line AHA to metformin therapy.

Materials and methods: Patients with T2DM, aged 18-80 years and diagnosed after 2004, who received metformin plus a second line AHA for at least 3 months, were identified from a large Electronic Medical Record database from the USA. Sulfonylurea (SU), thiazolidinedione (TZD) or insulin (INS) users who had ever received a DPP-4i or GLP-1 receptor agonist (GLP-1RA) were excluded, as were patients with any disease of pancreas or any type of

cancer that occurred prior to initiation of second line AHA therapy (baseline). The rates of events per 1000 person-years were estimated. With DPP-4i as the reference group, the risk analyses were conducted balancing on age and follow-up time, and adjusting for appropriate confounders.

Results: Baseline characteristics varied among SU (n=110,747), DPP-4i (n=50,095), INS (n=34,805), TZD (n=17,597), and GLP-1RA (n=12,654) treatment groups with mean age: 53-60 years; male proportion: 34-52%; mean weight: 98-108 Kg; median HbA1c: 7.2-8.9%; and mean follow-up: 2.8-4.6 years.The rates/1000 person-years of AP were similar in the DPP-4i, GLP-1RA and SU groups (Table 1). Compared to DPP-4i group, patients treated with INS had significantly higher AP rate and those treated with TZD had significantly lower AP rate. Except for INS group, the rate/1000 person-years for ODP were similar across the treatment groups, while there was no significant difference in the rate of COP/1000 person-years among all groups. In the DPP-4i group, the adjusted mean time to AP was 2.63 (95% CI: 2.38, 2.88) years; time to COP was 2.70 (95% CI: 2.19, 3.21) years; and time to ODP was 2.73 (95% CI: 2.33, 3.12) years. Compared to the DPP-4i group, INS patients developed AP 0.48 years ($p<0.01$) earlier and GLP-1RA patients (n=12,654) developed COP 3 years later ($p<0.01$). However, with the constraint of no event within 6 months of INS initiation, the risk of AP in INS group was insignificant. No other significant differences in mean times to events were observed between groups.

Conclusion: This real-world study based on large number of patients with reasonable follow-up time suggests no significant difference in the risk of developing pancreatic diseases in patients treated with different classes of anti-hyperglycaemic agents.

Table 1: Event rates (95% CI) per 1000 person-years; Adjusted Mean Time to Events (95% CI) in DPP-4 group and Adjusted Difference in Time to Events in other treatment groups with DPP-4i as a reference.

		Acute Pancreatitis (95% CI)	Cancer of Pancreas (95% CI)	Other Disease of Pancreas (95% CI)

Efficacy and safety of liraglutide in insulin pump treated people with type 1 diabetes: the lira pump trial

T.F. Dejgaard[1,2], C.S. Frandsen[2], S. Schmidt[2], D. Vistisen[1], S. Madsbad[2], H.U. Andersen[1], K. Nørgaard[2];

[1]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, [2]Dep. of Endocrinology, Hvidovre Hospital, University of Copenhagen, Hvidovre, Denmark.

Background and aims: Glucagon-like peptide-1 receptor agonists reduce body weight and risk of hypoglycaemia with moderate effect on HbA1c in people with type 1 diabetes (T1D) using basal-bolus insulin therapy. The evidence in people with insulin pump treated T1D is sparse.

Materials and methods: This randomised, double-blinded, placebo-controlled, 26-week trial evaluated the efficacy and safety of liraglutide 1.8 mg added to insulin pump therapy in overweight people with T1D and insufficient glycaemic control. In total 44 persons with insulin pump treated T1D, HbA1c >7.5 % and BMI >25 kg/m^2, were randomised to liraglutide 1.8 mg or placebo once daily added to insulin pump therapy.

Results: Baseline characteristics were similar between groups (mean (SD) or median (interquartile range)) HbA1c 8.2 (0.5) %, diabetes duration 20 (15;35) years, daily insulin dose 51 (17) IU/day and body weight 87 (12) kg. After 26 weeks of treatment, liraglutide reduced HbA1c and body weight compared with placebo (table). No differences were found in changes in daily insulin dose, time spent in hypoglycaemia (<3.9 mmol/l), heart rate or blood pressure between groups. Treatment satisfaction evaluated by the Diabetes Treatment Satisfaction Questionnaire version c (DTSQc) increased more with liraglutide than with placebo. Gastrointestinal adverse events occurred more frequently with liraglutide than placebo, e.g. nausea (39% vs. 20%). Finally, one event of severe hypoglycaemia was reported during the trial in a person treated with placebo.

Conclusion: Liraglutide 1.8 mg once daily added to insulin pump treatment in overweight people with T1D and insufficient glycaemic control reduces HbA1c, body weight and increases treatment satisfaction with no effect on daily insulin dose or time spent in hypoglycaemia compared with placebo after 26 weeks of treatment.

Key Results: 26 weeks of liraglutide 1.8 mg vs. placebo once daily added to insulin pump treatment

	Liraglutide, n=22 [95% CI]	Placebo, n=22 [95% CI]	Difference	*P* value

OP 26 Neuropathy: future targets

151

Olfactory function is associated with the intensity of self-reported physical activity in adults with type 1 diabetes

A. Duda-Sobczak[1], A. Araszkiewicz[1], M. Urbas[2], L. Borucki[2], M. Chudzinski[3], B. Falkowski[3], E. Jakubowska[3], A. Suwalska[3], D. Zozulinska-Ziolkiewicz[1];

[1]Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, [2]Department of Otorhinolaryngology, Raszeja City Hospital, [3]Department of Adult Psychiatry, Poznan University of Medical Sciences, Poznan, Poland.

Background and aims: Diabetes mellitus contributes to the central nervous system degeneration and cognitive decline. Olfactory dysfunction is related to the presence of diabetic neuropathy and suggested to be a clinical manifestation of central diabetic neuropathy. Regular physical activity is known to have beneficial effects on the metabolic control of diabetes, prevention of chronic neurovascular complications and cognitive function. The aim of this study was to assess olfactory function in relation to self-reported physical activity in adults with type 1 diabetes (T1D).

Materials and methods: We included 89 patients with type 1 diabetes (43 men), median age 35 (IQR 29-42) years, disease duration 17 (IQR 13-26) years, HbA1c 8.2 (IQR 7.3-9)%. The control group consisted of 22 healthy people matched for age and gender. The patients underwent ENT examination with nasal endoscopy to exclude other factors disabling sense of smell. Olfactory function was assessed with "Sniffin' Sticks. For the assessment of odor identification 12 pens with different odors were used and patient should select 1 of 4 presented items which best described each odor for every pen (score 0-12, normosmia: score 11-12). The short version of International Physical Activity Questionnaire (IPAQ) was used to assess self-reported physical activity. Higher IPAQ result reflects higher intensity of physical activity and is presented as the time spent on activities of different intensity in the last 7 days. We assessed the metabolic control of diabetes.

Results: Hyposmia was found in 70% of patients with T1D compared to 45% in control group (p=0.03). No differences in self-reported physical activity were found between T1D and control group (median score 1588 [IQR 975-3291] vs. 1968 [IQR 1257-3573], respectively; p=0.2). In T1D group we found a positive correlation between olfactory identification scores and IPAQ results (Rs 0.26; p=0.01) and a negative correlation of olfactory identification scores with body mass index (Rs -0.23, p=0.03) and triglycerides (Rs -0.22; p=0.04). Stepwise multiple linear regression analysis indicated IPAQ result (beta 0.26, p=0.01) and BMI (beta -0.24, p=0.03) as predictors of olfactory function independently from age, HbA1c and triglycerides.

Conclusion: Better olfactory function is observed in adults with type 1 diabetes who self-report higher intensity of physical activity. This study confirms the beneficial role of physical activity in type 1 diabetes within the structures of the central nervous system.

Somatosensory cortical plasticity determines clinical presentation in diabetic neuropathy

D. Selvarajah[1], I.D. Wilkinson[2], F. Fang[3], A. Sankar[1], J. Davies[1], E. Boland[1], R. Gandhi[3], I. Tracey[4], I. Tracey[4], S. Tesfaye[3];

[1]Department of Human Metabolism, University of Sheffield, [2]Academic Unit of Radiology, University of Sheffield, [3]Academic Department of Diabetes and Endocrinology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, [4]Functional Magnetic Resonance Imaging of the Brain Unit, Oxford University, Oxford, UK.

Background and aims: Cortical plasticity is a fundamental property of the human CNS that enables adjustment to nerve injury but it can have maladaptive consequences resulting in chronic pain. We have previously demonstrated significant brain volume loss localised to the primary somatosensory cortex (S1) in diabetic neuropathy (DN). More recently, we reported functional reorganisation of S1 in patients with painful DN who were also insensate. This study aims to examine the relationship between the degree of functional reorganisation and intensity of neuropathic pain.

Materials and methods: Clinical, neurophysiological and magnetic resonance imaging (MRI) data were compared for 35 Type 1 diabetes subjects [n=9 No-DN (male 6, mean age 45.9±10.1), 9 painless DN (5, 46.3±12.0), 9 painful DN sensate (4, 48.4±12.0) and 8 painful DN insensate (6, 44.5±12.1)] and 9 healthy volunteers (4, 51.5±7.9)]. 3T MRI system (Acheiva, Phillips) and cortical reconstruction and volumetric segmentation by FreeSurfer software were used. Blood oxygen level dependent (BOLD) functional magnetic resonance imaging (fMRI) was used to examine functional organisation of the S1 cortex in response to noxious thermal stimulation of the right foot. Linear regression analysis was performed to examine the contribution of brain structural changes (S1 cortical thickness), pain (neuropathic and evoked pain) and clinical parameters (age, neuropathy composite score, diabetes and pain duration) on observed S1 plasticity.

Results: Painful DN insensate subjects had significantly lower mean S1 cortical thickness [$F(4,39)=5.78$, $p=0.001$] compared to other study cohorts. No significant difference emerged between subjects in cortical thickness in the control region [frontal cortex $F(4,39)=1.23$, $p=0.31$]. On average somatosensory cortical thickness was 12.2% lower in painful DN insensate subjects compared to healthy volunteers. S1 plasticity was significantly correlated with overall neuropathic pain score (NTSS-6, r=-0.45, p=0.04), evoked foot pain score (r=-0.46, p=0.03) and S1 cortical thickness (r=-0.57, p=0.01). The most parsimonious regression model relied solely on neuropathy composite score as the independent variable ($R^2=0.54$, $F(1,15)=17.9$, $p=0.01$; adjusted $R^2=0.51$) that explained most of the variance in S1 plasticity.

Conclusion: Subjects with painful DN who were also insensate had the greatest reduction in S1 cortical thickness. FMRI demonstrated greater S1 cortical neuronal plasticity which was significantly associated with pain intensity and the severity of neuropathy. We have demonstrated in these experiments how structural brain changes are related to functional reorganisation of the S1 cortex which ultimately determines the clinical presentation of DN. This may provide clues to the pathogenesis of different sensory phenotypes of DN.

Nerve and vascular biomarkers in skin biopsies differentiate painful from painless advanced diabetic peripheral neuropathy

P. Shillo[1], D. Selvarajah[1,2], M. Greig[1], I.D. Wilkinson[2], Y. Yiangou[3], P. Donatien[3], P. Anand[3], S. Tesfaye[1];

[1]Diabetes Research Unit, Sheffield Teaching Hospitals NHS Foundation Trust, [2]University of Sheffield, Sheffield, [3]Peripheral Neuropathy Unit, Imperial College, London, UK.

Background and aims: Painful diabetic peripheral neuropathy (painful-DPN) can be intractable with major impact, yet the underlying pain mechanisms remain uncertain. While distal leg intra-epidermal nerve fibre density is recommended for the diagnosis of small fibre neuropathy, we found that intra-epidermal nerve markers may not differentiate between advanced painful-DPN and painless-DPN. The relationship of neuronal and vascular biomarkers was therefore investigated in painful-DPN and painless-DPN.

Materials and methods: 61 T2DM subjects and 19 healthy volunteers (HV) underwent detailed clinical and neurophysiological assessments and were subsequently divided into three groups based on the neuropathy composite score of the lower limbs [NIS(LL)] plus 7 tests (23 Painful-DPN, 19 Painless-DPN and 19 No-DPN). All subjects underwent calf skin punch biopsy, and immunohistochemistry was used to quantify intra-epidermal (IENF) and sub-epidermal (SENF) nerve fibres with structural marker PGP9.5, regenerating fibres with GAP43, sensory fibres with neuropeptide CGRP, and the dermal blood vessels with von Willebrand Factor (vWF).

Results: IENF density was severely decreased (p<0.001) in both DPN groups, with no differences for PGP9.5, GAP43, CGRP, or GAP43/PGP9.5 ratios. There was significant increase of vWF in Painless-DPN and no-DPN groups compared to controls, but this was markedly greater for painful-DPN, and significantly higher than painless-DPN (p<0.0001). The ratio of SENF CGRP:vWF showed a significant decrease in painful-DPN vs Painless-DPN (p =0.014).

Conclusion: In advanced neuropathy increased dermal vasculature and its ratio to nociceptors may differentiate painful-DPN from painless-DPN. Increased blood vessels following tissue ischaemia/hypoxia associated with disproportionate and abnormal nerve fibres (irritable nociceptors) may lead to a "painful vaso-neuropathy".

Corneal confocal microscopy detects improvements in small nerve fibres in subjects with latent autoimmune diabetes in adults with enhanced glycaemic control

U. Alam[1,2], I.N. Petropoulos[3], H. Fadavi[2], O. Asghar[2], G. Ponirakis[4], M. Jeziorska[2], A. Marshall[2], M. Tavakoli[2,5], A.J.M. Boulton[2], N. Efron[6], R. Malik[4,2];
[1]Department of Eye and Vision Sciences, Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, [2]University of Manchester, [3]Division of Diabetes, Endocrinology and Gastroenterology, Institute of Human Development, University of Manchester, Manchester, UK, [4]Weill Cornell Medicine-Qatar, Weill Cornell Medicine, Qatar, [5]University of Exeter, Exeter, UK, [6]Queensland University of Tecnology, Brisbane, Australia.

Background and aims: Latent Autoimmune Diabetes in Adults (LADA) is often misdiagnosed, and a prolonged period of poor glycaemic control may increase the risk of microvascular complications. We aimed to evaluate a cohort of subjects with LADA over 1 year and undertake detailed assessment of measures of large and small fibre neuropathy to assess the natural history of diabetic neuropathy.

Materials and methods: We have undertaken a detailed assessment of neuropathy in control subjects (C) (n=14), subjects with type 2 DM (T2DM) (n=14) and LADA (n=14) by quantifying: neuropathy disability score (NDS), peroneal and sural nerve conduction velocity and amplitude (PMNCV, PMNAmp, SSNCV, SSNAmp), cold threshold (CT), warm threshold (WT), corneal nerve fibre density (CNFD), branch density (CNBD) and fibre length (CNFL) at baseline and 1 year follow up.

Results: There was no significant difference in age (50.0±2.9 vs 54.0±6.5 vs 50.1±13.7 years, P=NS), duration of diabetes (T2DM: 5.3±3.9 vs LADA: 12.5 ±10.6 years, P=NS), blood pressure, total cholesterol, HDL, triglycerides and eGFR. HbA1c (39.7±2.8 vs 53.4±7.3 vs 83.8±25.3 mmol/mol, P<0.0001) was higher and BMI (29.4±5.2 vs 31.0±4.5 vs 26.5±4.6 kg/m^2, P=0.01) was lower in LADA compared to T2DM. There were no significant differences in NDS (0.3±0.6 vs 1.6±1.7 vs 3.8±3.3, P=NS), PMNCV (49.2±4.2 vs 44.3±8.8 vs 40.7±7.6 m/s, P=NS), PMNAmp (5.5±1.9 vs 4.0±2.1 vs 3.2±2.2 mV, P=NS), SSNCV (50.5±3.5 vs 47.8±5.1 vs 43.4±5.6 m/s, P=NS), SSNAmp (17.7±7.1 vs 12.6±7.6 vs 11.0±5.8 μV, P=NS), WT (37.0±3.1 vs 40.9±3.6 vs 42.4±5.0 °C, P=NS), CT (28.9±1.2 vs 27.0±3.2 vs 24.1±4.7 °C, P=NS) between LADA and T2DM. However, CNFL (16.9±4.6 vs 17.1±4.7 vs 11.7±3.3 mm/mm^2, *P*=0.003) and CNBD (37.8±18.0 vs 45.5±26.4 vs 21.0±10.6 no/mm^2, *P*=0.008) were significantly lower with no difference in CNFD (29.0±9.1 vs 28.8±9.8 vs 18.8±7.1 no/mm^2, *P*=NS) between LADA and T2DM. Comparing baseline to 1 year follow up, there were no changes in BMI, lipids, NDS, CT, WT and electrophysiology in C, T2DM and LADA. HbA1c, CNFD, CNBD and CNFL did not differ in C and T2DM. However, HbA1c was lower and approached significance (83.8±25.3 vs 70.0±17.4 mmol/mol, P=0.07) with a higher CNBD (21.0±10.6 vs 34.8±16.3 no/mm^2, *P*=0.005) and CNFL (11.7±3.3 vs 14.3±4.0 mm/mm^2, *P*=0.02) with no change in CNFD (18.8±7.1 vs 22.3±5.9 no/mm^2, *P*=NS) in LADA at 1 year follow up.

Conclusion: Subjects with LADA have a significant small fibre neuropathy due to poorer glycaemic control and enhanced glycaemic control improves neuropathy measured using CCM. CCM not only detects but also monitors progression of small fibre neuropathy and provides the ideal surrogate marker in therapeutic trials of diabetic neuropathy.

Genome-wide association study of neuropathic pain in individuals with type 1 diabetes

E. Valo[1,2], I. Toppila[1,2], N. Sandholm[1,2], C. Forsblom[1,2], P.-H. Groop[1,2], FinnDiane Study Group;
[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, [2]Abdominal Center Nephrology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background and aims: Neuropathic pain is one of the most common complications in individuals with diabetes, yet little is known about the genetic risk factors of the complication. Previous studies have suggested that part of the disease risk can be explained by genetic factors. We aimed to investigate the association of genetic factors with neuropathic pain in individuals with type 1 diabetes (T1D).

Materials and methods: This study included 2,292 individuals with T1D from the Finnish Diabetic Nephropathy Study (FinnDiane). The patients were required to have an age at onset of diabetes below 40 years and insulin treatment initiation within one year of diagnosis. Individuals were divided based on neuropathic pain into cases (N=677) and controls (N=1,615). Individuals filled a questionnaire and neuropathic pain was considered present if the individual was using drugs prescribed for neuropathic pain or if the individual had experienced burning or prickling pain in the foot or the leg. Controls were not using any of the pain medications and had not experienced burning or prickling pain in the feet or the legs after a minimum diabetes duration of 15 years. Genotyping was perfomed with the Illumina Human CoreExome chip. The genotype data was imputed using the 1000 Genomes Phase 3 version 5 reference panel. After quality control the imputed genotype data included approximately 7 million single nucleotide variants (SNVs). The association of the

genotype to neuropathic pain was tested using a score test with an additive model implemented in SNPTest.

Results: After adjusting for sex, age, diabetes duration, the 4 first genetic principal components and genotyping batch, 6 loci were suggestively associated with neuropathic pain with a p-value $\leq 10^{-5}$. The strongest association signal with a p-value of $9.5*10^{-7}$ was observed on chromosome 8q24.21 in an intergenic region between two uncharacterized non-coding RNA genes *LOC101927657* and *LOC105375749*.

Conclusion: We performed to date the largest GWAS study of neuropathic pain in T1D individuals. Suggestive association to neuropathic pain was observed for 6 loci. Further investigation of these variants in independent cohorts is required to confirm these associations.

Impairment of proopiomelanocortin-mu opioid receptor antinociceptive pathway contributes to painful diabetic neuropathy

D.D. Deshpande, T.H. Fleming, P.P. Nawroth;

Dept. of Internal Medicine I and Clinical Chemistry, University Hospital Heidelberg, Heidelberg, Germany.

Background and aims: One-third of diabetic patients experience hyperalgesia and/or allodynia. Current treatments are inefficient in reversing these symptoms and can have adverse side effects. Understanding the mechanisms underlying increased pain sensitivity will help design better treatment strategies. Pro-opiomelanocortin (POMC; endogenous opioid precursor) is cleaved to produce the opioid peptide β-endorphin, which binds to mu opioid receptor (MOR) resulting in alleviation of pain. This study examines the significance of POMC-MOR axis in context of painful diabetic periperhal neuropathy (DPN).

Materials and methods: Streptozotocin (STZ) induced C57Bl/6 mice were used to study changes in POMC-MOR. POMC and MOR expression was studied in the dorsal root ganglia (DRG), sciatic nerves(SN) and feet using ELISA, western blot and immunoflourescence. mRNA levels were determined by qPCR. Promoter studies were carried in AtT20 cells and in vivo using EMSA and ChIP techniques, while MOR regulation was studied in primary DRG culture and in vivo using live cell staining and kinase activity assay. Viral constructs of POMC and MOR were overexpressed in lumbar DRG of diabetic mice using direct DRG injections. Pain sensitivity was measured using hotplate, Hargreaves and Frey-filament technique. Lastly, POMC and MOR expression in human DRG were analysed by immunohistochemistry.

Results: Immune cells, previously identified to be opioid sources in injured nerves, were studied in the diabetic sciatic nerves. Although a two fold increase ($p<0.001$) in CD68+macrophages was observed in the sciatic nerves, an expression of opioids was not observed in these cells. Instead, the opioids were majorly present in the axons of sciatic nerves and neuronal cell bodies in lumbar DRG. At 12 weeks post STZ, opioid peptide level for the other classical opioids (proenkephalin and prodynorphin) were unchanged, but a significant downregulation was observed for POMC in DRG (46%; $p<0.05$), SN (62%; $p<0.01$) and feet (46%; $p<0.05$) compared to healthy controls. The downregulation in POMC was reflected in the decreased ß-endorphin (ng/mg protein) in SN (3.7 ± 1.17 vs 0.94 ± 0.79; $p<0.05$) and the feet (6.55 ± 0.02 vs 1.35 ± 0.55; $p<0.05$). High glucose induced NF-kB activation and its binding to POMC promoter was responsible for promoter suppression, and hence, the decreased POMC mRNA and peptide level. Surprisingly, MOR protein level, too, was decreased by 50% in DRG ($p<0.001$), SN ($p<0.05$) and feet ($p<0.05$). Downregulation of MOR was due to its lysosomal degradation induced by chronic PKC activation. Remarkably, the decreased POMC and MOR were associated with increased thermal and mechanical hypersensitivity in the diabetic mice, which was reversed upon overexpression of both genes. A decrease in POMC and MOR content was also observed in the lumbar DRG of diabetic patients.

Conclusion: This study reports for the first time, the importance of POMC-MOR antinociceptive pathway in the pathogenesis of DPN. Therefore, treatment strategies including stimulating the endogenous POMC levels and preventing the lysosomal degradation of MOR could help counter the pain.

Pharmacological autonomic blockade during experimental hypoglycaemia exacerbates cardiac repolarisation abnormalities

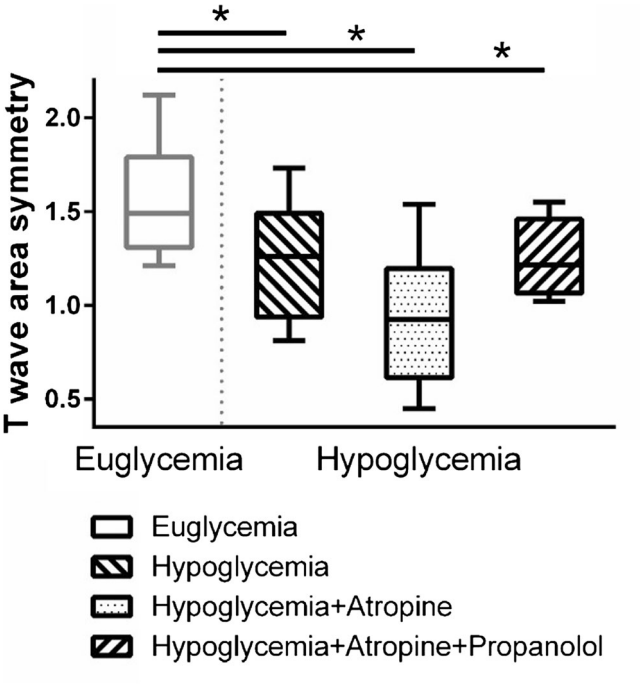
A. Bernjak[1], E. Chow[2], J. Lee[3], A. Iqbal[2], A. Lubina-Solomon[4], E. Walkinshaw[4], I.A. Macdonald[5], S.R. Heller[4], R.H. Clayton[6], P.J. Sheridan[3]; [1]Department of Oncology & Metabolism and INSIGNEO Institute for in Silico Medicine, University of Sheffield, [2]Department of Infection, Immunity and Cardiovascular Disease, University of Sheffield, [3]Department of Infection, Immunity and Cardiovascular Disease and Sheffield Teaching Hospitals NHS, University of Sheffield, [4]Department of Oncology & Metabolism, University of Sheffield, Sheffield, [5]School of Life Sciences, University of Nottingham, Nottingham, [6]Department of Computer Science, University of Sheffield, Sheffield, UK.

Background and aims: Hypoglycaemia may contribute to sudden death in patients with diabetes by provoking cardiac arrhythmias. Potential mechanisms include abnormal cardiac electrophysiology and autonomic neuropathy. We hypothesised that cardiac autonomic dysfunction may interact with direct effects of hypoglycaemia to increase arrhythmic risk. The aim of the study was to investigate the effect of hypoglycaemia and coincident pharmacological parasympathetic and sympathetic blockade on cardiac repolarisation and actaion potential duration.

Materials and methods: Six healthy subjects underwent sequential hyperinsulinaemic euglycaemic (5mmol/l) and hypoglycaemic (2.5mmol/l) clamp studies with parasympathetic (atropine) and sympathetic (propranolol) blockade given sequentially during hypoglycaemia. Twelve lead surface ECG and intracardiac electrograms at right ventricle apex and free wall were recorded. Corrected QT (QTc), parameters of ventricular repolarisation (T wave amplitude and area symmetry), complexity of repolarisation (PCA ratio) and intracardiac activation-recovery intervals (ARI) were calculated in all four conditions.

Results: During hypoglycaemia, mean adrenaline increased to 1.49 ±1.70nmol/l, noradrenaline to 2.31±0.84nmol/l and potassium fell to 3.38±0.22mmol/l (all $p<0.05$). Heart rate increased (Δ7±16bpm) and QTc prolonged (Δ29±35ms) during hypoglycaemia vs euglycaemia. Parasympathetic blockade under hypoglycaemia caused further increases in heart rate (Δ48±12bpm, $p<0.001$ vs euglycaemia) and QTc prolongation (Δ78±38ms, $p=0.004$). T wave symmetry significantly decreased (Δ-0.62±0.57, $p=0.04$, see figure), resulting in more symmetric waves and complexity of repolarisation increased (Δ11.6 ±10, $p=0.04$). ARIs shortened with atropine but non-uniformly across the right ventricle (Δ-33ms at apex, $p=0.004$ vs Δ-49ms, $p=0.001$ at free wall). After sympathetic blockade with propranolol all parameters were reversed to hypoglycaemia levels.

Conclusion: Blocking parasympathetic activity exacerbates abnormal cardiac repolarisation during experimental hypoglycaemia. This mechanism could contribute to arrhythmias that have been reported during clinical hypoglycaemic episodes. It is particularly relevant to diabetic autonomic dysfunction since diminished parasympathetic activity is an early manifestation.



Data: median and maximum range. * $p<0.05$

Severe hypoglycaemia, cardiovascular outcomes and death: the LEADER experience

B. Zinman[1], S.P. Marso[2], E. Christiansen[3], S. Calanna[3], S. Rasmussen[3], J.B. Buse[4], on behalf of the LEADER Trial Steering Committee and Investigators; [1]Mt Sinai Hospital, University of Toronto, Toronto, Canada, [2]University of Texas Southwestern, Kansas CityUSA, [3]Novo Nordisk A/S, Soborg, Denmark, [4]University of North Carolina School of Medicine, Chapel Hill, USA.

Background and aims: In the LEADER cardiovascular outcomes trial (N=9340), the risk of cardiovascular and hypoglycaemia events was reduced with liraglutide treatment vs placebo, when added to standard of care, in patients with type 2 diabetes and high risk for cardiovascular disease. This post hoc analysis examines the potential associations between severe hypoglycaemia and cardiovascular events and death.

Materials and methods: We analysed the time to first major adverse cardiovascular event (MACE) (cardiovascular death, non-fatal myocardial infarction or non-fatal stroke), cardiovascular death and all-cause death among patients with/without severe hypoglycaemia, and adjusted for different periods of follow-up and randomised treatment.

Results: During the trial, 267 patients experienced severe hypoglycaemia (liraglutide n=114, placebo n=153; rate ratio, 0.69; 95% CI: 0.51; 0.93). These patients were more likely than those without severe hypoglycaemia to experience MACE, cardiovascular death and all-cause death, with a considerably higher risk up to 60 days after the hypoglycaemic episode (Table), irrespective of treatment group. The protective effect of liraglutide on risk of MACE was unchanged when patients with severe hypoglycaemia were excluded from the analysis (patients with severe hypoglycaemia accounted for 5% of all MACE in the trial).

Conclusion: In conclusion, patients experiencing severe hypoglycaemia were at greater risk of cardiovascular events and death, particularly early after the hypoglycaemic episode. Reducing severe hypoglycaemia remains a cornerstone of diabetes management.

	Risk of outcome in patients with versus without severe hypoglycaemia, hazard ratio [95% CI], *p*-value

Efficacy and safety of insulin degludec/insulin aspart vs biphasic insulin aspart 30: an international randomised trial in adults with type 2 diabetes fasting during Ramadan

M. Hassanin[1], A. Echtay[2], R. Malek[3], M. Omar[4], S. Shaikh[5], E.G. Fita[6], K. Kaplan[6], N. Kamaruddin[7];

[1]Dubai Health Authority, Dubai, United Arab Emirates, [2]Rafic Hariri University Hospital, Beirut, Lebanon, [3]CHU Setif, Setif, Algeria, [4]KwaZulu University Natal, Durban, South Africa, [5]Prince Aly Khan Hospital, Mumbai, India, [6]Novo Nordisk, Søborg, Denmark, [7]Malaysia National University, Kuala Lumpur, Malaysia.

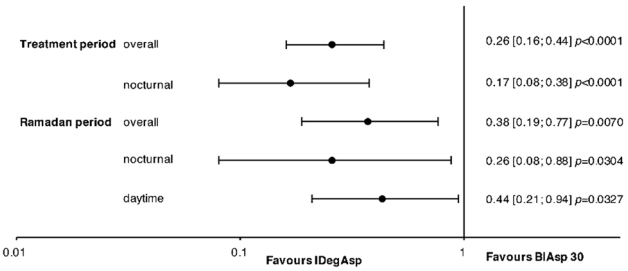
Background and aims: Muslims with type 2 diabetes (T2D) on twice daily (BID) mixed or basal-bolus insulin are at high risk of dehydration, hypoglycaemia and overt hyperglycaemia during Ramadan fasting (abstain from food or drink, dawn-sunset). Some are thus given medical and religious advice not to fast during Ramadan but many participate against this advice. Trials on insulin use in Ramadan are scarce. IDegAsp, a co-formulation of insulin degludec and insulin aspart is associated with reduced hypoglycaemia risk vs biphasic insulin aspart 30 (BIAsp 30) due to the flat pharmacokinetic profile and long duration of action of insulin degludec. This international, randomised, treat-to-target trial aimed to compare the efficacy and safety of IDegAsp vs BIAsp 30 during Ramadan.

Materials and methods: Adults with T2D who intended to fast and were on basal, pre- or self-mixed insulin ± oral antidiabetic drugs for ≥90 days, were randomised (1:1) to IDegAsp BID or BIAsp 30 BID. Treatment was for 16-28 weeks (treatment initiation: 8-20 weeks pre-Ramadan; Ramadan: 4 weeks; post-Ramadan: 4 weeks). Insulin doses were titrated to achieve a plasma glucose (PG) target of 4-5 mmol/L (72-90 mg/dL) during initiation and 5-7 mmol/L (90-126 mg/dL) during Ramadan. At Ramadan start, a 30-50% reduction in insulin dose taken at Suhur (pre-dawn meal) was recommended. Hypoglycaemia was recorded as severe (requiring third-party assistance), or confirmed (severe and/or PG <3.1 mmol/L) and analysed as overall, nocturnal (00:01-05:59), or daytime (2 h after Suhur-pre-Iftar [pre-sunset meal]; post hoc).

Results: Patients were randomised to IDegAsp (n=131) or BIAsp 30 (n=132). There was no significant difference with IDegAsp vs BIAsp 30 in HbA_{1c} reduction from baseline to end of Ramadan (end of treatment difference [ETD]: 0.02% [95% CI -0.20; 0.24], p=0.8426). During treatment, rates of overall and nocturnal hypoglycaemia were significantly lower with IDegAsp vs BIAsp 30 (Fig). During Ramadan, pre-Iftar self-measured PG (SMPG) was significantly lower with IDegAsp vs BIAsp 30 (ETD: -0.54 mmol/L [95% CI -1.02; -0.07], p=0.0247, post hoc). There were significantly lower overall, nocturnal and daytime hypoglycaemia rates with IDegAsp vs BIAsp 30 during Ramadan (Fig).

Conclusion: This trial in high-risk adults with T2D who fasted in Ramadan showed that IDegAsp had similar glycaemic efficacy to BIAsp 30 before and during Ramadan, but significantly lower overall and nocturnal hypoglycaemia rates during the treatment period. During Ramadan, despite achieving significantly lower pre-Iftar SMPG, IDegAsp had significantly lower overall, nocturnal and daytime hypoglycaemia rates vs BIAsp 30.

Figure. Hypoglycaemia rates of IDegAsp vs. BIAsp 30 during 28-week treatment period and 4-week Ramadan period



Data are presented as treatment rate ratios [95% CI]
CI, confidence interval; IDegAsp, insulin degludec/insulin aspart; BIAsp 30, biphasic insulin aspart 30

Weight gain is associated with mild to moderate hypoglycaemia in patients with type 1 diabetes: results from the DCCT

L. Potier[1], A. Bumbu[1], A. Moutairou[2], O. Matar[1], B. Detournay[3], R. Roussel[1];

[1]Endocrinology, Diabetology and Nutrition, AP-HP, [2]INSERM U1138, Paris, [3]CEMKA EVAL, Bourg La Reine, France.

Background and aims: In type 1 diabetes (T1D), the intensive glucose control has shown to prevent chronic complications of diabetes. However, this beneficial effect is associated with an increased rate of hypoglycemia and weight gain which can led to metabolic abnormalities similar to those found in the insulin resistance syndrome. Whether the higher weight gain observed during intensive glycemic control is associated with hypoglycemia is not clear. The aim of our study was to analyse the association between mild to moderate hypoglycemia and weight gain in patients with T1D from DCCT.

Materials and methods: We included the 1441 patients of DCCT. Mild to moderate hypoglycemia has been assessed by a score (hypo-score) calculated by dividing the number of self-monitoring blood glucose (SMBG) values <70 mg/dl by the total number of measurements done during all the DCCT quarterly visits. Weight was measured every 3 months and to calculate the annual weight gain we divided the total weight gain during the study by the years of follow up.

Results: The mean weight gain for all patients in DCCT was 1.19±1.37 kg/years. Mean number of SMBGs during the follow-up was 248±16 per patient. Mean hypo-score was 9.3±7.0. There was a significant association between the hypo-score and weight gain (p<0.001). The annual weight gain by tertile of hypo-score was 0.82±1.22 kg/years (T1), 1.32 ±1.47 kg/years (T2) and 1.42±1.32 kg/years (T3). There was a significant difference between the weight gain of tertiles T2 and T3 compared

with T1 (p<0.0001 for both comparison). After adjustment for age, sex, duration of diabetes, HbA1c at baseline and treatment arms, these differences remained significant (p<0.0001 for both comparison). Similarly, considering the weight gain from baseline during follow-up, a higher weight gain was observed in T2 and T3 compared with T1. We analyzed the risk of weight gain according to the hypo-score by dividing all the study population of DCCT in patients who gained more (25%) or less than 1.8 kg/years. The odd ration (OR) for a weight gain >1.8 kg/years was 2.14 (95%CI, 1.56-2.93) for T2 and 2.53 (95%CI, 1.85-3.45) for T3. After adjustment for the factors described above, the OR was 1.71 (95%CI, 1.19-2.47) for T2 and 1.57 (95%CI, 1.04-2.37) for T3.

Conclusion: In our study we observed that a higher rate of mild to moderate hypoglycemia, extrapolated from quarterly SMBG measurements, was significantly associated with a higher weight gain.

DPP-4 inhibition: preserved glucagon counterregulation during hypoglycaemia in elderly subjects with type 2 diabetes

J.H. Farngren, M. Persson, B. Ahren;
Lund University, Department of Clinical Sciences, Lund, Sweden.

Background and aims: Dipeptidyl peptidase-4 (DPP-4) inhibition is associated with a low risk of hypoglycemia when used as glucose-lowering therapy in type 2 diabetes. This is partially due to its glucose-dependency in stimulating insulin secretion but a sustained glucagon response if glucose levels decline may contribute. However, the glucose threshold for a glucagon counterregulation during DPP-4 inhibition is not known. In this study, we therefore evaluated the glucagon response to two-step lowering of glucose in patients treated with the DPP-4 inhibitor sitagliptin in combination with metformin. The study was undertaken in elderly subjects with mild type 2 diabetes, since DPP-4 inhibition is a common treatment in this group.

Materials and methods: The study was a single-center, double-blind, randomized, placebo (PBO)-controlled crossover study involving 28 subjects with type 2 diabetes (17 males, 11 females) with mean age 74 yrs (inclusion critera ≥65 yrs), diabetes duration 10 yrs, baseline HbA1c 51.5 mmol/mol and BMI 30 kg/m^2 who were treated with metformin (mean 1.7 g/day). Subjects received sitagliptin (100 mg OD) or placebo as add-on therapy for four weeks in random order with a four-week washout in-between. After each of the four week periods, the subjects underwent an initial meal test (to raise levels of incretin hormones), followed by a two-step hyperinsulinemic hypoglycemic clamp (target values of 3.5 and 3.0 mmol/l were preserved for 30 min), in turn followed by a lunch.

Results: After four weeks therapy, HbA1c was reduced by 2.3±0.6 mmol/mol during sitagliptin (P=0.001) vs. a non-significant increase of 0.6±0.4 mmol/mol during placebo. Glucose excursion after breakfast was lower after sitagliptin than after placebo (area under the 120 min curve 1.16±0.04 vs. 1.31±0.04 mmol/lxmin; P<0.001) and, similarly, the glucagon response to breakfast was lower after sitagliptin than after placebo (suprabasal area under the curve 260 ±119 vs. 649±111 pmol/lxmin; P=0.001). The glucagon response during clamp at 3.5±0.1 mmol/l was lower after sitagliptin than after placebo (1.6±1.0 vs. 5.5±1.5 pmol/l; P=0.021). In contrast, the glucagon response to further lowering glucose to 3.1±0.1 mmol/l was higher after sitagliptin than after placebo (14.5±2.3 vs. 11.0±2.6 pmol/l; P=0.007), resulting in similar glucagon values at end of clamp (see Fig.).

Conclusion: In elderly subjects with mild metformin-treated type 2 diabetes, the glucagon response to meal and the glucagon response to lowering glucose to 3.5 mmol/l are reduced by sitagliptin whereas the glucagon response to hypoglycemia at 3.1 mmol/l is sustained by sitagliptin. Hence, the glucose threshold for alleviating the inhibition by DPP-4 of glucagon secretion is between 3.5 and 3.1 mmol/l, assuring a sustained glucagon response to mild hypoglycemia. This may contribute to the low risk of hypoglycemia during DPP-4 inhibition in elderly subjects.

Glycaemic variability: a significant predictor of hypoglycaemia in type 1 and type 2 diabetes

S. Rama Chandran[1], W.L. Tay[1], W.K. Lye[2], L.L. Lim[3], J. Ratnasingam[3], A.T.B. Tan[3], D.S.L. Gardner[1];
[1]Endocrinology, Singapore General Hospital, [2]Centre for Quantitative Medicine, Office of Clinical Sciences, Duke-NUS Medical School, Singapore, Singapore, [3]Division of Endocrinology, Dept. of Internal Medicine, University of Malaya, Kuala Lumpur, Malaysia.

Background and aims: Hypoglycaemia is a major impediment to intensification of diabetes therapy. Whilst HbA1c is universally accepted as a marker of hyperglycaemia, it is a poor predictor of hypoglycaemia. To date, no specific marker for hypoglycaemia exists. We hypothesized that glycaemic variability (GV), measured by coefficient of variation (CV), is a significant predictor of hypoglycaemia, independent of HbA1c.

Materials and methods: HbA1c and blinded continuous glucose monitoring (CGM) over 4-6 days were performed in 100 type 2 diabetes (T2D) and 60 type 1 diabetes (T1D) subjects. CV: Standard deviation / Mean glucose (from CGM: CV-CGM, from self-monitored blood glucose: CV-SMBG). Hypoglycaemic episode = sensor glucose < 3mmol/L for ≥ 20 minutes (m). Outcomes: frequency of hypoglycaemic episodes / 24 hours (h) and duration of interstitial sensor glucose (ISG) < 3mmol/L (m / 24h). Statistical analyses included T tests, Mann Whitney U Test, multiple linear regression and ROC analysis.

Results: T1D patients were younger (35 ± 13y vs 57 ± 10y, p<0.001), leaner (BMI 22.3 ± 2.6 vs 28.9 ± 5.4 kg/m^2, p<0.001), had lower HbA1c [8.0 ± 1.6 vs 8.6 ± 1.7% (63.9 vs 70.5mmol/mol), p=0.015] and total daily dose (TDD) of insulin (0.71 ± 0.24 vs 1.0 ± 0.56 u/kg/d, p<0.001) compared to T2D. 94% of T2D were on sulphonylureas (SU) / insulin. Frequency of hypoglycaemia and duration of ISG <3mmol/L were higher in T1D than T2D (T1D vs T2D: episodes / 24h: 0.53 ± 0.69 vs 0.08 ± 0.17, m / 24h: 43.3 ± 69.3 vs 7.9 ± 27.3, both p<0.001). In T1D (Model r^2 =0.52, 0.55), CV was the only predictor of frequency of hypoglycaemia and duration of ISG <3mmol/l (β=0.68, β=0.70, both p<0.001). In T2D (Model r^2 =0.21, 0.27), CV was the main predictor of frequency of hypoglycaemia and duration of ISG <3mmol/l (β=0.49, β=0.45, both p<0.001) and was more predictive than HbA1c (β= -0.29, β= -0.08, both p<0.05). These were independent of age, gender, diabetes duration, race, insulin / SU use and TDD insulin. Mean CV was higher in T1D than T2D (0.4 + 0.1 vs 0.3 + 0.1, p<0.001). Hypoglycaemia episodes were differentiated by a significantly higher CV in both T1D and T2D, and a lower HbA1c only in T2D (Table 1). In T1D, a CV >0.37 predicted any hypoglycaemia with sensitivity 75%, specificity 75%, AUC 0.85. In T2D, a CV >0.30 predicted any hypoglycaemia with sensitivity 75%, specificity 65%,

AUC 0.80. CV-CGM correlated well with CV-SMBG in both T1D and T2D (both r=0.76, p<0.001).

Conclusion: CV of glucose is a major predictor of hypoglycemia in both T1D and T2D. HbA1c did not predict hypoglycaemia in T1D and was less predictive than CV in T2D. CV-SMBG correlated well with CV-CGM and could be used to target those at risk of hypoglycaemia for further intervention. Measures of glycaemic status and quality should go beyond HbA1c to incorporate CV.

Physical activity and premature mortality in patients with type 1 diabetes

H. Tikkanen-Dolenc[1,2], J. Waden[1,2], C. Forsblom[1,2], V. Harjutsalo[1,2], L.M. Thorn[1,2], M. Saraheimo[1,2], N. Elonen[1,2], H.O. Tikkanen[3,4], P.-H. Groop[1,2], the FinnDiane Study Group;

[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, [2]Abdominal Center Nephrology, University of Helsinki and Helsinki University Central Hospital, [3]Department of Sports and Exercise Medicine, Institute of Clinical Medicine, [4]Clinic for Sports and Exercise Medicine, Foundation for Sports and Exercise Medicine, Helsinki, Finland.

Background and aims: To assess whether baseline Leisure-Time Physical Activity (LTPA) is associated with mortality in patients with type 1 diabetes (T1D) with and without CKD.

Materials and methods: Prospective and observational study as part of the on-going nationwide multi-centre Finnish Diabetic Nephropathy (FinnDiane) Study. Mean follow-up time was 11.4 ± 3.5 years. The study included altogether 2369 patients with T1D (1633 normoalbuminuric, 312 microalbuminuric, 271 macroalbuminuric, and 153 with ESRD). Out of these patients 48.5% were men, mean age was 40.1±12.6 years, BMI 25.2±3.6 kg/m^2, SBP 135±19 mmHg, HbA_{1c} 8.3±1.4% and duration of diabetes 23.3±12.8 years. A total of 310 patients had chronic kidney disease (CKD) defined as eGFR ≤60 ml/min/1.73m^2. The primary end point was death from any cause. LTPA was assessed by a validated self-report questionnaire. The relationship between all-cause mortality and baseline total LTPA, as well as between all-cause mortality and exercise duration, frequency, and intensity were assessed.

Results: Of the patients with CKD, 127 died during follow-up. The total amount of LTPA (HR 1.47, 95%CI 1.02-2.12) and exercise frequency (1.90, 1.26-2.87) were associated with lower risk of mortality in these patients with CKD when adjusted for sex, diabetic nephropathy, duration of diabetes, age at onset of diabetes, systolic blood pressure, triglycerides, BMI and HbA_{1c}. Notably, all exercise components were associated with reduced premature mortality in the group of patients without CKD (N=2059, 143 events) adjusted for the previous covariates. In a separate analysis excluding patients with ESRD, there were altogether 200 deaths during follow-up. The total amount of LTPA (1.47, 1.10-1.96) and all exercise components (intensity [1.60, 1.17-2.17], duration [1.47, 1.01-2.16], frequency [2.09, 1.50-2.90]) were associated with reduced premature mortality also when adjusted for the same covariates as above.

Conclusion: Exercise is associated with lower risk of premature mortality in patients with type 1 diabetes. Frequent physical activity reduces the risk of premature mortality also in patients with type 1 diabetes and CKD.

Both type 2 diabetes and prediabetes are associated with low heart rate variability: the Maastricht Study

C. Coopmans[1], R. Henry[1], J. Heijman[1], A. Koster[1], P. Dagnelie[1], N. Schaper[1], C. van der Kallen[1], R. den Engelsman[2], H. Crijns[1], C. Stehouwer[1]; [1]The Maastricht Study Group; Cardiovascular Research Institute Maastricht (CaRIM); MUMC+, Maastricht, [2]Fysiologic ECG Services B.V., Amsterdam, Netherlands.

Background and aims: Autonomic dysfunction is a risk factor for cardiovascular morbidity and mortality in type 2 diabetes (T2D). Heart rate variability (HRV) is a marker of autonomic dysfunction and is known to be 'low' in individuals with T2D with established cardiovascular disease. Population-based data on the association between T2D and HRV is scarce. In addition, there is scarce data on the association between prediabetes and HRV, despite the fact that low HRV may explain prediabetes-associated increased

cardiovascular morbidity and mortality. We therefore investigated the association between glucose metabolism status and HRV in the population-based Maastricht Study with the use of 24hECG registrations.

Materials and methods: 2506 participants (mean age: 59±8 years; 52% men; 1421 with normal glucose metabolism (NGM), 383 with prediabetes and 702 with T2D (oversampled)) underwent an extensive phenotyping protocol including 24hECG registrations. HRV was defined in both the time and frequency domain (individual Z-scores for both, based upon 7 and 6 parameters, respectively). Linear regression analyses (with NGM as reference category) were used and adjusted for age, sex, BMI, alcohol use, smoking, physical activity (model 1), prior cardiovascular disease, hypertension, antihypertensive medication, estimated glomerular filtration rate, lipid profile and lipid-modifying medication (model 2).

Results: After adjustment for the variables of model 1, the time domain Z-score (β(95%CI)), as compared to NGM, was -0.28(-0.37;-0.18) in T2D and -0.11(-0.21;-0.01) in prediabetes. After full adjustment (model 2), the time domain Z-score was -0.24(-0.35;-0.14) in T2D and -0.08(-0.19;0.02) in prediabetes. After adjustment for the variables of model 1, the frequency domain Z-score, as compared to NGM, was -0.27(-0.35;-0.20) in T2D and -0.10(-0.18; -0.01) in prediabetes. After full adjustment (model 2), the frequency domain Z-score was -0.22(-0.30;-0.13) in T2D and -0.07(-0.15;0.01) in prediabetes. Further analyses showed independent and continuous associations between fasting and post-load OGTT glucose levels and HbA1c with both HRV domains (P<.001 for all).

Conclusion: In this population-based study both T2D and prediabetes are independent determinants of HRV. This is further substantiated by the independent and continuous associations between HRV and glucose and HbA1c. These data thereby strongly support, for low HRV, the 'ticking clock hypothesis' with its central role for hyperglycemia before the onset of T2D.

Disclosure: **C. Coopmans:** None.

Metabolic profile of cardiovascular disease risk in Chinese people with diabetes: the Da Qing Diabetes long-term follow-up study

Y. Chen[1], Z. Zou[2], X. Qian[1], H. Jia[2], J. Wang[3], H. Lee[3], Q. Gong[1], Y. An[1], N. Shi[1], G. Li[1];

[1]Fuwai Hospital, Chinese Academy of Medical Sciences, Beijing, [2]Institute of Medicinal Plant Development, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, [3]Da Qing First Hospital, Daqing, China.

Background and aims: Diabetes is a major risk factor for cardiovascular morbidity and mortality, but it is hard to predict early cardiovascular diseases (CVD) in type 2 diabetes. The aim of this study was to find potential biomarkers of CVD caused by hyperglycemia through metabonomics analysis in the cohort population of the China Da Qing Diabetes Study (CDQDS).

Materials and methods: UPLC-MS/MS analysis was performed in 120 subjects were new diagnostic diabetes mellitus (NDM) and 120 subjects were normal glucose tolerance (NGT) who were diagnosed by oral glucose tolerance test in 1986. The plasma samples were collected during the follow-up study in 2009 and selected the patients including 50% with CVD and without CVD in each group respectively. Principal component analysis and orthogonal partial least squares discriminant analysis were performed. Potential biomarkers were selected on the basis of variable importance in the project value and S-plot. The specific metabolites related to CVD caused by diabetes were obtained by subtracted the impact of diabetes and CVD to the metabolites.

Results: The clinical characters of the CDQDS cohort in 2009 showed more risk factors in NDM with CVD than in NGT with CVD, including higher Systolic blood pressur (152.2±24.8 vs. 143.6±22.0 mmHg, p<0.05), HbA_{1c} (8.2±1.2 vs. 6.2±1.0 %, p<0.001), Serum Total Cholesterol (5.6±1.5 vs. 4.8 ±1.0 mmol/L, p<0.01), Low density lipoprotein cholestero (129.2±45.8 vs. 110.2±32.0 mg/dL, p<0.01) and urinary albumin creatinine ratio [median(IQR): 57.0(17.0, 302.5) vs. 18.0(9.0, 51.5), p<0.001]. By UPLC-MS/MS analysis and subtraction, 72 specific metabolites related to diabetic CVD were obtained. The results of metabolic network analysis showed that eight metabolic pathways with impact value > 0.1 were considered as the most pertinent in the process of disease. According to the order of the impact value (from high to low), the pathways were glycerophospholipid, arachidonic acid, sphingolipid andglycerolipid metabolism, glycosylphosphatidylinositol-anchor biosynthesis, lysine degradation, fructose and mannose metabolism, and tyrosine metabolism. Further compare to NGT without CVD, thirty-four metabolites increased at least 1.0 fold in NGT with CVD and increased at least 2.4 folds in NDM with CVD that indicate they were closely related to CVD with diabetes. Eight out of the 34 metabolites increased1,000-8,000 folds in NDM with CVD compare with NGT with CVD. Four of the 8 metabolites were identified as phosphatidylglycerol (PG, 16:1(9Z)/18:1(9Z), phosphatidylcholine (PC, 18:3/P-18:1), phosphatidylcholine (PC,20:1/18:1) and 20-Hydroxyeicosatetraenoic acid, three of them belong to glycerophospholipid metabolism pathway which were the important metabolites with atherosclerosis and CVD risk.

Conclusion: Seventy-two specific metabolites and eight metabolic pathways were found and associated with diabetic CVD. The increase changes of plasma glycerophospholipid metabolites were the important markers for cardiovascular diseases risk, these metabolites increased more in diabetes with CVD. It suggests that the further studies will be focused on the glycerophopholipid metabolites.

Interactive changes in cardiovascular risk factors and the long-term cardiovascular risk differ by adiposity levels in incident type 2 diabetes patients: real world study

E. Adjah[1], O. Montvida[1], K. Khunti[2], S. Paul[3];

[1]QIMRB, Brisbane, Australia, [2]Uni of Leicester, Leicester, UK, [3]Uni of Melbourne, Melborune, Australia.

Background and aims: Patterns of interactive changes in cardiovascular risk (CVR) factors at different adiposity levels and their long-term consequences on CVR in patients (pts) with incident type 2 diabetes (T2DM) have not been studied at population level. Aim of this study was to evaluate the changes in HbA1c, body weight (WT), systolic blood pressure (SBP) and LDL-cholesterol (LDL) over 2 yrs post diagnosis of T2DM, and the association of interactions of such changes with long-term CVR.

Materials and methods: From UK primary care database, 10040 normal weight, 35941 overweight and 88391 obese pts at diagnosis of T2DM (after 1999), aged 18-70 years, without history of CV disease (CVD), kidney disease, cancer or bariatric surgery, and a minimum 2 yrs of follow-up, were identified. CVD was defined as first occurrence of heart failure, stroke or ischemic heart diseases. Adjusted CVR for different categories of risk factor reduction, compared to those who did not reduce any risk factor at 2 yrs from diagnosis, were estimated.

Results: Patients were on average 51 yrs old, 44% female, and 53% ever smokers. Among obese pts with mean HbA1c 8.6%, WT 101 Kg, SBP 140 mmHg and LDL 3.3 mmol/L at diagnosis: 24, 47 and 26% had reductions in WT ≥ 5%, SBP ≥ 5 mmHg and LDL ≥ 1 mmol/L at 2 yrs respectively. While 38% pts did not achieve reduction in any risk factor, 11% reduced both WT and SBP, and 1.6% reduced all 3 factors simultaneously. Among those with HbA1c ≥ 7.5% at diagnosis, 33% achieved HbA1c ≤ 7% at 2 yrs. Among obese, compared to those who did not reduce any CVR factor by above categories, those who reduced WT and SBP, and all risk factors simultaneously had 18% (CI of HR: 0.74, 0.91) and 55% (CI of HR: 0.33, 0.61) significantly reduced CVR (Table 1). Among overweight pts, only simultaneous reduction in SBP and LDL was associated with 38% significant reduction in CVR (CI of HR: 0.48, 0.80). Among normal weight pts with mean HbA1c 9.1%, WT 67 Kg, SBP 134 mmHg and LDL 3.3 mmol/L at diagnosis: 15, 44 and 29% reduced WT ≥ 5%, SBP ≥ 5 mmHg and LDL ≥ 1 mmol/L respectively at 2 yrs. While 44% pts did not achieve reduction in any risk factor, only 7 / 1.2% reduced WT and SBP / all factors simultaneously. Among those with HbA1c ≥ 7.5% at diagnosis, 36% achieved HbA1c ≤ 7% at 2 yrs. In normal weight pts, WT reduction alone or in combination with other risk factor reductions, did not significantly reduce CVR. Glycaemic control with HbA1c ≤ 7% was

independently associated with 19, 15 and 10% reduction in CVR in normal weight, over weight and obese patients respectively ($p < .05$).

Conclusion: This real-world study with 8 yrs of median follow-up suggests significant differences in the synergy between CV risk factors control in patients under different adiposity levels. While the association of WT and SBP reduction (independently or in combination with reduction in LDL) with CVR were significant among obese patients, significance of such dynamics was not clear among normal and overweight patients.

Table 1: Hazard Ratio (95% CI) for composite cardiovascular risk in different categories of risk factor control, compared to those who failed to reduce body weight, blood pressure and LDL cholesterol. Hazard Ratio (95% CI) for those who reduced HbA1c below 7% at 2 years from diagnosis of diabetes, compared to those who failed to achieve glycaemic control. Separately for BMI categories at diagnosis of diabetes; adjusting for age, sex, baseline weight, systolic blood pressure, LDL cholesterol, HbA1c; stratified by smoking status, quantiles of age and appropriate medications; and accounting for immortality bias.

Reduction in Risk Factors	Normal Weight (N=10,040)	Overweight (N=35,941)	Obese (N=88, 391)
Weight Reduction ≥ 5%	0.83 (0.59, 1.18)	1.25 (1.09, 1.44)	0.86 (0.78, 0.96)
SBP Reduction > 5 mmHg	0.79 (0.63, 0.98)	0.91 (0.82, 1.01)	0.92 (0.86, 0.98)
LDL Reduction ≥ 1 mmol/l.	0.74 (0.48, 1.15)	0.81 (0.64, 1.04)	0.77 (0.64, 0.92)
Weight and SBP Reduction	0.82 (0.59, 1.13)	1.00 (0.86, 1.16)	0.82 (0.74, 0.91)
Weight and LDL Reduction	0.24 (0.03, 1.75)	0.77 (0.46, 1.27)	0.57 (0.39, 0.84)
SBP and LDL Reduction	0.57 (0.36, 0.90)	0.62 (0.48, 0.80)	0.66 (0.55, 0.79)
Simultaneous Reduction in all Factors	0.36 (0.11, 1.13)	0.72 (0.48, 1.08)	0.45 (0.33, 0.61)
HbA1c ≤ 7%	0.81 (0.68, 0.97)	0.85 (0.79, 0.93)	0.90 (0.85, 0.96)

Development and validation of a decision support tool for individualising lipid, blood pressure and aspirin treatment in patients with type 2 diabetes

G.F.N. Berkelmans[1], S. Gudbjörnsdottir[2], S. Franzén[2], A.-M. Svensson[2], Y. van der Graaf[1], B. Eliasson[2], F.L.J. Visseren[1], J.A.N. Dorresteijn[1], Diabetes Collaborative Study Group;
[1]UMC Utrecht, Utrecht, Netherlands, [2]National Diabetes Register, Gothenburg, Sweden.

Background and aims: Patients with type 2 diabetes (DM2) are at high risk of cardiovascular disease (CVD). Therefore, CVD prevention is vitally important in patients with DM2. However, preventive treatment effects differ between patients depending on their baseline CVD-risk as constituted by their risk factor levels. Our aim was to develop and geographically validate in different continents a treatment decision support tool for individualizing lipid, blood pressure and aspirin treatment in patients with DM2 by estimating treatment effects on 10-year CVD-risk and CVD-free life-expectancy.

Materials and methods: The prediction algorithm was developed based on a random 75% of patients of the Swedish National Diabetes Registry included after 2002 (SNDR; n=295,614). The algorithm includes predetermined clinical patient characteristics that are commonly available in practice (figure 1). It consists of two complementary competing risk adjusted Cox proportional hazards models with left truncation (i.e. using age as the time-scale) and right censoring for prediction of the survival without CVD-events (vascular mortality, stroke or myocardial infarction) and non-vascular mortality. This algorithm can be used for the prediction of CVD-free life-expectancy and 10-year CVD-risk for individual patients. When combined with hazard ratios from randomized trials or meta-analyses, individualized preventive treatment effect can be estimated. Validation was performed in patients with DM2 enrolled in the ADVANCE-trial (n=11,139), ACCORD-trial (n=10,251), ASCOT-trial (n=4,646), ALLHAT-trial (n=3,903), SMART-cohort (n=1,910) and EPIC-NL-cohort (n=524), pooled by geographical origin.

Results: An example of an individual life-expectancy estimation is shown in figure 1 for a 60-year old man. The estimated effect of statin use for this patient is shown, assuming a 20% relative risk reduction for CVD. Similarly, the effects blood pressure-lowering and aspirin use or a combination of treatments can be estimated, both for immediate or postponed initiation. Predicted and observed survival without myocardial infarction or stroke showed good agreement in all external validation sets. The c-statistic, as a measure of model discrimination, was in Western Europe 0.65 (95% CI 0.64-0.67), Eastern Europe 0.67 (95% CI 0.64-0.70), Asia 0.66 (95% CI 0.63-0.68), North America 0.64 (95% CI 0.63-0.65), and Oceania 0.62 (95% CI 0.58-0.66).

Conclusion: CVD-free life expectancy can be estimated for individual patients with DM2 by using a validated prediction algorithm. When combined with hazard ratios from trials, the effect of lipid-lowering, blood pressure-lowering and aspirin treatment can be calculated for individual patients. This may facilitate personalized medicine and shared decision-making.

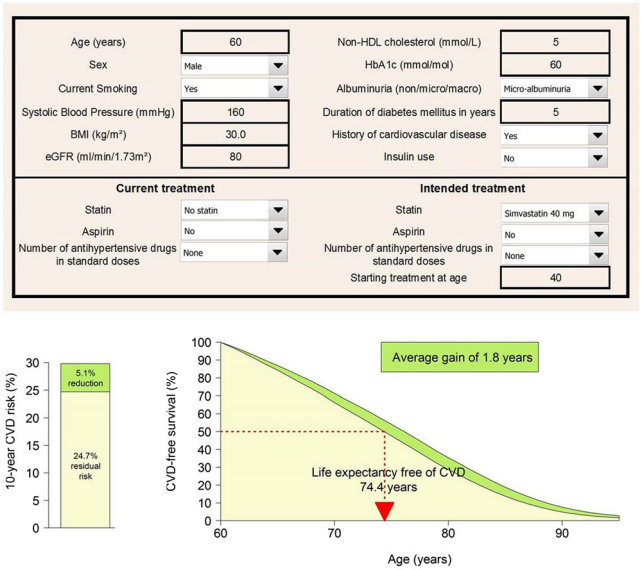

Figure 1: Screenshot of the decision-making support tool: example of an individual treatment effect estimation for a 40-year old patient, considering starting statin treatment in 20 years at age 60.

Lower risk of cardiovascular disease with higher refill adherence to lipid-lowering therapy in patients with type 2 diabetes

S.A. Karlsson[1], S. Franzén[2], C. Hero[1], B. Eliasson[1], A.-M. Svensson[2], M. Miftaraj[2], S. Gudbjörnsdottir[1,2], K. Eeg-Olofsson[1], K. Andersson Sundell[1,3];
[1]Institute of Medicine, University of Gothenburg, [2]Swedish National Diabetes Register, Gothenburg, [3]AstraZeneca AB, Mölndal, Sweden.

Background and aims: Lipid-lowering therapy (LLT) has shown to reduce the risk of cardiovascular disease (CVD) in patients with type 2 diabetes (T2D). The aim of this study was to analyze the risk of CVD in relation to refill adherence level in patients with T2D initiating LLT as primary or secondary prevention.

Materials and methods: Patients ≥ 18 years, registered with T2D in the Swedish National Diabetes Register, who filled at least one prescription for LLT between 1 Jan 2007 and 31 Dec 2010 were identified in the Swedish Prescribed Drug Register. Patients with filled LLT prescriptions within a year prior to inclusion were excluded to obtain new users. Patients with CVD prior to inclusion were defined as receiving LLT as secondary prevention; otherwise patients received primary prevention. Refill adherence was estimated by the medication possession ratio (MPR) during an 18-month exposure period following inclusion. MPR represent the proportion of days with LLT at hand and was divided into five levels; 0-20%, 21-40%, 41-60%, 61-80% and 81-100%. Risk of CVD was analyzed by MPR level from the day after the exposure period until migration, CVD, death, or 31 Dec 2013 using Cox proportional hazard regression and survival plot generated, adjusting for concurrent medicines, socioeconomic and clinical factors.

Results: In total, 86 568 patients were included, 70% were born in Sweden and 57% were men. The mean age was 63 years, average diabetes duration was 5 years and mean HbA1c was 54 mmol/mol. The mean BMI was 30 and 22% were physically active less than once a week. Mean MPR was 77% in primary prevention patients (n=74 909) and 83% in secondary prevention patients (n=11 659). compared to patients with MPR 81-100%, the hazard ratios for CVD increased with lower MPR level, from 1.33 to 2.36 (p<0.001) for primary prevention, and from 1.19 to 1.58 (p<0.001) for secondary prevention. The figure shows the survival probability at different MPR levels in patients with LLT as primary prevention.

Conclusion: The risk of CVD increased with lower refill adherence to LLT in primary and secondary prevention patients with T2D. This indicates that a high level of adherence to LLT is important to optimize the cardiovascular prevention in T2D.

Glucose uptake in skeletal muscle, brain and visceral adipose tissue assessed with PET/MR strongly predicts whole body glucose uptake during hyperinsulinaemia

G.J. Boersma[1], K. Heurling[2], M.J. Pereira[1], E. Johansson[2], M. Lubberink[2], J. Lau Börjesson[1], P. Katsogiannos[1], S. Skrtic[3], J. Kullberg[2], H. Ahlström[2], J.W. Eriksson[1]; [1]Medical sciences, University of Uppsala, [2]Surgical Science, Section of Radiology, University of Uppsala, Uppsala, [3]R&D & Dept. of Medicine, AstraZeneca, Gothenburg, Sweden.

Background and aims: Type 2 diabetes (T2D) is characterized by impaired glucose homeostasis, associated with beta-cell failure and insulin resistance. The current study aimed to assess: 1) in which main metabolic tissues glucose uptake (GU) has the highest predictive value for whole body insulin sensitivity, and 2) glucose uptake rates in various region of the brain in relation to whole body insulin sensitivity.

Materials and methods: 12 non-diabetic control (Con) and 12 T2D subjects ($HbA1_c$: Con: 33.7±0.6 mmol/mol; T2D: 57.1±3.4 mmol/mol,) matched for age (Con: 62±2 y; T2D: 62±2 y), sex (6 M /group) and BMI (Con: 30.1±1.3 kg/m^2; T2D: 30.4±1.1 kg/m^2) were recruited. Rate of glucose uptake (rGU) was measured in individual tissues using dynamic whole-body ^{18}FDG PET combined with MR during a hyperinsulinemic (approx. 110 mU/L) euglycemic clamp. This allowed for concomitant measurement of whole body insulin sensitivity and rGU in selected tissues; brain, visceral abdominal fat (VAT), subcutaneous abdominal fat (SAT), liver, heart, and the thigh muscle. To analyze the association of rGU of the different cortical regions within the brain to whole-body insulin sensitivity a voxel-wise analysis was performed.

Results: Subjects with T2D had significantly lower whole body glucose uptake (M-values in Con: 9.06 ± 1.15 mg/kg LBM/min; T2D: 5.12 ± 0.69 mg/kg LBM/min, p<0.01). In T2D, rGU was significantly lower in the thigh muscle, liver, VAT and SAT, but higher in the brain compared to con (all p<0.05). There were positive correlations between the M-value and rGU in SAT (r=0.524, p<0.05), VAT (r=0. 789, p<0.001) and muscle (r=0.871, p<0.001). In contrast, there was an inverse correlation with brain rGU (r=-0.678, p<0.05). There was a tendency (p= 0.053) for correlation with liver rGU, whereas there was no correlation with myocardial rGU. In multivariate regression analysis rGU in the muscle, VAT and brain had the highest predictive value for the M-value (r^2 for model= 0.88, p<0.001; muscle: Std.β Coeff. = 0.51, p<0.01; VAT: Std.β Coeff. = 0.28, p<0.05; brain: Std. β Coeff. = -0.34, p<0.01). Adding rGU in liver, SAT or heart did not improve the model, and this was also true for BMI, body fat percentage, sex, age, waist/hip ratio or $HbA1_c$. Using a voxel-wise analysis approach we observed the strongest inverse correlation in the brain rGU vs M-value in the associative visual cortex. The secondary visual, the somatosensory association and the premotor cortex and the angular and the inferior prefrontal gyrus also showed significant correlations (all p<0.001).

Conclusion: We showed that rGU in brain and peripheral organs displayed opposite associations with whole body GU and insulin sensitivity during hyperinsulinemia. Multivariate modeling suggests that skeletal muscle, brain and VAT rGU together strongly predict whole-body GU and insulin sensitivity. Thus, altered metabolic function of these tissues is of importance for impaired glucose turnover in T2D. Skeletal muscle quantitatively dominates in insulin-mediated glucose disposal. In contrast, dysregulated glucose handling in VAT and brain may be related to altered signaling from these tissue to muscle and other organs.

Endogenous glucose production is independently associated to brain glucose uptake in morbidly obese subjects

E. Rebelos[1], M. Bucci[1], H. Immonen[1], J. Hannukainen[1], L. Nummenmaa[1], P. Iozzo[2], P. Nuutila[1];

[1]Turku PET Centre, University of Turku and Turku University Hospital, Turku, Finland, [2]CNR, Institute of Clinical and Experimental Physiology, Pisa, Italy.

Background and aims: In preclinical studies, direct cerebral insulin action suppresses endogenous glucose production (EGP). Recent imaging studies during euglycaemic hyperinsulinemia have shown that brain glucose uptake is increased in subjects with impaired glucose tolerance. Our aim was to investigate whether brain insulin-stimulated glucose uptake (GU) is associated with EGP in healthy and morbidly obese insulin resistant subjects.

Materials and methods: Twenty morbidly obese (BMI 43.7±0.8 $kg \cdot m^{-2}$; 6 with T2D) and 14 age-matched healthy controls were recruited. Whole body and brain GU were measured during euglycemic hyperinsulinemic clamp with [^{18}F]FDG-PET. The obese group was studied before and 6 months after bariatric surgery. EGP was measured during clamp with [^{18}F]FDG. Brain GU parametric images were calculated using the Gjedde-Patlak plot. Voxel-based mapping analysis was done using SPM12. A p value <0.05 at cluster level, corrected for false discovery rate (FDR) was considered statistically significant.

Results: As compared to controls, morbidly obese were insulin resistant (M-value 11.5±1.4 vs. 36.4±2.6 $\mu mol \cdot kg^{-1} \cdot min^{-1}$, p<0.0001). Insulin-stimulated brain GU and EGP were significantly higher in obese when compared to controls (21.0± 3.0 vs 19.3± 1.7 $\mu mol \cdot 100g^{-1} \cdot min^{-1}$, p=0.01, and 2.80±0.66 vs -0.49±1.12 $\mu mol \cdot kg \cdot min^{-1}$, p=0.01, respectively). Brain GU associated inversely with M-value in the whole dataset and in the obese group alone (p<0.001, in both). Only in the obese group, brain GU correlated positively with EGP in the whole brain (p<0.0005) and separately in gray and white matter (p<0.001, both). The EGP-brain GU correlation remained significant after accounting for M-value or age (p=0.02 and p<0.0005 respectively). After surgery, BMI decreased by 24% (p<0.0001) and whole-body insulin sensitivity improved by 113% (p<0.0001). The positive correlation between insulin-stimulated brain GU and EGP persisted (p<0.0001) and so did the negative correlation between M-value and brain GU (p<0.001). When accounting for M-value or for age, the correlation between EGP and brain GU remained (p<0.001, for both). Interestingly, insulin-stimulated brain GU before surgery was associated with an increase in fasting glucose at 3 years of follow-up (p<0.001), but not with changes in body weight.

Conclusion: In the present study, independently from whole-body insulin sensitivity, insulin-stimulated brain GU correlated positively with EGP in morbidly obese subjects. This association persists after bariatric surgery-induced marked weight loss and improvement in insulin sensitivity. This study suggests an independent interrelation between liver and brain glucose metabolism and that enhanced brain GU might be a predictor of worse glycemic control in the future.

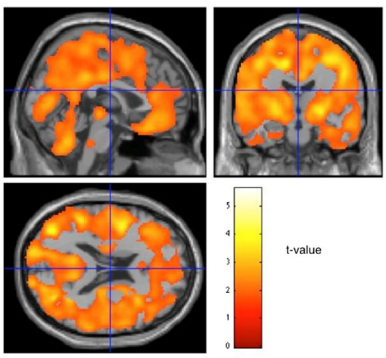

Fig. 1 Brain glucose uptake during insulin stimulation is positively associated with EGP in obese subjects (n=20) (p-value < 0.001, FDR-corrected)
*Brighter colours denote higher significance. Threshold p <0.05 (uncorrected)

GLP-1 receptor agonism preserves parahippocampal glucose metabolism in Alzheimer´s disease

M. Gejl[1], B. Brock[2], L. Egefjord[1], K. Vang[2], A. Gjedde[3], J. Rungby[3];
[1]Aarhus University, [2]Aarhus University Hospital, Aarhus, [3]University of Copenhagen, Copenhagen, Denmark.

Background and aims: T2D increases the risk of Alzheimer's disease (AD) and vice versa, but the understanding of underlying mechanisms is poor. Animal models point to hippocampus (HC) and parahippocampus (PHC) as sites of insulin resistance (IR) leading to cognitive dysfunction in T2D and AD. A major feature of AD is the steady decrease of cerebral metabolic rate of glucose (CMRglc). The decline of CMRglc is closely related to cognitive impairment as a marker of neuronal activity and disease progression. In experimental models, GLP-1 receptor agonism alleviates several features of neurodegeneration. We predicted that treatment with liraglutide would raise CMRglc measured with PET in AD patients.

Materials and methods: In this 26-week, double-blind, placebo-controlled trial, we randomized 38 patients with AD to treatment with liraglutide (n=18) or placebo (n=20). We mapped HC and PHC values of CMRglc and volume from regional radioactivity, and we scored changes of cognition with the WMS-IV scale during the observation period.

Results: With placebo, CMRglc declined significantly in PHC (P=0.048) and insignificantly in HC (P=0.17) but remained unchanged with liraglutide. Overall cognition did not change in either group, with significant impairment of orientation with placebo vs liraglutide (P =0.041). In PHC at baseline, we confirmed the predicted positive correlations between CMRglc and cognition (P=0.008, r=0.5), CMRglc and volume (P=0.039, r=0.37), and volume and cognition (P=0.008, r=0.5). We also confirmed the negative correlation between values of CMRglc and duration of AD (P=0.004, r=-0.5). PHC volume decreased with increasing BMI (P=0.01, r=-0.44), increasing fasting plasma glucose (P=0.02, r=-0.42) and increasing age (P=0.04, r=-0.36). Volumes remained constant within and between groups.

Conclusion: In AD, liraglutide prevented the decline of CMRglc in PHC seen with placebo, signifying cognitive impairment and disease evolution. As sites of imaging, the cognitively relevant PHC and HC regions are easily identified targets of determination of cerebral glucose metabolism.

Cerebral effects of ketone bodies in humans: reduced glucose uptake, unchanged oxygen consumption, and increased blood flow by positron emission tomography

M. Svart[1], L. Gormsen[2], J. Hansen[3], D. Zeidler[4], M. Gejl[5], K. Vang[2], J. Arnerud[2], N. Moeller[1];
[1]Department of Internal Medicine and Endocrinology & Department of Clinical Medicine, Aarhus University Hospital, [2]Department of nuclear medicine and PET Center, Aarhus University Hospital, [3]Section for Forensic Chemistry, Aarhus University Hospital, [4]5Centre of Functionally Integrative Neuroscience (CFIN) and MINDLab, Aarhus University Hospital, [5]Institute of Biomedicine, Aarhus University, Aarhus, Denmark.

Background and aims: High levels of ketone bodies have experimentally and clinically been shown to be effective in a number of neurological disorders and these neuroprotective effects have been linked to increased blood flow, decreased glucose utilization and - theoretically - improved oxygen efficiency. Here, we tested whether 3-hydroxybutyrate (3OHB) beneficially affects CNS blood flow and glucose and oxygen consumption in human subjects.

Materials and methods: Five men and four women were included in a randomized, controlled, crossover study. All subjects were investigated twice after an overnight fast during 1) saline infusion (CTR) or 2) ketone body infusion (KET) with Na-3-hydroxybuturate (3-OHB (75g/l)). We used positron emission tomography to estimate cerebral metabolic rate of glucose

(CMR_{glu} - by ^{18}F-labelled FDG) and oxygen (CMR_{oxygen} by ^{15}O-labelled O_2) consumption and blood flow (CBF by ^{15}O-labelled H_2O) in the brain in the two conditions.

Results: 3OHB was elevated during KET (5.5±0.4 mmol/l) compared with CTR (0.2±0.02 mmol/l), p<0.001. Ketosis resulted in 15% lower CMR_{glu} during KET (19.6±0.8 mmol/100g/min) compared with CTR (22.8±1.3 mmol/100g/min), p=0.02. CBF increased 30% during KET (52.0±2.0 ml/100 g /min) compared with CTR (40.9±2.1 ml/100 g/min), p<0.001, whereas CMR_{oxygen} was unaffected by 3-OHB. Paired two-tailed t-test was used to test for differences.

Conclusion: We conclude that acute ketone body infusion reduces CMR_{glu} and increases CBF, without detectable effects on CMR_{oxygen}. Increased oxygen supply in the presence of unchanged oxygen utilisation and - possibly - a favourable oxygen-ATP ratio may explain the neuroprotective effects of ketone bodies.

The role of maternal obesity on short-term modulation of offspring neural circuits

J.A. Faria, J.M. Gaspar, L. Velloso;
University of Campinas, Campinas, Brazil.

Background and aims: Maternal obesity is associated with significant changes in the metabolism of the offspring, which can have impact on weight gain, glucose homeostasis, adiposity and other physiological conditions during adulthood. Most studies have focused on the effects of maternal obesity on the functional regulation of metabolically relevant peripheral tissues such as the liver, muscle, adipose tissue and pancreatic islets. Very little is known about the effects of maternal obesity on the hypothalamic activity of the offspring. The hypothalamus responds to nutrients and hormones controlling caloric intake and energy expenditure, which impact on whole body energy homeostasis. Therefore, the aim of the present study was to determine if maternal obesity can influence development of hypothalamic POMC neurons, microglia and astrocytes and to elucidate potential underlying mechanisms.

Materials and methods: We used a mouse model of maternal diet-induced obesity. Female C57Bl/6J mice were fed either a control diet or an obesogenic diet from three weeks prior to mating and during pregnancy and lactation. Male offspring were weaned at 21 days and immediately studied. Distribution of POMC neurons, microglia and astrocytes was measured by fluorescence microscopy and zoometric parameters were determined at same point. In parallel, metabolic parameters related to dams were investigated at both pregnancy and lactation periods in order to define the maternal programming factors.

Results: Dams fed a high fat diet presented increased body weight before (t-test, p<0.05) and during (p<0.0001) pregnancy. Furthermore, there was increased adiposity (p<0.01 both), hyperglycemia (p<0.01 and p<0.05, respectively) and hyperinsulinemia (p<0.01 and p<0.05, respectively) at both stages, pregnancy and lactation. Male offspring born from obese dams presented decreased body weight at birth (p<0.01) and at third (p<0.05) week of age. At weaning, male offspring from obese dams presented decreased ACTH and IBA1 (microglia) staining whereas GFAP (astrocytes) staining was considerably increased in the arcuate nucleus.

Conclusion: Together, our findings revealed an impaired development of hypothalamic neural circuits modulated by maternal obesity even at premature stage of offspring life**.** As ACTH is a product of POMC neurons, our results suggest the offspring from obese dams presented losses in an important anorexigenic component at arcuate nucleus short-term. In addition, microglia and astrocytes, which control inflammation, gliosis, and neuronal stress were found modulated by maternal obesity at the same hypothalamic region. As arcuate nucleus provides many physiological roles involved in feeding and metabolism, the imbalance in the expression of its different neuronal types may be related to the development of metabolic diseases in offspring adult life. The evaluation of young adult offspring from lean and obese dams will be undertaken in future.

Exenatide modulates visual cortex response to food images

G. Daniele[1], P. Binda[2], R. Eldor[3], R. DeFronzo[4], J. Lancaster[5], P. Fox[5], S. Del Prato[1], M. Abdul-Ghani[6];
[1]Department of Clinical and Experimental Medicine, Section of Metabolic Diseases, University of Pisa, [2]Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, [3]Diabetes Unit, Institute of Endocrinology, Metabolism & Hypertension, Sourasky Medical Center, Tel-Aviv, Israel, [4]Division of Diabetes, University of Texas Health Science Center, [5]Imaging Research Center, University of Texas Health Science Center, [6]Division of Diabetes, University of Texas Health Science Center, San Antonio, San Antonio, USA.

Background and aims: GLP1 enhances metabolic activity in neural tissue and modulates food-related behavioral responses. We investigated whether this effect may involve changes in early sensory processing of stimuli such as visual appreciation of food images.

Materials and methods: The effect of Exenatide (Ex) on fMRI responses to food and non-food pictures was evaluated in 10 normal weight (NW: age 40.2±6.9 yrs; BMI 24.8±0.9 Kg/m^2) and 10 NGT obese subjects (OB: 49.4±6.1 yrs, 34.2±1.1 Kg/m^2). fMRI responses to images were evaluated before and after i.v. EX (0.05 μg/min). BOLD signal at rest (BSR) was calculated as the average of the raw fMRI signal in the last 3 volumes of the rest blocks. Visual activations (BSV) were computed as % signal change relative to BSR.

Results: Under baseline condition OB had comparable plasma glucose (93±3 vs. 93±2 mg/dl) and higher insulin (11±1 vs 6±1 μU/mL; p=0.002). BSR was higher in NW vs. OB in the parieto-occipital cortex (899±12 vs 837±13 a.u.) with no effect on temporal and frontal cortex. Across occipital cortex, there was a negative correlation between BSR and BMI (r= -0.43; p<0.001). With EX infusion, there was no difference in plasma glucose (94±2 vs 92±3 mg/dl) and insulin concentrations (32 ±9 vs 30±6 μU/mL) in the two groups. BSV increased in a parallel manner in both groups over most of the cortex, extra-striate areas (lateral-occipital, sparing V1) and prefrontal cortex so that BSV was higher in absolute terms in NW but with similar percent increase (+15 vs +17%). BSV was reduced in temporal pole in both groups.

Conclusion: BSR is higher in NW. EX modulated BSV responses to food images in a similar manner in OB and NW, though the former always had higher numerical BSV values. These preliminary results support a role for GLP-1 in food image brain processing

The Rab27 effector, exophilin-8, assembles insulin granules for exocytosis in the actin cortex via interaction with RIM-binding protein and myosin-VIIa

T. Izumi, F. Fan, K. Matsunaga;
Molecular Medicine, Institute for Molecular and Cellular Regulation, Maebashi, Japan.

Background and aims: Secretory granules generated at the *trans*-Golgi network must somehow pass through the actin cortex before they fuse with the plasma membrane. However, the precise mechanism by which they anchor and prepare for exocytosis is unknown. Exophilin-8 (also known as MyRIP and Slac2-c) is suspected to play a role in this process, due to its direct binding activities to Rab27 on the granule membrane and to F-actin and its motor protein, myosin-Va.

Materials and methods: We generated exophilin-8-knockout mice to examine its in vivo function in glucose tolerance and insulin secretion. We further identified exophilin-8-interacting proteins, using the tandem affinity purification approach followed by a liquid chromatography-tandem mass spectrometry analysis, and investigated their roles in insulin secretion in beta cells.

Results: Exophilin-8-null mouse pancreatic islets lose polarized granule localization at the beta-cell periphery and exhibit impaired insulin secretion. We further show that exophilin-8 accumulates granules in the cortical F-actin network not by direct interaction with myosin-Va, but by indirect interaction with myosin-VIIa through its previously unknown binding partner, RIM-binding protein (RIM-BP2). RIM-BP2 also associates with pivotal exocytic machinery, such as Cav1.3, RIM, and Munc13-1. Disruption of the exophilin-8-RIM-BP2-myosin-VIIa complex by ablation or knockdown of each component markedly decreases both the peripheral accumulation and exocytosis of granules.

Conclusion: The newly identified, exophilin-8-RIM-BP2-myosin-VIIa complex acts as a physical and functional scaffold and provides a mechanism supporting a releasable pool of granules within the F-actin network beneath the plasma membrane.

Glucocorticoids re-programme the beta cell signalling cassette to preserve functional identity and insulin secretion

N.H.F. Fine[1], C.L. Doig[1], Y. Elhassan[1], P. Marchetti[2], M. Bugliani[2], L. Piemonti[3], G.A. Rutter[4], D.A. Jacobson[5], G.G. Lavery[1], D.J. Hodson[1];
[1]Institute of Metabolism and Systems Research, University of Birmingham, Edgbaston, UK, [2]Department of Endocrinology and Metabolism, University of Pisa, Pisa, [3]Diabetes Research Institute, San Raffaele Scientific Institute, Milan, Italy, [4]Section of Cell Biology and Functional Genomics, Imperial College London, London, UK, [5]Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville, USA.

Background and aims: Excessive glucocorticoid exposure is considered to be deleterious for pancreatic beta cell function and insulin release. However, glucocorticoids at physiological levels are essential for many homeostatic processes, including normal glycemic control. Here, we set out to investigate the mechanisms by which glucocorticoid might directly affect beta cell function.

Materials and methods: Islets from wild-type and 11β-hydroxysteroid dehydrogenase type 1 (11B-HSD1) knockout animals were treated for 48 hrs with corticosterone or the less active 11-dehydrocorticosterone (11-DHC). Insulin secretion was measured using HTRF assay. Beta cell gene expression was determined with RT-PCR. Intracellular calcium (Ca^{2+}), ATP/ADP and cyclic AMP (cAMP) fluxes were monitored using fluo8/Fura2, Perceval and Epac2-camps, respectively. Insulin granule distribution was mapped in 3D using structured-illumination microscopy. Analogous studies were repeated in human islets but using instead cortisol and cortisone.

Results: Corticosterone (cort) and 11-DHC impaired beta cell Ca^{2+} responses to glucose but not incretin via effects on voltage-dependent Ca^{2+} channel function (amplitude = 5.01 vs. 3.21 AU, control vs. cort; P<0.01). However, beta cell identity was unaffected, with normal Ins1, Pdx1 and Nkx6.1 expression and ATP/ADP responses to fuel. Moreover, insulin content and glucose- and KCl-stimulated insulin secretion remained intact (2.55 vs. 3.28 ng/ml, control vs. cort; non-significant). Strikingly, glucocorticoid increased the number of membrane-proximal granules, and boosted glucose-induced cytosolic cAMP signals (AUC = 17.41 vs. 30.90 AU, control vs. cort; P<0.01). Notably, insulin secretory failure was induced using lipotoxicity to restrain cAMP responses to glucose (P<0.05). Effects of 11-DHC could be prevented by glucocorticoid receptor antagonism using RU486 (P<0.01) (amplitude = 2.23 vs. 2.51 AU, 11-DHC vs. 11-DHC + RU486; P<0.05), and were associated with pre-receptor glucocorticoid availability, since deletion of 11B-HSD1 rescued Ca^{2+} responses and normalized cAMP generation (11-DHC) (P<0.01). Similar results were seen in human islets, with both cortisone and cortisol impairing Ca^{2+} fluxes, while potentiating cAMP rises and maintaining insulin secretion.

Conclusion: We have identified a feedback loop whereby steroid boosts cAMP to maintain insulin secretion in the face of perturbed ionic signals in rodent and human islets. This is important from a translational viewpoint, since failure of this protective feedback loop may contribute to impaired beta cell function, insulin release and diabetes risk during states of glucocorticoid excess (e.g. Cushing's), which are associated with profound dyslipidemia.

Beta-arrestin2 plays a key role in GLP-1 receptor signalling in pancreatic beta cells

M.A. Ravier, M. Leduc, A. Varrault, J. Obeid, S. Costes, S. Dalle, G. Bertrand;
Institut de Genomique Fonctionnelle, Montpellier, France.

Background and aims: The scaffold protein β-arrestins (ARRB1 and ARRB2) are ubiquitously expressed and are known to uncouple G protein coupled receptors (GPCR) from G protein and to recruit new signaling pathways (such as ERK1/2) to the activated GPCR. We have recently shown the involvement of ARRB2 in the regulation of pancreatic β-cell mass and identified a defect of insulin signaling. Nevertheless, the role of ARRB2 in the signaling of the GLP-1 receptor (GLP-1R), a GPCR, remains to be elucidated. Our study aims to determine the molecular mechanism(s) involving ARRB2 in the signaling of GLP-1R in living β-cells by dynamic imaging measurements.

Materials and methods: The experiments were carried out in mouse β-cells from $Arrb2^{+/+}$ or $Arrb2^{-/-}$ mice. Four-month-old or twelve-month-old male mice were used. cAMP production, endogenous PKA and endogenous ERK1/2 activation were measured after adenoviral infection of mouse β-cells with FRET-based sensors of interest (CAMP-epac, AKAR3, EKAR; respectively) by live microscopy. CREB phosphorylation was determined by immunofluorescence. Expression of ARRB2 and GLP-1R were measured by qPCR and western blot. The islet mass was determined by morphometric analysis of pancreatic sections stained with eosin/hematoxylin.

Results: In β-cells from $Arrb2^{+/+}$ mice, GLP-1 (10pM/100pM/1nM/10nM) lead to cAMP production and rapid activation of PKA with a maximum reached between 100pM-1nM. Surprisingly, PKA activation under GLP-1 remained sustained (10nM) or persisted at least 25min (1nM) after stopping the stimulation in contrast to the effect of 1μM Forskolin (reversibility <2min), which produced more cAMP than 10nM GLP-1. In β-cells from $Arrb2^{-/-}$ mice, cAMP production and PKA recruitment were higher than in $Arrb2^{+/+}$ cells in the presence of pM range (1-100pM) of GLP-1 (p<0.05), but not at the nM range, suggesting that ARRB2 contributes to a partial uncoupling of the GLP-1R for the production of cAMP. Conversely, GLP-1-induced ERK1/2 activation was strongly decreased (~50%, p<0.001), indicating a major recruitment of ERK1/2 by ARRB2 to GLP-1R. Finally, the activation of CREB, a

transcription factor involved in β-cell survival, was also significantly decreased ($p<0.05$). Interestingly, during aging, the increase in pancreatic islet mass was correlated with an increase in the expression of GLP-1R and ARRB2, while Arrb2-/- aged mice were unable to fully compensate their pancreatic islet mass.

Conclusion: Our study revealed for the first time in living mouse β-cells, a significant role of ARRB2 in the signaling of GLP-1-R, involving not only inhibition of the cAMP/PKA pathway but also the recruitment of ERK1/2 kinases and activation of CREB. Most importantly, it occurs in the pM range of GLP-1, which is the physiological circulating concentration of the incretin. Thus, any variation in the expression of ARRB2 should affect the signaling of GLP-1R.

A TRPV1-to-secretagogin regulatory axis controls beta cell survival by modulating protein turnover

K. Malenczyk[1,2], F. Girach[2], E. Szodorai[2], R. Schnell[3], R. Romanov[1,2], T. Hökfelt[1], T. Harkany[1,2];

[1]Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden, [2]Department of Molecular Neurosciences, Center for Brain Research, Vienna, Austria, [3]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Ca^{2+} sensor proteins are generally implicated in insulin release through SNARE interactions. Secretagogin is an EF-hand Ca^{2+} sensor protein which is amongst the most abundant proteins in pancreatic β cells.

Materials and methods: Here, we combined bulk mRNA expression profiling of pancreatic islets obtained from a human cohort and single-cell RNA-seq from diabetic donors to establish a correlation between secretagogin expression and the incidence of type 2 diabetes. We then used pharmacological probing, *in silico* models, secretagogin promoter assays, biochemistry and mouse genetics to establish receptor-to-transcription factor signaling pathway controling secretagogin expression. Next, we generated secretagogin knockout$^{(-/-)}$ mice to determine the effects of secretagogin loss on glucose metabolism, integrity and function of pancreatic islets. By using cellular models and acute genetic manipulations combined with global proteomics and histochemical tools, we proposed an unexpectedly distinct mechanism of action for secretagogin.

Results: Secretagogin mRNA expression in human pancreatic islets correlates with their insulin content and the incidence of type 2 diabetes. Single cell RNA-seq reveals retained expression of the TRP family members in β cells from diabetic donors. Amongst these, pharmacological probing identifies Ca^{2+}-permeable transient receptor potential vanilloid type 1 channels (TRPV1) as potent inducers of secretagogin expression through recruitment of Sp1 transcription factors. Accordingly, agonist stimulation of TRPV1s fails to rescue insulin release from pancreatic islets of glucose intolerant secretagogin$^{-/-}$ mice. However, instead of merely impinging on the SNARE machinery, reduced insulin availability in secretagogin$^{-/-}$ mice is due to β cell loss, which is underpinned by the collapse of protein folding, ER stress and deregulation of secretagogin-dependent USP9X deubiquitinase activity.

Conclusion: Therefore, a ubiquitously Ca^{2+}-driven TRPV1-to-secretagogin transcriptional axis is suggested as a signal transduction pathway whose deregulation can curtail the life-long structural integrity and functional competence of pancreatic β cells.

FGF21/analogue suppresses high-fat diet induced islet cell dysfunction and cell apoptosis in mice

T. Xie, P. Leung;

School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China.

Background and aims: Lipotoxicity in the pancreas is a lipid metabolism disorder, which is due to the excessive accumulation of lipid intermediates in islets, finally leading to islet dysfunction and β-cell apoptosis, as seen in obesity-related type 2 diabetes mellitus (T2DM). Fibroblast growth factor 21 (FGF21) is a potent regulator of lipid homeostasis that has been reported to be beneficial for islet cell health. However, the protective mechanism(s) whereby FGF21 regulates islet fatty acid (FA) metabolism, thereby protecting islet failure under lipotoxic conditions remain elusive. We, therefore, sought to explore the protective effects of FGF21/analogue on islet lipid metabolism in lipototoxicity-induced animal and cell models.

Materials and methods: For in vivo models, C57/BL6J mice and global FGF21 knockout (KO) were fed with a 60% high-fat diet (HFD) and standard diet for 12-20 weeks; the HFD-treated mice were given with a long-acting mimetic of FGF21 (CVX-343/PF-0523102, a gift from Pfizer) for 6 weeks. For in vitro and ex vivo models, rat β-cell line INS-1E and islets isolated from normal C57/BL6J mice were cultured and exposed to palmitic acid (PA normal: 0mM; high: 0.7mM) with/without FGF21 (100nM), mimicking lipotoxic conditions for different time course studies. Real-time quantitative PCR, RNA-seq and Western blot analyses were performed for the expression levels of the genes and proteins of interest.

Results: In animal experiment-treated with the FGF21 analogue (CVX-343), there were significant reductions in the HFD-induced body-weight gain (44.18 ± 1.13 vs 35.13 ± 0.71 g, n=15, $p<0.0001$), the levels of fasting blood glucose (12.77 ± 0.48 vs 9.47 ± 0.48 mM, n=15, $p<0.0001$) and triglyceride accumulation (0.144 ± 0.003 vs 0.080 ± 0.004 ug/mg protein, n=15, $p<0.0001$); meanwhile, the levels of glucose tolerance (2722 ± 134.5 vs 1942 ± 96.4, n=15, $p<0.0001$) and insulin sensitivity (987.3 ± 118.3 vs 575.5 ± 57.1, n=15, $p<0.01$) were markedly improved, in relation to the HFD-fed control mice. Moreover, FGF21 KO mice fed with HFD exhibited decreases in insulin sensitivity (1292 ± 12 vs 1946 ± 137, n=5, $p<0.05$) and glucose tolerance (2984 ± 280 vs 3703 ± 132, n=5, $p<0.05$), in relation to HFD-fed control mice. Exogenous application of FGF21 in isolated islets from wildtype mice displayed higher expression of lipid oxidation-related genes, including carnitine palmitoyltransferase-1 (CPT1, 6.04 ± 0.33 vs 7.58 ± 0.34, n=4, $p<0.05$) and acyl-CoA oxidase (ACO, 2.50 ± 0.06 vs 3.11 ± 0.10, n=4, $p<0.01$), in relation to the PA-treated islets; these observed effects were due, in part, to the activation of the PPARα/RXR signaling, as demonstrated by RNA-seq. In INS-1E cell studies, FGF21 treatment ameliorated the PA-induced FA levels (16.84 ± 0.97 vs 9.66 ± 0.47 mEq/g protein, n=4, $p<0.001$) and triglyceride accumulation (1.32 ± 0.06 vs 0.90 ± 0.04 ug/mg protein, n=4, $p<0.01$); meanwhile, FGF21 reversed high PA-induced cell apoptosis (197.5 ± 10.1 vs 170.3 ± 5.7 %, n=4, $p<0.001$) and improved cell proliferation (62.0 ± 1.2 vs 71.8 ± 2.6 %, n=5, $p<0.05$), as well as enhanced glucose stimulated insulin secretion (1.95 ± 0.16 vs 2.62 ± 0.13, n=4, $p<0.05$).

Conclusion: Our study findings indicate that FGF21 is protective against lipotoxicity-induced islet cell dysfunction and cell demise, probably via the mediation of lipid homeostasis, in HFD-treated mice; these data lend furher support for FGF21 analogue as a therapeutic target for obesity and T2DM.

Dual Leucine zipper Kinase (DLK) activity is required for beta cell plasticity during gestation, obesity and postnatal development

A. Abderrahmani[1], H. Ezanno[1], C. Jacovetti[2], V. Plaisance[1], M. Tenenbaum[1], J. Bourry[1], A. Bonnefond[1], J. Kerr-Conte[3], F. Pattou[3], R. Regazzi[2], P. Froguel[1];

[1]CNRS UMR 8199, Lille 2 University, Lille, France, [2]Fundamental Neuroscience, Lausanne University, Lausanne, Switzerland, [3]INSERM U1190, Lille 2 University, Lille, France.

Background and aims: Multiple signaling pathways are involved in the physiological adaptation of the functional beta cell mass during gestation, obesity and postnatal development. We performed integrative unbiased

analyses including transcriptomics and kinomics, to identify most potent signaling pathways involved in the rat postnatal islet beta cell maturation.

Materials and methods: mRNA profiling was performed by Arraystar using Agilent Technologies and global serine/threonine kinases (kinome STK) was done by PamGene technology in isolated islets from newborn (p10) and weaned rats (p21 or p31). Islets were isolated from pregnant rats, obese mice fed high fat diet for 15 weeks and ob/ob mice. DLK knock out mice was used for measuring beta cell mass. The role of DLK was investigated in rat or human islets dispersed cells or insulin secreting cells using siRNAs. DLK mRNA and protein levels were quantified by quantitative real-time PCR and western blotting respectively. Proliferation and apoptosis were assessed by Ki67 staining and by counting pycnotic nuclei, respectively.

Results: Microarray analysis revealed a 70 fold increase in the expression of the MAPK activator Dual Leucine Zipper Bearing Kinase (DLK) as the most important modified gene in islets of newborn rat islets cells when compared to weaned rats. Increase of DLK expression was also found in compensatory islets of obese individuals when compared to obese diabetic patients, and in gestational rats and obese mice models including ob/ob and high fat diet, which are characterized by an increase in the beta cell number and function. Furthermore, the kinome analysis revealed that the dramatic increase of DLK expression was associated with a strong JNK activity, particularly JNK3, a kinase target of GLP-1 that is required for beta cell function and survival. We found that DLK positively regulates JNK3 activity, and that this regulation is essential for beta cell survival, proliferation and insulin secretion. DLK KO mice displayed reduced JNK activity and had drastic reduction in the beta cell number, whereas the alpha cells number was unchanged. The role of DLK was confirmed by in vitro experiments. Silencing of DLK in islet beta cells reduced JNK3 activity, beta cell proliferation and increased beta cell apoptosis. Inversely, overexpression of DLK improved beta cell survival and insulin secretion via JNK3.

Conclusion: DLK regulates the beta cell plasticity by controlling JNK3 activity. Activating DLK may have therapeutic implications for enhancing the functional beta cell mass in T2D

Safety and tolerability of empagliflozin in patients with type 2 diabetes and advanced kidney disease: a large pooled analysis of placebo-controlled trials

A. Levin[1], M. Nangaku[2], T. Kadowaki[2], K. Tuttle[3], S. Hauske[4], C. Zeller[5], S. Kohler[4], M. von Eynatten[4], C. Wanner[6];

[1]University of British Columbia, Vancouver, Canada, [2]Graduate School of Medicine, University of Tokyo, Tokyo, Japan, [3]Providence Health Care, University of Washington, Spokane, USA, [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, [6]Department of Medicine, Würzburg Univ Clinic, Würzburg, Germany.

Background and aims: Patients with T2D and overt CKD are considered at high risk of AEs. Since current European prescribing information for empagliflozin (EMPA) offers its use in patients with some degree of impaired renal function, we assessed its safety and tolerability in patients with T2D and advanced kidney disease.

Materials and methods: We pooled 12,620 patients randomized (1:1:1) to EMPA 10 mg, 25 mg or placebo (PBO) in 15 PBO-controlled trials and 4 extension studies: this identified 1590, 586 and 32 individuals with CKD Stage 3A, 3B and 4, respectively. Total exposure to PBO, EMPA 10 mg and EMPA 25 mg was 1099, 1183 and 1169 years (CKD Stage 3A); 441, 415 and 422 years (CKD Stage 3B); and 15, 19 and 26 years (CKD Stage 4). Analyses are descriptive and based on investigator-reported AEs.

Results: Rates of SAEs, AEs leading to discontinuation, and AEs of special interest were generally balanced between the 2 EMPA doses and PBO across all 3 CKD subgroups. Consistent with current European prescribing information, AE reporting for genital infections was higher for EMPA, and a numerical increase in UTI with EMPA in CKD Stage 4 was seen. The latter may be interpreted with caution due to the low number of events.

Conclusion: Our comprehensive analysis suggests that safety and tolerability of EMPA in patients at advanced stages of CKD is reassuring. However, careful consideration of the current prescribing information for the use of EMPA in this population is recommended.

Consistent effect of empagliflozin on composite outcomes related to heart failure: results from EMPA-REG OUTCOME

J. Schnee[1], S.E. Inzucchi[2], B. Zinman[3], J. McGinniss[1], J.T. George[4], D. Fitchett[5];

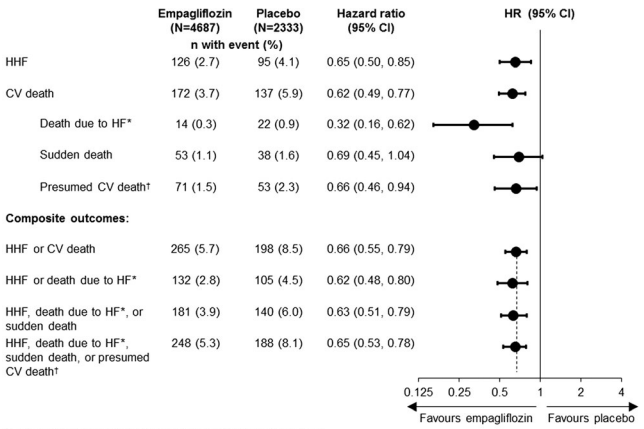
[1]Boehringer Ingelheim Pharmaceuticals, Inc, Ridgefield, [2]Section of Endocrinology, Yale University School of Medicine, New Haven, USA, [3]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, Division of Endocrinology, University of Toronto, Toronto, Canada, [4]Boehringer Ingelheim Ltd, Bracknell, UK, [5]St Michael's Hospital, Division of Cardiology, University of Toronto, Toronto, Canada.

Background and aims: In the EMPA-REG OUTCOME trial, empagliflozin (EMPA) given in addition to standard of care significantly reduced the risk of cardiovascular (CV) death by 38%, hospitalisation for heart failure (HHF) by 35%, and the composite of HHF or CV death by 34% vs placebo in patients with type 2 diabetes (T2DM) and established CV disease. CV outcomes and deaths were prospectively adjudicated by clinical event committees. Post-hoc, we investigated composite outcomes of HHF and modes of CV death commonly observed in patients with heart failure (HF): sudden death, death due to HF (worsening of HF or cardiogenic shock), and presumed CV death (insufficient data for adjudication committees to definitively categorise the cause).

Materials and methods: Patients were randomised to receive EMPA 10 mg, EMPA 25 mg, or placebo. Using a Cox proportional hazards model, we analysed three additional composite outcomes in the pooled EMPA group vs placebo: a) HHF or death due to HF; b) HHF, death due to HF, or sudden death; c) HHF, death due to HF, sudden death, or presumed CV death.

Results: A total of 7020 patients were treated. At baseline, mean age was 63.1 years, body mass index was 30.6 kg/m^2, HbA1c was 8.1%, 71.5% were male and 10.1% had investigator-reported HF. Risk reductions for the composite outcomes studied are shown in the figure.

Conclusion: Risk reductions in composite outcomes of HHF and modes of CV death commonly observed in patients with HF were comparable to the 34% reduction in the pre-specified composite of HHF or CV death in the EMPA-REG OUTCOME trial.



Cox regression analysis in patients treated with ≥1 dose of study drug.
*Death due to worsening of HF or cardiogenic shock.

Effects of the SGLT2 inhibitor dapagliflozin on tissue specific insulin sensitivity and liver fat content in type 2 diabetes patients: a randomised placebo controlled study

A.E. Hyypia[1], M.J. Honka[1], J. Makinen[1], L. Johansson[2], J. Oscarsson[3], J. Kullberg[2], J.C. Hannukainen[1], P. Nuutila[1];

[1]Turku PET Centre, University of Turku, Turku, Finland, [2]Antaros Medical AB, [3]AstraZeneca Gothenburg, Mölndal, Sweden.

Background and aims: The sodium-glucose cotransporter 2 inhibitor, dapagliflozin, improves glycaemic control and reduce weight in patients with type 2 diabetes mellitus (T2DM). Some studies also suggest that dapagliflozin ameliorates insulin resistance. The aim of this study was to investigate tissue specific effects of dapagliflozin on insulin sensitivity using positron emission tomography (PET) - imaging in patients with T2DM.

Materials and methods: This randomized, parallel-group, double-blind, placebo-controlled study enrolled 32 patients whose T2DM was inadequately controlled on oral medication. One patient did not complete the study. Groups were similar regard to age (mean 61 y), BMI (32 kg/m^2) and glycemic control (HbA1c 6.9 %). The majority of patients were male (81 %). All patients were on metformin and 16 patients (50 %) were also on sitagliptin. Patients were randomly assigned 1:1 to receive either dapagliflozin 10 mg/day or placebo daily for 8 weeks. Tissue specific insulin sensitivity was measured using PET and [18F]-fluorodeoxyglucose during an euglycemic hyperinsulinemic clamp before and after the intervention. M-values (μmol/kg/min) corrected for steady state (ss) insulin were calculated. Adipose tissue volumes and liver fat percent were assessed using MRI and blood biomarkers were measured.

Results: At week 8, placebo-corrected changes with dapagliflozin were as follows: body weight -2.9 kg ($p<0.001$), HbA1c -0.39% ($p<0.01$), plasma glucose -1.32 mmol/L ($p<0.01$), visceral adipose tissue volume -0.35 L ($p< 0.01$), liver fat% -3.74% ($p< 0.01$) and liver volume -0.10 L ($p<0.05$), interleukin-6 -1.87 pg/ml ($p<0.05$) and pro-BNP -96 ng/L ($p=0.03$). Whole body insulin sensitivity (M-value corrected for ss insulin) was numerically increased by dapagliflozin but the effects were not significantly different between the groups ($p=0.10$). In patients on sitagliptin (placebo n=7, dapagliflozin n=9), dapagliflozin improved ss insulin corrected M-value compared to placebo ($p=0.03$). There was no significant difference between the treatment groups in skeletal muscle, heart, white or brown adipose insulin stimulated glucose uptake. Changes in skeletal muscle insulin stimulated glucose uptake and M-values were significantly correlated in the dapagliflozin group ($r=0.75$, $p<0.01$). Statistical analyses were performed using two-way analysis of covariance (ANCOVA). Correlations were tested using Spearman rank correlation.

Conclusion: In addition to better glycemic control, dapagliflozin reduced visceral fat volume and lowered liver fat in obese insulin resistant T2DM patients. No direct effect on muscle, heart or adipose tissue insulin sensitivity was found suggesting that glucose utilisation was not changed in these tissues.

Drug-specific or class effects of SGLT2 inhibitors (SGLT2i) in the heart: SGLT2i inhibit NHE, reduce $[Na^+]_c$ and induce vasodilation in isolated mouse cardiomyocytes/hearts

L. Uthman[1], A. Baartscheer[2], B. Bleijlevens[3], C.A. Schumacher[2], J.W.T. Fiolet[2], A. Koeman[1], M.W. Hollmann[1], N.C. Weber[1], R. Coronel[2], C.J. Zuurbier[1];

[1]Department of Anesthesiology, Academic Medical Centre Amsterdam, [2]Clinical and Experimental Cardiology, Academic Medical Centre Amsterdam, [3]Medical Biochemistry, Academic Medical Centre Amsterdam, Amsterdam, Netherlands.

Background and aims: Empagliflozin (EMPA) reduced cardiovascular diseases in type 2 diabetes patients, yet the cardioprotective mechanism of this kidney-targeted diabetes drug remains unknown. We recently reported that EMPA lowers cytosolic sodium ($[Na^+]_c$) and calcium, while increasing mitochondrial calcium, through inhibition of the myocardial sodium/hydrogen

exchanger (NHE). Cardiac NHE has been shown to be upregulated in, and contribute to, heart failure and diabetes. We therefore investigated 1) whether two other SGLT2i (dapagliflozin (DAPA) and canagliflozin (CANA)) block cardiac NHE and reduce $[Na^+]_c$ as well, and 2) whether SGLT2i (EMPA, DAPA and CANA) affect physiological performance of the isolated-perfused mouse hearts.

Materials and methods: Molecular docking simulations were conducted on a homology model of the NHE-1 protein structure. Furthermore, NHE activity was indirectly measured from recovery of intracellular pH after loading of NH^{4+}-pulse in isolated mice cardiomyocytes. $[Na^+]_c$ was determined in cardiomyocytes using a fluorescent sodium indicator, SBF-1. Finally, Langendorff-perfused mouse hearts, perfused with 7 mM glucose, 1 mM lactate, 0.1 mM pyruvate, 0.5 mM glutamine and 50 mU/L insulin and 0.1% albumin, were subjected to either vehicle, 1 μM EMPA, 1 μM DAPA or 3 μM CANA for 30 minutes.

Results: Molecular docking simulations predicted that all three compounds bind with relatively high binding affinity to the extracellular Na+-binding site of NHE-1 (EMPA: -8.2, DAPA: -7.7 and CANA: -8.9 kJ/mol). Subsequently, all three SGLT2i inhibited NHE activity compared to vehicle (7.09±0.04), with EMPA showing the strongest inhibition of NHE (1 μM EMPA 6.69±0.03, p<0.001; 1 μM DAPA 6.79±0.03, p<0.001; 3 μM CANA 6.87±0.06, p<0.05). Moreover, measurements of [Na+]c showed that all three SGLTi significantly lowered [Na+]c (1 μM EMPA 9.9±0.3, p<0.001; 1 μM DAPA 10.7±0.3, p<0.01; and 3 μM CANA 11.0±0.5, p<0.01; vs. vehicle: 13.0±0.4 mM). Finally, in Langendorff-perfused mouse hearts, both EMPA and CANA induced vasodilation, determined by a 19% and 22% reduction in perfusion pressure respectively (p<0.05) compared to vehicle. In addition, EMPA significantly increased oxygen consumption (DMSO vs. EMPA; from 35.8 ±2.4 to 42.4±1.3 μmol/min/gdw; p<0.05). SGLTi did not alter cardiac mechanical performance.

Conclusion: Here, we show that SGLTi exhibit a class effect by blocking NHE and reducing $[Na^+]_c$ directly in the cardiac cell. CANA and EMPA induce vasodilation of the coronary circulation of the intact heart, and EMPA increases oxygen consumption. These direct cardiac effects may contribute to understanding previously reported cardiac protection by SGLTi.

24-week efficacy and safety of sotagliflozin, a dual SGLT1 and SGLT2 inhibitor, as adjunct therapy to insulin in type 1 diabetes (inTandem2)

T. Danne[1], B. Cariou[2], P. Banks[3], S. Sawhney[3], P. Strumph[3], The Sotagliflozin inTandem2 Writing Group;
[1]Kinderkrankenhaus auf der Bult, Diabetes-Zentrum für Kinder und Jugendliche, Hannover, Germany, [2]l'Institut du Thorax CHU Nantes, Nantes, France, [3]Lexicon Pharmaceuticals, Inc., The Woodlands, USA.

Background and aims: Sotagliflozin (SOTA) is a dual SGLT1 and SGLT2 inhibitor in Phase 3 development for type 2 diabetes (T2D) and as adjunct therapy to insulin in type 1 diabetes (T1D). SGLT1 inhibition delays and reduces glucose absorption in the proximal intestine, improving postprandial glycemic control. SGLT2 inhibition reduces renal glucose reabsorption.

Materials and methods: In a double-blind, 52-week international Phase 3 trial, 782 adults with T1D treated with MDI or pump therapy, with A1C 7.0-11.0% at Screening, were randomized 1:1:1 to placebo, SOTA 200 or 400 mg after a 6-week insulin optimization period. Baseline characteristics were comparable among groups. The primary outcome was change from Baseline in A1C at 24 weeks.

Results: SOTA 200 and 400 mg were statistically significant vs. placebo in lowering A1C and achieving the prespecified net benefit[a] endpoint. Overall incidences of TEAEs[b] were similar across groups. There were 2 deaths on placebo. There were more genital mycotic infections, diarrhea events, and DKA in the SOTA arms.

Conclusion: The international inTandem2 trial of SOTA as adjunct therapy to insulin met its primary endpoint with a statistically significant and clinically meaningful A1C reduction after 24 weeks, while demonstrating the general safety and tolerability of dual SGLT1 and SGLT2 inhibition in T1D. These results confirm the findings of inTandem1.

Efficacy and safety of sotagliflozin, a dual SGLT1 and SGLT2 inhibitor, as adjunct to insulin in young adults with poorly controlled type 1 diabetes (JDRF Study)

B. Bode[1], P. Banks[2], S. Sawhney[2], P. Strumph[2], The Sotagliflozin JDRF Study Writing Group;
[1]Atlanta Diabetes Associates, Atlanta, [2]Lexicon Pharmaceuticals, Inc., The Woodlands, USA.

Background and aims: Sotagliflozin (SOTA) is a dual SGLT1 and SGLT2 inhibitor in Phase 3 development for type 2 diabetes (T2D) and as adjunct to insulin in type 1 diabetes (T1D). SGLT1 inhibition delays and reduces glucose absorption in the proximal intestine, improving postprandial glycemic control. SGLT2 inhibition reduces renal glucose reabsorption.

Materials and methods: In a double-blind Phase 2 trial of young adults (age 18-30 years) with poorly controlled T1D (A1C ≥9.0%), 87 patients were randomized 1:1 to placebo or SOTA 400 mg once daily for 12 weeks. The primary outcome was change from Baseline in A1C at 12 weeks.

Results: SOTA decreased A1C by 0.35% compared with placebo (p=0.10). SOTA treatment resulted in lower postprandial glucose (PPG), higher net benefit[a], lower body weight, and lower A1C in a prespecified subgroup analysis (9.0% ≤ screening A1C ≤ 10.0%) than placebo. Overall incidences of treatment-emergent adverse events (TEAEs) were similar across groups. There were more genital mycotic infections and diarrhea events on SOTA. There was no DKA on SOTA.

Conclusion: In young adults with poorly controlled T1D, SOTA for 12 weeks as adjunct therapy to insulin, was well tolerated with evidence of improvements in glycemic control and weight reduction consistent with dual SGLT1 and SGLT2 inhibition.

A randomised clinical trial testing for optimal beta cell preserving treatment in Latent Autoimmune Diabetes in Adults (LADA)

I. Hals[1,2], V. Grill[1,2], H. Fiskvik Fleiner[3], N. Reimers[4], M. Astor[5], K. Filipsson[6], A. Björklund[7];

[1]Department of Endocrinology, St Olavs Hospital, Trondheim University Hospital, [2]Department of Cancer Research and Molecular Medicine, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology (NTNU), [3]Department of Clinical Pharmacology, St Olavs Hospital, Trondheim University Hospital, [4]Sjøsiden Legesenter, Trondheim, [5]Department of Medicine, Haukeland University Hospital, Bergen, Norway, [6]Department of Clinical Sciences, Unit of Molecular Metabolism, Lund University Diabetes Centre, Malmö, [7]Department of Molecular Medicine and Surgery, Endocrine and Diabetes Unit, Karolinska University Hospital Solna, Karolinska Institutet, Stockholm, Sweden.

Background and aims: The optimal beta cell preserving treatment of LADA patients is presently uncertain. This is due to a lack of randomized clinical trials in LADA. We aimed to compare the effect on beta cell function during either insulin or sitagliptin, a DDP-4 inhibitor, when added to ongoing treatment with metformin.

Materials and methods: Inclusion criteria included GADA positivity, age 30-75 years, no clinical need for insulin treatment and a diagnosis of diabetes made < 3 years before participation in the study. Further, HbA1C at inclusion was to be less than 60 but more than 5% above upper limit of normal. Patients were stratified by age, BMI and degree of GADA positivity (high/low). Beta cell function was evaluated by C-peptide glucagon tests which were performed after a 48 h temporary withdrawal of study medication.

Results: In a study population of 53 participants the mean age at randomization was 53 years and BMI 27.7 kg/m^2. These parameters and others (male/female participation, HbA1c, fasting C-peptide) were similar between arms of the study. HbA1c did not differ significantly between baseline and after 9 months of intervention (baseline 52.2 ± 1.4 mmol/mol, at 9 months, 50.8 ± 2.1 mmol/mol in the insulin, 50.6 ± 1.8 mmol/mol and 44.9 ± 1.8 mmol/mol in the sitagliptin arm). Stimulated C-peptide after 9 months of intervention was similar in the insulin and sitagliptin arm (incremental C-peptide 0.31 ± 0.04 nmol/l in the insulin, 0.31 ± 0.05 nmol/l in the sitaglitin arm). These findings did not negate a time-dependent negative effect of autoimmunity in the study population (taken as a whole); this was manifested by a decrease in stimulated C-peptide from 0.97 ± 0.09 to 0.82 ± 0.09 nmol/l in those with the highest titer of GADA (p< 0.02 for difference baseline vs 9 months).

Conclusion: This is the first randomized study to compare in LADA patients the effects on beta cell function of early insulin treatment vs. a DDP-4 inhibitor, the latter being a conventional treatment alternative in non insulin dependent diabetes. The results do not give evidence favoring early insulin during the time frame studied. Follow-up of the study population is underway to answer the question whether a longer observation period would detect differences between the arms of treatment.

Systematic analysis of the inflammatory tissue response to CSII catheters: steel versus teflon

J.R. Hauzenberger[1], J. Münzker[1], P. Kotzbeck[1], M. Asslaber[2], V. Bubalo[3], J.I. Joseph[4], T.R. Pieber[1];

[1]Internal Medicine, Medical University of Graz, [2]Institute of Pathology, Medical University of Graz, [3]Department of Biomedical Research, Medical

University of Graz, Graz, Austria, [4]Department of Anesthesiology, Thomas Jefferson University, Philadelphia, USA.

Background and aims: Continuous subcutaneous insulin infusion (CSII) catheters are considered the weak link of insulin pump therapy. The choice of CSII catheter material (steel or Teflon) is mostly based on personal experience or preference and wear-time varies between patients. Systematic evaluations of the adipose tissue inflammatory response - to determine advantages of one material over the other - are lacking. This present study evaluated the adipose tissue response to commercially available Teflon and steel CSII catheters over a maximum of 7 days of wear time.

Materials and methods: Steel and Teflon CSII catheters were inserted into the subcutaneous adipose tissue of 10 swine for 1, 4 and 7 days of wear-time. Skin and adipose tissue surrounding catheters were excised and stained with hematoxylin and eosin to determine morphological changes and inflammatory cell infiltration. We performed quantitative real-time PCR (qPCR) to assess changes in gene expression levels of cytokines and macrophages.

Results: While the total area of inflammation around catheters was similar between materials, fibrin deposition and mononuclear cell infiltration were significantly reduced around Teflon catheters compared with steel after 4 days of wear-time. Proinflammatory cytokines were upregulated within 24 hours independent of material but levels were slightly higher around steel over 7 days. Antiinflammatory cytokine gene expression did not resolve over time. The sharp tip of the steel catheter continuously ruptured connective tissue and vasculature throughout wear-time.

Conclusion: The combination of histopathology and qPCR allowed for an adequate trend analysis beyond the clinically recommended wear-time of CSII catheters. Our results suggest a better tolerability of Teflon catheters by the adipose tissue over 4 days of wear-time. These findings may have substantial implications for the choice of material for future CSII catheter development.

Effect of food intake on the absorption of oral basal insulin

E. Zijlstra[1], L. Plum-Mörschel[2], T. Heise[1], K. Lyby[3], K. Wassermann[3], I.B. Halberg[3];

[1]Profil, Neuss, [2]Profil, Mainz, Germany, [3]Novo Nordisk, Søborg, Denmark.

Background and aims: Oral insulin 338 in a GIPET® tablet (OI338GT) is a basal, acylated insulin analogue with a half-life of ~70 hours at steady state. In people with type 2 diabetes OI338GT given 1 hour before breakfast demonstrated safe improvement of glycaemic control to a similar extent as insulin glargine. Since it is well known that oral insulin absorption from the gastrointestinal tract changes with food intake, the aim of this trial was to investigate the effect of timing of food intake on the single dose pharmacokinetics (PK) of OI338GT.

Materials and methods: Healthy men received a single fixed dose of OI338GT in the fasting state at 4 different dosing visits. In a randomised, crossover design, they consumed an identical standardised meal (500 kcal, 57% carbohydrates, 13% fat, 30% protein) 0 min, 30 min, 60 min and 360 min post-dose. After the test meal participants received scheduled standardised meals at the investigational site for 48 hours post-dose after which they resumed their usual dietary habits. PK samples for insulin 338 concentrations were taken at regular time points up until 288 hours post-dose.

Results: Forty-four (44) subjects were enrolled (mean±SD age 35±8 years, BMI 24.2±1.9 kg/m^2) and 42 completed the trial. Mean insulin 338 concentration-time profiles over 24 hours showed the lowest exposure for OI338GT dosing immediately before food intake (0 min) and similar exposure for 30 min, 60 min and 360 min post-dose food intake (figure). Total insulin exposure ($AUC_{0-\infty}$, primary endpoint) and maximum insulin exposure (C_{max}) were lower for OI338GT dosing with food intake (0 min) compared to food intake 360 min post-dose (estimated ratio between geometric means [95% CI] $AUC_{0-\infty}$ 0.36 [0.26; 0.49], C_{max} 0.35 [0.25; 0.49]). There were no statistically significant differences with 360 min post-dose food intake when food was ingested 30 min ($AUC_{0-\infty}$ 0.85 [0.61; 1.21], C_{max} 0.86 [0.59; 1.26]) or 60 min post-dose ($AUC_{0-\infty}$ 0.96 [0.72; 1.28], C_{max} 0.99 [0.75; 1.31]). OI388GT administration was well tolerated with no serious adverse events reported. Hypoglycaemia, including both symptomatic events and asymptomatic events with a blood glucose below 63 mg/dL, was observed across the four post-dose fasting periods with a trend towards fewer hypoglycaemic events for the 0 min post-dose fasting period (13, 26, 25 and 26 events for 0 min vs. 30, 60 and 360 min post-dose periods, respectively). This result is consistent with the lower level of insulin 338 exposure in the 0 min post-dose fasting period.

Conclusion: This trial demonstrates that oral basal insulin 338 absorption in the fasted state is not affected by food intake from 30 min after administration. For convenience and compliance with future treatment this is a highly relevant finding meaning that patients with diabetes should not have to wait more than 30 min to eat their breakfast after a morning oral basal insulin dose.

The effect of an automated bolus calculator on glucose control, glucose variability and quality of life in patients with type 1 or 2 diabetes treated with insulin pumps

L.A.G. van Meijel, L.J. Zimmerman, S.P.W. van den Heuvel, C.J. Tack, B.E. de Galan;

Radboud University Medical Centre, Nijmegen, Netherlands.

Background and aims: Automated insulin bolus calculators are widely recommended for patients with type 1 or type 2 diabetes on insulin pumps, but their benefit is still disputed. We investigated whether a bolus calculator reduced glucose variability and improved quality of life in such patients.

Materials and methods: We conducted a 16-week randomized controlled trial, involving 34 patients (mean age 45.9 ± 15.1 years, 35% male, disease duration 26.6 ± 12.8 years, HbA_{1c} 64.2 mmol/mol (8.0%) ± 12.3), who were assigned to treatment with a bolus calculator or to continuation of standard care without a bolus calculator. All patients received extensive education on carbohydrate counting and on insulin therapy. The primary outcome was glucose variability, as assessed by standard deviation of 7-point glucose profiles over 5 days. Secondary outcomes were HbA1c, frequency of hypoglycaemia, low blood glucose index (LBGI) and high blood glucose index (HBGI), and quality of life assessed by different questionnaires.

Results: After 16 weeks of treatment, there were no differences between the two groups with respect to glucose variability (SD, 3.03 ± 0.59 vs. 3.00 ± 0.50 mmol/l, p = 0.096, bolus calculator vs. control group respectively), glucose control (HbA_{1c}, 59.1 ± 19.2 mmol/mol (7.6%) vs. 61.2 ± 9.0 mmol/mol (7.7%), p = 0.932), LBGI (p = 0.528), HBGI (p = 0.338) and frequency of hypoglycaemia (p = 0.534). Quality of life did not change during follow-up in both groups.

Conclusion: Use of a bolus calculator has no benefit with respect to various glycaemic parameters or quality of life in patients with longstanding type 1 or 2 diabetes treated with insulin pumps.

Subcutaneous tissue changes and dermal inflammation at insulin injections sites: a feasibility study using ultrasound to describe characterise and grade lipohypertrophy

H. Mulnier[1], R. Hashem[1], M. Duaso[1], J. Sturt[1], S. Halson-brown[2], J. Karalliedde[3], A. Forbes[1];
[1]Clinical Research in Diabetes, King's College London, [2]Women's Health - Medical and Vascular Ultrasound, King's College London, [3]Cardiovascular Division, King's College London, London, UK.

Background and aims: Subcutaneous (s/c) tissue changes in patients with type 1 diabetes (T1DM) are common and can affect glycaemic control. There are limited data on the utility of ultrasound to describe changes in s/c tissue with insulin use. This study aimed to assess the feasibility of using ultrasound to describe and characterise tissue changes to inform a future lipohypertrophy (LH) grading study.

Materials and methods: Patients with T1DM thought by diabetes clinicians to have LH or with clinical LH on examination were included. A SonoSite X-Porte ultrasound machine was used with a high frequency linear probe (6-13 MHz). Insulin injections sites and 'normal' non-injected adjacent tissues were scanned by a single operator.

Results: We scanned 15 patients with T1DM to establish a standard operating procedure (SOP). Then 11 additional patients with T1DM were scanned in detail using that SOP; mean age 41 years (range 24-59), mean duration of diabetes 22.7 years (range 4 - 49), and mean HbA_{1c} 7.3% (range 5.8 - 9.6%). Ultrasound images exhibited changes in the s/c tissue at a depth corresponding to approximate needle length (± 2-3mm). This tissue appeared as diffuse reflective areas of differing density in all of the 26 patients. More dense areas formed visible lumps: of the 11 patients studied in detail; 4 (33%) had large palpable lumps, 5 (45%) had small or medium nodules some of which were palpable, and 2 (18%) had large regions of diffuse changed tissue across the injection site. Compiling images from the 26 patients, a potential grading system has been proposed: Grade 0 (no evident nodules or diffuse areas of specific density), Grade 1 (small nodule <10mm), Grade 2 (medium nodule 10-20mm), Grade 3 (large nodule >20mm), Grade 4 (general diffuse area of specific density). Grade 1 to 3 can be single or multiple. Nine (82%) of the 11 participants also showed inflammatory tissue in the dermal layers of injections sites, <3mm thickness in 5 participants, and >3mm thickness in the other 4. Similar inflammation was also seen in a proportion of the first 15 patients, so this may be a common occurrence in this group. The inflammatory tissue has been provisionally graded as: 0 = normal, 1 for <3mm and 2 for >3mm. Normal tissue in all patients showed no increased reflectivity and normal dermal and s/c layers above muscle. See figure 1.

Conclusion: This feasibility study has been the first to report and measure dermal inflammation in people injecting insulin. It demonstrates the potential of ultrasound in characterising s/c tissue changes in people who inject insulin. The observations have informed preliminary grading systems, which will be validated in further studies to assess the clinical implication of these tissue changes in relation to glucose variability and insulin action.

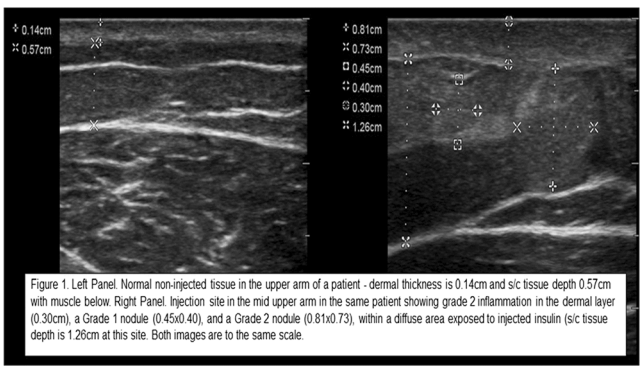

Figure 1. Left Panel. Normal non-injected tissue in the upper arm of a patient - dermal thickness is 0.14cm and s/c tissue depth 0.57cm with muscle below. Right Panel. Injection site in the mid upper arm in the same patient showing grade 2 inflammation in the dermal layer (0.30cm), a Grade 1 nodule (0.45x0.40), and a Grade 2 nodule (0.81x0.73), within a diffuse area exposed to injected insulin (s/c tissue depth is 1.26cm at this site. Both images are to the same scale.

A novel formulation of insulin lispro shows significantly faster absorption and improvement in postprandial glucose excursions versus insulin lispro in patients with type 2 diabetes

C. Kapitza[1], J. Leohr[2], R. Liu[2], S. Reddy[2], M. Dellva[2], M. Matzopoulos[2], M. Knadler[2], M. Loh[2], T. Hardy[2], C. Kazda[2];
[1]Profil, D-41460 Neuss, Germany, [2]Eli Lilly and Company, Indianapolis, USA.

Background and aims: LY900014 (LY) is a novel formulation containing locally-acting excipients citrate and treprostinil to accelerate insulin lispro absorption with the goal of providing an ultra rapid prandial insulin.

Materials and methods: This abstract focuses on the first part of a 2-part, 6-period crossover study evaluating pharmacokinetic and pharmacodynamic differences between LY and insulin lispro (IL). Twenty-nine patients with type 2 diabetes mellitus (T2DM) were randomised to receive individualized s. c. doses of LY or IL administered at the start of a mixed-meal tolerance test. Prior to the test, blood glucose was stabilised at 126 milligrams/decilitre.

Results: Patients treated with LY had accelerated early insulin lispro absorption and faster elimination compared to IL. LY reduced the time to early half-maximal drug concentration by 23% ($p<0.0001$) and increased the insulin lispro area under the concentration curve versus time (AUC) from 0 to 30 minutes by 116% ($p<0.0001$) compared to IL. The 90% CI of the ratio (LY : IL) for insulin lispro AUC(0-∞) was within bioequivalence criteria. The total glucose excursion over the 5-hour test-meal was reduced by 105% ($p<0.0001$) for LY versus IL (Figure 1). No differences were observed between LY and IL for tolerability and incidences or severity of hypoglycaemic events.

Conclusion: These results support continued development of this novel ultra rapid insulin lispro formulation as a next generation prandial insulin for patients with T2DM.

Impact of artificial sweeteners on glycaemic control in healthy humans

R.L. Young[1,2], N.J. Isaacs[1,2], G. Schober[1,2], T. Wu[1,3], N. Cvijanovic[1,2], N. Pezos[1,2], M. Bound[1], D.J. Keating[4], C.K. Rayner[1,3], M. Horowitz[1,3];
[1]Medicine, The University of Adelaide, [2]Nutrition & Metabolism, South Australian Health & Medical Research Institute, [3]Centre of Research Excellence in Translating Nutritional Science to Good Health, [4]Human Physiology, Flinders University, Adelaide, Australia.

Background and aims: Prospective epidemiological studies indicate that a high habitual intake of beverages sweetened with non-caloric artificial sweeteners (NAS) increases the risk of developing type 2 diabetes (T2DM), but the underlying mechanisms are unknown. In animals, acute exposure to NAS activates intestinal sweet taste receptors (STRs) to trigger the release of glucose-dependent insulinotropic polypeptide (GIP) from proximal K-cells, and glucagon-like peptide-1 and 2 (GLP-1, GLP-2) from more distal L-cells, while dietary NAS supplementation increases the function of the sodium-dependent glucose co-transporter-1 (SGLT-1) to augment glucose absorption and increase postprandial glycaemia. It is not known whether NAS alters glucose absorption in humans, and if so, whether this affects postprandial glycaemic control adversely.

Materials and methods: 27 healthy subjects (age 27 ± 2 years, body mass index 24 ± 1 kg/m^2, 14 male) were randomised, in double-blind fashion, to dietary supplementation with a NAS combination (92 mg sucralose plus 52 mg acesulfame-K, equivalent to ~1.5L of diet beverage/day, N=14) or placebo (N=13), taken in capsules three times daily before meals over 2 weeks. Subjects then attended the laboratory after an overnight fast and underwent non-sedated endoscopy incorporating a 30 min intraduodenal glucose infusion (30g/150ml, 3 kcal/min, including 3g of the glucose analogue 3-O-methyl glucose, 3-OMG) and biopsy collection, before and immediately after the intervention. Glucose absorption (serum 3-OMG), plasma glucose, insulin and gut peptides (total GLP-1, GLP-2 and GIP) were measured, and the incremental areas under the curve (iAUC, over 120 min) compared by 2-way ANOVA.

Results: NAS supplementation augmented the iAUC for glucose absorption (23%, $P \leq 0.05$) and blood glucose (27%, $P \leq 0.05$), and attenuated the iAUC for GLP-1 (35%, $P \leq 0.05$) compared to baseline, while none of these measures were altered with placebo. The GLP-2, GIP, and insulin responses to enteral glucose were similar between NAS and placebo groups, although GLP-2 and insulin were lower at 40 and 60 min, respectively, in the NAS group (37% for both vs. baseline, $P \leq 0.05$).

Conclusion: In healthy humans, 2 weeks of dietary NAS supplementation (i) enhances glucose absorption, (ii) augments blood glucose responses to enteral glucose, and (iii) attenuates GLP-1 release, the latter possibly reflecting reduced glucose exposure to more distally located L-cells. This study supports the concept that NAS have a deleterious impact on acute glycaemic control, and highlights the potential for exaggerated postprandial glycaemic excursions in high habitual NAS consumers, which could predispose to T2DM.

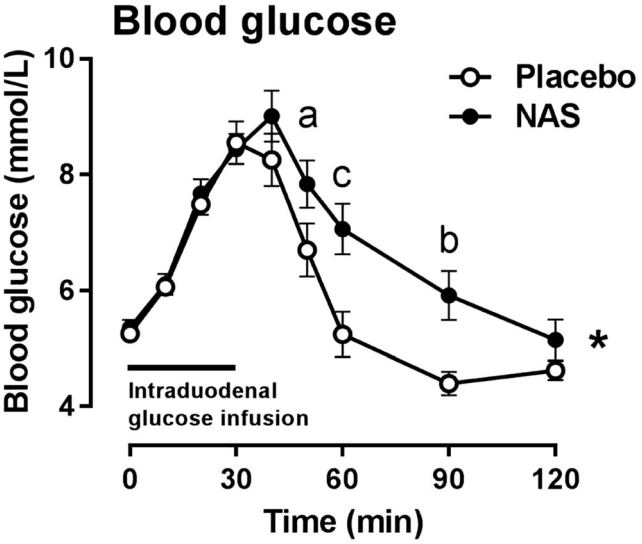

Figure: Blood glucose responses to enteral glucose in placebo (N=13) or NAS-supplemented humans (N=14). NAS vs Placebo: ^{a,b,c} $P \leq 0.05$, 0.01, 0.001; *$P \leq 0.05$ iAUC.

Differential gene profile of human enteroendocrine cells in metabolic diseases

A. Ribeiro[1], C. Osinski[1], E.L. Hubert[1], H. Soula[1], L. Genser[2], K. Clément[2], C. Poitou[2], A. Leturque[1], P. Serradas[1];
[1]INSERM UMRS 1138, Centre de Recherche des Cordeliers, Sorbonne Universités, UPMC Univ Paris 06, Sorbonne Cités, UPD Univ Paris 05, CNRS, [2]INSERM, UMRS 1166, NutriOmique, Sorbonne Universités, UPMC Univ Paris 06, Pitié-Salpêtrière Hospital, Nutrition Department and CRNH-Ile de France, Paris, France.

Background and aims: Enteroendocrine cells (EEC), despite their small proportion (1%) among intestinal epithelial cells represent the largest population of endocrine cells in the body. In adult intestine, EEC precursors are engaged toward terminal differentiation under the control of a complex network of transcription factors such as FOXA1/2, PDX1, PAX4/6, ARX, which define cell lineages, each EEC type secreting one of the 15 gut hormones. Among them, GLP (glucagon-like peptide)-1, contributes to glucose homeostasis and control of food intake. The continuous renewal and differentiation of EEC lineages allow a permanent capacity of cell adaptation to nutritional environment. Our hypothesis is that metabolic diseases, obesity and/or type 2 diabetes (T2D) are associated with different EEC commitment and gene expression patterns. We aim to characterize the differential transcriptional profile of EEC lineages between obese and diabetic obese subjects that could lead to modulation of local and systemic enterohormone levels.

Materials and methods: Jejunum samples were obtained of obese subjects (n=58), normoglycemic, glucose intolerant or diabetic, during gastric bypass procedure and of normal weight individuals (n=22). Expression of the transcription factor network involved in the EEC differentiation was studied by RT-qPCR using Taqman® Arrays Cards on isolated jejunal epithelial cells. A novel cell sorting strategy was developed to select EEC. RNA were purified and the EEC transcriptome was further analysed by RNA-Seq.

Results: The expression of the transcription factor network responsible for the commitment of EEC is altered in metabolic diseases. Multivariate analysis corrected for age and sex, reveals that FOXA1 and PDX1 gene expression is significantly increased in obese subjects when compare to lean subjects whereas ARX and proglucagon (encoding GLP-1) gene expression, is decreased. The diabetes severity (normoglycemia, glucose intolerance and T2D) in obese subjects is associated with an increase of FOXA1 gene expression and a decreased of ARX one. Because EEC are scattered throughout the intestinal epithelium, EEC gene expression profiling requires a cell-enrichment process. We developed a new cell sorting strategy starting from total epithelial cells isolated from fresh gut tissue that gave a 50-fold enrichment in EEC. We confirmed that sorted EEC expressed specific markers such as proglucagon (GLP-1), and chromogranin A at mRNA and protein levels. We obtained EEC fractions from non diabetic and diabetic obese subjects and the RNA seq analysis (Illumina technology) is undergoing.

Conclusion: Our study highlights differences on EEC gene expression profile according to the metabolic status of individuals. The development of this novel cell-sorting strategy to obtain EEC from huma jejunum will be key in the future to identify candidate targets potentially boosting endogenous secretion of enterohormones.

Endogenous glucagon-like peptide-1 mediates the lowering of glycaemia during small intestinal glucose infusion by bile acids in type 2 diabetes

T. Wu, M. Horowitz, K.L. Jones, C.K. Rayner;
Discipline of Medicine, University of Adelaide, Adelaide, Australia.

Background and aims: Bile acids are recognised to play an important role in glucose homeostasis. We have reported that small intestinal administration of taurocholic acid (TCA) reduces the glycaemic response to intrajejunal (IJ) glucose infusion markedly in healthy humans, associated with an increase in plasma glucagon-like peptide-1 (GLP-1). We have now evaluated the effect of TCA, with and without the GLP-1 receptor antagonist, exendin(9-39), on the glycaemic response to an IJ glucose infusion in patients with type 2 diabetes (T2DM).

Materials and methods: 10 T2DM patients (age 69.5 ± 2.9 years; 8 male; BMI 26.6 ± 0.9 kg/m^2; HbA1c 6.6 ± 2.2% (48.9 ± 2.3 mmol/mol); duration of known diabetes 13.6 ± 3.4 years), managed by diet or metformin alone, were each studied on four study days, separated by at least 7 days, in a double-blind, randomised fashion. On each day, an IJ catheter was positioned and a balloon inflated 30 cm beyond the pylorus to allow proximal aspiration of endogenous bile. An intravenous (IV) infusion of exendin(9-39) (600 pmol/kg/min) or 0.9% saline was commenced and maintained during t = -60-120 min. TCA (2 g in 0.9% saline), or saline, was given via IJ infusion during t = -30-0 min, followed by 2 g TCA or saline, together with 60 g glucose, during t = 0-120 min. Blood glucose and plasma insulin, C-peptide and glucagon were measured at regular intervals. The insulin secretion rate (ISR)/glucose ratio was calculated, based on C-peptide and blood glucose. Incremental areas under the curves (iAUCs) for these measures during t = -60-120 min were compared using two-factor repeated measures ANOVA, with TCA and exendin(9-39) as factors. Subgroup comparisons between TCA and control, with and without exendin(9-39), were also performed.

Results: TCA reduced blood glucose (P = 0.022, treatment effect), and increased plasma insulin (P = 0.007) and the ISR/glucose ratio (P = 0.037), without affecting plasma glucagon. In contrast, exendin(9-39) was associated with higher blood glucose (P = 0.003) and plasma glucagon (P = 0.011), and reductions in plasma insulin (P = 0.008) and the ISR/glucose ratio (P < 0.001). In the absence of exendin(9-39), blood glucose was lower (P = 0.010), and plasma insulin (P = 0.025) and the ISR/glucose ratio (P = 0.039) were greater, with TCA vs. control, without any difference in plasma glucagon. In the presence of exendin(9-39), plasma insulin was greater with TCA vs. control (P = 0.020), without any difference in blood glucose, the ISR/glucose ratio, or plasma glucagon.

Conclusion: In well controlled T2DM, small intestinal administration of TCA reduces the glycaemic response to IJ glucose, associated with an increase in insulin secretion, and these effects are attenuated by exendin(9-39). These observations support the concept of a "bile acid-GLP-1" axis in the regulation of postprandial glycaemia in T2DM.

	IV saline		IV exendin(9-39)		P-value		
	IJ saline	IJ TCA	IJ saline	IJ TCA	TCA	Exendin(9-39)	Interaction

GLP-1 receptor agonist impact gut microbiota and intestinal immunity to improve hyperglycaemia and dyslipidaemia in rodents

R. Burcelin[1], J.E. Christensen[1], J. Charpentier[1], A. Waget[1], T. Sulpice[2], B. Lelouvier[3], L. Guzylac[4], F. Briand[5];
[1]Hôpital Rangueil, Inserm1048 I2MC, Toulouse, [2]Physiogenex, Labege Innopole, [3]Vaiomer, Labège Innopole, [4]INRA, Saint Martin du Touch, [5]Physiogenex, Labège Innopole, France.

Background and aims: Recent evidence demonstrates the role of GLP-1 therapies on immune-metabolism. Since a change in gut microbiota is a feature controlling immune-metabolism, we aimed to demonstrate that GLP-1 receptor agonists liraglutide and exendin-4 (ex-4) control glycemia through their impact on gut microbiota and immune-metabolism. This gain of knowledge would help identify discriminant therapeutic features

Materials and methods: DIO mice were treated i.p. with vehicle, ex-4 10μg/kg BID or liraglutide 100μg/kg QD and drug effects were evaluated after 14 days of treatment. The intestinal immune system was studied on isolated lamina propria cells and the gut microbiota through targeted 16S sequencing. Gut microbiota was used to colonize germ free mice. The immune cell phenotype was identified by flow cytometry.

Results: Compared with vehicle, ex-4 induced a significant body weight loss (-3.6g) after treatment, while liraglutide showed a more pronounced effect (-6.2g). Ex-4 showed better glycemic control over liraglutide after an oral glucose tolerance test, which was due to stronger impact on gastric emptying (as measured with acetaminophen oral administration). However, following a test meal, both ex-4 and liraglutide significantly reduced blood glucose by 40% and triglycerides levels by 25%. Ex-4 significantly reduced intestinal cholesterol absorption by 40% after a ^{14}C-cholesterol labeled olive oil oral gavage, while liraglutide showed a more pronounced effect (50% reduction). Fecal cholesterol mass excretion was significantly increased by 62 and 75% with ex-4 and liraglutide, respectively. Gut microbiota taxonomic profiling further discriminated ex-4 and liraglutide with significant changes in various bacteria taxa, such as bifidobacteriaceae, clostridiaceae or lactobaciliceae. The intestinal immune system was oriented towards a dramatic reduction of the frequency of Th1-inf$^+$ cells (80%), no change in Th17 cells, and an increased frequency of TReg cells (60%). All these effects were abolished by antibiotic treatment suggesting a role of gut microbiota. We then demonstrated in germ free colonized mice that the architecture of the microbiota from liraglutide treated mice was responsible for the glycemic control

Conclusion: ex-4 and liraglutide differentially alter gut microbiota and intestinal adaptive immune system. The changes in gut microbiota improves intestinal adaptive immune system and explain, at least in part, the antidiabetic effect of the peptide. The DIO mouse model, combined with our in vivo phenotyping knowhow in microbiota sequencing, and intestinal immune system expertise represent useful tools to differentiate anti-diabetics, and demonstrate their benefits beyond glucose control.

Effect of acute elevations of plasma NEFA on incretin-stimulated insulin secretion

B.D. Astiarraga[1], E. Muscelli[2], A. Tura[3], S. Camastra[1], S. Baldi[1], A. Mari[3], A. Natali[1], E. Ferrannini[4];

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Department of Internal Medicine, Faculty of Medical Science, University of Campinas, Campinas, Brazil, [3]CNR Institute of Neurosciences, Padua, [4]CNR Institute of Clinical Physiology, Pisa, Italy.

Background and aims: Plasma nonesterified fatty acids (NEFA) are an important source of energy during both fasting and postprandial periods but their excess could have an inhibitory effect on insulin secretion. Information on the *in vivo* effects of NEFA on incretin-stimulated insulin secretion is lacking. We aimed to assess the effects of acute hyperlipidaemia on incretin-stimulated insulin secretion in healthy subjects.

Materials and methods: Ten healthy subjects aged 34 ± 3 years (mean ±SD), BMI 24 ± 2 kg/m^2 were studied in two sets of experiments. First, each subject received a 75-g oral glucose tolerance test (CT-OGTT) and, a week later, the glycaemic profile from CT-OGTT was matched with an isoglycaemic intravenous glucose infusion (CT-IIGT). Both tests were then repeated during a 20% Intralipid infusion (60 mL/hour) plus a primed-(200 U)-continuous (0.4 U·kg^{-1}·min^{-1}) heparin infusion started 2 hours before either test (L-OGTT and L-IIGT, respectively). The dynamics of insulin secretion were assessed by mathematical modelling of plasma glucose and C-peptide responses. The main parameters are: insulin secretion rate (ISR); glucose sensitivity (ßGS), *i.e.,* the mean slope of the insulin secretion/plasma glucose dose-response curve; glucose-induced potentiation (P_{GLU}), which represents a time-dependent modulation of the dose-response during IIGI; and incretin-induced potentiation (P_{INCR}), which quantifies the time-course of the incretin effect. The incretin effect (IE) was also indexed as the oral-to-IV ratio of insulin secretion.

Results: Plasma NEFA rose from 0.19 ± 0.03 to 3.55 ± 0.53 mmol/L on the L-OGTT, and from 0.23 ± 0.03 to 3.77 ± 0.45 mmol/L on the L-IIGT (p<0.005 for both). Plasma triglycerides increased from 0.7 ± 0.1 to 3.2 ± 0.6 mmol/L during L-OGTT and from 0.6 ± 0.1 to 3.2 ± 0.5 mmol/l during the L-IIGT (p<0.005 for both). While lipid infusion raised plasma glucose levels only marginally (p=ns), it increased total ISR from 61 [26] to 78 [31] nmol·m^{-2}, median [IQR] on the OGTT (p=0.005), and from 29 [26] to 57 [30] nmol·m^{-2} on the IIGT (p=0.02). While neither ßGS nor P_{GLU} was significantly affected (p=ns), P_{INCR} decreased from 1.6 [1.1] to 1.3 [0.2] dimensionless, p=0.05. Moreover, during Intralipid infusion IE was significantly decreased between 0-90 min (p=0.001). The time-courses of GLP-1 and GIP did not change significantly, while the plasma ghrelin response to the OGTT declined from 12.3 ± 2.6 to 8.2 ± 1.2 ng/mL, p=0.005. Lipid infusion also induced mild insulin resistance during the OGTT (as the oral insulin sensitivity index [OGIS] decreased from 402 ± 22 to 355 ± 28 mL·min^{-1}·m^{-2} p=0.05).

Conclusion: An acute increment in plasma lipids stimulates total insulin secretion but selectively impairs incretin-stimulated insulin secretion.

GIP(3-30)NH$_2$ is an efficacious GIP receptor antagonist in humans

L.S. Gasbjerg[1,2], A.R. Lanng[1], B. Hartmann[2,3], A.H. Sparre-Ulrich[2,3], F. Dela[2], M. Christensen[1,4], J.J. Holst[2,3], T. Vilsbøll[1,5], M.M. Rosenkilde[2], F.K. Knop[1,4];

[1]Center for Diabetes Research, Gentofte Hospital, Hellerup, [2]Department of Biomedical Sciences, University of Copenhagen, [3]NNF Center for Metabolic Research, University of Copenhagen, [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, [5]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, Denmark.

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) is an incretin hormone secreted from enteroendocrine K cells in the postprandial state. GIP stimulates insulin and glucagon secretion when blood glucose is high and low, respectively. In addition, GIP may inhibit bone resorption and stimulate fat deposition. Despite these therapeutically interesting targets, GIP physiology in humans remains relatively poorly characterised, mainly because until now, a GIP receptor (GIPR) antagonist (GIPRAn) has not been available for use in humans. We previously showed that a naturally occurring GIP fragment (GIP(3-30)NH$_2$) acts as a human GIPRAn *in vitro*. We aimed to establish GIP(3-30)NH$_2$ as a GIPRAn in humans.

Materials and methods: Insulin secretion was evaluated during four separate days in 10 healthy men (mean±SD: age 21.6±1.7 years, BMI 22.7±1.3 kg/m^2). They received a 45-minute infusion of the GIPRAn (800 pmol/kg/min), GIP (1.5 pmol/kg/min) and/or placebo during a hyperglycaemic clamp in a randomised, crossover design (day A: GIP; day B: GIPRAn; day C: GIP+GIPRAn; day D: placebo).

Results: To clamp plasma glucose levels on 12 mmol/l, we used significantly larger amounts of glucose (mean±SD: 54±14 g) on day A (GIP) compared to the three other days (B: 31±7.1 g, C: 37±5.1 g, and D: 39±7.3 g). Steady-state plasma levels of GIPRAn and GIP amounted to ~50 nmol/l and ~90 pmol/l, respectively. Elimination plasma half-life of GIP(3-30)NH$_2$ was 7.6±1.4 min (mean±SD). GIP-induced insulin secretion (day A, incremental $AUC_{0\text{-}40\ min}$ (mean±SEM): 29±3.4 nmol/l × min) was significantly (p<0.0001) lower on day C (GIP+GIPRAn) (12±1.7 nmol/l × min) corresponding to an inhibition of GIP-induced insulin secretion by the GIPRAn by 81±14% (mean±SD). The GIPRAn had no effect on insulin alone compared to placebo (day B: 6.6±1.1 nmol/l × min, day D: 8.1±0.9 nmol/l × min). There were no significant effects of GIP and/or GIP(3-30)NH$_2$ on glucagon, somatostatin, glucagon-like peptide-1 (GLP-1), triglycerides, cholesterol, glycerol or free fatty acids.

Conclusion: Supraphysiological levels of the naturally occurring GIP fragment, GIP(3-30)NH$_2$ robustly inhibits GIP-induced insulin release. Thus, GIP(3-30)NH$_2$ is efficacious GIPRAn in humans that can be used to investigate the physiological effects of GIP.

Short leukocyte telomere length is associated with increased risk for albuminuria progression in type 2 diabetes in Asians

R.L. Gurung[1], Y. M[1], S. Liu[1], J.J. Liu[1], S.C. Lim[1,2];
[1]Clinical Research Unit, Khoo Teck Puat Hospital, [2]Diabetes Centre, Khoo Teck Puat Hospital, Singapore, Singapore.

Background and aims: Progression of albuminuria in type 2 diabetes (T2D) patients is associated with increased cardio-renal complications. Telomere length, a marker for biological aging is implicated with T2D. However, little is known on the association between leukocyte telomere length (LTL) and progression of albuminuria among T2D with preserved renal filtration function. The aim of this study was to investigate whether shorter LTL is associated with albuminuria progression in T2D with preserved renal filtration function (eGFR > 60mL/min/1.73m^2) in Asians.

Materials and methods: This 3-year prospective study included 568 nonprogressors and 123 progressor from participants in the SMART2D cohort. Baseline LTL was measured by real time polymerase chain reaction and expressed as the telomere repeat length (T) / copy number of a single-copy gene (S) ratio (T/S). Albuminuria progression was defined as a change in albuminuria category to a higher level.

Results: Progressors had significantly shorter median LTL compared to nonprogressors (0.58 [0.38-0.79] vs 0.62 [0.45-0.88], p=0.039). Compared to subjects with longer LTL (fourth quartile), subjects with shorter LTL (first quartile) had 1.93 (1.04-3.60, p=0.038) folds increased risk for albuminuria progression after adjustment for traditional risk factors. 1-SD decrement in the natural log transformed LTL was associated with a 25% (OR=1.25. 95% CI 1.01-1.53, p=0.037) higher adjusted odds for albuminuria progression. Sensitivity analysis showed that association of LTL with microalbuminuria to macroalbuminuria progression is stronger than its association with normoalbuminuria to microalbuminuria. Addition of LTL significantly improved the predictive performance of albuminuria as reflected by an increased category-free NRI of 0.428 (95% CI 0.243-0.613, p=1e-5) and IDI of 0.063 (95% 0.63-0.124, p=0.000).

Conclusion: Our results provide evidence that shorter LTL may predispose T2D patients to increased risk for early albuminuria progression.

Table 1. Combined and sub-group univariate and multivariate association between baseline LTL and progression of albuminuria

	Univariate OR (95% CI)	*P value*	Multivariate OR (95% CI)*	*P value*
Combined analysis (1-SD decrement)	**1.21 (1.02-1.43)**	**0.032**	**1.25 (1.01-1.53)**	**0.037**
Sub-group analysis				
normal to microalbuminuria LTL (1-SD decrement)	1.13 (0.91-1.40)	0.263	1.17 (0.93-1.47)	0.185
micro to macroalbuminuria LTL (1-SD decrement)	**1.39 (1.03-1.87)**	**0.032**	**1.54 (1.02-2.32)**	**0.042**

Genetic deletion of the Set7 lysine methyltransferase attenuates renal damage in a mouse model of diabetic nephropathy

H. Rodriguez[1,2], H. Rafehi[1], M. Ziemann[1], B. Chow[1], J. Okabe[1], M. Bhave[2], M. Cooper[1], A. El-Osta[1,3];
[1]Monash University, [2]Swinburne University Of Technology, [3]University of Melbourne, Melbourne, Australia.

Background and aims: Chronic hyperglycaemia promotes the production of pro-inflammatory and pro-fibrotic mediators that lead to the development of chronic kidney disease. Increasing evidence implicates epigenetic modifications, particularly histone methylation, in this process. Set7, a lysine methyltransferase that mono-methylates lysine 4 on histone H3 as well as and non-histone proteins, has been associated with increased expression of pro-fibrotic genes in various models of kidney disease. The aim of this study was to further define the role of Set7 in the development of diabetic nephropathy and evaluate it as a target for developing reno-protective therapies in diabetes.

Materials and methods: Diabetes-induced structural and functional kidney damage was studied in *ApoE*$^{-/-}$ and *Set7*$^{-/-}$*ApoE*$^{-/-}$ male mice compared to non-diabetic controls. Mice were euthanised after 10 weeks of streptozotocin-induced diabetes and kidneys were harvested for histological and molecular analyses including transcriptome sequencing (RNA-seq). Renal cell culture models were used for studying the effects of pharmacological inhibition of Set7.

Results: Set7 deletion conferred renal protection as evidenced by attenuated albuminuria, mesangial expansion and glomerular deposition of collagen I and IV in diabetic *Set7*$^{-/-}$*ApoE*$^{-/-}$ when compared to diabetic *ApoE*$^{-/-}$ mice. Global renal cortical gene expression by RNA-seq revealed that diabetes deregulates the expression of almost 5,000 genes in the kidney (adjusted p value<0.05) and that deletion of Set7 largely attenuates these changes in gene expression. Gene Set Enrichment Analysis (GSEA) showed that deregulated genes are associated with pathways related to inflammation, fibrosis and energy metabolism. This approach allowed us to identify novel targets for Set7 regulation in the diabetic kidney such as *Ncf1*, which encodes a NADPH oxidase subunit, and *Bmper*, a regulator of the bone morphogenic protein pathway. The changes in the expression of these genes, as well as known Set7 targets (*Ccl2/Mcp1*, *Fn1*, *Col4a1*, *Icam1*), were validated by qRT-PCR. *In vitro* experiments were used to investigate the effect of pharmacological inhibition of Set7 in specific renal cell populations. Exposure of cultured human podocytes and primary mesangial cells to high glucose and/or TGFβ1 increased the expression of pro-inflammatory (*CCL2/MCP1*, *RELA*) and pro-fibrotic genes (*ACTA2/SMA*, *VEGF*, *COL4A1*, *CTGF*), this was significantly attenuated in the presence of (R)-PFI-2, a potent and selective inhibitor of Set7.

Conclusion: Collectively, our results suggest that Set7 may represent a target for developing therapies aimed at reducing the burden of diabetic nephropathy.

The effect of transforming growth factor beta1 on cell-cell coupling and cell-to-cell communication in tubular epithelial cells of the diabetic kidney

P.E. Squires[1], G.W. Price[1], M.J. Wall[2], T.J. Kaufman[2], C.E. Hills[1];
[1]School of Life Sciences, University of Lincoln, Lincoln, [2]School of Life Sciences, University of Warwick, Coventry, UK.

Background and aims: Efficient tubular function within the proximal nephron relies on inter-cellular communication between epithelial cells via connexin-mediated gap-junctions. In early diabetic nephropathy, a loss of epithelial (E)-cadherin mediated cell-adhesion instigates a series of events that culminate in disrupted cell-cell coupling, cell-to-cell communication and dissociation of the epithelia. In the current study, we utilized model epithelial cells from human renal proximal tubules, to demonstrate a role for the glucose associated beta1 isoform of the pro-fibrotic cytokine transforming growth factor (TGFβ1) on connexin expression, gap-junction intercellular communication and hemi-channel activity.

Materials and methods: Connexin-26 (Cx26) and connexin-43 (Cx43) expression were assessed by immunoblot analysis in human kidney (HK2) tubular epithelial cells treated with low glucose (5mmol/L) +/- TGFβ1 (10ng/mL) for 48hr or 7days. Whole cell paired-patch electrophysiology assessed junctional conductance between TGFβ1 treated HK2 cells, whilst

carboxyfluorescein (200μM) uptake determined hemi-channel opening at 48hr and 7day, with ATP bio-sensing measuring real-time nucleotide release.

Results: Immunoblot suggests a biphasic change in connexin expression following acute (48hr) and chronic (7day) exposure with TGFβ1 (10ng/mL). At 48hr, Cx26 was down regulated to 58.3±5.7% and Cx43 to 48.1±3.8% of control. Conversely, 7day exposure to the pro-fibrotic cytokine, increased Cx26 and Cx43 expression to 203.9±7.5% and 151.1 ±7.1% respectively (n = 4; P<0.001). Despite time-dependent differences in connexin expression, gap junctional intercellular communication (GJIC) decreased from 4.5±1.3nS (n=5) between control cells to 1.15±0.9nS (P<0.05, n=5) and 0.42±0.2nS (P<0.05, n=5) in cells treated with TGFβ1 at either 48hr or 7day. Removing extracellular calcium opens connexin-mediated hemi-channels and allows uptake of the membrane-impermeant dye carboxyfluorescein. Dye uptake in to TGFβ1-treated cells increased to 346±33% compared of control at 48hr and 430±18% at day 7. These effects were negated by pre-incubation with the hemi-channel blocker carbenoxolone (200μM, 30mins; 110±5.4% of control at 48hr and 64±2.6% at 7day; P<0.001, n=3). ATP bio-sensing confirmed that the TGFβ1 increased ATP hemi-channel release (1.99±0.47μM compared to 0.29± 0.06μM, P<0.01, n=3).

Conclusion: The current study suggests that despite biphasic changes in connexin expression following acute (48hr) and chronic (7day) exposure to the glucose-dependant pro-fibrotic cytokine TGFβ1, hemi-channel mediated ATP release increases at the expense of GJIC as cells attempt to maintain cell-to-cell communication. Linked to fibrosis in the diabetic kidney, a switch favouring local increases in purinergic signalling, may actually exacerbate disease progression in diabetic nephropathy.

A role for connexin mediated cell communication in fibrosis of tubular epithelial cells in the diabetic kidney

C.E. Hills[1], G.W. Price[1], M.J. Wall[2], S.W. Yiu[3], S. Tang[3], P.E. Squires[1];
[1]School of Life Sciences, University of Lincoln, Lincoln, [2]School of Life Sciences, University of Warwick, Warwick, UK, [3]Department of Medicine, University of Hong Kong, Hong Kong, China.

Background and aims: In diabetic nephropathy, pivotal to early tubular injury is loss of expression of cell adhesion protein; epithelial (E)-cadherin. Co-localized with E-cadherin at sites of cell-cell contact, connexins (Cx) oligomerise into hexameric hemi-channels that can form gap-junctions. Intercellular adhesion is a pre-requisite for gap junction formation and in the absence of neighbouring cells, uncoupled Cx-hemi-channels permit local paracrine release of adenosine triphosphate (ATP). Recent studies link elevated ATP levels to increased tissue fibrosis in disease and altered Cx expression &/or function is linked to the development and progression of secondary complications of diabetes. The current study examines if glucose-evoked changes in Cx-mediated ATP release drive extracellular matrix (ECM) remodelling and increased fibrosis.

Materials and methods: Biopsy material was isolated from patients with diabetic nephropathy and stained for Cx-26 and Cx-43. Changes in expression of key candidate proteins were examined by immunoblotting in model epithelial cells from human renal proximal tubules (HK2) cultured in either low glucose (5mmol/L) +/- TGF-β1 (10ng/mL) or high glucose (25mmol/L) for 7days. Lastly to assess the effects of ATP, cells were cultured in non-hydrolysable ATPγS (1-100μM) for 48hrs. ELISA and cytokine arrays measured protein secretion (TGF-β1, Interleukin-6 (IL-6) and Beta Nerve Growth Factor (β-NGF)). Lastly, Carboxyfluorescein uptake assays determined hemichannel activity in control vs TGF-β1 treated (10ng/mL) HK2 cells.

Results: Cx-26 expression was significantly up regulated in biopsy material from patients with diabetic nephropathy, compared to normal control (102700 ±6226 versus 21030±4727; n=10, P<0.01). Similarly, Cx-43 expression increased to 116300±5908 as compared to control 21460±10920 (n=10, P<0.01). In response to high glucose (25mmol/L) treatment for 7days, HK2 cells increased TGFβ1 secretion to 994.4±43.6pg/ml compared to 5mmol/L glucose (334±14.9pg/ml; n=3; P < 0.01). Immunoblot analysis confirmed that TGFβ1 (10ng/mL) up-regulates expression of Cx-26 and Cx-43 to 203.9 ±7.5% and 151.1±7.1% respectively compared to control (n = 4; P<0.001). Dye uptake in TGFβ1-treated cells increased to 430±18% at day 7. Immunoblotting confirmed that ATPγs up-regulated Collagen I to 177±12%, 182±21%, and 187±21% (n=3 P<0.01) and Collagen IV to 233±26%, 344 ±18.5%, and 390±10% compared to control (n=3 P<0.001) at 1, 10 and 100 μM. In addition, ATPγs significantly increased expression of Fibronectin to 274±47%, 350±23%, and 433±81% of control (n=3 P<0.01) at 1, 10 and 100 μM. Array analysis of supernatant from ATPγs treated cells confirmed a significant increase in secretion of both IL-6 and β-NGF to 261±24 and 194 ±44 respectively compared to control (n=3 P<0.01).

Conclusion: Expression of Cx-26 and Cx-43 increased in biopsy material isolated from patients with diabetic nephropathy, changes corroborated in HK2 cells treated chronically with TGF-β1. This increased expression was linked to increased hemi-channel mediated ATP release. ATP increased whole cell expression and secretion of key of ECM components and pro-fibrotic markers, suggesting that increased hemichannel-mediated ATP release may exacerbate fibrosis in the diabetic kidney.

Exposure to high glucose levels or starvation induces cellular tolerance towards harmful levels of the reactive dicarbonyl methylglyoxal in murine kidney cells

J. Zemva[1,2], C. Fink[1,2], T. Fleming[1], J. Tyedmers[1,2], P.P. Nawroth[1,3];
[1]Internal Medicine I, University Clinics Heidelberg, [2]Center for Molecular Biology of Heidelberg University (ZMBH), Heidelberg, [3]German Center for Diabetes Research, Neuherberg, Germany.

Background and aims: Toxic metabolites, such as reactive carbonyl species (RCS) and reactive oxygen species (ROS), are inevitably produced during energy production and contribute to ageing and degenerative diseases. Whilst ultimately detrimental to a cell, these metabolites can also have the potential to be beneficial. Methylglyoxal (MG) is formed at an early stage in energy metabolism as compared to ROS, which are mainly produced from the respiratory chain at the end of energy production. MG accumulates with increasing glycolytic flux, which can be sensed by a cell, as a first indicator for rising metabolic stress. In yeast cells, we have previously shown that high glucose or low MG concentrations can initiate a complex defense response that protects against toxic levels of reactive metabolites. In this study we focus on whether a similar mechanism exists in mammalian cells and if it can also be activated by short-term starvation, a treatment shown to be effective in type 2 diabetes.

Materials and methods: Murine mesangial and tubular epithelial cells were studied, cultured in low glucose (5mmol/l) conditions. Cell viability in response to MG, following either glucose starvation (1.5mmol/l) or pre-stimulation with high glucose (HG, 35mmol/l) was assessed by MTT assay. MG-induced protein aggregation was quantified by flow cytometry and fluorescence microscopy. Quantitative PCR and Western Blotting were used to analyze induction and expression of mediators and effectors of either the HG pre-treatment or starvation.

Results: Treatment with HG or starvation over 12 hours increased tolerance against MG in both cell lines. Furthermore, cellular MG-H1 concentrations that can ultimately lead to MG-induced protein-aggregation, were decreased in cells that were either starved or pre-treated with HG. This increased tolerance was associated by an up-regulation of the antioxidant stress response (Nrf2 & SOD2), as well as of the protein quality control system (Hsp70).

Conclusion: Short-term elevation of glucose levels as well as starvation induces cellular defense mechanisms that enable cells to handle reactive metabolites released during increased metabolic stress. Further studies are needed to identify the underlying signaling mechanisms. As RCS and ROS are involved in the development of diabetic late complications, this might lead to new therapeutic options for diabetic nephropathy.

Prediction of progression to microalbuminuria based on baseline metabolomic profile in patients with type 1 diabetes

J. Haukka[1], C. Forsblom1[1], N. Sandholm[1], J. Cobb[2], P.-H. Groop[1], E. Ferrannini[3];
[1]Folkhälsan Research Center, Helsinki, Finland, [2]Metabolon, Durham, USA, [3]Department of Internal Medicine, University of Pisa, Pisa, Italy.

Background and aims: Biomarkers are important measures in explaining onset and progression of complex diseases. In previous studies, metabolomic profile panels have been shown to predict progression of diseases better than single biomarkers. In order to detect the onset and progression of diabetic nephropathy (DN), albumin excretion rate (AER) and estimated glomerular filtration rate (eGFR) are the most widely used measures. Here we performed an untargeted metabolomic study to assess baseline differences between patients with type 1 diabetes (T1D) who either progressed to microalbuminuria or who remained normoalbuminuric during the follow-up.

Materials and methods: Altogether 200 subjects were recruited from the Finnish Diabetic Nephropathy Study (FinnDiane) cohort. All patients had T1D and normal AER at baseline. Of these patients 102 progressed to microalbuminuria during follow-up, whereas 98 remained normoalbuminuric. The prospective metabolomic study was performed using the Metabolon platform. The metabolite concentrations were expressed as relative intensities and scaled to the median of 1. Machine learning based random forest (RF) analysis was performed with normalized metabolite concentrations. Odds ratios (OR) are presented as per standard deviation of the index.

Results: Metabolomic screening identified 1,242 peaks, of which 770 metabolites had known chemical composition. Progressors developed microalbuminuria during a median of 3.2 years. Baseline HbA_{1c} (OR 2.46 [1.65-3.82]), AER (2.29 [1.51-3.65]) and age of diabetes onset (2.03 [1.40-3.02]) were higher in progressors than in non-progressors. ROC_{AUC} for these clinical variables was 0.797. Of 30 metabolites selected by RF, 17 were named ones. An index score formed from these named metabolites resulted in ROC_{AUC} of 0.841, and an OR of 6.85 [4.06-12.60]. When we formed an index by selecting only 5 of the top 30 metabolites from the biochemical groups of polyols (erythritol), amino acid- and oligopeptide intermediates (γ-glutamylglutamate, cis-Cyclo[L-ala-L-Pro] and 3-phenylpropionate), and cortisone together with C-glycosyltryptophan (previously associated with DN but not within in our top 30 metabolites), the ROC_{AUC} for the progression index was 0.821 and the OR 4.57 [2.93-7.64].

Conclusion: The progression index based on the chosen panel of metabolites was able to predict the progression to microalbuminuria significantly better than age of diabetes onset, baseline HbA_{1c} or AER.

OP 35 Inflammation in obesity and type 2 diabetes: studies in animals and humans

205

Plasma WISP1 is a marker of systemic and adipose tissue inflammation in subjects with type 2 diabetes

I. Barchetta, F.A. Cimini, D. Capoccia, R. De Gioannis, A. Porzia, F. Mainiero, M. Di Martino, L. Bertoccini, F. Leonetti, M.G. Baroni, A. Lenzi, M.G. Cavallo;
Sapienza University of Rome, Rome, Italy.

Background and aims: WISP1 is a novel adipokine participating in adipose tissue (AT) dysfunction; so far, no data on WISP1 in diabetes are available. Aim of this study was to evaluate plasma WISP1 in subjects with type 2 diabetes for detecting its correlates linked to AT inflammation.

Materials and methods: For this cross-sectional study, 97 consecutive dysmetabolic subjects were recruited in our Diabetes outpatient clinics; among them, 71 had type 2 diabetes, with (n=35) or without (n=36) obesity, and 26 were obese non-diabetic subjects. Twenty-one normal weight non-diabetic individuals were enrolled as a control group. Study participants underwent clinical workup and blood sampling for metabolic/inflammatory characterization. Moreover, magnetic resonance imaging (MRI) data on subcutaneous (SAT) and visceral (VAT) AT area, hepatic fat content and VAT homogeneity were available for the majority of diabetic patients.

Results: Results: Plasma WISP1 significantly increased throughout classes of obesity and correlated with greater VAT area, IL-8, IL-6, TNFa and lower adiponectin levels, without differing between diabetic and non-diabetic subjects. Higher IL-8 was the main determinant of increased WISP1 (r^2= 0.58, p<0.001). MRI sequences highly suggestive of VAT inflammation were detected in 13.4% diabetic subjects and associated with higher WISP1, IL-8 and CRP independent of obesity. High WISP1 predicted VAT inhomogeneity with AUROC= 0.87 (p<0.001).

Conclusion: WISP1 levels are increased in obese subjects and directly related to adiposity, independently from glycemic status or insulin resistance; moreover, they tightly associate with increased plasma IL-8 and signal abnormalities of VAT. The overall data add new insights to the mechanisms underlying metabolic alterations and may open a novel scenario for innovative therapeutic approaches for diabetes prevention and care.

Senescent $CD8^+$ T cells contribute to development of diabetes via enhancing hepatic inflammation and glucose production

H.-S. Yi, B. Ku;
Internal Medicine, Chungnam National University Hospital, Daejeon, Republic of Korea.

Background and aims: Chronic inflammation has an essential role in the pathogenesis of insulin resistance and diabetes. The aging of the immune system contributes to the development of chronic inflammation and has an important effect on metabolic disease. However, the role of immunosenescence of T cells in patients with prediabetes is not fully understood.

Materials and methods: The participants who visited the hospital for routine health check-up were divided into the following two groups: normal controls and prediabetes. Microarray was conducted to evaluate gene expression profiling in peripheral blood mononuclear cells (PBMCs) from normal controls and drug-naïve patients with diabetes. We have also analyzed the functional characteristics of senescent T cells by fluorescence-activated cell sorting (FACS) in patients with prediabetes and normoglycemia. Furthermore, we co-cultured senescent T cells with hepatocytes or islets to investigate the effect of senescent T cells on hepatic gluconeogenesis and glucose-stimulated insulin secretion, respectively. Finally, we transferred splenic $CD8^+CD28^{null}$ T cells ($1x10^6$) into the mice via

tail vein 3 times per week for 1 week for studying the role of senescent T cells on hepatic inflammation.

Results: Gene expression profiling of the PBMCs revealed elevated levels of the molecules such as CD44, CD69, CD83 and CTLA-4, which link to T cell activation. Gene annotation enrichment analysis based on DAVID algorithm showed that most of the upregulated genes in diabetes might be functionally responsible for T cell activation, phagocytosis, and inflammatory response. Patients with prediabetes also exhibit increased expression of pro-inflammatory cytokines in PBMCs. FACS analysis showed that there are more immunosenescent $CD8^+$ T cells in patients with prediabetes compared to subjects with normoglycemia. Pro-inflammatory cytokines and cytotoxic molecules are highly expressed in senescent $CD8^+$ T cells from patients with prediabetes. In ex vivo co-culture model system, the expression of G6pase and Pepck in hepatocytes was significantly increased by co-culturing with senescent $CD8^+$ T cells. Moreover, glucose-stimulated insulin secretion was reduced in co-cultured islets compared to controls. The mice injected with $CD8^+CD28^{null}$ T cells showed significantly enhanced composition of infiltrating monocytes ($Ly6C^{high}CD11b^+F4/80^{int}$) in the liver, but the population of hepatic resident macrophages ($CD11b^+F4/80^{high}$) was reduced. Populations of $CD4^+CD44^+CD62L^-$ and $CD8^+CD44^+CD62L^-$ (memory/effetor) T cells were not changed in the liver between the mice injected with $CD8^+CD28^{null}$ T cells and vehicles. However, $CD8^+CD44^-CD62L^+$ (naive) T cells were markedly decreased in the liver from the mice injected with $CD8^+CD28^{null}$ T cells.

Conclusion: Senescent $CD8^+$ T cells are more frequently observed in patients with prediabetes compared to normal subjects. Senescent $CD8^+$ T cells are also important for the development of hepatic inflammation and gluconeogenesis in mice.

Diabetes, obesity and inflammation: persistence of elevated Il-1b after bariatric surgery

D. Guarino[1], L. Antonioli[2], M. Fornai[2], C. Pellegrini[2], C. Blandizzi[2], M. Anselmino[3], S. Taddei[4], E. Ferrannini[5], M. Nannipieri[2];
[1]Dpt Clinical and Experimental Medicine, University of Pisa and CNR Institute of Clinical Physiology, [2]Dpt Clinical and Experimental Medicine, University of Pisa, [3]Surgery, Azienda Ospedaliera Universitaria Pisana, [4]Clinical and Experimental Medicine, University of Pisa, [5]CNR Institute of Clinical Physiology, Pisa, Italy.

Background and aims: A growing body of evidence suggests that interleukin-1β (IL-1β) is involved in obesity-associated inflammation and the pathogenesis of type 2 diabetes mellitus (T2DM). The aim of the present study was to correlate serum IL-1β levels with weight loss as well as changes in glucose metabolism and insulin resistance after bariatric surgery.

Materials and methods: Thirty-seven morbidly obese subjects with T2D (O-T2D) and 33 morbidly obese subjects without T2D (O), who had undergone Roux-en-Y gastric bypass (RYGB), received an oral glucose tolerance test (OGTT) before and 1 year after surgery. Eleven healthy individuals (C), age-matched to the Mo group, served as control group. Insulin sensitivity was assessed by oral glucose insulin sensitivity (OGIS) method. Fasting plasma IL-1β levels were measured at the time of OGTTs.

Results: At baseline, BMI was similar in O and O-T2D (46.5±5.6 *vs* 43.2±6.3 kg/m^2) groups, while being in the normal range in the C group (22.2±4.0 kg/m^2). Fasting plasma glucose and HbA_{1c} were higher in O-T2D, as compared to O and C ($p<0.05$ for both variables). Insulin sensitivity was progressively lower from C to O to O-T2D ($p<0.0001$). Fasting plasma IL-1β levels were significantly lower in C as compared to O and O-T2DM (2.4±0.6 *vs* 4.7±2.8 *vs* 4.9±1.9 pg/ml, p<0.004), and were positively related to BMI ($r=0.34$, $p=0.03$), mean glucose during OGTT ($r=0.34$, $p<0.02$), and HbA_{1c} ($r=0.69$, $p=0.0001$) and inversely related to insulin sensitivity ($r=0.37$, $p<0.02$). After surgery, BMI decreased to similar levels (32.5±5.9 and 31.1±5.6 kg/m^2, $p<0.0001$), and insulin sensitivity improved to a similar extent ($p<0.0001$), in O and O-T2D. In contrast, plasma IL-1β levels did not change after surgery (4.6±3.5 and 5.2±2.2 pg/ml, in O and O-T2D, respectively) and were not different from pre-surgery values. Based on fasting glycaemia and HbA_{1c}, at 1 year post-surgery T2D resolved in 20 of 37 patients. Plasma IL-1β concentrations did not differentiate regressors from non-regressors.

Conclusion: Plasma IL-1β concentrations are higher in very obese subjects regardless of the presence of diabetes, and are inversely related to insulin sensitivity. However, following surgery-induced major weight loss and improved insulin sensitivity, plasma IL-1β levels do not change, suggesting the persistence of a systemic inflammatory condition.

Adipocyte specific deletion of integrin-linked kinase regulates lipid and glucose homeostasis in high fat diet-fed C57BL/6 mice

A. Bugler-Lamb, C. Hennayake, A. Gammack, C. Sneddon, L. Kang;
University of Dundee, Dundee, UK.

Background and aims: ILK (integrin-linked kinase) as an adaptor protein, is a key component of the IPP (ILK-Parvin-PINCH) complex which associates with the β-subunit of integrin, linking the extracellular matrix (ECM) with intracellular signalling. Deletion of ILK in muscle or liver, respectively decreases insulin resistance in high fat diet (HFD)-fed mice. HFD-induced insulin resistance and obesity is tightly associated with adipose tissue (AT) remodelling and inflammation. We hypothesize that adipocyte-specific deletion of ILK diminishes insulin resistance in HFD-fed mice via regulating lipid and glucose homeostasis and inflammation.

Materials and methods: ILK was knocked out (KO) in AT using Cre transgenic mice under an adiponectin promoter. Both wildtype (WT) and KO mice were fed with 60% HFD for 16 weeks.

Results: Body weight, water and food intake, energy expenditure, respiratory exchange ratio and physical activity did not differ between WT and KO mice. The KO mice had decreased percent fat mass (21.6 ±1.6% vs. 27.3±1.4%; p=0.01) and increased percent lean mass (73.4 ±1.7% vs. 67.8±1.6%; p=0.02) than WT mice. Glucose tolerance was improved in the KO mice (2412±142 Area under the curve (AUC)) than WT mice (2921±70 AUC; p=0.003). In AT, the KO mice displayed a trend of decrease in expression of both anti- and pro-inflammatory genes including Arg-1, TNFα, IL-1β, IL-6, and collagen 24α with a significant decrease in IL-10 (p=0.02), whilst a trend of increase in adipogenic genes including PPARγ and CEBPα with a significant increase in fatty acid synthase (p=0.006) than WT mice.

Conclusion: In summary, we show that AT-specific ILK deletion in HFD-fed mice increases lean mass, decreases fat mass and improves glucose tolerance possibly via regulating inflammation-associated and adipogenic genes. These results further suggest a pivotal role of the ECM-integrin-ILK pathway in AT in adipogenesis and inflammation, which could contribute to obesity-associated insulin resistance and may represent as a therapeutic target.

The TNF family member 4-1BBL is a key player in the pathogenesis of B cells driving obesity-induced insulin resistance by inducing cytotoxic $CD8^+$T cells in the peritoneal cavity

S. Santa Cruz Calvo, M. Bodogai, A. Biragyn, J.M. Egan;
National Institute of Health, Baltimore, MD, USA.

Background and aims: The prevalence of obesity is increasing the risk of chronic inflammation, type 2 diabetes and fatty liver disease. In these conditions, resident B lymphocytes (B cells) in insulin-sensitive organs, such as adipose tissue (AT) and liver, are altered due to excess of glucose and fatty acids resulting in an accumulation of cytotoxic $CD8^+$T lymphocytes (CTL) and recruitment of M1 macrophages. This scenario favors sustained secretion of pro-inflammatory cytokines, specifically TNFα, which directly promotes insulin resistance (IR). The TNF

'superfamily' member 41BBL (alias TNFSF9) found in immune cells, liver and AT, plays a key role in sustaining TNFα secretion by interacting with its receptor, 4-1BB (TNFRSF9) a costimulatory molecule found in activated CTL, besides transducing signals on its own. Within the peritoneal cavity (PC), B1-a cells ($CD19^+CD5^+$) are known to be the most abundant B cells. In a tumor environment, B-1a cells expressing 4-1BBL (4BL cells) highly accumulate in the PC of old mice as inducers of CTL. Since IR is a key feature associated with obesity-induced low-grade inflammation, we hypothesize that 4BL cells play a key role in triggering the recruitment and activation of CTL. In this study, we aimed to investigate the role of PC infiltrating 4BL cells, as a source of TNFα, in driving IR and regulating glucose homeostasis in obese mice

Materials and methods: Eight week-old *C57BL/6* WT and *Tnfsf9*$^{-/-}$ mice on a *C57BL/6* background (4-1BBL KO) were placed on HFD for 24 weeks and compare to age-matched WT mice on SD. PC B cells ($8x10^6$) from different donors were adoptively transferred (i.p.) into recipient mice lacking mature B cells, J_HT (BKO), fed a HFD for 12 weeks. After 7 days, intraperitoneal glucose tolerance test and PC lymphocytes immune profiling were analyzed in recipient mice

Results: 4-1BBL KO-HFD mice showed improved insulin sensitivity ($p^*<0.001$), with a 1.5-fold reduction in liver size, when compared to their WT counterparts. Immune profiling of PC infiltrating immune cells indicated a 3-fold increase in 4BL cells secreting TNFα in WT-HFD when compare to WT-SD mice. Moreover, the number of B-1a cells secreting TNFα in obese 4-1BBL KO mice were reduced to half when compare to WT-SD and WT-HFD mice. Also, the number of CTL secreting TNFα were increased 2.3-fold in WT-HFD mice when compare to WT-SD mice, but only a 1.6-fold increase was observed in 4-1BBL KO-HFD mice. Likewise, CTL secreting IFNγ were augmented 2-fold in HFD, but only 1.6-fold in 4-1BBL KO mice. HFD caused a 10-fold increase in the PC infiltrating B cells ($CD19^+$) in both strains, when compared to SD. Interestingly, the concentration of the pro-inflammatory adipokine leptin, which upregulates B cell cytokine production and T cell responsiveness, increased more than 2-folds in the PC of WT-HFD mice when compared to SD, while only a 1.6-fold increase was observed in 4-1BBL KO-HFD mice. Recipient mice adoptively transferred with WT-HFD B cells had worse glucose tolerance and a 2-fold increase in the number of infiltrating CTL secreting TNFα, when compared to mice receiving WT-SD B cells or saline. In contrast, mice receiving B cells from 4-1BBL KO-HFD, had similar glucose tolerance as saline-injected mice

Conclusion: These findings point to the blockade of 4-1BBL as a promising therapeutic treatment against the deleterious effects of obesity, bringing new insights in the pathogenesis of PC 4BL cells driving IR

Invalidation of the small GTPase Rab4b in T cells leads to adipose tissue inflammation and dysfunction, and insulin resistance

M. Cormont[1], J. Gilleron[1], G. Bouget[1], S. Ivanov[2], L. Yvan-Charvet[2], N. Venteclef[3], J.-F. Tanti[1];
[1]Centre Méditerranéen de Médecine Moléculaire, Team 7, [2]Centre Méditerranéen de Médecine Moléculaire, Team 13, Nice, [3]Cordeliers Research Center, Paris, France.

Background and aims: Changes in adipose immune cells in obesity is involved in the inflammation of adipose tissue (AT) and in its impaired expandability leading to the development of insulin resistance (IR) and metabolic disease. However, the underlying mechanisms involved in this change remain not completely understood. A fine-tune control of intracellular trafficking is crucial for the function and fate of the immune cells. The Rab GTPases govern intracellular trafficking and we previously found that the expression of Rab4b, a key protein of the early/recycling endosomes, was decreased in the AT of obese mice and humans. We recently found a down-regulation of Rab4b in the adipose T lymphocytes, both in obese mice and humans. We thus aimed at determining the consequences of the down-modulation of Rab4b in T cells on AT function and glucose and lipid homeostasis.

Materials and methods: We generated mice with a specific invalidation of Rab4b in T cells ($Rab4b^{Tcell\ KO}$) by crossing $Rab4b^{flox/fox}$ mice with Lck-Cre mice. We analysed the metabolic phenotype of these mice fed a normal chow diet (NCD) or a high-fat diet (HFD) and characterized the cellular events underlying the phenotypic changes.

Results: On NCD, 35-week-old $Rab4b^{Tcell\ KO}$ mice have the same body and AT weight but exhibited a defect in AT expandability with hypertrophic adipocytes and an increase in pro-inflammatory macrophages compared to wild-type mice. Consequently, $Rab4b^{Tcell\ KO}$ mice exhibit ectopic lipid deposition in liver and muscles and are glucose intolerant and IR at this age. Those mice when fed a HFD, became as obese as wild-type but exhibited an exacerbation of IR. Young 10-week-old $Rab4b^{Tcell\ KO}$ mice have no metabolic disturbance but their AT contains more adipose mesenchymal stem cells and the secretome produced by this AT inhibits adipocyte differentiation. This secretome contains inflammatory cytokines, especially IL-17 and IL-6. Moreover, the lack of Rab4b in T cells induced a decrease in Treg and an increase in Th17 in the AT of 10-week-old $Rab4b^{Tcell\ KO}$ mice. This early inflammation of AT can explain the perturbation of AT expandability and the development of IR observed in 35-week-old $Rab4b^{Tcell\ KO}$ mice. The change in the balance between Treg and Th17 found in AT of 10-week-old $Rab4b^{Tcell\ KO}$ mice is a cell autonomous effect driven by the lack of Rab4b in T cells because ex vivo differentiation of Th0 from $Rab4b^{Tcell\ KO}$ mice is skewed towards Th17 whereas Treg differentiation is impaired.

Conclusion: This study uncovers a control of T cell fate by Rab4b and reveals that the loss of Rab4b expression in T cell during obesity contributes to the insulin resistance by promoting disturbance in adipose T cell homeostasis leading to inflammation and impaired expandability of AT.

IGFBP-3 is a marker of impaired adipose tissue function and a novel causal mediator of type 2 diabetes risk: a report from the ORIGIN study

M. Pigeyre[1], J. Sjaarda[1], S. Mao[1], S. Hess[2], S. Yusuf[1], H. Gerstein[1], G. Paré[1];
[1]Population Health Research Institute, McMaster University, Hamilton, Canada, [2]R&D Division Diabetes, Sanofi Aventis Deutschland GmbH, Frankfurt, Germany.

Background and aims: Obesity is a strong risk factor for type 2 diabetes (T2D), yet only 15% of obese individuals develop diabetes. There is currently no satisfactory explanation for this paradox and the mediators linking adiposity to T2D are incompletely understood. We hypothesized that genetically determined body mass index (BMI) can distinguish metabolically deleterious from neutral and beneficial BMI, and can help identify blood biomarkers mediating adiposity's metabolic effects.

Materials and methods: We partitioned 1.9 million genetic variants associated with BMI in the GIANT consortium into three categories according to genetic covariance with diabetes (DIAGRAM consortium): BMI-increasing variants linked to low T2D prevalence (20,255 SNPS) were assigned to the "beneficial" BMI genetic risk score (GRS); those linked to high T2D prevalence to the "deleterious" GRS (190,372 SNPs); with the remaining ones allocated to the "neutral" GRS (1,691,424 SNPs). We then assessed the association of each GRS with BMI itself, T2D and 237 cardiometabolic biomarkers in 4,147 participants from the ORIGIN trial with genetic material.

Results: All 3 GRSs were positively associated with BMI. However, the beneficial GRS was inversely associated with T2D prevalence (OR=0.50 [0.29-0.85] per 1 kg/m^2 increase, p=0.011) and the deleterious GRS was positively associated with T2D prevalence (OR=1.26 [1.07-1.50] per 1 kg/m^2 increase, p=0.006). No relationship was observed between the neutral GRS and prevalent T2D. Of the 237 biomarkers tested, only the adipokine Insulin-like Growth Factor-Binding Protein 3 (IGFBP-3) discriminated between genetically beneficial and deleterious BMI: IGFBP-3 levels were inversely associated with both the beneficial GRS (β= -0.27±0.07 SD per kg/m^2, p=0.0001) and the measured BMI (β= -0.01±0.002 SD per kg/m^2, p=4.9x10^{-07}). Moreover, after adjustment for clinical covariates, higher IGFBP-3 levels predicted a higher prevalence of T2D (OR=1.11 [1.03-1.20] per SD IGFBP-3 level, p=0.005); and a higher incidence of major adverse cardiovascular events (MACE) (HR=1.11 [1.05-1.18] per SD IGFBP-3 level, p=0.0005). Finally, when applying a Mendelian randomization approach to the DIAGRAM consortium, genetic determinants of higher IGFBP-3 levels were also linked to a higher prevalence of T2D (OR=1.26 [1.11-1.43] per SD IGFBP-3 level, p=0.0004).

Conclusion: Our data suggest that high IGFPB-3 concentrations reflect low "beneficial" BMI and may be a causal mediator of T2D. These results are consistent with *IGFBP3* transgenic mice, which exhibit fasting hyperglycemia and impaired glucose tolerance. Together, these data position IGFPB-3 as a marker of impaired adipose tissue function, as well as a potential therapeutic target.

Blood metabolites associate with glycaemic control in type 2 diabetes independent of glucose lowering medication

L.M. 't Hart[1,2], N. Vogelzangs[3], M.M. van Greevenbroek[4], C.J. van der Kallen[4], R.C. Slieker[5,2], D.O. Mook-Kanamori[6], K. Willems van Dijk[7], J.M. Dekker[2], G. Nijpels[8];
[1]Molecular Cell Biology & Molecular Epidemiology, Leiden University Medical Center, Leiden, [2]Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, [3]Epidemiology; MaCSBio; CARIM, Maastricht University, Maastricht, [4]Internal Medicine, Cardiovascular Research Institute Maastricht (CARIM), Maastricht University Medical Center, Maastricht, [5]Molecular Cell Biology, Leiden University Medical Center, Leiden, [6]Clinical Epidemiology & Endocrinology and Metabolic Diseases, Leiden University Medical Center, Leiden, [7]Einthoven Laboratory for Experimental Vascular Medicine & Human Genetics & Endocrinology, Leiden University Medical Center, Leiden, [8]General Practice and Elderly Care, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: To facilitate personalized therapeutics in type 2 diabetes patients, there is a growing interest to discover factors associated with poor treatment response. In a search of better markers we have used a targeted metabolomics approach to study the association of metabolites in blood with treatment and treatment response.

Materials and methods: Blood metabolites (n=164) were measured using a targeted approach (Nightingale Health, FI) in independent samples from four type 2 diabetes patient cohorts from the Netherlands (Hoorn DCS cohort, CODAM, NEO and Maastricht study, n=2653). We applied linear and logistic regression analysis with adjustment for age, sex, BMI, lipid lowering medication, glucose lowering medication (if applicable) and diabetes duration as covariates. We first analysed the effect of different drugs on metabolite levels. Next we examined associations of metabolite levels with HbA1c levels and with the ability to reach the clinical target of an HbA1c below 53 mmol/mol. In addition we used stratified analyses to examine the effect of different glucose lowering drugs on the association of metabolite levels and HbA1c. A Bonferroni adjusted threshold p-value was used to account for multiple hypothesis testing after meta-analysing the results of the four independent studies in a fixed effects model (164 tests, P<3.1x10^{-4}).

Results: Our results show that a substantial number of metabolites were affected differently by the various types of glucose lowering medication. Especially insulin treatment affected the metabolome (n=46 altered, all p≤3.1x10^{-4}). In addition a large number of metabolites were associated with HbA1c levels (n=80) or the ability to reach the treatment target (HbA1c <53 mmol/mol, n=63, all p≤3.1x10^{-4}). Most significantly associated metabolites were amino acids (Gln, Leu, Ile) and measures of lipoprotein subclasses (mainly VLDL). Interestingly the associations of metabolites with HbA1c were hardly affected by the different types of drugs these patients are treated with.

Conclusion: Blood metabolites are associated with treatment response in type 2 diabetes patients. These associations are independent of glucose lowering treatment regimen and other covariates.

Metabolic phenotyping of first degree relatives of patients with type 1 diabetes

E.E. Zügner[1], G. Treiber[2], B. Prietl[2], E. Gander[1], N. Bordag[3], C. Magnes[1], T.R. Pieber[1,2];
[1]HEALTH, Joanneum Research, [2]Div. of Endocrinology and Diabetology, Medical University of Graz, [3]CBmed GmbH, Graz, Austria.

Background and aims: Incidence rates of type 1 diabetes (T1D) are rising by more than 3% / year worldwide. New cases of T1D are rising by even 70% in children <15 years while the frequency of high risk genotypes is decreasing in newly diagnosed T1D cases. The risk for children to develop T1D is ~8% when they have a T1D affected sibling; it increases up to 20% if two first-degree relatives (FDR) have T1D. Recent studies suggest a profound influence of "diabetogenic" environmental factors in the pathogenesis of T1D, making early prediction of T1D development a topic of major interest. Metabolomics is a new tool to identify patterns of metabolites to detect early changes in people developing T1D. The advantage of metabolomics is, that metabolites fall downstream of genetic, proteomic and environmental variation, thus providing the most integrated phenotype measure. But since T1D is seen as a primarily immune mediated disease, metabolomics studies of T1D are scarce. This study aimed to identify metabolite patterns indicative of a high risk of developing T1D and consequently identify candidate biomarkers for early prediction of T1D. FDR with a 10-fold higher risk to develop T1D should

have characteristic metabolite patterns compared to matched groups of healthy and T1D patients.

Materials and methods: Three subgroups of the Austrian Diabetes Prevention Program cohort were selected: 19 newly diagnosed T1D patients (diabetes duration <3 months), 17 healthy FDR and 19 unrelated healthy controls (age, gender and BMI matched). The metabolomics plasma sample analysis was performed using HILIC-HRMS (sample extraction with cold 80% MeOH) for targeted and untargeted data analysis.

Results: The preliminary targeted analysis yielded 186 known metabolites covering all major classes with 156 metabolites showing the highest possible analytical quality (median technical variability 7.4%). Principal Component Analysis (PCA) of these 156 metabolites showed a distinct separation of patients with T1D from healthy controls. FDR clustered between T1D and healthy controls (Fig. 1, left). The PCA loadings plot showed differences in 14 metabolites among the three groups ($p<0.01$, Fig. 1, right).

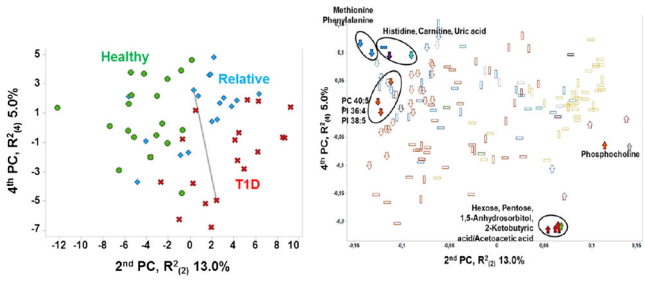

Figure 1: Selected PCA of 156 known metabolites, performed on logarithmic data (scaled to unit variance, centered). Left: PCA scores plot. The line indicates one direct relationship between a T1D patient and a first-degree relatives. Right: PCA loadings plot. Filled arrows: p-value <0.01; hollow arrows: p-value <0.05; up/down-arrows: higher/lower metabolite levels in T1D patients relative to healthy contro

Conclusion: In this study we were able to show that healthy FDR of patients with T1D showed distinct metabolic patterns correlating with the higher risk of developing T1D. We hypothesize that this metabolic pattern may be a biomarker for early diagnosis or prediction of T1D.

Liver and plasma metabolomics on two mouse models with progressive diabetes development uncovers shared biomarkers for beta cell dysfunction in pre-diabetes

L. Li[1], P. Krznar[2], A. Agazzi[3], V. Deo[4], J. Martin-Levilain[1], S. Supale[1], N. Zamboni[2], P. Maechler[1];

[1]Department of Cell Physiology and Metabolism, University of Geneva, Geneva, [2]Institute of Molecular Systems Biology, ETH Zurich, Zurich, [3]Theoretical Physics Department, University of Geneva, Geneva, Switzerland, [4]Electrical Engineering Department, Stanford University, Stanford, USA.

Background and aims: Early diagnosis of beta-cell failure remains unsuccessful despite its crucial importance in the diabetes prevention. Identification of patients with beta-cell dysfunction in the pre-diabetic stage is therefore essential. In recent years, metabolomics emerged as a powerful tool in providing read-outs of early perturbations in diseases. We aimed to identify novel biomarkers for beta-cell dysfunction in the pre-diabetic stage of two distinct mouse models displaying progressive diabetes development independently of drug or diet treatments, i.e. db/db mice and beta-cell specific prohibitin-2 knockout mice (beta-Phb2$^{-/-}$).

Materials and methods: Liver and plasma were collected from 18 male C57BLKS/J db/db mice aged 4, 6 and 8 weeks, and 18 age-matched heterozygous db/+ controls. Same collection was also done from a total of 21 male beta-Phb2$^{-/-}$ mice aged 4, 5 and 6 weeks and 24 age-matched control mice. Total pancreas was fixed for immunohistochemistry quantification of beta-cell mass and islets were isolated for glucose-stimulated insulin secretion (GSIS). Metabolite profiling was performed by non-targeted flow injection-time-of-flight mass spectrometry (MS), complemented by targeted liquid chromatography (LC)-MS and gas chromatography (GC)-MS.

Results: At the age of 8 weeks and 6 weeks, respectively, db/db mice and beta-Phb2$^{-/-}$ mice began to display hyperglycaemia. Before the appearance of diabetes, both db/db mice and beta-Phb2$^{-/-}$ mice had a transient expansion of beta-cell mass, along with decreased GSIS from isolated islets. This was followed by the progressive loss of beta-cells and development of hyperglycaemia a few weeks later. However, unlike db/db mice with marked body weight gain during the pre-diabetic stage, beta-Phb2$^{-/-}$ mice maintained the same body weights as their age-matched controls. In the liver, cortisol increased in db/db mice during pre-diabetes, not in beta-Phb2$^{-/-}$ mice. Branched-chain amino acids (BCAA) increased in the liver of db/db mice, while they slightly decreased in beta-Phb2$^{-/-}$ mice, showing the association of BCAA with obesity and insulin resistance rather than with beta-cell dysfunction. Importantly, a specific group of deoxy sugars decreased in liver and plasma of the two mouse models at the pre-diabetic stage, showing strong correlation with the development of early asymptomatic beta-cell failure before the appearance of hyperglycaemia. These biomarkers continued the same trend after the loss of functional beta-cells in both db/db and beta-Phb2$^{-/-}$ mice.

Conclusion: The present study identified metabolite signatures specifically associated with early beta-cell dysfunction by comparing two diabetes mouse models. We also uncovered metabolic similarities between liver and plasma, providing insights into the systemic effects caused by early changes in beta cells in pre-diabetes.

Skin autofluorescence predicts 4-years risk of incident type 2 diabetes in a large scale general population

R.P. van Waateringe[1], B.T. Fokkens[2], S.N. Slagter[1], R. Graaff[1], M.M. Van der Klauw[1], J.V. van Vliet-Ostaptchouk[1], A.D. Paterson[3], H.L. Lutgers[4], A.J. Smit[2], B.H.R. Wolffenbuttel[1];

[1]Endocrinology, University Medical Centre Groningen, [2]Vascular Medicine, University Medical Centre Groningen, Groningen, Netherlands, [3]Program in Genetics and Genome Biology, Hospital for Sick Children, Toronto, Canada, [4]Internal Medicine, Medical Centre Leeuwarden, Leeuwarden, Netherlands.

Background and aims: The rising prevalence of type 2 diabetes mellitus (T2DM), accompanied with its cardiovascular complications, is a major problem worldwide. Screening of high-risk individuals might be beneficial as early treatment may delay the development into overt disease and its complications. In the present study, we examined whether the measurement of skin autofluorescence (SAF), a non-invasive biomarker of advanced glycation end products (AGEs) accumulation, is able to predict 4-years risk of T2DM in a large-scale, general population.

Materials and methods: For this prospective analysis, we included 80,253 participants of the Dutch Lifelines Cohort Study, who underwent baseline investigations between 2007-2013 and had a SAF measurement available. Individuals were diagnosed with incident T2DM in 2014-2016 by self-report or by a fasting blood glucose >6.9 mmol/l or HbA1c ≥6.5% at 4-years of follow-up. SAF was measured non-invasively at baseline using the AGE Reader. Subjects were divided into quartiles of SAF (quartile 1=low; quartile 4=high). Odds ratio (OR) for pre-specified risk factors were calculated.

Results: After 4 years of follow-up (range 1-9 years), 995 subjects had developed T2DM (1.2%). Baseline SAF was 2.19 ± 0.45 arbitrary units (AU) in T2DM and 1.91 ± 0.43 AU in subjects without diabetes ($p<0.01$). Univariate factors predicting incidence of T2DM were SAF, age, gender, BMI, waist circumference, fasting glucose, HbA1c, current smoking and coffee consumption. After adjusting for these common risk factors, SAF remained associated with a higher risk of T2DM (OR 1.27 per AU; 95% CI 1.06-1.52, $p<0.01$), but not after further adjustment for HbA1c. Individuals with a high SAF level at baseline had an increased risk of T2DM compared to subjects with a low SAF level (OR 1.37 per AU; 95% CI 1.03-1.81, $p<0.05$). For individuals in the third

and second SAF quartile, SAF was not associated with incident T2DM (p=0.27 and p=0.91).

Conclusion: SAF is elevated in subjects with incident T2DM compared to individuals without diabetes. Individuals with a high SAF level have an increased risk of T2DM after 4 years of follow-up compared to subjects with a low SAF level, even after adjusting for other conventional risk factors.

Plasma N-glycans and C-reactive protein as biomarkers of HNF1A-MODY in young adults

O. Gornik[1], T. Pavić[1], A. Juszczak[2,3], E. Pape-Medvidović[4], A.J. Bennett[2,3], A.L. Goyn[2,3], M.I. McCarthy[2,3], G. Lauc[1], K.R. Owen[2,3];

[1]University of Zagreb Faculty of Pharmacy and Biochemistry, Zagreb, Croatia, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, [3]Oxford NIHR Biomedical Research Centre, Oxford, UK, [4]Merkur University Hospital, Vuk Vrhovac Clinic for Diabetes, Endocrinology and Metabolic Diseases, Zagreb University School of Medicine, Zagreb, Croatia.

Background and aims: HNF1A-MODY is frequently misdiagnosed due to lack of accepted diagnostic protocols and limited availability of genetic testing. Benefits of making the diagnosis include first-line treatment with sulphonylureas and screening of relatives. While absence of islet antibodies and preserved insulin secretion can differentiate MODY from type 1 diabetes, non-genetic biomarkers are not routinely available to differentiate from type 2 diabetes in adults, and this remains challenging. We previously showed that defects in key processes regulated by HNF1A result in a distinctive plasma N-glycan profile and lowered CRP in HNF1A-MODY. We aimed to evaluate these agents in identifying those at high risk of HNF1A-MODY in an unselected population of young adults with antibody negative, C-peptide positive diabetes.

Materials and methods: Individuals (n=1032) with diabetes onset below 45 years were recruited in the UK and Croatia. N-glycans were analysed using Hydrophilic Interaction Liquid Chromatography-UPLC and profiles were divided into 38 glycan groups (GP1-GP38) with glycan structures assigned. HsCRP was measured by immunoassay. Sanger sequencing of HNF1A was performed and rare HNF1A variants (MAF&lt1%) underwent a systematic assessment of their functional effect.

Results: Twenty-five rare HNF1A variants were found in 29 probands. Fourteen variants were previously reported as disease causing, of which 12 had familial co-segregation of the variant allele with diabetes. Seven variants were protein truncating and assumed to be functionally damaging, while 18 were missense. Eight of the missense variants were predicted by three bioinformatics tools as likely damaging. In vitro functional studies reported before, or performed in this study, in 14 variants supported disease causality of the variant allele in 6 cases. Thirteen out of 25 variant alleles were present in the ExAC database with minor allele frequency (MAF) of 0.001-0.1%. After the above assessment, we assigned 13 variant alleles, found in 18 individuals, as HNF1A-MODY-causing. The glycan groups GP30, GP36 and GP38, all containing fucosylated glycans, showed good discriminative power between HNF1A-MODY and those without variants (p&lt5x10^{-8}, C-statistics of 0.86-0.90). Glycan group GP30 had the best performance, with sensitivity of 89% and specificity of 76%. Using cut-off of 0.73, GP30 detected 16 out of 18 patients with damaging HNF1A alleles. Median hsCRP of those with damaging HNF1A variants was 0.30 mg/L (IQR 0.86) versus 2.20 mg/L (IQR 4.78) in the remainder (p=2.4x10^{-5}). HsCRP had a C-statistic of 0.82 in classification performance, and using a cut-off of 0.9 mg/L, showed sensitivity of 78% and specificity of 73% and identified 14/18 probands with damaging HNF1A variant alleles.

Conclusion: Fucosylated glycans and hsCRP are good discriminative markers for HNF1A-MODY among young adults with non-type 1 diabetes. Use of these markers in diagnostic protocols could assist in identifying adults at high risk of HNF1A-MODY.

Kisspeptin: a novel regulator of glucose homeostasis during pregnancy

T.G. Hill, P.M. Jones, J.E. Bowe;

Diabetes Research Group, Diabetes and Nutritional Sciences, King's College London, London, UK.

Background and aims: During pregnancy, the maternal pancreatic islets of Langerhans undergo adaptive changes in order to compensate for the normal progression of insulin resistance that occurs during gestation. Recently placentally-derived kisspeptin (KP) and its cognate receptor, G protein-coupled receptor-54 (GPR54), have been suggested to play a role in the regulation of these adaptive changes and maintaining glucose tolerance during pregnancy. Although global GPR54 knockdown mice have previously been established, they are unsuitable for studying the role of KP during pregnancy because they do not progress through puberty and lack adult reproductive function due to effects of KP within the hypothalamus. Consequently, we have generated a novel, beta cell-specific GPR54 knockout (KO) mouse model in order to investigate the effects of KP on glucose homeostasis during pregnancy.

Materials and methods: Transgenic targeting of GPR54 specifically within the islet beta cells was achieved by crossing MIP-Cre/ERT^{1Lphi} mice with LoxP-flanked GPR54 animals and beta cell-specific deletion of GPR54 was induced by injection of i. p. tamoxifen (TMX, 75 mg/kg body weight). Islet GPR54 knockdown was confirmed by quantitative PCR and immunohistochemistry, and normal reproductive function was confirmed by analysis of vaginal smears. Following GPR54 knockdown and TMX washout, female mice were mated and i. p. glucose (30% glucose/kg body weight) and insulin tolerance tests (0.75 IU/kg body weight) were performed at gestational days 16 and 18 respectively. Mice of identical genotype but without TMX administration (Cre controls) and Cre negative mice administered tamoxifen (TMX controls) were used as controls. Characterization of insulin secretion from islets isolated from beta cell-specific GPR54 knockdown and control animals exposed to stimulatory glucose (20 mmol/l) together with exogenous KP (1 μmol/l) were assessed by dynamic perifusion.

Results: Tamoxifen administration induced a 60% knockdown in beta cell *GPR54* mRNA expression (beta cell GPR54 KO: 0.69±0.17 x10^{-3}, Cre control; 1.79±0.41 x10^{-3} relative to *beta-actin*, n=3). Both male and female mice demonstrated no adverse phenotype and normal reproductive function. In pregnant mice, GPR54 knockdown resulted in significantly impaired glucose tolerance (AUC glucose excursion in beta cell GPR54 KO vs Cre controls; 482.8±54.0 vs 306.8±44.5; n=4-7, p=0.027) but no change in insulin tolerance (AUC glucose excursion in beta cell GPR54 KO vs Cre controls; 405.7±10.7 vs 400.9±28.9; n=4-7), when compared to controls. Similar effects were seen when compared to TMX controls, confirming that this effect was due to GPR54 knockdown. Islets isolated from beta cell-specific GPR54 knockdown mice demonstrated normal glucose-stimulated insulin secretion but an impaired incremental response to the addition of exogenous KP, when compared to control islets (AUC insulin excursion in response to KP, beta cell GPR54 KO: 49.9±8.2 pg/islet/20min, Cre controls: 80.3±34.0, TMX controls 98.7 ±14.3; n=4, p<0.05 beta cell GPR54 KO vs TMX controls).

Conclusion: These data validate the hypothesis that KP could represent a novel and important placentally-derived signal that plays a physiological role in the islet adaptation to pregnancy and helps to maintain normal maternal glucose homeostasis by acting through the beta cell GPR54 receptor.

Reduced production of isoprostanes by the peripancreatic adipose tissue from Zucker fa/fa rats as a new mechanism for beta cell compensation in insulin resistance and obesity

J. Laget, C. Vigor, A. Rocher, J. Leroy, G. Reversat, C. Oger, J.-M. Galano, T. Durand, J. Vercauteren, S. Peraldi-Roux, J. Azay-Milhau, A.-D. Lajoix;

University Montpellier, Montpellier, France.

Background and aims: In type 2 diabetes, ectopic fat deposits develop in parallel with visceral adipose tissue and participate to the onset of metabolic disorders. Among them, peripancreatic adipose tissue (PPAT) is increased in obesity and infiltrates the pancreas to establish direct contact with pancreatic islets. Interestingly, we have shown that factors secreted by the PPAT can modulate both function and proliferation of β-cells, what is in favor of a local biocommunication between PPAT and pancreatic islets. Among them, F_2-isoprostanes (F_2-IsoPs) are oxygenated metabolites derived from the non-enzymatic peroxidation of arachidonic acid, mainly present in phospholipids of cellular membranes. Our aim was to investigate whether IsoPs released by the PPAT could be modulators of β-cell function and proliferation, to influence its ability to compensate for insulin resistance.

Materials and methods: We used the Zucker fa/fa rat model, which displays hyperinsulinemia, insulin resistance and obesity, as a consequence of hyperphagia. Secretome from the PPAT was obtained after 24h culture in RPMI medium. Pure IsoPs were obtained by total synthesis, and were quantified by liquid chromatography-mass spectrometry after an initial solid phase extraction. Secretome or IsoPs were then incubated with INS-1 cells or isolated islets from Wistar rats and insulin secretion or proliferation were measured.

Results: When INS-1 cells were cultured 24h with the PPAT secretome from fa/fa rats, we observed an increase in glucose-induced insulin secretion *versus* lean (NS) and Wistar rats (P<0.05), along with an enhanced proliferation of 40 % (P<0.05). We then asked whether changes in local production of IsoPs by PPAT could be responsible for the observed effects. In PPAT secretome from fa/fa rats, the concentration of 5-F_{2t}-IsoP and 15-F_{2t}-IsoP reached respectively 18.41 ± 2.42 and 4.23 ± 0.61 ng/ml *versus* 135.28 ± 42.16 and 53.89 ± 19.1 ng/ml in lean *fa/+* rats (NS), and 129.6 ± 18.26 and 49.27 ± 8,24 ng/ml in Wistar rats (P<0.001). At the opposite, we observed an increased concentration of 5-F_{2t}-IsoP in plasma from fa/fa rats (10.11 ± 1.25 ng/ml) *versus* lean (3.86 ± 0.32 ng/ml; P<0.001) and Wistar rats (5.28 ± 0.29 ng/ml; P<0.01), as well as that of 15-F_{2t}-IsoP (1.44 ± 0.23 in fa/fa rats *versus* 0.57 ± 0.044 in lean (P<0.01) and 0.83 ± 0.072 ng/ml in Wistar rats (P<0.05)). Finally, we evaluated the effects of synthetic IsoPs on insulin secretion in isolated islets from Wistar rats. After a 24h-incubation period, 15-F2t-IsoP and its 15 epimer decreased glucose-induced insulin at the concentration of 10 μM by respectively 42.8 ± 5.3% (P<0.001) and 30.7 ± 6.5% (P<0.01), but not at lower concentrations.

Conclusion: PPAT secretome obtained from obese Zucker rats stimulated both insulin secretion and proliferation of β-cells. Part of this effect could be related to a decreased production of 5-F_{2t}-IsoP and 15-F_{2t}-IsoP by the PPAT, inhibiting insulin secretion at high concentrations. These data possibly highlight a new mechanism for β-cell compensation in insulin resistance and obesity.

Impaired beta cell function predicts the islet functional capacity following partial pancreatectomy

C.M.A. Cefalo, G. Sorice, T. Mezza, F. Cinti, S. Moffa, V.A. Sun, A. Mari, A. Giaccari;

Università Cattolica del Sacro Cuore, Rome, Italy.

Background and aims: Several lines of evidence suggest that β-cell functional defects temporally anticipate (and eventually cause) the subsequent development of hyperglycemia. Still, a significant reduction (~50%) of beta-cell mass is observed at diagnosis of type 2 diabetes.

Materials and methods: To further investigate the relative role of beta-cell mass reduction/dysfunctionin the development of diabetes we performed oral glucose tolerance tests (OGTT) and hyperglycemic clamps (HC), followed by arginine stimulation, in 22 patients undergoing pancreatoduodenectomy (PD), pre- and post-surgery. Based on post-surgery OGTT, subjects were divided into 3 groups depending on glucose tolerance: normal (NGT, n=6), impaired (IGT, n=6) or diabetic (DM, n=10) (12 F/10 M, 51±15 yrs.). To evaluate β-cell function, β-βcell glucose sensitivity (GS) during HC was calculated as the ratio of insulin secretion and glucose increments.

Results: Before surgery, Arginine-stimulated Insulin Secretion rates (AIS) were similar across groups, whereas GS and incremental 1st phase insulin secretion were significantly lower in IGT and DM as compared with NGT subjects (p=0.02 and p<0.01). Following PD, AIS decreased in all patients (p<0.05 for all groups) but the reduction was greater in DM compared to IGT and NGT patients (p<0.001). A similarly scaled reduction was observed in 1st and 2nd phase of insulin secretion (p=0.03 and p<0.01) and in GS (p<0.01). Compared to baseline secretion, only DM group experienced a significant reduction in 2nd phase insulin secretion (348±118 vs. 105±40.3 pmol·min^{-1}·m^{-2}, p=0.05) and in GS (34.4±11.3 vs.13.1±6.13 pmol·min^{-1}·m^{-2}mM^{-1}, p=0.01).

Conclusion: In this study the acute beta-cell mass reduction had a different impact on insulin secretory capacity, despite comparable functional mass at baseline, according to pre-surgery insulin secretion characteristics. This suggests that underlying beta-cell dysfunction anticipates the decline of beta-cell responses, being the pivotal mechanism for the development of hyperglycemia.

Overexpression of c-Kit in aged mice stimulates beta cell proliferation, but leads to impaired beta cell function

A.M. Oakie[1,2], Z.-C. Feng[1], J. Li[1,3], J. Silverstein[1], R. Wang[1,3];

[1]Children's Health Research Institute, [2]Pathology, University of Western Ontario, [3]Physiology and Pharmacology, University of Western Ontario, London, Canada.

Background and aims: Activation of the c-Kit receptor on β-cells regulates intracellular pathways that enhance insulin secretion, up-regulation of the insulin receptor (IR), β-cell proliferation and survival, and islet vascularization. c-Kit overexpression in β-cells is able to improve glucose levels in mice up to 28 weeks of age and on a short-term high fat diet. However, the prolonged effect of c-Kit activity on sustained insulin release from β-cells or on overall β-cell function has not been previously examined. This study determines if the long-term overexpression of c-Kit on murine β-cells maintains glucose homeostasis through increased insulin release.

Materials and methods: We generated mice with a β-cell specific c-Kit overexpression (*c-KitβTg*) and monitored aged males to 60 weeks compared with wild-type (WT) littermates. Metabolic tests (IPGTT, IPITT, *in vivo* and *ex vivo* GSIS) were performed to measure glucose tolerance and insulin release. Islet histology and isolated islet protein were analyzed to examine intracellular signalling, proliferation, and expression of transcription factors and proteins that maintain β-cell function. To examine the effects of c-Kit-induced insulin resistance during aging, a β-cell specific, tamoxifen inducible IR knockout mouse line (*βIRKO*) was generated and crossed with *c-KitβTg* mice (*c-KitβTg:βIRKO*). IR loss was induced at 40 weeks of age and glucose metabolic tests were performed at 60 weeks.

Results: Aged *c-KitβTg* mice progressively developed high fasting blood glucose and demonstrated significant glucose intolerance (p<0.05) compared to age matched WT mice. The survival rate of *c-KitβTg* mice declined with aging over a two-year period. *In vivo* and *ex vivo* GSIS results revealed a reduction of insulin secretion from islets of *c-KitβTg* mice (p<0.05 vs WT). Histological analyses of *c-KitβTg* pancreatic islets found enlarged β-cell mass and high proliferation (p<0.05 vs WT), indicating that high glucose levels in *c-KitβTg* mice are not due to a loss of the β-cell population. Protein analyses from isolated islets showed an increase in MAPK/Erk/cyclin D1 signalling pathway in *c-KitβTg* mice (p<0.05 vs WT), with no change through Akt signalling between WT and *c-KitβTg* mice. Reduced syntaxin 1a and Munc18-1 levels were detected in aged *c-KitβTg* islets (p<0.05 vs WT), suggesting possible dysfunctions in insulin granule exocytosis. Preliminary studies have found that loss of β-cell IR in aged *c-KitβTg:βIRKO* mice resulted in normal glucose tolerance when compared to aged *c-KitβTg* mice.

Conclusion: This study shows that c-Kit activation maintains increased β-cell mass and proliferation in *c-KitβTg* mice over 60 weeks of age, yet chronic overexpression of c-Kit results in reduced insulin release and glucose intolerance as associated with the reduction of exocytotic proteins. The results from this study demonstrate that regulation of c-Kit signalling (time- and dose-dependent) is important for optimal β-cell function and insulin secretion.

The effects of ethnicity on the development of prediabetes among immigrant populations living in low vs high walkability areas: a population-based cohort study

G.S. Fazli[1], R. Rezai[2], A.S. Bierman[1], R. Moineddin[1], G.L. Booth[1];
[1]University of Toronto, [2]Institute for Clinical Evaluation Sciences, Toronto, Canada.

Background and aims: Evidence on urban environments have shown that immigrants living in less activity-friendly neighbourhoods are at a higher risk of developing diabetes compared to long-term residents. However, the association between neighbourhood walkability and prediabetes has not been studied. We conducted a population-based cohort study to examine whether walkability modifies the relationship between ethnicity and prediabetes among immigrant populations living in Canada.

Materials and methods: We used linked health, laboratory and immigration data for the province of Ontario, Canada to identify adults aged 20-85 who immigrated to Canada and were living in urban areas within Southern Ontario between Jan 1, 2002 and Dec 31, 2013. We used Cox proportional hazards modeling to examine the incidence of prediabetes across ethnic groups, stratifying by high and low walkability. Walkability was assigned to individuals using their postal code of residence at cohort entry. We previously found a threshold effect between walkability and diabetes; therefore, we divided walkability into two categories: high, based on the top quintile (Q5) and low, based on the bottom 4 quintiles (Q1-Q4).

Results: Our cohort consisted of 193,899 immigrants (mean age 40 years) of different ethnic origins including Sub-Saharan African and Caribbean (N=20,324), South Asia (N=38,441), South-East Asia (N=18,541) and Western European (N=14,227). The incidence of prediabetes was higher among all non-Western European populations after adjusting for age, sex and area income. However, these effects were more marked in low walkability neighbourhoods and reduced or eliminated in high walkability neighbourhoods (Figure 1). For example, the incidence of prediabetes among Sub-Saharan and African Caribbeans was twofold higher among those living in low walkability areas (HR: 1.99, 95%CI: 1.86-2.14, p<0.001) but only 1.2 times higher in high walkability areas (HR: 1.22, 95%CI: 1.09-1.36, p<0.001). Similarly, West Asian/Arab populations living in low walkability areas had a 1.5-fold higher incidence compared with Western Europeans (HR: 1.54, 95%CI: 1.43-1.66, p<0.001) but this association was not significant in high walkability settings. The interaction between ethnicity and walkability was less among South Asians (HR:2.39, 95%CI: 2.24-2.55, p<0.001 in low vs. HR:1.98 95%CI: 1.78-2.19, p<0.001 in high walkability areas). The effects of ethnicity on prediabetes development were less pronounced among adults aged 65+ living in both high and low walkability areas.

Conclusion: Neighbourhood designs may amplify the risk of prediabetes development among immigrant populations. Further research on interactions between socioeconomic, environmental and immigration factors are necessary to guide the design of population interventions and policies targeting prediabetes among high-risk populations.

Sodium intake and the risk of type 2 diabetes and Latent Autoimmune Diabetes in Adults (LADA)

B. Rasouli[1], E. Ahlqvist[2], T. Andersson[1,3], P.-O. Carlsson[4], L. Groop[2,5], R. Hjort[1], J.E. Löfvenborg[1], M. Martinell[6], A. Rosengren[2], T. Tuomi[5,7], A. Wolk[1], S. Carlsson[1];
[1]The Institute of Environmental Medicine (IMM), Karolinska institutet, Stockholm, [2]Department of Clinical Sciences in Malmö, Clinical Research Centre, Lund University, Lund, [3]Center for Occupational and Environmental Medicine, Stockholm County Council, Stockholm, [4]Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [5]Finnish Institute of Molecular Medicine, Helsinki University, Helsinki, Finland, [6]Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden, [7]Division of Endocrinology, Abdominal Center, Helsinki University Hospital, Helsinki, Finland.

Background and aims: It has been suggested that salt (sodium chloride) may increase the risk of T2D, hypothetically through an effect on insulin resistance and/or by way of promoting hypertension and weight gain. Whether sodium intake is related to onset of autoimmune diabetes has not been investigated. However, experimental studies have shown that excessive sodium intake may initiate an autoimmune reaction by enhancing the production of T_H17 cells which are highly proinflammatory. We aimed to study, for the first time, whether sodium intake is associated with an increased risk of LADA.

Materials and methods: We used data from ESTRID (epidemiological study of risk factors for LADA and T2D), a Swedish population-based study which includes incident cases of LADA (n=355) and T2D (n=1136) from ANDIS/ANDiU, together with population-based matched controls (n=1379). Dietary intake reported in a food frequency questionnaire was used to calculate daily energy and nutritional intake, using standard values cited in the Swedish National Food Agency Database and taking into account age-specific portion sizes. Sodium intake was energy adjusted using nutrition density method. HLA genotype was dichotomized as high risk or other. Odds ratios (OR) with 95% confidence intervals (CI) were calculated and adjusted for age, sex, BMI, education, smoking, physical activity, family history of diabetes, total energy, alcohol and potassium intake.

Results: Sodium intake was associated with an increased risk of LADA (OR per gr/day; 1.73, 95% CI; 1.23-2.43); comparing the highest to lowest tertile of sodium intake indicated an OR of 2.19 (95% CI; 1.33-3.61) (Table 1). The risk was even more pronounced for LADA patients with high risk HLA genotypes; an almost four-fold (OR 3.87, 95% CI 1.87-8.01) increased risk was seen in the high consumers. We could also confirm that sodium intake was associated with an increased risk of T2D (OR per gr/day; 1.43, 95% CI; 1.09-1.88).

Conclusion: Our findings suggest that high sodium intake may be a risk factor for LADA, especially in carriers of high risk HLA genotypes. We could also confirm an association between sodium intake and T2D. If confirmed in other populations, these findings may have important implications in the primary prevention of diabetes with adult onset.

Table 1. OR of LADA and type 2 diabetes in relation to sodium consumption, ESTRID study, 2010-2016

	Type 2 diabetes			LADA		LADA With other HLA genotype [a]		LADA With high risk HLA genotype [a]

Protein intake in relation to development of type 2 diabetes and the role of obesity

Z. Chen, O.H. Franco, T. Voortman;
Epidemiology, Erasmus MC, Rotterdam, Netherlands.

Background and aims: Type 2 diabetes (T2D) is one of the most common chronic diseases with increasing prevalence over the world. Diet is considered an important component of a healthy lifestyle in the prevention of T2D. Investigations into the effect of dietary factors on risk of T2D have become very important. One of the dietary factors of interest is protein intake. Overall, total and animal protein intake seems to be associated with higher risk of T2D, but the association between plant protein intake and risk of T2D is still uncertain, appears to be either inverse or null. Besides, the evidence for protein intake in relation to earlier stages in the development of T2D including insulin resistance and prediabetes is scarce. Therefore, we aimed to examine the associations between habitual protein intake with insulin resistance, risk of prediabetes and risk of T2D in a large population-based cohort study.

Materials and methods: Our current study was embedded within three cohorts of the Rotterdam Study (RS), a population-based cohort study including people aged ≥45 years living in the Ommoord District of Rotterdam, the Netherlands. The study has been approved by the Medical Ethics Committee of Erasmus University Medical Center and all participants gave written informed consent. We followed 2976 subjects in Rotterdam Study I (1990-2012), 1410 subjects in Rotterdam Study II (2000-2012), and 2418 in Rotterdam Study III (2006-2012). All 6814 subjects in our current study were free of diabetes at baseline; of whom 5795 were without prediabetes, and 3932 had repeated assessments of glucose and insulin, from which we calculated the homeostatic model assessment for insulin resistance (HOMA-IR). Protein intake was assessed at baseline with the use of validated food-frequency questionnaires. We used multivariable cox proportional hazard regression models to analyze the associations between protein intake and risk of prediabetes and T2D. We used multivariable linear mixed models to analyze the associations between protein intake and insulin resistance, and we used joint models to examine the role of longitudinal obesity data in the associations of protein intake with insulin resistance and risk of prediabetes and T2D.

Results: We documented 643 cases of T2D during a median 7.2 years of follow up; and 931 cases of prediabetes during a median 5.7 years of follow up. In pooled multivariable models, higher intake of total protein was positively associated with HOMA-IR (β=0.10 (95%CI 0.07-0.12) per 5 energy percent (E%)), risk of prediabetes (HR=1.35 (95%CI 1.20-1.51) per 5E%), and risk of T2D (HR= 1.38 (95%CI 1.20-1.60) per 5E%). Additional adjustment for repeatedly measured BMI or waist circumference attenuated these associations, but the associations of protein intake with higher insulin resistance and prediabetes risk remained significant. Results were mainly explained by protein from animal food sources. Results were irrespective of whether protein substituted total fat or carbohydrates, independent of protein intake at follow-up, and independent of other cardio metabolic risk factors.

Conclusion: Total protein intake is positively associated with insulin resistance, risk of prediabetes and T2D, which is mainly driven by animal protein. It appears likely that obesity partly mediates the associations.

Physical activity, fatty liver and glucose metabolism over the life course: the LifeLines cohort

O. Byambasukh[1,2], D. Zelle[3], E. Corpeleijn[1];
[1]Department of Epidemiology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Department of Endocrinology, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, [3]Department of Nephrology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background and aims: Fatty liver is strongly associated with type 2 diabetes mellitus (T2DM), and may be influenced by lifestyle factors. We aimed to examine whether there is an association of habitual physical activity with biochemical markers of Non-alcoholic fatty liver disease (NAFLD) and whether this association is stronger with age and degree of impaired glucose metabolism.

Materials and methods: We included 44,491 participants from the Dutch LifeLines Cohort Study, aged 18-80 years (39.2% males, 44±12 years of age, BMI 26±4.3 kg/m^2 and Waist Circumference (WC) 90.3±12.3 cm). Moderate-to-vigorous physical activity (MVPA) was assessed by the SQUASH, a self-reported questionnaire. Glucose status was defined as (1) normal glucose tolerance (NGT) based on fasting plasma glucose (FPG) <6.1 mmol/L, (2) impaired glucose metabolism (IGM) - FPG 6.1 - 6.9 mmol/L or HbA1C 5.7 - 6.4%, and (3) diabetes - FPG ≥7.0 mmol/L or HbA1C ≥6.5% or self-report of diagnosis by a physician, or use of glucose-lowering agents. NAFLD was defined as a fatty liver index (FLI) >60, which is based on BMI, WC, triglycerides and gamma-glutamyltransferase (GGT). Furthermore, we assessed alkaline phosphatase (AP), alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Exclusion criteria were previously diagnosed hepatitis or cirrhosis and excessive alcohol use. All analysis were adjusted for age, gender and education level.

Results: Participants spent a median of 420 (165-1200, 25th-75th %) minutes per week in MVPA. NAFLD was found in 21.4% of the participants. Higher MVPA reduced the risk for NAFLD in a dose-dependent manner. Compared to "no MVPA" odds ratios (OR) and 95% confidence intervals (CI) for quintiles of MVPA (all participants with MVPA >0 minutes/day) were 0.73 (0.66; 0.80), 0.57 (0.51; 0.63), 0.53 (0.48; 0.59), 0.49 (0.45; 0.55) and 0.50 (0.45; 0.55) for the highest level of MVPA. Regarding glucose status, the highest level of MVPA, compared to "no MVPA", showed an OR of 0.56 (0.48; 0.64) for NGT, 0.48 (0.41; 0.56) for IGM and 0.38 (0.21; 0.67) for T2DM. Furthermore, the association between MVPA and NAFLD was dependent on age. The OR was 0.75 (0.57; 0.99) in young people (<35 years) and 0.15 (0.05; 0.51) in older people (> 65 years) when comparing the highest level of MVPA with "no MVPA". Furthermore, the association was dependent on gender. The OR was 0.44 (0.39; 0.50) for men and 0.58 (0.49; 0.65) for women. In linear regression, MVPA was inversely associated with Log GGT (p<0.01), Log ALT (<0.01) but not Log AP (p=0.248) and positively associated with Log AST (p<0.01).

Conclusion: A higher level of MVPA is associated with a lower level of NAFLD risk as well as the individual liver enzymes such as GGT and ALT. This association is stronger in diabetic and older subjects.

Diabetes care and mortality in England and Wales 2006-2014

B. Young, P. Knighton, J. O'Keefe, C. Cartwright;
National Diabetes Audit, Leeds, UK.

Background and aims: There is substantial excess mortality among people with diabetes. We investigated whether completion of NICE recommended standards of diabetes care (annual care processes and treatment targets) and levels of HbA1c and BP achieved are related to subsequent mortality.

Materials and methods: The National Diabetes Audit for England and Wales (NDA) extracts data annually from primary care and specialist electronic records. Cohorts of people were selected from the 2006-07 NDA with Type 1 and Type 2 diabetes (also includes secondary diabetes, MODY etc) whose data completeness fulfilled the following criteria: age at least 20 years and still alive on 31st March 2013. This comprised 113,748 Type 1 and 863,850 Type 2 records i.e. 80% of the people in the 2006-07 NDA. The cohort was split: (A) into groups according to completion of three annual care processes (measurement of HbA1c, BP, cholesterol) over the seven year period (Good = all three checks each year between 2006/07 and 2012/13. Poor = not more than 12 out of a possible 21 checks over the seven year period); (B) according to measured levels of HbA1c, BP and cholesterol (the boundaries were dictated by trying to get an even spread of records across the groups, rather than by any clinical significance). Mortality rates for "good" and "poor" care process completion groups were determined, as were rates for the highest and lowest levels of HbA1c, BP and cholesterol at the start and end of the 6 year period.

Results: For both Type 1 and Type 2 diabetes there were age related relationships between mortality (between 1st April 2013 and 31st March 2015) and care process completion and treatment target achievement over the previous 7 years. For each age group and for both people with Type 1 diabetes or Type 2 diabetes, mortality rates were halved for those with a good record of care process completion compared to those with a poor record. For people with Type 2 diabetes, mortality rates were about one third lower for those with consistently low HbA1c recorded compared those with consistently high HbA1c whereas the pattern for Type 1 diabetes was more complex. For baseline systolic blood pressure those in the highest groups as compared to the lowest groups mortality rates were 100% greater in Type 1 and 20% greater in Type 2

Conclusion: Successful completion of NICE recommended annual care processes are associated with lower mortality in all types of diabetes in all age groups. A more complex picture is observed for achieved levels of HbA1c and BP, but higher levels of HbA1c and blood pressure are associated with higher mortality rates.

Factors associated with poor glycaemic control in adults with type 1 diabetes in Norway

J.G. Cooper[1], G. Thue[2], I. Dalen[3], S. Carlsen[1], Å. Bakke[1], K. Løvaas[2], S. Sandberg[2];
[1]Department of Medicine, Stavanger University Hospital, Stavanger, [2]Norwegian Quality Improvement of Laboratory Examinations (Noklus), Bergen, [3]Research Department, Stavanger University Hospital, Stavanger, Norway.

Background and aims: Randomized studies in patients with type 1 diabetes have shown that improved blood glucose control significantly reduces the risk of developing microvascular complications. Observational studies have demonstrated a substantial increase in the risk of death with higher HbA_{1c} levels. A registry based study from Norway has shown that 22% of adult patients with type 1 diabetes had an $HbA_{1c} \geq 9\%$ in 2012. The aim of this study is to assess factors associated with poor glycaemic control using variables registered in the Norwegian Diabetes Registry for Adults (NDV) between 2013 - 2015, together with socioeconomic data obtained from Statistics Norway in 2015.

Materials and methods: 7602 participants over 18 years of age with a diabetes duration of more than two years who had an HbA_{1c} recorded in the NDV between 1st January 2013 and 31st December 2015 were included in the study. The primary outcome of the study was poor glycaemic control defined as $HbA_{1c} \geq 9\%$. Variables potentially associated with glycaemic control were investigated using univariable and multivariable regression analyses adjusted for clustering of observations within hospital diabetes clinics. Odds ratio for $HbA_{1c} \geq 9\%$ and 95% confidence intervals are reported. In view of the large sample size and the number of variables evaluated $p < 0.01$ was chosen as the level of statistical significance. Statistical analyses were performed in Stata 14.0.

Results: The average age of the 7602 participants was 43 years, average duration of diabetes was 22 years and 46.8% were female. The overall mean HbA_{1c} level was 8.0% and 18.7% had an $HbA_{1c} \geq 9\%$. Multivariable regression analysis showed that age between 18 - 25 years and current smoking were significantly associated with an increased risk of having an $HbA_{1c} \geq 9\%$, whereas higher level of education, increasing numbers of glucose measurements and exercise more than three days a week were significantly associated with attenuated risk. In addition several variables from the univariable analysis (not included in the multivariable regression analysis due to feedback issues) were significantly associated with poor glycaemic control. For example insulin pump therapy and higher daily insulin dose per kg were associated with increased risk of $HbA_{1c} \geq 9\%$, whereas increasing numbers of hypoglycaemic episodes per month was associated with attenuated risk of $HbA_{1c} \geq 9\%$.

Conclusion: This study has provided representative national data that demonstrate a strong association between blood glucose control and several patient and socioeconomic factors. A better awareness and understanding of these factors could lead to more individualized management strategies, better glycemic control and a lower risk of diabetes complications.

Predictors of transitioning from adherence to non-adherence among elderly patients with diabetes

J. Schmittdiel[1], W. Dyer[1], G. Nichols[2], M. Raebel[3];
[1]Kaiser Permanente Northern California Division of Research, Oakland, [2]Kaiser Permanente Center for Health Research, Portland, [3]Kaiser Permanente Institute for Health Research, Denver, USA.

Background and aims: Good medication adherence to evidence-based drug therapies to control blood sugar levels is a significant factor in reducing cardiovascular disease risk in patients with diabetes. There is very little research that examines the predictors of good medication adherence in older diabetes patients, or on barriers and facilitators to maintaining good adherence over time. The purpose of this study is to determine factors that predict transitioning from good medication adherence to non-adherence for oral diabetes agents in patients with diabetes age 65 and older.

Materials and methods: Kaiser Permanente (KP) is an integrated delivery system that provides comprehensive health care to its members in 8 regions of the United States. This retrospective cohort study included patients aged $\geq$65 from 3 KP regions who received oral diabetes agents in 2010 for whom the Proportion of Days Covered (PDC) could be calculated ($\geq$2 dispensings per year). The study sample was limited to the 83% of the population that were considered adherent using a definition of PDC$\geq$0.8 in 2010. Patients were followed through 2014 or until they disenrolled from the health plan or had less than 2 dispensings of oral diabetes agents per year. To assess predictors of transitioning from adherent to non-adherent we employed the standard generalized estimating equation approach for longitudinal data.

Results: The cohort included 46,406 patients. Characteristics associated with transitioning from adherent in 2010 to non-adherent in 2011-2014 included being female (OR=1.15; 95%CI 1.10-1.10), age ≥75 (OR=1.27; 95% CI 1.20-1.33) compared to age 65-69, African American (OR=1.24; 1.14-1.34) or American Indian/Alaska Native (OR=1.43; 95%CI 1.05-1.94) compared to White, and ≥2 comorbidities (OR=1.38; 95%CI 1.29-1.48) compared to no comorbidities. Patients were less likely to become non-adherent if the mean days' supply dispensed was >90 days (OR=0.56; 95%CI 0.53-0.60) or they received oral diabetes agents via mail order >50% of the time (OR=0.69; 95%CI 0.66-0.72).

Conclusion: Patient characteristics can increase the likelihood of transitioning from adherent to non-adherent to oral diabetes medications. However, health care system-level factors including days' supply and mail order pharmacy use can decrease the likelihood of becoming non-adherent over time. These findings can help policy-makers, clinicians, and health plans to develop interventions that target establishing and maintaining long-term adherence to oral diabetes medications.

Overtreatment of older patients with type 2 diabetes

H.E. Hart[1,2], K.N. Bontje[1], G.E.H. Rutten[1], R.C. Vos[1];
[1]Julius Center of Health Sciences and Primary Care, Department of General Practice, University Medical Center Utrecht, [2]Leidsche Rijn Julius Health Centers, Utrecht, Netherlands.

Background and aims: According to EASD Guidelines, in older people with type 2 diabetes, especially those with macrovascular complications and other comorbidity and with a long duration of diabetes, less stringent HbA1c levels are requested. In the Netherlands the National Diabetes Guidelines on type 2 diabetes include an HbA1c algorithm with HbA1c targets above 7% (53 mmol/mol) for people ≥ 70 years, who are using more than metformin alone. If they are known < 10 years with diabetes, the HbA1c target is ≤ 7.5% (58 mmol/mol), when the diabetes duration ≥ 10 years the target is ≤ 8% (64 mmol/mol). In this study we investigated, three years after the publication of the Dutch guidelines, whether these personalised HbA1c targets are implemented or whether overtreatment is common.

Materials and methods: Observational study using routine care date of 1002 patients with type 2 diabetes treated in Health Centers. Data were retrieved from the electronic patient files. Frailty was assessed using the Frailty Index. In overtreated persons we scrutinised the files for records of hypoglycaemia, fall accidents and visits to the emergency room of the hospital. Patients with an HbA1c target > 7% were compared with those with an HbA1c target ≤ 7% using the Pearson Chi square test. Characteristics of the persons on target were compared with those who were either undertreated or overtreated using the Pearson Chi square or Kruskal-Wallis test.

Results: Among all 1002 people with type 2 diabetes and treated in the health centers, 31.8% (n=319) were 70 years or older. All people < 70 years had an HbA1c target < 7%. The same held true for 154 people ≥ 70 years who were treated with only a lifestyle advice or with metformin monotherapy. For the remaining people (n=165, 16.5%) a target ≥ 7% should be defined; 53 persons had an HbA1c target ≤ 7.5% and 112 persons ≤ 8%. These 165 persons had more micro (54.0% vs. 35.2%) - and macrovascular (33.3% vs. 17.7%) complications, used more often ≥ 5 medicines (87.3% vs 53.2%) and were more often frail (44.2% vs 13.9%) compared to those with a target < 7%. Of these 165 persons 47 (28.4%) were above their respective HbA1c targets, whereas 64 (38.8%) had an HbA1c below their target and even below 7%. Especially in the 'severely' overtreated group of persons with an average age of 76 years, many were frail, on insulin and complaining of hypos according to their medical files. In this group, almost 3 out of 10 persons reported fall accidents (Table).

Conclusion: Of the 165 persons ≥ 70 years with an HbA1c target > 53 mmol/l 64 persons were overtreated, representing 20% of all 319 people with type 2 diabetes of 70 years or older. Almost half of the overtreated persons were frail. Many experienced hypoglycaemic events. Evidence based, HbA1c targets > 53 mmol/ l in older persons with type 2 diabetes are not well practiced in daily diabetes care and cause iatrogenic damage.

Table: Characteristics of overtreated patients with HbA1c < 7%.

Obesity caused by melanocortin-4 receptor (MC4R) defects can be treated with a glucagon-like peptide 1 (GLP-1) receptor agonist

E.W. Iepsen[1], J. Zhang[1], H. Thomsen[2], E. Chabanova[2], S. Madsbad[3], T. Hansen[4], J.J. Holst[1], J.-C. Holm[5], S.S. Torekov[1];

[1]Department of Biomedical Sciences, University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, [2]Department of Radiology, Herlev University Hospital, Herlev, [3]Department of Endocrinology, Hvidovre University Hospital, Hvidovre, [4]Section for Metabolic Genetics, University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, [5]Department of Pediatrics, Holbæk University Hospital, Holbæk, Denmark.

Background and aims: The most common monogenic form of obesity is caused by loss of function mutations in the hypothalamic expressed melanocortin-4 receptor (MC4R) gene, but treatment options are limited. The gut hormone glucagon-like-peptide 1 (GLP-1) reduces food intake. The central mechanisms underlying this effect may either occur independent of the MC4R by inhibiting orexigenic neurons or dependent of the MC4R by stimulating anorectic neurons. We therefore tested if the GLP-1 receptor agonist (GLP-1 RA) liraglutide could induce weight loss in adult obese MC4R mutation carriers.

Materials and methods: Fourteen adult individuals with loss of function MC4R obesity were identified as the biological parent to a child diagnosed with MC4R mutation, and 28 BMI, age and gender-matched adults without MC4R mutation served as control participants. All participants were treated with liraglutide 3.0 mg for 4 months. Bodyweight, waist circumference, and magnetic resonance (MR)-assessed liver and muscle fat were measured before and after liraglutide treatment.

Results: Baseline BMI was 37.1±1.7kg/m^2 in MC4R carriers and 36.9±0.8kg/m^2 in control subjects (p=0.8 between groups). After 4 months of liraglutide treatment, the MC4R carriers lost -6.8±1.8kg, p=0.003 (equivalent to -5.7 ±1.4% bodyweight) and the obese control subjects lost -6.1±1.2kg, p<0.0001 (equivalent to -5.4±1.1% bodyweight) (p=0.8 between groups). Waist circumference decreased by -5.4±1.4cm, p<0.0001 in MC4R carriers and by -6.4±1.6cm, p<0.0001 in control subjects (p=0.1 between groups). Total body fat percentage decreased by -2.5±0.8%, p=0.009 and by -2.6 ±0.5%, p<0.0001 (between groups, p=0.9), liver fat decreased by -1.2±1.7%, (p=0.5) and by -3.0±1.5%, p=0.06 (p=0.5 between groups) and muscle fat decreased by -0.13±10.7%, p=0.9 and by -0.4±0.8%, p=0.8 (p=0.5 between groups), respectively, in MC4R carriers and control subjects.

Conclusion: We show that liraglutide can treat MC4R-induced obesity. The GLP-1 RA liraglutide caused similar, clinically significant weight loss in obese MC4R carriers and matched controls participants, indicating that the appetite reducing effects of GLP-1 is independent of the MC4R pathway.

Chronic effects of repetitive transcranial magnetic stimulation on satiety and body weight control

L. Luzi[1,2], A. Ferrulli[1], S. Massarini[1];

[1]Endocrinology and Metabolic Diseseas, IRCCS Policlinico San Donato, San Donato Milanese, [2]Department of Biomedical Sciences for Health, University of Milan, Milan, Italy.

Background and aims: Repetitive Transcranial Magnetic Stimulation (rTMS) is a non invasive technique inducing long lasting and reversible changes in neural excitability and dopamine release. Hence, rTMS has been developed as a treatment for neuropsychiatric disorders associated with abnormal dopamine release. Consistently with its modulatory effect on the reward system, we hypothesized a potential role of rTMS in inducing satiety and body weight loss, through modulation of food craving circuitries ("food reward system").

Materials and methods: Twenty-eight obese patients (8 M, 20 F; age: 46.3±9.4; BMI: 36.6±4.9 kg/m^2) were randomized to receive 15 daily sessions of high frequency (18 Hz, promoting cortical excitability), low frequency (1 Hz, inhibiting cortical excitability) or sham stimulation (3 per week for 5 weeks). Prior to stimulation, obese subjects were either shown a series of palatable food images (cue) or not (no cue). The coil version used in this study (H-coil) was designed to stimulate deeper brain regions (3 cm *vs* 1.5 cm from the skull) and targeted to the Pre-frontal Cortex and Insula, bilaterally. Body weight, metabolic, neuro-endocrine parameters and food craving were evaluated at baseline, at the end of 15 rTMS sessions, after 1 and 6 months of follow-up.

Results: After 5 weeks, a significant weight loss was found in the 18 Hz group (-4.1±2.5% *vs* basal, p<0.001) which continued up to 1 month (-5.5±3.2% *vs* basal, p<0.001) and 6 months of follow-up (-4.8±3.5% *vs* basal, p=0.014). 18 Hz group obese patients experienced also a decrease in food craving (-42.3±15.2% *vs* basal, p<0.0001) which continued even after 1 month (-38.5 ±14.5% *vs* basal, p=0.0001) and 6 months of follow-up (-41.5±8.8% *vs* basal, p<0.0001; p<0.01 *vs* sham). In the 18 Hz (cue) sub-group, a significant decrease of glucose (-5.3±4.8% *vs* basal, p=0.042) and a trend to decrease of cholesterol (-8.2±8.1% *vs* basal, p=0.086) were observed after 5 weeks of treatment. Concerning pituitary hormones, in the 18 Hz group, significant reductions of ACTH (-36.6±17.1% *vs* basal, p=0.002), prolactin (-43.1 ±11.7% *vs* basal, p<0.0001), and TSH (-20.6±21.7% *vs* basal, p=0.019) were found at the end of the 15 rTMS sessions; TSH decrease persisted up to 1 month of follow-up (-19.2±25.9% *vs* basal, p=0.009). In the 18 Hz group, a trend to reduction in the norepinephrine levels (-10.8±32.9% *vs* basal, p=0.078) was observed after 15 rTMS sessions. Conversely, in the 1 Hz group, neither significant weight change, or the above described hormone and metabolite variations were shown, whilst a significant decrease in Beta-endorphin levels was found (-10.6±7.6% *vs* basal, p=0.05).

Conclusion: In summary, high frequency rTMS has proven to be effective in reducing food craving leading to a significant decrease of body weight up to 6 months since the end of treatment, via modulation of the HPA axis and sympathetic activity. These findings support the role of rTMS as a novel promising treatment for obesity.

Voluntary exercise can modify the preference for palatable food through the modulation of central reward circuit by peripheral ghrelin signal

Y. Tajiri[1], Y. Sakai[2], Y. Kawahara[3], A. Nishi[3], M. Kojima[4], H. Mifune[2];

[1]Department of Internal Medicine, Division of Endocrinology and Metabolism, Kurume University School of Medicine, [2]Institute of Animal Experimentation, Kurume University School of Medicine, [3]Department of Pharmacology, Kurume University School of Medicine, [4]Molecular Genetics, Life Science Institute, Kurume University, Kurume, Japan.

Background and aims: We previously reported that voluntary exercise contributed to an amelioration of abnormal feeding behavior with a concomitant restoration of ghrelin production in high fat diet (HFD)-induced obese model (Peptides, 2015). In obese human subjects, hedonic eating is often present because palatable foods may promote addiction like drugs. Because it's known that hedonic eating is related to the activation of central reward circuit via ghrelin receptor in ventral tegmental area (VTA), we investigated whether voluntary exercise could modify the food preference in relation to peripheral ghrelin and central dopamine systems in rats.

Materials and methods: Male Sprague-Dawley (SD) rats at 4 weeks old were either housed as sedentary group (Se) in ordinary cages throughout the experiment or exercise group (Ex) in ordinary cages from Monday to Thursday and in special acrylic chambers equipped with a running wheel from Friday to Sunday. All rats were allowed to freely access to either control chow diet (CD;10 kcal%fat) or HFD (60 kcal%fat) according to their preference. Food preference was measured on Monday morning up to 10 weeks old. Subsequently, dopaminergic activity in nucleus accumbens (NAc) in either Ex or Se was measured using microdialysis method. Furthermore, synthesized rat ghrelin (3 nmol/2mL) was administered intravenously to Se at 10 weeks old, therafter microdialysis procedures were performed as well.

Results: Body weight at 10 weeks old was higher in Se than in Ex (459±12 vs. 412±16 g, $P<0.05$). In Se, most of consumed food was HFD throughout experimental periods. In contrast, the preference for HFD was attenuated by the induction of voluntary exercise, and around 40% of food consumption was substituted for CD after 5 weeks old to the end of the experimental period (Figure). In Se, dopamine (DA) level in NAc was increased in response to either CD or HFD fed for 20 minutes by 50% of basal levels. Voluntary exercise abolished HFD-induced DA surge in spite of no effect on CD-induced one. Systemic ghrelin administration to Se abolished HFD-induced DA surge with no effect on CD-induced one in the same manner as voluntary exercise did.

Conclusion: It was reported that systemic ghrelin administration brought about the inhibition of DA surge associated with HFD through the activation of dynorphin A/kappa opioid receptor pathway of DA neurons in VTA (Neuropharmacology, 2013). It is thus plausible that voluntary exercise could attenuate the food preference for palatable HFD through the modulation of central dopamine system by peripheral ghrelin signal, taking the amplification of ghrelin production by regular exercise into account.

Hypothalamic ATP up-regulation is the mechanism for the amelioration of leptin resistance by celastrol and withaferin A

C. Ebihara, K. Ebihara, M. Isoda, A. Murakami, D. Yamamuro, M. Takahashi, S. Nagashima, S. Ishibashi;
Division of Endocrinology and Metabolism, Department of Internal Medicine, Jichi Medical University, Tochigi, Japan.

Background and aims: Leptin is an adipocyte-derived hormone involved in the regulation of food intake and energy expenditure. Obese subjects generally have hyperleptinemia and leptin resistance. Leptin sensitizers rather than leptin itself are expected as anti-obesity drugs. Although the precise mechanism underlying leptin resistance is still unclear, it has been reported that endoplasmic reticulum (ER) stress in the hypothalamus plays a key role. Recently, two natural compounds, celastrol and withaferin A, has been identified as leptin sensitizers (Cell 161: 999, 2015, Nat Med 22: 1023, 2016). Withaferin A has a similar gene expression signature to that of celastrol. Both of them alleviate hypothalamic ER stress and restore the sensitivity of the hypothalamus to leptin. Thus, celastrol and withaferin A are promising agents for the treatment of obesity and its complications including diabetes. However, the molecular mechanism by which celastrol and withaferin A alleviate ER stress and restore leptin sensitivity remains completely unknown. Under ER stress, protein folding in the ER is impaired leading to the accumulation of misfolded proteins. The accumulation of misfolded proteins is harmful to cells and thus the ER has evolved mechanisms designed to detect misfolded proteins and either refold them or target them for degradation. These responses against ER stress are called unfolded protein response (UPR). UPR requires appreciable amounts of ATP. Indeed, ATP-deficient cells are vulnerable to ER stress and treatment of ATP protects cells against ER stress. For these reasons, we investigated the role of ATP in the development of hypothalamic ER stress and leptin resistance and their improving effect of celastrol and withaferin A. It is well known that high fat diet induces ER stress and leptin resistance in the hypothalamus. Thus, we measured ATP concentrations in the hypothalamus of mice with or without celastrol and withaferin A treatment.

Materials and methods: 8 weeks old male C57B/6J wild type and ob/ob mice were used. For high fat diet loading, mice were fed an ad libitum high-fat pellet diet containing 20% weight for weight (wt/wt) protein, 20% wt/wt carbohydrate, and 60% wt/wt fat. Celastrol (100 ng/gBW) and withaferin A (2 mg/gBW) were intraperitoneally administered once a day. Hypothalamic ATP concentrations were measured by luciferase activities.

Results: A month of high fat diet feeding decreased hypothalamic ATP concentrations in C57B/6J mice. Celastrol and withaferin A suppressed body weight gain and food intake and increased hypothalamic ATP concentrations in C57B/6J mice fed high fat diet. Celastrol and withaferin A had no effect not only on body weight and food intake but also on hypothalamic ATP concentrations in C57B/6J mice fed standard diet, indicating that celastrol and withaferin A do not increase hypothalamic ATP concentrations but inhibit high fat diet-induced ATP reduction. Celastrol and withaferin A increased hypothalamic ATP concentrations but showed only minimal effect on body weight and food intake in ob/ob mice, suggesting that increase of hypothalamic ATP concentrations by celastrol and withaferin A is not the secondary effect of metabolic improvement.

Conclusion: Taken together, it is suggested that celastrol and withaferin A maintain leptin sensitivity by up-regulating hypothalamic ATP concentrations under high fat diet.

The SGLT2 inhibitor dapagliflozin preserves human beta cell function in diabetic mice

D. Karlsson, A. Ahnmark, A.-C. Andréasson, A. Sabirsh, D. Lindén, M. Sörhede Winzell;
AstraZeneca, Gothenburg, Sweden.

Background and aims: Dapagliflozin is a sodium-glucose cotransporter 2 (SGLT2) inhibitor used for the treatment of type 2 diabetes. Dapagliflozin decreases plasma glucose levels by inhibiting the renal reabsorption of glucose, leading to an increased urinary glucose excretion. Our aim was to examine the effect of dapagliflozin treatment on human β cell function in vivo using a human islet transplanted diabetic mouse model.

Materials and methods: Human pancreatic islet equivalents from three different donors (Prodo Labs, USA) were transplanted into the subrenal capsular space in the left kidney (1,500 islets per mouse) of normoglycemic immunodeficient male NUDE (NMRI-Foxn1nu; Charles River) mice (n=59, 9 weeks of age). After two weeks, diabetes was induced (alloxan monohydrate, 72.5 mg/kg) and five days later, the mice were randomized into two groups per donor based on non-fasting glucose levels. Dapagliflozin (3 mg/kg/day) was provided in the drinking water for 53 days. Non-fasting glucose and human C-peptide plasma levels were monitored during the study and an intravenous arginine/glucose tolerance test was performed. At termination, the grafted human islets were stained for insulin, glucagon and the proliferation marker Ki67.

Results: Blood glucose before treatment start was 15.5±1.5 mM. Dapagliflozin treated mice showed reduced plasma glucose levels compared to control mice over the 53 day study period ($p<0.0001$, 2-way ANOVA). Human C-peptide levels were similar between the two groups at start (veh: 319±32 pM vs. Dapa: 382 ±33 pM, not significant (NS)). After 4 weeks, the levels started to decline in both groups (veh: 120±27 pM vs. Dapa: 221±24 pM, NS). However at termination, hC-peptide levels were significantly elevated in Dapagliflozin treated mice (322 ±77 pM vs. 101±58 pM in controls, $p<0.05$). Dapagliflozin also improved the human β cell acute insulin response to the iv glucose/arginine test compared to controls (0.38±0.05 ng/ml vs. 0.20±0.06 ng/ml in controls, $p<0.05$). At the end of the study, dapagliflozin treated mice had increased number of insulin positive cells in the grafted human islets (56.4±2.1 % vs. 47.4±3.4 % in controls, $p=0.031$), while the number of glucagon positive cells were decreased (39.4±1.8 % vs. 50.8±3.5 % in controls, $p=0.006$). Proliferation, measured as insulin or glucagon co-staining with Ki67 was, however, increased in both β cells (0.9±0.1 % vs 0.4±0.1 % in controls, $p=0.007$) and α cells (3.3±0.7 % vs 1.4±1.7 % in controls, $p=0.018$), following dapagliflozin treatment.

Conclusion: The SGLT2 inhibitor dapagliflozin maintained long-term glycemic control by preserving human β cell number and in vivo function in a humanized diabetic mouse model.

Impact of primary graft function long-term (10 years) outcome of islet allotransplantation in type 1 diabetes

M.-C. Vantyghem[1], M. Chetboun[2], K. Benomar[1], K. Le Mapihan[1], R. Caiazzo[2], J. Kerr-Conte[3], F. Pattou[2];
[1]Endocrinology and Metabolism, Lille University Hospital, [2]Endocrine Surgery, Lille University Hospital, [3]Lille University Hospital, Lille, France.

Background and aims: Islet transplantation (IT) is a treatment of type 1 diabetes in case of brittleness, hypoglycaemia unawareness or after kidney transplantation. The procedure is demanding for the patient requiring 2 to 3 islets injections under an immunosuppressive regimen. Short-term results are continuously improving but long-term results have not been studied. The **aim** of this work was to assess long-term results and the predictive factors of success of IT.

Materials and methods: This prospective observational single-arm study combines the analysis of 33 consecutive patients having received since 2003 either an islet transplantation alone (ITA, n=19) or an islet-after-kidney transplantation (IAK, n=14), under an Edmonton immunosuppressive regimen. Each patient received 2 to 3 intraportal islet injections through surgical or radiological route over a 6-month period. Metabolic results and graft survival assessed by a fasting C-peptide level greater than 0.3 ng/mL) and insulin-independency with normal A1c were prospectively assessed during more than 10 years. The β-score calculated 1 month after the last islet injection was classified as optimal (β-score greater or equal to 7) or sub-optimal (β-score below 7) to define the primary graft function (PGF).

Results: The median islet-transplanted mass was 13.9[11.1-15.8] x 10^3 islet-equivalent/kg of body weight. 32 patients (97%) reached insulin-independence. At last news (September 2016), the graft was functional in 25 patients (14 ITA, 11 IAK) among whom 11 patients still insulin-independent (4 ITA, 7 IAK) with a median follow-up duration of 3723[2141-4028] days. In the whole group, the percentage of graft survival (Kaplan-Meier, KM) was respectively 85% at 5 and 76% at 10 years. The percentage of insulin-independence (KM) was 46% at 5 and 28 % at 10 years. The graft type (IAK or ITA) had no significant influence on the results. In contrast, graft survival and insulin-independence rates were significantly higher in patients with optimal PGF (n=21) *vs.* sub-optimal PGF (n=12), with respectively at 5 years 100 *vs.* 64 % and at 10 years 93 *vs.* 53% of graft survival ($p=0.0008$; log-rank test) The insulin-independence rate was at 5 years 66 *vs.* 18 % and at 10 years 42 *vs.* 0 % ($p=0.0002$) respectively in the optimal *vs.* suboptimal graft function.

Conclusion: This study shows the long-term persistence of graft function and insulin-independence with the Edmonton protocol, both in ITA and IAK. The primary graft function is essential for long-term good results.

Mcl-1 is a key anti-apoptotic protein in human and rodent pancreatic beta cells

N. Violato[1], K. Meyerovich[1], M. Fukaya[1], N. Pachera[1], P. Marchetti[2], L. Marselli[2], A. Strasser[3], D. Eizirik[1], A. Cardozo[1];
[1]ULB Center for Diabetes Research, Université Libre de Bruxelles, Brussels, Belgium, [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [3]The Walter and Eliza Hall Institute of Medical Research-Department of Medical Biology, University of Melbourne, Melbourne, Australia.

Background and aims: Induction of endoplasmic reticulum (ER) stress and activation of the intrinsic apoptotic pathway contribute to β-cell death in type 1 diabetes (T1D). MCL-1 is an anti-apoptotic member of the BCL-2 protein family, whose depletion causes apoptosis in rodent β-cells in vitro. Importantly, decreased MCL-1 expression was observed by histology in islets from T1D patients. Given the important role of MCL-1 in the survival of β-cells, the aim of this study was to clarify the role of MCL-1 both in human β-cells and in an in vivo murine model of T1D and to determine the mechanisms involved in the post-transcriptional regulation of the MCL-1 protein in β-cells.

Materials and methods: The in vitro studies were performed in the human β-cell line EndoCβH1, the rat insulinoma cell line INS-1E and human islet cells exposed or not to IL-1β or TNF +, IFNγ. Knockdown of the proteins of interest were performed by the use of specific small interfering RNAs while overexpression was achieved using adenoviral vectors. To evaluate the role of Mcl-1 in vivo, a β-cell specific Mcl-1

knockout (βMcl-1 KO) mouse was generated. Both βMcl-1 KO and wild type mice were subjected to multiple low-dose streptozotocin (MLDS) treatment. Non-fasting blood glucose levels were measured every 7 days for 10 weeks. Pancreases were then collected for histological analysis and measurement of insulin content.

Results: Exposure of EndoC-βH1 cells to IL-1β+IFN-γ or TNF+IFN-γ for 24 hours decreased MCL-1 protein expression by 42 and 50%, respectively ($p<0.05$). Silencing MCl-1 sensitised EndoC-βH1 cells to apoptosis induced by the different cytokine combinations, (36-48% increase in cell death; $p<0.01$). In mirror experiments, overexpression of MCl-1 protected EndoC-βH1 cells and dispersed human islet cells against cytokine-induced apoptosis (36 and 52% protection, respectively; $p<0.05$). βMcl-1 KO mice showed normal development and preserved islet function/morphology under basal condition. Islets from βMcl-1 KO mice, however, were more susceptible to IL-1β + IFN-γ- and TNF+IFN-γ-induced β-cell apoptosis (50%-81% increase respectively, $p<0.05$ vs WT). Moreover, βMcl-1 KO mice displayed higher hyperglycaemia (50% increase AUC, $p<0.05$ vs WT) and lower pancreatic insulin content (54% decrease, $p<0.05$ vs WT) after MLDS treatment. Mechanistic studies in INS-1E cells identified the kinase GSK3β, the E3 ligases MULE and βTrCP and the deubiquitinase USP9x as the key regulators of cytokine-mediated MCL-1 protein turnover in β-cells.

Conclusion: The present findings identify MCL-1 as a critical protein for preventing β-cell death in T1D and unveil the role for E3 ligases and ubiquitination in its down-regulation by pro-inflammatory cytokines. Development of strategies to prevent MCL-1 loss in the early stages of T1D may enhance β-cell survival and thereby serve as a relevant adjuvant therapy to delay or prevent disease progression.

Beta cell-derived microparticles as early biomarkers of rejection in islets transplanted patients: Toward the identification of the cause of the graft loss?

L. Amoura[1,2], F. Zobairi[1], G. Kreutter[1], A. El Habhab[1], S. Sahraoui[2], F. Toti[1], L. Kessler[1,3];

[1]EA 7293 : Vascular and Tissular Stress in Transplantation, University of Strasbourg, Strasbourg, France, [2]CLINICA Groupe, CRO, Alger, Algeria, [3]Department of Endocrinology, Diabetes and Nutrition, University Hospitals of Strasbourg, Strasbourg, France.

Background and aims: Microparticles (MPs) are vesicles shed from the plasma membrane in response to stress and circulating surrogate markers of the initial cell damage. High levels of circulating MVs are associated with transplant rejection of renal, cardiac or mesenchymal stem cell grafts. We previously reported a peak of procoagulant MPs preceding the rise in insulin needs in islets transplanted patients thereby suggesting early graft dysfunction. In the present pilot study, plasma variations of procoagulant MPs released from insulin cell (IC) and bearing the characteristic PSA-NCAM were monitored in islet transplanted patients.

Materials and methods: Venous sampling of 19 T1D transplanted pancreatic islet patients, (Man,Women ratio:10/9. Age (years): 56 (29-74). Diabetes duration (years): 38 (14-44). HbA1c (%) : 7,5 (5,9-9.6). Daily insulin requirements (UI/kg): 0,6 (0,32-1,05). Islet after kidney: 5 patients (26,3%), was prospectively performed before each transplant and 3, 6, 9, 12, 24 and 36 months post-last islet injection. MPs-PSA-NCAM+ (PSA-MPs) were measured after capture on an anti-PSA-NCAM antibody using an original and highly sensitive prothrombinase activity assay. Values of the international graduation β-score, that combines four indicators of transplantation efficacy (HbA1c, C-peptide, daily insulin dose, fasting glucose) were also calculated. Transplanted patients were allocated to 3 groups: functional (FG, n = 8) or partially functional (PFG, n = 8) graft, with respective β-score values ($6\leq FG \leq 8$ and $3 < PFG < 6$), or to Graft failure (GrF β-score ≤ 3, n = 3). Control groups were T1D (n = 4) and T2D (n = 7) patients and healthy subjects (HV, n = 3).

Results: Mean plasma MPs concentrations in FG and HV were similar (0.26 ± 0.05 nM vs. 0.3 ± 0.0 nM) indicating minimal cell damage. A peak of PSA-MPs (x 2-3) was observed before each β-score drop and the rise of insulin needs, suggesting early alteration of ICs. In GrF or PFG, the mean value of PSA-MPs levels is higher than in FG (0.51 ± 0.42 nM 0.44 ± 0.26 nM, vs. 0.26 ± 0.05 nM, $p < 0.0001$) and close to values measured in T2D (0.62 ± 0.17 nM), suggesting that resident dysfunctional β cells still shed MPs. In GrF, the PSA-MP concentrations measured at distance of the peak did not statistically differ from those in DT1 patients (0.40 ± 0.08 nM vs. 0.28 ± 0.04 nM, p= 0,297), in agreement with the massive loss of β cells. Analysis of the circulating PSA-MPs values obtained in the transplanted patients using a survival model (function or non-function of the graft) with time-dependent variables of PSA-MPs showed that a longitudinal study in 40 patients would be suitable for statistical validation of an eventual prognosis value of PSA-MPs.

Conclusion: Our data suggest that PSA-MPs might prove valuable for the early and non-invasive detection of pancreatic islet transplant dysfunction. Combination with values of circulating hepatocyte-derived MPs as a signature of the altered host tissue of the islet graft could increase sensitivity. Finally, measurement of circulating MPs of leukocyte origin could add value to this putative monitoring tool by facilitating the identification of the activated immune cells contributing to graft failure or dysfunction.

Tissue sodium content is increased in type 2 diabetes

D. Kannenkeril[1], M.V. Karg[1], A. Jumar[1], C. Ott[1], P. Linz[2], J. Titze[3], M. Uder[2], R.E. Schmieder[1];

[1]Department of Nephrology and Hypertension, University Hospital Erlangen, [2]Radiology, University Hospital Erlangen, Erlangen, Germany, [3]Molecular Physiology and Biophysics, Vanderbilt University, Nashville, USA.

Background and aims: The measurement of tissue sodium content by 23Na magnetic resonance imaging (23Na-MRI) has been validated in experimental and human studies. Increased tissue sodium content has been reported in patients with treatment resistant hypertension (TRH), hyperaldosteronism and chronic renal failure. We analyzed whether tissue sodium content is increased in patients with type-2 diabetes.

Materials and methods: In patients, most of them treated for hypertension, with cardiovascular risk, we compared patients with type-2 diabetes to those with primary arterial hypertension without type-2 diabetes. Baseline clinical characteristics were determined with same methods: fasting glucose, office blood pressure, body weight, and medical history. Patients with type 2 diabetes were off any antidiabetic therapy (antihypertensives were kept constant) and hypertensive patients off any antihypertensive or antidiabetic therapy for at least 4 weeks. At baseline tissue sodium content was assessed non-invasively with a 3.0 T clinical MRI system (Magnetom Verio, Siemens Health Care, Erlangen, Germany) in each patient. Subject placed their lower legs in the center of a 23Na knee coil and sodium content in skin and muscle (musculus triceps surae) were measured. Coefficient of variation of the same images was 2.1 % for skin sodium and 0.5 % for muscle sodium content (inter-reader variability).

Results: In patients with type 2 diabetes (N=59) we observed significantly greater muscle sodium content (diabetes: 20.6 ± 3.7 vs hypertension: 16.3 ± 2.5 mmol/L, p<0.001) and skin sodium content (diabetes: 24.5 ± 7.2 vs hypertension: 20.8 ± 5.9 mmol/L, p=0.01) than in those with primary hypertension (N=33). Age was similar in the two groups (diabetes: 60.3 ± 7.6 vs hypertension 59.6 ± 10.9 years; p=0.72) and body mass index was not significantly different (diabetes: 29.7 ± 4.4 vs hypertension 28.4 ± 4.0 kg/m², p=0.14). Blood pressure was greater in the hypertensive than in diabetes patients (156 ± 8.3 / 92.8 ± 8.0 vs 130 ± 14 / 79.1 ± 9.4 mmHg, both p<0.001). Estimated glomerular filtration was greater in the diabetic than hypertensive patients (89.9 ± 12 vs 83.8 ± 14 ml/min/1.73 m², p=0.03). When these potential confounders (age, body mass index, gender, systolic and diastolic blood pressure, glomerular filtration rate) were entered in the covariance analysis, skin sodium content (p=0.037) and muscle sodium content (p<0.001) were still clearly elevated.

Conclusion: With the innovative 23Na-MRI technology, we could demonstrate that patients with type 2 diabetes have greater tissue sodium content, irrespective of age, blood pressure and other potential confounders (including renal function). Since tissue sodium content is related to organ damage, therapeutic intervention should aim at reducing tissue sodium content.

Hyperkalaemia in patients with diabetes: incidence, risk factors, and clinical outcomes. A Danish population based cohort study

R.W. Thomsen[1], S.K. Nicolaisen[1], E. Svensson[1], P. Hasvold[2], H.T. Sørensen[1];

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [2]Medical Department, AstraZeneca Nordic, Etterstad, Oslo, Norway.

Background and aims: Elevated potassium levels (hyperkalemia, HK) are frequent in clinical practice and associated with increased mortality. Data are scarce on HK in patients with diabetes (DM). We investigated the incidence of HK in patients with incident type 1 or 2 DM, and examined associated risk factors and clinical outcomes.

Materials and methods: Population-based cohort study based on prospective medical and laboratory databases in Northern Denmark during 2000-2012. We included 76,942 people with a first incident record of DM. The incidence rate of HK among patients with DM was calculated based on a first blood test in primary care or hospital with K+ level >5.0 mmol/L. For each patient with DM who developed HK, a comparison DM patient without HK was matched on age, sex, and time since DM diagnosis. Risk factors were compared for DM patients with HK vs. without HK. Clinical outcomes (including acute hospitalizations, cardiac diagnoses, ICU treatment, and death) were assessed before and after HK in a self-controlled analysis, and were compared with DM patients without HK further matched on comorbidity, diabetes complications, and HbA1c level.

Results: The median age of 76,942 patients with incident DM was 62 years, 47% were female, 18% had concomitant chronic kidney disease, 6% congestive heart failure, and 47% hypertension. At baseline, 22% were treated with ACE-inhibitors, 13% with ARBs, and 6% with K+-sparing diuretics (99% spironolactone). During a mean follow-up of 3.4 years (317,980 person-years), 17.6% (n=13,530) of the DM patients had a first event of HK (incidence rate 42 per 1,000 person-years), increasing with age and comorbidity burden. Median time to first HK event was 2 years; 45% of events were hospital-diagnosed. Patients with DM who developed HK had more chronic kidney disease (odds ratio, OR, 2.4; 95% CI: 2.3-2.5), chronic heart failure (3.0; 95% CI: 2.8-3.2), hypertension (1.4; 95% CI:1.4-1.5), and use of ACE-inhibitors (1.3; 95% CI: 1.3-1.4), K^+ supplements (1.9; 95% CI:1.8-2.0), and spironolactone (3.2; 95% CI: 3.0-3.5), compared with DM patients without HK. In DM patients with HK, 55% experienced any acute hospitalization including and within 6 months after the HK event vs. 32% within 6 months before the HK event [before-after relative risk, RR 1.73 (95% CI 1.68-1.79)]. During this time frame, the risk for any cardiac hospital diagnosis increased from 17% to 28% (1.69, 95% CI 1.61-1.77), ICU admissions from 2% to 15% (6.24, 95% CI 5.56-7.01), and cardiac arrest from 0.1% to 0.7% (11.25, 95% CI 5.46-23.17). Six-month mortality following HK was 22%. Compared with matched DM patients without HK, the prior-event-rate-ratio adjusted hazard ratio was 2.14-fold increased for any acute hospitalization 6 months after HK, while the HR for death was 6.16 (95% CI 5.61-6.75).

Conclusion: One out of six patients with DM develops HK; those with concomitant kidney disease and heart failure are at particularly increased risk. HK was found to be associated with severe clinical outcomes and mortality in a real-world population of patients with DM.

Hypertriglyceridaemia and osteopenia in type 2 diabetic patients and the effect of TG-rich lipoproteins on RANKL expression in cultured osteoblastic cells

M. Eto, F. Kumagai, M. Saito;

Clinical Medicine, Ohu University, Koriyama, Japan.

Background and aims: Skeletal fragility is considered among the complications associated with diabetes. Type 2 diabetic patients have increased fracture risk and lower bone mineral density (BMD). Last year in this meeting we reported that there exists diabetic osteopenia. Thus, association between diabetes mellitus and osteopenia has been clear, but little information is available about the effect of hyperlipidemia on osteopenia. Recently it was reported that midlife women with high fasting plasma triglyceride had an increased risk of incident non-traumatic fracture (SWAN study). In this study we examined whether hypertriglyceridemia (HTG) contributes to lower bone mineral density in type 2 diabetic patients. RANKL produced by osteoblastic cells is the essential factor for osteoclast formation, activation and survival, thus resulting in bone resorption and bone loss. We examined whether TG-rich lipoproteins derived from patients affect RANKL expression in cultured osteoblastic cells to elucidate the association between HTG and osteopenia.

Materials and methods: We evaluated 157 postmenopausal type 2 diabetic patients, ages 50-89 years, with HTG (n=80) and without HTG (n=77). HTG was defined as fasting plasma TG higher than 150 mg/dl. They were divided into 4 groups according to the ages; 50-59 years, 60-69 years, 70-79 years and 80-89 years. Lumbar spine BMD and femoral neck BMD were evaluated with dual energy X-ray absorptiometry (DXA) according to the guideline of Japan Osteoporosis Society 2015. BMD was expressed as the percent ratio to the young adult mean BMD. BMD was compared in each age group with and without HTG. Patients who took drugs affecting bone metabolism or had diabetic nephropathy (renal failure stage) were excluded from this study. Apolipoprotein (apo) E2 is one of the strong genetic factors which cause HTG. Apo E genotypes were determined by isoelectric focusing and immunoblotting method. Human osteoblastic cells from Promo Cell Co. USA were cultured, and then were incubated for 24 h with TG-rich lipoproteins at the concentration of 0 and 100 μg/ml. RT-PCR procedure was performed to evaluate the expression of RANKL m-RNA. TG-rich lipoprotein were isolated from patient's plasma by ultracentrifugation.

Results: In 50s diabetic patients with HTG had significantly ($p<0.001$) lower femoral neck BMD than diabetic patients without HTG (73.9 vs 96.6%). In 60s diabetic patients with HTG had significantly ($p<0.001$) lower femoral neck BMD than those without HTG (79.5 vs 86.6%). In 70s diabetic patients with HTG had significantly ($p<0.001$) lower femoral neck BMD than those without HTG (74.9 vs 86.3%). In 80s diabetic patients with HTG tended to have lower femoral neck BMD. Similarly, in each age group diabetic patients with HTG had significantly ($p<0.001$) lower lumbar spine BMD than diabetic patients without HTG (81.0 vs 94.0% in 50s, 79.7 vs 88.6% in 60s, 78.4 vs 92.4% in 70s and 74.7 vs 84.0% in 80s). The frequency of apo E2 genotype was significantly ($p<0.001$) higher in diabetic patients with HTG than in those without HTG (34% vs 10%). In cultured human osteoblastic cells TG-rich lipoproteins significantly ($p<0.001$) stimulated the expression of RANKL mRNA.

Conclusion: This clinical study showed that HTG contributes to lower BMD in type 2 diabetic patients, and that apo E2 genotype is associated with HTG and diabetic osteopenia. TG-rich lipoproteins stimulated the expression of RANKL. This finding explains one mechanism by which HTG contributes to osteopenia.

A hip fracture risk equation for type 2 diabetes: the Fremantle Diabetes Study

W.A. Davis[1], E.J. Hamilton[2], D.G. Bruce[1], T.M.E. Davis[1];
[1]School of Medicine, University of Western Australia, [2]Department of Endocrinology and Diabetes, Fremantle Hospital, Fremantle, Australia.

Background and aims: Type 2 diabetes (T2D) is associated with an increased risk of osteoporotic fractures, resulting in disabilities and increased mortality. Currently available fracture risk calculators do not include diabetes-related variables. Therefore we have developed a hip fracture risk calculator for T2D.

Materials and methods: The Fremantle Diabetes Study is a community-based longitudinal observational study. 1251 participants with T2D and aged 40-89 years at study entry were followed from baseline (1993-6) for 10 years or until they experienced a hip fracture or died. Hip fracture during follow-up was identified from linkage with the Western Australian hospital morbidity data collection and death registry. Cox proportional hazards modelling with backward elimination identified clinically plausible independent predictors of hip fracture within 10 years of study entry. Calibration was assessed using the modified Hosmer and Lemeshow test for survival data. Discrimination was assessed by the area under the receiver-operating characteristic curve (*c*-index), and then adjusted for optimism using 1000 bootstrap re-samples (internal validation). Accuracy was assessed by the Brier score (mean squared error; range 0-1, the lower the better). Positive and negative predictive values (PPV and NPV), sensitivity and specificity were determined for a 10% 10-year hip fracture risk. Sensitivity analyses were performed: Multiple imputation (n=20) generated complete datasets, Cox modelling was applied to each imputed dataset, and the results from these multiple analyses pooled to produce overall regression coefficients, with accompanying 95% confidence intervals (CIs). StataIC 13 and IBM SPSS Statistics 22 were used for statistical analyses.

Results: The 1251 participants were on average 65 years old at study entry, 49% were men, with median diabetes duration 4 years and mean BMI 29.4 kg/m^2. During 10,306 patient-years of follow-up, 50 participants (4.0% (95% CI 3.0%-5.3%); 80% women), had at least one hip fracture. Variables in the final Cox model (n=1162 (44 with incident hip fracture)) comprised age, sex, BMI, any difficulties with activities of daily living (ADL), peripheral sensory neuropathy (PSN), and estimated GFR (eGFR) <45 ml/min/1.73m^2. The proportional hazards assumption was not violated overall or for any of the individual variables ($p>0.19$). The mean 10-year predicted risk of hip fracture was 6.0%. Discrimination of the model was good (*c*-index: 0.84 (95% CI 0.79-0.89), $p<0.001$). The optimism-adjusted *c*-index was 0.83 (0.77-0.88). Accuracy (mean squared error (95% CI): 0.04 (0-0.96)) and goodness-of-fit ($p>0.64$)) were also good. The positive and negative predictive values, sensitivity and specificity for a 10% 10-year hip fracture risk cut-off were 37.5% and 96.4%, 90.9% and 67.5%, respectively. The regression coefficients for the final Cox model were similar to those for the pooled imputed estimates and lay well within the 95% CIs.

Conclusion: Available hip fracture risk calculators developed for the general population do not take important diabetes-related variables into account. We found that community-based women, in particular, aged 40-89 years with T2D and PSN, eGFR<45 ml/min/1.73m^2 or who had any difficulty with ADLs had an increased risk of hip fracture. External validation of this prognostic model is underway.

OP 43 Metformin: oldie but goodie

241

The effect of metformin on a healthy human gut microbiota

T. Nielsen[1], T. Bryrup[1], C.W. Thomsen[1], T.H. Hansen[1], T. Kern[1], K.H. Allin[1], N.R. Jørgensen[2,3], H. Vestergaard[1], T. Hansen[1], O. Pedersen[1];

[1]Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, [2]Department of Clinical Biochemistry, Rigshospitalet, Glostrup, [3]Odense Patient data Explorative Network, Odense University Hospital, Institute of Clinical Research, University of Southern Denmark, Odense, Denmark.

Background and aims: Within recent years it has been shown that patients with type 2 diabetes have an altered bacterial composition of their gut microbiota compared with non-diabetic individuals. However, these alterations may be confounded by medication, notably metformin. We investigated adaptations in gut microbiota composition in response to metformin treatment, independent of the diabetic state.

Materials and methods: Twenty-six young, healthy, lean men were enrolled in the study. They underwent a 6-week run-in period, a 6-week intervention period with metformin, and a 6-week wash-out period. During the intervention participants were given 500 mg metformin daily, increasing with 500 mg weekly to a total dosage of 2000 mg daily. Participants were examined five times in the fasting state, with blood-sampling and recording of gastrointestinal symptoms. Examinations took place before and after the run-in period, halfway through and immediately after the intervention and after the wash-out period. Stools were collected at nine, evenly distributed time-points, and bacterial DNA was extracted and subjected to 16S-rRNA-sequencing in order to evaluate gut microbiota composition.

Results: Twenty-three men completed the intervention. The mean (SD) age was 25.7 (2.7) years with a mean BMI of 22.9 (2.1) kg/m^2. Plasma vitamin B12 and HbA1c concentrations declined following intervention (p=0.01 and p=0.03 respectively). The relative abundance of 20 operational taxonomic units (OTUs) changed significantly (10% false discovery rate) during the 6-week intervention. Several OTUs of the order *Clostridiales* were depleted, including one assigned to *Intestinibacter Bartlettii and* two *Clostridium* spp. In contrast, *Alistipes finegoldi* of order *Bacteroidales* and an OTU assigned to genus *Escherichia*|*Shigella* were enriched. All OTUs recovered to pre-intervention levels within 3-6 weeks of treatment cessation. Changes in gut microbiota composition were accompanied by an increase in self-reported intestinal discomfort.

Conclusion: Metformin intake changes the gut microbiota composition, independent of the diabetic state. This intervention substantiates and extends our previous cross-sectional findings in type 2 diabetes patients. More studies are needed to examine to which extent metformin exert its glucose-lowering effect, and adverse gastrointestinal effects, partly by modifying the gut microbiota.

Metformin potentiates bile acid-induced GLP-1 secretion in patients with type 2 diabetes

A. Brønden[1], A. Albér[1], U. Rohde[1], J.F. Rehfeld[2], J.J. Holst[3,4], T. Vilsbøll[1,5], F.K. Knop[1,6];

[1]Center for Diabetes Research, Gentofte Hospital, Hellerup, [2]Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, [3]Department of Biomedical Sciences, University of Copenhagen, Copenhagen, [4]Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, [5]Steno Diabetes Center Copenhagen, Copenhagen, [6]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.

Background and aims: The glucose-lowering mechanisms of the biguanide metformin remain to be fully clarified despite a position as the first-line pharmacotherapy in type 2 diabetes. An increasing focus on potential gut-derived modes of action, including suppression of bile acid reabsorption and consequent increased glucagon-like peptide 1 (GLP-1) secretion, has surfaced during recent years. The aim of the present study was to investigate the effects of cholecystokinin (CCK)-induced gallbladder emptying and concomitant single-dose metformin on GLP-1 secretion and glucose metabolism in patients with type 2 diabetes.

Materials and methods: This was a randomized, placebo-controlled and double-blinded cross-over study including 15 metformin-treated patients with type 2 diabetes. Plasma GLP-1 excursion as measured by incremental AUC (iAUC) was the primary endpoint. Each patient was submitted to four experimental study days with administration of either single-dose metformin 1,500 mg or placebo in combination with intravenous infusion of CCK (0.4 pmol/kg/min) or saline. Patients were instructed to pause ongoing treatment with metformin seven days prior to each of the study days. One-way repeated measures ANOVA with Fisher's LSD post hoc test was used to test for differences between the individual study days.

Results: A significant increase in iAUC for GLP-1 was evident following CCK-induced gallbladder emptying ($P < 0.05$), whereas isolated administration of metformin did not meet statistical significance in terms of GLP-1 iAUC compared to the day with placebo and saline ($P = 0.15$). Interestingly, the combination of metformin and CCK elicited a significant potentiation of bile-acid induced GLP-1 secretion with significantly higher iAUC for GLP-1 compared to the day with CCK alone ($P < 0.05$). Single-dose administration of metformin 1,500 in the applied fasting setting was observed to elicit statistically significant placebo-corrected reductions in plasma glucose excursions, both alone ($P < 0.05$) and in combination with CCK-induced gallbladder emptying ($P < 0.05$), whereas no glucose-lowering effect of isolated CCK infusion was observed ($P = 0.73$). No effects of either metformin or CCK infusion were observed with respect to insulin secretion or resting energy expenditure.

Conclusion: In conclusion, we found single-dose administration of metformin to potentiate bile acid-induced GLP-1 secretion in patients with type 2 diabetes, whereas no significant isolated effect of metformin on GLP-1 secretion was observed. The underlying mechanisms remain speculative, but might involve metformin-mediated modulation of bile acid circulation with potential subsequent implications for bile acid receptor activation in the GLP-1-secreting L cells. No clear associations were evident between the observed GLP-1-inducing effects and insulin secretion or plasma glucose excursions, which might be due to an impaired beta cell responsiveness to GLP-1 in patients with type 2 diabetes.

Delayed-release metformin targeting the lower bowel elicits sustained improvements in HbA_{1c} and fasting glucose with minimal systemic exposure

M. Fineman[1], J. Frias[2], G. Bakris[3], S. Skare[1], B. Walsh[1], C. Burns[1], R. Henry[4];

[1]Elcelyx Therapeutics, Inc., San Diego, [2]National Research Institute, Los Angeles, [3]University of Chicago Medicine, Chicago, [4]University of California, San Diego, La Jolla, USA.

Background and aims: Delayed-release metformin (Met DR) is being developed for T2DM patients with chronic kidney disease (CKD Stage 3B or 4). By utilizing an enteric coating to bypass the stomach and upper intestine, Met DR delivers metformin to the lower bowel to retain its gut-based glucose-lowering properties but with greatly reduced absorption and systemic exposure. This

blinded study evaluated 16 weeks of Met DR or Placebo (PBO) in subjects with T2DM; unblinded immediate-release metformin (Met IR) was included as a reference. Due to Met IR restrictions of use/contraindication in CKD Stages 3B and 4, only subjects with CKD Stage 1 or Stage 2 were enrolled.

Materials and methods: 571 subjects with T2DM and CKD Stage 1 or 2 were randomized to 16 weeks of double-blind Met DR (600, 900, 1200, 1500 mg QD) or PBO, or to unblinded 2000 mg Met IR (1000 mg BID; 1000 mg QD for first week). Data are LS mean±SE change from baseline in the modified-ITT (mITT) population (≥1 post-baseline HbA_{1c}).

Results: 542 subjects (56 y; 53% male; 7.9±6.7 y T2DM; BMI 32±5 kg/m^2; HbA_{1c} 8.6±0.9%) were included in the mITT population. Metformin plasma exposure (estimated $AUC_{0\text{-}24h}$) with Met DR was ≤37% of Met IR. Met DR resulted in a significant ($p<0.05$) dose-dependent HbA_{1c} reduction with no plateau (1200 mg: -0.49±0.13%; 1500 mg: -0.62±0.12%; PBO: -0.06 ±0.13%). Met IR 2000 mg elicited a -1.10±0.13% HbA_{1c} improvement. Fasting plasma glucose (FPG) improvement ($C_{average\ Week\ 4\text{-}16}$) was significantly greater with 900-1500 mg Met DR vs PBO, and the effect with 1500 mg Met DR approached that of 2000 mg Met IR (-25.1±4.1 vs -32.6±4.2 mg/dL, respectively; NS). Thus, 1500 mg Met DR exhibited 1.5-fold (HbA_{1c}) and 2.1-fold (FPG) greater relative efficacy than Met IR when adjusting for plasma metformin exposure. Adverse events were primarily gastrointestinal and incidence was lower with Met DR (<16% at all doses) vs Met IR (28%). Nausea incidence was markedly lower with Met DR (1-3% vs 10% Met IR), likely due to Met DR bypassing the stomach.

Conclusion: The improved efficacy relative to plasma exposure with Met DR may result in an improved benefit/risk profile for patients with CKD Stage 3B or 4, in whom minimizing exposure is desirable. Delivery of Met DR at higher doses may result in greater efficacy but at the expense of increased systemic exposure. Importantly, reducing current metformin dosage in an attempt to achieve the low exposure of Met DR would result in a disproportionate loss in efficacy.

Metformin exposure with gut-restricted delayed-release metformin in CKD Stage 4 does not exceed that of current metformin used on-label: results from population PK modelling

G. Bakris[1], A. Taylor[2], B. Walsh[3], C. Burns[3], M. Fineman[3];
[1]University of Chicago Medicine, Chicago, [2]Certara Strategic Consulting, Raleigh, [3]Elcelyx Therapeutics, Inc., San Diego, USA.

Background and aims: By utilizing an enteric coating to bypass the stomach and upper intestine, delayed-release metformin (Met DR) delivers metformin to the lower bowel and thereby retains its gut-based glucose-lowering properties but with greatly reduced absorption and systemic exposure. The relative bioavailability of Met DR from doses of 1500 mg to 2400 mg is ~40% of that seen with typical clinical doses of immediate-release metformin (Met IR). Thus, a dose of 2400 mg Met DR results in similar systemic exposure to 1000 mg Met IR. In a 16-week study, 1500 mg Met DR provided 56% (HbA_{1c}) and 77% (fasting glucose) of the efficacy of 2000 mg Met IR with only 37% of the exposure. Taken together, 1500 mg Met DR exhibited 1.5-fold (HbA_{1c}) to 2.1-fold (fasting glucose) greater efficacy relative to exposure than 2000 mg Met IR. This greater efficacy/exposure ratio may provide an improved benefit/risk profile in patients for whom minimizing metformin exposure is desirable, such as patients with advanced chronic kidney disease (CKD). Metformin is currently restricted in CKD Stage 3B and contraindicated in CKD Stage 4 due to lactic acidosis risk secondary to increased systemic metformin exposure. Met DR may provide a treatment option for these patients. To describe the range of exposures expected in patients with CKD Stage 3B/4, a population PK model was developed to characterize the absorption and disposition of Met IR, extended-release metformin (Met XR), or Met DR at varying doses in subjects across a range of renal impairment.

Materials and methods: The population PK model was developed using 5,854 plasma and 762 urine observations from 108 subjects who received orally administered single or multiple doses of Met IR, Met XR, or Met DR in subjects with varying degrees of renal impairment. Each simulation comprised 1000 subjects with varying body weight and renal function. eGFR values were assumed to arise from uniform distributions between 45-59.5 mL/min/1.73 m^2 (CKD Stage 3A), 30-44.5 mL/min/1.73 m^2 (CKD Stage 3B), and 15-29.5 mL/min/1.73 m^2 (CKD Stage 4). The simulations also assumed 50% females and 61% Caucasians. Met DR relative bioavailabilities were estimated from noncompartmental analyses of data from two comparative bioavailability studies.

Results: Predicted steady-state exposures ($AUC_{0\text{-}24h}$) with Met DR doses of up to 2100 mg were no higher in CKD Stage 4 than those with on-label use of 2000 mg Met IR in patients with CKD Stage 3A.

Conclusion: We conclude that Met DR at doses up to 2100 mg daily may provide a favorable benefit/risk profile for patients with CKD Stage 3B currently receiving metformin, or a novel option to initiate metformin for patients with CKD Stage 3B/4.

OP 44 Novel aspects in the regulation of glucose metabolism

245

Fatty liver disease is associated to increased glucogenic amino acids and decreased de novo alanine synthesis

A. Gastaldelli[1], F. Carli[1], M. Gaggini[1], C. Rosso[2], G. Mingrone[3], E. Buzzigoli[1], C. Barbieri[1], V. Della Latta[1], D. Ciociaro[1], M. Marietti[2], M. Abate[2], E. Bugianesi[2];

[1]Metabolism Unit, CNR Institute of Clinical Physiology, Pisa, [2]Dept. of Medical Sciences, University of Turin, Division of Gastroenterology and Hepatology and Lab. of Diabetology, Turin, [3]Catholic University, Department of Internal Medicine, Rome, Italy.

Background and aims: Amino acids (AA) are the main substrate of muscle proteins and several studies have shown that insulin resistance (IR) is associated to increased protein catabolism with net release of AA. In fasting state, AA, in particular alanine and glutamine, are used as substrate for de novo gluconeogenesis and energy metabolism. During postprandial state, alanine and glutamine are synthesized from glucose and used by the muscle for protein synthesis. The goal of this study was to evaluate 1) if concentrations of glucogenic AA (GNG-AA) were increased in condition of hepatic insulin resistance (Hep-IR) like obesity or NAFLD, 2) if de novo synthesis of alanine/glutamine after a labeled glucose load was associated to severity of NAFLD, explaining the increased risk of sarcopenia present in these subjects.

Materials and methods: We studied 44 non diabetic NAFLD subjects with liver biopsy (29 NAFLD-NO and 15 NAFLD-Ob) and 20 non-obese controls (CT-NO). We measured plasma GNG-AA (alanine, glutamate, branched chain amino acids (BCAA), and aromatic amino acids (AAA)) by GCMS, fasting EGP (by tracer infusions), and calculated Hep-IR (EGPxInsulin), HOMA, Adipo-IR (FFAxInsulin). We also developed a novel protocol to study de-novo AA synthesis by measuring the rate of de-novo alanine, glutamine and glutamate synthesis from U-^{13}C-glucose given orally. We studied 20 subjects with a double tracer OGTT (1.5g U-^{13}C-glucose plus 75g of unlabeled glucose), and ^{13}C-AA production was measured by GCMS

Results: From CT-NO to NAFLD-NO to NAFLD-Ob we observed an increase in total EGP (584±44 to 710±23 to 839±40 umol/min, p<0.0002) and Hep-IR (52±6 to 96±6 to 166±23 umol/kg/min x mU/l, p<0.001). Fasting GNG-AA, in particular alanine and glutamate, were also higher in NAFLD (NAFLD-ob 1588±98, NAFLD-NO 1467±36, CT 1296±55 umol/l, p<0.005). Total GNG-AA positively correlated with both EGP (R=0.47 and p=0.0006) and Hep-IR (R=0.35, p=0.0096). This was associated to an increased protein catabolism as indicated by the higher BCAA concentration in NAFLD compared to controls (NAFLD-ob 355.3±9.8, NAFLD-NO 389.7±23.4, CT 313.1 ±12.9 umol/l, p<0.001). We followed de-novo alanine, glutamine and glutamate synthesis after a 13C-glucose load but we were able to detect reliable levels of 13C-enrichment only in alanine, while the 13C-incorporation into glutamine or glutamate was very low. De-novo alanine production was positively correlated with glucose rate of disappearance (R=0.45, p=0.04) indicating that reduced peripheral insulin sensitivity is playing a major role. The alanine de-novo synthesis tended to be reduced in NAFLD with severe fibrosis independent of obesity.

Conclusion: Subjects with NAFLD exhibit increased GNG-AA and BCAA concentrations and reduced alanine turnover that might explain the increased risk of Hep-IR and sarcopenia.

Global and tissues-specific Ogt deletion revealed various effects of O-GlcNAcylation in glucose metabolism

S. Ida[1], K. Morino[1], N. Ohashi[1], O. Sekine[1], S. Kume[1], K. Iwasaki[2], N. Harada[2], N. Inagaki[2], S. Ugi[1], H. Maegawa[1];

[1]Department of Medicine, Shiga University of Medical Science, Otsu, [2]Department of Diabetes, Endocrinology and Nutrition, Kyoto University, Kyoto, Japan.

Background and aims: Post-translational modifications to intracellular proteins regulate a variety of cellular functions. Growing evidence indicates that dysfunction of post-translational modifications disrupts cellular homeostasis and is strongly associated with the pathogenesis of numerous diseases. O-GlcNAcylation is one of the post-translational modifications that is characterised by the addition of *N*acetylglucosamine to various proteins by O-GlcNAc transferase (Ogt) and serves as "an intracellular nutrient sensor" by modulating various cellular processes. Although it has been speculated that O-GlcNAcylation is associated with glucose metabolism, its exact role in whole body glucose metabolism has not yet been fully elucidated. Here, we investigated whether loss of O-GlcNAcylation globally and in specific organs affected glucose metabolism in mammals under physiological conditions.

Materials and methods: Tamoxifen-inducible global *Ogt* knockout mice were generated by crossbreeding *Ogt*-flox mice with R26-Cre-ER^{T2} mice. Liver-, skeletal muscle-, adipose tissue- and pancreatic beta cell-specific *Ogt* knockout mice were generated by crossbreeding *Ogt*-flox mice with Alb-Cre, Mlc1f-Cre, Adipoq-Cre and Pdx1^{PB}-CreER^{TM} mice, respectively. Various metabolic phenotypes including glucose metabolism were evaluated in each model.

Results: Tamoxifen-inducible global *Ogt* knockout (*Ogt*-KO) mice exhibited severe weight loss (*Ogt*-flox 29.1±1.4 vs. *Ogt*-KO 9.8±0.46 g, p<0.01), hypoglycaemia (5.65±0.17 vs. 4.87±0.15 mmol/l, p<0.01) and hypoproteinemia (4.3±0.1 vs. 2.9±0.3 g/dL, p<0.01) 3 week after Tamoxifen injection, although food intake was preserved. Moreover, tissue-specific *Ogt* deletion from insulin-sensitive organs, including liver, skeletal muscle and adipose tissues, had little impact on glucose metabolism under physiological conditions. However, pancreatic beta cell-specific *Ogt* knockout (*Ogt*-betaKO) mice displayed transient hypoglycaemia (*Ogt*-flox 5.46±0.41 vs. *Ogt*-betaKO 3.88±0.26 mmol/l, p=0.015) associated with enhanced insulin secretion and accelerated adiposity, followed by subsequent hyperglycemia (*Ogt*-flox 6.34±0.32 vs. *Ogt*-betaKO 26.4±2.37 mmol/l, p<0.01) with insulin depletion accompanied by beta cell apoptosis.

Conclusion: Our findings suggest that O-GlcNAcylation is indispensable for survival also in adult mice. O-GlcNAcylation does not impact glucose metabolism in insulin-sensitive tissues but plays crucial roles in pancreatic beta cell function, and survival under physiological conditions. Our results provide novel insight into O-GlcNAc biology and physiology in glucose metabolism.

A novel stepwise eu-, hyper- and hypoglycaemic clamp using stable tracer method to compare glucose fluxes and lipolysis in type 1 and type 2 diabetes

E. Svehlikova[1], S. Sach-Friedl[1], H.-P. Schadler[2], T. Augustin[2], C. Magnes[2], A. Eberl[2], S. Narath[3], M. Urschitz[1], M. Wolf[1], G. Treiber[1], T.R. Pieber[1,2];

[1]Department of Internal Medicine, Division of Endocrinology and Diabetology, Medical University of Graz, [2]HEALTH – Institute of Biomedicine and Health Sciences, Joanneum Research, [3]CBmed – Center for Biomarker Research in Medicine, Graz, Austria.

Background and aims: Recently it was proposed that some diabetes medications shift the fuel balance towards lipolysis and ketogenesis. The aim of this study was to establish a novel stable tracer method to assess endogenous glucose production (EGP) and lipolysis (rate of appearance [Ra] glycerol) during eu-, hyper-, and hypoglycaemia in type 1 (T1DM) and type 2 diabetes mellitus (T2DM).

Materials and methods: A stepwise eu- (5.5 mmol/L) and hyperglycaemic (11.1 mmol/L) clamp with ambient insulin levels was followed by an insulin induced (T1DM: 1.5 mU/kg/min; T2DM: 2.5 mU/kg/min) hypoglycaemic

clamp (5.5, 3.5, 2.5 mmol/L). Primed tracer infusion of [6,6-2H2]glucose (prime: 9.6 mg/kg, constant: 0.08 mg/kg/min) and [1,1,2,3,3-2H5]glycerol (prime: 1.5 μmol/kg, constant: 0.1 μmol/kg/min) was used to assess EGP, peripheral glucose uptake (PGU) and Ra glycerol throughout all glycaemic levels (Fig.). Glucagon was measured by specific double sandwich ELISA (Mercodia AB, Sweden), all other hormones by routine assays, isotopic glucose and glycerol by gas-chromatography mass spectrometry. Ten C-peptide negative T1DM (age 42±14 ys, diabetes duration 21±13 ys, BMI 23.2±2.0 kg/m^2, HbA1c 60±11 mmol/mol) were compared to 17 metformin only treated T2DM patients (age 53±6 ys, diabetes duration 6.6±5.1 ys, BMI 28.9±3.3 kg/m^2, HbA1c 61±11 mmol/mol).

Results: Glucagon levels were significantly lower in T1DM compared to T2DM during euglycaemia (2.2±1.1 vs. 9.4±4.1 pmol/L; p<0.001) and during hypoglycaemia (at 2.5 mmol/L: 1.5±1.1 vs. 18.9±14.0; p<0.001). At euglycaemia insulin (17.0±8.0 vs. 28.7±48.3 mU/L, ns), EGP (2.3±0.4 vs. 2.2±0.5 mg/kg/min; ns), Ra glycerol (2.5±0.8 vs. 2.0±0.9 μmol/kg/min; ns) and ketones (0.09±0.06 vs. 0.06±0.04 mmol/L; ns) were comparable in T1DM and T2DM. During hyperglycaemia, EGP (3.5±1.8 vs. 1.8 ±0.4 mg/kg/min, p<0.02), Ra glycerol (4.1±2.0 vs. 2.3±0.9 μmol/kg/min; p<0.02) and ketones (0.85±0.36 vs. 0.14±0.15 mmol/L; p<0.001) were substantially higher in T1DM, but insulin lower (5.3±4.9 vs. 30.8±38.4 mU/L; p<0.02). During induction of hypoglycaemia EGP and ketones were comparable, but T2DM had higher Ra glycerol (1.3±0.4 vs. 0.9 ±0.3 μmol/kg/min; p<0.01) despite higher insulin levels (229±42 vs. 104±38 mU/L; p<0.001). NEFA levels were not different throughout the clamp.

Conclusion: This novel stepwise clamp using a stable tracer method allows assessment of glucose fluxes (EGP and PGU) and lipolysis (Ra glycerol) over a wide range of glycaemic levels in subjects with diabetes. Distinct differences in fuel shifts (e.g.in lipolysis) are not detected by NEFA measurement, but by rate of appearance of glycerol using a stable tracer method.

Mild physiologic hyperglycaemia induces hepatic insulin resistance in healthy Normal Glucose Tolerant (NGT) subjects

D. Tripathy, A. Merovci, M. Abdul-Ghani, R. DeFronzo;
Diabetes, Medicine, University of Texas Health Science Center, San Antonio, USA.

Background and aims: Chronic hyperglycemia worsens skeletal muscle insulin resistance and causes beta cell dysfunction; i.e. glucotoxicity. However, effect of mild chronic hyperglycemia on hepatic insulin sensitivity never has been examined. The aim of the present study was to evaluate effect of a physiologic increase in plasma glucose concentration on endogenous glucose production (EGP) in healthy NGT individuals.

Materials and methods: 16 NGT subjects: 8 with family history of T2DM (FH+((5M/3F, age = 47± 14 yrs, BMI = 27 ± 1 kg/m^2) and 8 without FH (FH-) (4M/4F, Age = 42±9, BMI = 26±1 kg/m^2) participated in a 3-step hyperinsulinemic (10, 20, 40 mU/m^2·min) euglycemic clamp before and after a 48 hour glucose infusion to increase plasma glucose conc by ~50 mg/dl above baseline. Endogenous (primarily reflects liver) glucose production was measured with [3-3H] glucose and gluconeogenic rate was measured as (EGP) (plasma C5/ C2 glucose ratio) using the deuterated water method.

Results: FPG concentration increased from 97± 4.5 to 138± 5 mg/dl following 48 hours of glucose infusion while basal EGP increased from 2.05±0.09 to 3.06±0.29 mg/kg•min (p=0.003) and hepatic insulin resistance index (EGP X Fasting Plasma Insulin) increased markedly and similarly (20.1±1.8 vs 51.7± 6.6, p<0.005) following glucose infusion in FH+ and FH- subjects. Following chronic glucose infusion, the rate of gluconeogenesis (5.58± 1.8 vs 5.78±2.06 μmol/kg•min) remained unchanged. The rate of glycogenolysis (total EGP minus gluconeogenic rate) increased following chronic glucose infusion (6.55± 3.3 to 8.25±2.4 μmol/kg•min, p<0.10). Thus, both increased glycogenolysis and gluconeogenesis contributed to the increase in basal EGP following chronic glucose infusion. Following 48 hr glucose infusion, total body insulin sensitivity declined from 8.75±2.1 to 6.92± 6 mg.kg/min (p<0.05) during the 40 mU/m^2•min insulin clamp. There was no significant change in plasma glucagon or free fatty acid concentrations.

Conclusion: Chronic (48 hr) physiologic hyperglycemia to levels seen in T2DM increases basal endogenous (hepatic) glucose production and induces hepatic and skeletal muscle insulin resistance in healthy NGT subjects. These results demonstrate, for the first time in man, that glucotoxicity causes hepatic insulin resistance to the suppressive effect of insulin on hepatic glucose production.

Clustering of diabetes into novel subgroups provides improved prediction of outcome

E. Ahlqvist[1], A. Käräjämäki[2], M. Martinell[3], P. Storm[1], M. Dorkhan[1], P. Vikman[1], R.B. Prasad[1], D. Mansour Aly[1], N. Shaat[1], E. Lindholm[1], T. Tuomi[4,5], A.H. Rosengren[1], L. Groop[1,4];

[1]Lund University Diabetes Centre, Lund University, Malmö, Sweden, [2]Primary Health Care, Vaasa Central Hospital, Vaasa, Finland, [3]Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden, [4]Finnish Institute for Molecular Medicine, Helsinki University, [5]Folkhälsan Research Center, Helsinki, Finland.

Background and aims: The current classification of diabetes into two main forms (T1D and T2D) has been useful in delineating T1D as an insulin-deficient form requiring insulin therapy but less useful for dissecting the heterogeneity of T2D. A refined classification could provide a powerful tool to identify those at greatest risk of complications already at diagnosis and tailor individualized treatment.

Materials and methods: We performed unsupervised clustering (k-means and hierarchical) based on six variables (age, BMI, HbA1c, HOMA2-B, HOMA2-IR and GAD auto-antibodies) in ANDIS, a Swedish cohort of 15,000 newly diagnosed diabetes patients. Disease progression, treatment and development of complications were followed using medical records and national registries. Risk of complications was analyzed using cox regression with the largest cluster as reference. Genetic loci known to be associated with T2D and related traits were analysed using MLE comparing each cluster to a non-diabetic cohort from the same geographical region.

Results: ANDIS patients clustered into one GADA-positive cluster (referred to as SAID, Severe Autoimmune Diabetes) and four GADA-negative clusters. This was replicated in three independent cohorts from Sweden and Finland. Cluster 2 (SIDD, Severe Insulin Deficient Diabetes; 17.5% of patients) was characterized by early onset, insulin deficiency and high HbA1c. During a mean follow-up of 4 years SIDD had higher HbA1c, was more likely to be prescribed insulin and develop diabetic retinopathy compared to other GADA-negative clusters. Cluster 3 (SIRD, Severe Insulin Resistant Diabetes; 15.3%) had the highest risk of kidney disease including CKD stage 3B (HR 3.30[2.67-4.08], $p=3.6\times10^{-28}$) and macroalbuminuria/end-stage renal disease (ESRD; HR 2.40[1.69-3.42], $p=9.8\times10^{-7}$). This was replicated in a cohort with longer follow-up (SDR, mean 11 years), where SIRD had five-fold increased risk of ESRD (HR 5.04[2.76-9.23], $p=1.5\times10^{-7}$). Cluster 4 (MOD, Mild Obese Diabetes; 21.6%) and cluster 5 (MARD, Mild Age-Related Diabetes; 39.1%) showed only modest metabolic derangements. Using $p<0.01$ as cut-off, no genetic variant was associated with all clusters. Strikingly, the T2D-associated variant, rs7903146, in the *TCF7L2* gene was associated with SIDD (OR 1.51[1.33-1.71], $p=2.8\times10^{-10}$), MOD (OR 1.38[1.21-1.56], $p=25.7\times10^{-7}$) and MARD (OR 1.41 [1.28-1.55], $p=1.1\times10^{-12}$), but not with SIRD (OR 1.00[0.87-1.15], p=0.86). A variant in *IGF2BP2* (rs4402960) was associated with SIDD (OR 1.23[1.08-1.40], $p=2.0\times10^{-4}$) and MARD (OR 1.22[1.11-1.33], $p=2.1\times10^{-6}$), but not with SIRD (OR 1.01[0.88-1.16], p=0.53) or MOD (OR 1.04[0.92-1.18], p=0.31).

Conclusion: This study provides a first step towards a more precise, clinically useful, classification of diabetes representing an important step towards precision medicine in diabetes.

Clustering on baseline clinical variables identifies subgroups of type 2 diabetes patients with different rate of progression over 18 months: a DIRECT study

C.A. Brorsson[1], H. Krogh Pedersen[1], V. Gudmundsdottir[1], A. Mari[2], A. Kurbasic[3], A. Viñuela[4], J. Fernandez[5], A. Mahajan[5], R. Gupta[1], E. Dermitzakis[4], M. MacCarthy[5], P. Franks[3], E. Pearson[6], S. Brunak[1,7], for the DIRECT Consortium;

[1]Department of Bioinformatics, Technical University of Denmark, Lyngby, Denmark, [2]Institue of Neuroscience - National Research Council, Padova, Italy, [3]Lund University, Malmö, Sweden, [4]University of Geneva, Geneva, Switzerland, [5]University of Oxford, Oxford, [6]University of Dundee, Dundee, UK, [7]University of Copenhagen, Copenhagen, Denmark.

Background and aims: Type 2 diabetes is characterized by a heterogeneous presentation with varying degrees of insulin resistance and β-cell failure. Taking advantage of the detailed clinical information collected for type 2 diabetes patients included in the DIRECT study, our aim was to characterize inter-individual heterogeneity and identify subgroups with different presentations of diabetic phenotypes at baseline, and investigate the effect on the rate of progression during follow-up. Genotyping data was used to evaluate genetic differences between subgroups.

Materials and methods: 836 newly diagnosed individuals were enrolled in the DIRECT study. The clustering was based on 20 clinical variables from the baseline visit consisting of anthropometric, biochemical and glycaemic modeling variables. We clustered the individuals using an unsupervised, agglomerative clustering method. Diabetes progression was assessed using individual HbA1c slopes obtained from a conditional linear mixed-model using data at 0, 9 and 18 month adjusted for weight, diabetes medication and baseline HbA1c. An extra time-varying covariate defined to be 1 at baseline and zero for all other visits was introduced to account for presence of effect from baseline to subsequent visits. Linear regression models with cluster membership as predictor was used to calculate effect, 95% CI and p-values for differences between subgroups. A genetic risk score (GRS) was calculated from the cumulative number of risk alleles of 65 published GWAS SNPs for type 2 diabetes.

Results: Full clinical data was available for 790 individuals. We identified three major patient subgroups that differed significantly in regards to their baseline characteristics. The three groups could broadly be described as insulin resistant (IR), β-cell deficient (βD), and mixed. The most significant difference was seen in insulin sensitivity (ln(Matsuda), beta (95% CI): Mixed= -0.61 (-0.68- -0.55), $p=9.9*10^{-68}$; IR=-1.3 (-1.3- -1.2), $p=4.9*10^{-203}$) compared to the βD group, but also insulin secretion, C-peptide, BMI, basal glucose, triglycerides and ALT ($p<10^{-16}$). The IR group was treated with significantly more metformin compared to the βD group (% maximum dose: IR= 5.13 (1.79-8.47), p=0.003). Investigating the rate of progression in HbA1c between baseline and 18 months showed that the IR group had the fastest progression compared to the βD group, which had the slowest progression (change in HbA1c (mmol/mol)/year: IR=0.77 (0.32-1.22), p=0.0008). There was no difference for the GRS constructed of 65 GWAS SNPs.

Conclusion: We have demonstrated that the newly diagnosed type 2 diabetes cohort from DIRECT has a heterogeneous presentation of their diabetic phenotype at baseline. Clustering identified three major subgroups, driven by their level of insulin resistance-related traits. The subgroups showed differences in their rate of progression over 18 months with the insulin resistant group showing the fastest progression.

Single antibody positivity associates with two distinct phenotypes in people with young-onset diabetes: insights from the MY DIABETES study

S. Misra[1], A. Sebastian[2], X. Liu[2], L. Lupak[1], E.L. Williams[1], D.G. Johnston[2], N.S. Oliver[2];

[1]Metabolic Medicine, Imperial College Healthcare NHS Trust, [2]Metabolic Medicine, Imperial College London, London, UK.

Background and aims: Pancreatic autoantibody status may be used as a biomarker to differentiate diabetes subtype. Single antibody positivity in individuals presenting at older age has uncertain significance, but has not been

fully explored in young-onset individuals. Using a cross-sectional cohort we sought to determine the phenotype of individuals with single antibody positivity.

Materials and methods: The MY DIABETES study recruits people diagnosed <30 years with any type of diabetes from white, south Asian & African-Caribbean ethnicity. Participants are phenotyped using fasting serum C-peptide (FCP) and anti-GAD-65, IA-2 & ZnT8 autoantibodies. We studied 3 groups; those with single antibody positivity (AB+), those with multiple antibodies positive (AB++) and those negative (AB-). We focussed analysis on people with residual beta cell function (FCP>99pmol/L). Clinical features of those with FCP>99pmol/L were compared across the 3 antibody groups.

Results: 229 of 701 (33%) individuals were AB+ at assessment (66% GAD, 17% IA-2 & 17% ZnT8), 165 (24%) were AB++ & 307 (44%) were negative to all three antibodies. Features of AB+: Of these 36 (17 %) had an FCP>99 pmol/L. People with FCP>99pmol/L were diagnosed older (24.5 vs 16 yrs, p<0.0001) with shorter durations (7.9 vs 22 yrs p<0.0001), had higher BMI (28 vs 25kg/m^2 p=0.02), were more likely to be from a non-white ethnic group (55% vs 20% p=0.003) & less likely to be insulin-treated (77% vs 100%) than those with FCP<100pmol/L. AB+ vs AB++: 39 of 165 (21%) individuals with AB++ had a FCP>99pmol/L. Compared to this group, people with AB+ & FCP>99pmol/L had longer durations of diabetes (7.9 vs 1.2 yrs p =0.0001), significantly higher FCP (467 vs 265 pmol/L p=0.005), less likely to be insulin-treated (77% vs 92% p=0.04) and no ethnic differences were observed. AB+ vs AB-: 127 of 307 (41%) individuals that were AB- had FCP>99pmol/L. Compared to this group, people with AB+ and FCP>99pmol/L had similar ages at diagnosis (21 vs 24.5 yrs p=0.22), durations (10.7 vs 7.9 yrs, p=0.42), BMI (28.1 vs 27.9 p=0.9) & FCP (580 vs 467, p=0.18). No differences in ethnicity or proportion insulin treated were observed. Key Findings: 1) An FCP cut-off of 100pmol/L identified two distinct AB+ groups; those with long duration who are FCP deficient and those with shorter durations who have preserved FCP. 2) Despite longer duration of diabetes, the AB+ group with preserved FCP has significantly higher FCP than the AB++. 3) The AB+ group with preserved FCP is non-significantly different from the AB- group.

Conclusion: Single antibody positivity in young-onset diabetes associates with two phenotypes; a long-duration FCP deficient phenotype similar to those with multiple antibodies positive & a shorter duration phenotype with preserved FCP. This latter group aligns more closely to the AB- group than the AB++ group with preserved FCP, suggesting mixed diabetes aetiology. This group requires further study to investigate if they represent a discrete phenotype of type 1 diabetes or non-type 1. In a multi-ethnic young-onset diabetes population, single antibody positivity may be associated with a non-type 1 diabetes phenotype. Individuals with single antibody positivity require more detailed follow-up and FCP assessment to determine subtype of diabetes.

Overweight, obesity, genetic susceptibility and the risk of LADA: Latent Autoimmune Diabetes in Adults

R. Hjort[1], J.E. Löfvenborg[1], E. Ahlqvist[2], L. Alfredsson[1], T. Andersson[1,3], P.-O. Carlsson[4], L. Groop[2,5], M. Martinell[6], B. Rasouli[1], A. Rosengren[2], T. Tuomi[7,5], S. Carlsson[1];

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, [2]Department of Clinical Sciences in Malmö, Lund University, Malmö, [3]Center for Occupational and Environmental Medicine, Stockholm County Council, Stockholm, [4]Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [5]Finnish Institute of Molecular Medicine, Helsinki University, Helsinki, Finland, [6]Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden, [7]Division of Endocrinology, Abdominal Center, Helsinki University Hospital, Research Program for Diabetes and Obesity, University of Helsinki, and Folkhälsan Research Center, Helsinki, Finland.

Background and aims: Excessive weight is a major risk factor for type 2 diabetes (T2D) but its role in the promotion of autoimmune diabetes is not clear. We investigated the risk of latent autoimmune diabetes in adults (LADA) in relation to overweight and obesity and the interaction with high risk HLA-genotypes using data from a large population-based case control study from Sweden.

Materials and methods: We used data from ESTRID (epidemiological study of risk factors for LADA and T2D), including incident cases of LADA (Glutamic acid decarboxylase antibodies (GADA) positive, n=425) and T2D (GADA negative, n=1420) from ANDIS/ANDIU and 1704 population-based matched controls. We present odds ratios (OR) with 95% confidence intervals (CI) adjusted for age, sex, family history of diabetes, physical activity, and smoking. HLA genotypes where categorized as high risk (DR4-DQ8, DR4/3-DQ8, DR3/4, DR3/3, DR4/4, and DQA1*0501-DQB1*0201) or other (DR3/X, DR4/X, DR4-DQ7, and DRX/X). Interaction between overweight (BMI ≥25 kg/m^2) and high risk HLA was assessed by attributable proportion due to interaction (AP).

Results: Obesity (BMI ≥30 kg/m^2) was associated with an increased risk of LADA (OR 2.93; CI 2.17-3.97) and even more so with T2D (OR 18.88; CI 14.29-24.94). The association was stronger in LADA with low GADA (<median) (OR 4.25; CI 2.76-6.52) than LADA with high GADA (OR 2.14; CI 1.42-3.24). The combination of overweight and high risk HLA yielded an OR 8.40; CI 5.04-14.00 with AP estimated at 0.39 (CI 0.13-0.64). Obese vs. normal weight LADA patients had lower GADA levels (51 vs. 250 vs. IU/ml, p<0.001), better β-cell function [HOMA] (26.1 vs. 60.8, p<0.0001) and less insulin sensitivity [HOMA] (32.1 vs. 54.1, p<0.0001).

Conclusion: Overweight/obesity is associated with increased risk of LADA, especially in carriers of high risk HLA genotypes. Obese LADA patients had a more type-2 like phenotype, but high BMI was also associated with more autoimmune LADA. These findings support the hypothesis that even in the presence of autoimmunity, factors linked to insulin resistance such as excessive weight will promote onset of diabetes.

Background and aims: The G protein-coupled metabotropic cannabinoid receptor type-1 (CB1R) is a major regulator of metabolism, growth and inflammation. Yet, its potential role in the skin is little understood. We found that CB1R expression was decreased in diabetic mouse skin. Our aim was to evaluate the role of CB1R in the skin alterations related to aging in diabetes with the use of a CB1R knockout mice model.

Materials and methods: We quantified by q-RT-PCR markers of proliferation, inflammation, angiogenesis, oxidative stress, collagen (COL1A2, COL3A1) in the skin of wyld-type control (WT), WT streptozotocin (STZ)-induced diabetic mice (DM WT), CB1R knockout (CB1RKO) and DM CB1RKO mice. We stained the skin collagen with trichrome masson. Also, we measure the levels of reactive oxygen species (ROS) and the macrophage phenotype, M1 and M2, in skin by immunohistochemistry.

Results: We found that the mRNA CB1R expression and the CB1R protein levels were decreased in the skin of diabetic mice (0.5±0.03 fold-change and 72.6±5.3% of WT, respectively, $p<0.05$). The expression of collagen was significantly decreased in diabetic and CB1RKO mice (COL1A2, 0.29±0.1 and 0.28±0.03 fold-change, respectively, $p<0.01$; and COL3A1, 0.24±0.1 and 0.19±0.04 fold-change, respectively, $p<0.01$), and similar alteration was found in DM CB1RKO mice, suggesting an early ageing process. The absence of CB1 receptors significantly augmented the expression of several inflammatory markers, interleukin-6 (IL-6, 5.6±1.5 fold-change, $p<0.01$), keratinocyte-derived chemokine (KC, 5.2±2.2 fold-change, $p<0.01$), and tumor necrosis factor-alpha (TNF-α, 3.7±0.6 fold-change, $p<0.01$), and similar levels were found when compared with DM WT and DM CB1RKO mice. Moreover, the ratio M1/M2 macrophage and the ROS levels were significantly higher under diabetic conditions (M1/M2: DM WT, 0.4±0.03 comparing with WT, 0.2±0.03, $p<0.05$, and ROS: DM WT, 189±16.9% of WT, $p<0.05$) and in CB1RKO mice (M1/M2: CB1RKO, 0.5±0.07 comparing with WT, 0.2±0.03, $p<0.05$, and ROS: DM WT, 176±21.3% of WT, $p<0.05$), which was consistent with the decrease in the antioxidant capacity of the skin, particularly a decrease in superoxide dismutase (SOD)-1 (DM WT: 0.58±0.1 fold-change, CB1RKO: 0.69±0.1 fold-change, DM CB1RKO, 0.39±0.1 fold-change, $p<0.05$), catalase (DM WT: 0.41±0.1 fold-change, CB1RKO: 0.49±0.1 fold-change, DM CB1RKO, 0.36±0.1 fold-change, $p<0.05$) and heme-oxigenase1 (Hox1) expression (DM WT: 0.35±0.1 fold-change, CB1RKO: 0.51±0.1 fold-change, DM CB1RKO, 0.1±0.03 fold-change, $p<0.05$).

Conclusion: Our results indicate that the lack of CB1R impairs the expression of markers involved in the control of inflammation and tissue regeneration. These lead to accelerated skin aging by the increased production of reactive oxygen species, a decrease in the antioxidant defenses and a higher pro-inflammatory environment. We conclude that the decreased CB1R expression may be a major pathologic mechanism in accelerated skin aging in diabetes.

Relation to skin microvessel proliferation and vascular endothelial growth factor expression to microvascular complications in patients with type 2 diabetes

K. Sugimoto[1], H. Murakami[2], T. Deguchi[3], A. Arimura[3], S. Suzuki[1], M. Daimon[2], S. Yagihashi[4];

[1]Diabetes Center, Ohta Nishinouchi Hospital, Koriyama, [2]Department of Endocrinology and Metabolism, Hirosaki University Graduate School of Medicine, Hirosaki, [3]Department of Diabetes and Endocrine Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, [4]Department of Pathology and Molecular Medicine, Hirosaki University Graduate School of Medicine, Hirosaki, Japan.

Background and aims: Previous studies have indicated the involvement of vascular endothelial growth factor (VEGF) in the pathophysiology of diabetic neuropathy, retinopathy and nephropathy, but the expression of VEGF in skin microvasculature in relation to type 2 diabetic microvascular complications has yet to be fully explored.

Materials and methods: The current study enrolled 26 patients with type 2 diabetes (20 males/6 females; mean (SD) age, 51 (16) years; HbA1c, 76 (25) mmol/l), and 16 male non-diabetic subjects (mean (SD) age, 41 (10) years) with fasting plasma glucose levels of <5.6 mmol/l and HbA1c of <33 mmol/mol. All participants provided written informed consent. Three-mm skin biopsies were performed 10-cm above the lateral malleolus, and 60-μm-thick cryostat sections of the skin were double immunostained with type 4 collagen and VEGF-A or the pan-neuronal marker protein gene product (PGP) 9.5. Projected images of 30-μm optical sections at 2-μm increments were acquired by confocal microscopy to quantify the occupancy rate of subepidermal type 4 collagen-immunoreactive microvascular basement membrane area (ORT4C), the subepidermal VEGF-A/type 4 collagen immunoreactivity ratio (VEGF/T4C), and the linear density of PGP 9.5-immunoreactive intra-epidermal nerve fiber (IENF) in three dimensions. IENF density (IENFD) was deemed to be reduced if it was <7.4 fibers/mm. Diabetic retinopathy was detected by ophthalmoscopy and fluorescein angiography. Diabetic nephropathy was defined by the presence of either microalbuminuria or macroalbuminuria.

Results: IENFD was significantly ($P<0.001$) decreased in diabetic patients compared with non-diabetic subjects (median (interquartile range); 5.8 (0.4-9.6) fibers/mm vs. 13.9 (11.6-17.5) fibers/mm). Nine diabetic patients had reduced IENFD, 10 had retinopathy, and 15 had nephropathy. ORT4C was significantly ($P<0.001$) increased in diabetic patients compared with non-diabetic subjects (median (interquartile range); 3.90 (3.08-5.35) % vs. 2.43 (1.88-2.97) %) regardless of the presence or absence of reduced IENFD, retinopathy, or nephropathy. VEGF/T4C was significantly ($P=0.005$) decreased in diabetic patients compared with non-diabetic subjects (mean (SD); 0.13 (0.09) vs. 0.29 (0.20), regardless of the presence or absence of retinopathy or nephropathy, while it was significantly ($P=0.006$) decreased in diabetic patients with reduced IENFD, but not in those without.

Conclusion: The present study provided the first direct evidence of skin microvascular basement membrane thickening and its impaired expression of VEGF, which occur before the emergence of chronic microvascular complications and may represent part of the earliest manifestations of generalized microangiopathy in patients with type 2 diabetes. Whether basement membrane thickening and impaired VEGF expression in the skin microvasculature can be a novel therapeutic target to prevent late complications warrants further investigation.

Local administration of microRNA-210 promotes wound healing in db/db diabetic mice

X. Zheng[1], S. Narayanan[1], S. Eliasson[1], J. Grünler[1], C. Xu[1], M. Ivan[2], S.-B. Catrina[1];

[1]Karolinska Institutet, Stockholm, Sweden, [2]Indiana University, Indianapolis, USA.

Background and aims: Diabetic foot ulcers represent a major medical and socioeconomic challenge to the global healthcare system. The current therapeutic strategies are limited and specific treatment avenues are still being pursued. A better understanding of the pathogenic mechanisms underlying

the chronic foot ulcers would lead to novel therapeutic strategies. Besides hyperglycemia, chronic wound hypoxia has been recently shown to play important role in delayed wound healing. microRNAs (miRNAs) are a major class of small RNAs which are 20-24 nucleotide long oligonucleotides that inhibit gene transcription by translation inhibition or mRNA degradation. miRNAs have been recently implicated in various diseases and its therapeutic value is still evolving. There is increasing evidence for the role of various miRNAs in wound healing. miR-210 is a major hypoxia-responsive miRNA upregulated by Hypoxia Inducible Factors (HIF). miR-210 mediates various hypoxic responses such as mitochondrial metabolism, cell survival and angiogenesis reflecting HIF function in hypoxia. In this study, we intend to study the role of microRNA-210 in diabetic wound healing.

Materials and methods: The effect of diabetes on miR-210 expression in skin and wounds was studied in the type 2 diabetic mouse model db/db mice and controls. The wound model consists of full-thickness wounds made on the dorsum of the animals. The influence of miR-210 reconstitution in wounds was studied by transdermal injection with a mature miR-210 mimic on the wound edges. The wound area was determined every second day using a digital camera. *In vitro*, the modulation of miR-210 by glucose and oxygen was investigated in human dermal fibroblasts (HDF) cultured in normal (5mM) and high (30mM) glucose concentrations and exposed to normoxia (21% O_2) or hypoxia (1% O_2) for 24 hours. The effect of miR-210 on HDF migration was studied by transfecting miR-210 mimic in HDF cells and performing scratch assay. The expression of miR-210 was evaluated both *in vitro* and *in vivo* by qPCR.

Results: The expression of miR-210 in the skin of db/db mice was significantly reduced compared with the skin from the control mice ($p<0.01$, t-test; n=10). After wounding, miR-210 was induced by 1.7 folds in wounds compared with uninjured skin ($p<0.01$, t-test; n=10). However, miR-210 expression was markedly reduced in the wounds of db/db animals than controls ($p<0.05$, n=10). Wound healing was impaired in db/db mice compared with normoglycemic controls ($p<0.01$, two-way ANOVA, n=7). However, injection of miR-210 mimic locally at wound edges led to a significant improvement in wound healing in db/db mice ($p<0.01$, two-way ANOVA, n=7), but not in non-diabetic animals. *In vitro*, hypoxia increased miR-210 levels in HDF, but it was significantly inhibited in cells that were exposed to both hypoxia and hyperglycemia ($p<0.05$, t-test, n=5). Reduced miR-210 expression was accompanied with decreased migration and proliferation of HDF that were exposed to both hypoxia and hyperglycemia ($p<0.05$, t-test, n=4). Reconstitution of miR-210 in HDF restored cell migration and proliferation.

Conclusion: miR-210 expression in skin and wound is inhibited in diabetes. Reconstitution of miR-210 expression locally in wounds is a promising strategy to promote wound healing in diabetes.

Regulation of miRNA-146a and miR-29a during wound healing in a mouse model of type 1 diabetes

M. Petkovic[1], A.E. Sørensen[2], E.C. Leal[1], J. Moura[1], R.J. Willemoes[2], P.T. Jørgensen[3], J. Wengel[3], E. Carvalho[1,4], L.T. Dalgaard[2];

[1]Center for Neuroscience and Cell Biology, Coimbra, Portugal, [2]Roskilde University, Department of Natural Science and Environment, Roskilde, Denmark, [3]University of Southern Denmark, Odense, Denmark, [4]Department of Geriatrics, University of Arkansas for Medical Sciences, Little Rock, USA.

Background and aims: Impaired wound healing of diabetes patients can result from a combination of inflammation, microvascular and macrovascular complications, leading to development of chronic diabetic foot ulcers. The role of microRNAs miR-146a and miR-29a, both increased by inflammation, is not well characterized in wound healing. We aim to evaluate the impact of miR-146a and miR-29a, in wound healing using a diabetic mouse model and also to characterize the role of these miRNAs on migration in an in vitro wound healing model (scratch assays of HaCAT cells).

Materials and methods: Diabetes was induced in C57Bl/6 mice using a multiple low-dose streptozotocin injections. Eight weeks later, 6-mm full-thickness excisional wounds were made and skin wound biopsies obtained at 3 and 10 days after wounding. MicroRNA-146a and miR-29a were measured in RNA extracted from skin at day 0, 3 and 10 after wounding. In vitro scratch assays in human keratinocyte (HaCAT) cells were made after transfection with miR-146a and miR-29a inhibitors. Predicted target genes in skin were investigated using TargetScan 7.1 and filtered using an mRNA expression array (E-GEOD-23006), and analyzed for Gene Ontology enrichment using DAVID tools.

Results: Relative to control (ctrl) mice, STZ diabetic mouse skin had 13.7 (95%CI: 2.9-24.7) fold increased miR-146a and 4.9 (1.9-7.9) fold increased miR-29a levels. Whereas ctrl skin had significantly increased miR-146a (3.1 fold) and miR-29a (2.0 fold) at day 3 of wounding, levels in diabetic skin were suppressed after wounding both at day 3 and 10. Scratch wound assays in HaCAT showed a faster scratch closure after 24hrs when miR-146a or miR-29a was inhibited. Gene Ontology analysis showed that predicted target genes of miR-29a were over-represented in the GO category 0030199~collagen fibril organization ($p=0.045$).

Conclusion: MicroRNAs miR-146a and miR-29a are dynamically regulated by wounding and differentially regulated during wound healing in a diabetic mouse model. Moreover, inhibition of miR-146a and miR-29a increased migration of HaCAT keratinocytes. These findings suggest that normalizing expression levels of miR-146a and miR-29a in diabetic wounds could improve healing, however, more studies are needed.

Gut inflammation and mucus layer alterations trigger intestinal activation of islet-reactive T cells and autoimmune diabetes

M. Falcone[1], C. Sorini[2], I. Cosorich[1], L. De Giorgi[1], R. Lucianò[1], M. Rocchi[1], D. Saita[1], R. Ferrarese[1], F. Canducci[1], F. Sanvito[1];
[1]Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milan, Italy, [2]Karolinska Institute, Stockholm, Sweden.

Background and aims: Signs of intestinal inflammation and alteration of gut mucosal immunity are found in patients and animal models of Type 1 Diabetes (T1D). Low-grade intestinal inflammation precedes the clinical signs of diabetes thus suggesting that is mechanistically linked with T1D pathogenesis rather than being secondary to diabetes-induced metabolic alterations. While these results suggest a causative link between enteropathy and the pathogenic process of T1D, it is yet to be determined whether gut inflammation does promote β cell autoimmunity and, if it does, how this process occurs. The intestine has several means to maintain immune homeostasis and avoid chronic inflammation. Those include physical barriers such as the epithelial barrier and the vascular barrier and biological barriers such as the mucin protein barrier, a complex system of molecules released by intestinal cells that have crucial immune modulatory functions and anti-microbial activities. Our aim is to assess whether gut inflammation and functional loss of mucin barrier function promotes activation of diabetogenic T cells by increasing antigen trafficking and mucosal immune dysregulation.

Materials and methods: We induced chronic colitis by administration of low-dose DSS (two cycles of 2% DSS in drinking water with a two-week interval) to TCR transgenic BDC2.5XNOD mice that carry the rearranged TCR alpha (Valpha1) and beta (V beta 4) chain of a diabetogenic BDC2.5 T cell clone and do not normally develop autoimmune diabetes even if 90% of their T cell repertoire is constituted of islet-reactive T cells. In this chronic colitis model we studied modification of mucus layer structure by histological analysis and mucin protein barrier composition by RT-PCR. Moreover, we analyzed the activation state and cytokine-secretion phenotype (intracellular FACS analysis) of the diabetogenic T cell clone within the gut mucosa, pancreatic lymph nodes (PLN) and intra-islet lymphocytes (IIL) of BDC2.5XNOD mice with or without DSS-colitis. Incidence of T1D was assessed by weekly measurements of glycemia and microbiota composition by 16S rRNA analysis on the Illumina HiSeq2000 platform.

Results: Our data show that DSS-induced breakage of the mucus layer and alteration of mucin barrier composition lead to intestinal activation of islet-specific T cells within the gut mucosa and occurrence of autoimmune diabetes in TCR transgenic BDC2.5XNOD mice. Specifically, we found that loss of mucus barrier integrity with increased expression of pro-inflammatory mucin MUC-4 and reduction of immune-regulatory mucin MUC-1 leads to immune dysregulation with increased activation and effector phenotype of diabetogenic T cells in the gut mucosa, PLN and IIL. The presence of the microbiota is necessary for islet-reactive T cell activation in those mice thus suggesting the physical interaction between islet-reactive T cells and microbial antigens is required for triggering islet-reactive T cells within the gut mucosa.

Conclusion: Our data demonstrate that gut inflammation is not an epiphenomenon in T1D pathogenesis but it is directly responsible for triggering islet-reactive T cell activation by disrupting the mucus barrier integrity and favoring the interaction between microbiota components and islet-reactive diabetogenic T cells.

Beta cell expression of interleukin-35 attenuates autoimmune diabetes and allograft rejection

S. Alvarez[1,2], L. Bischoff[1,2], M. Keene[1], P.C. Orban[3,2], B.C. Verchere[3,2];
[1]Pathology & Laboratory Medicine, University of British Columbia, [2]BC Children's Hospital Research Institute, [3]Surgery, University of British Columbia, Vancouver, Canada.

Background and aims: Interleukin-35 (IL-35) has recently been identified as a cytokine expressed by T regulatory cells and B cells, with the ability to suppress conventional T cell proliferation and effector functions. Transgenic beta-cell expression of IL-35 protects non-obese diabetic (NOD) mice from autoimmune diabetes, with decreased insulitis and a reduction in infiltrating [or insulitic] CD4+ and CD8+ T cells. We sought to determine whether a gene therapy approach could be used to express IL-35 for prevention of autoimmune diabetes and protection against islet allograft rejection.

Materials and methods: We generated an adeno-associated virus serotype 6 expressing IL-35 downstream of the rat insulin promoter (AAV6-RIP-IL-35) to express IL-35 specifically in beta cells. NOD mice received AAV6-RIP-IL-35 (or AAV6-RIP-empty, as control) via injection into the pancreatic duct at 6 weeks of age. Beta-cell specific expression of IL-35 was confirmed by quantitative real-time PCR and immunofluorescence. To assess allograft rejection, Balb/c donor mice were given AAV-RIP-IL-35 (or AAV-empty) by pancreatic duct injection, and their islets isolated 3 weeks later and transplanted under the kidney capsule of streptozotocin-diabetic C57Bl/6 recipients. Blood glucose was measured weekly to monitor diabetes development and allograft rejection.

Results: Beta cell expression of IL-35 in NOD mice from 6 weeks of age prevented diabetes development compared to mice that received empty virus and untreated controls (0 % vs. 50% vs. 20% respectively, $p<0.05$). Peripheral beta cell-specific CD8+ T cells tended to be decreased in mice that received AAV6-RIP-IL-35. Allogeneic transplants of Balb/c IL-35-expressing islets into diabetic C57Bl/6 recipients had better survival than did empty control (33% vs 0% respectively; $p<0.05$).

Conclusion: These data demonstrate that beta-cell expression of IL-35 reduces diabetes incidence in NOD mice and protects against islet allograft rejection, suggesting that IL-35 may have therapeutic potential in autoimmune diabetes and islet transplantation.

Virus infections affect the activity of regulatory T cells in young children

T. Ruohtula[1], A. Kondrashova[2], J. Lehtonen[2], S. Oikarinen[2], J. Honkanen[1], J.K. Nieminen[1], A.-M. Hämäläinen[3], A. Peet[4], V. Tillmann[4], J. Ilonen[5], O. Niemelä[6], M. Knip[1], H. Hyöty[2], O. Vaarala[1,7];
[1]Clinicum, University of Helsinki, Helsinki, [2]School of Medicine, University of Tampere, Tampere, [3]Department of Pediatrics, Helsinki University Hospital, Jorvi Hospital, Espoo, Finland, [4]Department of Pediatrics, University of Tartu, Tartu, Estonia, [5]Immunogenetics Laboratory, University of Turku, Turku, [6]Laboratory Medicine and Medical Research Unit, Seinäjoki Central Hospital, Seinäjoki, Finland, [7]Respiratory, Inflammation and Autoimmunity, Innovative Medicine, AstraZeneca, Gothenburg, Sweden.

Background and aims: Virus infections have been implicated in triggering islet autoimmunity and type 1 diabetes. Incidence of type 1 diabetes (T1D) differs significantly between Finland and Estonia, two populations with similar genetic risk for T1D. We studied the hygiene hypothesis by comparing Tregs in peripheral blood samples and viral RNAs from stool samples of infants from these two countries with different standards of living.

Materials and methods: Subjects: A subgroup of children participating in the DIABIMMUNE (*Pathogenesis of type 1 diabetes: testing the hygiene hypothesis*) study. These index cases from Estonia and Finland (n=161; 85/76, Estonia and Finland, respectively) carried HLA-conferred T1D susceptibility. We studied with flow cytometry (FACS) samples from 3, 6, 12, 24, and 36 month old infants. We also performed RT-qPCR analysis of stool samples collected monthly, from ages one month to one year. (715 samples / 84 children). Methods: FACS analysis of Treg cell frequencies and FOXP3 protein expression was performed in whole blood samples (CD4, CD127, CD25, and FOXP3 Fluorecent mAbs). Virus mRNA expression was analyzed from a 10% stool suspension from the sample and viral RNA was extracted and reverse transcribed and amplified with RT-qPCR.

Results: The Treg (CD4+ CD127-/lo CD25+) frequencies and FOXP3 protein expression remained relatively stable during the first year of life and then, in both countries, decreased clearly. When analyzing FOXP3 expression, we found a population of Tregs expressing high levels of FOXP3 (TregFOXP3High) as a "tail" in the histogram. Estonian children had significantly more TregFOXP3High cells compared to the Finnish children at 3 months of age (p=0.0023; Mann Whitney U-test), but not at the other time points. Frequent virus infections before the age of 12 months were clearly associated with higher FOXP3 expression in Tregs at the age of 36 months (P=0.002). FOXP3 expression was higher in children with at least one virus infection within 60 days prior to Treg sampling (P=0.02). Infants with only Rhinovirus infections had more FOXP3 expression in Treg cells (P=0.032) than children without, in TregFOXP3High cells, a similar trend could be seen. Interestingly, Enterovirus infected infants had lower FOXP3 expression in Tregs (P=0.22) and, more significantly in TregFOXP3High cells at 60 days (P=0.018) and 30 days (P=0.003) prior to sampling. Infections that occurred more than 60 days before Treg sample was taken had no such effect.

Conclusion: Our data show that virus infections during the first year of life are associated with high FOXP3 expression in Tregs. The overall viral exposure was associated with increased Treg activity both near the infection (during the following 60 days), and at older age (age of 36 months). The results suggest that early virus infections may promote the function of immunoregulatory cells.

HERV-W-Env, an ancestral protein as novel therapeutic target in type 1 diabetes

S. Levet[1], J. Medina[1], J. Joanou[1], A. Demolder[1], N. Queruel[1], K. Reant[1], J. Dimier[2], R. Germi[3,2], J. Portoukalian[4], H. Perron[1];
[1]Geneuro Innovation, Lyon, [2]IBS, UMR 5075 CEA-CNRS-UGA, Grenoble, [3]Dep. of Virology, CHU, Grenoble, [4]Laboratoire des déficits immunitaires, University of Lyon, Lyon, France.

Background and aims: Human endogenous retroviruses (HERVs), known to represent 8% of the human genome, have been associated with several autoimmune diseases. In particular, the HERV-W family has been involved in the pathogenesis of Multiple Sclerosis (MS), a disease in which the envelope protein of HERV-W (HERV-W-Env) exerts immuno-inflammatory effects and promotes autoimmunity. These pathogenic properties have been shown to be mediated by TLR4, a receptor involved in innate immune response. As part of MS studies, cohorts of patients suffering from other autoimmune disorders have been assessed for the presence of HERV-W-Env protein in their sera. Only T1D patients were found to display significant HERV-W-Env expression in this pilot study, prompting further investigations on HERV-W-Env involvement in T1D pathogenesis.

Materials and methods: HERV-W-Env expression has been assessed in humans T1D patients and control individuals, in serum by ELISA, in PBMC by RT-qPCR and in pancreas by IHC. Macrophages infiltration in pancreas has been assessed through CD68 staining; HERV-W-Env and CD68 staining have been automatically quantified. In vitro properties of HERV-W-Env have been studied on primary human Langerhans islets, and *in vivo* effects have been evaluated in a transgenic mouse model expressing HERV-W-Env.

Results: We observed that HERV-W-Env protein is expressed in the sera of 60% of T1D patients (n=30 and $p < 0.0001$ vs controls), and that its RNA is upregulated in PBMC of 57% of T1D patients (n=23 and $p < 0.0001$ vs controls). An extensive immuno-histological study revealed that HERV-W-Env is also expressed in 75% of human T1D pancreas (n=20 and $p < 0.001$ vs controls). Quantification of HERV-W-Env and CD68 staining then revealed a significant correlation between HERV-W-Env expression within the pancreas and macrophages infiltrates ($p < 0.01$). Notably, this infiltration of macrophages was found in the exocrine pancreas ($p < 0.001$ vs controls), in accordance with recent studies supporting the importance of pancreatic exocrine abnormalities in T1D pathogenesis. This histological study further revealed that acinar cells is the cell type producing HERV-W-Env, raising the question of direct pathogenic effects on beta cells, which are known to expressed TLR4 receptor. To test this hypothesis, series of in vitro experiments on human primary Langerhans islets have been performed and revealed that insulin secretion is inhibited by HERV-W-Env in a dose dependent manner ($p < 0.01$ at 100ng/mL). Importantly, a treatment with a neutralizing monoclonal antibody allowed to maintain normal insulin secretion despite the presence of HERV-W-Env. We then developed and characterized a transgenic mouse model in which HERV-W-Env is expressed under the control of CAG promoter. In accordance with human histological data and *in vitro* results, transgenic mice also displayed immune cells infiltrates in their exocrine pancreas ($p < 0.01$), a feature associated with significant hyperglycemia ($p < 0.0001$) and decreased levels of insulin ($p < 0.05$).

Conclusion: Taken together, the combination of the pancreatic pro-inflammatory effects of HERV-W-Env and its direct inhibitory effects on insulin secretion indicates that HERV-W-Env is a potential pathogenic target in T1D, thus unveiling novel therapeutic perspectives.

OP 48 Nephropathy: new approaches

261

Evaluation of the effect of empagliflozin on improving hyperfiltration in diabetic nephropathy

Y. Sogawa, K. Kidokoro, A. Uchida, S. Itano, H. Nagasu, M. Satoh, T. Sasaki, N. Kashihara;

Kawasaki Medical School, Kurashiki, Okayama, Japan.

Background and aims: Diabetic kidney disease (DKD) is one of the most common vascular complications associated with diabetes mellitus (DM). Recently, sodium-glucose cotransporter 2 (SGLT2) inhibitor was reported to have renal protective effects. In the EMPA-REG OUTCOME trial, empagliflozin, which is a SGLT2 inhibitor, reduced the risk of cardiovascular events and suppressed the progression of DKD in type 2 DM patients. In this trial, the incidence of albuminuria occurred in 11.2% of the empagliflozin group and in 16.2% of the placebo group, which is a significant relative risk reduction. And this reduction also coincided with the reduction of estimated glomerular filtration rate (GFR). These results suggested that empagliflozin may reduce intraglomerular hyperfiltration such as renin-angiotensin system (RAS) inibitor. However, the molecular mechanism is unclear. We focused on tubuloglomerular feedback (TGF) and investigated by using in vivo imaging technique whether empagliflozin reduces the vascular tonus of the glomerular afferent artery via TGF activation.

Materials and methods: We used wild-type mice (WT; C57 BL/6 background) and type 1 diabetic Akita mice (Akita). We prepared five groups as follows: WT +Vehicle (Vehi), WT +Empagliflozin (5mg/kg; Empa), Akita +Vehi, Akita +Empa, and Akita +Insulin. The mice were sacrificed and blood and tissue samples were harvested after 4 weeks' treatment. Glomerular reactive oxygen species (ROS) and nitric oxide (NO) bioavailability were checked by an ex vivo study. To evaluated ROS and NO bioavailability, diaminofluorescein (DAF) and CellROX® Deep Red were perfused into the kidneys, and fluorescent images of NO and ROS were obtained using multiphoton microscope (MPM). Next, we established a new technique of intravital imaging to evaluate the single nephron GFR and any changes in the glomerular diameter and single nephron GFR were evaluated by using MPM before and 3 hours after the administration of hypoglycemic agents. Next, an nNOS inhibitor or a COX2 inhibitor was administered to these groups to inhibit vasodilator factors delivered from the macula densa. Finally, single nephron GFR were evaluated.

Results: The changing ratio in the diameter of a single nephron was decreased in the Akita +Empa group compared with the Akita +Vehi and Akita +insulin groups. Hyperfiltration was also decreased. Intra-glomerular ROS production was increased and intra-glomerular NO production was decreased in the Akita +Vehi group. These changes were improved in the Akita +Empa group much more than in the Akita +insulin group. More over these effects of Empa were impaired with administrations of nNOS inhibitor and COX2 inhibitor. These data indicated Empa could reduce glomerular hyperfiltration in DKD by activating TGF.

Conclusion: Empagliflizon improved glomerular hyperfiltration via TGF activation in DKD mice. The renoprotective effect of empagliflozin was, in part, independent of the plasma glucose.

DPP4 inhibitor reduces urinary albumin excretion through the protection of glomerular endothelial function

N. Hajime, A. Unhid, Y. Sogawa, M. Satoh, T. Sasaki, N. Kashihara;

Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.

Background and aims: Diabetic nephropathy is a major microvascular complication of diabetes and a leading cause of end-stage renal disease. Recently, inhibitors of type 4 dipeptidyl peptidase (DPP-4) have been developed and approved for the oral treatment of diabetes mellitus (DM). In TECOS and SAVOR trials, DPP-4 inhibition did not reduce cardio-vascular events. However several pre-clinical studies suggested that DPP-4 inhibition not only reduces plasma glucose levels but also reduces the risk of cardio-vascular events (CVE) and shows kidney protection. We hypothesize that the DPP-4inhibitor linagliptin has the potential to prevent glomerular endothelial dysfunction beyond the reduction of plasma glucose levels.

Materials and methods: To prove our hypothesis, we used wild type mice (WT) and Akita diabetic model mice, which have a C57BL/6 genetic background. The mice were divided into three groups (Con, Akita, and Akita-Lina). Linagliptin (5 mg/kg/day) or PBS was administrated beginning at six weeks and continuing to 14 weeks of age. Blood samples were collected to determine HbA1c. Kidney tissues were harvested after sacrifies. Urine samples were collected 24 h before sacrifice. Urinary albumin and creatinin were quantified and expressed as the ratio of albumin to creatinine. Urinary 8-OHdG was detected by ELISA to assess the redox status in the kidney. Glomerular hyperfiltration was assessed using intravital microscopy. Data were expressed as mean ±s.e.m. Differences between the groups were assessed for statistical significance using one-way analysis of variance for multiple groups. Statistical significance was defined as $P<0.05$.

Results: The HbA1c levels in the Akita mice were same as those in the Akita-Lina (HbA1c 10.8 ±0.12% in Akita and 10.3 ± 0.17 % in Akita-Lina mean ±S.E.M.), while urinary albumin excretion/creatinin levels were significantly reduced in the Akita-Lina mice compared with the Akita (100.4 ± 14.6 mg/g in Akita and 56.5 ± 4.2 mg/g in Akita-Lina, $P<0.05$). This suggests that the DPP4 inhibitor can reduce urinary albumin excretion beyond lowering blood glucose effects. Glomerular size which is indicated for hyperfiltration in the Akita mice was larger than in the Akita-Lina mice (127 ± 2.7% in Akita and 116 ± 2.6% in Akita-Lina, $P<0.05$). Next, we addressed the endothelial surface layer, which can be detected with tomato lectin. The lectin staining areas remained more prevalent in the Akita-Lina than in the Akita mice. However Podocyte injury which is detected by podocin staining were not differ in Akita and in Akita-Lina. Next, we used intravital microscopy to assess glomerular filtration. Leakage of FITC-labeled dextran into the Bowman's capsule space was undetectable in the WT and Akita-Lina mice, whereas it was detectable in the Akita. Finally, we addressed oxidative stress, which is one of the most likely mechanisms to explain how the DPP-4 inhibitor attenuates glomerular hyperfiltration. Urinary 8-OHdG levels normalized to creatinine were significant lower in the Akita-Lina than in the Akita mice (30.3 ± 3.5 ng/g in Akita and 20.5 ± 1.5 ng/g, in Akita-Lina $P<0.05$).

Conclusion: Linagliptin reduces urinary albumin excretion beyond blood glucose lowering effects. These data suggest that linagliptin is a potential new drug to treat diabetic nephropathy via the prevention of endothelial dysfunction.

Renal outcomes with DPP-4 inhibitors compared with sulfonylurea as add-on to metformin among patients with type 2 diabetes

H.H. Teh[1], U. Desai[2], N.Y. Kirson[2], M. Hellstern[2], P.S. Leigh[3], J. Mukherjee[4], K. Khunti[5];

[1]AstraZeneca, Gaithersburg, [2]Analysis Group, Inc., Boston, USA, [3]AstraZeneca, Cambridge, UK, [4]Bristol-Myers Squibb, Wallingford, USA, [5]University of Leicester, Leicester, UK.

Background and aims: Prior studies have demonstrated that compared with placebo, dipeptidyl peptidase-4 inhibitors (DPP-4i) may be associated with nephro-protective effects among people with type 2 diabetes (T2D) who also have mild to moderate renal impairment. This study compared the renal outcomes between patients with T2D using DPP-4i versus sulfonylurea (SU) as an add-on to metformin (MET) in the UK.

Materials and methods: Patients aged 18-79 years diagnosed with T2D who used MET only prior to initiating DPP-4i or SU in 2007-2014 were selected using the UK Clinical Practice Research Datalink. The first record with DPP-4i or SU in addition to MET after MET monotherapy was the index event.

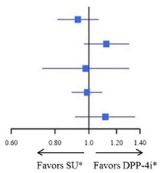
Patients were required to have ≥1 valid test result for ≥1 of the following tests during the 6 months before (baseline) and ≥12 months after (follow-up) the index date: urine albumin and urine creatinine reported separately or urine albumin-creatinine ratio (UACR), or urine microalbumin; serum creatinine (SCr), or estimated glomerular filtration rate (eGFR). Multivariate Cox proportional hazard models were used to compare incidence of the following outcomes: microalbuminuria, UACR <30 mg/day, doubling of SCr, worsening of kidney function (eGFR <60 mL/min/1.73m^2), and decrease in eGFR by ≥25% for at least 12 months after index. Models were adjusted for: age, gender, body mass index, baseline HbA1c, Charlson comorbidity index (CCI), duration of monotherapy, duration of diabetes, year of index date, baseline UACR/SCr/eGFR level (depending on the outcome), and use of antihypertensive agents or statins.

Results: Of the 23,341 patients included in the sample, 5,757 (24.6%) were DPP-4i users. Compared with SU users, DPP-4i users were significantly (p<0.05) younger (58.6 years vs. 59.7 years), were less likely to be men (60.2% vs. 62.1%), had lower mean HbA1c level (8.7% [71.6 mol/mol] vs. 9.1% [76.0 mmol/mol]), and had lower CCI (0.49 vs. 0.58) during baseline. The DPP-4i cohort had better renal function during baseline, as indicated by lower mean UACR (44.1 vs. 49.8) and SCr (79.4 vs. 87.1) levels, and higher eGFR (81.9 vs. 78.9 mL/min/1.73m^2). After adjusting for differences in patient characteristics, there was no statistically significant association between treatment cohort and incidence of any renal outcome during the follow-up period (Figure 1).

Conclusion: The findings of this study suggest that DPP-4i and SU have comparable effects on renal outcomes as add-on therapy among patients with T2D.

Figure 1: Likelihoods of incident microalbuminuria, UACR <30 mg/day, doubling of SCr, worsening of kidney function, and decrease in eGFR by ≥25% for at least 12 months after index among T2D patients using SU compared with DPP-4i

Outcome	Hazard ratio (SU relative to DPP4i)	95% CI	P-value
Microalbuminuria	0.93	0.81 - 1.07	0.2968
Improvement in albumin to <30 mg/day	1.12	0.97 - 1.30	0.1224
Doubling of SCr	0.98	0.74 - 1.30	0.8881
Worsening kidney damage	0.99	0.89 - 1.09	0.8075
Sustained decreases in eGFR ≥ 25%	1.11	0.92 - 1.36	0.2781



Notes:
*Except for 'improvement in albumin to <30 mg/day' where HR >1 indicates better outcome with SU than DPP-4i. DPP-4i users were the reference cohort for all comparisons.
CI = confidence interval; DPP-4i = dipeptidyl peptidase-4 inhibitor; eGFR = estimated glomerular filtration rate; SCr = serum creatinine; SU = sulfonylurea; T2D = type 2 diabetes; UACR = urine albumin-creatinine ratio.

Nephroprotective properties of vildagliptin and metformin combination in randomised, comparative, prospective clinical study

V. Bayrasheva[1,2], A. Babenko[1,2], I. Pchelin[3], A. Arefjeva[2], S. Chefu[1,2], A. Ivanova[3], P. Andoskin[1], A. Bairamov[1], I. Shatalov[4], E. Grineva[1,2];
[1]Federal Almazov North-West Medical Research Centre, [2]Pavlov First St. Petersburg State Medical University, [3]Saint Petersburg State University, [4]Saint Petersburg National Research University of Information, Technologies, Mechanics and Optics, Saint Petersburg, Russian Federation.

Background and aims: Accumulating evidence suggests that the modulation of incretin signaling is beneficial in both glycemic control, as well as nephroprotection. Metformin has been reported to inhibit DPP-4 and stimulate GLP-1 secretion. Thereby, DPP-4 inhibitor vildagliptin in combination with metformin could additively improve glycemic control and metabolic status in type 2 diabetes (DM2) with attractive therapeutic option in regard to diabetic nephropathy (DN). A randomized comparative study assessed the effect of the combination of vildagliptin in daily dose 50 mg and metformin in daily dose 1500 mg added-on insulin therapy on renal function in type 2 diabetic patients.

Materials and methods: We investigated the dynamic of metabolic parameters, estimated GFR using creatinine (eGFRcr) and cystatin C(eGFRcys), UACR, and excretion of liver-type fatty acid binding protein (L-FABP) in 43 insulin-treated near-compensated patients with normal/mildly impaired renal function (CKD C1-2,A 1-2) randomizing either to continue insulin therapy (IG group, n=21), or to receive 6-month combined vildagliptin and metformin treatment added to insulin (VMIG group, n=22). Main non-inclusion criteria were allergy to metformin/vildagliptin, severe micro-/macrovascular complications of DM2, non-diabetic renal diseases, nephrotoxic drugs usage, uncontrolled hypertension/ dyslipidemia, inflammatory/oncological conditions.

Results: The mean age of patients in IG group was 60.1 ± 6.13 years, in VMIG - 63.7 ± 4.21 years, p=0.032, and majority were women (about 60 %). Duration of DM2 was approximately 10 years. Albuminuric stage of DN was present in 42.9 % of participants in IG group and in 54.6% in VMIG group, p=0.048. eGFR, UAER level, and main assessed metabolic parameters were comparable in both groups. After 6 months, there were no significant changes in main assessed parameters in IG group. VMIG group showed significant decrease in HbA1c (-5.5 %, from 7.2 ± 0.5% до 6.8 ± 0.7 %, p=0.0003), fasting plasma glucose (-12.9 %, from 6.9 ± 1.5 to 6.0 ± 1.22 mmol/l, p=0.014), and blood triglycerides (-21.4 %, from 2.2 ± 1.4 to 1.76 ±0.75 mmol/l, p=0.016) compared to IG group. Whiles eGFRcr and eGFRcys in VMIG group did not significantly change (eGFRcr +1.2 % from 76.4 ± 13.1 ml/min/1.73 m^2), UACR and urinary L-FABP decreased significantly (-11.8 % (from 33.7 [17.5;84.0] to 27.4 [16.5;63.9] mg/g, p=0.019) and -7.3% (p=0.028), respectively. Multivariate regression analysis revealed glucose- and metabolic-independent pattern of UAER changes. However, the dynamic of L-FABP in VMIG group was correlated with dynamics of fasting blood glucose (r = - 0.58, p=0.004) and triglycerides (r=0.66, p=0.001).

Conclusion: The study showed that 6-month combined vildagliptin and metformin treatment added on insulin therapy in near-compensated type 2 diabetic patients demonstrated nephroprotection regarding albuminuria and urinary excretion of tubular injury marker L-FABP. Moreover, UAER decreased beyond normalization of DM2 compensation parameters

Relative contributions of fasting and postprandial glycaemia to HbA_{1c} among persons with normal, pre-diabetes and diabetes HbA_{1c} levels

K. Faerch[1], M. Alssema[2], D. Mela[2], R. Borg[3], H. Zheng[4], D. Nathan[4], D. Vistisen[1];
[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark, [2]Unilever Research and Development Vlaardingen, Vlaardingen, Netherlands, [3]Roskilde University Hospital, Roskilde, Denmark, [4]Massachusetts General Hospital, Boston, USA.

Background and aims: Lowering of postprandial glucose (PPG) is physiologically relevant for patients with diabetes, and possibly also beneficial for reducing diabetes risk in the general population. However, the contributions of PPG and fasting glucose (FG) to the HbA_{1c} level are not clear. We aimed to quantify the relative contribution of real-life PPG versus FG levels to HbA_{1c} among persons with different glycaemic status.

Materials and methods: Data from 80 individuals without diabetes and 94 non-insulin-treated patients with type 2 diabetes from the A1c-Derived Average Glucose Study were used. Continuous glucose monitoring in periods of at least two days and measurement of HbA_{1c} were performed at baseline and monthly over 3 months. PPG was estimated as the area under the curve 2 hours after meal intake. The study participants were sub-dived into groups with HbA_{1c} levels in the normal (<39 mmol/mol, n=86), pre-diabetic (39-47 mmol/mol, n=48) and diabetic range (≥48 mmol/mol, n=40). Associations of HbA_{1c} with FG and PPG were analysed by linear regression stratified by HbA_{1c} groups and adjusted for age, sex and BMI. In linear regression analysis using the same three HbA_{1c} groups, we calculated the proportion of variance in HbA_{1c} explained by PPG and FG.

Results: Each 1 SD higher level of FG (1.8 mmol/L) was associated with HbA_{1c} levels which were 1.8 (0.3-3.4), 2.1 (1.1-3.0), and 6.8 (4.6-9.0) mmol/mol higher among individuals with HbA_{1c}<39, 39-47, and ≥48 mmol/mol, respectively (P<0.05). Each 1 SD higher PPG (1.3 mmol/L) was associated with HbA_{1c} levels which were 1.5 (0.3-2.6) and 1.0 (0.2-1.7) mmol/mol higher in individuals with HbA_{1c}<39 and 39-47 mmol/mol, respectively (P<0.05). Among individuals with HbA_{1c}≥48 mmol/mol, PPG was not associated with HbA_{1c} (P=0.985). The figure shows the proportion of variance in HbA_{1c} explained by FG and PPG by categories of HbA_{1c}. Proportions are scaled to the total proportion of variance explained by FG and PPG combined.

Conclusion: Using real-life data, the relative contribution of FG to HbA_{1c} increases as HbA_{1c} levels increase from normoglycaemic levels to pre-diabetic and diabetic levels. The contribution of PPG is less, but most apparent in the non-diabetic HbA_{1c} range. These findings suggest that a reduction in PPG may be most advantageous for glycaemic control among healthy individuals and well-regulated type 2 diabetes patients with HbA_{1c} levels in the normal and pre-diabetic range.

Association of HbA_{1c} values with haemopoietic parameters in a selected population of healthy individuals

D. Tsilingiris[1], K. Makrilakis[1], E. Voskaridou[2], S. Pagkrati[1], S. Liatis[1];
[1]First Propaedeutic Internal Medicine Department, [2]National Center of Thalassemia and Hemoglobinopathies, Athens Medical School, Athens, Greece.

Background and aims: Glycated hemoglobin (HbA_{1c}) values are influenced by a number of factors other than glucose concentration, those implicated in erythropoiesis being of critical importance. In previous studies, HbA_{1c} levels have been associated with markers such as hemoglobin, erythrocyte indices (MCV, MCH) and red cell distribution width (RDW) in individuals with or without diabetes mellitus. However, in these observations, subjects with a variety of hemopoietic defects that could potentially affect the overall results were usually included. This study aims to determine the association of HbA_{1c} levels with erythrocyte indices in a selected population of individuals without apparent hemopoietic defects.

Materials and methods: A total of 88 individuals (43 males, 45 females, mean age 31.7 years) with no past medical history having a complete blood count within normal range, were examined. Apart from a complete blood count, a number of laboratory parameters, possibly contributing to HbA1c variance (hemoglobin electrophoresis for detection of hemoglobinopathies, fasting serum glucose [FSG], creatinine, fructosamine, albumin, hsCRP and ferritin) were measured. Statistical analysis was carried out using SPSS statistical package version 21.

Results: In univariable regression analysis, HbA1c levels were positively correlated to age (r= 0.25, p=0.020), body mass index (BMI) (r= 0.38, p<0.001), serum creatinine (r= 0.24, p=0.023) and RDW (r= 0.33, p=0.002). There was also a trend towards negative correlation between HbA1c and both MCH (r=-0.19, p=0.08) and MCV (r=-0.17, p= 0.10). Four multivariable linear regression models were created to examine the association of HbA1c (dependent variable) with: (1) hemopoiesis (hemoglobin, erythrocyte indices and ferritin), (2) glycaemia (FSG, fructosamine and BMI), (3) inflammation (hsCRP, serum albumin, ferritin) and (4) all the above. All models were adjusted for age, gender and serum creatinine. The RDW was the only hemopoietic parameter significantly associated with HbA1c, both in the first model (B=0.09, p=0.01) and in the fully adjusted model (B=0.08, p=0.02). In addition, BMI was the only other parameter that was significantly associated with HbA1c in the fully adjusted model (B=0.02, p=0.03).

Conclusion: Our study verified the independent correlation of HbA1c to RDW, this time however, in a healthy population with apparently normal hemopoietic function and glycaemic levels. This may indicate that slight interindividual variations of normal hemopoiesis project an effect on HbA1c values.

Disclosure: **D. Tsilingiris:** None.

Study of insulin and glucose parabolas and dysglycaemia timeline using oral glucose tolerance test

S.N. Shinde[1], R. Shinde[2];
[1]Medicine, Poona Hospital and Research Center, [2]Medicine, Sanjeevan Institute of Cardiology and Research, Pune, India.

Background and aims: Type 2 Diabetes (T2DM) is characterised by progressive loss of Beta cell Function (BCF) with varying degree of obesity. Need was felt to study the interrelation between these etiological factors.

Materials and methods: A cross sectional study of 600, not previously diagnosed diabetic individuals with 'standard two hours and 75 grams' oral glucose tolerance test with addition of insulin levels using the time points of 0, 30, 60 and 120 minutes. These subjects were further grouped into 14 categories, based on their fasting(FG) and 120-minute post-glucose(PG) values, such as ' NoDM, MatIR, HepIR, IFG, IR30, IR60, IR3060, IGT, IFG-IGT, DM-IFG, DM-IGT, DM-NFG, DM-NPPG and DM. These categories actually represented the various stages on the timeline of T2DM. These categories were further grouped into Fasting (n=107)(FP), Prandial (n=161)(PP), Overlap

(n=192)(OP) pathways depending on the values in FG-PG pair and their Homa1-IR and Matsuda Indexes. The parabolas of glucose and insulin for all the fourteen categories were analysed and their trend-lines were extrapolated till they met the baseline again. The data was used to prepare a timeline of events.

Results: In FP categories, fasting insulin (FI) and BMI values were significantly correlated. (P <.0002) The Insulin and glucose parabolas followed quadratic distribution rules. Hence, increment in FI lead to exponential rise in post-glucose insulin values and manifested as post-glucose-load hyperinsulinemia (HI). During the first hour secretory phase of OGTT, all categories except the diabetes category ('DM') showed positive incremental change with proportional HI. The rising trend of insulin secretion reverses when the pancreatic beta cell reserve is exhausted, that is when the 'BetaMax' is reached. During the second hour of OGTT, the FP categories show downward trend whereas the PP categories continue their upward secretory trend past two hours. However, the insulin secretory defect (ISD) results in proportionately lower rate of rise of insulin and results in longer time interval to return back to the basal fasting level. This interval was slightly more than two hours for the NoDM category and almost eight hours for the 'diabetes with Normal Fasting Glucose' (DM-NFG) category. The insulin and glucose parabolas are interdependent and are also linked to the insulinogenic index (IGI), Incremental Area Under the Curve of insulin as well as the disposition index (ISSI-2) and showed a very typical 'inverted tick mark' distribution. Using this data, it was possible to develop a new timeline showing the evolution of 'Lipo-Diabesity'.

Conclusion: Evolution of T2DM occurs mainly via the fasting and prandial pathways or an overlap of these two. The FP is associated with calorie excess (CE) and obesity whereas PP with ISD and BCF loss. A timeline of dysglycemia with glucose and insulin levels, ISSI-2, rising BMI and continued CE is proposed. Continued CE is suggested to explain the relentless progressive nature of diabetic dysglycemia.

Glucose energy spectrum as a function of dysglycaemia progression

P. Strange, L. Shi, M.F. Miller;
Integrated Medical Development, West Windsor, USA.

Background and aims: Glucose homeostasis is maintained physiologically by B-cell insulin secretion being sensitive to both absolute and increasing glucose concentrations. A glucose increase is rapidly followed by insulin secretion resulting in a fast return toward the baseline. With progression to Impaired Glucose Tolerance first or early phase insulin release diminishes and glucose return times become longer. In type 2 (T2) Diabetes Mellitus (DM) insulin secretory capacity is further compromised resulting in fasting glucose increases and prolonged elevated glucose following meals. In late type 1 (T1) DM insulin secretion is absent and glucose will continue to rise without exogenous insulin. As B-cells deteriorate glucose variability would thus be expected to increase and shift from fast to slower components. The total variability energy (TE) for a given 24 hour CGM curve f is defined as the area under the curve $(df/dt)^2$, or the summation over time of the glucose "velocity" (df/dt) squared. Using the finite Fourier transform, TE can be distributed across the cycles of oscillation, being the sum of the energy components for each of frequencies 1, 2, 3, .. per 24 hours describing successively faster glucose changes. This study summarizes the TE from the first 24 cycles, and the distribution of this energy by frequency over cycles 1 through 24, called the "glucose energy spectrum". Given the natural history outlined above and that we in the treatment setting measure the combination of the disease and the affected person's therapy, we predict TE would increase and shift to slower components through populations of normals, T2 DM on metformin only, T2 DM on insulin, well controlled T1 DM and finally pediatric T1 DM, reflecting more variability and slower glucose changes.

Materials and methods: Using baseline CGM profiles from 341 T1 and T2 DM subjects from 4 clinical trials, and a cohort of 25 normal subjects, the geometric mean TE's and corresponding energy spectra were estimated.

Results: Results as shown on the graph were consistent with the hypothesis. The mean TE for T2 DM was about double the corresponding mean TE for the normals, and even larger for T1 DM. The distribution of this energy, expressed as log(base 10) energy versus cycle, was similar for all DM, concentrated in slow cycles 3-5, while the normal energy peaked at cycles 16-20 resulting in a large mean frequency.

Conclusion: These results show the glucose energy spectrum reflects disease progression and may suggest DM therapy goals should include more rapid response to glucose changes in addition to lowering glucose.

Glycated haemoglobin is increased in critically ill patients with stress hyperglycaemia: implications for risk of diabetes in survivors of critical illness

Y.T. Du[1], P. Kar[2], Y. Ali Abdelhamid[2], M. Horowitz[1], A.M. Deane[2];
[1]Royal Adelaide Hospital, [2]The University of Adelaide, Adelaide, Australia.

Background and aims: Stress hyperglycaemia occurs frequently in critically ill non-diabetic patients and typically resolves. It remains uncertain if stress hyperglycaemia is indicative of a predisposition to the development of type 2 diabetes. Glycated haemoglobin (HbA1c) is a strong predictor of future diabetes risk, particularly with HbA1c values in the range 5.4 - 5.6% (36 - 38mmol/mol). The aim of this study is to determine if stress hyperglycaemia is associated with an increased HbA1c and, by inference, a greater risk of diabetes.

Materials and methods: This is a single centre retrospective observational study, performed at a mixed medical/surgical intensive care unit (ICU) in a tertiary hospital in Adelaide, South Australia. All adult patients admitted between March 2014 and November 2016 were screened for inclusion into the study. Patients with diabetes or HbA1c ≥ 6.5% (48mmol/mol) were excluded. Stress hyperglycaemia was defined as a blood glucose ≥11.1 mmol/l on at least two occasions within a 24-hour period and/or having insulin administered via intravenous infusion for ≥ 2 hours for a blood glucose ≥10.0 mmol/l in patients without a history of diabetes. Patients who did not meet the criteria for stress hyperglycaemia were classified as normoglycaemic. HbA1c was measured in all patients between March and September 2014 and, thereafter, only on patients identified with stress hyperglycaemia until November 2016. The difference in HbA1c between the two groups was tested using an independent samples t-test. Multiple linear regression was used to adjust for differences in sex, age and illness severity (APACHE II score).

Results: Stress hyperglycaemia was identified in 63 of 631 patients without diabetes from March to September 2014, with the remaining 568 patients classified as normoglycaemic. A further 136 patients with stress hyperglycaemia were identified between September 2014 to November 2016 for a total of 199 patients with stress hyperglycaemia. There was no difference in age or sex between the two groups. Patients with stress hyperglycaemia had a higher HbA1c (5.57 ± 0.48% (37.4 ± 5.3 mmol/l) vs 5.45 ± 0.46% (36.1 ± 5.0mmol/l), P = 0.001), greater illness severity (APACHE II score 19.5 ± 6.8 vs 16.2 ± 6.7, P < 0.001), longer hospital length of stay (17.3, IQR: 10.6 - 36.6 days vs 13.3, IQR: 7.2 - 23.7 days, P < 0.001) and higher in hospital mortality (17.1% vs 10.2%, P = 0.01) compared to normoglycaemic patients. After adjusting for sex, age and illness severity, HbA1c was 0.14% ± 0.038 (1.5 ± 0.4 mmol/mol, P=0.001) higher in stress hyperglycaemia patients.

Conclusion: Stress hyperglycaemia is associated with increased HbA1c, indicative of an increased risk of incident type 2 diabetes.

Effect of resveratrol on glucose control and insulin sensitivity in subjects with type 2 diabetes: a systematic review and meta-analysis

X. Zhu[1], C. Wu[1], L. Li[1,2];

[1]Medical School of Southeast University, [2]Department of Endocrinology, Affiliated Zhongda Hospital of Southeast University, Nanjing, China.

Background and aims: Although the regular consumption of polyphenol resveratrol has been considered to improve glucose homeostasis and reverse insulin resistance in type 2 diabetes mellitus (T2DM), the reported results are conflicting. The aim of this systematic review was to assess the effects of resveratrol on glycemic control and insulin sensitivity in patients with T2DM.

Materials and methods: A literature search was conducted of PubMed, the Cochrane Library and Web of Science through the reference lists of relevant articles until March 2017. Randomized controlled trials in T2DM patients in whom resveratrol were administered as an intervention were included. Using random or fixed effect model, standardized mean differences across trials were calculated for changes in fasting plasma glucose, fasting insulin, glycated hemoglobin A1c (HbA1c) and homeostasis model assessment of insulin resistance (HOMA-IR). We performed subgroup and sensitivity analyses to evaluate potential heterogeneity. Two reviewers independently selected trials, extracted data, and evaluated the methodological qualities and evidence levels.

Results: Nine randomized controlled trials involving 283 participants were included. Meta-analysis showed resveratrol significantly improved fasting plasma glucose [standardized mean difference (SMD)= -0.29, 95% confidence interval (CI): -0.51, -0.06, p = 0.013], fasting insulin (SMD = -0.64, 95% CI: -0.95, -0.32, p = 0.000), reduced HOMA-IR index(SMD = -0.52, 95% CI: -1.00, -0.04, p = 0.000), systolic blood pressure (SMD = -0.58, 95% CI: -0.86, -0.30, p = 0.000), diastolic blood pressure (SMD = -0.43, 95% CI: -0.70, -0.15, p = 0.003) in participants with T2DM. Changes in HbA1c, low-density lipoprotein cholesterol and high-density lipoprotein cholesterol were negligible. A subgroup analysis comparing resveratrol supplementation dose of <100mg/d versus ≥100mg/d, exhibited a significant difference for fasting plasma glucose in favor of the latter subgroup.

Conclusion: The consumption of resveratrol appears to have a beneficial role in the management of T2DM; however, larger, longer term and high-quality randomized controlled trials are needed to inform the development of evidence-based treatment guidelines.

The GLP-1RA exenatide LAR increases circulating miR-27b in patients with type 2 diabetes: an 8-month prospective study of cardiometabolic and epigenetic response

D. Nikolic[1], R.V. Giglio[1], R. Chianetta[1], C. Castruccio Castracani[2], V.A. Sardo[1], G. Castellino[1], A.M. Patti[1], C. Mannina[1], G. Li Volti[2], R. Citarrella[1], G. Montalto[1], A.A. Rizvi[3], M. Rizzo[1,3];

[1]Biomedical Department of Internal Medicine and Medical Specialties, University of Palermo, Palermo, [2]Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy, [3]Division of Endocrinology, Diabetes and Metabolism, University of South Carolina, School of Medicine, Columbia, USA.

Background and aims: The impact of once-weekly exenatide (long-acting release, LAR) on microRNAs (miRNAs), endogenous 21-25 nucleotides noncoding RNA, which regulate gene expression at the post-transcriptional level, is unknown. Specific miRNA-27b appears to exert pro-angiogenic effects on endothelial cells. We investigated whether exenatide LAR may improve expression of miRNA-27b and whether this effect is associated with the modulation of several evaluated cardio-metabolic parameters, including carotid intima-media thickness (cIMT), endothelial function and adipokines.

Materials and methods: Sixty subjects with T2DM (41 men and 19 women; 60±10 yrs) naïve to incretin-based therapies, were treated with exenatide LAR as add-on to metformin (from 1500 up to 3000 mg/day) for 8 months. Exclusion criteria included the presence of a previous major cardiovascular event, as well as moderate and severe renal and liver function. Fasting blood samples were collected at baseline and after 8 months. miRNA-27b was isolated from sera using the mirVana miRNA Isolation Kit (Ambion, Waltham, MA, USA), and then quantified by SYBR Green Real-Time (RT) polymerase chain reaction (PCR). cIMT was assessed by B-mode real-time ultrasound, while endothelial function by flow mediated dilation (FMD) of the brachial artery.

Results: Statistical analysis was performed by paired t-test and Spearman correlation. After 8 months of exenatide LAR therapy, significant improvements were observed in body weight (from 89±18 to 86±17 kg, p=0.0002), BMI (from 33±9 to 31±6 kg/m^2, p=0.0348), waist circumference (from 109±13 to 106±13 cm, p=0.0105), fasting glycaemia (from 8.8±2.8 to 7.3±2.2 mmol/L, p<0.0001), A1c (from 8.0±0.4 to 6.9±1.1 %, p<0.0001), total-cholesterol (from 4.4±0.9 to 4.2±1.0 mmol/L, p=0.0012), LDL-cholesterol (from 2.5±0.8 to 2.2 ±0.9 mmol/L, p<0.0001), HDL-cholesterol (from 1.2±0.3 to 1.3±0.3 mmol/L, p=0.0188), cIMT (from 0.98±0.14 to 0.87±0.15, p<0.0001) and FMD (from 5.8±1.3 to 6.8±1.7 %, p<0.0001). Adiponectin, leptin and resistin improved, although the statistical significance was achieved for adiponectin level only (3.6±2.7 to 4.3±2.9 μg/ml, p=0.0393). A cell adhesion molecule with a key role in endothelial function, soluble(s) L-selectin, improved significantly (from 0.49±0.17 to 0.55±0.22 μg/ml, p=0.0426). Levels of miR-27b were significantly increased after exenatide therapy (1.33 mean fold change, p=0.0355). By correlation analysis we found a significant association between changes in the miRNA-27b and those in adiponectin (r=0.269; p=0.0377), leptin (r=-0.307; p=0.0170) and L-selectin (r=0.436; p<0.0001), respectively.

Conclusion: Exenatide LAR, beyond cardio-metabolic control, may exert epigenetic effect in patients with T2DM by regulating miRNA-27b involved in the maintenance of endothelial cell homeostasis. A potential interplay between miRNA-27b and adipokines in endothelial angiogenesis seems to exist, however, further investigations are needed for better understanding.

Cell-free insulin and amylin DNA as biomarkers of progressive beta cell loss during first 12 months of type 1 diabetes in children and adolescents

N. Samandari[1], L.A. Kenna[2], P. Hougaard[3], L. Hansen[1], H.B. Mortensen[1], F. Pociot[1], E. Akirav[2];

[1]Paediatrics, Herlev University Hospital, Herlev, Denmark, [2]Winthrop-University Hospital Research Institute, Mineola, USA, [3]Research unit of Epidemiology, Biostatistics and Biodemography, Odense, Denmark.

Background and aims: DNA methylation can be used as a biomarker of beta-cell loss in type 1 diabetes (T1D). This study was designed to measure the levels of demethylated insulin and amylin DNA in the sera of children and adolescents with new onset T1D during the first 12 months post-diagnosis. In addition, these findings were associated with residual beta-cell function (stimulated C-peptide [SCP]), glycaemic control and glucagon.

Materials and methods: Serum samples drawn 3 and 12 months after diagnosis from 126 children and adolescents with new onset T1D were analysed. DNA was extracted and treated with bisulfite prior to methylation analysis. The methylation pattern for insulin DNA was measured with methylation sensitive probes using droplet digital PCR (ddPCR), while methylation specific primers were used to quantify amylin DNA using nested qPCR.

Results: An increase of the demethylated insulin DNA was observed in 46% samples, whereas 47% had declining values from three to 12 months after diagnosis. Amylin DNA demethylation index (DMI) increased in 52% and decreased in 48% of patients. Gender and age had no significant effect on the level of demethylated insulin DNA or amylin DMI. No correlation was found between demethylated insulin DNA and SCP, Glucagon, HbA_{1c} or $IDAA_{1c,}$ whereas amylin DNA was significantly associated with SCP at 12 months (p=0.016). Demethylated insulin was correlated with amylin DNA at 3 months (p=0.024) after diagnosis.

Conclusion: Circulating demethylated amylin DNA correlated with biomarkers of disease progression 12 months post-diagnosis whereas insulin DNA did not. These findings support the results of a previous report, which showed a loss of insulin but not amylin expression in beta cells following T1D presentation. The observation suggests that demethylated amylin DNA patterns may serve as more sensitive biomarker of beta-cell loss than demethylated insulin DNA during the first 12 months of T1D progression.

Insulin resistance, BMI and cholesterol levels associate with DNA methylation in human myoblasts from obese individuals

C. Davegårdh[1], C. Broholm[2], A. Perfilyev[1], T. Henriksen[3], P. Volkov[1], M. Pedersen[3], B.K. Pedersen[3], E. Nilsson[1], A. Vaag[4], C. Scheele[3], C. Ling[1];

[1]Epigenetic and Diabetes Unit, Clinical Sciences, Lund University, Malmö, Sweden, [2]Department of Endocrinology, Rigshospitalet, Copenhagen, [3]The Centre of Inflammation and Metabolism and the Centre for Physical Activity Research, Rigshospitalet, Copenhagen, Denmark, [4]Translational Medical Unit, AstraZeneca, Mölndal, Sweden.

Background and aims: Reduced skeletal muscle mass and insulin resistance are risk factors for type 2 diabetes (T2D). Skeletal muscle repair and maintenance are dependent on proper proliferation and differentiation (myogenesis) of muscle stem cells (satellite cells). Satellite cells from obese and T2D individuals show impaired glucose and lipid metabolism after in vitro differentiation, suggesting a memory of the in vivo environment. Recently, we mapped the DNA methylome and transcriptome in human myoblasts before and after differentiation into myotubes for the first time in a human cohort of controls and obese individuals. We showed that myoblasts from obese are epigenetically and transcriptionally reprogrammed. In the same dataset we observed that a number of CpG sites showed a high variability within only obese or non-obese. The obese population is heterogeneous and the current aim is to look at CpG sites with high variation in methylation in myoblasts from obese

individuals. We hypothesize that demographics associated with obesity, such as insulin resistance, BMI and physical activity, may contribute to this variation.

Materials and methods: Human satellite cells were isolated from vastus lateralis biopsies and the myoblasts harvested before being 50% confluent. DNA methylation was analyzed with the Infinium HumanMethylation450 BeadChip Kit in primary human myoblasts from 14 non-obese and 14 obese individuals. The relative standard deviation (RSD) (standard deviation/mean) was calculated for methylation of each CpG site in obese and non-obese, respectively. Methylation of CpG sites with a high RSD in only the obese group were correlated to the homeostatic model assessment of insulin resistance (HOMA-IR), BMI, plasma cholesterol levels and VO_2-max using spearman correlations.

Results: DNA methylation data were obtained for 477,226 CpG sites in myoblasts from 14 obese and 14 non-obese individuals. 41,538 CpG sites had an RSD of more than 30% in the obese group and 31 of these sites had an RSD of less than 10% in the non-obese group. The majority of the 31 sites (28) had a low degree of methylation (<17%) and 21 were annotated to CpG islands. Methylation of 5 of the 31 sites correlated significantly with HOMA-IR, 3 with BMI, 2 with LDL, 4 with HDL, and 1 with VO_2-max. Interestingly, several of these CpG sites are annotated to genes coding for transcription factors important for development and differentiation. For example, methylation of a CpG site in the gene encoding the anti-adipogenic factor GATA3 correlates with BMI and methylation of CpG sites in SOX5 and ONECUT1 correlate with both HOMA-IR and BMI.

Conclusion: This study shows that the variation in DNA methylation at a number of CpG sites increases with obesity and may be explained by differences in insulin resistance, BMI, cholesterol levels and physical fitness. The results implicate that several factors associated with obesity influence the DNA methylation pattern in primary human myoblasts and may contribute to the epigenetic and metabolic reprogramming observed during myogenesis in obese individuals.

Induction of permanent epigenetic changes in Treg signature genes after repeat BCG vaccination of subjects with type 1 diabetes

D.L. Faustman, W. Kuhtreiber, S. Plager, T. Kim, H. Zheng;

Immunobiology Laboratory, Massachusetts General Hospital, Charlestown, USA.

Background and aims: Increasing the potency or numbers of active regulatory T cells (Tregs) may be beneficial in the treatment of autoimmunity and is therefore a goal of many clinical trials. In a published study, BCG-treated subjects with type 1 diabetes (T1D) had statistically significant increases in Treg numbers for 4-6 weeks after repeat BCG vaccination. A longer-lasting effect would be optimal and may be able to stably reverse diabetic autoreactivity. Chronic Mycobacteria infections evade host recognition on a cellular level via measurable Treg increases and induction of host Tregs. For BCG's virulent counterpart, tuberculosis, epigenetic imprinting of host genes is a mechanism for host Treg production and infection chronicity. We therefore investigated if the effect of repeat BCG vaccinations on Tregs could be permanent and driven by host epigenetic modifications to Treg signature genes.

Materials and methods: BCG's impact on methylation was studied at methylation sites on 6 Treg signature genes (Foxp3, TNFRSF18, IL2RA, IKZF2, IKZF4, CTLA4) by profiling transcriptional start site (TSS) clusters located within the Treg-specific demethylation region in T1D subjects before and 8-weeks after in vivo BCG dosing.

Results: BCG induced demethylation at almost all TSS in all 6 signature genes. In vivo documented epigenetic changes correlated with increased mRNA expression of all 6 Treg signature genes in isolated CD4 T cells.

Conclusion: Overall, repeat BCG vaccinations reset the immune system by consistent and rapid demethylation of all 6 key Treg genes for enhanced mRNA expression, as monitored via CD4 T cells in blood from BCG-treated T1D subjects. This suggests that not only are Treg cell numbers transiently elevated after BCG vaccination, but also that permanent epigenetic expression of Treg genes that control Treg potency is stably re-established by BCG treatment. BCG vaccination, like tuberculosis, powerfully modulates Treg induction. Studies are underway to follow vaccinated T1D subjects for long-term beneficial clinical effects of Treg upregulation by BCG.

Epigenetic modifications of the ZNF423 gene control adipogenic commitment and are dysregulated in human hypertrophic obesity

M. Longo[1], F. Zatterale[1], S. Formisano[1], G.A. Raciti[1], A. Hammarstedt[2], S. Hedjazifar[2], J.M. Hoffmann[2], U. Smith[2], F. Beguinot[1];

[1]URT-GDD, National Council of Research, Department of Translational Medical Sciences, Federico II University of Naples, Naples, Italy, [2]Lundberg Laboratory for Diabetes Research, Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Background and aims: Subcutaneous adipocyte hypertrophy (SAT) is associated with insulin resistance and increased risk of type 2 diabetes (T2D) and predicts future development of T2D independent of obesity. In humans, SAT hypertrophy is a consequence of impaired adipocyte precursor cell recruitment into the adipogenic pathway rather than lack of precursor cells. Recently, the zinc-finger transcription factor Zfp423 was identified as a major determinant of preadipocyte commitment and maintained white adipose cell function. While its levels do not change during adipogenesis, ectopic expression of Zfp423 in non-adipogenic cells is sufficient to activate Pparγ expression and to increase the adipogenic potential of these cells. Here, we have investigated whether the Zfp423 gene is under epigenetic regulation and whether this plays a role in the restricted adipogenesis associated with hypertrophic obesity.

Materials and methods: 3T3-L1 and NIH-3T3 cells were used as fibroblasts committed and uncommitted to the adipocyte lineage, respectively. Human preadipocytes were isolated from the Stromal Vascular Fraction (SVF) of SAT of 20 lean non-diabetic individuals characterized by a wide adipose cell size range. mRNA levels were measured by Real-time PCR, while methylation levels were analyzed by bisulfite sequencing. Chromatin structure was analyzed by Micrococcal nuclease protection assay and DNA-methyltransferases were chemically inhibited by 5-azacytidine (AZA). Adipocyte differentiation rate was also evaluated by Oil Red O staining.

Results: Comparison of uncommitted (NIH-3T3) and committed adipose precursor cells (3T3-L1) revealed that *Zfp423* expression is increased in parallel with the ability of the cells to differentiate into mature adipocytes due to both decreased promoter DNA methylation and nucleosome occupancy in the 3T3-L1 compared to NIH-3T3 cells. Interestingly, non-adipogenic epigenetic profiles can be reverted by treatment of NIH-3T3 cells with 5-Azacytidine (AZA), as AZA increases *Zfp423* mRNA levels, reduces DNA methylation at a specific CpG site, decreases its nucleosome occupancy and induces adipocyte differentiation. These epigenetic modifications can also be initiated in response to changes in the adipose cell microenvironment, and where BMP4 plays a key role. We finally show that, in human adipocyte precursor cells, impaired epigenetic regulation of the *ZNF423* (human ortholog of the murine *Zfp423*) is associated with inappropriate subcutaneous adipose cell hypertrophy. As in the NIH-3T3 cells, normal *ZNF423* epigenetic profile can be rescued by AZA exposure.

Conclusion: Our results show that epigenetic events regulate the ability of precursor cells to commit and differentiate into mature adipocytes by modulating the *ZNF423* gene and indicate that dysregulation of these mechanisms accompanies SAT hypertrophy in humans.

Asymmetry in fingerprints as an early indicator of type 2 diabetes

J.H. Shubrook[1], B. Ludwar[2], R. Mullin[1], S.M. Holayel[2], C. Young[1], M. Morris[3];

[1]Touro University California, Fairfield, [2]Longwood University, Farmville, [3]Ohio University Heritage COM, Athens, USA.

Background and aims: Early screening tools, coupled with an effective intervention, could help reduce the growing problem of type 2 diabetes mellitus. Current models for determining risk of T2DM include phenotypic characteristics and are based on characteristics that are often manifested after the development of hyperglycemia (high BMI, waist circumference). Models that incorporate genetic variants can provide insights into risk prior to the development of associated health problems. However, the costs involved for the models that involve genetic testing can be prohibitive. Fingerprints form during gestation, and are potentially influenced by the same environmental factors that influence the expression of genes involved in T2DM. In a previous study in Southeastern Ohio (100% White/Caucasian; 165 prints), asymmetry scores for finger pairs IV and V significantly predicted T2DM controlling for gender and age. In this study we tested the hypothesis that fluctuating asymmetry in fingerprints can be used as an early predictor of T2DM by assessing asymmetry scores for each finger pair using a wavelet-based analysis in an ethnically diverse population from Northern California.

Materials and methods: The study population was recruited from a series of public health primary clinics that provided a focused diabetes consultation service. The participants were eligible if they were adults (18 years or older) and had medically confirmed type 1 diabetes, type 2 diabetes, or were above the age of 40 and had no personal or family history of type 2 diabetes, metabolic syndrome, PCOS or any insulin resistant condition. People with chromosomal syndromes (Down's, Turner's, Klinefelter's), cleft palate or those with cystic fibrosis were also excluded. Rolled fingerprints were collected at the time of medical care using a Crossmatch Verifer 320 LC scanner at a resolution of 500 ppi and 256 level grayscale. The prints of all fingers on both hands were stored as uncompressed digital images on a dedicated laptop with encryption. The fingerprints were scored for similarity between corresponding fingers on each hand using a wavelet-based analysis.

Results: This study population (n=64) was a more ethnically diverse population (41% White/Caucasian, 26.5% African American, 14.5% Asian American, 18% Hispanic). In the multivariate model that best fit our data (Likelihood Ratio Chi-square = 29.3, df = 12, P = 0.004), asymmetry in finger pair IV was significant (P = 0.036), as well as interactions between finger pair IV and ethnicity (P = 0.046) and finger pair IV and age (P = 0.040).

Conclusion: These results add additional support to the hypothesis that asymmetry in fingerprints has the potential to be a powerful, early predictor of propensity to develop T2DM. In addition, fingerprint asymmetry could compliment genetic studies to improve current understanding of the genetic and environmental interactions involved in T2DM.

Paternal exercise increased the susceptibility to develop type 2 diabetes by trigger an incapacity of beta cell to compensate insulin resistance

J.M. Costa-Júnior[1], S.M. Ferreira[1], G.J. dos Santos[1], M.A. Kurauti[1], E.G. Ruano[2], J.F. Vettorazzi[1], J. Schug[3], C.C. Zoppi[1], K.H. Kaestner[3], A.C. Boschero[1], C.A.M. de Oliveira[4], E.M. Carneiro[1];

[1]Department of Structural and Functional Biology, University of Campinas, Campinas, Brazil, [2]Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Barcelona, Spain, [3]Department of Genetics and Institute for Diabetes, Obesity and Metabolism, University of Pennsylvania Perelman School of Medicine, Philadelphia, USA, [4]Department of Biosciences, Federal University of Sao Paulo, Santos, Brazil.

Background and aims: The pancreatic beta cell failure is a hallmark in the type 2 diabetes development and susceptibility , and the risk to develop it is dependent on genetics and environmental factors. The epigenetic mechanism helps to explain the link between environment alterations and transcriptional activity. The effect of paternal endurance exercise training upon offspring pancreatic islet function as well as DNA methylation profile have not been investigated yet.

Materials and methods: Female were kept in sedentary conditions as well as half of male progenitors, whereas the other half was subjected to 10 weeks of endurance exercise training. During the last week of the exercise protocol, the progenitors were mated. At weaning, the offspring were kept on high fat diet and distributed into two groups: male offspring from sedentary progenitors (H) and male offspring from trained male progenitors (HT). We measured glucose and insulin tolerance, as well as pancreatic islet insulin secretion and, calcium influx. Gene expression was realized by Real-time PCR, and DNA methylation by BisPCR^2 on pancreatic islets of offspring. To analyze the data, we used students'-t test. $p \leq 0.05$

Results: The insulin resistance was worst in HT compared to H mice (1.8 ±0.51 %/min from K_{ITT} H vers. 0.8± 0.44 HT, $p \leq 0.05$). HT insulin secretion was lower than H mice (21±3.32 ng/mL H vers. 8.22 ± 5.54 HT, $p \leq 0.05$), which trigger a very high glucose intolerance compared to offspring from control fathers (2000±20.02 AUC H vers. 2700±32.90 HT, $p \leq 0.05$). The reduced glucose stimulated insulin secretion by isolated pancreatic islets observed in the offspring from trained fathers was also associated with reduced pancreatic islet calcium influx (7.53±1.33 AUC H vers. 5.44±1.78 HT, $p \leq 0.05$). Due to knew function of HNF4-a gene to control the beta cell capacity to adapt its function in the context of insulin resistance, we look at HNF4-a gene expression in the pancreatic islet from offspring fed on high fat diet, and as we expected the HNF4-a gene expression was reduced in the offspring from trained fathers (1.00±0.44 arbitrary unit (UA) H vers 0.50±0.32 HT, $p \leq 0.05$), and the DNA methylation level in the HNF4-a gene promoter was higher explaining, at least in part how paternal exercise may impact the pancreatic islet function and HNF-4a gene expression (0.8±0.02 UA H vers. 0.95±0.01 HT, $p \leq 0.05$).

Conclusion: Taken together, paternal exercise training seems to increased the susceptibility to develop type 2 diabetes through beta cell reprograming, probably by orchestrated HFN4-a gene expression through DNA methylation modifications.

Expression of leptin receptor gene in HUVECs related to degree and duration of intrauterine hyperglycaemia

P. Popova[1,2], L. Vasilieva[1], A. Tkachuck[1], M. Puzanov[1], Y. Bolotko[1], E. Pustozerov[1,3], A. Gerasimov[1], I. Zazerskaya[1], R. Dmitrieva[1], E. Grineva[1,2];

[1]Federal Almazov North-West Medical Research Centre, [2]Department of internal diseases and endocrinology, St Petersburg Pavlov State Medical University, [3]Saint Petersburg State Electrotechnical University, Saint Petersburg, Russian Federation.

Background and aims: Gestational diabetes mellitus (GDM) is associated with an increased incidence of type 2 diabetes and obesity in offspring. However, the mechanisms through which the GDM in the mother affects the development of these diseases in the offspring has not been studied thoroughly yet. The reason for those disorders can be either genetic predisposition or epigenetic influence of intrauterine hyperglycemia. One of the important regulators of energy homeostasis and the action of insulin is known to be leptin. Our aim was to study the effect of the degree and duration of maternal hyperglycemia on the level of expression of leptin and its receptor genes in HUVECs of newborns from women with gestational diabetes mellitus.

Materials and methods: The study included 22 women with GDM treated for GDM starting before 30-th week of gestation (GDM1), 6 women treated for GDM after 34-th week of gestation (late treatment group or GDM2) and 10 women without GDM (control group). All women underwent an OGTT at 24-28 weeks of gestation. The diagnosis of GDM was based on International Association of Diabetes and Pregnancy Study Groups criteria. HUVECs were isolated end expanded in vitro up to passage 2 and tested for viability and

replicative senescence. Samples with viability > 85% and low level of senescent cells (<10%) were used. Immunophenotype was determined by Flow Cytometry analysis. The level of genes expression was determined by RT-PCR. Women with GDM kept electronic nutrition and glycemic control diaries with the help of a specially developed mobile application and sent data to the doctor. According to the personal diaries automatic calculations of the integral indicators characterizing the self-control of glycemia (mean fasting and postprendial glycemia, the frequency of exceeding the target levels of glycemia) were accomplished. Statistical analysis included Kruskal-Wallace test, Mann-Whitney test and Spearman correlations.

Results: The increase in the expression of the leptin receptor (LEPR) gene in GDM2 group ($p < 0.001$) and in GDM1 group ($p = 0.039$) compared with the control group appeared to be 23.8 ± 6.8, 17.0 ± 3.7 and 4.5 ± 0.77, respectively. Notably, LEPR gene expression was higher in GDM2 than in GDM1 group though the difference didn't reach statistical significance (p= 0,1). The expression of the leptin gene was observed as below the detection threshold. Age and pregestational BMI did not differ among the groups. There was a positive correlation between the level of LEPR gene expression and the fasting blood glucose (BG) elevation rate above 5.3 mmol / L at 35 weeks gestation period ($r = 0.507$, $p = 0.032$), and the BG elevation rate above 7.0 mmol / L 1 hour postprandially at 35 weeks of gestation ($r = 0.488$, $p = 0.040$) and the value of 2 hour BG in OGTT ($r = 0.503$, $p = 0.004$).

Conclusion: The expression of LEPR gene in HUVECs of newborns was positively associated with the degree and duration of maternal hyperglycemia.

Correlation between circulating microRNAs and chronic kidney disease in patients with and without type 2 diabetes

K. Geiger[1], A. Muendlein[1], A. Leiherer[1], C.H. Saely[2], J. Ebner[1], E.-M. Brandtner[1], D. Zanolin[1], A. Vonbank[2], A. Mader[3], P. Schwerzler[3], P. Fraunberger[4], H. Drexel[5];

[1]Vorarlberg Institute for Vascular Investigation and Treatment (VIVIT), [2]Academic Teaching Hospital Feldkirch, Feldkirch, Austria, [3]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, [4]Medical Central Laboratory, Feldkirch, Austria, [5]Drexel University College of Medicine, Philadelphia, USA.

Background and aims: MicroRNAs (miRNAs) are small non-coding RNAs that usually function as intracellular repressors of target genes involved in many pathophysiologic processes. MiRNAs can also be detected outside cells including circulating cell-free body fluids. Circulating miRNAs have been proposed repeatedly in the literature as new attractive biomarkers in many diseases, including type 2 diabetes (T2DM) and chronic kidney disease (CKD). T2DM is closely linked to the development of CKD and it is unclear if putative associations between miRNAs and CKD differ in patients with or without T2DM.

Materials and methods: We therefore investigated the association between a panel of 40 candidate-miRNAs and CKD (based on estimated glomerular filtration rate) in 120 angiographied coronary patients with (n=65) and without (n=55) T2DM, respectively. P-values of less than 0.05 were regarded as statistically significant after correction for multiple testing.

Results: In the total patient cohort, miR-320a and miR-320b were significantly increased and miR-451a, miR-106b-5p, miR-25-3p, miR-20a-5p, miR-19b-3p, miR-16-5p, and miR-140-3p were significantly decreased in patients with CKD (corrected p-values ranging between 0.003 and 0.045). In the subpopulation of patients without T2DM associations between miR-451a, miR-106b-5p, miR-25-3p, miR-20a-5p, miR-19b-3p, miR-16-5p, and miR-140-3p and CKD were still significant (corrected p-values ranging between 0.011 and 0.039). In addition the association between miR-19a-3p and miR-99b-5p with CKD was significant in non-diabetic patients (corrected p-values = 0.039 and 0.021, respectively). None of the investigated miRNAs were significantly associated with CKD in patients with T2DM, at least after correction for multiple testing.

Conclusion: We conclude that numerous circulating miRNAs are significantly associated with CKD and that this association may be masked by the prevalence of T2DM.

Disclosure: **K. Geiger:** None.

Plasma circulating microRNAs: novel clinical parameters to monitor autoimmune disease progression in children with type 1 diabetes

P. de Candia[1], M. Galgani[2], M. Santopaolo[3], A. Franzese[4], E. Mozzillo[4], G. Matarese[2];

[1]Fondazione Multimedica Onlus, Milan, [2]Istituto per l'Endocrinologia e l'Oncologia Sperimentale "G. Salvatore" Consiglio Nazionale delle Ricerche, [3]Dipartimento di Biologia Molecolare e Biotecnologie Mediche, Università degli studi Federico II, [4]Centro Regionale di Diabetologia Pediatrica, Università degli studi Federico II, Naples, Italy.

Background and aims: Type 1 Diabetes (T1D) is an autoimmune disorder characterized by lymphocyte-mediated destruction of the insulin producing β cells of the pancreatic islets. Triggers of islet autoimmunity, the time course and the mechanism beyond the progressive β cell failure have not been completely clarified and we are in urgent need of novel biomarkers able to predict the rate of disease progression and to trace the progressive immune-mediated loss of insulin-secreting islet cells. One highly suitable source of blood-associated biomarkers is represented by extracellular microRNAs that, released by most cells in the body, reach the circulation, remain very stable, and may be used to assess cell activity at distance. Our published work shows that blood circulating microRNAs can be used as biomarkers of human lymphocyte activation in health and disease: in particular, our group has identified a specific microRNA signature that is massively released by activated CD4+ T lymphocytes in vitro, significantly deregulated in vivo in blood of individuals affected with auto-immunity (psoriasis) and then reverts to healthy donors' levels upon effective treatment with anti- inflammatory drugs. The aim of the present work was to test whether the quantification of plasma microRNAs may help to monitor and improve the prediction of T1D disease course.

Materials and methods: To test our hypothesis, we have retrospectively screened plasma samples from children who received the diagnosis of T1D (n=65) and healthy control subjects (n=26). microRNAs were quantified by RT qPCR and upon normalization with the average cQ value, differentially expressed microRNAs in diabetic children compared to the healthy counterpart were identified. We also performed a correlation analysis to evaluate the relationship i) among the differentially expressed microRNAs and ii) between the microRNAs and available clinical data of our patients, including C-peptide, hemoglobin A1c and the numbers of blood circulating lymphocyte subpopulations.

Results: The majority of the identified differentially expressed microRNAs are indeed part of the specific microRNA signature released by activated T lymphocytes, suggesting their blood modulation may be directly connected to disease-associated lymphocyte deregulation. Moreover, the subsequent correlation analysis was able to highlight complex microRNA co-modulation patterns, and potentially important relations between microRNAs and the traditionally used disease markers.

Conclusion: In conclusion, the present project has led to identifying blood circulating microRNAs as novel and potentially useful clinical parameters, directly connected to the pathological deranged activity of T cells in T1D patients.

A single dose of dapagliflozin, an SGLT-2 inhibitor, induces higher glycosuria in GCK and HNF1A-MODY than in type 2 diabetes

J. Hohendorff[1], M. Szopa[1], J. Skupien[1], M. Kapusta[1], B. Zapala[1], T. Platek[1], S. Mrozinska[1], T. Parpan[2], W. Glodzik[3], A. Ludwig-Galezowska[1], B. Kiec-Wilk[1], T. Klupa[1], M.T. Malecki[1];

[1]Jagiellonian University Medical College, [2]Brothers Hospitallers' of St. John of God Hospital, [3]Sanatio Medical Center, Krakow, Poland.

Background and aims: Maturity Onset Diabetes of the Young (MODY) is estimated to account for 1-2% of all cases of diabetes. Dietary intervention is generally sufficient to maintain good glycemic control in subjects with Glucokinase (GCK) gene mutation. Hepatocyte Nuclear Factor 1 Alpha (HNF1A) gene mutations affect insulin secretion to a greater extent. For patients with genetically confirmed HNF1A-MODY sulfonylurea therapy should be considered as the first-line treatment. The extra-pancreatic features of HNF1A-MODY include glycosuria due to a low renal threshold for glucose, which has been linked to decreased sodium/glucose co-transporter 2 (SGLT2) expression in tubular cells. SGLT2 inhibitors are widely used in type 2 diabetes (T2DM). Their effectiveness in MODY is unknown. It can hypothesized that response to SGLT2 inhibitors, such as dapagliflozin, may be altered among HNF1A-MODY individuals, thus influencing their efficacy in these patients. We aimed to assess the response to a single dose of 10 mg dapagliflozin in patients with HNF1A-MODY, GCK-MODY, and T2DM.

Materials and methods: We examined 14 HNF1A-MODY, 19 GCK-MODY, and 12 T2DM patients. All studied individuals received a single morning dose of 10 mg of dapagliflozin added to their current therapy of diabetes. To assess the response to dapagliflozin we analyzed changes in urinary glucose to creatinine ratio (GCR), serum 1,5-Anhydroglucitol (1,5-AG) level and fasting plasma glucose (FPG) level. All parameters were measured in the morning of the dapagliflozin administration day and the day after.

Results: T2DM patients were older (61.8±5.6 vs. 34.1±11.0 and 40.3±10.8 years, p=0.00), more obese (31.3±5.3 vs. 24.4±4.9 and 23.4±2.8 kg/m^2, p=0.00), and were characterized by worse glycemic control (HbA1c: 6.9±0.9 vs. 6.0±0.7 and 6.4±0.4%, p=0.03) than HNF1A-MODY and GCK-MODY subjects what is in line with the way how groups were defined. There were no differences between study groups in terms of sex distribution and kidney function. There were only 4 patients with positive urine glucose before dapagliflozin administration (1 with HNF1A-MODY, 2 with GCK-MODY, and 1 with T2DM), whereas after SGLT-2 inhibitor use, glycosuria occurred in all studied participants. Considerable changes in mean GCR after dapagliflozin administration were observed in all three groups (20.51±12.08, 23.19±8.10, and 9.84±6.68 mmol/mmol for HNF1A-MODY, GCK-MODY, and T2DM, respectively, p<0.001 for all comparisons). Post-hoc analysis revealed significant differences in mean GCR change between T2DM and each monogenic diabetes in response to dapagliflozin (p=0.02, p=0.003 for HNF1A and GCK-MODY, respectively), but not between the two MODY forms (p=0.7231). Significant change in serum 1,5-AG was noticed only in T2DM (-6,57±7,34 mg/ml, p=0.04). Subgroup analyses revealed significant mean FPG reduction in GCK-MODY (0.50±0.72 mmol/l, p=0.007), but not in HNF1A-MODY (0.14±0.90 mmol/l, p=0.56) and T2DM (0.23±1.20 mmol/l, p=0.52).

Conclusion: A single dose of dapagliflozin, an SGLT-2 inhibitor, induces higher glycosuria in GCK- and HNF1A-MODY than in T2DM. Whether flozins are a valid therapeutic option in these forms of MODY requires long-term clinical studies.

Modelling of ER-stress in beta cells using genome edited patient-derived iPSC carrying insulin gene mutations

D. Balboa[1], J. Saarimäki-Vire[1], S. Eurola[1], J. Ustinov[1], H. Grym[1], K. Wartiovaara[1,2], H. Huopio[3], T. Otonkoski[1,4];

[1]University of Helsinki, [2]Clinical Genetics, HUSLAB, Helsinki University Central Hospital, Helsinki, [3]Department of Pediatrics, University of Eastern Finland and Kuopio University Hospital, Kuopio, [4]Children's Hospital, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background and aims: Permanent neonatal diabetes is caused by mutations in genes important for the function of the pancreatic beta cell. Insulin mutations result in the misfolding and endoplasmic reticulum (ER) retention of the insulin protein. Long-term accumulation of aberrant insulin eventually leads to ER-stress, activation of the unfolded protein response pathway and apoptosis of the beta cells. ER-stress is also associated with the progression of T1 and T2 diabetes. To establish a new model for ER-stress induced diabetes, we derived iPSC lines from two Finnish families carrying different heterozygous dominant insulin mutations that result in neonatal diabetes onset at 3-4 months of age.

Materials and methods: Differentiation efficiency towards the beta cell varies between cell lines with different genetic background. This may obscure the disease phenotype when studying the specific effect of the insulin mutation in beta cells. To overcome this, we generated corrected isogenic cell lines by repairing the insulin gene mutations using CRISPR/Cas9. Corrected cells were differentiated in parallel with mutant cells using an optimized suspension differentiation protocol for 30 days. The resulting islet-like 3D clusters were transplanted under the kidney capsule of immunodeficient mice to complete the beta cell maturation in vivo.

Results: We analyzed the islet-like clusters before and three months after transplantation. Increased ER-stress was detected specifically in the INS+ mutant beta cells, with strong BIP (HSPA5) expression progression from a few BIP+INS+ cells before transplantation to virtually all INS+ after transplantation. Corrected cell lines did not present increased ER-stress markers at any stage. Insulin-reporter cell lines were generated using CRISPR/Cas9 from mutant and corrected cell lines, enabling INS+ cells FACS-sorting followed by RNA-seq. We also conducted single cell RNA-seq of islet-like clusters before transplantation to study the transcriptional changes at the cell level.

Conclusion: We envision this model will provide new insights into the molecular mechanisms behind ER-stress based demise of the beta cells and serve as a drug-screening platform for novel antidiabetic agents.

StarSeq, an innovative method based on NGS for accurate detection of punctual mutations and copy number variants in obese children

A. Bonnefond[1], M. Derhourhi[1], L. Montagne[1], E. Durand[1], I. Rabearivelo[1], O. Sand[1], B. Delobel[2], P. Froguel[1];

[1]CNRS UMR8199, [2]Hopital St Vincent, Lille, France.

Background and aims: Although targeted or exomic next generation sequencing (NGS) is now widely used for the detection of punctual coding mutations, DNA microarrays (SNPs or CGH) are still the current methods for the detection of copy number variants (CNVs) in the molecular diagnosis of genetic disorders. We have developed a groundbreaking, NGS-based, one-step tool for an accurate and cost effective detection of both punctual mutations and CNVs. We assessed its usefulness and accuracy for the molecular diagnosis of patients with monofactorial metabolic diseases.

Materials and methods: We used a custom capture (NimbleGen SeqCap EZ Choice XL) which included probes regularly spaced in the entire genome, in combination with a capture targeting the whole exome (NimbleGen SeqCap EZ MedExome Enrichment Kit). The resulting probes covered >80 Mb of the genome. Probes were placed every 10 kb apart in the regions known to be affected by CNVs (based on the literature and public database), and probes were placed every 25 kb in the rest of the genome. We tested this capture in a cohort of 100 obese children with developmental delay and 20 controls, whose 50% had already been analyzed by DNA microarrays (CGH Agilent 60k v2) for CNV detection. The sequencing was performed through Illumina HiSeq

4000, using 100 bp paired-end reads, and a mean sequencing depth higher than 85× was achieved for each individual.

Results: We detected all the CNVs previously identified by DNA microarrays and we found additional CNVs which were not found by DNA microarrays in our patients, probably due to the better resolution of our method. In parallel, we were also able to detect novel punctual mutations with the same accuracy as a standard exome sequencing. We were able to diagnose more than half of the patients, establishing causality to either punctual mutations and/or CNVs.

Conclusion: We demonstrated that our custom capture in combination with NGS enables an accurate, inexpensive detection of CNVs and punctual mutations in only one step. StarSeq dramatically improves genetic diagnosis and thus has the potential to replace standard exome sequencing and DNA arrays as this method is cost-effective and fast.

A novel mutation in the IPF-1/PDX-1 gene identified in a Japanese family with MODY

N. Iwasaki[1,2], H. Akagawa[2], M. Hase[3,1], R. Ide[1], M. Ogata[1], T. Furukawa[2], S. Mitani[4,2], Y. Uchigata[1];

[1]Diabetes Center, [2]Institute of Integrated Medical Science, [3]Institute of Geriatrics, [4]Second Department of Physiology, Tokyo, Japan.

Background and aims: Maturity onset diabetes of the young (MODY), a subtype of diabetes mellitus, is a single gene disorder. We have been studying for one large Japanese family with MODY. Although screening for mutations in *MODY1*, *2*, *3*, and *5* of the proband was performed, and non-parametric linkage analysis had disclosed marginal peaks on chromosome 6, 7 and 22, the pathogenic variant has not yet been identified. Hence, the aim of this study was to identify the causative mutation in this family.

Materials and methods: The family consisted of 31 individuals with three generations. Standard 75g OGTT was performed to determine the phenotype and genomic DNA were obtained from 31 members. Whole exome sequencing were performed for two individuals with MODY (the proband and his daughter) and proband's wife for the reference. Exomes capture was performed with solution-based hyblidization using Sure-Select Human All Exon Kit Ver. 5 (Agilent Technologies, Santa Clara, CA, USA), and captured DNA fragments were subsequently sequenced using the HiSeq2000 system (Illumina, San Diego, CA, USA) by paired-end 100-bp reads. Reads were mapped to the Genome Reference Consortium human build 37 using the BWA-MEM. Variants were identified by single-sample calling with UnifiedGenotyper using GATK ver. 3.5 and annotated using ANNOVAR. Functional effects of the detected variants were assessed using SIFT, PolyPhen-2 and CADD v1.3.

Results: The variant c.443G>T:p.R148L in IPF-1/PDX-1 (MODY4) gene was found in the proband and his daughter in heterozygous form, but not in the spouse. Although R148G on the same position was reported as rs193922355 and interpreted as likely pathogenic in ClinVar, R148L is not presented in Exac, gnomAD or T2D portal. This variant was located in the homeodomain (Exon 2). SIFT and PP2 predicted Damaging, and CADD score was 34.0. Those data strongly suggested that this variant could be pathogenic. Sanger sequence in the member of this family disclosed that the variant was segregated with diabetes except for one individual with MODY. Interestingly, he was identified to have p2 prompter c.-79C>T (hetero) in HNF4A (MODY1) gene, which was inherited from his father who did not have diabetes. Therefore, p2 promoter c.-79C>T in HNF4A gene does not seem to be pathogenic even CADD score was 18.11. We could not find any meaningful signal at least in 13 known MODY genes in this patient.

Conclusion: We identified the MODY4 family in Japanese with a novel substitution. Moreover, one phenocopy has a possibility to carry the different mutation within a single family.

Genome wide association search for variants influencing age of diagnosis in HNF1A-MODY diabetes

A.H. Ludwig-Galezowska[1], J. Skupien[2], S. Pruhova[3], D. Gasperikova[4], C. Bellanne-Chantelot[5], A. Hattersley[6], A. Doria[7], M.T. Malecki[2], T. Klupa[2], NEMO Study collaborators;

[1]Center for Medical Genomics OMICRON, [2]Department of Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland, [3]Charles University in Prague, Prague, Czech Republic, [4]Inst. of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia, [5]Department of Genetics, Hôpital Pitié-Salpêtrière, Paris, France, [6]Exeter Medical School, Exeter, UK, [7]Joslin Diabetes Center Harvard Medical School, Boston, USA.

Background and aims: Diabetes caused by mutations in the HNF1A gene is one of the most frequent forms of monogenic diabetes. Since the age of diagnosis is variable we aimed to examine whether common genetic variants influence the age of onset of the disease.

Materials and methods: A genome-wide association study (GWAS) on 814 HNF1A diabetic mutation carriers was performed. Numbers of study participants from different countries were as follows: 257 patients from France, 247 from the UK, 90 from the USA, 86 from Czech Republic, 78 from Poland, and 56 from Slovakia. The GWAS was performed using Illumina Human Core chip. In total, 222,662 autosomal polymorphisms with minor allele frequency > 5% were eligible for the analysis. The analysis was performed with R version 3.3.1 and PLINK 1.07 and 1.9.

Results: We identified 5 loci on chromosomes 4, 2, 3 and 10 showing suggestive evidence of association with age at diabetes diagnosis ($p < 10^{-5}$). The most significant association was for LOC105374493 on chromosome 4. Its rare allele G postponed diabetes diagnosis by an average of 2.8 years. Similar effect was seen for another intronic variant rs2070633 and one regulatory region variant (rs1033287). Twenty seven variants were associated with age of diagnosis at the level $p < 10^{-4}$. Most of them were intronic variants, 7 intergenic, 3 downstream or upstream gene variants, 1 non coding transcript exon variant and 1 missense variant.

Conclusion: There is a suggestive evidence that common polymorphic variants contribute to age of diabetes onset in HNF1A-MODY. We were however unable to find any high impact loci associated with age of diagnosis. It is possible, that rare genetic variants influence this phenotype.

A novel pathogenic variant mutation of MODY type 3

A.K.R. Pande[1,2], M. Gutch[3];

[1]Endocrinology, Sahara Hospital, [2]Endocrinology, Lucknow Endocrine Diabetes and Thyroid Clinic, [3]Endocrinology, King George Memorial University, Lucknow, India.

Background and aims: Maturity onset diabetes of young is a type of diabetes inherited which has autonomous dominant inheritance

Materials and methods: Case report: We report a case of lean 37 year male who came to us with history of diabetes for 19 years diagnosed at age of 18 years. When seen first he was on 4 OHA, metformin 2 gm , canaglifozin 100 mg, sitagliptin 100mg, pioglitazone 15 mg his fasting blood glucose was 160

and post prandial blood glucose was 280 and a HbA1c of 9.4 %. On carefully reviewing the history we found that he had family history diabetes involving three generation at similar age. Patient was shifted on glimepride 3 mg and all the other OHA was stopped. He had good response the same and his fasting blood glucose came to 110 and post prandial blood glucose 160 and HbA1c after three months was 6.7%. Genetic analysis was done by Sanger sequencing. His report came out to be positive for novel Pathogenic variant c.599G>A p>Arg200Gln in HNF1A gene. This variation is located in a conserved region and the bioinformatic analysis using Polyphen_2, Sorting Intolerant From Tolerant (SIFT), mutation tester predict this variant as probaly damaging. This mutation has not been described by exome sequencing project or exome aggregation consortium.

Results: N/A

Conclusion: Therefore, this novel variation with a previous reports of mutation at this codon and damaging in silico predictions suggest that this variant is clinically relevant and is likely pathogenic based on American College of Medical Genetics and Genomics (ACMG) 2015 guidelines

Predicting the effects of glucokinase mutations: Are we there yet?

P. Heneberg, D. Simcikova, M. Tesinsky;

2nd Department of Internal Medicine, Charles University, Prague, Czech Republic.

Background and aims: Inactivating mutations of the glucokinase (GCK) are causative for monogenic diabetes (*GCK*-MODY), permanent neonatal diabetes mellitus and insulin-deficient hyperglycemia, while the activating mutations lead to the persistent hyperinsulinemic hypoglycemia of infancy (PHHI). Characterization of inhibitory mutations is a laborious and time-consuming task, which prevents large-scale analyses conducted for clinical purposes, particularly when considering a structural perspective. Recently, computational evolution- and structure-based prediction analyses were suggested to be used in order to predict the effects of particular GCK mutations but were never matched with the data obtained *in vitro* or with clinical data.

Materials and methods: We analyzed the usefulness of eight most frequently used *in silico* methods, which have a potential to predict the effects of GCK mutations (PolyPhen2, SIFT, SNAP2, PoPMuSiC 2.1, I-Mutant 3.0, SNPs&GO, PhD-SNP and AlignGVGD). These methods were based on biophysical characterization, evolution-based sequence information, and structural data. The resulting data were calculated using either neural networks or Bayesian methods and mathematical operations. We compared these predictions with outcomes of direct measurements of enzyme kinetics *in vitro* (126 mutations) and reported previously or reported newly in course of this study and with the clinical information known from patients carrying these mutations (161 MODY-associated mutations, 14 PHHI-associated mutations, 14 neutral mutations, and polymorphisms).

Results: The clinical data and the data on enzyme kinetics of GCK constructs carrying particular disease-associated mutations corresponded with the *in silico* predictions to only a limited extent. The prediction methods were particularly ineffective when attempting to identify the activating mutations known to cause PHHI, and were unable to distinguish between the activating and inhibitory mutations at all. Some prediction methods had high sensitivity when predicting MODY-associated mutations (e.g., the sensitivity of Align GVGD was 93%). However, their sensitivity for neutral mutations was low, usually below 80%, or with a high ratio of false positive predictions of the neutrality among the disease-associated mutations (up to 29%). Similar results were obtained when matching the outcomes of the prediction methods to the GSIR-T or Hill coefficient.

Conclusion: This study provides the first robust evidence allowing to choose the best-fit model for a prediction of effects of GCK mutations, for which the *in vitro* data are still absent. Low precision of the available methods still suggests that the laborious *in vitro* functional analyses of the enzyme kinetics of disease-associated GCK mutations are still needed.

Developing high throughput assay for functional classification of novel missense variants in HNF1A

L. Najmi[1], S. Althari[2], L. Gundersen[1], R. Rice[3], M. McCarthy[2], A. Gloyn[2], P. Njølstad[1], A. Majithia[3];

[1]KG Jebsen Center for Diabetes Research, Department of Clinical Science, University of Bergen, Bergen, Norway, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, UK, [3]Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, USA.

Background and aims: Variants in the transcription factor gene *HNF1A* are associated with different diabetes phenotypes and can be identified in subjects with maturity-onset diabetes of the young (MODY) type 3, type 2 diabetes and children with apparent type 1 diabetes. With increasingly effective sequencing methods identifying variants with unknown significance in these subjects, tools are needed to determine the true pathogenicity of such variants. Bioinformatics based programs have limitations. Current functional assay are low throughput and laborious. Furthermore, these assays utilize artificial transcriptional reporter constructs that may not have fidelity with in vivo function. In order to accurately discriminate human disease causing and benign variants, we aim to develop a high throughput cell-based HNF1A functional assay based on multiple endogenous target genes in multiple cellular contexts.

Materials and methods: To develop assays with higher fidelity with in vivo function, we assessed the full complexity of *HNF1A* transcriptional response in different cellular contexts. For this purpose we generated *HNF1A*- free cell lines by knocking out endogenous *HNF1A* in HUH7 and Hep3B hepatoma cells using CRISPR/Cas9. *HNF1A* was re-introduced into the knock-out cell lines at varying doses, then gene expression profile analysed by RNA sequencing. We selected target genes with the highest expression fold-change in response to *HNF1A* induction. Significance of differential expression was assessed by the Wald test. mRNA level expression of selected targets will use in RNA-Fish FACS-based system that allows segregation of cell populations based severity of *HNF1A* dysfunction

Results: Transcriptomic profiling identified multiple target genes; some were cell line specific while others were common across both cell lines. Of the most significantly differentially expressed genes ($q \leq 7.2 \times 10^{-31}$) the highest fold changes for HUH7 was *CLDN2* (fold-change 24), *AKR1B10* (fc=22) and *HABP2* (fc=21). In Hep3B the highest fold-changes were *KRT39* (fc=133), *FOLR1* (fc=100) and *KL* (fc=61). *LIPC*, *CLDN2*, *CYP3A* genes showed significantly increased expression in both cell lines ($q \leq 1.7 \times 10^{-28}$). Some canonical HNF1A target genes showed different expression profile between the two cell lines. For example *TMEM27* and *TM4SF4* were expressed only in Hep3B and *AFP* and *FGB* only in HUH7. The mRNA expression levels of multiple target genes will characterize in single cells by RNA-FISH. The level of expression is indicative of HNF1A function

Conclusion: In conclusion we have identified multiple novel, endogenous cell-specific targets for *HNF1A* that can be used for developing a high throughput functional assay. RNA-FISH in combination with flow cytometry enables us to measure multiple targets simultaneously in single cells, thus leading the way towards high-throughput disease-relevant assays of gene function.

PS 004 Cardiovascular outcomes in diabetes

289

Reduction of cardiovascular event risk by a pragmatic lifestyle intervention in rural India

M. Lotfaliany[1], T. Sathish[1,2], S. Braat[1], B. Oldenburg[1], on behalf of the K-DPP research team;

[1]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, [2]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore.

Background and aims: India has a substantial burden of cardiovascular disease (CVD). Evidence regarding the effect of pragmatic strategies targeting the burden of CVD in India is lacking. The Kerala Diabetes Prevention Program (K-DPP) was a clustered randomised controlled trial of a pragmatic lifestyle intervention program for prevention of type 2 diabetes among individuals at high risk for diabetes recruited using a diabetes risk score from rural communities in Kerala, India. This presentation aims to answer the following question: Whether a pragmatic lifestyle intervention program could reduce CVD risk compared with the control arm among K-DPP participants?

Materials and methods: The intervention arm of K-DPP received a 12-month group-based peer support lifestyle intervention. Control arm received a booklet on lifestyle modification advice. Participants were assessed at the end of intervention and 12 months post-intervention. The analysis set included those aged ≥40 years at baseline. The risk of having a CVD event within 10 years was estimated for every participant at baseline and at 12 and 24 months, using the "GloboRisk" equation. Participants with a predicted risk of at least 20% were defined as being at high risk for a CVD event. Due to the clustered and repeated nature of the data, a logistic regression model was fitted using a generalised estimating equation to estimate the odds ratio (OR) and 95% confidence interval (CI) for having a high predicted CVD risk in lifestyle intervention arm compared to control one. The models included predicted CVD risk status (≥20% vs. <20%) as the outcome and intervention status, time point, and the interaction term between intervention status and time point as well as baseline values of age, sex, total cholesterol, systolic blood pressure, current smoking status, fasting plasma glucose, 2-hour plasma glucose, and HbA1c as independent variables. The estimated coefficients of interaction term at 12 and 24 months were used to interpret the effect of the lifestyle intervention on CVD risk.

Results: Overall, 387 participants (47% female) in the control arm and 375 (46% female) in the intervention arm with the mean (standard deviation) age of 49.7 (6.0) and 50.5 (5.7) years, respectively, were included in the analysis set. There was no clinically important difference in baseline characteristics between the study arms. The median (25th -75th percentile) of estimated CVD risk in control and intervention arms were 8.6 (4.9; 14.5) and 8.9 (5.6; 14.6) at baseline, 8.9 (5.2; 14.2) and 8.9 (5.7; 15.1) at 12 months, and 9.9 (6.1; 16.4) and 9.8 (6.4; 15.3) at 24 months, respectively. The proportion of participants with high predicted CVD risk in the control arm was 10.1% and 12.0% in the intervention arm at baseline. In the control arm, the proportion of those with CVD risk increased to 12.4% at 12 months and 17.2% at 24 months and the corresponding proportions in the intervention arm were 12.8%, and 13.8%, respectively. The OR [95% CI] of having a high CVD risk in the intervention compared to control was 0.80 [0.38, 1.67] at 12 months and 0.45 [0.20, 1.00] at 24 months.

Conclusion: In the population that the study represents, the risk of CVD and proportion of those with high CVD risk increased over a period of 2 years in absence of any intervention. Compared to this, a pragmatic lifestyle intervention showed a reduced risk.

Effect of depression and/or anxiety on the presentation of cardiovascular events in a large cohort with metabolic syndrome

Y. Ortega[1], J.J. Cabre[2], J.L. Piñol[3], E. Aragones[4], J. Basora[2], A. Araujo[1];

[1]Catalan Health Institute, Salou, [2]Catalan Health Institute, Reus, [3]Catalan Health Institute, L'Ampolla, [4]Catalan Health Institute, Constantí, Spain.

Background and aims: Metabolic syndrome (MetS) is a common condition in all developed countries. The effect of anxiety and/or depression as manifestations of stress on the adrenal axis, gluconeogenesis, cardiovascular disease or glucose tolerance has been widely demonstrated. But association of stress with poor prognosis and cardiovascular disease remain still unclear. To determine the role of anxiety and depression on the incidence of cardiovascular events (CVE) in a Catalonian population with MetS over a five-year follow-up according to the number/type of MetS criteria.

Materials and methods: Prospective study to determine the incidence of CVE according to the presence of anxiety and depression disorders among individuals with different combinations of clinical traits of the MetS. Setting: Primary Care, Catalonia (Spain). Subjects: 35-75 years old fulfilling MetS criteria without CVE at the initiation of follow-up (2009). We studied 16 MetS phenotypes [NCEP-ATPIII criteria] based on the presence of depression/anxiety. The primary endpoint was the incidence of CVE at five years.

Results: We analyzed 401,743 people with MetS (17.2% of the population); 8.7% had depression, 16.0% anxiety and 3.8% both. 14.5% consumed antidepressants and 20.8% tranquilizers. At the 5-year follow-up, the incidence of CVE was 5.5%, being 6.4% in men and 4.4% in women. On comparing individuals with and without depression the incidence of CVE was 6.7% vs. 5.3%, respectively ($p<0.01$), being 5.5% in both groups in relation to anxiety.The graphic shows data about mood disorders and CVE according to phenotypes; then, anxiety was more frequent in the MetS9, MetS2 and MetS14 phenotypes; depression in the MetS14, MetS2 and MetS6 phenotypes; and the MetS9, MetS14 and MetS2 phenotypes were more often found in both anxiety and depression.

Conclusion: Unlike other European cohorts the predominant MetS phenotypes in Catalonia do not include obesity as a criterion. Depression and anxiety play a role in the poor prognosis of patients with MetS.

Indexes of body fat, but not BMI, are associated with cardiovascular (CV) mortality in subjects with diabetes (DM) during 17 year follow-up in the Norwegian HUNT2 study

A.P. Ofstad[1], C. Sommer[2], K.I. Birkeland[3], M.R. Bjørgaas[4], J.M. Gran[5], O.E. Johansen[6], H.L. Gulseth[7];

[1]Medical department, Boehringer Ingelheim Norway, Asker, [2]Oslo University Hospital, [3]Department of transplantation medicine, University of Oslo and Oslo University Hospital, Oslo, [4]Department of Endocrinology, St. Olavs Hospital, Trondheim University Hospital, Trondheim, [5]Oslo Centre for Biostatistics and Epidemiology, Research Support Services, Oslo University Hospital, Oslo, [6]Boehringer Ingelheim Norway, Asker, [7]Department of

Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway.

Background and aims: Obesity may be associated with increased CV risk and mortality, but the best measure to quantify metabolic unhealthy obesity is still debated. In a large Norwegian population-based cohort, we aimed to explore the association between four different indexes of obesity and CV mortality in subjects with or without DM.

Materials and methods: We used data from the Nord-Trøndelag Health Study (HUNT2), a Norwegian,population-based cohort study of 63 978 subjects, of whom 1955 had DM. Baseline assessments were done in 1995-1997 and validated markers of adiposity were calculated: Body mass index (BMI), waist-hip-ratio (WHR), index of central obesity (ICO=waist /height) and estimated total body fat ($eTBF_{men}$: 100*(-98.42 + [4.15*WC] - [0.082*weight])/ weight; $eTBF_{women}$:100*(-76.76 + [4.15*WC] - [0.082*weight])/weight). Causes of death were retrieved from the Norwegian Cause of Death registry from August 15th 1995 to December 31st 2015 with a mean±SD follow up of 17.2±4.8 years. The associations between adiposity markers and CV death were explored by Cox regression.

Results: At baseline, mean ± SD of the fat markers in the DM population were: BMI: 28.8±4.6 kg/m^2, WHR: 0.89±0.08, ICO: 0.57±0.07, and eTBF: 29.6±8.8%. During follow-up 560 (28.6%) and 4803 (7.7%) CV deaths occurred in the DM and non-DM subgroups, respectively. The marker with the strongest association to CV death in DM was eTBF (HR (95% CI) per 1 SD increase: 1.35 (1.25-1.45), p<0.0001), followed by ICO (1.26 (1.17-1.35), p <0.0001) and WHR 1.17 (1.07-1.27), p=0.022), while BMI was not significant (1.01 (0.94-1.09), p=0.792). In the non-DM group, findings were similar for eTBF, ICO and WHR, with HR per 1 SD increase eTBF (95% CI): 1.91 (1.86, 1.96), ICO: 1.90 (1.86, 1.95), and WHR: 1.75 (1.70, 1.80), but in this group also BMI was significant: 1.24 (1.21, 1.28). Of interest is that the curves that describe the relationship between eTBF and proportion of CV death differ between DM and non-DM groups indicating that CV mortality does not increase in the highest eTBF categories (Figure).

Conclusion: In this population-based cohort study, eTBF was the fat marker with the strongest association to CV death in subjects with DM, whereas BMI was not significantly associated. eTBF may be suitable for risk stratification in a clinical setting.

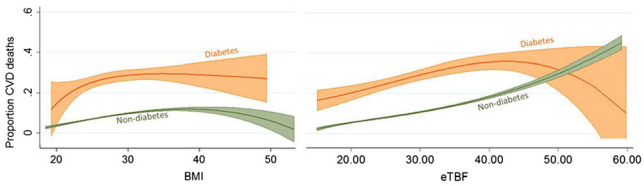

Figure: Relationship between BMI (kg/m2) and estimated total body fat (eTBF, %) and estimated mean (95% CI) proportion of CV deaths in the diabetes and non-diabetes population.

Sex differences in major cardiovascular events by diabetes status in England: a nationwide study 2004-2014

E.P. Vamos, A. Bottle, S.-H. Kim, B. Visani, A. Majeed, C. Millett, A.A. Laverty;

Department of Primary Care and Public Health, Imperial College London, London, UK.

Background and aims: Secondary prevention of cardiovascular disease (CVD) has improved immensely during the past decade but controversies persist on cardiovascular benefits among women. While secondary prevention has become more equitable between men and women, women are still less likely to achieve treatment targets. We investigated recent trends in hospital admission rates for acute myocardial infarction (AMI), stroke, percutaneous coronary intervention (PCI), and coronary artery bypass graft (CABG) by sex and diabetes status in England.

Materials and methods: We identified all hospital admissions for major CVD events and procedures among people aged ≥17 between 2004 and 2014 in England. We calculated diabetes-specific and non-diabetes-specific rates for study outcomes by sex. To assess temporal changes, we fitted negative binomial regression models.

Results: Age- and sex-standardised rates were higher in men compared with women in people with and without diabetes for all outcomes except for stroke in the non-diabetes group. During the 11-year follow-up time, diabetes-related admission rates remained unchanged for AMI (rate ratio 0.99 [0.98-1.01]), increased for stroke by 2% (1.02 [1.01-1.03]) and PCI by 3% (1.03 [1.01-1.04]) and declined for CABG by 3% (0.97 [0.96-0.98]) annually. Trends did not differ significantly by diabetes status. Women with diabetes had significantly lower rates of AMI (0.46 [0.40-0.53]) and stroke (0.73 [0.63-0.84]) compared with men with diabetes. However, sex differences in AMI rates attenuated in diabetes compared with the non-diabetic group. While diabetes tripled admission rates for AMI in men (3.15 [2.72-3.64]), it increased it by over 4-fold among women (4.3 [3.8-4.93]). Proportional changes in rates were similar in both sexes for all outcomes, leaving the relative risk of events unchanged.

Conclusion: Diabetes still confers a greater increase in risk of AMI in women relative to men. However, the absolute risk remains higher in men. These results call for intensified CVD risk factor management among people with diabetes and treatment intensity to align with risk.

Disclosure: **E.P. Vamos:** None.

Life years lost and cardiovascular risk in type 2 diabetes patients requiring glucose-lowering treatment 2008-2015: nationwide data from Norway and Sweden

H.L. Gulseth[1], J. Bodegard[2], A. Norhammar[3], D. Nathanson[4], M. Thuresson[5], K.I. Birkeland[6], J.W. Eriksson[7], T. Nyström[4];

[1]Oslo University Hospital, Oslo, Norway, [2]AstraZeneca Nordic-Baltic, Södertälje, [3]Karolinska Institutet, Stockholm, [4]Södersjukhuset, Stockholm, [5]Statisticon AB, Uppsala, Sweden, [6]University of Oslo, Oslo, Norway, [7]Uppsala Akademiska Sjukhus, Uppsala, Sweden.

Background and aims: Type 2 diabetes (T2D) carries severe long term consequences for the patient by shortening life expectancy and increasing risk of cardiovascular (CV) disease. Considering recent T2D treatment strategies, it is vital to fill the lack of current data on changes in patient related disease consequences. The aim was to examine life-years lost and age-adjusted rate ratios of myocardial infarction (MI), stroke and all-cause mortality (ACM) in Norway and Sweden, two neighbouring countries with similar health care systems.

Materials and methods: All patients dispensed with glucose lowering drugs (GLDs) during 2008—2015 were identified in nationwide registries in Norway and Sweden. Patients aged <18 years, and those with polycystic ovarian syndrome, type 1- or gestational diabetes were excluded. Life-years lost was estimated by age calculating the difference between life expectancy in a general population vs the T2D population. Rate ratios were calculated by comparing age adjusted rates in the T2D population with rates in the corresponding general population.

Results: In Norway and Sweden, 604,936 T2D patients were identified in 2015. In 2015, younger patients lost more life years and results were similar in both countries (figure, upper panels). In Sweden, women had a slightly higher life-year loss compared to men, while no gender differences were seen in Norway. With increasing age, life-years lost showed a linear decrease up to 80 years of age. In 2015, age adjusted rate ratios were 1.72, 1.41 and 1.17 for MI, stroke and ACM, respectively (figure, lower panels). The rate ratios for MI, stroke and ACM showed small but non-significant changes over time in both countries, except for slight increase for MI in Norway.

Conclusion: T2D patients on glucose lowering drugs and in the age of 40 years, are expected to have about 5 years shorter life expectancy than the general population in Norway and Sweden. The frequency of severe CV complications showed similar patterns over time in the two countries. These nationwide results highlight the importance to prevent

diabetes development at early ages and improve CV prevention when T2D is present.

Epidemiological characteristics of lower extremity arterial disease in Chinese diabetes patients: a prospective, multicenters, cross-sectional study

X. Zhang[1], Z. Xu[2], X. Ran[3], L. Ji[1,4], China DIA-LEAD Study Investigators; [1]Department of Endocrinology, Peking University International Hospital, [2]Department of Endocrinology, The 306th Hospital of PLA, Beijing, [3]Department of Endocrinology, West China Hospital, Chengdu, [4]Department of Endocrinology and Metabolism, Peking University People's Hospital, Beijing, China.

Background and aims: Lower extremity arterial disease (LEAD) is associated with a 5.9-fold increased risk of cardiovascular mortality in type 2 diabetes patients. However, LEAD is often neglected because of asymptomatic intermittent claudication in real-life settings. This study was designed to determine the epidemiological characteristics of LEAD and identify practical gaps in LEAD management in China.

Materials and methods: This cross-sectional study consecutively enrolled 7113 inpatients and 3568 outpatients aged 50 years and older who had been diagnosed with diabetes from 30 hospitals across China between June 2016 and January 2017. Patient demographics, medical history, recent blood glucose measurements, and medications were recorded. The Ankle-Brachial Index (ABI) for each leg was separately calculated, and the lower value was used for analysis. All patients were assessed for LEAD by ABI and/or lower limb ultrasonography according to 2013 Chinese guidelines on LEAD screening and management. Multivariate logistic regression was used to identify risk factors for LEAD.

Results: A total of 10,681 eligible patients, 5714 men (53.5%) and 4967 women (46.5%), were included in the present analysis. The mean age was 64.2 years; 16.1% of patients were obese; and 26.6% were smokers. The mean fasting blood glucose and glycosylated hemoglobin (HbA1c) levels were 8.9 mmol/L and 8.4%, respectively. Only 28.2% (n=3012) of patients achieved the goal of HbA1c <7.0%. The median duration of diabetes was 9.0 years (range: 0.1-60 years). The overall prevalence of LEAD was 21.2%, with 10.6% (n=1134) of patients diagnosed with LEAD before enrollment and 11.8% (n=1131) newly diagnosed at the present visit. Most cases of newly diagnosed LEAD were easily confirmed by ABI (defined as ABI >1.3 or ABI ≤0.9). Interestingly, the percentage of patients with an ABI >1.3 was significantly lower among newly diagnosed patients than among patients with a prior diagnosis (7.6% *vs.* 51.0%, $p<0.001$). There was no gender disparity regarding LEAD diagnosis. A significantly greater percentage of inpatients (25.5%) were diagnosed with LEAD compared with outpatients (12.6%, $p<0.001$). Of patients with newly diagnosed LEAD, the percentages of patients receiving antiplatelet, antihypertension, lipid modification, and vasodilator therapies were 42.8%, 54.4%, 46.4%, and 39.3%, respectively. In multivariate logistic regression analysis, older age, abnormities on skin examination, higher systolic blood pressure, cerebrovascular comorbidity, and diabetic retinopathy were independent risk factors for LEAD among both inpatients and outpatients.

Conclusion: LEAD is highly prevalent in Chinese diabetes patients, and half of cases are underdiagnosed. The noninvasive ABI measurement can easily identify most patients with previously unrecognized LEAD. The current treatment approach for diabetes patients with LEAD is suboptimal. Efforts are need to optimize both diagnosis and therapy to further bridge the gap between guideline recommendations and real practice.

Relationship between weight change and incident stroke based on Korean National Health Screening Database

J.-H. Cho, E.-J. Rhee, S.-W. Park, K.-W. Oh, W.-Y. Lee, C.-Y. Park, S.-E. Park, H.-M. Kwon, D.-Y. Lee;

Division of Endocrinology and Metabolism, Department of Internal Medicine, Kangbuk Samsung Hospital, Seoul, Republic of Korea.

Background and aims: The association between overweight and risk of ischemic stroke is well known. However, it remains controversial how weight change affects the stroke development, especially in Asians. In our study, we used Korean Nationwide Health Screening Database to study the association between weight change and incidence of stroke.

Materials and methods: Our study enrolled 11,084,683 Koreans who participated in National Health Screening Program from 2009 to 2012, and we measured weight change by checking the weight of four years ago. The occurrence of ischemic stroke, which was diagnosed for the first time in life, was observed until 2012. We categorized the study population according to weight change and analyzed the risk of ischemic stroke with Cox regression hazard model.

Results: 113,591 subjects (1.02% of total) were newly diagnosed with stroke during the mean observation period of 5.2 years. After multivariate-adjusted subgroup analyses, the hazard ratio of stroke was higher in subjects who had weight loss (≤-5%) or weight gain (≥+5%) compared with those who maintained weight (-5%~+5%) {1.152 (1.135~1.17) and 1.087 (1.069~1.106) vs. 1.000}. When the analyses were performed in 8 groups according to weight change, the risk for stroke showed a U-shaped curve with those who had weight changes within ±5% showed the lowest risk and gradually increased as weight loss or gain. When the incidence of stroke was analyzed according to the pre- and post-analysis body mass index (BMI), those who were obese and became lean, and those who were lean and became obese showed the higher incidence of stroke compared with those who maintained their BMI.

Conclusion: The risk of ischemic stroke showed a U-shaped curve with the group of maintaining weight (-5%~+5%) having the lowest risk, and the risk increased in those who had weight loss or gain. Further follow-up studies are required to analyze the long-term effects of weight change on the incidence of ischemic stroke.

Rationale and design of a longitudinal nationwide study on management and real-world outcomes of diabetes in India (LANDMARC): a 3-year Pan-India cohort

A. Mithal[1], P. Kumar[2], A.G. Unnikrishnan[3], S. Kalra[4], H. Thacker[5], B. Sethi[6], A. Mathew[7], D. Chodankar[7], S. Menon[7], C. Trivedi[7], M. Naqvi[7], S. Chowdhury[8], A.H. Zargar[9], A.K. Das[10], S. Joshi[11];

[1]Medanta - The Medicity, Gurgaon, [2]Bangalore Diabetes Hospital, Bangalore, [3]Chellaram Diabetes Institute, Pune, [4]Bharti Hospital, Karnal, [5]Bhatia Hospital, Mumbai, [6]Care Hospital, Hyderabad, India, [7]Sanofi India Ltd, Mumbai, [8]IPGME & R and SSKM Hospital, Kolkata, [9]Center for Diabetes and Endocrine Care, Srinagar, [10]Pondicherry Institute of Medical Sciences, Pondicherry, [11]Lilavati Hospital, Mumbai, India.

Background and aims: India, the second most populous country of the world, has been severely affected by the global diabetes epidemic. While the incidence and prevalence of diabetes is being studied through cross-sectional studies, there are only limited longitudinal studies to understand the development of diabetes complications over time and to explore their regional occurrence. LANDMARC (A **L**ongitudin**A**l **N**ationwide Stu**D**y on **M**anagement **A**nd **R**eal-world Out**C**omes of Diabetes in India) is by design, the first prospective, long-term, longitudinal and observational study conducted in India, investigating a large cohort of patients with type 2 diabetes (T2D) across the country. The study is primarily designed to document and analyse the management of diabetes and its complications over time.

Materials and methods: Overall, 6300 adult patients, with diagnosed T2D from 450 sites across India, who are currently on 2 or more anti-diabetic agents (either controlled or un-controlled on HbA1c) are planned to be enrolled. Study participants will be prospectively followed-up for 3 years. Data collection will include key baseline patient characteristics, comorbidities, glycaemic parameters, use of oral and injectable anti-diabetic agents, and any cardiovascular or other diabetes related event occurring during the observational period.

Results: This study will identify the proportion of patients developing macrovascular complications during 3 years follow-up. Other endpoints include microvascular complications (composite of renal and retinal), glycemic control, and time to treatment adaptation or intensification during 3 years. We will also be able to note the changes in physician preferences, how new drugs have changed the treatment paradigm in India. LANDMARC is also expected to help us in understanding the common trends of diabetes management in India (e.g. emergence of complications at a relatively earlier age, delayed insulinization, high use of OAD combinations, dose titration patterns).

Conclusion: The LANDMARC study aims to to capture and understand the progression of the disease, its control and treatment, and complications over time.

White blood cell count is associated with incident cardio-renal complications in Chinese patients with type 2 diabetes

C.H.T. Tam, A.O.Y. Luk, A.P.S. Kong, R. Ozaki, W.-Y. So, J.C.N. Chan, R.C.W. Ma;

Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong.

Background and aims: Previous studies revealed that chronic inflammation is one of the major mechanisms responsible for the development of diabetic complications. This study aims to investigate the relationship between white blood cell count (WBCC), a biomarker of inflammation, with cardio-renal complications in a prospective cohort of Chinese patients with type 2 diabetes (T2D).

Materials and methods: We included 7893 patients with T2D (47.0% male, mean age 57.8 ± 13.2 years and BMI 25.2 ± 4.1 kg/m^2) who had undergone a comprehensive assessment of complications and cardiometabolic risk factors based on the European DIABCARE protocol. The WBCC was measured and we removed outliers beyond 4 standard deviations from the mean. In the analysis for each incident diabetic complication, patients with history of the particular complication at baseline were excluded. Sex-specific associations between WBCC and incident diabetic complications were assessed by Cox proportional hazard regression adjusted for conventional risk factors including age, duration of diabetes, body mass index, HbA_{1c}, smoking status and the use of drugs at baseline. The sex-specific association results were meta-analyzed using the inverse-variance weighting approach. Cochran's Q test was used to assess heterogeneity of effects between sexes. We conducted a 4-knots restricted cubic spline regression analysis to test for the non-linear relationship between WBCC and complications.

Results: During a mean follow up period of 10.7 years, 734 (10.1%) patients developed coronary heart diseases (CHD), 711 (9.3%) developed stroke, 1232 (18.4) developed cardiovascular diseases (CVD), 648 (8.4%) developed congestive heart failure (CHF), 2422 (36.1%) developed chronic kidney disease (CKD), 976 (12.5%) developed end stage renal disease (ESRD), and 762 (9.9%) developed cancer. In the meta-analysis, each 1-unit (1×10^{-9}/l) increment of WBCC was associated with increased risk of incident CHD by 5.3% (95% CI 1.4-9.5), incident stroke by 5.1% (1.0-9.3), incident CVD by 5.7% (2.5-8.9), incident CHF by 9.7% (5.4-14.2), incident CKD by 7.0% (4.7-9.4), and incident ESRD by 10.3% (6.8-13.8). We further observed a sex-specific association for incident stroke in female patients (P for heterogeneity test = 0.0322). Moreover, we observed a non-linear relationship between WBCC and cancer (P for non-linearity test = 0.022 and 0.029 in male and female, respectively).

Conclusion: High WBCC is associated with increased risk of incident cardio-renal complications. Our findings support the role of low grade inflammation in the development of diabetic complication in T2D.

Cardiovascular events before and 15 years after diagnosis of adult onset type 1 and type 2 diabetes and levels of C-peptide and mortality

M. Thunander[1,2], M. Landin-Olsson[1], S. Holmberg[3,4];

[1]Endocrinology, Clinical Sciences, Lund, [2]Endocrinology and Diabetes, Internal Medicine, Växjö, [3]Occupational and Environmental Medicine, Clinical Sciences, Lund, [4]Research and Development, Region Kronoberg, Växjö, Sweden.

Background and aims: Cardiovascular disease (CVD) is the main threat to health in type 2 (T2D), and also for adults with type 1 diabetes (T1D). Treatment goals and means have changed the last decades. We report baseline and 15-year follow-up incident CVD from the Diabetes Incidence in Kronoberg study 1998-2001, where diabetes type was determined by serology.

Materials and methods: All 1666 with new diabetes diagnosis during 3 yrs in Kronoberg. In onset/15yrs follow-up analyses/fasting (C-peptide, FCP) 1580/1299/1110 (95%) were included, 109/88/80 (7%) had T1D by serological criteria: GADA+, ICA+, or C-peptide <0.25 nmol/mol) and 1471/1211/1030 (93%) had T2D. Patients were followed until 20141231. We report prevalence of hypertension (HT), myocardial infarction/ischemic heart disease (IHD), and stroke/TIA by physician report at diagnosis and these + congestive heart failure (CHF) after 15 years follow up according to compulsory National Registers of Hospital discharge diagnoses according to ICD-10, I20-I25, I50-51 and I60-69. Several models for simple and multiple (MRA), linear and logistic regression and cox proportional hazards models, were applied to explore associations, including with different levels of FCP at onset. R^2 given are adjusted Nagelkerke, <2% (0.02) not shown; CIs are 95%.

Results: At onset of diabetes present in patients with new T1D / T2D were HT in 26% (22/86) / 46% (548/1201); IHD 17% (15/86) / 26% (309/1191); stroke/TIA in 1% (1/85) / 7% (84/1201). FCP was associated with the risk of having had a CVD event already at/before the onset of diabetes (OR (CI)) of HT 4.1 (1.5-10.9), p 0.005, R^2 0.14 / 1.3 (1.1-1.4), p 0.002; IHD 3.9 (1.3-11.3), p 0.013, R^2 0.12 / 1.3 (1.1-1.5), p< 0.0001; Stroke/TIA ns / ns. The influence of BMI was much smaller than that of age at diagnosis for the risk of already having CVD, R^2 <2% for both diabetes types, vs for age 0.13 for T1D; 0.10 for T2D, p all< 0.001. In MRA including age at diagnosis, BMI and FCP their combined R^2 was, 0.26 in T1D / 0.16 in T2D, mostly driven by age. The influence of BMI was ns in T1D / 1 (< 0.02, p < 0.001) in T2D. First HbA1c (T1D mean 8.1±2.1 / T2D 7.1±1.7% DCCT) was not related to risk of IHD or any CVD in T2D, but in T1D R^2 was 0.04, p 0.038, and for any CVD 0.06, p 0.017, but lost significance to age in MRA. After 15 years of follow-up were registered 2003 episodes of the following types of CVD: 1082 (54.0%) first

episodes of any kind of IHD (I20-25), of which 49.7% (538) were angina pectoris (I20) and 50.3% (544) myocardial infarction or close complications to this (I21-I25). There were 565 (28.2%) episodes of CHF; and 356 (17.8%) of Stroke/TIA (I60-69). FCP predicted time to death in T1D R^2 0.07, p 0.09; and T2D R^2 0.08, p< 0.0001; FCP for dead after 15 yrs in T1D OR 10.1 (3.2-31.6) R^2 0.31, p<0.0001; in T2D OR 2.0 (1.7-2.4) R^2 0.07, p<0.0001; and FCP <0.60 nmol/l T1D OR 6.4 (2.1-19.1), p<0.001; T2D OR 1.8 (1.2-2.6), p 0.007.

Conclusion: At diagnosis of adult-onset diabetes and after 15 yrs, especially in T2D, hypertension and other CVD were frequent, 50% of T2D patients had died, and many T2D patients had CVD, while prognosis was better in adult-onset T1D. FCP influenced prevalence of CVD, both at diabetes onset and follow up; time to death, and OR of being dead within 15 years, as did age at onset, but the influence of BMI was very limited

Risk of anaemia with long-term metformin use in a community setting

L.A. Donnelly[1], K. Gardner[2], R.L. Coleman[3], N. Sattar[4], A.T. Hattersley[5], R.R. Holman[3], E.R. Pearson[1];
[1]University of Dundee, Dundee, [2]Crosshouse Hospital, Ayshire, [3]University of Oxford, Oxford, [4]University of Glasgow, Glasgow, [5]University of Exeter, Exeter, UK.

Background and aims: The DPP Outcomes Study showed that metformin use in individuals with impaired glucose tolerance was associated with increased risk of anaemia at 5 years, independent of vitamin B12 status. In people with type 2 diabetes (T2D), anaemia is a common finding but the impact of long-term metformin use on anaemia risk has not been studied. We examined whether cumulative exposure to metformin in T2D is associated with an increased risk of anaemia using data from a large population-based cohort containing longitudinal prescribing and repeated haematology measures.

Materials and methods: We utilised the electronic medical records from patients in the Genetics of Diabetes Audit and Research (GoDARTS) cohort, Scotland. Anaemia was defined as haemoglobin (Hb) <11g/dL. Microcytic anaemia was defined as a mean corpuscular volume <80fl and macrocytic anaemia as >100fl. Individuals with T2D diagnosed from 1996 onwards who had a baseline Hb measured and were not anaemic were followed until they became anaemic, died, left the area or to 30th September 2015 as the end of the follow-up period. Discrete-time failure analysis was used to model the effect of cumulative drug exposure on anaemia risk. This model is set up as a logistic regression model in which each patient contributes one observation for each 28 day time interval from T2D diagnosis to study end. Observational pharmacoepidemiological studies are often prone to allocation bias. To be satisfied that an estimate of a drug's potential causal effect cannot be due to time invariant between person confounding we include two time-updated terms in our model: one for ever-exposure and one for cumulative exposure. We focus the inference of causality on the cumulative term. In addition to metformin exposure, we also evaluated sulfonylureas as a comparator group. The model also included age at diagnosis, sex, baseline Hb and year of T2D diagnosis as fixed covariates, and diabetes duration, social class, eGFR, and BMI as time dependent covariates.

Results: Of 3,485 individuals studied, 2,487 had accumulated some exposure to metformin by the end of follow-up. Median (IQR) follow-up time and number of Hb measures per individual was 8.3 (5-11.5) years and 11 (6-20) respectively. A total of 1,458 (41.8%) individuals became anaemic: 745 in current users, 194 in ex-users and 519 in never-users. Anaemia risk was higher with age at diagnosis (OR 1.03 (95% CI 1.02-1.04) per year) and duration of diabetes (1.05 [1.03-1.08] per year) and decreased with higher baseline Hb (0.70 [0.66-0.74] per 1g/dL) and higher eGFR (0.98 [0.98-0.99] per ml/min/1.73m^2). Cumulative metformin exposure was independently associated with increased risk of anaemia (1.06 [1.02-1.09] per year), but there was no anaemia association with sulfonylureas use. Of those who developed anaemia in the metformin exposed patients, microcytic anaemia was more frequent (12.1% vs. 7.3%) and macrocytic anaemia less frequent (7.6% vs. 12.3%), compared with the non-metformin exposed group.

Conclusion: In this large, observational, population-based study with a maximum follow-up period of almost 20 years, we show that metformin treatment was associated with a 6% higher risk of anaemia for every cumulative year of metformin exposure. As this increased risk was not associated with increased macrocytosis it is unlikely that it relates to vitamin B12 deficiency.

Impact of pioglitazone on stroke outcomes: a real world database analysis

C.L. Morgan[1], S. Inzucchi[2], S. Jenkins-Jones[1], J. Puelles[3], C. Currie[1];
[1]Epidemiology, Pharmatelligence, Cardiff, UK, [2]Yale University, New Haven, USA, [3]Takeda, London, UK.

Background and aims: RCT data from the PROactive trial demonstrated a potent effect of pioglitazone in reducing recurrent stroke in patients with T2DM. More recently, the IRIS Trial showed pioglitazone decreased the risk of vascular events following stroke or TIA in those with insulin resistance without diabetes. The purpose of this study was to investigate this important pleiotropic effect in people exposed to pioglitazone as a glucose-lowering therapy.

Materials and methods: Routine data from the Clinical Practice Research Datalink for people with T2DM were extracted from January 2000 to December 2012, with follow-up to 2016. Cases were selected if exposed to pioglitazone >=90 days. The index date was first prescription for pioglitazone. Patients with prior history of heart failure were excluded. Two sets of non-exposed controls were matched on age, sex, HbA1c, diabetes duration, stroke history, co-morbidities, and prior glucose- lowering regimen. Control set 1 were patients who initiated a new therapy at a comparable time as their respective case initiated pioglitazone. Control set 2 were those patients who continued on the same regimen as their respective case. Outcomes were risk of incident stroke, proportion of strokes resulting in death within 30 days, hospital length of stay and stroke recurrence. Two time-frames were used; duration of treatment and full follow up within the database. Time to events was evaluated using the Cox proportional hazards model adjusted for potentially confounding factors, including atrial fibrillation. Proportion of strokes resulting in death and discharge to usual residence were compared using logistic regression, length of hospital stay was compared using ANCOVA.

Results: 4,267 patients were matched to control set 1 and 3,629 to control set 2. For the primary outcomes there was a trend for a reduced hazard ratio for cases versus controls which was statistically significant for control set 1; 0.627 (0.404-0.972) during therapy period and 0.640 (0.485-0.843) over the entire database period. There was no significant difference between cases and controls in either the 30 day mortality rate or rate of recurrent stroke. For events resulting in hospital admission, there was no difference in overall mean length of stay but there was a significant difference when considering those admissions that resulted in discharge to the patient's usual place of residence (6.3 days versus 12.4; p<0.001) for control set 1. However there was no difference in the proportion of admissions resulting in immediate discharge to the patient's usual residence in either control set.

Conclusion: In support of evidence from two randomized trials, these observational data show that pioglitazone has an apparent potent effect in reducing stroke events in people with T2DM.

Table: Number, crude rate and adjusted hazard ratio for incident stroke for patients initiated with pioglitazone and matched controls.

	Case		Control			
	Events	Rate	Events	Rate	Hazard ratio* (95% CI)	p
Control set 1						
On therapy	32	3.1	55	5.2	0.627 (0.404-0.972)	0.037
Until end of follow up	86	4.3	126	6.9	0.640 (0.485-0.843)	0.002
Control set 2						
On therapy	25	2.8	44	4.4	0.641 (0.382-1.074)	0.091
Until end of follow up	73	4.3	82	5.4	0.809 (0.584-1.122)	0.204

*Adjusted for age, gender, Charlson index, prior 12 month primary care contacts, smoking status, body mass index, systolic blood pressure, total cholesterol, HbA1c, prior history of atrial fibrillation.

Glycaemic, lipid and blood pressure control according to guidelines in patients initiating second-line glucose-lowering therapy: results from the global DISCOVER study

M.B. Gomes[1], B. Charbonnel[2], J. Cid-Ruzafa[3], P. Fenici[4], N. Hammar[5,6], K. Khunti[7], M. Kosiborod[8,9], A. Nicolucci[10], S. Pocock[11], M.V. Shestakova[12,13], H. Watada[14], I. Shimomura[15], F. Tang[8], L. Ji[16], DISCOVER;

[1]Rio De Janeiro State University, Rio de Janeiro, Brazil, [2]University of Nantes, Nantes, France, [3]Evidera, Barcelona, Spain, [4]AstraZeneca, Cambridge, UK, [5]AstraZeneca Gothenburg, Mölndal, [6]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, [7]University of Leicester, Leicester, UK, [8]Saint Luke's Mid America Heart Institute, [9]University of Missouri, Kansas City, USA, [10]Center for Outcomes Research and Clinical Epidemiology, Pescara, Italy, [11]London School of Hygiene and Tropical Medicine, London, UK, [12]Endocrinology Research Center, [13]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, [14]Graduate School of Medicine, Juntendo University, Tokyo, [15]Graduate School of Medicine, Osaka University, Osaka, Japan, [16]Peking University People's Hospital, Beijing, China.

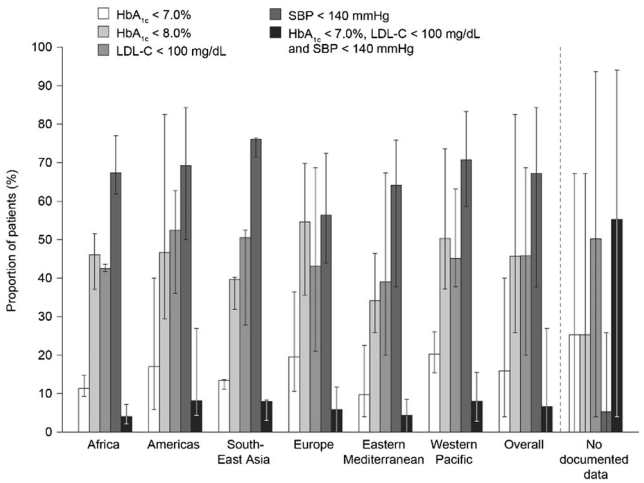
Background and aims: In addition to glycaemic control, guidelines recommend management of LDL cholesterol (LDL-C) and BP in patients with type 2 diabetes mellitus (T2DM). Global patterns of HbA_{1c}, LDL-C and BP control among patients with T2DM are currently not well described.

Materials and methods: DISCOVER is a 3-year observational study of patients with T2DM initiating a second-line therapy, conducted in 37 countries. Clinical variables at baseline were measured according to routine clinical practice at each site, and recorded using a standardized electronic case report form.

Results: Of a total of 14 391 patients, HbA_{1c}, LDL-C and systolic BP (SBP) levels were documented in 74.7%, 49.8% and 94.8%, respectively. All three variables were documented in 44.7%. Mean HbA_{1c} levels varied greatly across countries, but were consistently high (8.44%; across country range [ACR] 7.37-9.20%). Overall, 15.9% of patients had HbA_{1c} < 7.0% (ACR 3.9-40.0%), and 45.7% had HbA_{1c} < 8.0% (ACR 25.7-82.5%). A total of 45.8% of patients had LDL-C < 100 mg/dl (ACR 20.0-68.7%) and 42.4% were taking statins (ACR 14.3-78.4%). Overall, 67.2% of patients had SBP < 140 mmHg (ACR 37.7-84.3%) and 48.2% were taking an antihypertensive drug (ACR 19.1-84.4%). Only 6.6% had HbA_{1c} < 7.0%, LDL-C < 100 mg/dl and SBP < 140 mmHg (ACR 0.0-26.9%). Regional differences are shown in the Figure.

Conclusion: Management of cardiovascular risk factors is inadequate in most patients initiating a second-line glucose-lowering therapy; large proportions of patients are not reaching guideline-recommended targets for LDL-C and SBP. Very few patients achieve target levels for all three parameters (HbA_{1c}, LDL-C and SBP), although elevated HbA_{1c} is expected in this population of patients initiating second-line therapy.

Figure. Proportion of patients attaining recommended goals for HbA_{1c}, LDL-C and SBP.



Whiskers represent across-country ranges. LDL-C, LDL-cholesterol; SBP, systolic BP. Africa: Algeria and South Africa; Americas: Argentina, Brazil, Canada, Colombia, Costa Rica, Mexico and Panama; South-East Asia: India and Indonesia; Europe: Austria, Czech Republic, Denmark, France, Italy, Netherlands, Norway, Poland, Russia, Spain, Sweden, Turkey; Eastern Mediterranean: Bahrain, Egypt, Jordan, Kuwait, Lebanon, Oman, Saudi Arabia, Tunisia and United Arab Emirates; and Western Pacific: Australia, China, Malaysia, South Korea and Taiwan.

Glycaemic control in 14,005 patients with type 2 diabetes initiating second-line therapy in 36 countries: the DISCOVER study

L. Ji[1], A. Nicolucci[2], N. Arya[3], J. Cid-Ruzafa[4], P. Fenici[5], M.B. Gomes[6], N. Hammar[7,8], M. Kosiborod[9,10], S. Pocock[11], M.V. Shestakova[12,13], H. Watada[14], I. Shimomura[15], F. Tang[9], K. Khunti[16], DISCOVER;

[1]Peking University People's Hospital, Beijing, China, [2]Center for Outcomes Research and Clinical Epidemiology, Pescara, Italy, [3]AstraZeneca, Gaithersburg, USA, [4]Evidera, Barcelona, Spain, [5]AstraZeneca, Cambridge, UK, [6]Rio de Janeiro State University, Rio de Janeiro, Brazil, [7]AstraZeneca Gothenburg, Mölndal, [8]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, [9]Saint Luke's Mid America Heart Institute, [10]University of Missouri, Kansas City, USA, [11]London School of Hygiene and Tropical Medicine, London, UK, [12]Endocrinology Research Center, [13]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, [14]Graduate School of Medicine, Juntendo University, Tokyo, [15]Graduate School of Medicine, Osaka University, Osaka, Japan, [16]University of Leicester, Leicester, UK.

Background and aims: There is a lack of data on the extent of glycaemic control among patients with type 2 diabetes in many countries. DISCOVER, a global, prospective, observational study, recruited patients initiating second-line glucose-lowering therapy. Here, mean HbA_{1c} levels at baseline are presented from 36 countries.

Materials and methods: In total, 14 005 patients were evaluated. HbA_{1c} levels were measured in 74.8% of patients according to standard clinical practice in each country.

Results: Patients had a mean HbA_{1c} level of 8.45%, with an across-country range of 7.37-9.20%. A total of 45.5% of patients had an HbA_{1c} level < 8.0%, 24.7% had an HbA_{1c} level ≥ 8.0 and < 9.0%, and 29.8% had an HbA_{1c} level ≥ 9.0%. The proportions of patients in each country with HbA_{1c} ≥ 9.0% at initiation of second-line therapy are shown in the Figure.

Conclusion: HbA_{1c} levels at initiation of second-line therapy varied greatly across countries but were consistently high, suggesting that intensification of glucose-lowering treatment is currently delayed in many people. In some countries, HbA_{1c} levels are not routinely measured; this may be compensated for by assessment of fasting plasma glucose.

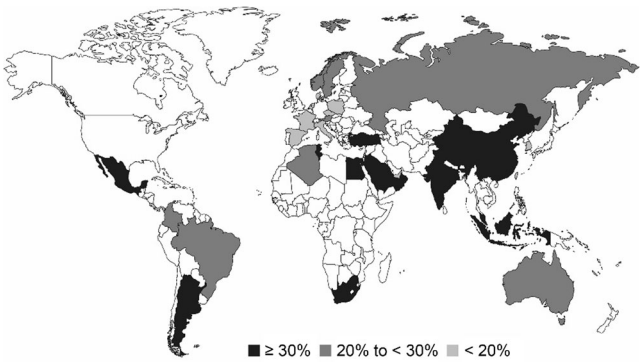

Figure. Proportion of patients with HbA_{1c} ≥ 9.0% at baseline (initiation of second-line glucose-lowering therapy)

Temporal changes in inpatient and outpatient hypoglycaemia among patients treated with sulfonylureas or dipeptidyl peptidase-4 inhibitors in the US

S. Rajpathak[1], Y. Tang[1], J. Liu[1], S.S. Engel[2], H. Hannachi[3];
[1]Merck & Co., Inc., North Wales, [2]Merck & Co., Inc., Rahway, [3]Merck & Co., Inc., Kenilworth, USA.

Background and aims: Recent evidence suggests hypoglycemia rates, mainly in inpatient setting, have not changed much in recent years. Less is known about hypoglycemia in other healthcare settings and by treatment groups with known differential hypoglycemia risk. This real world study aimed to assess changes in annual rates of both inpatient and outpatient hypoglycemia among patients either on sulfonylureas (SU) or dipeptidyl peptidase-4 inhibitors (DPP-4i) during 2007-2013.

Materials and methods: This retrospective cohort study using MarketScan Commercial Claims database included adult patients with type 2 diabetes mellitus using either SU (n=245,201) or DPP-4i (n=176,786) (mono- or combination therapy with other drugs, excluding insulin). Hypoglycemia, defined by ICD-9 diagnosis codes, was assessed during 12-month follow-up period after drug initiation. Poisson regressions were used to calculate Poisson models were used to generate 95% confidence interval (CI) for hypoglycemia rates. Patient demographic and clinical characteristics were assessed within one year prior to drug initiation. (Figure)

Results: Outpatient hypoglycemia rates (100 person-years) increased from 2007 to 2013: 4.4 to 9.2 in SU; 3.0 to 6.0 in DPP-4i users. Inpatient hypoglycemia rates ranged 1.0-1.3 in SU; 0.2-0.4 in DPP-4i users. (Figure)

Conclusion: There was apparent increase outpatient hypoglycemia rate in recent years in both SU and DPP-4i, which might be related to improved awareness and coding/reporting. Changes in inpatient hypoglycemia overtime were relatively small. In both settings, hypoglycemic events were consistently higher among SU than DPP-4i users.

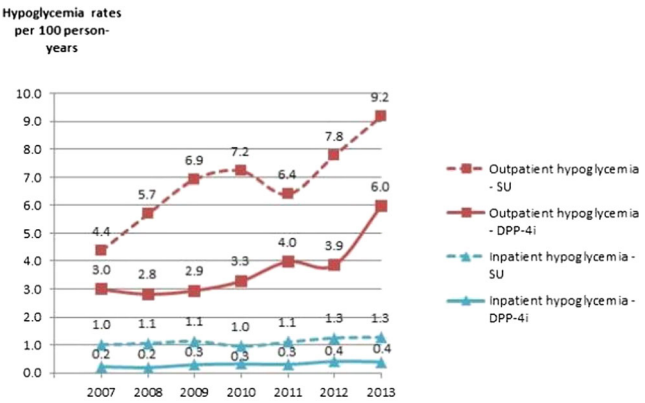

Figure. Inpatient and outpatient hypoglycemia rates in SU and DPP-4i users.
Notes: SU: sulfonylurea; DPP-4i: dipeptidyl peptidase-4 inhibitor.
SU group: N = 245,201; age=51.9 years, female=43.5%, Charlson Comorbidity Index=1.50;
DPP-4i group: N = 176,786; age=52.8 years, female=45.5%, Charlson Comorbidity Index=1.59.
Poisson models were used to generate 95% confidence interval (CI) for hypoglycemia rates:
Outpatient hypoglycemia rates from 2007 to 2013: 4.4 (95% CI: 4.1-4.7) to 9.2 (95% CI: 8.7-9.7) in SU; 3.0 (95% CI: 2.7-3.3) to 6.0 (95% CI: 5.5-6.4) in DPP-4i;
Inpatient hypoglycemia rates from 2007 to 2013: 1.0 (95% CI: 0.9-1.2) to 1.3 (95% CI: 1.1-1.5) in SU; 0.2 (95% CI: 0.2-0.3) to 0.4 (95% CI: 0.3-0.5) in DPP-4i.

Metformin regulates mitophagy through AMPK signalling pathway in human-derived mononuclear cells

S. Bhansali[1], A. Bhansali[2], V. Dhawan[1];
[1]Experimental Medicine and Biotechnology, Post Graduate Institute of Medical Education and Research, [2]Endocrinology, Post Graduate Institute of Medical Education and Research, Chandigarh, India.

Background and aims: Metformin is recommended as a first-line drug in the management of T2DM. Besides the dual defects in T2DM namely; insulin resistance and insulin deficiency, the role of autophagy has also been implicated in β-cell function and health. Recent evidences report that metformin, apart from being a classical insulin sensitizer, also induces autophagy. However, its effect on mitophagy (selective autophagy of mitochondria) has

not been explored so far. The present study aims to elucidate the effect of metformin and its underlying molecular mechanism involved in the regulation of mitophagy.

Materials and methods: Peripheral blood mononuclear cells (PBMCs) were obtained from the healthy volunteers. The cells were cultured and treated independently with rapamycin (autophagy-inducer), bafilomycin (autophagy-inhibitor) and metformin. For exploring the role of AMPK signaling pathway, cultured PBMCs were pretreated with AMPK inhibitor (AMPKi), followed by metformin treatment. Acridine orange (AO) staining, transcriptional and translational expression studies of mitophagy-related genes (*PINK1, PARKIN, MFN2, NIX, LAMP2* and *LC3II)* and transmission electron microscopic (TEM) studies were performed.

Results: Metformin treatment led to a significant increase in the number of autophagolysosomes ($p< 0.05$) as shown by AO staining. Also, TEM studies revealed an increased percentage of mitophagy in metformin-treated cells ($p< 0.01$). This was also strengthened by the real-time qPCR studies, which showed an augmented expression of mitophagy markers in response to metformin treatment ($p < 0.05$). Further to elucidate the molecular mechanism of metformin-induced mitophagy, our observations revealed a significant up-regulation in the mRNA and protein expression of mitophagy markers in metformin-treated cells ($p < 0.05$), whereas, in the presence of AMPKi, the expression of mitophagy-related genes was significantly down-regulated ($p < 0.05$).

Conclusion: Metformin induces mitophagy and the pharmacological inhibition of metformin-activated AMPK phosphorylation suppresses the expression of mitophagy markers, suggesting metformin regulates mitophagy in an AMPK-dependent manner. Besides its classical role as an insulin sensitizer, metformin also promotes mitophagy, which might be beneficial in maintaining β -cell function, as mitochondria are involved in ATP generation and consequent insulin biosynthesis and secretion.

Disclosure: **S. Bhansali:** None.

Acute and long-term effects of saxagliptin on post-prandial glycaemic response and cardiovascular parameters in obese patients with impaired glucose tolerance

A. Rezki, M. Fysekidis, B. Merioud, A. Sutton, S. Chiheb, I. Banu, E. Cosson, P. Valensi;

Service Endocrinologie Diabétologie Nutrition, Hôpital Jean Verdier, Bondy, France.

Background and aims: Impaired glucose tolerance (IGT) is associated with a high cardiovascular risk. Diabetes prevention should be proposed in this situation. In obese patients, cardiac output (CO) is increased and autonomic cardiovascular changes are common. The issue of cardiovascular safety concerns all new anti-diabetic treatments. The aim of this study was to examine the acute and long-term effects of saxagliptinon plasma glucose and various cardiovascular parameters before and after a breakfast in patients with IGT.

Materials and methods: We included 24 IGT patients, normotensive or with well-controlled hypertension, without any history of cardiovascular disease. The patients were randomized in a double blind trial with saxagliptin 5mg (S) *vs* placebo (P). The tested treatment was taken from the first to the second visit, during 12 weeks. The biological and physiological investigations were performed every hour before and after a standardized breakfast (75g carbohydrates), during 4 hours, at visit 1(day 0) and visit 2 (day 90). Sympatho-vagal balance (LF/HF-HR) was assessed by spectral analysis of heart rate variations; cardiac output (CO) and left ventricular ejection time (LVET) by thoracic impedance (Task Force Monitor®) at controlled breathing rate (12/min); mean cutaneous blood flow (CBF) was measured on the forearm during 6 minutes by laser doppler (Periflux®); and endothelial function using iontophoretic cutaneous infusion of acetylcholine (area under curve AUC-CBF).

Results: Sex-ratio (Females S: 83% *vs* P: 75%), age (S: 49.8±14.6*vs*P:40±10.7 years) and BMI (S: 36.2±5.6*vs*P: 37.5±4.1kg/m²) were similar in the two groups. Compared to the placebo group, patients treated by saxagliptin had similar level of plasma glucose at fasting at day 0 and day 90 but lower plasma glucose at 1 and 2 hours after breakfast by day 0 and at day 90 as compared to placebo-treated patients ($p<0.01$ to $p<0.004$). There was no significant difference for sympatho-vagal activity, CO, LVET, mean CBF and AUC-CBF between the 2 groups at day 0 and day 90, before and after breakfast.

Conclusion: Saxagliptin has a beneficial effect on post-prandial plasma glucose in obese patients with IGT without altering the cardiovascular parameters such as CO, cardiovascular autonomic activity or cutaneous microcirculation and endothelial function. Saxagliptin lowered immediately post-prandial plasma glucose values.

Factors associated with type 2 diabetes disease progression in a longitudinal cohort (2006 - 2014)

W. Weng[1], Y. Liang[2], E. Kimball[1], T. Hobbs[1], S. Kong[1];

[1]Novo Nordisk Inc, Plainsboro, [2]Truven Health, Cambridge, USA.

Background and aims: There is little real world evidence available on the relationship between outcomes for type 2 diabetes (T2D) and different treatment pathways. This longitudinal study of a cohort of newly diagnosed T2D patients with 8 continuous years of enrollment examined the relationship over time between disease progression based on the Diabetes Severity Complications Index (DCSI) score, patient demographics, and changes in prescription drug use and adherence from 2006-2014.

Materials and methods: This was a retrospective study using an administrative claims database in the US. It included newly diagnosed T2D patients in 2006 with DCSI score of 0. DCSI score ranges from 0 to 13, the higher the score, the more severe the disease. Inclusion criteria were: ≥2 diagnoses for T2D or ≥1 T2D diagnosis + ≥1 OAD claim, and no more than 1 T1D diagnosis according to ICD-9 codes, ≥18 years of age, and continuous enrollment to 2014. Based on the year 8 DCSI score, patients were divided into three cohorts: DCSI of 0, 1-2, and ≥3. In addition, sub-group analyses based on 3 age groups (18-44, 45-64, and 65+ yrs) were conducted. Comparisons among the 3 DCSI cohorts were conducted using an ANOVA model for continuous variables and a logistic regression model for categorical variables.

Results: 16,950 newly-diagnosed T2D patients in 2006 were included in this study. By year 8, the proportions of patients with DCSI score 0 was 29.9% (N=5,070), 1-2 36.1% (N=6129), and ≥3 33.8% (N=5751), respectively. The most prominent difference among the 3 DCSI groups was age at diagnosis: 49.6, 52.3, and 59.8 yrs, $p<0.001$. The percentage of males was higher in the DCSI ≥3 group: 49.4%, 48.4%, 53%, $p<0.001$. Insulin usage was observed to increase over the course of the study and was significantly different among the 3 DCSI groups at year 8 (6.2%, 8.8%, 11.5%, $p<0.001$). Drug adherence rate over the whole study period with any antidiabetic medication was assessed by proportion of days covered (PDC): 58%, 62%, and 62%, $p<0.001$. When assessing the DSCI related comorbidities for 3 age groups (18-44, 45-64, and 65+ yrs), the two comorbidities which progressed the most were neuropathy/retinopathy for age 18-44 group, cerebrovascular/neuropathy for age 45-64 group, and cerebrovascular/cardiovascular for age 65+ group.

Conclusion: This study using real world data shows a relationship between T2D disease progression and age at diagnosis. Higher drug adherence rates did not appear to reduce DCSI score worsening. Insulin usage was observed to increase over the course of the study, and more so in the group with DCSI ≥3.

Trajectories of obesity by spousal diabetes status in the English Longitudinal Study of Ageing

O. Silverman-Retana[1,2], A. Hulman[1,2], R.K. Simmons[1,2], J. Nielsen[3], D.R. Witte[1,2];
[1]Department of Public Health, Aarhus University, Aarhus, [2]Danish Diabetes Academy, Odense, [3]Global Health Section, Department of Public Health, University of Copenhagen, Copenhagen, Denmark.

Background and aims: People with a spouse with diabetes have an increased risk of diabetes, most likely due to assortative mating and their shared home and social environment. Spousal concordance in cardiometabolic risk factors has been observed across different populations, but has not been studied longitudinally. We examined whether the development of obesity with age was different for people with and without a spouse with diabetes.

Materials and methods: We analysed age-related trajectories of obesity by spousal diabetes status in the English Longitudinal Study of Ageing. We fitted quadratic age-trajectories using mixed-effects models. Outcomes of interest were body mass index (BMI) and waist circumference (WC). Our main exposure was having a spouse with diabetes defined by either self-reported medical diagnosis or screen-detected with fasting glucose or glycated hemoglobin during one of the follow-up waves. We restricted this analysis to opposite-sex spouses (based on self-report of marriage or cohabitation) of index individuals without diabetes.

Results: Our analysis included 7,156 individuals (49% women). At age 50, BMI levels were not different between individuals with and without a spouse with diabetes (Figure). Across all groups, BMI increased with age until 70 years and then showed a slight decline. Men with a spouse with diabetes experienced a steeper increase in BMI than men with a spouse without diabetes up to the age of 60 years. Women with a spouse with diabetes had a similar BMI trajectory to women who did not have a spouse with diabetes but their average BMI levels were higher. We observed similar shapes in waist circumference trajectories by spousal diabetes status for men and women (data not shown). Individuals with a spouse with diabetes had higher levels of waist circumference throughout follow-up. This difference was only statistically significant among women (2.6cm larger (95%CI: 0.5, 4.8) waist circumference at age 50 years in women with a spouse with diabetes compared to women whose spousal diabetes).

Conclusion: Individuals with a spousal history of diabetes have higher levels of obesity beyond the age of 55 years compared to individuals with no spousal diabetes. Middle-age spouses of individuals with diabetes may benefit from assessment of their weight status.

Associations between socioeconomic positions and lifestyle and motivation for change of lifestyle among individuals with diabetes in Denmark

A.-S.D. Bjørkman[1,2], M.B. Andersen[1,2], O. Ekholm[3], S. Molsted[1];
[1]Department of Clinical Research, Nordsjællands Hospital, Hillerød, [2]Master of Science in Public Health, University of Southern Denmark, Esbjerg, [3]National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark.

Background and aims: The increasing prevalence of diabetes mellitus (DM) constitutes an important public health problem. The risk of development of complications related to DM is a major burden for the individual and for the society. The risk of complications is influenced by lifestyle factors. Whilst the burden of complications may increase with a declining socioeconomic position (SEP), SEP has been found to be lower among individuals with DM than among non-DM individuals. The aim of this study was to examine the association between SEP and lifestyle factors: smoking, alcohol consumption and physical inactivity, and motivation for change of lifestyle among individuals with DM in Denmark.

Materials and methods: This cross-sectional study analyzed SEP based on educational level stratified into three categories: low, middle and high, and lifestyle factors including smoking status, alcohol consumption and physical activity. The data were provided by the Danish Health and Morbidity Survey, a nationwide survey in the general population (n=~15,000). Individuals with DM and age ≥ 40 years were included. All data were self-reported. Multiple logistic regression analyses were performed to analyze the associations and were adjusted for age and gender.

Results: The study population included 612 individuals with DM. The mean ± SD age were 64.3 ± 10.8 years and included 328 (53.6%) males and 284 (46.4%) females with a body mass index of 29.1 ± 5.4 kg/m^2. Among the participants 17.6% smoked, 15.6% consumed alcohol above the maximum limit of recommendations (7 and 14 alcohol units for women and men, respectively) and 23.1% were physically inactive. There were no association between SEP and smoking status. The odds ratio (OR) for exceeding alcohol consumption above the national recommendations was 2.78 (95% CI: 1.32-5.84) in individuals with high educational level compared to those with low educational level. In individuals with middle educational level OR was 0.50 (0.27-0.74) of being physically inactive (also adjusted for body mass index) compared to low educational level. There were no association between SEP and motivation for smoking cessation. Being motivated to decrease the alcohol consumption for individuals with high educational level compared to low educational level was OR 3.68 (1.03-13.19). No association was found between SEP and motivation for being more physically active.

Conclusion: Higher SEP assessed as educational level was associated with an alcohol consumption that exceeded the national recommendations and associated with an increased motivation for a reduction of alcohol consumption. Furthermore, higher SEP was associated with a reduced risk of being physically inactive. The results may have clinical implications in terms of a focus on new physical activity programs to persons with diabetes and low SEP. In general, there were limited associations between SEP and motivation for change of lifestyle among individuals with DM.

Long term consequence of breastfeeding on maternal obesity in middle-aged elderly women

S. Kan;
Department of Endocrinology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.

Background and aims: The relationship between breastfeeding and body composition changes among reproductive-aged women is highly variable in different nations. The longer term effect of breastfeeding history on bodyweight, especially for women around perimenopausal period, is still not clear. Our objective was to evaluate the long-term effects of breastfeeding on maternal obesity in developing country.

Materials and methods: We performed a population-based study in 6,430 eligible women aged 40 years or older. Information on breastfeeding and its duration was self-reported. Obese was defined as body mass index (BMI) equal or greater than 28 kg/m^2 while overweight was defined as BMI equal or greater than 24 kg/m^2 and less than 28 kg/m^2. Central obesity for women was defined as waist circumference (WC) equal or greater than 80 cm.

Results: Compared with normal weight women, the proportion of breastfeeding was significantly higher in overweight, obese and central obesity women (all $P < 0.05$). Breastfeeding duration was significantly correlated with both BMI and WC (all $P < 0.0001$). Compared with no breastfeeding women, those ever breastfeeding have a significant increased odds of overweight (OR 1.19, 95% CI, 1.04 - 1.37), obese (OR 1.39, 95% CI, 1.08 - 1.80) and central obesity (OR 1.22, 95% CI, 1.08 - 1.39) after multiple adjustments. A nonlinear relationship between breastfeeding duration and adiposity was also detected and longer breastfeeding period seems to increase prevalent overweight, obese and central obesity (all P for trend < 0.001).

Conclusion: Breastfeeding and its duration were associated with increase of prevalent overweight, obese and central obesity in middle-aged and elderly Chinese women. Dietary and exercise guidelines for breastfeeding women should include ways to prevent postpartum obesity in China. As there were many other factors associated with postpartum weight change and many positive benefits to breastfeeding, further prospective studies are necessary to verify our findings in other developing countries.

	Breastfeed druation (months)				
	0	0.1 - 6	6 - 9	9 - 12	> 12
Obese	1	0.85 (0.60 - 1.19)	1.28 (0.91 - 1.79)	1.54 (1.10 - 2.15)	2.00 (1.47 - 2.73)

Associations of dairy products intake with fat and lean mass distribution in the Fenland Study, UK

E. Trichia[1], F. Imamura[1], S. Brage[1], S.J. Griffin[1,2], N.J. Wareham[1], N.G. Forouhi[1];
[1]MRC Epidemiology Unit, University of Cambridge School of Clinical Medicine, [2]Department of Public Health and Primary Care, Institute of Public Health, University of Cambridge, Cambridge, UK.

Background and aims: Accumulating evidence suggests that fermented dairy products, including yoghurt are inversely associated with type 2 diabetes risk, though findings are less consistent for other types of dairy products. The mechanisms of the link between dairy products and metabolic disease have not been established, but effects on body composition have been proposed as one pathway. Our aim was to investigate the association between dairy products intake and objectively measured markers of body composition.

Materials and methods: We evaluated 12,065 adults (55% women) aged 30 to 65 years recruited to the Fenland study between 2005 and 2015 in Cambridgeshire UK. Diet was assessed with a validated food frequency questionnaire. Markers of body composition were derived from dual energy X-ray absorptiometry and ultrasonography including visceral-to-subcutaneous adipose tissue ratio (VAT/SCAT), total and peripheral body fat mass, and total and appendicular body lean mass. Cross-sectional associations were investigated between total and subtypes of dairy products (servings/day) and markers of body composition using MM-robust regression adjusting for socio-demographic, lifestyle, dietary factors and BMI. Missing values were imputed and the false discovery rate (FDR) correction was used to account for multiple testing. Interactions with sex and BMI were examined.

Results: The mean±SD dairy product intake was: total dairy 372±193 g/day; milk 288±176 g/day; yoghurt 52±64 g/day; and cheese 18±18 g/day. Total and high-fat dairy were not related to any body composition marker, but low-fat dairy products intake was inversely associated with VAT/SCAT [% difference per serving (95% CI): -2.58 (-3.91, -1.23)]. Among dairy subtypes, no association was observed for yoghurt, cheese, butter or ice-cream for any outcome. Milk intake was associated with body lean mass, with a glass of milk per day being associated with higher lean mass by 0.33kg (95% CI: 0.19, 0.46) and both low- and full fat milk showed similar associations. There were no significant interactions by sex and BMI for any associations, with exception for the interaction by BMI for the association of high-fat dairy consumption with appendicular lean mass. Appendicular lean mass was lower by 0.11 kg (95% CI: -0.22, -0.001) per one serving of high-fat dairy among adults with normal body weight, but not significant among overweight (+0.05 kg; -0.07, +0.18) or obese adults (+0.02 kg; -0.16, +0.20).

Conclusion: These findings suggest that total low-fat dairy products and milk intake may be associated with metabolic risk through the distribution of visceral fat relative to subcutaneous fat and body lean mass respectively, as potential pathways. Further research is warranted to confirm these findings in prospective analyses.

Eating out increases the risk of being overweight and deteriorates glucose control in patients with type 2 diabetes: a cross-sectional study

Y. Kondo[1], S. Satoh[2], Y. Terauchi[1];
[1]Endocrinology and Metabolism, Yokohama City University, [2]Endocrinology and Metabolism, Chigasaki Municipal Hospital, Kanagawa, Japan.

Background and aims: In patients with type 2 diabetes (T2D), weight gain increases insulin resistance and exacerbates poor glycemic control. Unfortunately, it is quite difficult to manage weight in patients with T2D. Several studies have revealed a relationship between the habit of eating out and weight gain. However, the effects of the frequency of eating out on weight status and glucose control in patients with T2D are unclear. Therefore, we investigated the effects of the habit of eating out on weight and glucose control in patients with T2D.

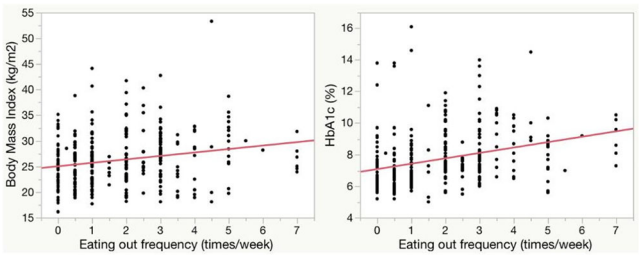
Materials and methods: We performed a cross-sectional study of patients with T2D (June 2010 to March 2017), and assessed eating out frequency (times/week) and diabetes-related information using a medical chart review. Univariate and multivariate regression analyses were performed to determine the association of eating out frequency with BMI (overweight status: BMI ≥ 25 kg/m^2), and HbA1c levels.

Results: After the screening, we included 324 consecutive patients with T2D in our analysis. Their mean eating out frequency was 1.8 ± 1.6 times/week,

mean BMI was 26.3 ± 5.2 kg/m^2, and mean HbA1c was 7.7 ± 1.8 %. In the univariate regression analysis, eating out frequency was positively related to BMI levels (β = 0.67, standard error (SE): 0.17, 95% confidence interval (CI): 0.33 to 1.02, p < 0.001). In the multivariate regression analysis, the relationship between eating out frequency and BMI levels was preserved even after adjustment for potential confounders including age, sex, estimated glomerular filtration rate (eGFR), diabetes duration, and diabetes treatment (adjusted β = 0.39, SE: 0.17, 95% CI: 0.06 to 0.71, p = 0.02). Eating out ≥ 2 times/week increased the risk of being overweight by 72% (adjusted odds ratio: 1.72, 95% CI: 1.06 to 2.83, p = 0.03). In the univariate and multivariate regression analysis, the eating out frequency was also positively related to HbA1c levels (univariate: β = 0.34, SE: 0.06, 95% CI: 0.23 to 0.46, p < 0.001, multivariate: β = 0.36, SE: 0.06, 95% CI: 0.24 to 0.49, p < 0.001). In the receiver operating characteristic (ROC) analysis, the cut-off value of eating out frequency for having an HbA1c level ≥ 7% was 2 times/week (sensitivity: 65%, specificity: 78%).

Conclusion: In this cross-sectional study, eating out frequency was positively related to BMI, being overweight, and HbA1c levels in patients with T2D. These findings suggest that encouraging eating at home for T2D patients might reduce the risk of being overweight, and improve glucose control.

Figure 1. Univariate regression analysis between eating out frequency, body mass index, and HbA1c



β = 0.67, SE 0.17, 95% CI 0.33 to 1.02, p < 0.001

β = 0.34, SE 0.06, 95% CI 0.23 to 0.46, p < 0.001

The effectiveness of a community lifestyle intervention progamme in the improvement of perceived health status and health-related quality of life. The DE-PLAN study

G. Karamanakos[1], B. Costa[2], A. Gilis-Januszewska[3], D. Velickiene[4], F. Barrio[2], X. Cos[2], S. Mestre[2], B. Piwońska-Solska[3], A. Hubalewska-Dydejczyk[3], K. Makrilakis[1], S. Liatis[1];

[1]First Department of Propaedeutic/Internal Medicine, University of Athens Medical School, Laiko General Hospital, Athens, Greece, [2]Catalan Diabetes Prevention Research Group, Jordi Gol Primary Care Research Institute, Catalan Health Institute, Primary Health Care Division, Reus-Barcelona, Catalonia, Barcelona, Spain, [3]Department of Endocrinology, Jagiellonian University, Medical College, Krakow, Poland, [4]Lithuanian University of Health Sciences, Institute of Endocrinology, Kaunas, Lithuania.

Background and aims: Apart from the objectively diagnosed and managed complications of diabetes, the subjective evaluation of health status and quality of life (HRQOL) by the patient is often overlooked. Therefore it is important to include assessment of these parameters in all interventions aiming to improve quality of care or prevent the disease. Our aim was to examine the impact of a community based lifestyle intervention on perceived health status and HRQOL in individuals at high risk for type 2 diabetes (T2D) from four European countries participating in the DEPLAN study, through a post-hoc analysis.

Materials and methods: The DE-PLAN was a European multicentre study, designed and implemented with the primary objective of testing whether a community lifestyle modification program could serve as a means of primary prevention of T2D in high-risk individuals. Each centre was allowed to follow any intervention strategy-assisted, self-managed, group-based or individual-based consultation- of one-year duration. Anthropometric measurements and clinical evaluation, including an oral glucose tolerance test and lipid profile were performed at baseline and after one year. Health-related quality of life was assessed using the validated HRQOL-15D questionnaire before and after the intervention. This questionnaire contains 15 dimensions, each having five different levels of functional status and can be presented as a 15-dimensional profile or as a one-index score (15D). In the present analysis, individuals from four centres (Athens, Barcelona, Krakow and Kaunas) with complete data regarding the HRQOL during the study were included.

Results: Data from 919 participants (494 females) were analyzed (Athens: 125, Barcelona: 551, Krakow: 165, Kaunas: 78). The mean age and BMI of the population were 61.8±11.2 years, and 31.6±4.6 respectively. After 1 year, a significant weight reduction was observed (-0.84±4.3kg, P< 0.01). A significant overall improvement in HRQOL, as depicted by the 15D score, was shown (from 0.89 to 0.91, P<0.01). Improvement was consistent among all centers, albeit in different degrees. Significant positive changes in functionality were found in breathing, sleeping, excretion, usual activities, mental function, discomfort and symptoms, depression, distress and vitality (all p<0.01). In multivariable analysis, improvement in HRQOL was positively associated with lower 15D score at baseline, female gender, higher baseline fasting plasma glucose, younger age and amount of weight loss.

Conclusion: A community-based lifestyle intervention programme aiming at T2D prevention, even when implemented in diverse populations and by different centers, is a realistic mean to improve overall health-related quality of life, achieve weight reduction and thus serve in the primary prevention of the disease burden in Europe.

Impact of sugar sweetened beverages on incidence of type 2 diabetes in Ireland

K.N. O'Neill, A.P. Fitzgerald, P.M. Kearney;

Department of Epidemiology and Public Health, University College Cork, Cork, Ireland.

Background and aims: Habitual sugar sweetened beverage (SSB) consumption is associated with increased incidence of type 2 diabetes (T2D). The rising prevalence of T2D is a significant public health concern. Our aim is to estimate the impact of SSB consumption on T2D incidence in Ireland and subsequently the potential impact of public health interventions targeting SSB consumption.

Materials and methods: Data from the nationally representative Survey of Lifestyle and Nutrition 2007 (SLAN) were analysed. Food frequency questionnaires were used to measure SSB consumption. A risk prediction algorithm (QDScore2015) was applied to the data to estimate individual risk of developing T2D and absolute event rate. Population attributable fraction was calculated using these ten-year risk estimates of developing T2D, SSB consumption and previously published relative risk of incident T2D diabetes per SSB serving. The absolute event rate and population attributable fraction were applied to census data, estimating absolute numbers of incident diabetes cases attributable to SSB consumption in the Irish population.

Results: Of the 7272 participants in SLAN, 53.3% consumed SSBs. The mean SSB consumption was 44.1(SD106.3) g/day. Applying the risk prediction algorithm, the absolute rate of diabetes over ten years from 2007 was estimated to be 4.5%. The population attributable fraction calculated for SSB consumption was 1.8%. When applied to the national adult population, this equates to 129,664 incident diabetes cases over the previous ten-year period with 2,334 of these cases attributable to SSB consumption.

Conclusion: Assuming a causal association, a notable number of incident cases of diabetes over the previous ten years may be attributed to SSB consumption in Ireland. Interventions aimed at reducing SSB consumption in the population have the potential to prevent up 1.8% of diabetes cases over a ten-year period.

The association between multiple sleep-related characteristics and the metabolic syndrome in the general population: the New Hoorn study

F. Rutters[1], J.W. Beulens[1], A.D.M. Koopman[1], J. Lakerveld[1], A.A. van der Heijden[2], G. Nijpels[2], P.J. Elders[2];
[1]Department of Epidemiology and Biostatistics, Vumc, [2]Department of General Practice, VUmc, Amsterdam, Netherlands.

Background and aims: Previous studies have investigated the association between sleep duration, insomnia, day-time napping and metabolic syndrome individually, but never conjointly and the association with sleep medication use has yet to be investigated. Our aim was to examine the associations between these sleep-related characteristics and the metabolic syndrome in a population-based cohort, individually and conjointly.

Materials and methods: We used cross-sectional data of 1679 participants from the New Hoorn study, 52.6% women and age 60.8±6.4y. Sleep duration, insomnia and day-time napping were measured using validated questionnaires. Use of sleep medication was measured by registration of dispensing labels. Metabolic syndrome was defined according to ATP III. Linear and Poisson regression were used and all analyses were adjusted for age, sex, education level, job status, smoking, physical activity, depression and BMI.

Results: In our population-based cohort, 447 (26.6%) persons had the metabolic syndrome. The individual associations showed that after correction, day-time napping for ≤30 minutes and >30 minutes was associated with a prevalence ratio for the metabolic syndrome of 1.28 (95% CI: 1.1-1.5) and 1.74 (95% CI: 1.4-2.2), respectively, compared to participants who did not nap. Sleep duration, insomnia, and sleep medication use were not associated with the metabolic syndrome individually. The conjoint analysis, showed after correction that having ≥2 sleep-related characteristics was associated with a PR of 1.36 (95% CI: 1.0-1.8) of having the metabolic syndrome, compared to having no sleep-related characteristics.

Conclusion: Sleep-related characteristics were associated with a higher prevalence of the metabolic syndrome in the general population.

Increasead HbA_{1c} in non diabetic night shift workers and former night shift workers with a self reported bad sleep quality

S. Rizza, A. Luzi, A.M.V. Fiore, M. Mavillo, R. Menghini, M. Federici;
University of Tor Vergata, Rome, Italy.

Background and aims: Sleep has a regulatory effect on glucose metabolism and on hormones regulating appetite, and therefore disturbances in sleep may promote precocious glucose disturbance among shift workers. Recent data suggested that shift working activity increases the prevalence of diabetes although the effect of prolonged nightshift work pattern is still under investigation

Materials and methods: This is a cross-sectional work. The aim of the study is to identify whether sleep disturbances might mediate the relationship between night shift work and alteration in glucose metabolism in individuals without metabolic cardiovascular risk factors. Nurse hospital employees working a shift schedule of four up to seven 12 h nights per month, followed by 2 days off (NSW, n=111) were compared with former-night shift workers (ex-NSW, n=98) and with day-only workers (controls, n=64). We acquired anthropometric data and dosed glucose and lipid levels, and inflammation among the 3 groups. We used the Pittsburgh Sleep Quality Index (PSQI) global score as a potential mediator in the relationship between night shift work and precocious unknown glucose disturbances.

Results: Night shift and former-night shift work status was significantly associated with higher diastolic blood pressure (74.8±9.3 and 73.6±8.4 mmHg) respect to control group (71.0±9.5 mmHg, p:0.024). In addition, NSW and ex-NSW had higher A1c levels (5.3±0.3% for both) compared with controls (5.1±0.2%, p<0.001 controlled for age, BMI and gender) but not C-Reactive Protein, fasting glucose levels or insulin resistance (HOMA). Similarly, good sleepers (PSQI global score <6) compared to bad sleepers (PSQI global score ≥6) showed only lower levels of A1c (5.2±0.3% vs 5.3±0.3%, p=0.025). Next, we created 6 groups according to PSQI global score and shift work status (NSW-bad sleepers, NSW-good sleepers, ex-NSW-bad sleepers, ex-NSW-good sleepers, controls-bad sleepers and controls-good sleepers). Again, both NSW and ex-NSW with a self reported bad sleep quality had significantly higher A1c levels, but not inflammation, glucose or insulin resistance, respect to control groups either good or bad sleepers.

Conclusion: In a cohort of nightshift and non nightshift workers we observed that dysfunctional sleep pattern in night shift workers is associated with subtle differences in glucose tolerance as measured using A1C. This difference is also observed in former night shift workers suggesting that a metabolic memory may remain independently from age, sex and BMI. Whether the subtle defect in A1c depends from postprandial glucose levels as well as the role of sleep quality affects glucose tolerance are still under investigation.

The effect of smoking and smoking cessation on the development of peripheral vascular disease in patients with type 1 diabetes

M. Feodoroff[1,2], M. Kallio[3,1], V. Harjutsalo[1,4], C. Forsblom[1,2], P.-H. Groop[1,2], FinnDiane Study Group;
[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Biomedicum Helsinki, University of Helsinki, [2]Abdominal Center Nephrology, University of Helsinki and Helsinki University Hospital, [3]Abdominal Center Vascular Surgery, University of Helsinki and Helsinki University Hospital, [4]National Institute for Health and Welfare, Helsinki, Finland.

Background and aims: Previous studies regarding smoking and peripheral vascular disease (PVD) in diabetes have mainly included patients with type 2 diabetes. Furthermore, the effect of smoking cessation on the development of PVD is poorly studied. Our aim was therefore to study the effect of smoking and smoking cessation on the development of PVD in patients with type 1 diabetes.

Materials and methods: The study included 4,352 patients with type 1 diabetes participating in the FinnDiane (Finnish Diabetic Nephropathy) Study. Based on baseline smoking status, patients were divided into three groups: never, former or current smokers. Incident PVD was defined as lower extremity amputation, radiological or surgical revascularization. Follow-up data for the development of PVD were based on hospital discharge registers until end of 2014. Overall follow-up time was 54,086 person years and median follow-up time 13.7 (IQR 10.9-15.8) years. Risk of PVD was estimated by Cox-regressions. Smoking status was used as categorical variable, and years since smoking cessation as continuous variable. Never smokers or current smokers were used as reference groups. Sex, age, HbA_{1c}, hypertension, BMI, duration of diabetes, HDL-cholesterol, log triglycerides and baseline nephropathy status were used as covariables.

Results: Compared with never smokers, the risk of PVD was increased in current smokers with a HR of 1.55 (95% CI 1.15-2.07). The corresponding HR for former smokers was 1.08 (0.81-1.44) and did not differ from never smokers after multivariable adjustments (Figure). Smoking cessation decreased the risk of PVD in former smokers with a HR of 0.70 (0.51-0.95) compared with current smokers. Finally, when years since smoking cessation was used as continuous variable, the risk of PVD was reduced in former smokers with a HR of 0.979 (0.961-0.999) per each year without smoking before the baseline visit.

Conclusion: Smoking is a significant risk factor for PVD in patients with type 1 diabetes. After smoking cessation, the risk of PVD is gradually decreases in former smokers and finally reaches the level seen in never smokers.

PS 007 Prediction and screening for type 2 diabetes

318

Use of EZScan test for differentiation of normal, diabetes and prediabetes state

I. Daskalova, T. Totomirova, N. Petrov;
Military Medical Academy, Sofia, Bulgaria.

Background and aims: The early detection of prediabetes and diabetes is an important part for successful treatment and control of the disease. EZScan is a novel screening methodology based on detection of peripheral nerve complications that could be used for screening and disease control. The aim of our observation was to assess the potency of EZScan to discover disordrs in carbohydrate metabolism.

Materials and methods: 187 patients (95 women, 92 men, mean age 49.4±8.3years) were screened by using EZScan test to differentiate normal, diabetic and prediabetic state. Each patient underwent oral glucose tolerance test (OGTT) with 75 g glucose with assessing glucose level on 0 minute and 120 minute. Results from EZScan were compared with results from OGTT to find the coincidence of defined carbohydrate disorder.

Results: Among patients with normal carbohydrate metabolism diagnosed by EZScan, 70 patients (93%) were confirmed with OGTT and 5 patients (7%) were with impaired carbohydrate metabolism. Among patients with prediabetes, impaired glucose tolerance or impaired fasting glucose were found in 64 patients (96%) but 3 patients (4%) had already diabetes. In patients described as diabetics by EZScan, only 2 patients (4%) had prediabetes and the other 43 (96%) patients were with diabetes based on EZScan test.

Conclusion: EZScan shows good coincidence in defining carbohydrate disorder state compared with OGTT and is reliable method for assessing prediabetes/diabetes state. As it is easy to be performed, it is a promising tool that could be used in diabetes screening and prevention programs.

Disclosure: **I. Daskalova:** None.

A simple screening model for type 2 diabetes in primary care patients treated for hypertension or dyslipidaemia

L. Rydén[1], B. Shahim[1], V. Gyberg[1], D. De Bacquer[2], K. Kotseva[3], G. De Backer[2], L. Mellbin[1], O. Schnell,[4], D. Wood[5], J. Tuomilehto[6];
[1]Cardiology, Medicin, Stockholm, Sweden, [2]Department of Public Health, Ghent, Belgium, [3]National Heart and Lung Institute, Imperial College of London, London, UK, [4]Forschergruppe Diabetes e.V., Munich, Germany, [5]National Heart and Lung Institute, Imperial College of London, London, UK, [6]National Institute for Health and Welfare, Helsinki, Finland.

Background and aims: People with hyperlipidemia, hypertension and abdominal obesity are at increased risk for type 2 diabetes (T2DM) as part of the metabolic syndrome (MetS). In the presence of other cardiovascular (CV) risk factors T2DM becomes an even more important cause of premature CV morbidity and mortality. Still the presence of T2DM often remains undetected until the time of a coronary event. Since the MetS is a strong predictor of glycaemic perturbations there may be many individuals with undetected T2DM among people, who due to hypertension and/or hyperlipidemia are cared for in a primary care setting. A feasible screening model for T2DM would be of great value. To test the hypothesis that a combination of the simple Finnish Diabetes Risk Score (FINDRISC) and an oral glucose tolerance test (OGTT) would decrease the need for the more time consuming laboratory test when screening for T2DM in people at increased risk for but without established CV disease in a primary care setting

Materials and methods: The study cohort comprised 2395 patients (age 18-80 years) in the primary care arm of the EUROASPIRE IV survey without (i) a history of CV disease or TDM2, (ii) prescribed blood pressure lowering and/or lipid lowering drugs and (iii) complete information of FPG, 2hPG, HbA1c and FINDRISC questionnaire.

Results: According to the OGTT 22% (n=527) of the studied population had T2DM. The distribution of participants on FINDRISC risk levels to develop T2DM was: low 10% (n=244), slightly elevated 36% (n=857), moderate 29% (n=686), high 23% (n=549) and very high 3% (n=59). As demonstrated in the figure there was an almost linear relationship between FINDRISC category and the proportion of patients diagnosed with TDM2 by an OGTT increasing from 1% of those in the low risk to 17% in the very high risk category respectively.

Conclusion: About more than one fifth of people without CV disease treated for hyperlipidemia and/or hypertension had T2DM. Screening for this condition is simplified by the use of the FINDRISC questionnaire as a tool to select those in demand of an OGTT.

Validation of the diabetes screening methods suggested by the American Diabetes Association in an aging Chinese population

Y.C. Woo[1], C.H. Lee[1,2], D.T.W. Lui[1], C.H.Y. Fong[2], A.W.K. Tso[2], B.M.Y. Cheung[2,1], K.S.L. Lam[2,1];
[1]Department of Medicine, Queen Mary Hospital, [2]Research Centre of Heart, Brain, Hormone and Healthy Aging, University of Hong Kong, Hong Kong, Hong Kong.

Background and aims: Diabetes is a serious global health problem with increasing prevalence worldwide. Many diabetes subjects are undiagnosed or have already developed chronic diabetic complications at the time of diagnosis. Opportunistic diabetes screening for high risk subjects appears more practical in China, a populous country being threatened by an alarming increase in diabetes prevalence. A simple and effective screening tool for identifying at-risk subjects for diabetes testing should have substantial public health benefit. We therefore investigated the performance of the latest diabetes screening methods suggested by the American Diabetes Association (ADA), namely the age- and body mass index-based screening criteria (screening criteria) and ADA diabetes risk test (risk test), in our aging Chinese population.

Materials and methods: Subjects free of diabetes who returned for the 4th Hong Kong Cardiovascular Risk Factors Prevalence Study (CRISPS) in 2010-2012 were evaluated for the probability of having diabetes with reference to the screening criteria and the risk test, respectively, and the conclusion drawn was compared to their measured glycaemic status. Diabetes was defined by fasting glucose ≥ 7 mmol/L, or 2-hour post oral glucose tolerance test glucose ≥ 11.1 mmol/L or HbA1c ≥ 6.5% at CRISPS4.

Results: 1434 Hong Kong Chinese without known diabetes, aged 58.1 ±10.2, were evaluated. 157 (11.1%) were tested to have diabetes. The risk test showed good accuracy in screening for diabetes. The area under the receiver operating curve was 0.725 and the optimal cut-off score was 5, being identical to the cut-off suggested by the ADA. Compared to the screening criteria, the risk test had significantly better specificity (0.658 vs. 0.414, p<0.001), positive predictive value (PPV) (0.205 vs. 0.142, p<0.001) and positive diagnostic likelihood ratio (2.068 vs. 1.326, p<0.001) but no significant difference in sensitivity (0.707 vs. 0.777, P=0.101), negative predictive value (NPV) (0.947 vs. 0.937, P=0.282) and negative diagnostic likelihood ratio (0.445 vs. 0.538, P=0.266) To diagnose 1 case of diabetes, only 7 high risk subjects were needed to screen using the risk test as the screening tool, comparing to 13 subjects if the screening criteria was adopted.

Conclusion: Our findings suggested that, as a screening method for diabetes, the ADA diabetes risk test might be more effective than the ADA screening criteria in our aging Chinese populations, with good NPV, better specificity and PPV. It is simple to use in community or clinic setting involving only 7 questions and can be easily adopted as a public health strategy for identifying people with undiagnosed diabetes for early and appropriate treatment.

Haemoglobin A_{1c} as a screening tool for type 2 diabetes and prediabetes in populations of Swedish and Middle-East ancestry

M.I. Hellgren[1], K.H. Steiner[2], L. Bennet[3];
[1]Department of Public Health and Community Medicine/Primary Health Care, Sahlgrenska Academy, University of Gothenburg, Gothenburg, [2]Department of Neurobiology, Care Sciences and Society, Division of Family Medicine, Karolinska Institutet, Academic Primary Healthcare Centre, Stockholm County Council, Huddinge, [3]Center for Primary Health Care Research, Clinical Research Centre, Skåne University Hospital, Malmö, Sweden.

Background and aims: To explore and compare sensitivity for HbA1c ≥48mmol/mol as a predicitor for type 2 diabetes mellitus (T2DM) in populations with Swedish and Middle-Estern ancestry and to examine the predicitive value of two levels of HbA1c (≥42mmol/mol and ≥39mmol/mol) for prediabetes in these populations.

Materials and methods: Populations from four different cohorts of Iraqui, Turkish (defined as Middle-Eastern) or Swedish ancestry were included in this study. 1) The MEDIM study (n=1991 individuals of Swedish and Iraqui ancestry); 2) The Skaraborgs Project (n=1327 individuals of Swedish ancestry) 3) The 4-D study (n=354 individuals of Swedish and Turkish ancestry) 4) The Flemingsberg study (n=208 participants of Turkish ancestry). All participants were examined with an oral glucose tolerance test and a careful physical examination. T2DM was defined by one fasting plasma glucose ≥7.0 mmol/l or one venous 2-hour glucose tolerance test ≥11.1 mmol/l.

Results: HbA1c ≥48 mmol/mol had a sensitivity for T2DM of 31% and 25% respectively in individuals of Middle-East and Swedish ancestry. The positive and negative predictive value was high in both populations (70.3, 96.4 and 96.2, 97.6 respectively). Using HbA1c ≥42mmol/mol as a predictor for prediabetes gave a sensitivity of 17% in individuals of Middle-East and 15% in individuals of Swedish ancestry whereas HbA1c ≥39mmol/mol increased the sensitivity to 36% and 34% respectively. Sensitivity for impaired glucose metabolism was age-dependent and slightly higher in individuals with Middle-East ancestry.

Conclusion: Even if HbA1c ≥48mmol/mol is a valuable diagnostic tool, it is a blunt and insensitive tool for screening and would exclude most people with T2DM, independent ancestry and age. HbA1c is an inefficient way to detect individuals with prediabetes independent of ethnicity and age and thus glucose tolerance tests and fasting plasma glucose measurements are still important.

Optimal cut-points of different anthropometric indices and their performance in prediction of type 2 diabetes

N. Zafari, M. Lotfaliany, F. Hadaegh;
Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Tehran, Islamic Republic of Iran.

Background and aims: Like many developing countries, Iran has a high burden of the type 2 diabetes (T2D). The first step for preventing T2D is identifying high-risk individuals. Non-invasive and feasible methods such as measuring anthropometric indices can potentially be useful to identify high-risk individuals. This presentation aims to first assess sex-specific discriminatory power of anthropometric indices (i.e. body mass index (BMI), waist circumference (WC), waist to height ratio (WHtR), and waist to hip ratio (WHR)) in predicting T2D incidence and delineate their optimal cut-points; second, to evaluate the performance of the derived cut-points in identifying individuals with high risk of T2D in a cohort study of an Iranian population.

Materials and methods: Overall, 2419 men and 3319 women aged 20-60 years and free of T2D at baseline were selected. To compare the discriminatory power of anthropometric indices in each sex, area under the receiver operating characteristics curves (AUC) for all the indices were calculated and the equality of AUCs were assessed. Sex-specific cut-point for each index was derived at the sensitivity of 75%. Sensitivity, specificity, positive predictive value (PPV), and negative predictive values (NPV) were calculated for every cut-point.

Results: During a median follow-up (Interquartile range) of 11.91 (4.57) years, 354 new cases of T2D in men and 490 ones in women were detected. AUCs for BMI, WC, WHtR, and WHR were 0.68 (95% Confidence interval: 0.65-0.71), 0.67 (0.64-0.70), 0.69 (0.66-0.72), and 0.68 (0.65-0.71) in men and 0.72 (0.69-0.74), 0.74 (0.72-0.76), 0.75 (0.73-0.77), and 0.71 (0.69-0.73) in women, respectively. WHtR had the highest AUC in both sexes compared to other indices; however, this difference was statistically significant only in women. Derived cut-points for BMI, WC, WHtR, and WHR were 25.56 kg/m^2, 89 cm, 0.52, and 0.91 in men and 27.12 kg/m^2, 87 cm, 0.56, and 0.83 in women, respectively. Table 1 reports the performance of derived cut-points. In the sensitivity of 75%, all of the anthropometrics had acceptable specificity ranging from 52% to 63%, leading to the PPVs ranging from 21% to 26% and NPVs ranging from 92% to 94%.

Conclusion: In the Iranian population, optimal cut-points for anthropometric indices generally differ from those of other ethnicities**.** All anthropometric indices had acceptable discriminatory power and performance in both sexes. Out of every 4 to 5 individuals with high anthropometric measures, one developed T2D, while more than 90% of individuals with normal anthropometric measures did not develop T2D. Therefore, as a non-invasive, inexpensive, feasible, and easy-to-measure tool, anthropometric indices can be used to identify individuals with high-risk of T2D in the Iranian population.

Table 1. Sex-specific Predictive Accuracy [a] of the Anthropometric Indices for Incident Type 2 Diabetes, TLGS study (1999-2015)

	Cut-point	TP	FP	TN	FN	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Men (N=2419)									
BMI	≥25.56 kg/m^2	269	989	1076	85	75.9	52.1	21.3	92.6
WC	≥89.00 cm	265	989	1076	89	74.8	52.1	21.1	92.3
WHtR	≥0.52	262	967	1098	92	74.0	53.1	21.3	92.2
WHR	≥0.91	267	980	1085	87	75.4	52.5	21.4	92.5
Women (N=3319)									
BMI	≥27.12 kg/m^2	373	1246	1583	117	76.1	55.9	23.0	93.1
WC	≥87.00 cm	376	1181	1648	114	76.7	58.2	24.1	93.5
WHtR	≥0.56	373	1041	1788	117	76.1	63.2	26.3	93.8
WHR	≥0.83	371	1218	1611	119	75.7	56.9	23.3	93.1

[a] Cut-points were derived by fixing the sensitivity at 75%, using receiver operating characteristics curves.
TP, true positive; FP, false positive; TN, true negative; FN, false negative; PPV, positive predictive value; BMI, body mass index; WC, waist circumference; WHtR, waist to height ratio; WHR, waist to hip ratio; HC, hip circumference.

Visceral adiposity is a significantly stronger predictor of diabetes incidence in men than in women

H. Drexel[1], C.H. Saely[2], C. Lins[3], D. Zanolin[3], A. Leiherer[3], A. Schuler[2], P. Rein[2], A. Muendlein[3], A. Mader[4], P. Schwerzler[4], A. Vonbank[2];
[1]Drexel University College of Medicine, Philadelphia, USA, [2]Academic Teaching Hospital Feldkirch, [3]Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria, [4]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Visceral adiposity is a paramount risk factor for the development of type 2 diabetes. Whether it equally increases diabetes risk in men and in women is not known and is addressed in the present study.

Materials and methods: We prospectively recorded diabetes incidence in a large high-risk cohort of 1142 nondiabetic patients, including 755 men and 387 women who were undergoing coronary angiography for the evaluation of established or suspected coronary artery disease. Visceral adiposity was measured with the validated visceral adiposity index using waist circumference, serum triglycerides, age and gender to diagnose this metabolic abnormality; diabetes was diagnosed according to ADA criteria.

Results: At baseline, visceral adiposity did not differ significantly between men and women (p=0.247). Prospectively, 133 (10.4 %) of our patients newly developed diabetes during a follow-up period of 3.7±0.9 years. Visceral adiposity significantly predicted the incidence of diabetes in men but not in women both univariately (ORs 1.71 [1.40-2.10]; p<0.001 and 1.09 [0.81-1.49]; p=0.565, respectively) and after multivariate adjustment including fasting plasma glucose (ORs 1.56 [1.24-1.97]; p<0.001 and 1.05 [0.75-1.46]; p=0.790, respectively). Interaction terms visceral adiposity x gender were significant both for univariate and for multivariate analyses (p<0.001 and p=0.017, respectively), indicating that visceral adiposity was a significantly stronger predictor of diabetes among men than among women.

Conclusion: We conclude that in angiographied coronary patients visceral adiposity is a significantly stronger predictor of diabetes incidence in men than in women.

Fatty liver index predicts the development of diabetes among the Japanese general population with and without impaired fasting glucose

A. Hirata[1], D. Sugiyama[1], K. Kuwabara[1], T. Hirata[2], H. Tsutatani[3], M. Funamoto[3], K. Watanabe[3], N. Miyamatsu[4], T. Okamura[1];
[1]Department of Preventive Medicine and Public Health, Keio University School of Medicine, [2]Center for Supercentenarian Medical Research, Keio University School of Medicine, Tokyo, [3]Habikino City, Osaka, [4]Department of Clinical Nursing, Shiga University of Medical Science, Shiga, Japan.

Background and aims: Fatty liver is considered to be the hepatic manifestation of the metabolic syndrome related to insulin resistance, and associated with the development of type 2 diabetes. Fatty liver index (FLI) has been recently introduced as a useful indicator of hepatic steatosis, which makes it possible to diagnose fatty liver without performing imaging tests. We aimed to examine whether FLI predicts the development of diabetes in the general population, especially, in those with normal fasting glucose (NFG).

Materials and methods: We followed population who received Specific Health Checkups conducted from April 1st, 2008 to March 31st, 2009 in Habikino city, Osaka, Japan for five years. 4,445 participants (1,501 men and 2,944 women) without diabetes at baseline were selected in this study. All participants were divided into six groups according to tertile of FLI (low, moderate and high) and the presence or absence of impaired fasting glucose (IFG), by gender. The development of diabetes was defined by fasting blood glucose ≥126mg/dL (7.0 mmol/L), HbA1c (NGSP) ≥6.5%, non-fasting blood glucose ≥200mg/dL (11.1mmol/l), or receiving any medication for diabetes. Hazard ratios (HRs) for incident diabetes according to each group were calculated using a Cox proportional hazard model after adjusting for age, systolic blood pressure, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, smoking habits, and alcohol drinking status.

Results: Mean follow-up period was 3.0 years. During follow-up, 496 incident diabetes cases (176 men and 320 women) were identified. Compared to low FLI with NFG group, high FLI with NFG group was significantly associated with incident diabetes in men (HR: 1.90, 95% confidence interval (CI): 1.08-3.36) and women (HR: 1.73, 95%CI: 1.19-2.52). In addition, IFG groups were significantly associated with incident diabetes regardless of FLI in men (low; HR: 3.94, 95%CI: 2.10-7.30, moderate; HR: 5.70, 95%CI: 3.27-9.93, high; HR: 6.80, 95%CI: 4.01-11.51) and women (low; HR: 4.25, 95%CI: 2.46-7.34, moderate; HR: 6.17, 95%CI: 3.97-9.59, high; HR: 6.08, 95%CI: 4.04-9.15).

Conclusion: Our results showed that FLI was associated with the development of diabetes regardless of sex and the presence or absence of IFG, and it

might be a useful predictor to identify the future risk for incident diabetes even in individuals with NFG.

Modelling the dynamics of glycated haemoglobin in persons with type 2 diabetes to predict all-cause mortality

R.P.T. van Wijngaarden[1,2], L.M. Peelen[3], J.S. Yauw[3], T.L. Feenstra[4], G. Nijpels[2], K.G.M. Moons[3], C.A. Baan[4], J.W. Beulens[5], R.M.C. Herings[1,2], A.A. van der Heijden[2];

[1]PHARMO Institute for Drug outcomes Research, Utrecht, [2]Amsterdam Public Health Department of General Practice and Elderly Care Medicine, VU University Medical Centre, Amsterdam, [3]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, [4]National Institute for Public Health and the Environment, Department for Prevention and Health Services Research, Bilthoven, [5]Amsterdam Public Health, Department of Epidemiology and Biostatistics, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Glycated hemoglobin (HbA1c) measurements for people with type 2 diabetes (T2D) are used in prediction models in various ways. The dynamics of HbA1c measurements over time and its relation to complications is poorly understood while it may be very important to clinical decision making. We aim to determine which measure, designed to capture the dynamics of HbA1c over time, best predicts all-cause mortality in people with T2D.

Materials and methods: 5903 persons with T2D from the Hoorn Diabetes Care System (DCS) cohort were included in this study. In the DCS cohort patients were included from 1998 onward and followed annually on both clinical parameters and complications. Eight measures to express HbA1c dynamics were investigated. The baseline, highest, lowest and average HbA1c were used as absolute values. The slope between the first two measurements, the slope between the last two measurements, the linear regression over the measurements and the range between the lowest and highest HbA1c values were used as relative values. The measures were calculated after either 3, 4 or 5 years of follow-up from baseline while the model predicted from that point onward until either death or censoring. The measures were standardized and compared for these time windows. A multivariable analysis was performed using a Cox regression model adjusted for the baseline variables sex, age, diabetes duration, HbA1c, BMI, triglycerides and total cholesterol. Hazard ratios (HRs) with 95% confidence intervals (CIs) were reported.

Results: Of the 5903 participants of the cohort, 480 died. Mean follow up was 7.3 years, mean age at baseline was 61.1 years and mean HbA1c at baseline was 55.6 mmol/mol. In the analysis hazard ratios (HR) ranged from 1.05 (CI 95% 0.94-1.17) for lowest HbA1c to 1.42 (CI 95% 1.23-1.65) for linear regression, both for time window 5. The results are presented graphically in figure 1.

Conclusion: The results for the linear regression measure clearly stand out and suggest that the overall HbA1c trajectory of a person over time should play a role in clinical decision making with regards to all-cause mortality. Further investigation is needed to determine the role of the measures of HbA1c dynamics with regards to other complications and whether they can be combined to increase prediction accuracy.

Incidence and predictors of metabolic syndrome in an urban, adult Sri Lankan population: a community cohort 7-year follow-up study

S.T. De Silva[1], M.A. Niriella[1], A. Kasturiratne[1], D. Kottahachchi[1], U.K. Ranawaka[1], A.S. Dassanayaka[1], A.P. De Silva[1], A. Pathmeswaran[1], A.R. Wickremasingha[1], N. Kato[2], H.J. De Silva[1];

[1]Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka, [2]National Center for Global Health and Medicine, Tokyo, Japan.

Background and aims: In 2007, we reported a 38.9% prevalence of metabolic syndrome (MetS) in an urban, adult population. Published data on incident MetS from South Asia is lacking. This study investigated the incidence and risk factors for MetS after a 7-year follow-up of the initial cohort.

Materials and methods: The study population (selected by age-stratified random sampling from the Ragama MOH area) was screened in 2007 (aged 35-64 years) and re-evaluated in 2014 (aged 42-71 years). On both occasions, structured interview, anthropometric measurements, liver ultrasound, biochemical and serological tests were performed. MetS was diagnosed on established International Diabetes Federation (IDF 2012) criteria. Total body fat (TBF) and visceral fat percentage (VFP) were measured in 2014, using impedance. Abnormal TBF was defined as >32% for females and >25% for males. Abnormal VFP was defined as >10% for both sexes. Non-alcoholic fatty liver disease (NAFLD) was diagnosed on established ultrasound criteria, safe alcohol consumption (Asian standards: <14 units/week for men, <7 units/week for women) and absence of hepatitis B and C markers.

Results: 2137/2967 (72.0%) of the initial cohort attended follow-up [1229 (57.5%) women; mean-age 52.4 (SD-7.7) years]. 1000/2137 [548 (54.8%) women; mean age 57.5 years (SD-7.74)] had MetS (prevalence-46.8%). Out of 1246 individuals who initially did not have MetS in 2007, 318 [225 (70.8%) women; mean age 57.5 (SD 7.7) years] had developed incident MetS after 7 years (annual incidence-2.13%). Comparison of incident MetS with those with no MetS in 2014 is shown in Table 1. On logistic regression, female sex (OR 3.6, p<0.001), central obesity [OR 4.58, p<0.001], BMI >23kg/m2 [OR 4.84, p<0.001], increase in weight 2%-5% [OR 2.02, p<0.001], increase in weight >5% [OR 5.3, p<0.001), increase in waist circumference (WC) 5-10-cm [OR 3.68, p<0.001], increase in WC >10cm [OR 10.34, p<0.001] and NAFLD (OR 2.44, p<0.001) in 2007 were independently predictive of incident MetS in 2014. Abnormal VFP [OR 4.23, p<0.001] and abnormal TBF [OR 5.25, p<0.001] were also associated with incident MetS.

Conclusion: In this prospective community study, the annual incidence of MetS was 2.13%. Female gender, increase in weight and WC from baseline and the presence of NAFLD predicted the development of incident MetS.

Obesity at baseline was the only defining individual component of MetS that predicted future MetS.

Table 1 – Comparison of participants with Incident MetS and no MetS (2014)

	Incident MetS (n=318)	No MetS (n=928)	P value*
Males (%)	93 (29.25)	567 (61.43)	<0.001
Mean age (SD)	57.5 (7.7)	58.8 (7.9)	0.037
BMI >23 kg/m² (%)	213 (67)	274 (29.5)	<0.001
Increase in weight	84 (26.4) /	203 (21.9) /	<0.001 /
2-5% (%) / >5% (%)	104 (32.7)	96 (10.3)	<0.001
Central obesity (%)	146 (45.9)	145 (15.6)	<0.001
Increase in waist >5 cm (%)	156 (49.1)	148 (15.9)	<0.001
Abnormal TBF (%)	288 (90.6)	600 (64.7)	<0.001
Abnormal VFP (%)	172 (54.1)	202 (21.8)	<0.001

Implementation and outcomes of a Diabetes Prevention Programme for people at high risk of developing diabetes in the workplace

C. Martin Ridaura[1], O. Borrego Hernando[2], N. Calle Fernandez[1], M. Dama Carvajal[1], C. Segador Galán[1], J. Moreno Arnedillo[2], M. Ceinos Arcones[3], I. Bordel Nieto[4], F. Sobrino Serrano[4], M. Martínez Cortés[3], P. Garcia Crespo[3]; [1]Diabetes Unit, Madrid City Council, [2]Healthy Habits Unit, Madrid City Council, [3]Prevention and Promotion Health Service, Madrid City Council, [4]Health Workers Unit, Madrid City Council, Madrid, Spain.

Background and aims: In people with pre-diabetes, lifestyle intervention programmes directed at weight loss are effective in preventing the progression to type 2 diabetes. The Madrid City Council has developed and implemented a Diabetes Prevention Program (ALAS, High Risk Strategy), among its employees. Aims: 1 -To achieve 5%-7% weight reduction; 2- To improve glycemic regulation.

Materials and methods: During a Health examination, workers are encouraged to complete the Findrisc test. Those with positive results that means, punctuation >14 are asked to undergo Oral glucose tolerance test (OGTT).When they were Findrisc (+) and BMI more than 30 Kg/m^2 or fulfilled criteria for pre-diabetes, they were invited to participate in the Prevention programm. It is delivered over 6 months and it is made up of 10 group sessions focused on modest (5 - 7 %) weight loss through diet, physical activity and behaviour modification. From February 2014 up to now 147 employees were recruited and have finished the workshops.

Results: 147 participants have completed the Program; 99 were Prediabetic (67%) and 48 Normoglycemic at high risk (33%). Participant's ages ranged from 37 to 71 (an average age of 53.6 SD=7, 6), 59 males (40,13%) and 88 females (59,87%). After six months, participants lost an average of 5,65 Kg or 7% of body weight and 28,05% had normalized the glycemic control; 50,34 % achieved 5% or more weight loss; 77, 85 % people attended 5 or more sessions. Weight loss was negatively associated with age, and positively with attendance.

Conclusion: Working people spend a lot of time at their work place which is an ideal setting for health programs targeting weight loss and disease prevention. The work site intervention caused a big improvement in glycemic status and revert pre-diabetes to normal glucose regulation. The Findrisc Test should be included in health tests in the workplace. In addition, the implementation of a group-based, Diabetes Prevention workshop could be introduced as part of the health screening examination that companies provide.

PS 008 Microvascular complications and diabetic ketoacidosis

328

Decreasing incidence of blindness in people with and without diabetes in southern Germany, 2008-2012

H. Claessen[1], T. Kvitkina[1], M. Narres[1], C. Trautner[2], I. Zöllner[3], A. Icks[1];
[1]Institute for Health Services Research and Health Economics, German Diabetes Centre, Düsseldorf, [2]Department of Public Health, University of Applied Sciences, Wolfsburg, [3]Department of Epidemiology and Health Care Research, Baden-Württemberg State Health Office, Stuttgart, Germany.

Background and aims: The St Vincent Declaration in Europe (1989) aimed to improve diabetes treatment and thus reduce the risk of diabetes related blindness by one third in 5 years. However, surveillance for blindness among persons with diabetes has not been conducted nationally and population-based data on incidence rate (IR) of blindness in in the diabetic population compared with the non-diabetic population are scarce worldwide. In a previous study in 2008 in a large region in Southern Germany IR of blindness was found to be 2.4-fold higher in the diabetic compared to the non-diabetic population. The aim of the study was to estimate the time trend of IR of blindness in the diabetic and the non-diabetic populations in Germany and the corresponding relative risk over a 5-year period.

Materials and methods: The data were based on administrative files of the welfare administration (35 rural and 10 urban districts in the federal state of Baden-Württemberg, Southern Germany) to assess all individuals who were newly registered as blindness allowance recipients between 1.1.2008 and 31.12.2012. We could use data of 22 out of these 45 districts (total population: n=4,823,570), where the written medical statement was available to define the diabetes status. We estimated age-sex standardised IR of blindness in people with and without diabetes. Furthermore, we estimated relative risks comparing diabetic and non-diabetic population from the standardized IR. We examined age and sex adjusted time trends of IR using Poisson regression models for individuals with and without diabetes. In order to investigate if the relative risk changed over time, we additionally computed Poisson models including a variable presence of diabetes (yes vs. no) and an interaction term for diabetes and years since 2008.

Results: In our study region, we identified 1,897 new cases of registered blindness allowance recipients in the years 2008-2012 (62.5% female, 54.8% ≥ 80 years, diabetes prevalence 2008: 26.1%, 2012: 20.7%). We observed a strong decrease of IR in the population with diabetes (2008: 17.3, 95% CI: 13.6-21.1 per 100,000 person years; 2012: 8.9, 6.3-11.6). Likewise, we found a somewhat weaker but still considerable decrease of IR in the population without diabetes (2008: 9.3, 8.3-10.3; 2012: 6.6, 5.8-7.4). The relative risk fell slightly from 1.9, 1.5-2.4 in 2008 to 1.4, 1.0-1.9 in 2012. With regard to time trend, we found during the observation period a significant decline of IR in the population with diabetes by 16% per year. When considering the population without diabetes, we observed a weaker albeit significant decrease of IR by 9% per year. The interaction diabetes*calendar year was non-significant, indicating that the relative risk between diabetic and non-diabetic populations did not materially alter. All results were similar in both sexes.

Conclusion: We found a significant reduction in risk of blindness in both the population with and without diabetes. Therefore the relative risk did not materially change. These findings may be explained by effective secondary prevention therapies and a better ophthalmologic care beyond diabetic retinopathy, in particular with regard to macular degeneration, which means earlier detection of the diseases.

Impact of ideal cardiovascular health in childhood on the retinal microvasculature in mid adulthood: the cardiovascular risk in young Finns study

M.D. Campbell[1], T.T. Laitinen[2], A.D. Hughes[3], M. Kähönen[4], T.Y. Wong[5], T. Lehtimäki[6], P. Sahota[1], N. Hutri-Kähönen[6], O. Raitakari[7], R.J. Tapp[1];
[1]Leeds Beckett University, Leeds, UK, [2]University of Turku, Turku, Finland, [3]University College London, London, UK, [4]Tampere University Hospital and the University of Tampere, Tampere, Finland, [5]National University of Singapore, Singapore, Singapore, [6]University of Tampere, Tampere, Finland, [7]University of Turku and the Turku University Hospital, Turku, Finland.

Background and aims: Cardiometabolic risk factors in childhood and adulthood are associated with changes in the retinal microvasculature. These changes are closely linked with an increased future risk of diabetes as well as its two major microvascular complications; diabetic retinopathy and nephropathy. We examined the association between ideal cardiovascular health (CVH) and the retinal microvasculature in mid adulthood, using a life course approach that takes account of the contribution of CVH in both childhood and adulthood.

Materials and methods: The Cardiovascular Risk in Young Finns Study included children, from five Finnish University cities, with participants chosen randomly from the national population register. Of these, 418 underwent retinal imaging and provided complete ideal CVH data. The age of participants included in the current analyses in childhood (1986) ranged from 12 to 18 years and in mid-adulthood (2011) ranged from 37 to 43 years. Ideal CVH was defined according to the American Heart Association criteria. Retinal microvascular measures included diameters, lengths, length/diameter (L/D) ratio and tortuosity.

Results: There was a positive association between improved ideal CVH from childhood to adulthood and adult arteriolar diameter ($\beta = 0.122$; 95% CI: 0.01 to 0.24; $p = 0.033$), with no association evident for childhood ideal CVH, after adjustment for confounding factors (age and sex). A negative association was evident between improved ideal CVH from childhood to adulthood and adult L/D ratio ($\beta = -0.666$; 95% CI: -1.25 to -0.08; $p = 0.026$), with no association shown for childhood ideal CVH. Improved ideal CVH from childhood to adulthood showed no association with adult arteriolar tortuosity, but childhood ideal CVH was negatively association with adult arteriolar tortuosity ($\beta = -0.008$; 95% CI: -0.01 to -0.003; $p = 0.001$). When stratified by glucose metabolism, among those with diabetes and impaired fasting glucose (IFG) there was a negative association between childhood ideal CVH and adult venular diameter (diabetes $\beta = -2.75$; 95% CI: -5.46 to -0.04; $p = 0.047$ and IFG $\beta = -2.13$; 95% CI: -4.18 to -0.08; $p = 0.042$).

Conclusion: Cardiovascular health and ideal CVH from childhood to adulthood appear to have a protective effect on the retinal microvasculature.

Mortality rate in patients with type 1 diabetes with multiple micravascular complications

L. Bjerg[1,2], A. Hulman[3,4], M. Charles[2], B. Carstensen[1], M.E. Jørgensen[1,5], D.R. Witte[3,4];
[1]Epidemiology, Steno Diabetes Center Copenhagen, Gentofte, [2]Department of Public Health, Section of General Practice, [3]Epidemiology, Institution of Public Health, Aarhus, Denmark, [4]Danish Diabetes Academy, Odense, [5]National Institute of Public health, Southern Denmark University, Denmark.

Background and aims: It is known that the presence of microvascular complications in type 1 diabetes is associated with higher mortality. However, it is unclear whether the different combinations of complications and different sequences in which they occur carry a different mortality risk. We set out to describe the effect of an individual's microvascular complication status on their risk of death in a Danish patient cohort.

Materials and methods: We used a cohort of type 1 diabetes patients treated between 2001 and 2013 at the Steno Diabetes Center Copenhagen, a specialized tertiary care centre. Neuropathy (biothesiometry ≥ 25 mV on either limb), retinopathy (≥ grade two in either eye) and diabetic kidney disease (micro- or

macro-albuminuria) were assessed at regular structured screening examinations (2-4 times a year), creating a dataset with dates of onset of all microvascular complications as well as date of death. We included all patients attending the clinical center in the outlined time period regardless of the complication status at first assessment. Poisson regression models were used to calculate mortality rate ratios between groups with different combinations of microvascular complications in comparison to the reference group without any complications. Models were adjusted for sex, baseline duration of diabetes and HbA1c.

Results: The 4221 patients (54.3% men) fulfilling the inclusion criteria were followed for a median of 8 years (IQR: 3;11). At inclusion the median age was 43 years (32;56), median HbA1c was 70 (mmol/mol) (61;83) and median duration of diabetes was 17.0 years (7;19). During the 29.000 person years of follow-up, 526 deaths occurred (crude mortality rate in patients without complications was 5.2 per 1000 person years (95%CI: 3.9;6.9)). The mortality rate for a woman with diabetes duration of 15 years and HbA1c of 60 mmol/mol was 4.9 /1000 PY (3.6;6.7). Mortality rate was not statistically significantly higher for men (RR: 1.11(0.9;1.3). Table 1 shows mortality rate ratios between groups with different level of complications and the reference group with no complications adjusted for sex, baseline diabetes duration and HbA1c.

Conclusion: Patients affected by all three complications have a 6 times higher mortality rate than patients free of complications. Patients with diabetic kidney disease alone had higher mortality rate ratio than patients with neuropathy, which was higher than both retinopathy alone and with concurrent nephropathy. This observation may be due to the limited time patients remain in the intermediate compliation status groups on their course from 0 to 3 complications.

Complication level	Number of deaths	Mortality Rate Ratio (95%CI)
None	46	-
Diabetic kidney disease	25	4.8 (2.9;7.8)
Neuropathy	48	3.9 (2.5;5.9)
Retinopathy	52	1.2 (0.8;1.8)
Diabetic kidney disease + Retinopathy	34	1.3 (0.8;2.1)
Diabetic kidney disease + Neuropathy	0	-
Neuropathy+ Retinopathy	0	-
Diabetic kidney disease + Retinopathy + Neuropathy	321	6.0 (4.3;8.6)

Number of deaths at different complication level and Mortality Rate Ratios between different complication level and patients with out complications.
Adjusted for sex, duration of diabetes and HbA1c at baseline.

Narrower retinal microvascular calibre is not associated with reduced estimated glomerular filtration rate in type 2 diabetes

G.J. McKay[1], E. Paterson[1], A.P. Maxwell[1], C. Cardwell[1], R. Wang[2], S. Hogg[2], T.J. MacGillivray[3], E. Trucco[2], A.S. Doney[4];
[1]Centre for Public Health, Queen's University Belfast, Belfast, [2]School of Science and Engineering, University of Dundee, Dundee, [3]Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, [4]Ninewells Hospital and Medical School, University of Dundee, Dundee, UK.

Background and aims: The retinal blood vessels provide a non-invasive "window" to study changes in the microcirculation, with similarities between the microvascular physiology in the eye and kidney. Previous studies have suggested change in retinal vessel calibre may be a useful predictor of estimated glomerular filtration rate (eGFR) in patients with diabetes but the reported direction of this association has not always been consistent. Our objective was to evaluate longitudinal changes in retinal vascular morphometry and eGFR in a population with type 2 diabetes mellitus (T2D).

Materials and methods: GoDARTS is a bioresource with comprehensive longitudinal electronic medical records including hospital admissions, mortality, clinical biochemistry and medicine prescription records linked by patient-specific identifiers for a population of individuals with T2D. Through routine diabetic retinopathy (DR) screening, the earliest available fundus image of 1072 individuals were assessed with a follow-up (FuP) image captured 2 to 4 years later. Biochemical and blood pressure (BP) assessments during a period of 6 months either side of the date of each retinal photograph were obtained and the median value used to reflect the burden of these risk factors. Median serum creatinine was used to estimate GFR with the CKD-EPI equation. Retinal vascular measurements were captured using VAMPIRE 3.0 software to determine calibre-related coefficients, tortuosity and fractal dimension.

Results: The mean time between baseline and follow-up was 3.01 years. At follow-up, eGFR and diastolic BP were significantly lower but HbA1c was higher, compared with baseline measures. At follow-up retinal arterioles and venules were significantly narrowed with associated diminished fractal dimension and increased venular tortuosity, compared with baseline (P<0.001). Following linear regression to adjust for potential confounders, retinal parameters were no longer associated with percentage change in eGFR. Using logistic regression, no retinal parameters were found to be associated with DR at baseline.

Conclusion: While we were able to demonstrate significant temporal changes in retinal vascular calibre during the study period we were unable to identify any changes in retinal parameters significantly associated with declining eGFR in individuals with T2D over a 3-year time period. This study has used existing clinical data to evaluate potential early prognostic indicators. Failure to detect significant associations may be due to several reasons. (1) Variation in retinal parameters may not reflect ongoing changes in eGFR. (2) Our sample has insufficient power to detect associations of this effect size. (3) The 3-year time period between sampling is of insufficient duration to detect significant change in eGFR beyond normal age-related decline. (4) A specific eGFR threshold may be more relevant to detectable morphological changes. (5) It is possible that the progressive changes observed in the retina simply track temporal changes in the kidney.

332

The different clinical phenotypes of type 1 diabetes due to the age of diabetes onset

M. Isakov[1], O. Vikulova[2,3], M. Shestakova[2,3], I. Dedov[2];
[1]Aston Consulting Group, [2]Endocrinology Research Center, [3]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Background and aims: The aim of the study was to conduct a comparative analysis of clinical data (HbA1c, BMI, insulin doses, diabetic complications frequency) in type 1 diabetic patients with different age of onset.

Materials and methods: We included in the study the patients from the database of Federal diabetes registry of Russian Federation with newly diagnosed type 1 diabetes (T1D) with marked date of onset from 1st January to 31st December, 2016, duration less 1 year (n=9130). All patients stratified into three groups by the age of T1D onset: 0-20 years (group 1, n=3815), 21-40 years (group 2, n=3661) and >40 (group 3, n=1654). Statistics performed by SPSS 22.0 (IBM) and tables Microsoft Excel, 2013. Intergroup differences examined for statistical significance (p<0.05) using Mann-Whithey U-test.

Results: The groups differed significantly by the average age [10,82±0,09/ 31,98±0,09/ 52,66±0,24], age at onset [9,82±,09/ 30,98±0,09/ 51,66±0,24], gender distribution: men [54,7%/63.7%/58.1%], BMI [17,57±0,07/ 23,36 ±0,09/ 25,30±0,17] and HbA1c [9,10±0,05/ 8,63±0,06/ 8,91a±0,10], while parameters of lipids were similar: total cholesterol [4,63±0,03/ 4,60±0,03/ 4,62±0,04], LDL [2,56±,04/ 2,57±,04/ 2,53±,06]. The mean insulin dose [0.83±0.01/ 0.65±0.01/ 0.61±0.01] and proportion of basal-bolus treatment [90.2%/ 88.7%/ 75.9%] were highest in group 1, as well as rate of acute complications: coma [18(0.5%)/ 4(0.1%)/ 3(0.2%)], ketoacidosis without coma [169(4.4%)/ 105(2.9%)/ 34(2.1%)] and severe hypoglycemia [3(0.1%)/ 4(0.1%)/0], p<0.05 while the frequency of chronic vascular complications prevailed in group 3 (table data).

Conclusion: Clinical phenotypes of T1D differs depend on the age of onset: classic T1D with highest insulin dose, worst DM control and high frequency of

acute complications in the youngest group, intermediate phenotype in the middle age group and features of type 2 diabetes with high frequency of micro and macrovascular complications in patients with onset age >40, that might reflect the late diagnostics in cases of late autoimmune diabetes in adults.

Type 2 diabetes in general practice in Norway, status and time trends

Å. Bakke[1,2], J.G. Cooper[1,3], G. Thue[2,3], I. Dalen[4], S. Skeie[1], S. Carlsen[1,3], E.R. Oord[1], K.F. Løvaas[3], T.V. Madsen[3], A.T. Tran[5], A.K. Jenum[5], T.J. Berg[6], B. Gjelsvik[5], T. Claudi[7], S. Sandberg[2,3];
[1]Department of Medicine, Stavanger University Hospital, Stavanger, [2]Department of Public Health and Primary Health Care, University of Bergen, [3]Norwegian Quality Improvement of Laboratory Examinations, Haraldsplass Deaconess Hospital, Bergen, [4]Department of Biostatistics, Stavanger University Hospital, Stavanger, [5]Institute of Health and Society, University of Oslo, [6]Institute of Clinical Medicine, University of Oslo, Oslo, [7]Nordlandssykehuset, Bodø, Norway.

Background and aims: Improved risk factor control reduces the risk of cardiovascular disease among type 2 diabetes patients. Systematic screening for diabetes complications and prompt intervention may prevent or delay the development of target organ disease. Guidelines recommend that general practitioners (GPs) should perform an annual structured screening program. There is no up-to-date study assessing GPs implementation of guidelines in Norway. The objectives of this study are to assess changes in quality of care between 2005 and 2014 and identify areas of diabetes care that need improvement.

Materials and methods: Two cross-sectional surveys in selected areas in three of four health regions were performed that identified all patients (n=5463 attending 59 practices in 2005, n=9464 attending 77 different practices in 2014) with type 2 diabetes. Quality of care was assessed based on key recommendations in National guidelines. Data was extracted electronically with manual verification. Differences in clinical performance between 2005 and 2014 were assessed and tested for statistical significance in regression models adjusting for age, sex, county and clustering within GP practices.

Results: Recommended treatment targets were achieved in a higher proportion of patients in 2014 compared with 2005; HbA1c ≤ 7.0% (53 mmol/mol) in 62.5% vs 54.6% , blood pressure ≤135/80 treated/ ≤140/85 untreated in 50.0% vs. 42.8%, and total cholesterol ≤4.5 mmol/l in 49.5% vs. 34.1% (all, p<0.001). Screening for important microvascular complications was poor in both surveys. Screening for all three of the complications albuminuria, retinopathy and neuropathy was only recorded in the case notes of 13.4% in 2014, and 9.6% in 2005. There was no record of screening for any of the complications in 28.0% of patients in 2014 compared with 22.8% in 2005.

Conclusion: Between 2005 and 2014 there has been statistically significant improvements in risk factor control for patients with type 2 diabetes in general practice, accompanied by an intensification in glucose lowering-, antihypertensive- and lipid lowering therapy. However screening for microvascular complications remains disturbingly low and we suggest that additional incentives to encourage practitioners to adhere to national guidelines are required.

Event rates and risk factors for diabetic ketoacidosis in adult type 1 diabetes: analysis from the German/Austrian DPV registry based on 48,067 patients

S.M. Schmid[1,2], S. Lanzinger[3,2], W. Karges[4], D. Bergis[5], J. Seufert[6], W. Kerner[7], J.K. Mader[8], S. Zimny[9], M. Hummel[10], J. Rosenbauer[11,2], R.W. Holl[3,2];
[1]Dpt. of Endocrinology, Diabetes and Metabolism, University of Lübeck, Lübeck, [2]German Center for Diabetes Research (DZD), München-Neuherberg, [3]Institute for Epidemiology and Medical Biometry, University of Ulm, Ulm, [4]Division of Endocrinology and Diabetology, University of Aachen, Aachen, [5]Department of Internal Medicine 1, Goethe University Hospital, Frankfurt, [6]Division of Endocrinology and Diabetology, University of Freiburg, Freiburg, [7]Diabetes Center Karlsburg, Karlsburg, Germany, [8]Endocrinology and Diabetology, Medical University of Graz, Graz, Austria, [9]Endocrinology and Diabetology, Helios Clinic Schwerin, Schwerin, [10]Specialised Diabetes Practice, Rosenheim, [11]German Diabetes Center, Düsseldorf, Germany.

Background and aims: Prevention of diabetic ketoacidosis (DKA) in patients with established type-1 diabetes (T1DM) is a major goal in the long-term care for patients. Recent data indicate that in children and adolescents, the rates of DKA during the course of diabetes are not declining. For adult T1DM patients, only few data on DKA event rates, and risk factors for the development of DKA, are available to date.

Materials and methods: Between 1995 and 2017 the DPV registry longitudinally collected standardized data on 491654 patients with diabetes in Austria and Germany. Data are documented in a dedicated electronic health record at participating institutions (n=455) and anonymized, aggregated data are exported for central analysis every 6 months. This report is based on 48067 adult T1DM patients (52.3 % males, median age 38.6 [Q1-Q3: 21.2 - 55.1] years, median duration of diabetes 13.6 [7.0-24.2] years). For the most recent year of observation in each patient, DKA event rate was analysed based on a Poisson regression model accounting for overdispersion (SAS 9.4).

Results: On average, 2.54 hospital admissions due to diabetic ketoacidosis per 100 patient years (py) were observed (95% confidence interval: 2.10-3.05). Event rate was highest in patients aged 18-30 years (3.98/100 py) compared to 1.9/100 py (age 31-45 years), 1.5/100 py (age 46-65 years), and 1.3/100 py (age > 65 years), respectively (adjusted p < 0.0001). For the entire group, no significant difference between males (2.44/100 py) and females (2.64/100 py) was found. Insulin pump therapy was not associated with a higher rate of DKA (2.43/100 py) compared to multiple daily insulin injections (MDI; 2.83/100 py; p=0.11).

Conclusion: These data from a large, multicentre, binational registry report low rates of hospital admissions due to DKA in patients with type-1 diabetes during the course of the disease. Interestingly, pump therapy is not associated with a higher DKA rates. However, event rates are significantly higher in younger adults, both males and females and decline with age.

Mortality due to diabetic ketoacidosis: population-based findings from the Yorkshire register of type 1 diabetes in children and young people

T.C. Evans-Cheung[1], H.J. Bodansky[1,2], R.G. Feltbower[1], R.C. Parslow[1];
[1]University of Leeds, [2]The Leeds Teaching Hospitals NHS Trust, Leeds, UK.

Background and aims: Data from the population-based Yorkshire register of type 1 diabetes in children and young people (YRDCYP) previously showed a four-fold excess in mortality compared to the general population. Deaths due to diabetic ketoacidosis (DKA) by age at death, time since diagnosis and place of death was assessed.

Materials and methods: The YRDCYP includes children under 15 years diagnosed with type 1 diabetes within Yorkshire between 1978 to 2013, and young people aged 15 to 29 diagnosed within West Yorkshire between 1991 to 2013. The YRDCYP was linked to death certification data. Underlying cause of death was verified by a specialist clinician. Death due to DKA was identified by ICD10 code E101. Mortality rates per 10,000 person-years for DKA were calculated for the overall cohort by age at death and time since diagnosis. Place at death was also examined.

Results: The cohort total was 5,498 individuals, contributing 100,959 person-years of follow-up. Previous research found 229 deaths. Median age at death was 29.7 years (range 6.5 to 52.5). Deaths due to type 1 diabetes accounted for 52% of deaths. Of all type 1 diabetes deaths, 47.1% (n=56) were due to acute complications, 36.1% (n=43) were due to chronic complications and 16.8% (n=20) had no recorded complications. Of deaths due to acute complications, three times more deaths were due to DKA (n=42) compared with severe hypoglycaemia (n=14). More than two thirds (64.3%) of DKA death occurred at the deceased's home. Remaining deaths occurred in hospital or elsewhere. The largest number of deaths at home occurred in the 15 to 19, 25 to 29 and 30 to 34 year age groups (n=7 for all groups). The largest number of deaths in hospital occurred in the 15 to 19 year age group (n=5). Overall mortality rate for DKA was 4.2 per 10,000 person-years (95% CI 3.5 - 5.6 per 10,000 person-years). Death at 15 to 19 years of age had the largest number of fatalities (n=13). This was the only age group where the mortality rate (18.2 per 10,000 person-years (95%CI: 10.6 - 31.3 per 10,000 person-years)) was significantly higher than the overall DKA mortality rate. This was also significantly higher than all older age groups, apart from 25 to 29 year olds. Analysis by time since diagnosis showed higher DKA mortality rates for shorter diabetes duration. The highest number of deaths appear in the 5 to 9 years duration group (n=12), with a mortality rate of 17.5 per 10,000 person-years (95%CI: 9.9 - 30.7 per 10,000 person-years). Of the 13 deaths in the 15 to 19 age group, 8 occurred within 10 years since diagnosis.

Conclusion: The majority of people who die from DKA die at home, suggesting that these individuals did not receive hospitalised treatment which could have prevented their death. Deaths due to DKA peaked at younger ages, particularly during adolescence and before 10 years of diabetes duration. This suggests that surveillance and DKA awareness education should be targeted within this particular group of individuals to avoid premature DKA death.

PS 009 Genetics and novel risk factors for type 1 diabetes

336

AGER gene polymorphisms in various HLA-DR/DQ haplotypes and their effects on the risk of type 1 diabetes: a transmission analysis

J. Ilonen[1], A.-P. Laine[1,2], M. Kiviniemi[1], M. Knip[2];
[1]Immunogenetics Laboratory, University of Turku, Turku, [2]The Children´s Hospital, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background and aims: The AGER gene located within the HLA class II region close to the DQ locus is encoding the receptor for advanced glycation end-products (RAGE). High quantities of advanced glycation end-products derived from the Western diet have been implicated to contribute to the increasing incidence of type 1 diabetes (T1D) and the effect to be transmitted through the RAGE receptor. Polymorphisms of the AGER gene have also been shown to be associated with the risk of T1D but this finding may also be explained by the strong linkage disequilibrium with HLA gene alleles affecting T1D risk. In the current study we compared various HLA-DR/DQ haplotypes for the presence of AGER gene polymorphisms observed earlier to be associated with T1D risk and further analyzed the possible effects of such SNPs on the transmission of these HLA haplotypes to a diabetic child in a family series.

Materials and methods: We genotyped rs17493811, rs9469089 and rs2070600 SNPs using Sequenom platform in 1838 trio families from the Finnish Paediatric Diabetes Register where information on HLA-DR/DQ haplotypes and their transmission was also available. Allele and transmission frequencies were compared using the Chi-square test.

Results: In all SNPs a clearly dominant allele was found with frequencies varying between 81.2% and 96.5%. Minor alleles were strongly associated with particular HLA-DR/DQ haplotypes, rs9469089 minor allele was actually found in the majority of the (DR1/10)-DQB1*0501 haplotypes and rs2070600 minor allele was present in most (DR4)-DQA1*03-DQB1*0301 and (DR9)-DQA1*03-DQB1*0303 haplotypes and was common also in T1D associated DRB1*0401-DQA1*03-DQA1*0302 haplotypes. This strongly T1D associated haplotype also carried more often the minor allele of rs17493811 than other haplotypes (151/1147=13.2% vs. 69/5052=1.4%). Transmission analysis revealed that this haplotype was significantly less often transmitted to the affected child when the minor allele of rs9469089 was present (69.7% vs. 87.0%. P=0.00005). A less significant deviation was also observed in the case of the minor allele of rs17493811 (79.5% vs. 85.9%, P=0.04) and rs2070600 where the minor allele was associated with an increased transmission (89.4% vs. 84.1%, P=0.03). The minor allele of rs9469089 also decreased the transmission of the HLA-(DR8)-DQB1*04 haplotype (9.1% vs. 52.5%, P=0.004).

Conclusion: The results suggest that polymorphisms of the AGER gene or other genetic factors in linkage disequilibrium with it affect the T1D risk conferred by various HLA DR/DQ haplotypes.

Pancreatic islet regulatory variants broadly influence type 1 diabetes risk

K.J. Gaulton, A. Aylward, N. Kadakia, M.-L. Okino, U. Jhala;
University of California San Diego, San Diego, USA.

Background and aims: Genetic studies of T1D have identified 57 risk loci, and previous studies reported enrichment of T1D loci at immune-related regulatory sites. However, the mechanisms of how causal variants at most loci influence T1D pathology are unknown. We aimed to more comprehensively define cellular mechanisms of T1D risk by integrating genetic data with epigenome, expression QTL, and transcription factor binding data.

Materials and methods: We used a Bayesian model to determine the effects of >200 annotations from the Epigenome Roadmap and ENCODE on variants at 57 loci using T1D GWAS data. We used the model effects as priors on the evidence for variants at each locus, and calculated a causal probability (PPA) at each variant. We grouped T1D loci based on the PPA of variants in each annotation, and determined the direction of effect of T1D risk alleles in each group on GWAS data for 26 complex traits. We used accessible chromatin profiled in four islet samples with ATAC-seq, mapped reads with BWA and identified sites using MACS2. Genomic sequence around alleles of candidate islet chromatin variants were cloned in both directions into pGL4 minimal promoter vectors and transfected into MIN6 cells in triplicate. We tested candidate variants for shared eQTLs using published data from 118 islet RNA-seq samples using Bayesian co-localization. We collected >2k transcription factor motifs and predicted motifs using allelic sequence at each variant with fimo. We used a Bayesian model to determine the effect of motif variants across 1MB windows genome-wide using T1D GWAS data.

Results: In a joint model of variants at 57 T1D loci we identified enrichment of variants in coding exons and UTRs (enrich=3.2,2.4), active regulatory sites in immune-related cells including primary, helper and regulatory T cells, natural killer cells, and fetal thymus (enrich=3.1,2.7,4.8,1.5,2.5), and active enhancers in pancreatic islets (enrich=1.7). We identified distinct groups of T1D loci based on annotation patterns at likely causal variants, one of which was specific to islet enhancers and included 9p24, 2p23 and 16q23 among other loci. T1D risk alleles at islet enhancer loci had no apparent effects on other autoimmune disease, and had both risk and protective effects on T2D. A single candidate variant at each locus mapped within islet accessible chromatin, and several demonstrated allelic differences (P<.05) in islet regulatory activity in gene reporter assays in MIN6 cells. Candidate T1D variants also had evidence (P_{shared}>.9) for islet eQTLs at 2p23 and 16q23, and both variants were also predicted *in silico* to disrupt CREB3L1/2 binding. We tested whether variants disrupting CREB3L1/2 binding broadly influence T1D risk. We identified 3k variants genome-wide in islet enhancers that disrupt *in silico* CREB3L1/2 binding, and collectively these variants had strong enrichment for T1D risk (enrich=5.1). Among these variants were 7 outside of established loci (PPA>.01) that may represent novel T1D risk factors.

Conclusion: These results demonstrate a role for both immune and pancreatic islet regulatory variants in the mechanistic basis of T1D, suggest a complex relationship of islet variants on T1D and T2D risk, and implicate CREB3L1/2 as a broad regulator of T1D-relevant islet regulatory processes.

HLA-B supertype frequencies in Finnish families with type 1 diabetic offspring and in control families

M.E. Miettinen[1], L. Kinnunen[1], J. Tuomilehto[2];
[1]National Institute for Health and Welfare, Helsinki, Finland, [2]Dasman Diabetes Institute, Dasman, Kuwait.

Background and aims: Human leukocyte antigen (HLA) gene region associates with the risk of several autoimmune diseases including type 1 diabetes. The difference in HLA-B allele/ supertype frequencies between families with type 1 diabetic patients and control families has not been extensively studied. We evaluated HLA-B supertype frequencies in Finnish families with type 1 diabetic patient and in control families.

Materials and methods: HLA-B alleles were genotyped in type 1 diabetic patients (n=246), mothers of the patients (n=234), non-diabetic control children (n=193) and mothers of the control children (n=191). Due to high polymorphism of the HLA-B locus, the alleles were divided into supertypes that share similar peptide binding specificity as follows: Supertype B07 (B*07, B*35, B*51, B*55, B*56), B08 (B*8), B27 (B*14, B*27, B*38, B*39, B*48), B44 (B*18, B*37, B*40, B*41, B*44, B*45), B58 (B*57, B*58), B62 (B*15). B*13, B*47 and B*49 do not belong to any of the HLA-B supertypes. The supertype frequencies between type 1 diabetic patients and control children, and between mothers of the patients and control mothers, were compared.

Results: The frequency of HLA-B7 and HLA-B8 supertypes differed between type 1 diabetic patients and non-diabetic control children (p=0.001 and p<0.001, respectively). The frequency of HLA-B8 supertype differed between mothers of the patients and mothers of the control children (p=0.004).

Conclusion: In this study we found that certain HLA-B supertype frequencies differ not only between the type 1 diabetic patients and controls, but also between mothers of the patients and mothers of the non-diabetic control children.

Polymorphisms in ST3GAL4, ST6GAL1, PHIP, and FUT8 are associated with variation within the serum N-glycome of Scottish type 1 diabetes patients

M.L. Bermingham[1], M. Colombo[2], S. McGurnaghan[1], L. Blackbourn[1], F. Vučković[3], M. Pučić Baković[3], G. Lauc[3], F.A. Agakov[4], A.S. Agakov[4], C. Hayward[1], L. Klaric[1], P.M. McKeigue[2], H.M. Colhoun[1,5], SDRNT1BIO Investigators;
[1]The Institute of Genetics and Molecular Medicine, University of Edinburgh, [2]Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, Edinburgh, UK, [3]Genos Glycoscience Research Laboratory, Zagreb, Croatia, [4]Pharmatics Ltd, Edinburgh, [5]Department of Public Health, NHS Fife, Edinburgh, UK.

Background and aims: We conducted a genome wide association study (GWAS) of N-glycans in people with type 1 diabetes (T1DM). N-glycans are of interest in T1DM, as altered flux through the hexosamine pathway, hypothesised as a pivotal pathway in diabetic complications, would be expected to yield increased UDP-N acetylglucosamine, the substrate for N-linked glycosylation. We previously identified associations of serum N-glycan profile with HbA_{1c}, albumin:creatinine ratio (ACR) and estimated glomerular filtration rate (eGFR) slope in T1DM. Ascertaining genetic effects on these N-glycans will enable assessment of causality of such associations through a Mendelian randomisation approach.

Materials and methods: Ultra-performance liquid chromatography-hydrophilic interaction chromatography profiling was used to measure total and IgG serum N-glycans in 767 patients from the Scottish Diabetes Research Network Type 1 Bioresource (SDRNT1BIO). We tested for association between 8,443,390 directly genotyped and imputed SNPs with N-glycans in these participants. We further used MultiABEL to conduct multivariate GWAS testing.

Results: SNPs in four loci were associated (p<5E-8) with N-glycans that varied with HbA_{1c}, ACR or eGFR slope. Two of these are novel associations unreported in GWAS of N-glycans in non-T1DM individuals and are in regions containing strong biologically plausible candidate genes: ST3GAL4 (β=-0.73[SE=0.11], p=1E-10) which catalyses the transfer of sialic acids to N-glycans, and PHIP (β=-0.64[SE=0.11], p=1E-8) a probable regulator of the insulin signalling pathway. The other significant associations in ST6GAL1 (β=0.21[SE=0.102], p=4E-24) and FUT8 (β=-0.38[SE=0.05], p=2E-12) were reported previously in people without T1DM.

Conclusion: The results from this and existing GWAS will now be used to generate polygenic risk scores for all patients in SDRNT1BIO resource (N = 6,127), that can be tested for prediction of incident diabetic kidney disease.

Gut microbiome dynamics during progressive beta cell destruction in LEW.1AR1-iddm rats: a model of autoimmune diabetes

T. Schoeppe[1], J.-H. Sachs[1], B. Kreikemeyer[2], D. Herlemann[3], M. Tiedge[1];
[1]Institute of Medical Biochemistry and Molecularbiology, University Medical Center Rostock, [2]Institute of Medical Microbiology, Virology, Hygiene, University Medical Center Rostock, [3]Leibniz-Institute for Baltic Sea Research, Rostock, Germany.

Background and aims: The composition of the gut microbiome plays an important pathogenic role in autoimmune diseases including type 1 diabetes mellitus. It is a major challenge to investigate the changes of the gut microbiome communities within the network of genetic determinants, nutrients and viral infections as potential trigger for activation of autoaggressive T cells. The LEW.1AR1-iddm rat model has several advantages to monitor the role of the gut microbiome: (1) a homozygous genetic background, (2) islet infiltration around day 40 and (3) diabetes manifestation after complete beta cell loss between day 60 and 70 after birth. In this study we analyzed changes of the gut microbiome during development of autoimmune diabetes in the LEW.1AR1-iddm and diabetes-resistant LEW.1AR1 control rats.

Materials and methods: Stool samples were collected at the age of 40, 50, 60 days and the timepoint of diabetes manifestation from LEW.1AR1-iddm (n= 68) and LEW.1AR1 (n= 20) rats. Total chromosomal DNA was isolated from stool samples using a Qiagen Kit^{TM} extraction kit. The 16S rRNA genes were amplified on the V3-V4 regions and sequenced on using the paired end Illumina MiSeq platfrom. The resulting sequences were analyzed and quality controlled using QIIME and SILVA_NGS.

Results: Multidimensional scaling based on Bray-Curtis dissimilarities showed clear differences of the gut microbiome of LEW.1AR1 and LEW.1AR1-iddm rats. The differences in the bacterial community in the early phase of islet infiltration were higher at the age of 40 and 50 days but absent at day 60 after progressive beta cell loss. LEW.1AR1 rats revealed an age-dependent decrease of Bacteroidetes/Firmicutes ratio (2.0/0.6) between day 40 and 50 while the ratio in LEW.1AR1-iddm rats remained constant at a level of 1.3. Furthermore we observed a low abundances of Coprococcus and Blautia in LEW.1AR1-iddm rats in the phase of progressive beta cell destruction. On the other hand LEW.1AR1 rats showed a significantly higher abundance of Akkermansia ($p < 0.05$) in the trigger phase (day 40). Akkermansia was correlated with protective effects in human autoimmune diseases. In the time course from day 40 to day 60 the abundance of the genus Prevotella decreased in the LEW.1AR1 rats whereby an increase could be documented for the LEW.1AR1-iddm. The genus Prevotella comprises several species which are linked to inflammatory and autoimmune diseases in humans.

Conclusion: Our study has several implications for microbiome studies in humans: (1) Strong dissimilarities of the microbiome occur during the triggering phase of autoimmunity but not after onset of diabetes. (2) A high Bacteroidetes/Firmicutes ratio apparently provides a proinflammatory milieu, which favors activation of autoaggressive cells. (3) Microbiome signatures significantly change during aging. (4) Minor genomic differences from diabetes susceptibility loci confer significant changes of the microbiome signature. Thus, the dynamic changes of the microbiome may be more relevant than identification of a specific "diabetic microbiome signature".

Immunogenetic factors influencing the rate of pancreatic beta cell destruction: five-year follow up study of residual beta cell function

H. Suda[1], J. Ogino[1], A. Ishino[1], S. Saito[1], K. Tashima[1], C. Yoneda-Karasawa[1], Y. Sakuma[2], Y. Suzuki[1], N. Hashimoto[1];
[1]Department of Diabetes, Endocrine and Metabolic Diseases, Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo, [2]Department of Diabetes and Metabolism, Asahi General Hospital, Asahi, Chiba, Japan.

Background and aims: Type 1 diabetes usually leads to absolute insulin deficiency due to destruction of pancreatic β-cells by cellular-mediated autoimmunity. The disease is defined by the presence of autoimmune markers containing autoantibodies to GAD (GADA), tyrosine phosphatase IA-2 (IA-2A), and ZnT8 (ZnT8A). Type 1 diabetes also has strong HLA association, especially with linkage to the DQA and DQB genes. However, the pathogenesis of the disease is heterogeneous and the rate of β-cell destruction is variable, especially in the adult-onset type. The aim of the study is to evaluate the influence of factors such as islet-related autoantibodies and HLA-DR/DQ alleles on long-term insulin secretion.

Materials and methods: The subjects were 69 patients (20 males and 49 females) diagnosed as autoimmune diabetes with elevated GADA. Their age at diagnosis was 45±15 years. The patients were continuously investigated IA-2A, ZnT8A and HLA DRB1-DQB1 haplotypes. Data for serum C-peptide and C-peptide index were examined in three periods after diagnosis: 0 to 1 year (0-1 y), 2-3 y, and 4-5 y.

Results: Onset was rapid in 35 patients, presenting as metabolic disorder such as ketosis or ketoacidosis as the first manifestation of the disease, and was relatively slow in 34 patients. The residual C-peptide level at 4-5 y was significantly lower in the rapid onset group (0.18±0.30 vs. 1.38±1.04 ng/mL, $p<0.0001$). The rate of reduction in insulin secretion compared to that at 0-1 y was significantly accelerated at 4-5 y in patients with rapid onset (81.8±22.7 vs. 29.6±55.7%, $p<0.0001$). Thirty-three patients were positive for GADA only and 36 patients were positive for two or three autoantibodies. Insulin secretion during the study period was markedly decreased in patients with plural autoantibodies. The rate of reduction of insulin secretion at 4-5 y was significantly higher in patients with plural autoantibodies compared to those with GADA only (75.8±34.6 vs. 34.8±54.5%, $p<0.0005$). Reduction in insulin secretion at 4-5 y was significantly lower in patients with HLA haplotypes resistant to the disease compared to patients without these haplotypes (24.3 ±54.3 vs. 65.4±44.4%, $p<0.005$). Residual insulin secretion was reduced by approximately seven times in patients with plural autoantibodies and non-resistant or sensitive haplotypes for the disease, compared with patients with GADA only and resistant haplotypes. This suggests that the combination of autoantibodies with HLA-DR/DQ alleles may influence pancreatic β-cell destruction.

Conclusion: Our findings strongly suggest that at least three factors, metabolic disorder at onset, plural islet-related autoantibodies, and HLA-DR/DQ alleles resistant for the disease, are important for predicting future residual β-cell function in patients with type 1 diabetes.

342

Progression of albuminuria among patients with type 1 diabetes: a 30-year follow-up study

T. Stratigou[1], N. Vallianou[1], S. Koutroumpi[1], B. Vlassopoulou[1], T. Apostolou[2], G. Ioannidis[1], S. Tsagarakis[1];
[1]Department of Endocrinology, Diabetes and Metabolism, [2]Department of Nephrology, Evangelismos Hospital, Athens, Greece.

Background and aims: In type 1 diabetes mellitus (DM1) good glycemic control and early specific intervention may delay kidney disease. The purpose of the present study was to determine whether patients with DM1 have shown improvement, stabilization or deterioration of their urine albumin excretion (UAE) levels during a close follow-up.

Materials and methods: A cohort of 256 patients with DM1, 18 to 79 years of age, a median duration of diabetes of 20 years and a mean follow-up duration of 13 years were included in the study. All patients used intensive insulin management and at baseline they were educated for titration of basal insulin & for counting carbohydrates and correction boluses of rapid insulin. Patients were treated with RAAS inhibition and statins when indicated. Age, sex, duration of diabetes, duration of follow-up, smoking habits, BMI, data regarding diabetic retinopathy, ischemic heart disease, UAE levels and values of various biochemical parameters were recorded too. Participants were divided into three groups according to the UAE levels normoalbuminuric, microalbuminuric and macroalbuminuric, if UAE levels were <30mg/24h, 30-300mg/24h and > 300mg/24h, respectively. The non-parametrical Kruskal-Wallis criterion was used for all analyses.

Results: Mean glycosylated hemoglobin was statistically significantly decreased during the follow-up period, from 8.2% to 7.8% (p=0.004). Normoalbuminuria was present in 66 patients and remained so in 56 patients until the end of the follow-up, while 9 patients progressed to microalbuminuria and one patient to macroalbuminuria by the end of the study. Microalbuminuria was present in 15 patients: regression was observed in 8 patients, and progression in one patient. Regression of macroalbuminuria to microalbuminuria was noted in one patient and to normoalbuminuria was noted in one participant, too. Treatment with ACE or AT2 inhibitors as well as treatment with statins resulted in statistically significant improvement when compared with deterioration of the UAE levels (p=0.009 and p=0.023 respectively). Mean decrease in annual eGFR was less than expected, ie. 0,66ml/min/1.73m^2, using the CKD-EPI equation. Thirty-seven participants had diabetic retinopathy at the beginning of the study and 51 patients had diabetic retinopathy at the end of the study. One hundred and twelve patients had no retinopathy at the beginning of the study among whom 82 had no retinopathy at the end of the study, too.

Conclusion: Improvement of glycemic control with close monitoring of DM1 patients together with the appropriate use ACE or AT2 inhibitors and statins, where indicated, seems to exert nephron-protective potential and to delay or even reverse the presence of micro/macroalbuminuria.

Chronic fatigue is more prevalent in patients with type 1 diabetes than in the background population: a cross-sectional study

Ø. Jensen[1], T. Bernklev[2], C. Gibbs[3], R.B. Moe[4], D. Hofsø[2], L.-P. Jelsness-Jørgensen[1];

[1]Østfold University College, Fredrikstad, [2]Vestfold Trust Hospital, Tønsberg, [3]Telemark Trust Hospital, Skien, [4]Østfold Trust Hospital, Moss, Norway.

Background and aims: Fatigue is a common symptom in chronic diseases, but in a recent systematic review, few studies were identified focusing primarily on fatigue in patients with type 1 diabetes mellitus (T1DM). Even though one study reported significantly more chronic fatigue (CF) in T1DM patients compared to matched controls (40% versus 7%; 95% CI, 34- 47%), data comparing T1DM to background population (BP) data is lacking. Moreover, there is limited knowledge about factors associated with fatigue and T1DM. The primary aim of the present study was to determine the prevalence of CF in T1DM compared to BP. Secondary aims were to identify socio-demographic and clinical factors associated with CF.

Materials and methods: In the period of April 2015 to December 2016, patients with established T1DM who attended diabetes outpatient clinics for routine follow-up at three Norwegian hospitals were invited to participate in the study. Patients were included after providing written informed consent. Socio-demographic data were collected during clinical examination, while clinical data were collected through clinical examination, medical records and laboratory tests. Fatigue was measured using the Fatigue Questionnaire (FQ), while symptoms of anxiety and depression were measured using the Hospitality Anxiety and Depression scale (HADS). In addition, sleep problems were measured using the Basic Nordic Sleep Questionnaire (BNSQ) item on sleep quality in the last three months. BP comparison was based on FQ data from 2287 Norwegian citizens. The FQ consists of 11 questions, each asking if there is less of a problem than usual (0), no more than usual (1), more than usual (2) or much more than usual (3), total score range is 0-33. Higher FQ scores indicate greater levels of fatigue. The same questions can be dichotomized (0 or 1), a score of 4 or above combined with a symptom duration of 6 months or more defines that the patient has CF. The HADS is divided into two scales: (A) anxiety and (D) depression. Each scale has seven items that are scored on a four-point Likert scale (0-3); the higher the score, the greater the level of anxiety and depression. Sum scores of 8 or above for each dimension indicates borderline anxiety or depression. The BNSQ item on sleep quality was dichotomized into, "no sleep problems" and "sleep problems". Potential associations between clinical and socio-demographic variables and CF, was calculated using multivariate logistic regression analysis.

Results: In total, 288 patients were included, (F:M = 152/136), mean age F:M= 44,6/45,0 years (NS). Mean duration of T1DM was F: M = 23.4/22.4 years (NS). CF was reported in 26.4% (76/288) of the T1DM patients compared to 11% (260/2287) in the BP ($p < 0.001$), with no significant gender differences. Multivariate logistic regression analysis revealed that HADS-D ≥ 8 (OR 4.78, p<0.001), HADS-A ≥8 (OR 2.76, p=0.003), time since diagnosis (OR 1.04, p=0.003) and sleep problems (OR 4.47, p<0.001) to be factors significantly associated with CF in T1DM.

Conclusion: Chronic fatigue was significantly more prevalent in T1DM patients compared to the Norwegian background population. Symptoms indicating borderline anxiety or depression, time since diagnosis and sleep problems were factors significantly associated with CF.

Disclosure: **Ø. Jensen:** None.

High prevalence of IA-2ic- and ZnT8-R-antibody positivity in people with adult-onset diabetes from Singapore

B. Boehm[1], W. Koh[1], Y. Ong[1], S. Lim[2], E. Tai[3], R. Dalan[4], E. Chew[4], Adult-Onset Autoimmune Diabetes Mellitus Consortium (ADAMS);

[1]Lee Kong Chian School of Medicine, [2]Clinical Research Unit, Diabetes Centre, [3]Saw Swee Hock School of Public Health, [4]Endocrine and Diabetes (Clinic 4B, Department of Endocrinology), Singapore, Singapore.

Background and aims: Autoantibodies against islet-cell antigen 2 (IA-2icA), Zinc transporter 8 (ZnT8-R) as well as GAD2 can occur in adult-onset subjects considered on clinical grounds as Type 2 diabetes patients. The aim of this study was to determine the prevalence and pattern of islet-cell antibodies in subjects with adult-onset diabetes from Singaporean and Europe.

Materials and methods: Subjects with adult-onset diabetes mellitus were recruited during the first year of disease onset; 1,020 Europeans (age at disease onset: 42.0 ± 1.2 years, age range 20 to 60 years; males 61.1%) and 1,652 Singaporeans (age at disease onset: 45.0 ± 1.4 years, range 20-60 years; males 63.4%). Inclusion criteria: Diabetes diagnosis according to WHO criteria. Exclusion criteria: Prior insulin therapy, ketosis at diagnosis, pregnancy, presence of any other severe disease. The responsible ethics committees approved the study. GAD-, IA-2- and ZnT8R-antibodies were measured according to IASP protocols. The phenotype was assessed by age of disease onset, BMI and subsequent insulin therapy.

Results: Prevalence of GADA-positivity was 13.9% (95%-CI: 12.1-16.0; p<0.001) in the European cohort as compared to 7.7% (95%-CI: 5.2-11.2; p<0.001) in Asians. Among Asians, GADA-positivity was highest in Indians with 11.4% (95%-CI: 7.7 -16.6) and lowest in both Malay and Chinese (Malay: 6.03% [95%-CI: 3.6-9.9]; Chinese: 5.75% [95%-CI: 4.3-7.7]; p<0.001). In Europeans IA-2icA-positivity was 7.8% (95%-CI: 6.4-9.4) as compared to 16.5% (95%-CI: 12.8-17.0; p<0.001) in Asians. Among Asians, IA-2icA-positivity was highest in Malays (16.8% [95%-CI: 12.6-22.2]) and Chinese people (15.7% [95%-CI: 13.2-18.6]). ZnT8-RA-positivity in Europeans was 4.09% (95%-CI: 3.0-5.4) compared to a significantly higher rate 19.8% (95%-CI: 17.9-21.8; p<0.001) in Asians. Among Singaporeans, ZnT8-RA-positivity was lowest in Indians with 6.7% (95%-CI: 4.2-10.5) and highest in Malays (38.9% [95%-CI: 34.1-44.0]) and intermediate in Chinese with 15.6% (95%-CI: 13.6-18.0). The mean GAD-, IA-2ic-, and ZnT8-R-ab-titres for Europeans were 35.1 DK, 2.9 DK and 0.9 DK units/ml, respectively. Singaporeans revealed mean GAD-, IA-2ic- and ZnT8-R-titres of 12.2 DK, 3.7 DK, and 1.2 DK units/ml. The rates of double autoantibody-positivity were also different between the Asian and the European cohorts; Asians: GADA and IA2A: 1.3%; GADA and ZnT8A: 0.3%; IA2A and ZnT8A: 0.5%; Europeans: GADA and IA2A: 5.7%; GADA and ZnT8A: 2.3%; IA2A and ZnT8A 0.4%. Islet-cell antibody-positive Europeans revealed a lower BMI (Mean BMI 23.9 kg/m^2 [95%-C.I. 19.9-27.9; p<0.001)] as compared to antibody-negatives (27.2 [25.2-29.2]), whereas this association is absent in Asians (ab-positives mean BMI 27.9 kg/m^2 (27.5-28.3) vs. antibody-negatives (27.5 [26.7-28.3]).

Conclusion: A significant involvement of islet-cell autoimmunity was seen in Asian and European adult-onset diabetes patients. IA-2iCA- and ZnT8A-positivity was highest in the three ethnic groups in Singapore, whereas GADA-positivity was the key feature of the European cohort. Our data suggest

significant ethnic-specific differences both related to antibody profiles as well as clinical features.

Fetuin-A and fetuin-A/palmitic acid indices in newly diagnosed diabetes

K. Siewko[1], A. Fiedorowicz[2], A. Zielinska[1], R. Maciulewski[1], B. Telejko[1], A. Poplawska-Kita[1], D. Lipinska[1], A. Milewska[3], H. Car[4], M. Gorska[5], M. Szelachowska[6];

[1]Department of Endocrinology, Diabetology and Internal Medicine, Medical University, [2]Department of Experimental Pharmacology, Medical University of Bialystok, [3]Department of Statistics and Medical Informatics, Medical University of Bialystok, [4]Department of Experimental Pharmacology, Medical University, [5]Deparment of Endocronology, Diabetology and Internal Medicine, Medical University, [6]Department of Endocrinology, Diabetology and Internal Medicine, Medical University, Bialystok, Bialystok, Poland.

Background and aims: Free fatty acids play a role in the pathogenesis of diabetes, but the mechanism of an inflammatory response in beta-cells is still unclear. Fetuin-A is a proinflammatory cytokine which plays a role in the pathogenesis of insulin resistance. There have been some reports suggesting that fetuin-A/free palmitic acid (PA) index may be used as a new biomarker of insulin resistance in diabetic patients. The aim of the study was to compare fetuin-A/free PA, fetuin-A/ceramide contained PA and fetuin-A/sphingomyelin contained PA indices in patients with newly diagnosed diabetes and healthy controls.

Materials and methods: 60 subjects with newly diagnosed diabetes were recruited, including 40 subjects with autoimmune diabetes (AD): 20 with type 1 diabetes (T1D), 20 with LADA, and 20 patients with type 2 diabetes (T2D). The control group consisted of 20 volunteers (CG). Fetuin-A concentration was measured by ELISA method. Ceramide and sphingomyelin contained palmitic acid concentrations and also free PA concentration were analyzed by gas-liquid chromatography. Insulin resistance was calculated using eGDR (estimated glucose disposal rate).

Results: Serum fetuin-A concentration and all three indices of fetuin-A/PA were significantly higher in LADA, T1D and T2D groups in comparison to the control group ($p<0.001$). eGDR was significantly lower in LADA, T1D and T2D as compared to CG ($p<0.001$). Negative correlations were found between eGDR and fetuin-A/free PA ($r=-0.228$, $p=0.04$), fetuin-A/ceramide contained PA ($r=-0.330$, $p=0.003$) and fetuin-A/sphingomyelin contained PA ($r=-0.332$, $p=0.004$) in AD. In the patients with LADA, eGDR negatively correlated with fetuin-A/fPA and fetuin-A/sphingomyelin contained PA indices ($r=-0.575$, $p=0.004$ and $r=-0.446$, $p=0.04$). In T2D group a negative correlation between eGDR and fetuin-A/ceramide contained PA ($r=-0.594$, $p=0.03$) was found.

Conclusion: Significantly higher fetuin-A concentrations in newly diagnosed AD and T2D may confirm the role of this cytokine in the pathogenesis of both types of diabetes. Moreover, our preliminary results suggest that not only fetuin-A/fPA but also fetuin-A/ceramide contained PA and fetuin-A/sphingomyelin contained PA indices probably might be used as a biomarkers of insulin resistance in diabetes, in particular in AD. The study on greater number of patients is ongoing.

Association between plasma phospholipid saturated fatty acids and metabolic markers in eight European countries: a cross-sectional analysis in the EPIC-InterAct study

J. Zheng, InterAct consortium;

University of Cambridge, Cambridge, UK.

Background and aims: Accumulating evidence suggests that individual circulating saturated fatty acids (SFAs) are heterogeneous in their associations with cardio-metabolic diseases, but evidence about associations of SFAs with metabolic markers of different pathogenic pathways is limited. We aimed to examine associations of plasma phospholipid SFAs with metabolic markers of lipid, hepatic, glycaemic and inflammation pathways.

Materials and methods: We measured nine individual plasma phospholipid SFAs and derived three SFA groups (odd-chain: C15:0+C17:0, even-chain: C14:0+C16:0+C18:0 and very-long-chain: C20:0+C22:0+C23:0+C24:0) in individuals from the European Prospective Investigation into Cancer and Nutrition (EPIC)-InterAct case-cohort study across 8 European countries. Using linear regression in 15919 members of the subcohort, adjusted for potential confounders and corrected for multiple testing, we examined cross-sectional associations of SFAs with 13 metabolic markers. Multiplicative interactions of the 3 SFA groups with prespecified factors, including body mass index and alcohol consumption, were tested.

Results: Higher odd-chain SFA group levels were associated with lower levels of major lipids (total cholesterol [TC], triglycerides, apolipoprotein A-1 [ApoA1], apolipoprotein B [ApoB]) and hepatic markers (alanine transaminase [ALT], aspartate transaminase [AST], gamma-glutamyl transferase [GGT]). Higher even-chain SFA group levels were associated with higher levels of low-density-lipoprotein-cholesterol (LDL-C), ratios of TC to high-density-lipoprotein cholesterol (HDL-C), triglycerides, ApoB, ApoB/A1 ratio, ALT, AST, GGT and CRP, and lower levels of HDL-C and ApoA1. The very-long-chain SFA group levels showed inverse associations with triglycerides, ApoA1 and GGT, and positive associations with TC, LDL-C, TC/HDL-C, ApoB and ApoB/A1. Associations were generally stronger at higher levels of BMI or alcohol consumption.

Conclusion: Sub-types of SFAs are associated with metabolic markers of lipid metabolism, liver function and chronic inflammation differentially, suggesting that odd-chain SFAs are associated with lower metabolic risk, even-chain SFAs with adverse metabolic risk, and with mixed findings for very-long-chain SFAs. Clinical and biochemical implications of these findings may vary by dietary exposure and adiposity.

Insulin secretion is inversely associated with high-molecular-weight adiponectin levels in a Japanese population-based study

A. Nakamura[1], H. Miyoshi[1], S. Ukawa[2], K. Nakamura[2], T. Nakagawa[3], Y. Terauchi[4], A. Tamakoshi[2], T. Atsumi[1];

[1]Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, [2]Hokkaido University Graduate School of Medicine, [3]The Hokkaido Centre for Family Medicine, Sapporo, [4]Graduate School of Medicine, Yokohama City University, Yokohama, Japan.

Background and aims: Loss of beta-cell function is progressive over time, and decreased insulin secretion is far advanced by the time diabetes is diagnosed clinically. Recently, it has been reported that increases in adiponectin concentration were related to worsening of insulin secretion in people with newly diagnosed diabetes. In the current study, we investigated the association between insulin secretion and high-molecular-weight (HMW) adiponectin levels in a Japanese population-based study.

Materials and methods: We analyzed data from the Dynamics of Lifestyle and Neighborhood Community on Health Study (DOSANCO Health Study), which was a Japanese population-based cohort study. From these data, subjects whose fasting blood was collected were included in this analysis. Insulin secretion was estimated by homeostasis model assessment of beta-cell function (HOMA-%B). Simple linear regression analysis was performed to examine the association between HOMA-%B ($\log_e$-transformed) and serum HMW adiponectin levels ($\log_e$-transformed). Multiple linear regression analysis was used to calculate age-, sex-, and body mass index (BMI)-adjusted coefficients.

Results: A total of 546 subjects (245 males and 301 females) were included. The mean age and BMI were 58.8 ± 12.5 years and 23.9 ± 3.7 kg/m^2, respectively. Serum HMW adiponectin levels were 4.4 ± 3.1 μg/ml. HOMA-%B was significantly associated with age, BMI, and HMW adiponectin levels in simple linear regression analysis. Additionally, a multiple linear regression analysis revealed that HOMA-%B was inversely associated with HMW adiponectin levels adjusted for age, sex, and BMI (standard partial regression coefficient=−0.17, P<0.01). When the subjects were classified into non-elderly (below 65 years of age) and elderly groups (above 65 years of age), HOMA-%B was inversely associated with HMW adiponectin levels adjusted for age, sex, and BMI in both groups (non-elderly group: standard partial regression coefficient=−0.11, P<0.05; elderly group: standard partial regression coefficient=−0.26, P<0.01). Furthermore, in subjects without diabetes, HOMA-%B was inversely associated with HMW adiponectin levels adjusted for age, sex, and BMI (standard partial regression coefficient=−0.26, P<0.01). When insulin secretion was estimated by fasting insulin or C-peptide levels, similar results were observed.

Conclusion: Our results demonstrated that insulin secretion was inversely associated with HMW adiponectin levels in a Japanese population-based study. This association was applicable to elderly subjects as well as subjects without diabetes. Further prospective observational studies are needed to elucidate the causal association.

Elevated alpha-hydroxybutyrate and branched-chain amino acids during an OGTT characterise insulin resistance and predict deteriorations of glycaemic control in youth

D. Tricò[1,2], H. Prinsen[1], C. Giannini[1], R. de Graff[1], C. Juchem[1], F. Li[1], A. Natali[2], S. Caprio[1], N. Santoro[1], R.I. Herzog[1];

[1]Yale University School of Medicine, New Haven, USA, [2]University of Pisa, Pisa, Italy.

Background and aims: Traditional risk factors for type 2 diabetes mellitus (T2DM) are weak predictors of changes in glucose tolerance and insulin sensitivity in youth. The oral glucose tolerance test (OGTT) provides a dynamic view of biochemical changes produced by glucose-induced hyperinsulinemia; therefore, it offers higher sensitivity than fasting metabolite analysis in identifying subtle early alterations of insulin-induced fuel processing that mark incipient insulin resistance. By measuring the time-course during an OGTT of six metabolites that reflect different axes of insulin action (i.e. proteolysis, ketogenesis, and glycolysis), we aimed at identifying early metabolic features of insulin resistance in youth and whether they can predict longitudinal deterioration of glucose homeostasis.

Materials and methods: Seventy-eight non-diabetic children and adolescents aged 8-18 years were recruited. Plasma concentrations of α-hydroxybutyrate (αHB), branched-chain amino acids (BCAAs; valine, leucine, and isoleucine), β-hydroxybutyrate, and lactate were measured at fasting and every 30 min during an OGTT by proton magnetic resonance spectroscopy. Associations between newly-identified baseline metabolic alterations and longitudinal changes in glucose tolerance and β-cell function relative to insulin sensitivity were tested after 2.3±0.6 years follow-up.

Results: Elevated fasting αHB levels were observed in adolescents with reduced insulin sensitivity, as indicated by a lower OGTT-derived whole-body insulin sensitivity index (WBISI), after adjusting for age, gender, ethnicity, Tanner stage and BMI *z*-score (p=0.01). In the same group, plasma αHB and BCAA levels were increased throughout the course of the OGTT (p<0.03). Notably, a gradual decline in αHB levels during the OGTT identified adolescents with borderline insulin resistance (p=0.02), in whom plasma αHB shifted from elevated baseline concentrations characteristic of subjects with marked insulin resistance to low post-load concentrations typical of insulin sensitive adolescents. Increased baseline αHB concentrations during the OGTT were associated with longitudinal worsening of glucose tolerance, as indicated by higher 2h glucose (beta 79.8, SE 25.0, p=0.01), and of the disposition index (beta -7.89, SE 3.34, p=0.04) after adjustment for confounding factors.

Conclusion: Fasting concentrations of αHB and the time-courses of αHB and BCAAs in response to a glucose challenge characterise insulin resistance in youth. Furthermore, alterations of αHB metabolism predict incipient deterioration of β-cell function relative to insulin sensitivity and longitudinal worsening of glycemic tolerance. These findings provide new insights into the pathogenesis of insulin resistance and novel strategies for early risk stratification of adolescents with a high likelihood of developing impaired glucose metabolism.

Serum uromodulin is significantly associated with both type 2 diabetes and prediabetes

S. Waeger[1], A. Leiherer[1], A. Muendlein[1], C.H. Saely[2], E.-M. Brandtner[1], A. Schuler[2], A. Mader[3], P. Schwerzler[3], P. Fraunberger[4], H. Drexel[5];
[1]Vorarlberg Institute for Vascular Investigation and Treatment (VIVIT), [2]Academic Teaching Hospital Feldkirch, Feldkirch, Austria, [3]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, [4]Medical Central Laboratory, Feldkirch, Austria, [5]Drexel University College of Medicine, Philadelphia, USA.

Background and aims: Serum uromodulin has recently been described to be associated with chronic kidney disease and type 2 diabetes. Whether it is also associated with prediabetes is unknown and is addressed in this study.
Materials and methods: We measured serum uromodulin in 494 subjects who prospectively were investigated over a follow-up period of 4 years.
Results: At baseline, uromodulin was significantly and inversely correlated with fasting plasma glucose (r=-0.165; p<0.001), plasma glucose two hours after an oral 75g glucose challenge (r=-0.164; p=0.001), and HbA1c (r=-0.106; p=0.018). It was positively correlated with insulin sensitivity (r=0.199; p<0.001) as well as with beta cell function (r=0.102; p=0.025). In subjects with prediabetes (n= 267; FPG 100-125 mg/dl; 2h post challenge glucose 140-199 mg/dl, or HbA1c 5.7-6.4%) uromodulin (168±81 ng/ml) was significantly lower than in subjects with normal glucose metabolism (n=81; 184±72ng/ml, p=0.012) but significantly higher compared to patients with diabetes (n=146; 148±70 ng/ml, p=0.014). Taking into account parameters of glucose metabolism after 4 years of follow-up, serum uromodulin significantly decreased from subjects with normal glucose metabolism both at baseline and after 4 years, over patients with normal glucose metabolism at baseline who developed abnormal glucose metabolism during follow-up to those who already had abnormal glucose metabolism at baseline (188±74, 173±66, and 161±78 ng/ml, respectively; p_{trend}=0.001).
Conclusion: We conclude that serum uromodulin is significantly associated with abnormal glucose metabolism including prediabetes.

Localisation of Advanced Glycation End products (AGEs) and fluorescence in skin

I.M. Atzeni[1], P. van der Zee[2], H.H. Pas[3], G.F.H. Diercks[4], A.J. Smit[1];
[1]Department of Internal Medicine, University Medical Center Groningen, [2]Diagnoptics Technologies, [3]Department of Dermatology, University Medical Center Groningen, [4]Department of Pathology, University Medical Center Groningen, Groningen, Netherlands.

Background and aims: Skin autofluorescence (SAF) is a non-invasive method to assess dermal accumulation of AGEs, which is considered to reflect systemic AGE burden. SAF is used for assessment of cardiovascular risk and detection of diabetes mellitus (DM). Although SAF has been validated against AGEs measured in dermis homogenates of skin biopsies in Caucasian skin, it has not been validated in subjects with high skin pigmentation. SAF measurement is hampered by absorption of excitation and emission fluorescent light by melanin. This limits its performance in subjects with dark skin types. Furthermore, little is known about the location of AGEs in different layers of the skin and their relative contribution to non-invasively assessed SAF. This is of relevance for interpretation of SAF in dark skin types, as well as for its reflection of the systemic AGE burden. Therefore, aim of our present study is to assess the histological distribution, and fluorescence signals of AGEs in the dermis and epidermis in dark skinned subjects with and without DM in relation to non-invasively assessed SAF.
Materials and methods: In 6 healthy young subjects (median age 22 (20-41) years, 4 male) and 6 older DM (type 1 and 2) patients (median age 65 (45-71) years, 5 male) with skin pigmentation Fitzpatrick scale IV (Mediterranean) to VI (African), volar forearm measurements and subsequently two skin biopsies from the same site were obtained. SAF, using the AGE Reader (excitation 370, emission 420-600 nm), and pigmentation measurements, using the Mexameter, were performed. Confocal fluorescence microscopy was used to measure intrinsic fluorescence (Excitation = 375, 405 and 440 nm, emission spectra between 414 and 690 nm) and light microscopy to measure depth distribution of specific AGEs (Alkaline phosphatase chromogenic reporter for carboxymethyl lysine (CML), pentosidine and the hydroimidazolone MG-H1) from these skin biopsies. Immunohistochemical (IHC) staining was performed with anti-AGE-antibodies (anti-CML, anti-pentosidine and anti-MG-H1).
Results: CML, pentosidine and MG-H1 were preferentially visible around blood vessels, colocalized with collagen, elastin, and near fibroblasts in the dermis, and were also present in the stratum corneum and suprabasal layer. Intrinsic fluorescence was most prominent in the dermis, but also present in the stratum corneum and suprabasal layer. Immunohistochemically CML and MG-H1 were more visible in the dermis of patients, as was fluorescence intensity with confocal microscopy. A clear change in pentosidine levels with age could not be observed. In healthy subjects MG-H1 levels in the epidermis appeared more prominent than in patients. SAF levels increased with age, and were concordant with the IHC and fluorescence data.
Conclusion: Although skin AGEs accumulation and intrinsic fluorescence occur in different skin layers, in older diabetic patients they are most prominent in the dermis. This pattern was more pronounced for CML and MG-H1, underscoring the accumulation of AGEs with age and diabetes. Concordance often existed with non-invasively measured SAF, although more research is needed to allow reliable SAF measurements in very dark skinned subjects.

Skin autofluorescence improves the Finnish diabetes risk score in the detection of diabetes in a large population cohort

B.T. Fokkens[1], R.P. van Waateringe[2], D.J. Mulder[1], B.H.R. Wolffenbuttel[2], A.J. Smit[1];
[1]Internal Medicine, University Medical Center Groningen, [2]Endocrinology, University Medical Center Groningen, Groningen, Netherlands.

Background and aims: In type 2 diabetes mellitus, a long, clinically latent period often exists in which diabetes is not yet detected, but in which silent development of micro- and macrovascular complications frequently occurs. These complications may be prevented or delayed by early detection and treatment of diabetes in high risk individuals. Several diabetes detection approaches exist of which the Finnish diabetes risk score (FINDRISC) is one of the most accepted. The aim of the present study was to investigate whether skin autofluorescence (SAF) further improves the FINDRISC in detecting undiagnosed diabetes in a large population based cohort.
Materials and methods: Subjects included were participants of Lifelines, a large population cohort study in the northern region of the Netherlands. SAF, as a reflection of advanced glycation endproduct accumulation in the skin, was assessed in an unselected subset of the participants using the AGE reader. After exclusion of participants with previously diagnosed diabetes (n=1635), pregnant women (n=58), and participants using corticosteroids (n=345), 79,248 subjects remained for analysis. Diabetes was defined by fasting blood glucose ≥7.0 mmol/l, non-fasting blood glucose ≥11.1 mmol/l, or HbA1c ≥6.5%. Discrimination of the risk models was estimated using the area under the

receiver operating characteristic curve (AUROC), calibration was assessed by Hosmer-Lemeshow (HL) chi^2 test, and clinical relevance was addressed by reclassification analysis.

Results: Diabetes was detected in 1042 participants (aged 55 ± 12 years, 54% male). Participants without diabetes were 44 ± 12 years old and comprised 42% men. SAF improved the AUROC of the FINDRISC from 0.802 to 0.811 (p<0.001). The FINDRISC + SAF model showed good calibration (HL chi^2 = 11.7, p=0.113). Risk reclassification showed that 8 -15% of all participants were reclassified into more accurate risk categories due to the addition of SAF to the FINDRISC (NRI = 0.080, 95% CI 0.052 - 0.110). The FINDRISC + SAF model had a score range between 0 and 21. At a score of 8, the sum of sensitivity and specificity was maximised (sensitivity 76%, specificity 72%). When SAF was added to a simplified model (using age and BMI categories only), the discriminative performance of this model was similar to the full model + SAF (AUROC=0.806, p=0.062).

Conclusion: In the Lifelines cohort study, discrimination, calibration, and reclassification criteria showed significant and clinically relevant additional value of SAF in diabetes detection screening. The new model was especially useful in reclassifying participants in intermediate risk categories in which further blood glucose or HbA1c testing should confirm the presence of diabetes. Furthermore, a simplified model (using age, BMI, and SAF only) was found that did not affect the discriminative value of the full model.

Diabetes risk reclassification comparing the FINDRISC model and the FINDRISC model + SAF.

The association between serum testosterone and insulin resistance: Is it really bidirectional?

K. Ottarsdottir, M.I. Hellgren, U. Lindblad, B. Daka;
Department of Primary Health Care, University of Gothenburg, Gothenburg, Sweden.

Background and aims: Low concentrations of testosterone have been associated with increased risk for type 2 diabetes and the risk is presumed to act through the increase in insulin resistance. It has been suggested that the association between insulin resistance and testosterone concentrations is bidirectional. The aim was to investigate whether testosterone concentrations predict insulin resistance and whether the levels of insulin resistance predict the concentrations of testosterone in a prospective study.

Materials and methods: Longitudinal observational study. Between 2002-2005 a sample of 2816 subjects (M=1400) were randomly selected for a cohort study with the goal to detect risk factors for cardiovascular disease at an early stage. The cohort was followed up 2012-2014. The mean follow-up time was 9.9±1.1 years and the protocol was completed in a subset of 1327 (M=657) subjects. Measurements of all hormones and plasma glucose were performed at fasting at both visits. Insulin resistance was defined using homeostatic model assessment of insulin resistance (HOMA-Ir). Immunoassay techniques were used for measurements of sex hormones. Analyses were stratified for sex. Linear regressions were computed to investigate the association between sex hormones and insulin resistance. General linear models were also performed to compare the variance of testosterone concentrations in different quartiles of logHOMA-Ir and the variance of logHOMA-Ir in different quartiles of testosterone.

Results: In men, concentrations of testosterone were strongly associated with insulin resistance both at baseline (β=-0.112 p=0.003), and at follow-up (β= -0.208 p<0.001), in multivariable analysis including age and waist hip ratio. In the longitudinal analysis in men, low concentrations of testosterone at baseline were associated with high levels of HOMA-Ir at the follow-up in a multivariate model including age, waist hip ratio, follow-up time and HOMA-Ir at baseline as covariates (β=-0.105 p=0.002). Men within the lowest quartile of testosterone at baseline had significantly higher logHOMA-Ir at follow-up than other quartiles (Q1 vs Q2 p=0.006, Q1 vs Q3 p=0.001, Q1 vs Q4 p=0.004). No differences were observed between quartiles 2, 3 and 4 in this matter. In women, there were no significant associations between testosterone levels and insulin resistance at baseline (β=0.055 p=0.141) or at follow-up (β=0.021 p=0.554). In the longitudinal analyses investigating the impact of insulin resistance on testosterone concentrations in men and women at follow up no significant associations were found in a multivariable analysis including baseline concentrations of testosterone (Men β=-0.012 p=0.738, Women β=0.051 p=0.231). The variance of testosterone levels at follow up was also investigated in different quartiles log HOMA-Ir at baseline in the multivariable model but no significant differences between quartiles were observed.

Conclusion: In this longitudinal observational study testosterone concentrations at baseline predicted high insulin resistance at follow-up in men, while high insulin resistance at baseline did not predict low testosterone. The results suggest a strong effect of testosterone on the development of insulin resistance and on the incidence of diabetes in men.

Gene-diet interaction analysis, fine mapping and genomic annotation of the FADS1-2-3 gene cluster reveals regulatory potential in diabetes

P.W. Franks[1,2], Y. Chen[3], A. Estampador[3], M. Keller[1], A. Poveda[1], J. Dalla-Riva[1], F. Renström[4], A. Kurbasic[4], T.V. Varga[1];

[1]Genetic and Molecular Epidemiology Unit, Lund University Diabetes Center, Malmö, [2]Department of Public Health and Clinical Medicine, Umeå University, Umeå, [3]Genetic and Molecular Epidemiology Unit, Lund University Diabetes Centre, Malmö, [4]Clinical Sciences, Genetic and Molecular Epidemiology Unit, Lund University Diabetes Center, Malmö, Sweden.

Background and aims: Polymorphisms at the fatty acid desaturase gene cluster (FADS1-FADS2-FADS3) have been associated with multiple metabolic and anthropometric traits in Greenlandic Inuit. We systematically assessed whether loci in the FADS region modify the association between dietary fat intake and cardiometabolic traits and functionally annotated top variants to estimate causal loci.

Materials and methods: Data analyses consisted of: 1) interaction analyses between the six candidate genetic variants; 2) gene-centric joint analyses to detect interaction signals in the FADS region; 3) haplotype-centric joint tests across 30 haplotype blocks in the FADS1-3 region to refine interaction signals: 4) functional annotation of top loci. These analyses were undertaken in Swedish adults from the GLACIER Study (N=5,160); data on gene variation (Metabochip array) and height, body weight, fasting and 2hr-glucose, triglycerides, and HDL-, LDL- and total cholesterol were available. Dietary intakes of n-3, n-6 and total polyunsaturated fatty acids (PUFA) were calculated from food-frequency questionnaires. Results were adjusted for multiple testing.

Results: SNP-level multiplicative interactions were observed between rs174570 and n-6 PUFA intake on fasting glucose ($P_{interaction}$=0.007) and between rs174602 and n-3 PUFA intake on total cholesterol ($P_{interaction}$=0.015). Gene-centric analyses demonstrated evidence for joint main and interaction effects for FADS on body weight ($P_{n\text{-}3.joint}$ = 0.018, $P_{n\text{-}6.joint}$ = 0.021, $P_{PUFA.joint}$ = 0.024) and on BMI ($P_{n\text{-}3.joint}$ = 0.031, $P_{n\text{-}6.joint}$ = 0.029, $P_{PUFA.joint}$ = 0.033) irrespective of types of fatty acid intake. An interaction was detected for FADS1-3 and n-3 PUFA on triglycerides (P_{int}=0.005). The haplotype analyses revealed three blocks ($P_{int} \leq 0.011$) that drive the interaction between FADS1-3 and n-3 PUFA on triglycerides. Genomic annotation showed that the rs5792235 variant demonstrated the highest functionality score (Figure).

Conclusion: The association between FADS1-3 variants and triglycerides may be modified by PUFA intake. The intronic rs5792235 variant is a potential causal variant in the region. It is likely that the region harbours multiple causal loci.

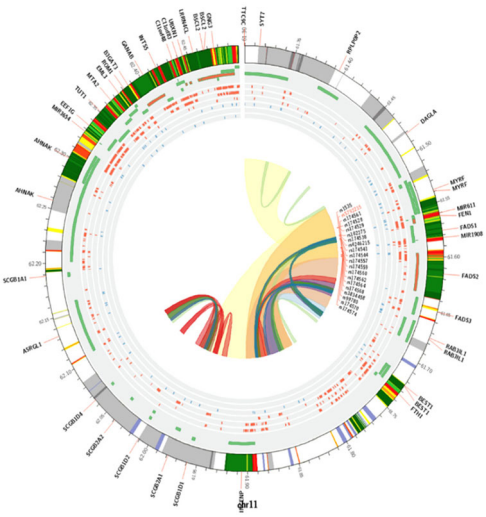

Figure. Circos plot based on rs5792235 (shown in red text). The plot shows rs5792235 and its proxies (shown in black text around rs5792235). From outer to inner, the circles represent ChromHMM chromatin states, annotated genes (green), histone modification set (red), transcription factor set (blue), current SNP (rs5792235) and associated SNPs, and 3D chromatin interactions, respectively. The three circles in the histone modification set are H3K4me1, H3K4me3, H3K27ac, and the three circles in the transcription factor set are CTCF, CEBPB and CEBPD. Color schemes for the ChromHMM chromatin states and the 3D interaction loops are found at http://biotech.bmi.ac.cn/3dsnp/documentation/tutorials/ .

Diabetes protection is associated to a C3H-specific locus on chromosome 15

D. Altenhofen[1], T. Schallschmidt[1], S. Lebek[1], A. Pelligra[1], J. Masuch[1], T. Stermann[1], B. Knebel[1], A. Schürmann[2], A. Chadt[1], H. Al-Hasani[1];

[1]German Diabetes Center, Düssledorf, [2]Deutsches Institut für Ernährungsforschung, Potsdam, Germany.

Background and aims: The genetic factors underlying the susceptibility for type 2 diabetes are not fully understood. To identify new diabetes-associated genes we investigated an outcross population generated by crossbreeding of diabetes-susceptible New Zealand Obese (NZO) mice with the diabetes-resistant C3HeB/FeJ mouse strain.

Materials and methods: We measured diabetes-related traits in a (NZOxC3H)NZO backcross population of 300 males. Animals were fed a high-fat-diet (45% fat/cal.) throughout the experiment. Body weight, body composition, plasma glucose and insulin were measured at different time points. At 21 weeks mice were sacrificed and tissues were harvested. The N2 population was genotyped using a genome-wide high-density SNP panel. Linkage analysis was performed by *in silico* calculation of phenotype-genotype associations. Differential gene expression between the parental strains in liver, skeletal muscle, white adipose tissue, brown adipose tissue and pancreatic islets was analyzed by microarray and qPCR.

Results: A major QTL (Quantitative Trait Locus) for blood glucose was identified on chromosome 15 (LOD score 7.5). A locus located at 13 cM was associated to a lowering of 100 mg/dl in blood glucose of the protective C3H allele carriers at 15 weeks of age. A significant lowering ($p<0.05$) in glycemia could be associated to identified locus from 8 weeks of age on, demonstrating an early diabetes protective effect linked to C3H allele carriers. Moreover, diabetes prevalence in Chr.15/C3H was 57% compared to 81% in Chr15/NZO at 21 weeks. This effect has shown to be independent of the QTL locus found on body weight. Similarly, mortality rate was strongly reduced in C3H alleles carriers, 6,5% compared to 26,4% at 21 weeks of age. Microarray expression profiling revealed 44 genes ($p<0.05$) differentially expressed in

liver, brown adipose tissue, white adipose tissue, muscle and/or pancreatic islets, and mapping to the critical regions of the identified QTL. Comparisons using the SNP database (SANGER) identified 16 genes with C3H-specific variants. As revealed by a Variant effect Predictor analysis (Ensembl), protein function could be affected by those SNP.

Conclusion: A major QTL was found on Chr. 15 triggering diet-induced effects on diabetes development already at early stages of life. We hypothesized that the C3H allele confers diabetes protection by improving islet function and survival in NZO mice background. Future analysis aimed to investigate the pathophysiological effect of the current candidate genes associate to the presented diabetes locus on chromosome 15.

The changes in serum metabolites after meal challenge are affected by genetic variants of TCF7L2

E. Adamska[1], W. Bauer[1], P. Samczuk[1], M. Ciborowski[1], J. Godzien[2], K. Maliszewska[3], N. Wawrusiewicz-Kurylonek[3], M. Gorska[3], C. Barbas[2], A. Kretowski[1,3];

[1]Clinical Research Centre, Medical University of Bialystok, Bialystok, Poland, [2]Center for Metabolomics and Bioanalysis (CEMBIO), Universidad CEU San Pablo, Madrid, Spain, [3]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland.

Background and aims: The single nucleotide polymorphisms (SNPs) of TCF7L2 gene were found to be one of the most predictive genetic factors of type 2 diabetes mellitus (T2DM) development and have been implicated in the pathogenesis of T2DM primarily due to its influence on pancreatic β-cell function and insulin secretion. It has been shown that a low carbohydrate diet of TCF7L2 risk carriers may decrease the risk of T2DM development. To study the potential mechanism of this effect, we reached for a metabolomics approach. LC-QTOF-MS was used to evaluate changes in serum metabolites after high-carbohydrate (HCarb) and norm-carbohydrate (NCarb) meal intake, performed in men carrying 2 or 0 risk alleles for investigated SNP of TCF7L2 (rs7901695).

Materials and methods: The study group consisted of 21 men without T2DM. We genotyped previously identified SNP TCF7L2 rs7901695. The study population was divided into 2 groups: individuals carrying 2 risk alleles (homozygous genotype CC, n=8, 31±6 y, BMI=29±8) and subjects with 0 risk alleles (homozygous genotype TT, n=13, 35±10 y, BMI=28 ±6). Fasting, 0.5hr, 1hr, 2hr and 3hr, serum samples were taken during HCarb (89% of energy from carbohydrate) and NCarb (45% of energy from carbohydrate) meal challenges. Samples were fingerprinted using LC-QTOF-MS. Data was collected in both ESI (+/-) modes (50-1,000 m/z). Based on the relation between time points and metabolite's intensity, AUC was calculated for each metabolite. Obtained AUCs were forwarded for partial least square discriminant analysis (PLS-DA) modelling. Based on PLS-DA model volcano plots were built to select significant metabolites according to multivariate statistics. Additionally, for each significant metabolite, p-value was calculated by Welch's t-test.

Results: Based on AUCs obtained for metabolites after HCarb meal PLS-DA models were built showing a perfect separation between men with and without risk alleles (CC vs. TT). The parameters of the models were as follow: R2=0.992, Q2=0.818 in ESI+ and R2=0.999, Q2=0.729 in ESI- ion modes. Individuals with 2 risk alleles showed significantly lower AUCs for acylcarnitines (- 61-84%, p=0.001-0.05), lysophospholipids (- 30-85%, p=0.001-0.09), phospholipids (- 20-49%, p=0.009-0.1), diacylglycerols (- 27-80%, p=0.009-0.08), oxidized fatty acids (- 36-83%, p=0.01-0.2), and oxoproline (- 65%, 0.03). After NCarb meal no significant differences were observed. In fasting state participants carrying 2 risk alleles had lower levels of hydroxyarachidonic (- 67%, p=0.1) and hydroxylinoleic (- 91%, p=0.03) acids and higher level of phosphatidylethanolamine, PE 40:7 (+ 66%, p=0.1).

Conclusion: The carriers of 2 risk alleles of TCF7L2 rs7901695 responded differentially to HCarb, but not to NCarb meals, than individuals without risk alleles. HCarb meals influenced lipid metabolism, which was manifested by decreased AUCs of metabolites involved in energy metabolism (acylcarnitines) and oxidative stress (oxidized fatty acids, oxoproline). The potential impact of observed changes in lipid metabolism after HCarb meals on T2DM development in TCF7L2 risk carriers requires further investigations.

The changes in serum metabolites after meal challenge are affected by genetic variations in rs340874 PROX1

P. Samczuk[1], K. Maliszewska[2], W. Bauer[1], E. Adamska[1], M. Ciborowski[1], J. Godzien[3], N. Wawrusiewicz-Kurylonek[2], M. Gorska[2], C. Barbas[3], A. Kretowski[1,2];

[1]Clinical Research Centre, Medical University of Bialystok, [2]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland, [3]Center for Metabolomics and Bioanalysis (CEMBIO), Universidad CEU San Pablo, Madrid, Spain.

Background and aims: The single-nucleotide polymorphism (SNP) of PROX1 gene rs340874 was found to be associated with glucose metabolism, fasting glucose concentration and type 2 diabetes mellitus (T2DM). Moreover, previously we have observed that it is associated with alterations in postprandial glucose and lipid metabolism. The mechanism by which PROX1 gene affects the susceptibility to T2DM seems to be more complex and it was not well established yet. To study the potential mechanisms we reached for a metabolomics approach. LC-QTOF-MS was used to evaluate changes in serum metabolites after high-carbohydrate (HCarb) and norm-carbohydrate (NCarb) meal challenge tests performed in men dependently on genotypes of PROX1 rs340874.

Materials and methods: The study participants were divided into 2 groups dependently on PROX1 rs340874 genotype: the carriers of CC (n=12, 35±9 years old, BMI=29±8) and carriers of CT or TT (n=16, 35±6 years old, BMI=27±4). Fasting, 0.5h, 1h, 2h and 3h serum samples were taken from participants during HCarb (89% of energy from carbohydrate) and NCarb (45% of energy from carbohydrate) meal challenge. Samples were fingerprinted by LC-QTOF-MS. Data were collected in both ESI (+/-) modes (50-1,000 m/z). Based on the relation between time points and metabolite's intensity for each metabolite AUC was calculated. Obtained AUCs were forwarded for partial least square discriminant analysis (PLS-DA) modelling. Based on PLS-DA models volcano plots were built to select significant metabolites according to multivariate statistics. Additionally for each significant metabolite p-value was calculated by Welch's t-test.

Results: PLS-DA models built based on AUCs obtained from HCarb and NCarb data showed a clear separation of studied groups and good models parameters (e.g. for ESI+ data: R2=0.992, Q2=0.753 for HCarb and R2=0.998, Q2=0.43 for NCarb). After both meals AUC for acetylcarnitine was increased in CC carriers (+92%, p=0.003 and +55% p=0.07 for HCarb and NCarb meal, respectively). In case of NCarb meal individuals with risk alleles showed significantly lower AUCs for oxidized fatty acids (- 32-81%, p=0.02-0.1) and higher for linoleic acid (+80%, p=0.01). After HCarb meal in the CC carriers group decreased AUC for ornithine (-45%, p=0.05), ketosphingosine (- 48%, p=0.01), linoleamide (- 45%, p=0.1), and several lysophospholipids (- 40-56%, p=0.01-0.05) was observed. After both meals differences in AUCs for bile acids between studied groups were noticed. In the CC carriers group higher AUC for sulfodeoxycholate (+42%, p=0.08) and lower for taurocholate (-59%, p=0.07) after HCarb meal, while after NCarb meal higher AUC for glycodeoxycholate (+70%, p=0.1) were observed.

Conclusion: The carriers of 2 risk alleles of PROX1 rs340874 responded differentially to HCarb and NCarb meals. The obtained results indicate for differences in fatty acid metabolism (after NCarb meal), phospholipid metabolism (after HCarb meal) likewise differences in bile acids signalling between CC and CT/TT carriers. Further investigations are needed for deeper exploration of mechanisms by which CC phenotype promotes T2DM.

Built environmental characteristics and diabetes risk: a systematic review and meta-analysis

N.R. den Braver[1], J. Lakerveld[1], F. Rutters[1], L.J. Schoonmade[2], J. Brug[1,3], J.W.J. Beulens[1,4];

[1]Epidemiology and Biostatistics, VU University Medical Center, [2]University Library, VU University, [3]Faculty of Social and Behavioural Sciences, University of Amsterdam, Amsterdam, Netherlands, [4]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands.

Background and aims: Physical inactivity, poor dietary habits and lack of sleep are established lifestyle-related risk factors for type 2 diabetes mellitus (T2DM). Built environmental characteristics may influence these risk factors, and in turn T2DM development. We aimed to systematically review the evidence on built environmental characteristics related to these lifestyle factors and the prevalence and incidence of T2DM as well as glycaemic markers.

Materials and methods: A literature search was performed in PubMed, Embase and Web of Science. We included studies reporting: 1) populations ≥18 years old, 2) T2DM prevalence, T2DM incidence, or glycaemic markers as outcomes, and 3) built environmental characteristics related to physical activity, dietary behaviour and sleep. After screening by two independent reviewers, data were extracted by one reviewer according to a standardized protocol and quality of the studies was assessed by two reviewers according to the Quality Assessment Tool for Quantitative Studies. When ≥3 studies investigated the same outcome and exposure, adjusted for at least age and gender and received a strong or moderate quality rating, we included these for meta-analyses using a random effects model.

Results: After screening 9,089 studies, 86 studies were eligible for data extraction. In total, 46 studies compared T2DM risk or prevalence in urban built environments versus rural built environments. Thirty-two of these studies were not meta-analysed; 14 due to a weak quality rating and 19 studies for not correcting for confounders. Pooled risk ratios of 13 included studies indicated a significant association such that more urbanized areas were associated with a higher T2DM prevalence (1.50 (95%-CI: 1.24 - 1.81; I^2 72.8%)). These findings mainly originated from studies in lower middle income countries (n=5) and higher middle income countries (n=6). A pooled risk ratio of four studies indicated that higher neighborhood walkability was associated with lower T2DM risk (0.87 (95%-CI: 0.81 - 0.93; I^2 0%)). Three green space studies indicated a non-significant inverse association (0.84 (95%-CI: 0.61 - 1.15; I^2 96.6%)). Higher availability of fast-food outlets/convenience stores (n=4) and perceived healthiness of food environment (n=2) were relatively consistently associated with increased and decreased T2DM risk, respectively. Associations between supermarkets/grocery stores (n=4), combined index scores of food environment (n = 8), residential noise (n=3), availability of recreational facilities (n=4), infrastructure (n=4), safety (n=3) and T2DM were more heterogeneous.

Conclusion: A large body of literature is available linking built environmental characteristics with T2DM. Most studies investigated urbanisation, where T2DM risk/prevalence in urban areas is generally higher compared to rural areas, especially in middle-income countries. Physical activity environment was relatively consistently associated with T2DM risk, whereas associations were more heterogeneous for food environment.

Changes in objective physical activity in a randomised lifestyle intervention among diabetes prone Middle-Eastern immigrants and its association with insulin sensitivity

F. Siddiqui[1], R. Koivula[1], A. Kurbasic[1], U. Lindblad[2], P.M. Nilsson[1], L. Bennet[1];

[1]Lund University, Malmo, Sweden, [2]Gothenburg University, Gothenburg, Sweden.

Background and aims: Middle-Eastern immigrants in Sweden exhibit high levels of physical inactivity, obesity and type 2 diabetes. The aim of this study is to examine changes in objectively assessed physical activity levels following a culturally adapted lifestyle intervention among Middle-Eastern immigrants. The secondary aim is to examine the association between changes in insulin sensitivity and objectively assessed physical activity levels.

Materials and methods: A randomized controlled trial of four-months duration, addressing Iraqi immigrants exhibiting one or more risk factors for type 2 diabetes. The intervention group (n=50) was offered a culturally adapted lifestyle intervention comprising of seven group sessions including self-empowerment and cooking sessions. The control group (n=46) received "usual care", comprising of written information on healthy lifestyle habits. All participants underwent health examinations and wore accelerometers for 10 days at the start, mid and end of the study. A novel approach was used to process accelerometer data which summarized average physical activity intensity as vector magnitude (VM) in units of acceleration (mG's).

Results: At baseline, participants spent approximately 80 percent of the time in sedentary activities. The intervention and the control group didn't differ in terms of change over time in average physical activity intensity (VM) (β=0.011 95% CI -0.011 to 0.033, *P*=0.32). However, there was a significant increase in number of hours per day spent in light intensity physical activity in the intervention group compared to the control group (β=0.023 95% CI 0.001 to 0.045, *P*=0.046). This was accompanied by a trend towards decrease in number of hours per day spent in sedentary activities. Improvement in insulin sensitivity index was significantly associated with objectively measured physical activity (β= 0.01 95% CI 0.004 to 0.025, *P*=0.006).

Conclusion: Increase in the time spent in light intensity physical activity combined with a trend toward decrease in sedentary time, in a sedentary immigrant population, will potentially have beneficial effects for diabetes prevention in this group at high-risk of type 2 diabetes.

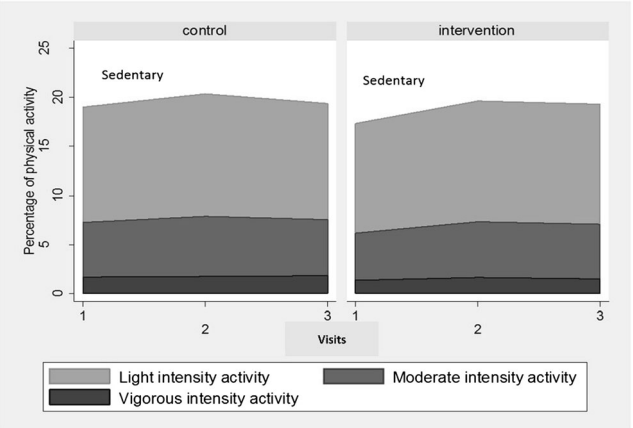

Figure 1: Change over time in percentage of time spent in light, moderate and vigorous intensity activities in the two groups.

Differential effects of bisphenol S and bisphenol F on ion channel activity and expression in pancreatic beta cells

L. Marroqui[1,2], M. Castellano-Muñoz[1,2], S. Villar-Pazos[1,2], I. Quesada[1,2], A. Nadal[1,2];

[1]Biochemistry Institute, Miguel Hernandez University, [2]Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Elche, Spain.

Background and aims: Many dairy products found in plastics, cosmetics and food packaging material among others, have been proved to be harmful to human health due to its actions as endocrine-disrupting chemicals (EDCs).

Low doses of bisphenol A (BPA), one of the most widespread EDCs, alter pancreatic beta-cell function, induces insulin resistance and other metabolic alterations in cellular and animal models. The increasing concern about BPA has led to its substitution with other compounds chemically similar. Recent findings, however, suggest that these "alternatives to BPA" might elicit similar physiological alterations. In the present work we study the effects of bisphenol S (BPS) and bisphenol F (BPF) on ion channels activity and gene expression in pancreatic beta-cells.

Materials and methods: Whole islets or dispersed islets from C57BL/6 or beta estrogen receptor knockout (BERKO) mice treated either, acutely or during 48 h with BPA (as a positive control), BPS or BPF. We used the patch clamp techniques in its single channels recording form or in the whole-cell configuration to measure K_{ATP} channel activity and calcium currents, respectively. Gene expression of ion channels was analyzed by quantitative RT-PCR.

Results: Both BPS and BPF reproduced the inhibitory effect of BPA on beta-cell K_{ATP} single channel. Nevertheless, a higher BPF concentration was needed to reach K_{ATP} inhibition similar to that observed with BPA or BPS. In beta-cells from WT mice, K_{ATP} activity was reduced by 65 ± 20% (n=9, p=0.04) and 40 ± 15% (n=7, p=0.01) after addition of BPS (1 nM) or BPF (10 nM), respectively. This reduction was not observed in BERKO mice under the same conditions (97 ± 51% and 80 ± 34%, respectively; n=7). Upon 48 h of treatment with BPS or BPF, calcium channel activity was measured in isolated beta-cells. Low concentration (1 nM) of BPS, but not BPF, reduced peak calcium currents compared with vehicle (vehicle: 29.2 ± 1.9; BPS: 24.1 ± 1.6; BPF: 27.2 ± 2.6 pA/pC; n=11, n=15 and n=21, respectively). A higher BPF concentration (1 μM) was needed to reduce calcium currents (vehicle: 36.1 ± 3.0 pA/pC at 0 mV (n=13) *vs.* 1 μM BPF: 23.3 ± 2.2 pA/pC (n=17, p=0.001)) in isolated beta-cells. However, this reduction was not observed in beta-cells from BERKO mice, supporting the hypothesis that these effects are mainly produced through estrogen receptor beta. These effects on calcium currents were associated with lower Cav2.3 channel mRNA levels compared to beta-cells treated with vehicle.

Conclusion: Our results show that, as BPA, BPS can act as a xenoestrogen, modulating K_{ATP} activity, calcium currents and gene expression at low concentrations (1 nM). On the other hand, concentrations 10-fold to 1000-fold higher were necessary to reach the same effects with BPF. Therefore, BPS fully imitate BPA and should not be considered a safe alternative. More experiments are needed to identify BPF as a safer substitute of BPA.

TNFα antagonism and insulin resistance in non-diabetic patients suffering from psoriasis: secondary analysis of a randomised active-controlled trial

C.T. Herz[1], J.M. Brix[2,3], A. Tanew[4], G. Holzer[4,5];
[1]Department of Medicine III, Medical University of Vienna, [2]Department of Medicine I, Rudolfstiftung Hospital, [3]Karl Landsteiner Institute for Obesity and Metabolism, Vienna, Austria, [4]Department of Dermatology, Medical University of Vienna, [5]Department of Dermatology, SMZ Ost, Vienna, Austria.

Background and aims: Patients suffering from psoriasis exhibit an increased cardio-metabolic burden due to the systemic inflammatory nature of the disease. According to numerous scientific reports the pro-inflammatory cytokine TNFα plays a major role in the pathogenesis of psoriatic disease and it also has been demonstrated to increase insulin resistance including diminished peripheral glucose uptake. TNFα blockers have been shown not only to mitigate the course of psoriasis, but also to improve metabolic parameters including insulin resistance. In this secondary analysis of a RCT we hypothesized that the TNFα blocker Adalimumab (ADA) is superior to fumaric acid esters (FAE), a well established conventional, immuno-modulatory systemic treatment for psoriasis, in improving insulin resistance in non-diabetic patients with chronic moderate to severe plaque type psoriasis.

Materials and methods: Between 2009 and 2012, 65 patients were randomized to receive either ADA or FAE as active control at a tertiary university hospital. Five patients were excluded because of pre-existing treated diabetes resulting in 32 receiving FAE and 28 receiving ADA in our final analysis. The duration of treatment was 24 weeks with visits at baseline, 12 weeks and 24 weeks. At each visit disease severity was assessed, blood was drawn and a standard 2h OGTT (75g of glucose) was performed with measurements at 0 and 120 min. The main outcome parameters were the HOMA-IR index and the composite insulin sensitivity index (ISI) by Matsuda which were log-transformed for further analysis and reported by their geometric means. We used Student's t-test for the comparison of baseline values and linear mixed models to estimate treatment differences at follow-up adjusting for baseline values.

Results: The study population consisted of 80% men and were 44±11 years of age. The patients displayed a median baseline disease severity score (PASI) of 14(IQR: 12 -20) and a median affected body surface area of 15(12 - 28)%. Before treatment, HOMA-IR was 1.54±2.57 in FAE-treated and 1.19±2.21 in ADA-treated patients (p=0.302). ISI values were 6.37±2.78 in FAE patients compared to 7.80±2.07 in ADA patients(p=0.424). After the initiation of treatment, there was a significantly higher HOMA-IR of 2.17 (95%CI: 1.67 - 2.67) in the FAE group compared to 1.51 (1.22 - 1.88) in the ADA group (p=0.021) with a trend towards an increase by 18(-2 - 43) % between the two follow-up visits(p=0.081). At follow-up, ISI was significantly lower in FAE-treated (4.65 (3.76 - 5.74)) compared to ADA-treated patients (7.33 (5.92 - 9.08), p=0.004) without a significant temporal effect. Disease severity scores and CRP decreased comparably in both groups (p<0.05).

Conclusion: In our population of non-diabetic psoriasis patients, ADA might be superior to FAE in maintaining insulin sensitivity. Contrary to previous reports, ADA did not improve insulin sensitivity, which could be due to the low baseline degree of insulin resistance in our sample. Since ADA was able to slow the progression of insulin resistance, while FAE was not, ADA might be a better choice for psoriasis patients at a high risk for developing type 2 diabetes.

Diabetes and impaired glucose metabolism is associated with more cold-related cardiorespiratory symptoms

T.M. Ikäheimo[1], J. Jokelainen[2,3], J. Hassi[1], L. Hiltunen[4], S. Keinänen-Kiukaanniemi[5,3], T. Laatikainen[6,7], P. Jousilahti[6], M. Peltonen[6], L. Moilanen[8], J. Saltevo[9], S. Näyhä[1];

[1]Center for Environmental and Respiratory Health Research, University of Oulu, [2]Faculty of Medicine, University of Oulu, [3]MRC and Unit of Primary Care, Oulu University Hospital, [4]City of Oulu, [5]Center for Life Course Health Research, University of Oulu, Oulu, [6]National Institute for Health and Welfare, Helsinki, [7]University of Eastern Finland, Kuopio, [8]Department of Medicine, Kuopio University Hospital, Kuopio, [9]Central Finland Central Hospital, Jyväskylä, Finland.

Background and aims: Diabetes and impaired glucose metabolism cause metabolic, neural and circulatory disturbances that may predispose to adverse cooling, elicit symptoms and increase health risks during the cold season. This cross-sectional study assessed the prevalence of cold-related cardiorespiratory symptoms in the general population according to glycaemic status.

Materials and methods: The study population consisted of 2436 men and 2708 women aged 45-74 years from the National FINRISK cold sub-studies in 2002 and 2007. A questionnaire assessed cold-related symptoms (respiratory, cardiac, peripheral circulation). Glycaemic status was determined based on fasting blood glucose, oral glucose tolerance tests or reported diagnosis of diabetes and categorized into normal glucose metabolism, impaired fasting blood glucose, impaired glucose tolerance, screen-detected type 2 diabetes and type 2 diabetes.

Results: Type 2 diabetes was associated with increased odds for cold-related dyspnoea [Adjusted OR 1.72 (95% CI, 1.28-2.30)], chest pain [2.10 (1.32-3.34)] and respiratory symptoms [1.85 (1.44-2.38)] compared with normal glucose metabolism. Screened type 2 diabetes showed increased OR for cold-related dyspnoea [1.36 (1.04-1.77)], cough [1.41 (1.06-1.87)] and cardiac symptoms [1.51 (1.04-2.20)]. Worsening of glycaemic status was associated with increased odds for both cardiac (from 1.11 in impaired fasting glucose to 1.99 in type 2 diabetes, p=0.000, Fig. 1 a) and respiratory (1.14 to 1.84, p=0.000, Fig. 1 b) symptoms. Also, individual cardiorespiratory symptoms were reported more often with worsening glycaemic status. These were dyspnoea (from 1.16 in impaired fasting glucose to 1.72 in type 2 diabetes, p=0.000), cough (1.02 to1.27, p=0.032), chest pain (1.28 to 2.10, p=0.006) and arrhythmias (0.87 to 1.74, p=0.020).

Conclusion: Diabetes is related to higher occurrence of cardiorespiratory symptoms in the cold. These are reported increasingly with worsening glycaemic status and may predict either an aggravated diabetic condition in cold, or reveal individuals with impaired glucose metabolism or diabetes. Increasing awareness assist individuals with impaired glucose metabolism to protect themselves from cold weather. Health care personnel may utilize this information for providing appropriate advice for health risk management in cold conditions.

Enteroviruses in the pancreas of live adult patients with newly diagnosed type 1 diabetes. Results from the DiViD study

L. Krogvold[1], A. Genoni[2], A. Puggioni[2], D. Campani[3], S. Richardson[4], B. Edwin[5], T. Buanes[5], K. Dahl-Jørgensen[1], A. Toniolo[2];

[1]Division of Paediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway, [2]Department of Biotechnology and Life Sciences, University of Insubria, Varese, Italy, [3]Department of Oncology, University of Pisa, Pisa, Italy, [4]University of Exeter Medical School, Exeter, UK, [5]Department for HPB Surgery, Oslo University Hospital, Oslo, Norway.

Background and aims: One possible environmental factor contributing to the development of type 1 diabetes (T1D) is enterovirus (EV) infection of pancreatic endocrine cells. The lack of well-preserved pancreatic tissue taken at the time of the clinical onset is a restriction for virus investigations. One of the aims of the Diabetes Virus Detection study (DiViD) is to search for virus in pancreatic tissue of optimal quality collected from live adult patients newly-diagnosed with T1D. We have reported the presence of EV genome by PCR and of EV proteins by IHC. Here we further analyze the presence of viruses in the DiViD cases using new methods.

Materials and methods: Six recent onset T1D patients (age 24-35) were included in the DiViD study. Minimal pancreatic tail resection was processed under sterile conditions. 11 live cases of pancreatic carcinoma without diabetes served as controls. In the present study, we used EV detection methods that combine virus growth in cell culture, gene amplification, and immunofluorescence (IF) for viral proteins. Pancreas homogenates were produced in cell culture medium. Cell lines (AV3, RD, HEp-2, and LLC-MK2) were incubated with homogenates and serially passaged 3-6 times. DNA and RNA were extracted from both pancreas and cell cultures. Real time PCR was used for detecting >20 viruses other than EVs (6 herpesviruses, parvovirus B19, HBV, JCV, BKV, HCV, GBV-C, rubella, influenza A/B, parainfluenza 1-4, RSV, astrovirus, norovirus, rotavirus, HAV). EVs and polioviruses were searched for using end-point PCR with primer pairs targeting the 5'UTR region of the A, B, C, D species. Amplicons were directly sequenced. In cultured cells exposed to pancreas homogenates, the expression of EV capsid proteins was evaluated by IF with a panel of EV antibodies.

Results: 6/6 T1D cases and 2/11 non-diabetic control cases contained EV genomes ($p<0.05$). In contrast, genomes of over 20 human viruses other than EVs could be detected in only 2/17 cases (one EBV, one Parvovirus B19). EV detection was confirmed by IF of cell lines incubated with pancreatic extracts. EV proteins were expressed in the cytoplasm of approx. 1% of cells. Infection could be transmitted from EV-positive cell cultures to uninfected cell lines using cell culture supernatant that had been filtered through 100 nm membranes. This shows that an infectious agent of less than 100 nm in diameter is present in pancreata of diabetic subjects. Due to slow progression of infection in EV-carrying cell cultures, cytopathic effects could only be perceived using time-lapse microscopy. Sequences of 5'UTR amplicons were compatible with EVs of the A and B species. Compared to control cell cultures exposed to EV-negative pancreatic extracts, EV-carrying cell cultures produced high levels of IL6, IL8 and MCP1.

Conclusion: The results confirm with new, more sensitive assays that EVs in pancreas are consistently present in subjects newly diagnosed with T1D and rarely present in non-diabetic control patients. The data are consistent with an ongoing low grade enteroviral infection in the pancreas of newly-diagnosed diabetics.

Pandemic influenza diagnosis and subsequent risk of type 1 diabetes

P.L.D. Ruiz[1,2], G. Tapia[1], I.J. Bakken[1], S.E. Håberg[1], H.L. Gulseth[1,2], L.C. Stene[1];

[1]Norwegian Institute of Public Health, [2]Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway.

Background and aims: The 2009 pandemic influenza A H1N1 (swine flu) has been associated with development of several autoimmune diseases. In this register-based study, we aimed to test whether pandemic influenza diagnosis was associated with increased risk for type 1 diabetes (T1D).

Materials and methods: In this nationwide study, the Norwegian population under age 30 years was followed from October 2009 through June 2014 by linking prospectively collected data from national health registries with patient level information. We analysed data from the Norwegian Patient Register (inpatient and outpatient clinic data), the Primary Care Database, diabetes medication from the Norwegian

Prescription Database and laboratory confirmed influenza A (H1N1) infection (reverse-transcriptase polymerase chain reaction result) with influenza A (H1N1) from the Surveillance System for Communicable Diseases. We defined pandemic influenza as a clinical influenza or influenza like illness (ILI) diagnosis during the pandemic outbreak in Norway, or a laboratory-confirmed influenza A (H1N1). Incident cases of type 1 diabetes were defined as the first registration of at least one T1D diagnosis in primary or specialist health care and initial insulin treatment continued for at least 6 months. We used Cox regression to estimate hazard ratio (aHR) for associations between influenza and subsequent risk of T1D, adjusted for year of birth, sex, place of birth, education, and pandemic influenza vaccination.

Results: We identified 2297 individuals diagnosed with T1D after the pandemic, incidence rate: 26 per 100,000 person-years. Individuals registered with ILI during the 2009-2010 pandemic had an aHR for type 1 diabetes of 1.18 (95% CI: 0.96 - 1.45). When restricted to the age-group under 15 years, ILI was associated with a significantly higher risk of T1D (aHR=1.34, 95% CI: 1.06-1.68). A laboratory confirmed infection with influenza A (H1N1)pdm9, or hospitalization with an influenza diagnosis were both associated with a significant two- fold higher risk of T1D, while those diagnosed with ILI in the Primary Care Database during the pandemic season did not have a significantly increased risk of T1D (Figure 1).

Conclusion: ILI diagnosis was associated with increased incidence of new-onset T1D in children under 15 years. Patients with a lab-confirmed influenza A (H1N1) or who were hospitalized with influenza during the 2009-2010 pandemic had two-fold higher risk of developing T1D.

Figure 1. Association between pandemic influenza diagnosis in primary or specialist care, and risk of type 1 diabetes in up to 2.26 million Norwegians. Hazard ratios were adjusted for year of birth, sex, place of birth, education and pandemic influenza vaccination. ILI, Influenza Like Illness. Pandemic influenza outbreak from 1st October 2009 to 31st December 2009

TNFSF14: a potential contributor to hyperinsulinaemia in childhood obesity

H. Manell[1,2], Q. Shen[3], M. Kamali-Moghaddam[3], A. Forslund[2,1], P. Bergsten[1,2];
[1]Medical Cell Biology, Uppsala University, [2]Women's and Children's Health, Uppsala University, [3]Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden.

Background and aims: Chronic low-grade inflammation is a characteristic of obesity. Obesity is also associated with hyperinsulinemia and the risk for developing type 2 diabetes. Yet the role of inflammation in the early pathogenesis of hyperinsulinemia, impaired glucose tolerance and T2D has not been defined. We aimed to identify novel markers of inflammation associated with early onset obesity and to study their association with impaired glucose tolerance and hyperinsulinemia in obese children and adolescents.

Materials and methods: Children and adolescents with obesity (n=137) and lean controls (n=34) were recruited. Of the children and adolescents with obesity 64 had normal glucose tolerance (NGT), 65 had impaired glucose tolerance (IGT) and 8 had type 2 diabetes (T2D). Relative plasma levels of 92 proteins related to inflammation were measured by proximity extension assay (Olink Proteomics, Uppsala, Sweden). The method uses two antibodies for each protein. The two antibodies carry complementary single DNA-strands which, when bound in proximity on the target protein, hybridize and can be extended and amplified by qPCR to obtain relative protein levels. In this way 92 proteins are simultaneously quantified in 1 ul plasma. Plasma levels of the proteins were compared between the obesity and lean group and also between normal and impaired glucose tolerance groups within the obesity group. Human islets and human beta-cell line EndoC-betaH1 were cultured in the presence of 0, 10, 100 or 1000 ng/ml TNFSF14 and accumulated insulin secretion to the culture medium over 24 and 48 h was measured by ELISA.

Results: Plasma levels of 21 of the 92 proteins differed between children with obesity and lean controls, among these were 8 pro-inflammatory cytokines. None of the proteins differed between obese subjects with NGT and those with IGT or T2D. Eleven proteins correlated with fasting insulin concentrations, among these was TNFSF14. The addition of recombinant TNFSF14 to the culture medium increased insulin secretion from human islets by 31% during 48 hours culture with 100 ng/ml ($p<0.01$ vs control) and from human EndoC-betaH1 cells by 33% during 24 hour culture with 10 ng/ml ($p<0.05$ vs control).

Conclusion: Several pro-inflammatory cytokines are elevated in childhood obesity and also related to fasting plasma insulin concentrations but not to IGT. TNFSF14 is a potential contributor to fasting hyperinsulinemia through its direct effect on insulin secretion from human beta-cells.

PS 013 Trends in diabetes and obesity

365

Time-trends in incidence and prevalence of type 2 diabetes patients requiring glucose-lowering treatment from 2007-2015: nationwide data from Norway and Sweden

D. Nathanson[1], J. Bodegard[2], A. Norhammar[3], K.I. Birkeland[4,5], T. Nyström[1], M. Thuresson[6], J.W. Eriksson[7], H.L. Gulseth[5];
[1]Department of Clinical Science and Education Södersjukhuset (KI SöS), Karolinska Institutet, Stockholm, [2]AstraZeneca Nordic-Baltic, Södertälje, [3]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]University of Oslo, [5]Oslo University Hospital, Oslo, Norway, [6]Statisticon AB, [7]Uppsala Akademiska Sjukhus, Uppsala, Sweden.

Background and aims: Type 2 diabetes (T2D) is recognized as a growing concern, reaching epidemic proportions worldwide. Information on incidence and prevalence are important to monitor for health care providers to assess treatment strategies and plan for future health care resourcing. The aim was to examine time-trends in T2D incidence and prevalence, and to compare the development between two neighbouring countries with similar health care structure.

Materials and methods: All patients dispensed with glucose lowering drugs (GLDs) during 2007—2015 were identified in nationwide registries in Norway and Sweden. Patients aged <18 years, with polycystic ovarian syndrome, type 1- or gestational diabetes were excluded. Dispensed drugs were calculated annually. Annual incidence was calculated by comparing incident cases with the general T2D free population. Prevalence was assessed annually by dividing the total number of T2D patients by the total general population.

Results: In 2015, T2D patients in Norway were younger, 64.5 vs 68.4 years, and less often women, 46.5% vs 43.3%, compared to Sweden. Patients in Sweden were to higher extent treated with CV drugs (antihypertensives [ACEi and ARBs] and statins) vs Norway; 84.5% vs 73.9%. These proportions have remained relatively stable in both countries during the observation time. Metformin, sulphonylurea, insulin, DPP-4i and SGLT-2i proportions were in Norway vs Sweden, respectively, 59.9% vs 67.3%; 18.6% vs 14.0%; 18.7% vs 32.8%; 10.4% vs 9.2% and 5.1% vs 1.9%. The most prominent changes between 2010-2015 were decrease in sulphonylurea (>35%) and increase in DPP-4i (>130%) in both countries. T2D incidence decreased in Norway (-28%) but remained higher and stable in Sweden. In 2015 the incidence was 363 and 494 cases per 100,000 inhabitants respectively (figure, left panel). During the observation period the prevalence increased 58.3% in total in Norway and Sweden and was in 2015 182,923 (4.5%) and 422,013 (5.4%) patients, respectively (figure, right panel).

Conclusion: In a modern time-era, a marked GLD treated T2D prevalence increase of approximately 60% was observed in total in Norway and Sweden over the last decade. While incidence is declining in Norway it seems to persist at a high level in Sweden. These recent data confirm that occurrence of T2D is a growing problem, despite declining or stabilized incidence, and that the disease will continue to pose a challenge to the health care system.

366

Predicting total burden of diabetes in Denmark till 2030

B. Carstensen, M.E. Jørgensen;
Clinical Epidemiology, Steno Diabetes Center Copenhagen, Gentofte, Denmark.

Background and aims: In some countries (Scandinavia, Scotland) the total number of diabetes patients is largely known from health care registers. Predictions of the number of diabetes patients in the future has not been made based on a firm modeling basis however. In Denmark the regular update of the National Diabetes Register has been discontinued since 2012, and reliable figures are therefore not available.

Materials and methods: We used the National Patient Register, the Medicines Products Statistics Register ("Prescription register"), the Danish Adult Diabetes Register, the Health Services register and the Eye Screening Database to reconstruct the Danish National Diabetes Register. We used the person register of the entire Danish population to obtain information on deaths, immigration and emigration. Based on this we could estimate 1) incidence rates of diabetes and mortality rates of persons 2) with and 3) without diabetes for the period 1996–2015 in ages 0-99 years. These rates were modeled separately for men and women by age-period-cohort models with smoothing spline effects. The rates were predicted for the period 2016-2030 using the fitted models, and also under a scenario assuming a 2.5 % annual increase in diabetes incidence rates over the period. We used the rates and population predictions from Statistics Denmark to predict the number of prevalent diabetes patients in the population in the period 2016-2030 in all ages.

Results: Incidence rates of diabetes were declining about 3% per year since 2011; a tendency we found unlikely to persist, so apart from the model extrapolating this decline we also used a model where we assumed the diabetes incidence rate to increase 2.5% per year. In all models we assumed mortality to decrease at as slightly attenuated rates compared to the period 1996-2016. The simple prediction assuming a decline would predict a fall in the prevalent number of diabetes patients from 280,000 (2016) to 230,000 in 2030; whereas the scenario with increasing diabetes incidence rates resulted in a total number of diabetes patients in 2030 of 382,000.

Conclusion: The diabetes incidence rates showed a decline after 2011, a decline we were reluctant to extrapolate, as this may be a consequence of changing diagnostic criteria, so an alternative model to the simple extrapolation was chosen. The most realistic number of diabetes patients in Denmark in 2030 is 380,000, a 65% increase since 2016. This is somewhat less than previous extrapolations have predicted, but our prediction is based on a carefully developed statistical model and a critical appraisal of possible future scenarios of incidence rate development. It should also be borne in mind that the large birth post-war cohorts from the 1940s will begin do die out in the late 2020s, and this has an influence on the number of cases.

367

Trends of obesity prevalence among Spanish adults with diabetes, 1987-2012

F. Basterra-Gortari[1,2], M. Bes-Rastrollo[2,3], M. Ruiz-Canela[2,3], A. Gea[2,3], C. Sayon-Orea[2,4], M.-A. Martínez-González[2,3];
[1]Internal Medicine (Endocrinology), Hospital Reina Sofia, Tudela, [2]Preventive Medicine and Public Health, University of Navarra, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, [3]Centro de Investigación Biomedica en Red de Fisiopatología de la Obesidad y Nutricion (CIBERobn), Instituto de Salud Carlos III, Madrid, [4]Department of Preventive Medicine and Public Health, Complejo Hospitalario de Navarra, Pamplona, Spain.

Background and aims: Obesity is directly associated with mortality in patients with diabetes. Our objective was to examine the trend of obesity in Spanish adults with diabetes from 1987 to 2012.

Materials and methods: Data were collected from 8 waves of the national health surveys (from 1987 to 2012) that are cross-sectional studies conducted

in representative samples of the Spanish adult population. Data of 7378 adults (>= 16 years) who reported having been diagnosed of diabetes were analyzed. Previously validated self-reported weight and height were used to estimate body mass index (BMI). Following recommendations, overweight was defined as a BMI of 25.0 to 29.9 kg/m2 and obesity as a BMI of 30.0 kg/m2 or higher. Age-adjusted prevalences were calculated by the direct standardization method. The 2003 survey population with diabetes was chosen as standard population.

Results: From 1987 to 2012 age-adjusted prevalence of obesity in participants with diabetes increased from 18.2% (95% Confidence interval [CI]: 14.2%-22.2%) to 39.8% (95% CI: 36.8%-42.8%). Age-adjusted prevalence of obesity in males with diabetes increased from 13.2% (95% CI: 7.3%-19.1%) to 38.0% (95% CI: 33.8%-42.1%) and in females with diabetes increased from 23.0% (95% CI: 17.6%-28.4%) to 42.3% (95% CI: 38.0%-46.6%). Obesity prevalence increased in participants with diabetes of both sexes across all age groups (16-39, 40-59 and >=60 years). Between 1987 and 2012 the proportion of participants with a high BMI increased (figure).

Conclusion: Between 1987 and 2012 the prevalence of obesity markedly increased in Spain among adults with diabetes.

368

Estimates of pre-diabetes and undiagnosed diabetes in Denmark

M.E. Jørgensen, B. Carstensen;
Clinical Epidemiology, Steno Diabetes Center Copenhagen, Gentofte, Denmark.

Background and aims: Up-to-date information on unknown diabetes (DM) and pre-diabetes based on current diagnostic criteria as well as estimates for the entire adult age span are lacking. The aim of the study was to model the number of individuals with unknown diabetes and pre-diabetes in Denmark based on existing population based cohorts, correcting for differential response rates between person with and without disease.

Materials and methods: Four population-based Danish studies after 2000 were identified where information on HbA1c, date of examination, gender, age (date of birth), and known diabetes was available. It is known that response rates in surveys are smaller from person with disease than for persons without, so prevalences from the surveys will underestimate the prevalence of DM and possibly also unkown DM and pre-diabetes. Within each study we estimated the age-specific prevalences of DM, unknown DM and pre-diabetes (survey prevalences), and from a National Diabetes Register we estimated the population level age-specific prevalences of known DM. We could then estimate the survey participation rate among DM patients, and when combining this with the known overall response rates from the studies we could correct the survey prevalences to credible population level figures.

Results: The prevalence of known-, previously unknown- and pre-diabetes was highest among men and increased with age with a peak at age 70 (see figure). The prevalence of undiagnosed diabetes is about half of that of diagnosed diabetes, and the prevalence of pre-diabetes is close to the prevalence of diabetes among men, but substantially higher among women.

Conclusion: The estimated numbers with undiagnosed diabetes and prediabetes are markedly lower than suggested by previous studies, but it is not clear whether this reflects a true fall in incidence or the change to HbA1c-based diagnostic criteria in 2011. Correction for non-differential survey participation is essential in studies of diabetes and precursors.

The dramatically high prevalence of diabetes and pre-diabetes in the adult Kuwaiti population

A. Alkandari[1], R. Al-Wotayan[2], N.C. Barengo[3], J. Longenecker[4], Q. Al Duwairi[1], J. Tuomilehto[1];
[1]Dasman Diabetes Institute, [2]Ministry of Health, Kuwait City, Kuwait, [3]Florida International University, Miami, USA, [4]Kuwait University, Kuwait City, Kuwait.

Background and aims: Diabetes mellitus is one of the most important health burdens for the primary-health care system in Kuwait. The objective of this study was to determine the prevalence of diabetes and pre-diabetes in Kuwaiti adults in 2014.

Materials and methods: A total of 3918 randomly selected Kuwaiti men and women aged 18-69 years were surveyed in 2014 using the WHO Instrument for Chronic Disease Risk Factor Surveillance comprising demographics, medical and family history, physical measurements and blood biochemistry. Diabetes was defined as fasting plasma glucose ≥7 mmol/L, HbA1c ≥6.5% or being treated with glucose-lowering drugs. People with fasting plasma glucose between 6.1 and 6.9 mmol/L or HbA1c between 5.7-6.4% were considered as having pre-diabetes.

Results: In men, the prevalence of screen-detected diabetes was 9.4% and known diabetes 16.5%, giving a total diabetes prevalence of 26.0%. In women, the corresponding prevalence were 6.4%, 14.5% and 20.9%, respectively. The prevalence of pre-diabetes was 18.9% in men and 19.4% in women. The prevalence of diabetes increased with increasing age, BMI and waist circumference. Half of the adults in their fifties and almost 70% of adults in their sixties had diabetes. Almost 20% of overweight Kuwaiti men had diabetes and 23% had pre-diabetes. Over 51% of morbidly obese Kuwait men had diabetes. In overweight Kuwaiti women the prevalence of diabetes was 14.2% and pre-diabetes 17.6%, and almost half of morbidly obese Kuwaiti women had diabetes.

Conclusion: Our findings revealed that the prevalence of diabetes in Kuwait is higher than previously estimated. Since an oral glucose tolerance test was not

included in the survey, these percentages are likely underestimates. These figures illustrate the stark challenge facing Kuwait and other countries in the region and call for urgent action for detection and primary prevention.

Impact of weight changes on the incidence of diabetes: a Korean nationwide cohort study

S. Moon, E. Kim, S.-H. Ko, S.-H. Ko, Y.-B. Ahn, H.-S. Kwon;
College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Background and aims: Obesity is a well-known risk factor for type 2 diabetes (T2DM), but few data exist on the association between weight changes and future diabetes risk in nonobese subjects. This study was aimed to investigate the effect of weight changes on the incidence of T2DM using a Korean prospective nationwide data.

Materials and methods: A total of 51405 nondiabetic subjects who had received health examinations in 2002 and completed follow-up in 2006 were included.

Results: Individuals who developed incident T2DM were more likely to be older and men; have higher values of body mass index (BMI), blood pressure, fasting plasma glucose, and total cholesterol; have a greater prevalence of current smokers, higher alcohol consumption, HTN, and hyperlipidemia; and have more often family history of DM, as compared to those without T2DM. Compared with the continuously nonobese group, there were a higher hazard ratio for incident DM (95% confidence interval) in "becoming obese" [1.50 (1.27-1.78)], "slimming down" [1.89 (1.61-2.22)], and "still obese" subjects [2.60 (2.56-3.05)] during 4 -years after adjustment for confounding factors. In the analysis stratified by BMI categories, risks for incident DM were significantly decreased according to the reduced BMI amounts and the trends were more evident in nonobese group than obese group. Regarding increased BMI, however, there was no significant association with incident DM.

Conclusion: Weight loss was significantly associated with decreased DM risk both in nonobese and obese Korean population. Further long-term studies are needed to establish weight reduction as preventive strategy for T2DM.

Mortality and incidence of diabetes: retrospective cohort of hospitalised patients with stress hyperglycaemia

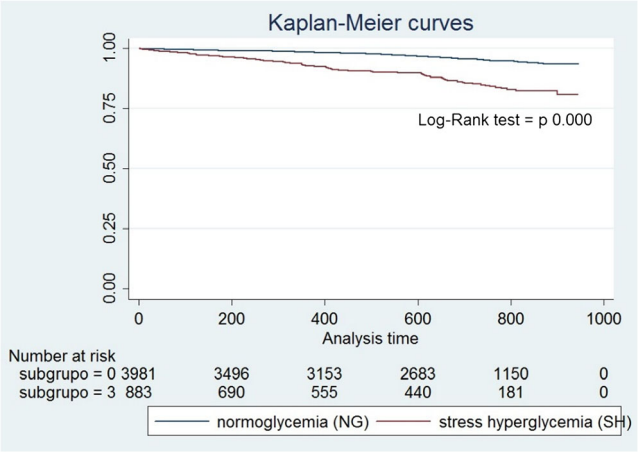
M.P. Russo, C.M. Elizondo, D.H. Giunta, M.F. Grande Ratti;
Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background and aims: The aim of this study was to estimate mortality and calculate the incidence of diabetes in hospitalized patients with stress hyperglycemia (SH) versus normoglycemia (NG), during the follow up after discharge.

Materials and methods: A retrospective cohort was conducted with adult non-diabetic inpatients admitted from 2014 to 2015 in an argentine university hospital. We included patients with SH (>=140 mg/dl and HbA1c<6.5) or NG (all glycemia values <140 mg/dl) during hospitalization. Patients were followed up from discharge to the occurrence of diabetes, death, lost (disaffiliation) or administrative censored data. Diabetes was defined with at least one of the following criteria (the first date): new problem in ambulatory medical history, or new insulin/hypoglycaemic consumption from pharmacy registry, or HbA1c>=6.5%.We calculated the frequency, proportion, and incidence rates of new diagnosis of diabetes and mortality. Incidence rates are reported as crude cumulative incidence at one year with their respective 95% confidence intervals (CI). Kaplan Meier curves for both groups were performed and compared with log rank test. We used a Cox proportional hazard model to calculate hazard ratios (HR) and 95%CI.

Results: We identified 3981 patients with NG and 884 with SH. During the observation period, there were 84 cases of diabetes and 831 deaths. The median observation period was 669 days.Diabetes incidence was 10.97% (95%CI 8.98-13.22) in SH and 3.97% (95%CI 3.38-4.62) in NG, with p<0.001. The one year diabetes incidence was 7.39% (CI95% 5.7-9.56) in SH and 1.59% (95%CI 1.23-2.06) in NG. SH was significantly associated with diabetes incidence (crude HR 1.33, 95%CI1.03-1.73, p 0.025), even after adjustment for age and gender (adjusted HR 1.38; 95%CI 1.06-1.78; p 0.014).Mortality rate occurred 20.36% (95%CI 17.75-23.16) in SH and 16.35% (95%CI 15.21-17.53) in NG, with p 0.004.

Conclusion: Cumulative incidence of diabetes and mortality were higher in SH group. This information may help to patient-physician decision-making, and could be used to determine prospective strategies of follow up after discharge. Mortality could be a competitive event for presenting new diabetes. Is still pending treating death as a competing risk analysis.



Disclosure: **M.P. Russo:** None.

New onset diabetes after kidney transplantation: incidence and associated factors

V. Gomes[1], F. Ferreira[1], J. Guerra[2], M.J. Bugalho[1];
[1]Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, [2]Nephrology and Kidney Transplantation Department, Santa Maria Hospital, Lisbon, Portugal.

Background and aims: New onset diabetes after transplantation (NODAT) is a frequent metabolic complication of kidney transplantation, associated with increased morbidity and mortality. Prior studies reported that approximately 15-30% of non-diabetic kidney transplant recipients develop NODAT in the first year after transplant. Multiple risk factors have been identified. These include older age, race, family history of diabetes, pre-transplant impaired fasting glucose (IFG) and impaired glucose tolerance, obesity, hepatitis C and cytomegalovirus infection, genetic factors, deceased donor, autosomal dominant polycystic kidney disease, acute rejection, as well as the type of immunosuppressive agents used to prevent or treat rejection. The aim of this study was to evaluate the incidence of NODAT and associated factors among kidney transplant recipients, in a central hospital and transplant center.

Materials and methods: Retrospective study of non-diabetic transplant recipients, who underwent kidney transplant between January of 2012 and March of 2016, with a minimum follow-up of 12 months. Patients were divided into two groups: with and without NODAT, for comparison.

Results: In total, 125 patients were eligible for the analysis. NODAT was identified in 27.2% of the patients (n=34; 53% female; mean age 49.6 ± 10.8 years). In the group that did not develop NODAT (n=91), 47% were female and the mean age was 46.0 ± 13.6 years**.** The mean time to diagnosis was 3.68 ± 5.7 months after transplantation and 76.5% of the patients developed NODAT in the first 3 months. All patients received immunosuppression

with corticosteroids, tacrolimus and mycophenolate mofetil. As inducing treatment, 6 patients received antithymocyte globuline (ATG) and 28 received basiliximab in the NODAT group, whereas 24 patients received ATG and 67 received basiliximab in the group without NODAT. In the NODAT group, the pre-transplant fasting plasma glucose levels were significantly higher ($p<0.05$) and the pre-transplant IFG was significantly more frequent (51.5% *versus* 27.7%, $p<0.05$). No differences were found between the two groups for other potential associated factors: age, race, body mass index, hepatitis C or cytomegalovirus infection, acute rejection and type of transplant (live or deceased donor).

Conclusion: The high incidence of NODAT observed was similar to that reported by others. NODAT was particularly frequent in the first 3 months after transplant. Pre-transplant IFG was significantly associated with NODAT, raising awareness to the need of periodical blood glucose screening. Identification of patients with IFG will allow early implementation of lifestyle modifications including weight control, diet and exercise in order to minimize future development of NODAT.

Disclosure: **V. Gomes:** None.

PS 014 Genetics of type 2 diabetes

373

Parent-of-origin effects on gene expression in trios with type 2 diabetic offspring

R.B. Prasad[1], G. Kovacs[2], A. Lindqvist[1], A. Lessmark[1], P. Almgren[1], M. Vitai[2], N. Oskolkov[1], T. Singh[1], P. Vikman[1], M. Åkerlund[1], N. Wierup[1], I. Artner[1], L. Koranyi[2], L. Groop[1,3];

[1]Department of Clinical Sciences, Diabetes and Endocrinology, Lund University Diabetes Centre, Malmö, Sweden, [2]Heart Center Foundation, Balatonfured, Hungary, [3]Finnish Institute of Molecular Medicine, Helsinki, Finland.

Background and aims: Type 2 diabetes (T2D) is seen more often in offspring of T2D mothers rather than of T2D fathers. Further, parental sex - specific effects on insulin concentrations have been reported, with lowest values seen in sons of diabetic mothers. Parent-of-origin effects (POE), wherein the phenotypic effect of an allele depends on whether it is inherited from the mother or the father, could explain these observations.

Materials and methods: We performed RNA sequencing of 80 independent trios enriched for type 2 diabetic offspring (77 offspring with T2D) and assessed for differences in correlation of expression between each parent-offspring pair on a background of parental expression correlations. Expression patterns of genes showing parent-of-origin effects in trios were studied in adult and fetal pancreas. Knockdown studies are ongoing to assess their influence on beta cell mass (proliferation) and function (insulin secretion).

Results: 4662 autosomal genes expressed in blood were assessed for parental biases in gene expression. 24 protein-coding genes showed parental biases in gene expression of which 6 genes showed the lowest paternal-maternal correlations including *BMP8A*, *CAMK2G*, *CLCF1*, *PA2G4*, *PSD4*, and *RPS23*. The Bone Morphogenic Protein 8A coding *BMP8A* showed significantly higher gene expression correlation between father-offspring (ρ_{BMP8A}=0.62, P_{BMP8A}=1.81x10^{-09}) than that of mother-offspring (ρ_{BMP8A}=0.11, P_{BMP8A} =3.42x10^{-01}, $Pdiff_{BMP8A}$=1.97x10^{-05}). These data were consistent even when assessed separately for sons and daughters. Differential expression analysis between genders was not significant either in blood or in pancreas ($p > 0.05$), showing clearly that these differences in correlations were not driven by gender. *BMP8A* showed significantly higher expression in the fetal pancreas whereas almost no expression was observed in adult pancreatic islets. The Beta-Actin encoding *ACTB* showed significantly higher father-offspring (ρ_{ACTB}=0.86, P_{ACTB}=3.42x10^{-23}) compared to mother-offspring (ρ_{ACTB}=0.60, P_{ACTB}=6.88x10^{-09}, $Pdiff_{ACTB}$=7.66x10^{-07}) . The only gene showing higher mother-offspring correlations was the cardiotrophin-like cytokine factor 1 coding *CLCF1* (ρ_{CLCF1}=0.23, P_{CLCF1}=4.24x10^{-02}, $Pdiff_{CLCF1}$ = 2.06x10^{-04}).

Conclusion: This study demonstrates that parental biases in gene expression exist beyond imprinted genes and can have strong spatial and temporal effects independent of gender. Some of these genes could have significant roles in fetal development.

Evaluation of the association of single nucleotide polymorphisms in the sodium glucose co-transporter 2 gene with glucose homeostasis and type 2 diabetes

A. Muendlein[1], J. Ebner[1], A. Leiherer[1], C.H. Saely[2], K. Geiger[1], E.-M. Brandtner[1], D. Zanolin[1], A. Vonbank[2], A. Mader[3], P. Schwerzler[3], P. Fraunberger[4], H. Drexel[5];

[1]Vorarlberg Institute for Vascular Investigation and Treatment (VIVIT), [2]Academic Teaching Hospital Feldkirch, Feldkirch, Austria, [3]Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, [4]Medical Central Laboratory, Feldkirch, Austria, [5]Drexel University College of Medicine, Philadelphia, USA.

Background and aims: Sodium glucose co-transporter 2 (SGLT2) is the major transporter involved in glucose reabsorption in the kidney and mutations in the SGLT2 encoding gene SLC5A2 cause renal glucosuria. However, the

association between genetic variation in SLC5A2 and T2DM is still unclear and is addressed in the present study.

Materials and methods: We genotyped the SLC5A2 tagging SNPs rs9934336, rs3813008, and rs3116150 (completely capturing all common genetic variations in the gene locus of SLC5A2 according to HapMap SNP database, release 27) in 1684 coronary patients, including 400 patients with T2DM.

Results: The rare allele of rs9934336 was significantly associated with decreased fasting glucose and 2-hour glucose in oral glucose tolerance tests (p=0.041 and 0.035, respectively) as well as decreased HbA1c and estimated average fasting glucose (p=0.033 and 0.026, respectively). Further, variant rs9934336 was significantly associated with the presence of T2DM, in univariate (OR=0.82 [0.68-0.99]; p=0.037) as well in multivariate regression analysis adjusting for age, sex, body mass index, metabolic syndrome, hypertension, and estimated glomerular filtration rate (OR=0.79 [0.64-0.95]; p=0.019). However, rs9934336 was not associated with serum insulin, or with the homeostatic model assessment indices of insulin resistance and beta cell function, respectively. Polymorphisms rs3813008 and rs3116150 were neither associated with fasting or postchallenge glucose nor with T2DM.

Conclusion: We conclude that genetic variation within the SLC5A2 gene locus contributes to fasting as well as postchallenge plasma glucose and to the manifestation of T2DM.

PPARG Pro12Ala variant in relation to adipose tissue metabolism and differentiation: a small genotype-based recall study

P.G. Kamble[1], M.J. Pereira[1], S. Gustafsson[2], P. Lundkvist[1], C. Castillejo-López[2], T. Fall[2], E. Ingelsson[2,3], J.W. Eriksson[1];

[1]Department of Medical Sciences, Clinical Diabetes and Metabolism, Uppsala University, [2]Department of Medical Sciences, Molecular Epidemiology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [3]Department of Medicine, Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, USA.

Background and aims: The minor (Ala) allele of the common Pro12Ala polymorphism in the peroxisome proliferator-activated receptor (PPARG) gene affects transcriptional activity of isoform 2 of the protein and has been associated with reduced risk of type 2 diabetes. Protective effects of this polymorphism have been considered to be mediated by effects on adipose tissue development and metabolism. We aimed to study the effect of the Pro12Ala variant on adipogenesis and metabolic activities and expression of PPARG target genes in adipose tissue.

Materials and methods: Using the genotype-based recall approach we recruited Pro12Pro (4M/8F, mean age 64 ±SD 9y), Pro12Ala (6M/9F, 63±9y) and Ala12Ala (4M/9F, 64±8y) carriers without diabetes to participate in a detailed clinical investigation. It included BMI, body fat %, waist circumference; fasting and post-oral glucose tolerance test (OGTT) glucose, insulin, non-esterified fatty acids and glycerol concentrations and HbA1c, C-peptide, HOMA-IR, and lipids. In addition, subcutaneous adipose tissue was obtained by a needle biopsy before and after OGTT to study the expression of PPARG target genes, glucose uptake and lipolysis regulation in isolated adipocytes. Furthermore, the stromal vascular fraction was collected to study preadipocyte differentiation (interim data, n=4+4 for Pro12Pro and Ala12Ala).

Results: No major differences were seen in any of the anthropometric or metabolic variables assessed between three groups Pro12Pro, Pro12Ala and Ala12Ala, respectively, for BMI (kg/m2), 26.8±3.3, 24.3±3.2 and 26.6±3.6, nor HbA1c (mmol/mol), 35.3±3, 34.7±3.2 and 35.0±3.6. Upon fasting overnight and post-OGTT, only a trend of an increased basal and insulin-stimulated glucose uptake in isolated adipocytes was observed in the Ala12Ala participants compared to other two groups (p=NS). Similarly, neither basal nor isoproterenol-stimulated or antilipolytic effect of insulin was altered in adipocytes on fasting state between the three groups. Post-OGTT, the antilipolytic effect of insulin was higher in the Pro12Pro participants compared to Pro12Ala (p<0.05), but not with Ala12Ala. The expression of PPARG target genes involved in adipogenesis (CD36, CEBPα, PPARG, FABP4, and ADIPOQ), glucose (GLUT4, IRS2) and lipid metabolism (LPL and FAS) remained unchanged in adipose tissue obtained before as well as after OGTT. The mean adipocyte diameter was also similar between all groups. Lastly, the preliminary analyses of preadipocyte differentiation rate assessed by percent of differentiated cells and expression of adipogenic marker genes (PPARG, CEBPα, ADIPOQ) did show any difference between Pro12Pro and Ala12Ala groups.

Conclusion: We could not show any major differences in adipocyte development, metabolism, or gene expression in adipose tissue between carriers and non-carriers of the PPARG Pro12Ala allele. Potential explanations to our findings include lack of power to detect small effects of this variant, or that the variant acts via mechanisms other than those assessed, including effects in other tissues.

The influence of dopamine-beta-hydroxylase and catechol o-methyltransferase gene polymorphisms on the efficacy of insulin detemir in patients with type 2 diabetes

T. Bozek[1], A. Blazekovic[2], M. Nikolac-Perkovic[3], K. Gotovac-Jercic[2], L. Smircic-Duvnjak[1], N. PIvac[3], F. Borovecki[2];

[1]Diabetology, University Clinic Vuk Vrhovac, Clinical Hospital Merkur, [2]Department for Functional Genomics, Center for Translational and Clinical Research, University of Zagreb School of Medicine, University Hospital Center Zagreb, [3]Division of Molecular Medicine, Rudjer Boskovic Institute, Zagreb, Croatia.

Background and aims: Neurotransmitters, such as dopamine, gamma-aminobutyric acid, serotonin and norepinephrine, are involved in the central nervous system's regulation of energy and glucose homeostasis and in food intake regulation. Dopamine-beta-hydroxylase (DBH) is an enzyme that catalyzes the conversion of dopamine to norepinephrine within norepinephrine and epinephrine producing neurons and neurosecretory cells. Plasma DBH activity is under the genetic control of a single-nucleotide polymorphism (SNP), DBH -1021C/T, in the 5' flanking region of the DBH gene. Catechol O-methyltransferase (COMT) is one of the major enzymes involved in catecholamine and estrogen degradation. Changes in the COMT activity, associated with genetic variants in the COMT gene have consequences in various mechanisms related to development of obesity, personality changes and behavior disturbances. The aim of the study was to investigate the association of COMT Val108/158Met and DBH-1021C/T polymorphisms with effectiveness of insulin detemir in achieving glucose control and body weight control.

Materials and methods: Observational study included 341 subjects, 185 T2DM patients inadequately controlled with premix insulin analogues, which were replaced with three doses of insulin aspart at mealtime and insulin detemir at bedtime that were followed for 52 weeks, and 156 healthy controls. After DNA isolation from blood samples, genotyping of DBH-1021C/T polymorphism (rs1611115) and COMT Val108/158Met polymorphism (rs4680) was performed.

Results: The mean age of T2DM patients was 67.1±8.01 years (mean age of healthy controls was 44.1±11.6 years), mean duration of T2DM was 16.1±5.9 years. HbA1c and fasting plasma glucose were significantly decreased after 52 weeks (8.58% vs. 7.78%, 11.7mmol/l vs. 8.7mmol/l, respectively, p< 0.001). Insulin detemir had a significant weight sparing effect in overweight patients. COMT A carriers (the combined AG and AA genotype) achieved significantly better HbA1c values after the 52-week treatment compared to patients carrying the GG genotype (7,7% vs. 8,0%, p=0.029, Mann Whitney test). This difference was not gender dependent. The group of patients who lost at least 1 kg of weight showed the most prominent difference in achieved HbA1c values between the COMT genotypes (A carriers: 7.55% vs. GG genotype: 8.1%, p=0.022, Mann Whitney test). Among the patients who had HbA1c decrease over 1% and achieved HbA1c<7%, the GG genotype of the COMT was less frequently present when compared to the patients with higher levels of HbA1c (p<0.005, Chi square). DBH-1021C/T genotypes were not significantly associated with any of the measured variables.

Conclusion: Presence of one or two A allele of the COMT Val108/158Met was associated with improved glycemic response, and with a better response to insulin detemir therapy in T2DM patients.

Clinical phenotyping of carriers of the R138X mutation in the SLC30A8 gene

M. Lehtovirta[1], L. Sarelin[2], R.C. Bonadonna[3], A.-M. Richard[4], J.M. Brosnan[5], T. Tuomi[6,7], L.C. Groop[8,9];

[1]University of Helsinki, Helsinki, [2]Folkhälsan Research Centre, Jakobstad, Finland, [3]University of Parma and Azienda Ospedaliero, Parma, Italy, [4]Cardiovascular and Metabolic Disease Department, Pfizer Inc, [5]Pfizer Inc, Cambridge, USA, [6]Department of Endocrinology, Abdominal Centre, [7]Folkhälsan Research Center, Helsinki, Finland, [8]Clinical Science, Lund University Diabetes Centre, Malmö, Sweden, [9]Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland.

Background and aims: A Loss-of-Function mutation (R138X, rs200185429) in the *SLC30A8* gene encoding the Zinc Transporter 8 (ZnT8) was shown to be associated with a 53% reduction in risk of Type 2 Diabetes (T2D) by Flannick in 2015, but the mechanisms have remained unclear. We, therefore, performed clinical and metabolic phenotyping of additional family members with the mutation by taking advantage of the enrichment of this mutation (0.22%) in a small Botnia region, as compared with the rest of Europe (0.01%).

Materials and methods: Altogether 53 (25 women) R138X carriers (LoF) and 47 (23 women) non-carriers (Contr) from the same families underwent a 190 min mixed meal test (75g glucose, 17g protein, 15g fat) with blood samples drawn at 0, 20, 40, 70, 100, 130, 160 and 190 min for the determination of glucose, insulin, c-peptide, glucagon and zinc (Zn) concentrations.

Results: There were no differences in mean age (LoF: 50.5 ± 2.1vs. Contr: 53.4 ± 2.2 years, p 0.34), BMI (27.4 ± 0.6 vs. 26.1 ± 0.4 kg·m^{-}2, p 0.09) or waist circumference (men: 91.8 ± 1.7 vs. 93.7 ± 1.3 cm, p 0.39 and women: 91.6 ± 2.6 vs. 87.3 ± 1.9 cm, p 0.20); neither were there differences in fasting glucose, HbA1c, insulin, c-peptide and glucagon concentrations, respectively. No differences were observed in stimulated glucose, insulin, c-peptide, glucagon/insulin AUC nor in early or late phase insulin secretion. Given the suggestion by Tamaki in 2013, we also estimated hepatic insulin clearance during test meal, but observed no differences between LoF and Control. Interestingly, among LoF carriers, Zn was higher both at fasting (14.7 ± 0.3 vs. 13.3 ± 0.3 μmol·L^{-1}, p 0.004) and during test meal (2500 ± 59 vs. 2333 ± 56 μmol·min·L^{-1}, p 0.044, respectively), the difference being more pronounced among men. We also explored the distribution of genotypes of the T2D-associated common arg325trp -variant (rs13266634) in the SLC30A8 gene and observed that LoF carriers lacked the TT genotype (CC 70% vs. 36%, CT 30% vs. 30% and TT 0% vs. 34%).

Conclusion: Comprehensive phenotyping of carriers with LoF mutation in the *SLC30A8* gene (R138X) did not provide any clear explanation for the protective effect of this genotype from T2D. However, mutation carriers had higher plasma zinc concentrations. Carriers also lacked the homozygous protective common variant genotype TT.

Estimation of heritability for diabetic complications based on genome-wide association study in Chinese population

G. Jiang[1], C.H.T. Tam[1], A.O. Luk[1], C.K. Lim[1], X. Fan[2], N. Tang[3], S. Tsui[4], W. Yu[5], B. Tomlinson[1], Y. Huang[4], H. Lan[1], C. Szeto[1], W. So[1], J.C.N. Chan[1], R.C.W. Ma[1];

[1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, [2]Department of Statistics, The Chinese University of Hong Kong, [3]Department of Chemical Pathology, The Chinese University of Hong Kong, [4]School of Biomedical Sciences, The Chinese University of Hong Kong, [5]Department of Electronic and Computer Engineering, Hong Kong University of Science and Technology, Hong Kong, China.

Background and aims: Genome-wide association studies (GWASs) have successfully identified a number of common single-nucleotide polymorphisms (SNPs) associated with diabetic complications or associated traits. However, genetic variants identified by GWAS explain only a small proportion of the expected narrow-sense heritability (h^2) defined as the ratio of additive effects of genotyped SNPs to phenotypic variance. In this study, we aim to estimate the narrow-sense heritability for diabetes complications and associated traits utilizing GWAS data from the Hong Kong Diabetes Registry (HKDR).

Materials and methods: The Hong Kong Diabetes Registry includes prospective follow-up of more than 8,000 patients with type 2 diabetes (T2D). Samples were genotyped using the Illumina Omni 2.5+ exome array. After standard quality control, ~1.2 million common SNPs were included in the final analysis. A recently developed method, genome-wide complex trait analysis (GCTA; v1.26.0), was used to estimate the heritability for different diabetes-related traits and diabetic complications based on the common SNPs. Phenotypes were adjusted for age, gender, top 20 principle components and use of medications at baseline. We also evaluated the genetic correlation between cardiometabolic traits and diabetic complications.

Results: After sample quality control, we included 5,742 unrelated Chinese subjects with T2D in this analysis (mean age of all subjects 57.5 ± 13 years, 45.5% male, median duration of diabetes 6 [IQR: 2-11] years at baseline). In the HKDR, the heritability h^2 accounted by common SNPs was 0.17 (SE=0.067) for eGFR, 0.07 (SE=0.07) for urine albumin/creatinine ratio (UACR), 0.36 (SE=0.072) for HDL cholesterol, 0.12 (SE=0.068) for LDL cholesterol, 0.24 (SE=0.07) for triglyceride, 0.28 (SE=0.071) for the ratio of total cholesterol and HDL. For binary outcomes, heritability on the liability threshold scale was 0.15 (SE=0.104) for chronic kidney disease (CKD), 0.23 (SE=0.149) for end-stage kidney disease (ESRD), 0.31 (SE=0.155) and 0.24 (SE=0.116) for neuropathy and retinopathy, respectively. The estimated genetic correlations between most pairs of traits were modest, except the correlation exhibited between HDL and UACR (ρ=-0.74, SE=0.456, P=0.009).

Conclusion: Our results provide novel insights on the genetic architecture of diabetic complications in Chinese. Our observed heritability is broadly similar to that recently reported for DKD in type 1 DM. Analysis are ongoing to identify the genetic overlap between the different complications in T2D.

Identification of susceptibility loci for diabetes-related traits in a mouse model for the metabolic syndrome

S. Lebek[1], T. Schallschmidt[1], D. Altenhofen[1], Y. Schulte[1], M. Damen[1], M. Blank[1], N. Hampe[1], A. Pelligra[1], C. de Wendt[1], T. Stermann[1], S. Walsh[1], B. Knebel[1], A. Schürmann[2], A. Chadt[1], H. Al-Hasani[1];

[1]Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, [2]Department of Experimental Diabetology, German Institute of Human Nutrition (DIfE), Nuthetal, Germany.

Background and aims: Inbred strains of mice can be used as model system for human metabolic diseases. New Zealand obese (NZO) mice present the metabolic syndrome with symptoms of obesity, hyperglycemia, hypercholesterolemia and hypertension and are considered as a polygenic model for obesity and type 2 diabetes (T2D). Until today, the genetic variants that predispose NZO mice for diabetes have not been elucidated. The aim of this study is to identify novel susceptibility loci for obesity and diabetes by combine gene-driven and phenotype- approaches. We crossbred obese diabetes-prone NZO with lean and diabetes-resistant 129P2 mice and performed QTL and expression analysis.

Materials and methods: Animals of the backcross population (300 females and 300 males) were phenotyped and genotyped by using a genome-wide high-density SNP panel. All mice received a high fat diet (45 % fat/calories) after weaning. After 21 weeks of age, mice were sacrificed and tissues as well as plasma were harvested. The calculation of phenotype-genotype associations was performed by QTL analysis. Expression levels were analysed using qRT-PCR and Microarray approaches.

Results: By linkage analysis four QTL for metabolic traits were identified on chromosome 4. A major QTL for blood glucose levels (Logarithm of the odds (LOD) 7.1) was detected at 35.4 cM. Heterozygous mice (NZO/129P2) showed higher levels of blood glucose, liver weight, final blood glucose and final plasma insulin compared to homozygous allele carriers (NZO/NZO). The T2D prevalence was nearly 20 % higher in NZO/129P2 compared to NZO/NZO mice. Expression analysis revealed candidate genes in adipose tissues

(brown adipose tissue and gonadal white adipose tissue) as well as skeletal muscle and liver tissue.

Conclusion: We identified novel susceptibility loci associated with T2D on mouse chromosome 4. Furthermore, we found several candidate genes carrying strain-specific variants and which were associated with the diabetogenic phenotype of the NZO/129P2 population. In the future, investigation of these candidates will be performed by functional studies in vitro and in vivo. Additionally, generation of recombinant congenic mice (RCS) is in process to narrow down the identified QTL region.

Deep re-sequencing of 9 type 2 diabetes GWAS loci by comparison of extremes of dynamic indices of insulin secrection

D. Bailetti[1], F. Sentinelli[1], L. Bertoccini[1], A. Di Costanzo[2], M. Incani[3], M. Arca[2], F. Leonetti[1], S. Prudente[4], M. Baroni[1,3];

[1]Experimental Medicine, la SAPIENZA, [2]Internal Medicine and Medical Specialties, la SAPIENZA, Rome, [3]Medical Sciences, University of Cagliari, Cagliari, [4]Mendel Laboratory, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy.

Background and aims: The susceptibility genes for Type 2 Diabetes (T2D) identified so far are mainly involved in beta-cell function. To this point, Genome-Wide Association Studies (GWAS) have identified a large number of *loci.* Despite this large number, the major part of T2D inheritance is still uncovered. This missing heritability might be explained by multiple, low-frequency variants that are not captured by GWAS. A powerful approach to highlight causal variants is to deep re-sequence candidate genes. To enhance the probability to highlight causal or protective variants together with the appropriate statistical power, we aimed to identify by Next Generation Sequencing (NGS) low-frequency variants in GWAS *loci* for T2D, searching for primary defects in beta-cell insulin secretion. For this, we applied a two stage study design: **Stage 1**, deep re-sequencing of coding and flanking regions of 9 candidate genes that reach GWAS significance ($p<10^{-8}$), in individuals selected from the extremes of insulin secretion, adjusted for insulin resistance, i.e. Disposition Index (DI); **Stage 2**, confirmation of the association by genotyping the variants differently distributed between the two extremes of insulin secretion in larger and independent groups of Italian adults and children (N=3130).

Materials and methods: In a large population, very well characterized from OGTT, measures of insulin secretion and resistance have been calculated, including insulinogenic index (IGI30), ISI (insulin-sensitivity index), and DI (IGI30xISI). NGS was performed on MiSeq system (Illumina) with TruSeq Custom Amplicon approach. Variants are investigated by proper bioinformatics tools. Discovered variants will be genotyped by Real-Time PCR or by suitable methods such as SNP array and genotyping by sequencing.

Results: We sequenced 383 subjects from the discovery sample. Preliminary results show more than 1500 variants in this sample. Bioinformatics tools predict that at least 122 of them may have a functional effect on protein, being missense or nonsense. A small but relevant part of passing-filter variants seems to be newly discovered (no rs) or to presumptively affect protein function. We then searched for a different distribution of all the infrequent variants within the two extremes of DI. Variants in one of the genes, ADAMTS9, were significantly associated with the higher extreme (>80%) of DI distribution (OR= 1.30 p=0.03). A similar trend was observed for four of the 9 candidate genes. Multivariate analyses showed that carriers of one o more variants have an OR= 9.06 (1.73-47.42) p=0.009 and OR= 8.52 (1.32-55.01) p=0.024 respectively, to be in the >80% extreme of DI.

Conclusion: The next stage involves the in-depth analysis of all the variants discovered, evaluating distribution, frequency, and possible function, together with the replication studies in large cohorts to confirm the association with altered insulin secretion. We expect that this study will deliver several results: from confirmatory gene association to newer T2D associated polymorphisms, to possible new insights into potential biological mechanisms influencing T2D pathogenesis.

Genetic variability in eIF2α gene can increase the risk for glucose disorder with aging or higher BMI in a Chinese Han population

N. Gu, X. Ma, J. Zhang, M. Jin, N. Feng, R. Deng, G. Bai, H. Zhang, X. Guo; Peking University First Hospital, Beijing, China.

Background and aims: The increasing evidence suggested that unfolded protein response plays an important role in chronic metabolism disease such as type 2 diabetes. Accumulation of unfolded protein in the endoplasmic reticulum (ER) retards mRNA translation through activation of the protein kinase PERK and eukaryotic translation initiation factor 2 alpha (eIF2α). Some studies had demonstrated that genetic variation of the PKR- like ER kinase (PERK)/ eIF2α pathway leads to β-cell function failure. The aims of this article was to assess the possible association between the eIF2α gene and the risk of glucose metabolism abnormality.

Materials and methods: We selected 2 SNPs (rs9840992 T>C and rs13072593 A>G) at eIF2α locus according to CHB database from HapMap R#27 (r2<0.8 and MAF≥0.05) and genotyped 1,466 unrelated non-diabetic individuals screened by 75g-OGTT (845 prediabetic subjects and 621 normal controls) using mass spectrometry assay. Out of all subjects, 733 did insulin release test following 75g-OGTT. We evaluated various indicators of insulin resistance and islet β-cell function. All statistical analyses were assessed using the SPSS statistical package (version 13.0; SPSS, Chicago, IL) and Haploview 4.1(http:// www.broadinstitute.org/haploview/haploview).

Results: The carriers of genotype CC at rs9840992 had a higher insulin level at 120min after 75g glucose load compared to the non-carriers [49.86(30.38-79.61) vs 44.32(26.42-70.75) mU/L, p=0.038]. We also found that homozygotes of CC had higher ΔI30/ΔG30 [10.82(6.25-19.35) vs 8.97(5.35-16.49), p=0.008] and ΔI120/ΔG120 [23.02(13.47-43.21) vs 19.38(10.45-36.57), p=0.017] compared to non-carriers, and the differences were still significant after adjusted for insulin resistance (p'=0.004 and p'=0.006, respectively). Homozygotes of CC had greater AUCi measurements compared to non-carriers (p=0.023, p'=3.7×10^{-4} adjusted for insulin resistance). When age ≥ 65yr or BMI≥24kg/m^2, or carrying the risk allele T of SNP rs9840992 was taken as a risk factor of prediabetes respectively, the cumulative risk analysis showed that the more factors the individuals carried, the higher risk they were at for prediabetes (p=0.000). The subjects who carried all the 3 risk factors had a risk of about 2.5 folds as high as those who carried none of the given three factors (OR=2.428, p=0.005) for glucose metabolism abnormality(Figure 1).

Conclusion: Genetic variability at eIF2α locus may increase the risk for glucose disorder with aging or higher BMI in the Chinese population.

Genetic control of glucose tolerance and insulin secretion by CD26/DPP4 is abrogated in prediabetes

R.S. Patarrão[1], N. Duarte[2], J.F. Raposo[1,3], J. Costa[2], R.T. Ribeiro[3], L. Gardete-Correia[3], R. Duarte[3,4], J.M. Boavida[3], I. Correia[3], R. Andrade[3], J. Medina[4], C. Penha-Gonçalves[2], M. P. Macedo[1,5];
[1]CEDOC, NMS-UNL, Lisbon, [2]Instituto Gulbenkian de Ciência, Oeiras, [3]APDP-Diabetes Portugal Education and Research Center, [4]Sociedade Portuguesa de Diabetologia, Lisbon, [5]Department of Medical Sciences, Institute of Biomedicine-iBiMED, University of Aveiro, Aveiro, Portugal.

Background and aims: CD26/DPP4 enzymatic activity targets the gastrointestinal hormones, glucagon-like polypeptide 1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) possibly counteracting their incretinic effect. Nevertheless, it is unclear the impact of CD26/DPP4 gene has a measurable action in glucose excursion and insulin secretion modulating thereby glucose metabolism. We have taken the approach of analysing the action of CD26/DPP4 on metabolic traits both in normoglycemic and prediabetes individuals using a human cohort and analysing a mutant mouse model.

Materials and methods: The PREVDIAB2 cohort was collected in 2014 and comprises 1,088 individuals from the Portuguese population that underwent OGTT analyzed at 0, 30 and 120min after the glucose challenge. We have genotyped this collection for 27 SNPs in the CD26 genomic region and preformed genetic association tests against glucose and C-peptide measurements taken in the course of the OGTT. We also analyzed glucose excursions and the C-peptide levels in the CD26 knockout mice upon OGTT as compared to wild-type mice.

Results: We found that in normoglycemic individuals, several CD26 SNPs were highly associated to measurements of glycemia excursion (highest association, $P=9.28X10^{-7}$) and C-peptide levels (highest association, $P=5.31X10^{-5}$) across the OGTT. This indicates that the CD26/DPP4 gene controls glucose metabolism efficiency in the post-prandial state. Strikingly, this control was absent in subjects with prediabetes. In accordance, serum CD26/DPP4 activity was increased in prediabetic individuals. Moreover, we found that CD26KO animals revealed a lower glucose excursion and increased insulin secretion in response to OGTT, reinforcing the notion that the CD26 gene has a measurable effect in glucose metabolism.

Conclusion: Together these results revealed that the CD26 gene region is controlling glucose metabolism through regulation of incretin effects under normoglycemia. Nevertheless, prediabetes states appear to override these mechanisms of metabolic control, possibly due to an increased expression of CD26/DPP4 activity in subjects with prediabetes. We hypothesize that in prediabetes, CD26 expression may be under epigenetic effects that may have an impact on therapies based in DPP4 inhibitors.

Key role of beta-arrestin 1 in preserving the function and mass of pancreatic beta cells in vivo

J. Obeid, D. Greuet, A. Varrault, S. Costes, J. Mathieu, S. Dalle, M. Ravier, G. Bertrand;
Institut de Génomique Fonctionnelle, CNRS, INSERM, Université de Montpellier, Montpellier, France.

Background and aims: Pancreatic beta cell function and mass alterations play a central role in the pathogenesis of type 2 diabetes (T2D). Our previous work suggests that beta-arrestin 1 (ARRB1), an ubiquitously expressed scaffold protein, plays a role in insulin secretion and beta cell survival. To characterize the precise role of ARRB1 in beta cells, we analyzed the physiological effects of conditional invalidation of Arrb1 specifically in beta cells (βArrb1KO mice).

Materials and methods: Mice invalidated for Arrb1 specifically in beta cells (βArrb1KO) were generated using the Cre-loxP system under the control of the Ins1 promoter. Male mice βArrb1KO and βArrb1WT (controls) were fed with standard or high-fat diet (HFD) for 11 weeks.

Results: Under standard diet, βArrb1KO mice displayed similar weight gain, fasting and postprandial glucose levels as well as glucose tolerance compared to βArrb1WT mice. In contrast, insulin secretion in response to glucose was altered both *in vivo* ($p<0.05$) and *in vitro* ($p<0.01$). In addition, morphometric analysis of pancreatic histological sections from βArrb1KO mice indicated a significant reduction in islet mass ($p<0.05$), with a population significantly enriched in small islets but depleted in large islets. On the other hand, under HFD, βArrb1KO mice displayed a comparable overweight to βArrb1WT mice but deficient compensatory hyperinsulinemia ($p<0.05$) and aggravated oral glucose intolerance ($p<0.05$). In addition, βArrb1KO mice did not show compensatory adaptation in islet mass unlike βArrb1WT mice. Interestingly, ARRB1 protein expression was increased in islets from prediabetic db/db mice. Conversely, ARRB1 protein expression was reduced in islets from mice under insulin resistance conditions (HFD, aged C57BL/6J, diabetic db/db mice).

Conclusion: Our results demonstrate the critical role of ARRB1 in the function, maintenance and plasticity of beta cell mass *in vivo*. A lack of ARRB1 protein expression in the states of insulin resistance could lead to defective compensatory increase in beta cell functional mass leading to T2D.

How does MICU2 regulate stimulus secretion coupling in pancreatic beta cells?

N.V. Vishnu, D. Nicholls, H. Mulder;
Unit of Molecular Metabolism, Lund University, Malmö, Sweden.

Background and aims: MICU2 and its homologue MICU1 heterodimerize and act as molecular gatekeepers of the mitochondrial calcium uniporter supercomplex (mtCUC). Although, MICU1 has been implicated in stimulus-secretion coupling, the role of MICU2 in pancreatic β-cell function is unclear. In this project, we specifically aimed to: Determine functional and bioenergetic consequences of MICU2 perturbation in rodent INS-1 832/13 and human EndoC-βH1 cell lines.

Materials and methods: Standard assays of insulin secretion, mitochondrial respiration measurement and live cell imaging tools and techniques were used in this study.

Results: Our experiments revealed that both the basal 2.8 mM and 16.7 mM glucose stimulated mitochondrial calcium ($[Ca^{2+}]_{mito}$) elevations were reduced by 33% (n=36 cells, $p<0.0001$) and 51% (n=36 cells, $p<0.0001$) respectively in INS-1 832/13 cells. Similar to our data in INS-1 832/13 cells, we obtained a 52% (n=23 cells, $p=0.0169$) and 62% (n=23 cells, $p=0.0066$) reduction in basal 2.8 mM and 20 mM glucose stimulated $[Ca^{2+}]_{mito}$ elevation in

EndoC-βH1 cells. Furthermore, Micu2 knock down hyperpolarized the inner mitochondrial membrane 50% (n=164 cells, p=0.0001) less than control INS-1 832/13 cells. Moreover, basal 2.8 mM glucose and 16.7 mM glucose stimulated ATP/ADP ratio rises were diminished by 20% (n=20 cells, p<0.0001) and 92% (n=20 cells, p<0.0001), respectively, in INS-1 832/13 cells. In contrast, in EndoC-βH1 cells, 2.8 mM glucose and 20 mM glucose stimulated ATP/ADP ratio elevation declined by 24% (n=21 cells, p=0.018) and 50% (n=21 cells, p=0.0078), respectively. In addition, 2.8 mM glucose and 16.7 mM glucose stimulated insulin secretion were diminished by 40% (n=3, p<0.0001) and 38% (n=3, p=0.0026), respectively, in INS-1 832/13 cells. Furthermore, fold change in insulin secretion from 2.8 mM to 16.7 mM glucose was diminished by 53% (n=3, p=0.0018) in EndoC-βH1 cells upon Micu2 knock down. $[Ca^{2+}]_{mito}$, and cytosolic calcium ($[Ca^{2+}]_c$) peaks were abrogated by 59% (n=109, p<0.0001) and 68.9% (n=217, p<0.0001) respectively upon 36 mM K^+ stimulation in INS-1 832/13 cells. Moreover, subplasmalemmal calcium ($[Ca^{2+}]_{mem}$) upon 36 mM K^+ stimulation was enhanced by 56.5% (n=64, p<0.0001) in Micu2 knock down INS-1 832/13 cells.

Conclusion: MICU2-associated $[Ca^{2+}]_{mito}$ mtCUC might be locally interacting and maintaining the plasma membrane Ca^{2+} channels desensitized in pancreatic β-cells. The perturbation of MICU2 might lead to dysfunctional $[Ca^{2+}]_c$ redistribution, disrupting metabolic control of insulin secretion in pancreatic β-cells.

Abn-CBD stimulates insulin secretion and promotes beta cell proliferation in human and mouse islets through GPR55-independent signalling

I. Ruz-Maldonado[1], A. Pingitore[1], B. Liu[1], G.C. Huang[1], D. Baker[2], F.J. Bermúdez-Silva[3], S.J. Persaud[1];

[1]Diabetes Research Group, Division of Diabetes and Nutritional Sciences, King's College London, [2]Barts and The London School of Medicine and Denstistry, Blizard Institute, London, UK, [3]Unidad de Gestión Clínica Intercentros de Endocrinología y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, Málaga, Spain.

Background and aims: GPR55 belongs to the highly specialised G-protein coupled receptor family. We and others have reported that its activation increases insulin secretion. The aims of the current study were to investigate the effects on insulin secretion and proliferation of Abn-CBD, an apparently selective GPR55 agonist, and to gain new insights into the signalling pathways operating downstream of Abn-CBD in human (H) and mouse (M) islets.

Materials and methods: Islets isolated from WT C57BL/6J and GPR55KO mice and human organ donors were perifused in the absence or presence of Abn-CBD, and insulin secretion and $[Ca^{2+}]$i were quantified by RIA and microfluorimetry respectively. The effect of Abn-CBD on beta cell proliferation (BrdU incorporation) in GPR55WT and KO M islets was evaluated over 5 days via fluorescence microscopy. PhosphoAKT and CREB, and total AKT and CREB expression were also evaluated by western blotting in H and M islets using Abn-CBD.

Results: 1μM Abn-CBD potentiated glucose-induced insulin secretion in WT and GPR55KO mice islets (WT: 9±1.5 pg/islet/min maximum increase (MI) above 20mM glucose response (20GR); KO: 9±1.2) and the effect of 10μM Abn-CBD was significantly increased in islets from GPR55KO mice (WT: 3±0.4 pg/islet/min MI above 20GR; KO: 13±0.5; n=3-4, p<0.0001). These results on insulin secretion were in agreement with the changes in $[Ca^{2+}]$i after treatment with 1 and 10μM Abn-CBD in WT and GPR55KO islets (WT, 1μM Abn-CBD: 0.02±0.01 fluorescence 340/380, MI above 20GR, 10μM Abn-CBD: 0.02±0.01; KO, 1μM Abn-CBD: 0.02±0.01, 10μM Abn-CBD 0.03 ±0.01). In addition, Abn-CBD stimulated concentration-dependent potentiation of glucose-induced insulin secretion from H islets (vehicle: 18±0.4 pg/islet/min, 0.1μM Abn-CBD: 48±0.4, 1μM Abn-CBD: 60 ±1.4, 10μM Abn-CBD: 83±1.1; n=4, p<0.0001). Similar stimulatory effects of Abn-CBD on $[Ca^{2+}]$i were observed in H islets (0.1μM Abn-CBD: 0.03±0.01 fluorescence 340/380, MI above 20GR, 1μM Abn-CBD: 0.04±0.02). Abn-CBD also significantly increased beta cell proliferation of islets isolated from WT mice (vehicle: 0.8±0.1 BrdU+ insulin cells, 1μM Abn-CBD: 1.6±0.3, p<0.0001, n=60) and it increased islet area (vehicle: 8,000μm^2, 1μM Abn-CBD: 10,500, p<0.01, n=60). Islets from GPR55KO mice showed significantly reduced basal BrdU incorporation compared to WT islets (0.2±0.03 *vs.* 0.8±0.07 BrdU+ insulin cells, p<0.001), but Abn-CBD was able to promote beta cell proliferation in GPR55KO mice islets (0.9±0.03 BrdU+ insulin cells, p<0.0001). 10μM Abn-CBD increased CREB phosphorylation by 30% in M islets and AKT phosphorylation by 20% in H islets.

Conclusion: Our results indicate that Abn-CBD increases insulin secretion and $[Ca^{2+}]$i in M and H islets. It also induced increases in CREB and AKT phosphorylation, in beta cell proliferation and in enhancing islet area. The data obtained with islets isolated from GPR55KO mice indicate that Abn-CBD exerts these stimulatory effects in a GPR55 independent manner. A broader knowledge of the novel mechanisms of action of Abn-CBD might offer new approaches to treat type 2 diabetes.

Extracellular nicotinamide phosphoribosyltransferase (eNAMPT) plays a dose- and time- dependent role in pancreatic beta cell function

S. Sayers, E. Evans, R. Beavil, P. Caton;

King's College London, London, UK.

Background and aims: Serum levels of nicotinamide phosphoribo syltransferase (eNAMPT; visfatin/PBEF) are elevated in patients with Type 2 diabetes (T2D). However, the role of eNAMPT in pathophysiology remains unclear. Here we examined acute and chronic dose-dependent effects of eNAMPT on pancreatic islet function.

Materials and methods: Islets from mice were isolated and treated with recombinant eNAMPT for 5 minutes-1 hour and 24-72 hours, at concentrations of 0.1-10ng/ml. Glucose-stimulated insulin secretion (GSIS) was measured by radioimmunoassay. Intracellular calcium ($[Ca^{2+}]_{cyt}$) was measured in MIN6 cells using Fura-2 and wide-field microscopy. Apoptotic activity was measured using Caspase-Glo 3/7 assay and cellular NAD/NADH by colorimetric assay. Gene expression was assessed by qPCR and proliferation by BrdU staining.

Results: Insulin secretion in response to elevated glucose (2 vs 20mM) was largely unchanged after less than 24 hours of eNAMPT exposure except for when treated with 0.1ng/ml eNAMPT for 30 minutes (no treatment: 0.474± 0.045ng/ml vs 0.1ng/ml: 1.157 ± 0.195ng/ml, n=8, 4 size matched islets/well, P<0.05). However, GSIS was increased after 24-72 hours treatment with 1ng/ml eNAMPT (no treatment: 1.948 ± 0.313ng/ml vs 1ng/ml: 4.600 ± 0.816ng/ml at 48 hours, n=8, P<0.05) via NAD-dependent effects. In contrast, islets treated with higher concentrations of eNAMPT (P<5ng/ml) showed NAD-independent impaired levels of GSIS (5ng/ml: 1.347 ± 0.120ng/ml, NS) and reduced intracellular $[Ca^{2+}]_{cyt}$ (no treatment: 111.7 ± 0.921% vs 5ng/ml: 106.5 ± 0.595%, n=22, P<0.05) after 48 hours treatment. Gene expression analysis revealed that exposure to eNAMPT (P<5 ng/ml) led to reduced expression of *Pdx1* (no treatment: 1.013 ± 0.096 vs 5 ng/ml: 0.636 ± 0.067 normalised to *Gapdh*, NS) and to an enhanced inflammatory response (increased mRNA levels of *Mcp1*: no treatment: 1.075 ± 0.196 vs 5ng/ml: 5.482 ± 1.258, P<0.001; *Il1β*: no treatment: 1.138 ± 0.291 vs 5ng/ml: 5.459 ± 2.002, P<0.05; *Tnfα*: no treatment: 1.258 ± 0.553 vs 5ng/ml: 2.503 ± 0.902, NS, all normalised to *Gapdh,* n=5). Correspondingly, apoptosis is enhanced in islets treated with high concentrations of eNAMPT in the presence of cytokines (no treatment: 103492 ± 11398 vs 5ng/ml: 169693 ± 20836 luminescence (RLU), n=8, 6 size matched islets/well, P<0.05). Numbers of proliferating beta cells are unchanged after eNAMPT treatment (n=4).

Conclusion: Chronic eNAMPT exposure at levels similar to those observed in T2D serum is detrimental to normal beta cell function. However, moderate eNAMPT exposure at levels similar to those observed in non-diabetic serum promotes insulin secretion. This data begins to clarify previous conflicting findings regarding eNAMPT in T2D. Additional mechanisms of eNAMPT action are being investigated including the role of monomeric eNAMPT in beta cell function as well as treating with eNAMPT *in vivo*.

Using recombinase-mediated cassette exchange to enginner MIN6 insulin secreting cells with a tetracycline-regulated expression system

H. Ishihara, A. Furukawa, A. Tanaka, M. Kosuda, M. Yamana, A. Nagasawa, S. Yamaguchi;
Division of Diabetes and Metabolism, Nihon University School of Medicine, Tokyo, Japan.

Background and aims: It has been widely accepted that pancreatic β-cell impairment, whether in terms of function, mass or both, is of central importance for the development not only of type 1 but also type 2 diabetes mellitus. Recent advances in genome-wide association analysis and a number of studies analyzing transcriptomes or proteomes in insulin secreting cells have revealed genes to possibly be involved in impaired β-cell function and/or mass. However, research progress beyond identification of these candidate genes has been hampered and analyses of the functional impacts of these abnormalities have been limited. Although imperfect, utilization of highly differentiated insulinoma cell lines, such as MIN6, is an approach to studying gene functions in insulin secretion. However, one of the disadvantages encountered in using these cells is the low transfection efficiency of nucleotides. When investing effects of abnormalities in candidate genes, 70-80% of cells, perhaps more, need to be genetically modified, because physiological phenotypes are not anticipated to be particularly large. A viral vector approach is one method overcoming this difficulty. However, producing viral vectors is not very easy. Therefore, generating stable cell lines would be preferable, offering the advantages of accuracy and reproducibility of experiments, although generating such cell lines from highly differentiated insulin secreting cells would also be time-consuming and laborious. We herein report a very efficient system based on the recombinase-mediated cassette exchange (RMCE) for generation of a MIN6-derived master cell line for gain-of-function and loss-of-function studies of candidate genes.

Materials and methods: A recipient platform for RMCE was generated that has the zeocin-resistant gene flanked with a set of hetero-specific yeast flippase recognition target (FRT) sites. MIN6 cells, first engineered to have a tetracycline-regulatable expression system, were randomly integrated the recipient platform and searched for clones expressing GFP uniformly and at a high level. Clones with multiple platform integration were eliminated by sequential RMCE and analysis of antibiotic sensitivity. Overexpression and suppression of gene-of-interest are achieved by delivery with an exchange vector of cDNAs and shRNAs, respectively, flanked with FRT sites together with a flippase expressing plasmid.

Results: We selected one clone based on their morphological features resembling those of parental MIN6 cells and their robust and uniform GFP expression after doxycycline induction and named MIN6CE. MIN6CE cells exhibit an approximately 10-fold induction of insulin secretion in response to high glucose concentrations. Using this cell line, we showed that engineered clones with induced or suppressed expression of glucokinase were generated within 6 weeks. Moreover, we could simultaneously generate clones overexpressing either *Fdft1, Gprc5c, Prss8, Gm773, Igsf21,* or *Serping1*, whose expressions are different between MIN6 subclones with high and moderately-low glucose responsiveness in our preliminary microarray analysis. We found that *Gprc5c* and *Prss8* overexpressions increased insulin secretion.

Conclusion: We established MIN6CE as a powerful tool for studying molecular mechanisms of insulin secretion.

Loss of intra-islet heparan sulfate represents a novel marker for the progression of type 1 diabetes in humans

C.J. Simeonovic[1], S.K. Popp[1], L. Jensen[1], D.J. Brown[1], A. Ziolkowski[1], B. Ludwig[2], S. Bornstein[2], J.D. Wilson[3], A. Pugliese[4], T.W.H. Kay[5], H. Thomas[5], T. Loudovarus[5], F. Choong[1], C. Freeman[1], C. Parish[1];
[1]The John Curtin School of Medical Research, The Australian National University, Canberra, Australia, [2]Technical University Dresden, Dresden, Germany, [3]The Canberra Hospital, Canberra, Australia, [4]University of Miami Miller School of Medicine, Miami, USA, [5]St Vincent's Institute of Medical Research, Melbourne, Australia.

Background and aims: Human type 1 diabetes (T1D) is an autoimmune disease and multiple destructive mechanisms are likely. In addition, a residual beta cell mass can exist at diagnosis, highlighting the potential for rescue by novel therapies. We have previously demonstrated unusually high levels of the polysaccharide heparan sulfate (HS) and heparan sulfate proteoglycans (HSPGs) inside mouse beta cells, a critical role for intracellular HS in beta cell survival, the progressive loss of islet HS during T1D progression in NOD mice and expression of the HS-degrading enzyme heparanase (Hpse) by islet-infiltrating leukocytes. Treatment of NOD mice with PI-88, a Hpse inhibitor/HS mimetic, reduced the incidence of T1D by 50% and preserved intra-islet HS, suggesting that Hpse-mediated loss of beta cell HS contributes to T1D disease. In this study we examined the clinical relevance of HS for the viability of human beta cells and as a target for destruction in human T1D.

Materials and methods: HS, HSPG core proteins (collagen type XVIII (Col18), syndecan-1 (Sdc1)), insulin, glucagon and Hpse were stained by immunohistochemistry/ immunofluorescence in paraffin sections (post-antigen retrieval) of normal (n=8) and T1D (n=8) human pancreases with insulin+ve islets, obtained from the JDRF Network for Pancreas Organ Donors with Diabetes (nPOD, USA); the stained islet area was quantified using Image J software. 10E4 anti-HS mAb was used to localise highly sulfated HS and HP130 mAb identified Hpse. Isolated human islets were dispersed into single cells (using Accutase) for flow cytometry analysis of HS/HSPGs in beta cells and of beta cell viability after culture with HS mimetics (heparin or PI-88) ± acute treatment with 30% hydrogen peroxide. Beta cells were identified using Newport Green (NG) and damaged cells were stained using 7AAD or Sytox Green.

Results: Localisation of HS, Col18 and Sdc1 in normal human pancreas correlated with insulin-containing beta cells. For insulin-positive T1D islets, the insulin-stained islet area was 85% of normal islets. However, the area stained for HS, Col18 and Sdc1 was significantly reduced to 41% ($P<0.0001$), 55% ($P<0.0001$) and 42% ($P<0.0001$) of normal islets, respectively. Insulitis leukocytes showed cell surface staining for Hpse. Flow cytometry analyses showed that 84.1±3.3% of human islet cells were beta cells and contained intracellular HS and HSPG core protein. Uptake of HS mimetics during culture of human beta cells significantly improved beta cell viability by 1.6-fold ($P<0.001$) i.e., as HS replacers, significantly reduced the proportion of damaged/non-viable beta cells to 25-31% of controls ($P<0.001$) and significantly reduced hydrogen peroxide-induced death by 3-fold ($P<0.001$).

Conclusion: These findings suggest that in human T1D, the loss of beta cell HS could be mediated by leukocyte-derived Hpse and result in increased susceptibility to oxidative damage. Dual activity Hpse inhibitors/HS replacers could therefore represent a novel class of T1D therapeutic.

Degradation of the histone acetyl transferase p300 by the ubiquitin-proteasome pathway contributes to beta cell injury in type 2 diabetes environment

S. Costes, L. Ruiz, A. Wojtusciszyn, M. Ravier, J. Mathieu, G. Bertrand, S. Dalle;

Institute for Functional Genomics, INSERM, CNRS, Univ of Montpellier, Montpellier, France.

Background and aims: In type 2 diabetes (T2D), chronic hyperglycemia, lipotoxicity and pro-inflammatory cytokines are detrimental to beta-cells, causing apoptosis and impaired insulin secretion. The histone acetyl transferase p300, involved in remodelling of chromatin structure by epigenetic mechanisms, is a key activator of the transcriptional machinery. We previously showed that p300 plays a key role in pancreatic beta-cell survival and function. The aim of the study is to understand the mechanisms that control p300 regulation in beta-cells exposed to pathological conditions.

Materials and methods: Experiments were performed with the pancreatic beta-cell line (INS-1E), isolated mouse pancreatic islets and human pancreatic islets. p300 and histone H4 acetylation levels were evaluated by western blot. Gene expression was analyzed by RT-PCR. p300 mRNA levels were evaluated using available islet transcriptomics analysis of T2D subjects from two independent datasets (Gene Expression Omnibus (GEO) repository: GSE20966 and GSE38642). Apoptosis was detected by cleaved caspase-3 emergence.

Results: Chronic exposure of INS-1E cells to high glucose or pro-inflammatory cytokines resulted in decreased p300 protein expression ($p<0.001$) associated with decreased histones H4 acetylation (targets of p300) and apoptosis. In isolated human islets, p300 protein levels were also decreased under high glucose exposure (30 mM glucose for 72h), chronic exposure to palmitate (0.5 mM palmitate for 72h) and this decrease was exacerbated under glucolipotoxicity (30 mM glucose + 0.5 mM palmitate) ($p<0.05$). Treatment of INS-1E cells with the proteasome inhibitor MG-132 prevented the decrease in p300 content induced by high glucose or pro-inflammatory cytokines exposure. However, p300 mRNA levels were not altered in INS-1E cells, and islet transcriptomics analysis of T2D subjects from two independent datasets revealed no change in p300 mRNA levels compared to normal glycemic controls. Altogether these data point to a proteasomal degradation involved in p300 loss in pathological beta-cells. The emergence of apoptosis in INS-1E cells with decreased p300 protein expression or function (knock-down by siRNA or treatment with an inhibitor of the histone acetyl transferase activity of p300 (C646), respectively) ($p<0.01$) suggested that loss of p300 integrity induced by pathological conditions contributes to beta-cell apoptosis and dysfunction.

Conclusion: This study demonstrates that p300 degradation by the ubiquitin-proteasome pathway contributes to beta-cell death and dysfunction upon physiopathological conditions mimicking the diabetic environment. Our data suggest the interest to consider this epigenetic modulator p300 as a potential therapeutic target in T2D.

Profound alteration in the expression of Wnt-associated gene in pancreatic islets induced by high fat/high sucrose diet and potential roles of Wnt4 in beta cells

T. Ohki, Y. Kurita, E. Soejima, K. Hara, X. Yuan, S. Otabe, H. Nakayama, Y. Tajiri, K. Yamada;

Division of Endocrinology and Metabolism, Department of Medicine, Kurume University School of Medicine, Kurume, Fukuoka, Japan.

Background and aims: Mice fed high-fat/high-sucrose (HF/HS) diet develop insulin resistance and hyperinsulinemia exhibiting the hyperplasia of pancreatic β-cells. However, the precise mechanism by which the intake of HF/HS diet induces β-cell hyperplasia and hyperinsulinemia remains to be determined. Dysregulation of Wnt signaling pathway is associated with various diseases including type 2 diabetes. Here we investigated the alterations in the Wnt signaling pathway caused by HF/HS diet in murine islets, and analyzed the potential role of Wnt4 in β-cells.

Materials and methods: Eight-weeks-old C57BL/6 mice were fed standard chow or HF/HS diet up to the age of 20 weeks, when islets and pancreatic sections were obtained. RT-qPCR was performed for measurement of the expression of Wnt pathway-related genes in islets. Immunofluorescence staining was done to identify the localization of Wnt4 protein. Transfection of the on-target siRNAs was carried out to knockdown (KD) Wnt4 in MIN6 cells. The CCK8 assay and batch incubation were performed to assess proliferation and insulin secretion in Wnt4-KD-MIN6 cells. Students' t-test was used to compare two groups.

Results: Among the Wnt ligand family, 7 genes were expressed at detectable levels in islets obtained from 20-week-old mice. Wnt4 and Wnt5b were significantly up-regulated in the islets of mice maintained on HF/HS diet, whereas Wnt2b, Wnt11 and Wnt14 were depressed. On the other hand, 9 of 10 known Fzd receptor genes were expressed in islets, showing the down-regulation of Fzd4, Fzd5, and Fzd6 in HF/HS diet-fed mice. The expression of Lrp5 and Lrp6 both of which serve as Wnt co-receptors for the canonical β-catenin pathway were decreased in HF/HS diet-fed mice. We further analyzed the role of Wnt4 of which the expression was higher in islet. Immunofluorescence staining of islets revealed that Wnt4 was highly expressed by non-β-cells located at the periphery of islets. Most of the cells strongly positive for Wnt4 were glucagon-containing cells, but not somatostatin-containing cells. Interestingly, however, the HF/HS diet feeding resulted in the up-regulation of Wnt4 expression by the β-cells. The siRNA transfection of MIN6 cells showed that the KD of Wnt4 augmented β-cell proliferation. However, glucose-induced insulin secretion was reduced by the KD of Wnt4.

Conclusion: Long-term feeding with HF/HS diet profoundly altered the expression of Wnt signaling pathway genes. In this study we further analyzed the role of Wnt4 in islets, because Wnt3a was shown to promote β-cell proliferation through the β-catenin pathway, and Wnt4 stabilizes β-catenin antagonizing the action of Wnt3a in various cells. The HF/HS diet increased the expression of Wnt4 in β-cells in which Wnt4 expression was low in mice fed standard chow. The effects of Wnt4 KD in MIN6 cells indicated that Wnt4 likely has a role in the regulation of β-cell proliferation and insulin secretion, and is involved in the impaired β-cell function in patients with type 2 diabetes.

Phenotypic characterisation of islet function in both male and female MIP-CreERT^{1Lphi} mice, a beta cell specific transgenic tool

L.I.F. Smith, T.G. HIll, P.M. Jones, J.E. Bowe;

Division of Diabetes and Nutritional Sciences, King's College London, London, UK.

Background and aims: The MIP-CreERT^{1Lphi} mouse has mouse insulin 1 promoter-driven Cre-recombinase expression, and offers the most tissue specific Cre model currently available for generating beta-cell specific gene knockouts. However, reports have described differences in beta-cell function in male MIP-CreERT^{1Lphi} mice, attributed to the expression of a human Growth Hormone (*hGH*) mini-gene in the Cre transgene cassette. hGH is capable of signalling via the prolactin receptor to increase levels of serotonin. Understanding this phenotype in both males and females is important for interpreting mouse models produced using this line. We here seek to confirm these previous findings and address whether the MIP-CreERT^{1Lphi} background influences studies of beta-cell function in female mice.

Materials and methods: Mice were split into four groups; wild type mice (WT control), tamoxifen-injected wild type mice (WT TMX), heterozygous MIP-CreERT^{1Lphi} mice (Cre control) and tamoxifen-injected MIP-

CreERT^{1Lphi} mice (Cre TMX). Tamoxifen was administered over 4 consecutive days at 6 - 8 weeks (20mg/ml, 100µl i.p.). Both an intraperitoneal glucose tolerance test (IPGTT) and intraperitoneal insulin tolerance test (IPITT) were carried out on all mice following 6 h fast. Islets were then isolated for *in vitro* assessment of glucose sensitivity, insulin content and mRNA expression of *hGH*, serotonin synthesis enzymes; Tryptophan hydroxylase 1 and 2 (*Tph1*, *Tph2*), and both anti-apoptotic and proliferative markers.

Results: TMX females displayed a trend towards improved glucose homeostasis in both WT TMX (AUC 1169±39) and Cre TMX (AUC 1240±57) groups compared to non-injected mice (AUC WT: 1337±69, Cre: 1377±56; *n*=6-9). This pattern was also weakly apparent in males. However, female Cre mice displayed significantly increased insulin sensitivity in IPITT experiments compared to WT controls (AUC WT control: 369±18 *vs* Cre control: 313±15, *P*<0.05; WT TMX: 399±23 *vs* Cre TMX: 335±12, *P*=0.06, two-way RM ANOVA, *n*=6-9). Expression of *hGH* (Male WT: 0.05±0.02, Cre: 1.6±0.5, *P*<0.05; Female WT: 0.05±0.02, Cre: 0.5±0.1, *P*<0.05, t-test), *Tph1* (Male WT: $0.7x10^{-8}$±$0.5x10^{-8}$, Cre: $4.2x10^{-8}$±$3.7x10^{-8}$, NS; Female WT: $0.6x10^{-3}$±$0.2x10^{-3}$, Cre: $9.8x10^{-3}$±$3.3x10^{-3}$, *P*<0.05, t-test) and *Tph2* (Male WT: $0.3x10^{-4}$±$0.1x10^{-4}$, Cre: $7.1x10^{-4}$±$2.8x10^{-4}$, *P*<0.05; Female WT: $1.0x10^{-4}$±$0.7x10^{-4}$, Cre: $2.9x10^{-4}$±$1.2x10^{-4}$, NS, t-test) are increased in all Cre mice compared to WT. However, mRNA levels of proliferative or anti-apoptotic markers (e.g. *Ccna2*, *Ccnd1*, *Ccne1*, *Birc5*) are not significantly altered.

Conclusion: Glucose tolerance in MIP-CreERT^{1Lphi} mice was unchanged from that of WT in males and females; however, insulin sensitivity was significantly increased in MIP-CreERT^{1Lphi} females. Pancreatic islets of MIP-CreERT^{1Lph} mice have increased expression of *hGH,* and serotonin-producing enzymes *Tph1* and *Tph2*, confirming hGH signalling by the Cre transgene. However, both male and female MIP-CreERT^{1Lphi} islets appeared to have similar expression profiles to WT mice for a range of anti-apoptotic, cell growth and proliferative factors. These data suggest that the phenotype previously identified in the male MIP-CreERT^{1Lphi} mice may be more pronounced in females. Though a mild effect, this phenotype should be considered when interpreting data from beta-cell specific transgenic mice generated using this model and the use of separate Cre and tamoxifen control groups is suggested.

Islet heparan sulfate and heparan sulfate proteoglycans in type 2 diabetes

S. Dhounchak[1], S.K. Popp[1], H. Vohra[1], T.J. Biden[2], D.R. Laybutt[2], C.R. Parish[1], C.J. Simeonovic[1];

[1]The John Curtin School of Medical Research, The Australian National University, Canberra, [2]The Garvan Institute of Medical Research, Sydney, Australia.

Background and aims: Type 2 diabetes (T2D) is a metabolic disorder characterised by insulin resistance, hyperglycaemia and lipidaemia. Endoplasmic reticulum (ER) stress, induced by insulin resistance, results in defective protein maturation and beta cell failure. Heparan sulfate (HS) is a polysaccharide normally expressed at unusually high intracellular levels in beta cells and is essential for beta cell survival. HS is synthesised directly onto core proteins, forming HS proteoglycans (HSPGs). This study examined whether (i) ER stress contributes to the loss of intra-islet HS and HSPG core proteins during T2D development and (ii) HS replacement preserves T2D beta cell viability and function.

Materials and methods: HS and HSPG core proteins (collagen type XVIII, syndecan-1 and CD44) in pancreases of wildtype (wt) and T2D-prone db/db mice at 3 to 20 weeks were examined by immunohistochemistry. Islets were isolated from wt and normoglycaemic or hyperglycaemic db/db donors (5-8 weeks) and dispersed into single cells using Accutase. The expression of ER stress-associated genes (CHOP, Bip, P58 and ATF3) were analysed by real-time RT-PCR. Intracellular HSPG core proteins and HS were examined by flow cytometry on day 0 and day 2 post-culture. Beta cell viability was assessed on day 0 and day 2 ± culture with heparin (HS mimetic; 50 µg/ml) using the fluorescent dyes calcein (Cal) and propidium iodide (PI) or Sytox Green. Db/db mice (n=8-10/group) were treated from 3.5-4 weeks of age with HS mimetic PI-88 (10 mg/kg/day i.p), TUDCA (chemical chaperone; 150 mg/kg/day i.p) or saline for 28-35 days. Non-fasting blood glucose was measured 3x/week and HbA1c levels were analysed on day 28-35. In parallel, ER stress was induced in MIN6 beta cells using thapsigargin (50 nM) and tunicamycin (2 µM). Intracellular HSPG core proteins and HS levels were examined by flow cytometry.

Results: HS and HSPG core proteins in db/db islets were reduced to 44% and 22-46% (p<0.001) of controls, respectively, by 6 weeks of age. Isolated db/db islets showed a 1.5, 4.7 and 6.3 -fold increase in CHOP, BiP (p<0.001) and P58 (P<0.001) mRNA, respectively, compared to controls. HS and HSPG core proteins in db/db beta cells were reduced to 17-37% of wt controls on day 2. Wt and db/db beta cells cultured with heparin showed a 3.5-fold and 1.8-2.8-fold increase in viable $Cal^{+}PI^{-}$ beta cells, respectively, compared to controls. Heparin-treatment reduced H_2O_2 -induced death in wt and db/db beta cells to 15% and 32-60% of controls, respectively. PI-88 treatment significantly reduced HbA1c levels in 5/10 db/db mice (5.0±0.3% vs 6.1±0.2%; P=0.02) and improved blood glucose levels; similar effects were observed after TUDCA treatment. Like beta cells, MIN6 cells treated with pharmacological ER stress inducers showed induction of ER stress genes and significantly reduced levels of HS and HSPG core proteins by day 3.

Conclusion: Diminished levels of HS and HSPG core proteins in db/db islets during the progression of T2D are consistent with ER stress effects on HSPG and HS synthesis. Treatment with HS mimetics rescued db/db beta cell viability and protected against acute oxidative damage in vitro and improved glycaemic control of db/db mice in vivo. HS mimetics acting as HS replacers may represent a new class of therapeutic for preserving beta cell survival and function in T2D.

Gata6 controls insulin biosynthesis and secretion in adult pancreatic beta cells

L. Villamayor[1], E. Rodríguez-Seguel[1], R. Araujo[1,2], M. Carrasco[1], E. Bru-Tarí[3], P. Martinelli[4,5], I. Quesada[2,3], B. Soria[1,2], F. Martín[1,2], D.A. Cano[6], A. Rojas[1,2];
[1]Centro Andaluz de Biología Molecular y Medicina Regenerativa-CABIMER, Universidad Pablo de Olavide, Seville, [2]Centro de Investigación Biomédica en Red, Diabetes y Enfermedades Metabólicas Asociadas, CIBERDEM, Madrid, [3]Universidad Miguel Hernández, Elche, [4]Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain, [5]Institute for Cancer Research, Medical Univesity of Vienna, Vienna, Austria, [6]Instituto de Biomedicina de Sevillla (Ibis)-Hospital Universitario Virgen del Rocío (HUVR), Seville, Spain.

Background and aims: Previous studies, including ours, have shown that GATA4 and GATA6 are crucial for pancreas organogenesis in both mouse and human. In mice, while single inactivation of either Gata4 or Gata6 has not impact in pancreas formation, the inactivation of both in the pancreatic primordia leads to pancreatic agenesis indicating a functional redundancy for these transcription factors during pancreas formation. Recently, GATA6 mutations have also been linked to adult-onset diabetes with subclinical or no exocrine insufficiency suggesting an important role for GATA6 in human β cell physiology. We investigate the potential contribution of GATA6 to adult ß cell function.

Materials and methods: We used Gata6 $^{flox/flox}$;Pdx1-Cre conditional knock-out and Gata6 $^{flox/flox}$ mice and performed glucose and insulin tolerance tests. Dissected adult pancreata were used to histological analysis and pancreatic insulin content. Isolated islets were used for quantitative PCR, Transmission Electronic Microscope (TEM) and insulin content analysis. We also used transgenic reporter mice in which Pdx1 regulatory sequences direct LacZ expression in adult ß cells.

Results: GATA6-deficient mice develop glucose intolerance at six month of age. We show that islets deficient in GATA6 activity display decreased insulin content and impaired glucose-induced insulin secretion. Ultrastructure micrographs of Gata6-deficient ß cells reveal a markedly reduction of mature insulin granules. In agreement, islets lacking GATA6 are defcient in the expression of in insulin biosynthesis, secretion and maturation markers. Gata6 KO ß cells display swollen mitochondrial and dilated endoplasmic reticulum (ER) cisternae in Gata6 KO ß cells, suggestive of mitochondrial and ER stress. Finally, we demonstrate that Pdx1 expression in adult ß cells depends on GATA sites in transgenic reporter mice.

Conclusion: These findings might explain the diabetic phenotype in patients harboring GATA6 mutations. Mutations resulting in decreased GATA6 expression or activity postnatally might lead to ß cell dysfunction by impairing insulin biosynthesis and secretion.

Characterising the role of the adhesion receptor GPR56 in islet development

O.E. Oladapo[1], K. Toczyska[1], S. Giera[2], X. Piao[2], P. Jones[1], S. Persaud[1];
[1]Faculty of Life Sciences and Medicine, King's College London, London, UK, [2]Children's Hospital and Harvard Medical School, Boston, USA.

Background and aims: GPR56 is an adhesion receptor that is known to regulate proliferation, apoptosis and organ development. Studies in neuronal development have indicated that it is critical for the proper formation of the cerebral cortex. Outside the CNS, GPR56 plays structural functions in seminiferous tubule development where its absence during embryogenesis leads to male infertility. It has been shown that GPR56 is highly enriched in endocrine progenitors in the developing pancreas. We have previously reported that GPR56 is abundantly expressed in islets where it regulates β-cell proliferation, but its function in islet development is not yet known. The aim of this study was to investigate the expression and function of GPR56 at different stages of islet development using GPR56 KO mice.

Materials and methods: Pregnant dams and post-natal day 9 (P9) mice were injected with BrdU (50mg/kg) intraperitoneally. Using fluorescence microscopy, GPR56 expression and its colocalisation with endocrine progenitor markers (PDX1, NGN3 and SOX9) were investigated in WT fixed-frozen pancreas sections at embryonic days E11, E13, E15, E18 and at P9. WT and GPR56 KO pancreas sections were immunoprobed for Ki67, BrdU, insulin, glucagon, and the neuronal and vascular markers TUJ1 and CD31. Immunostained images were quantified by Image J.

Results: Immunostaining revealed that GPR56 was expressed by PDX1$^+$, NGN3$^+$ and SOX9$^+$ endocrine progenitor cells. It was strongly expressed at the early days of pancreas development and became downregulated as the cells differentiated (% area GPR56$^+$ cells; E11:0.87±0.04, E13:0.85±0.06, E15: 0.36±0.08, E16: 0.15±0.05). It was then upregulated at the stage of β-cell replication (% area GPR56$^+$ cells; E18: 0.15±0.05, P9: 0.47±0.07, n=10 sections). At E16, there was an increased number of NGN3$^+$ progenitors in GPR56 KO pancreas (NGN3$^+$ cells/mm^2; WT: 3,012±211, KO: 3,880±266, n=6-12 replicates, p<0.05), suggesting reduced differentiation. However, there was no change in proliferation of progenitor cells at E16 (BrdU$^+$ cells/mm^2; WT: 475.8±44.6, KO: 448.2±18.2, n=6-12 replicates, p>0.2). The number of cells proliferating and still in the cell cycle was significantly lower in KO islets at P9 (BrdU$^+$Ki67$^+$ cells/mm^2; WT: 188.4±29.6, KO: 82.7±10.3, n=3 mice/genotype, p<0.05), leading to less β-cells (% β-cells/islet; WT: 68.5 ±0.8, KO: 54.8±3.0, n=3 mice/genotype, p<0.05), but higher numbers of α-cells in KO islets (% α-cells/islet; WT: 17.7±0.9, KO: 33.7±2.8, n=3 mice/genotype, p<0.01). There were no differences in islet capillary density (number/μm^2; WT: 0.03±0.007, KO: 0.02±0.009, n=3 mice/genotype, p>0.2) or percentage islet nerve area (WT: 0.75±0.10, KO: 0.72±0.06, n=3 mice/genotype, p>0.2).

Conclusion: Our data suggest that GPR56 is differentially expressed during mouse islet development, where it is required at key stages of proliferation and differentiation of endocrine cells. However, GPR56 is not required for islet innervation and vascularisation of the developing endocrine pancreas.

Purification of replicative pancreatic beta cells for gene expression studies

N. Tellez[1,2], R. Carballar[1], M. Canyelles[1], Y. Martí[1], E. Castaño[3], E. Montanya[1,2];
[1]IDIBELL-University of Barcelona, L'Hospitalet de Llobregat, [2]CIBERDEM, Barcelona, [3]CCiT-UB, L'Hospitalet de Llobregat, Spain.

Background and aims: β-cell proliferation is a rare event in adult pancreatic islets and varies within a range of 0.4% to 6% of β-cells per day depending on age. This low proportion of replicative beta cells precludes molecular analysis of β-cell replication-related pathways in entire islets, since it may be masked by the highly abundant post-replicative islet cells. Nucleoside analogues (ie. BrdU, CldU and IdU) have been extensively used for the identification of replicative cells. All of them require the use of DNA denaturation facilitating sterical access of antibodies to the nucleosides that may preclude downstream gene expression analysis. Alternatively, 5-ethynyl-20-deoxyuridine (EdU) is structurally similar to the natural nucleosides but its detection is based on a copper-catalysed covalent reaction between a dye-conjugated azide and the alkyne group of the EdU, known as Click chemistry. The small sized dye-azide complex allows for efficient EdU detection avoiding harsh conditions that degrade the structure of the cells. We sought to develop a method for replicative β-cells sorting based on EdU incorporation, suitable for gene expression analysis that could be used in a variety of experimental designs and species.

Materials and methods: Replicating cells were identified by EdU incorporation and Newport green in cultured rat islets. β-cell viability and replication of

islets exposed to EdU was determined by TUNEL and BrdU incorporation, respectively. For β-cell separation islet cells were sorted by size, granularity and Newport Green fluorescence emission that was combined with emitted fluorescence for EdU-labelled replicative cells sorting. The purity of the resulting sorted populations was evaluated by insulin staining and by EdU for β-cell and replicative cell identification respectively. Total RNA was isolated from purified cell-sorted populations and mRNA was linearly amplified using T7-RNA-polymerase based in vitro transcription. RNA quality was assessed in the Bioanalyzer 2100. cDNA synthesis was performed from 200ng of amplified RNA and qPCR was run in a 7900HT Fast Real-Time PCR system.

Results: β-cell viability and replication were not affected by islet exposure to EdU for 1 week in culture. However longer exposure was detrimental for β-cell viability (β-cell apoptosis in control: 0.65%±0.17%; 10μM EdU: 1.1%±0.17%; p=0.02). Accordingly, the percentage of EdU labelled β-cells at the end of the 7 day-culture was approximately 7-fold higher than the 1 day labelling with BrdU (24h-BrdU pulse: 0.51±0.08% labelling; 7 days-EdU pulse: 4.3±0.48% labelling) but a longer pulse of EdU did not result in higher percentage of labelled β-cells (14days-EdU pulse: 2.45±0.94% labelling). Cell sorting of dispersed islet cells resulted in 96.2% purity for insulin positivity in the collected β-cell fraction and 100% efficiency of the EdU-based cell separation. RNA integrity was similar between FACS-sorted replicative and quiescent β-cells. Differential gene expression analysis of replicative vs quiescent β-cells showed the expected pattern of cell cycle-related mRNAs; increased ki67, pcna, the epigenetic modulators ezh2 and bmi1, and decreased foxo1 and ins2 in replicative β-cells.

Conclusion: We have developed a method that achieves efficient purification of replicative β-cells that maintains the integrity of the RNA for downstream gene expression analysis.

A high-throughput phenotypic screen identifies selective modulators of human pancreatic beta cell proliferation for type 2 diabetes

N. Mullooly[1], S. Knight[1], A. Ramne[2], F. Chimienti[2], P. Eliasson[2], B. Isherwood[1];

[1]High Content Biology, Discovery Sciences, AstraZeneca, Cambridge, UK, [2]CVMD, Innovative Medicines, AstraZeneca, Gothenburg, Sweden.

Background and aims: Identification of novel compounds to selectively induce pancreatic beta cell proliferation has the potential to restore functional beta cell mass and insulin secretory demand in type 2 diabetes. Success has been limited due to lack of relevant cell lines for high-throughput in vitro screening and limited quantities of primary beta cells for hit validation and translational efficacy. The genetically engineered human pancreatic β-cell line, EndoC-βH1 (EndoCell) was employed to generate a high-throughput phenotypic screen to enable the identification of novel modulators of beta cell proliferation. A multiparametric high throughput high content dispersed primary islet assay was developed to facilitate detailed characterisation of hits in multicell type islet cell cultures.

Materials and methods: The EndoC-βH1 cells were shown to exhibit glucose-inducible insulin secretion and express β-cell transcription factors including PDX1 and NKX6-1 at levels similar to those in human islet cells. The newly developed HTS assay facilitated exposure to a large range of diverse chemical compounds previously unexplored in this context. An image based high throughput screen of 120K chemically diverse small molecules employed EdU incorporation and cell count end points to positively identify compounds which increase EndoC-βH1 proliferation. The hits were further profiled in pancreatic ductal cells for understanding of non-beta cell proliferative capacity. A 384-well multi-parametric dispersed primary islet assay employed EdU, insulin and Hoechst endpoints for identification of proliferating beta cell and non-beta cell sub populations and was sufficiently robust to enable concentration response data.

Results: Several chemical series were identified as robust proliferators of the EndoC-βH1 cells. Further analysis of proliferative capacity in pancreatic ductal cells facilitated prioritisation of compounds which specifically drive beta cell proliferation. The development and application of high-throughput translational primary islet assays enabled validation of hit compounds that selectively enhance beta cell proliferation and counts without effects on the non-beta cell population. Analysis of the EC50 of compounds across the EndoC-βH1 cell assay and the primary islet assay showed strong correlations of compound efficacy and potency.

Conclusion: A phenotypic screen identified novel compounds to increase pancreatic beta cell proliferative capacity. The multi-parametric concentration-response data in primary islets allowed detailed characterisation of compound efficacy and potency in ex vivo primary tissue, enabling better prediction of drug action and safety in future in vivo studies and in the clinic. The generation of concentration response curves has allowed direct comparisons of proliferative effect for compounds in primary tissue and diabetes relevant cell-lines, providing important insights into immortalised cell-line and primary cell translatability of novel targets.

Modulation of lamin isoforms expression protects from type 2 diabetes and favor beta cells biogenesis after STZ-induced type 1 diabetes

C. Chavey[1], M. De Toledo[1], I.C. Lopez-Mejia[2], P. Cavelier[1], J. Tazi[1];

[1]IGMM, CNRS, Montpellier, France, [2]Département de Physiologie, Université de Lausanne, Lausanne, Switzerland.

Background and aims: LaminA, laminC and progerin are alternative RNA processing of the *LMNA* gene. We investigated the function of laminC in aging and metabolism using mice expressing only LaminC (LCS). Intriguingly, these mice live longer, have decreased energy metabolism, increased weight gain, reduced respiration and decreased mitochondrial biogenesis. Consistently, transcriptome analysis of LCS adipose tissue reveal high variations in the expression of key regulators of energy expenditure. Interestingly, we observed that aged LCS mice are obese but remain glucose tolerant. The aim of the project is to investigate how LCS mice, that become obese under chow diet, remain protected from T2DM.

Materials and methods: All animal procedures were conducted in strict adherence with the European Community Council Directive of November 24, 1986 (86-609/EEC). Intra Peritoneal Glucose Tolerance Test, Insulin Tolerence Test, isolated islets, histological studies were all conducted on 25-weeks (young) and 75-weeks (old) old mice (n=5). T1DM was induced by one i.p. injection of Streptozotocin (STZ, 200mg/kg). Histological studies were performed on paraffin embedded pancreas and stained with either HE or by IHC using insulin, Glucagon, Phospho histone H3, Lectin antibodies or TUNEL staining. MIN6 LCS cell line was generated using CrispR/Cas9 technology. MIN6 LCS proliferation rate was monitored by Iprasense Technology. MIN6 LCS apoptosis rate was measured by FACS after AnnexinV staining.

Results: The metabolic status of young vs old LCS mice shows that old LCS mice become obese but stay more glucose tolerant because they exhibit a higher insulin secretion level than WT mice. Histological pancreas analysis of LCS mice shows an increased β cell mass since the number and the size of the islets increases in old LCS mice. Otherwise, isolated islets from old LCS mice exhibit a higher secretion capacity compared to WT isolated islets. Using the CrispR/Cas9 gene editing technology, we generated a specific expression of LaminC in the MIN6 β cell line. We confirmed that LCS MIN6 cells exhibit a higher insulin secretion in response to glucose stimulation. On the other hand, we cannot show any difference in cell proliferation or resistance to apoptosis induced by STZ, cytokine or H2O2. All these results suggest that LCS mice exhibit a better tissue-regenerative capacity. To investigate this point, we perform a STZ-induced T1DM. We show that exclusive laminC expression rescues STZ-induced diabetes since 5 weeks after STZ injection, LCS mice are normoglycemic whereas WT mice are still diabetic. In STZ-treated LCS mice we observed, using apoptosis and proliferation staining, a mild protection from apoptosis and a high number of proliferating cells including β cells duplication.

Conclusion: We demonstrate that mice expressing exclusively laminC become obese but are protected from diabetes because they develop islets

hyperplasia and have a higher insulin secretion capacity. We are now investigating, by genome wide analysis, the molecular mechanisms underlying this phenotype. Taken together, our results demonstrate that LMNA encodes functionally distinct isoforms that plays an important role on β cell plasticity.

Forced maturity in pancreatic beta cells impairs islet function

D.J. Hodson[1], D. Nasteska[1], N.H.F. Fine[1], G.A. Rutter[2], Q. Zhou[3];
[1]University of Birmingham, Birmingham, [2]Imperial College London, London, UK, [3]Harvard University, Cambridge, USA.

Background and aims: It is widely assumed that beta cell maturity is permissive for normal islet function. Indeed, type 2 diabetes (T2D) is regarded as a state of beta cell de-differentiation. However, recent RNASeq and in situ imaging studies have shown the existence of discrete beta cell subpopulations, including putative pacemakers. Using a viral strategy to "force" maturity throughout the beta complement, we sought to understand how heterogeneity may influence normal islet function and insulin release.

Materials and methods: Mouse islets were transduced with either control, adenovirus harboring a polycistronic construct for Ngn3, MafA, Pdx1 and mCherry (Ad3-NPM), or adenovirus harboring PATagRFP (Ad-PATagRFP), which encodes photoactivated TagRFP. Immunohistochemistry against Pdx1 and insulin was performed using specific antibodies and images captured using a Zeiss LSM780 confocal microscope. Gene expression was determined using QRT-PCR with SYBR Green chemistry. Islet-wide Ca^{2+} dynamics were analyzed using a Crest X-Light spinning disk head coupled to a Lumencor SPECTRA X light engine. Insulin secretion was measured by HTRF assay. All animal studies were regulated by the Home Office according to the Animals (Scientific Procedures) Act 1986 of the United Kingdom.

Results: Treatment with Ad3-NPM induced 2- and 8-fold increases in MafA and Pdx1 expression, respectively, in adult mouse islets. Ngn3 levels remained unchanged probably due to cross-repression mechanisms. Immunohistochemical analyses of Pdx1 showed that overexpression occurred preferentially in immature beta cells, forcing homogenous maturity throughout the population. Fast multicellular imaging approaches revealed sharply blunted Ca^{2+} responses to glucose and KCl (ΔF= 0.81 vs 0.44 AU, respectively; $P<0.01$), as well as a reduction in beta cell-beta cell coordination (12.0 vs 8.0 %; $P<0.05$), in Ad3-NPM-treated islets. The ensuing loss of functional connectivity was associated with a reduction in the number of hubs (12.6 vs 5.6 % hubs, Con vs Ad3-NPM, respectively; $P<0.05$), immature beta cells previously shown to act as pacemakers. Forced beta cell maturity increased basal insulin secretion, leading to impairments in glucose-stimulated insulin secretion (7.5 vs 5.0-fold, Con vs Ad3-NPM WT, respectively; $P<0.05$). Suggesting a specific role for transcription factor overexpression, Ad-PATagRFP was unable to affect Ca^{2+} fluxes, coordination indices, hub proportion or insulin secretion.

Conclusion: Loss of beta cell heterogeneity through homogenous de-differentiation (e.g. during T2D) or maturity (i.e. herein) is associated with islet failure. Thus, re-creation of subtle differences in the islet transcriptional and functional landscape- or so-called "islet identity"- may be required for the proper restoration of beta cell function during type 2 diabetes.

Pax8, a prosurvival gene in islets potentially implicated in gestational diabetes

A. Martin-Montalvo[1], L. López-Noriega[1], A. Herranz[2], L. Herranz[3], J. Moreno[2], B.R. Gauthier[1];
[1]CABIMER, Seville, [2]Thyroid Molecular Laboratory, La Paz University Hospital, [3]Endocrinology Department, La Paz University Hospital, Madrid, Spain.

Background and aims: We previously demonstrated that expression of the transcription factor PAX8 is barely to non-detectable in human islets and pancreatic neuroendocrine tumors. Notwithstanding, single nucleotide polymorphisms (SNPs) in the vicinity of the pax8 gene have been associated with Type 2 Diabetes Mellitus while expression of this factor is robustly induced in mouse islets during gestation. Thus the functional role of PAX8 in islet physiology and Diabetes including gestational Diabetes Mellitus (GDM) remains controversial. Herein we address this question by: 1) lentiviral-mediated forced expression of PAX8 in islets, 2) heterozygous deletion of the pax8 gene in mice 3) Screening for novel SNPs within the pax8 gene that may correlate with GDM in a human cohort.

Materials and methods: Islet metabolic activity (MTT assay), apoptosis, glucose-stimulated insulin secretion (GSIS) and gene expression profiling was performed on isolated islets 96 hours post PAX8 lentiviral-mediated transduction. Oral glucose tolerance test (OGTT) were performed on Pax8 heterozygous mice before and during gestation and treated or not with polyI:C (mimicking viral infection). The complete coding region of the pax8 gene was sequenced on candidates that fulfilled strict selective criteria.

Results: Islet metabolic activity was preserved subsequent to PAX8 overexpression (100% in control versus 117±35% in PAX8 over-expressing islets; $p=0.64$), consistent with unaltered GSIS (fold induction 2.65±0.4 in control vs. 2.65±0.53 in PAX8 over-expressing islets; $p=0.99$). In contrast, islet viability subsequent to isolation was significantly increased by PAX8 (100% in control versus 64±11% in PAX8 over-expressing islets; $p=0.02$), correlating with a reduced percentage of cleaved caspase 3-positive cells (17±1.6% in control versus 8.4±2.2% in PAX8 over-expressing islets; $p=0.04$). Accordingly, inflammatory signaling pathways such as interferon-gamma were significantly modulated in PAX8 overexpressing islet ($p<0.05$). Heterozygous PAX8 females treated or not with polyI:C exhibited similar OGTT at 14.5 gestation as compared to wild type mice. Notwithstanding, genetic screening in 7 families complying with the selection criteria revealed a yet uncharacterized SNP within the pax8 gene of one pedigree that correlated with GDM. This SNP generates an amino acid substitution (PAX8-T356M) within the C-terminal trans-activation domain (TAD) of PAX8. Accordingly, in silico analysis using web-based tools (PolyPhen, SIFT and PredictSNP) predicted a deleterious impact of this SNP.

Conclusion: Our data clearly demonstrate that increased expression of PAX8 impacts islet viability, an essential attribute to maintain glucose homeostasis in response to altered metabolic demand such as during pregnancy. Normal glucose tolerance during gestation in heterozygous pax8 mice might be explained by gene haplosufficiency. However, deleterious mutations within the TAD potentially resulting in a dominant negative phenotype may contribute to the pathogenesis of GDM. This premise is currently being investigated for PAX8-T356M.

Sfrp5 increases glucose-stimulated but not basal insulin secretion in rat INS-1E cells

M. Carstensen-Kirberg[1,2], K. Röhrig[1,2], C. Niersmann[1,2], M. Ouwens[1,2], B.F. Belgardt[1,2], M. Roden[1,3], C. Herder[1,2];
[1]German Diabetes Center, Düsseldorf, [2]German Center for Diabetes Research (DZD), München-Neuherberg, [3]Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany.

Background and aims: Secreted frizzled-related protein (Sfrp)5 belongs to the Sfrp family, the largest family of Wnt inhibitors. Protein and mRNA levels of Sfrp5 were downregulated in pancreatic islets from obese rodents and humans. In rodent models, Sfrp5 inactivated the canonical Wnt signaling pathway, reduced beta-cell proliferation and increased the ratio of proinsulin to C-peptide. However, the impact of Sfrp5 on insulin secretion in pancreatic beta-cells has not been analysed yet. Therefore, we aimed to investigate (i) whether Sfrp5 has an impact on cell proliferation and apoptosis, (ii) how Sfrp5 influences basal and glucose-stimulated insulin secretion and (iii) whether Sfrp5 acts via inhibiting the Wnt signaling pathway in rat beta cells.

Materials and methods: We treated rat INS-1E cells without or with (i) 1000 ng/ml or (ii) 5000 ng/ml recombinant Sfrp5 for 24h. We determined protein or mRNA levels of the proliferating cell nuclear antigen (PCNA), cyclin B1 and Ki-67 as markers for cell proliferation and cleaved caspase-3, cleaved caspase-9, B-cell lymphoma 2 (BCL2) and p53 upregulated modulator of apoptosis (PUMA) as markers for apoptosis using Western blotting and real-time PCR. To determine the effect of Sfrp5 on basal and glucose-stimulated insulin secretion we stimulated the cells with 2.5 mmol/l and 20 mmol/l glucose, respectively. The concentrations of insulin in the supernatant and cell lysate were measured by ELISA. To analyse whether Sfrp5 regulates the canonical Wnt signalling pathway we measured the protein levels of the active form of β-catenin and mRNA levels of the transcription factor 7-like 2 (TCF7L2). In addition, we determined the impact of Sfrp5 on the phosphorylation levels of cAMP response element-binding protein (CREB)-Ser133 representing an important transcriptional factor in the non-canonical Wnt signaling pathway regulating insulin production and processing.

Results: Glucose-stimulated insulin secretion was increased by 25% for 1000 ng/ml Sfrp5 (p=0.05) and by 34% for 5000 ng/ml Sfrp5 (p=0.02) compared to control, whereas basal insulin secretion was not affected at both concentrations. At 5000 ng/ml Sfrp5, protein levels of PCNA were decreased by 28% (p=0.04) and there was a trend towards a reduction of the mRNA levels of cyclin B1 by 17% and Ki-67 by 14%. Sfrp5 did not change mRNA or protein levels of cleaved caspase-3, cleaved caspase-9, BCL-2 and PUMA. Moreover, Sfrp5 neither altered the protein levels of the active form of β-catenin and mRNA levels of TCF7L2 nor the phosphorylation level of CREB-Ser133.

Conclusion: Sfrp5 increased glucose-stimulated but not basal insulin secretion without activating the canonical or non-canonical Wnt signalling pathway. While future experiments are necessary to confirm this finding in human beta cells, we report an incretin-like effect of Sfrp5 on insulin secretion in rat beta cells.

Islet heterogeneity in the healthy human pancreas

C. Ionescu-Tirgoviste[1], P. Gagniuc[1,2], E. Gagniuc[2];
[1]Department of Metabolic Diseases, National Institute of Diabetes, Nutrition and Metabolic Diseases "N.C. Paulescu", [2]University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania.

Background and aims: Previous studies related to the anatomy of the islets have been focused on the mice pancreas or the human diabetic pancreas (either from Type 1 diabetes or Type 2 diabetes patients). The spatial distribution of the islets in the human pancreas was until recently relatively unknown. Some of the obstacles have been often represented by an apparent lack of islet organization based on previous studies. The aim of our study was to find the anatomical organization of these micro-organs in a healthy pancreas.

Materials and methods: A healthy human pancreas from a 35 years male donor has been fixated and sectioned into four anatomical regions, namely the head, neck, body and the tail. These regions were further divided into a square matrix of 16 slides. Two parameters have been measured on each histological slide, namely the area and the perimeter of the islets. By using classical formulas and new algorithms for analysis, we have determined a series of parameters, such as the average value of the islet diameter, the mean islet volume, the total number of islets inside the pancreas, the total islet volume inside the pancreas, and the islet percentage from the total volume of the pancreas. 2D heat maps of the four slices have been built and analyzed.

Results: We have analyzed a total of ~5400 islets along the pancreas. The islet percentage from the total pancreas volume (45 cm^3) showed an approximate value of ~ 4.5% (~3.2 million islets). The mean islet diameter (108.92 μm (± 6.27)) and the mean islet volume (686,994.29 μm^3 ±107,297.82) have been used in conjunction with new algorithms for image analysis for the construction of four 2D heat maps. Our analysis have shown a clear cords-like structures in the organization of the islets along the pancreas. (Figure). The figure shows islet densities on four slices (red - high density of islets, blue - low density of islets). Figure reference system: the top of each slice represents the dorsal pancreas.

Conclusion: Our conclusion on the organization of the islets indicated a non-random spatial distribution. Furthermore, the spatial distribution of the islets, derived from 2D heat maps suggests cords-like structures with clear anatomical paths along the pancreas.

Morphometric analysis of stem/progenitor cell phenotypes in human diabetic pancreas

A. Zecca[1,2], C.A.M. Lagrasta[1], D. Madeddu[1], B. Lorusso[1], C. Frati[1], A. Falco[1], C. Mangiaracina[1], R. Vilella[1], R. Fioretzaki[1], F. Quaini[1], G. Graiani[1,2];
[1]University of Parma, [2]Azienda Ospedaliero-Universitaria di Parma, Parma, Italy.

Background and aims: Diabetes mellitus may represent a unique condition to estabilish whether organ pathology is primarily due to changes in the functional properties of stem or parenchymal cells or both. The variability in tissue response to chronic hyperglycaemia makes it difficult to sustain a unified hypothesis on diabetes multiorgan damage. The impairment of tissue homeostasis is still incompletely understood. The basic pathogenic process of type 2 diabetes is widely described as islet beta cell loss and dysfunction. However, a detailed tissue characterization of the human pancreas in diabetes is still lacking. In addition, we attempted to provide evidence of the hypothesis that in diabetes tissue homeostasis is compromised by alterations in progenitor cells.

Materials and methods: Our study describes structural changes in pancreas of 20 type 2 diabetic patients compared to 20 controls. Exocrine and endocrine parenchyma, and abundance and distribution of stem cell associated

phenotypes were documented in different portions of diabetic and normoglycemic pancreas.

Results: The morphometric assessment of the number and dimension of insulin or glucagon expressing islets documented a significant reduction in diabetic tissue ($p<0.05$). However, a significant increase in individual Ins ^{pos} and glucagon ^{pos} cells was observed in diabetes compared to control . Moreover, a lower dimension of endocrine islets was measured in diabetic pancreas compared to hyperglycemic tissues. Interestingly, the number and distribution of cells carrying the stem cell associated antigen c-kit ^{pos} were decreased ($p<0.05$) in diabetic pancreas compared to controls. c-kit ^{pos} cell compartment was found to be reduced in both interstitial and insular areas of the diabetic pancreas. Similarly, diabetes affected the number of individual CD34pos cells distributed throughout the pancreatic tissue. Conversely, the quantity of CD133 ^{pos} cells was unchanged in diabetic pancreas.

Conclusion: Our results suggest that changes in number of stem/progenitor cells occurs in huma pancreas subjected to diabetes. This finding may provide an innovative pathogenetic view with clinical implications.

Human islets exhibit variability in macronutrient-stimulated insulin release that cannot be explained by gross donor characteristics

J. Kolic[1], S. Skovsø[1], A.F. Spigelman[2], J.E. Manning Fox[2], J. Lyon[2], Z. Ao[3], G.L. Warnock[3], P.E. MacDonald[2], J.D. Johnson[1];

[1]Cellular and Physiological Sciences, University of British Columbia, Vancouver, [2]Pharmacology, Alberta Diabtes Institute, Edmonton, [3]Surgery, Ike Barber Human Islet Transplant Laboratory, Vancouver, Canada.

Background and aims: Type 2 diabetes (T2D) and obesity frequently occur together. The molecular mechanisms associated with the pathogenesis of these two conditions remain unclear. However, dysfunctional insulin-secreting beta cells are critical to the development and progression of both conditions. In pre-diabetes and early stage T2D, this dysfunction is associated with hyperinsulinemia. Central to this, obesity is prevented in mice that are genetically incapable of developing hyperinsulinemia. In human studies, long-term insulin therapy induces weight-gain, and drugs that reduce insulin secretion can aid in weight-loss. As such, a reduction in insulin levels may be beneficial to the metabolic health of individuals with hyperinsulinemia. This can be achieved with ketogenic diets which limit ingested carbohydrates, keeping insulin levels low. However, it is not known to what extent non-carbohydrate substrates such as lipids and amino induce insulin release, and whether individual-to-individual variations are seen in *ex vivo* human islet studies. Such variations could explain why 'low-carb' diets are only effective in a subset of individuals. Here we report dynamic insulin secretion measurements from multiple human islet donors in response to various macronutrient stimuli, and correlate these responses to islet culture time and gross donor characteristics.

Materials and methods: Human islets from 13 non-diabetic donors were from the IsletCore program (Alberta Diabetes Institute) or the Ike Barber human islet transplant laboratory (Vancouver General Hospital). Insulin secretion in response to high glucose (15 mmol/l), the amino acid leucine (5 mmol/l) or the free fatty acids oleate/palmitate (1.5 mmol/l; 1:1 mix) was measured via perfusion assay and assayed for insulin via RIA. Islet samples were flash-frozen to be used for parallel genetic, transcriptomic and metabolomic profiling.

Results: Unique human islet samples released insulin in a highly variable manner. In response to glucose (15 mmol/l), peak insulin release was 2 to 24-fold (over basal), with an average release of 10-fold. Leucine (5 mmol/l) induced peak insulin release by 2 to 21-fold (over basal), with an average release of 7-fold. Islets from 3/13 donors released insulin in response to oleate/palmitate (1.5 mmol/l; 1:1 mix) by 4 to 16-fold. We correlated the insulin response to each macronutrient stimulus with gross donor characteristics (age, sex, BMI), and the *ex vivo* culture time of the islets. No significant correlations were seen, but there was a moderate positive correlation between glucose-stimulated insulin release and BMI ($r^2=0.46$, $p=0.096$). We also examined intra-nutrient correlations and found a mild positive correlation between leucine-stimulated and glucose-stimulated insulin release ($r^2=0.29$, $p=0.056$). Ongoing studies are correlating insulin responses to genetic, genomic and metabolomic factors.

Conclusion: Our data now shows donor-donor variation in insulin release from isolated islets in response to the three main macronutrient categories. This variation could explain how macronutrient intake can have distinct effects on weight loss and diabetes risk in individuals.

CD36 is increased in human islets from obese type 2 diabetes donors, and affects beta cell function by the modulation of exocytotic proteins and insulin content

M. Nagao[1,2], J.L.S. Esguerra[1], J.K. Ofori[1], A. Wendt[1], A. Asai[2,3], H. Sugihara[2], S. Oikawa[2], C.B. Wollheim[1,4], L. Eliasson[1];

[1]Islet Cell Exocytosis, Department of Clinical Sciences-Malmö, Lund University, Malmö, Sweden, [2]Department of Endocrinology, Diabetes and Metabolism, Graduate School of Medicine, Nippon Medical School, Tokyo, [3]Food and Health Science Research Unit, Graduate School of Agricultural Science, Tohoku University, Sendai, Japan, [4]Department of Cell Physiology and Metabolism, Faculty of Medicine, University of Geneva, Geneva, Switzerland.

Background and aims: CD36 is known as a scavenger receptor involved in lipid influx and immunity. However, the role of CD36 in beta-cell function and its pathophysiological significance in type 2 diabetes (T2D) have not been fully elucidated. Our previous studies on mouse lines with different susceptibilities to diet-induced diabetes (SDG-P/R mice) demonstrated that islets from the pre-diabetic SDG-P mice have hereditary defects in insulin secretion with an increased gene expression level of CD36. Here, we aim to evaluate the expression level of CD36 in diabetic islets and to investigate the influence of CD36 on insulin secretion using clonal beta-cells.

Materials and methods: CD36 mRNA expression level in human islets was derived from RNA-seq data. Gene expression and protein levels of CD36 in the GK and Wistar rat islets were evaluated by qPCR and western blot. Insulin secretion at 16.7 mmol/L glucose for 1hr or at 50 mmol/L K^+ for 15 min, gene expression (qPCR) and protein levels (western blot) were evaluated in CD36 over-expressing INS-1 cells. CD36 over-expression was controlled by the Tet-on system using doxycycline (500 ng/mL for 72 hr).

Results: Human islets from obese donors with impaired glucose tolerance (IGT) or T2D (n=19) had an increased CD36 mRNA expression level (15%, $p<0.05$) as compared to those from obese donors with normal glucose tolerance (n=12). The GK rat islets (n=7) had increased gene expression (70%; $p<0.01$) and protein levels (25%; $p=0.085$) of CD36 as compared to the Wistar rat islets (n=8). CD36 over-expression in INS-1 cells reduced insulin secretion at 16.7 mmol/L glucose by 45% (n=5, $p<0.01$ v.s. control cells). Also, depolarization-induced insulin secretion (50 mmol/L K^+) was reduced by 25% (n=5, $p<0.01$). In agreement with the reduced depolarization-induced insulin secretion, gene expression of Snap25, Vamp2 and Syt7 (Synaptotagmin 7) was decreased by 35%, 15% and 15%, respectively (n=6, $p<0.05$ for each mRNA). Protein level of SNAP25 was decreased by 25% (n=5, $p<0.05$). Furthermore, CD36 over-expression reduced insulin content by 20% (n=5, $p<0.01$) and insulin gene (Ins1) expression by 30% (n=6, $p<0.05$).

Conclusion: CD36 was increased in pre-diabetic/diabetic islets, and over-expression in INS-1 cells reduced glucose-/depolarization-induced insulin secretion and insulin content. We suggest that CD36 causes defective insulin secretion by the reduction of exocytotic proteins and the inhibition of insulin gene expression in beta-cells. Given that the islets from T2D donors have decreased levels of exocytotic proteins and low insulin content, CD36 could be a potential therapeutic target to rescue the beta-cells in diabetic conditions.

Expression and function of Cl^- loaders, extruders and channels in pancreatic islet beta cells: implications for intracellular Cl^- regulation and insulin secretion

M. Di Fulvio[1], T. McMillen[2], S. Kursan[1], M. Bogdani[3], E. Dias-Junior[1], L. Kelly[1], L. Aguilar-Bryan[2];

[1]Pharmacology and Toxicology, Wright State University, Dayton, [2]Pacific Northwest Diabetes Research Institute, [3]Benaroya Research Institute, Seattle, USA.

Background and aims: The population with the highest risk for developing age-dependent diabetes is patients with Cystic Fibrosis (CF). Almost 50% of the cases develop diabetes by the 4th decade of life. Hyperglycemia in these patients worsens lung function and nutritional status and increases the number of hospitalizations resulting in higher mortality. Recent data suggests that patients with pancreatic insufficiency are at a higher risk to develop CF-related diabetes (CFRD) due to β-cell dysfunction. Glucose metabolism and plasma membrane depolarization are responsible for the initial secretory response in pancreatic β-cells and regulated primarily, though not exclusively, by the ATP-sensitive K^+ channel (K_{ATP}). In these cells, the intracellular chloride concentration ($[Cl^-]_i$) is kept above thermodynamic equilibrium providing an additional driving force for the depolarization and prolongation of action potentials necessary for sustained insulin secretion. In other cell types, at least seven cation-chloride co-transporters of the solute carrier protein family 12 group A (*Slc12a*) and some members of the *Slc4a* and *Slc26a* families are considered regulators of $[Cl^-]_i$. Whilst some of these transporters actively accumulate Cl^- ions, others extrude them, creating a Cl^- gradient across the plasma membrane which in turn is dissipated by functioning anion channels. The net functional balance between Cl^- loaders, extruders and channels determines whether Cl^- has a depolarizing, hyperpolarizing or no action in a given cell. The aim of this study was to systematically confirm, determine or extend the expression pattern of proteins involved in the regulation of $[Cl^-]_i$ in mammalian β-cells and to determine their role in the secretory response.

Materials and methods: We have used conventional and quantitative RT-PCR, Western blotting and immunolocalization studies in human and rodent pancreatic islets and clonal β-cell lines and available pharmacological tools to identify Cl^- transporters and channels involved in the secretory response.

Results: Insulin-secreting β-cells express *Slc12a1* and *Slc12a2* the prototypical Cl^- loaders, the Cl^- extruders *Slc12a4*, several splice variants of *Slc12a5, Slc12a6* and *Slc12a7* and channels such as *Cftr*, *Ano1, Ano2* and all the subunits of the volume-regulated anion channel *Vrac i.e.*, *Lrrc8a*, *Lrrc8b*, *Lrrc8c*, *Lrrc8d* and *Lrrc8e*. Treatment of β-cells with the diuretic bumetanide, inhibitor of *Slc12a1* and *Slc12a2* or with ML077, a recently developed selective inhibitor of *Slc12a5*, blocks or stimulates, respectively, insulin secretion in response to glucose. The stimulation of the secretory response observed upon inhibition of *Slc12a5* with ML077 did not require K_{ATP}-channels, as the effect still occurred in the presence of glibeclamide, but it was reduced by the addition of $CFTR_{inh172}$ and Ani9, inhibitors of *Cftr* and *Ano1/Vrac*, respectively.

Conclusion: Our experiments suggest that insulin-secreting β-cells tightly maintain an outwardly directed Cl^- gradient and that impairing its dissipation through inhibition of *Cftr, Ano1* and *Vrac* blunts insulin secretion in response to glucose.

Chronic fructose potentiates insulin secretion from beta cells through intra and extracellular ATP signalling mediated respectively by AMPK and P2Y receptors

T. Brun[1,2], C. Bartley[1,2], L. Oberhauser[1,2], M. Grimaldi[1,2], F. Molica[3], B. Kwak[3,4], D. Bosco[2,5], M. Chanson[1,6], P. Maechler[1,2];

[1]Cell Physiology and Metabolism, University of Geneva Medical Center, [2]Faculty Diabetes Center, University of Geneva Medical Center, [3]Pathology and Immunology, University of Geneva Medical Center, [4]Cardiology, Geneva University Hospital, [5]Cell Isolation and Transplantation Center, Surgery, Geneva University Hospital, [6]Pediatrics, Geneva University Hospital, Geneva, Switzerland.

Background and aims: Fructose massively appeared as a sweetener additive in the Western diet in the late 70's, preceding the high incidence of obesity and type 2 diabetes. In the hypothalamus, a major intracellular effect of chronic exposure to fructose is energy-sensing alterations mediated by AMPK activation. In pancreatic beta-cells, AMPK is activated in conditions of nutrient deprivation and renders the cell more sensitive to glucose. Although fructose *per se* does not acutely stimulate insulin exocytosis, we investigated the effects of chronic exposure to fructose in standard culture medium on beta-cell function.

Materials and methods: INS-1E beta-cells or freshly isolated human islets and islets from WT or pannexin1 knockout mice were exposed for 4 days to 5.5 mM fructose in their respective standard medium. At the end of this pre-

treatment period, we measured AMPK phosphorylation, mitochondrial respiration, intracellular ATP, calcium levels and insulin secretion. We performed immunodetections of KIR6.2, pannexin1 channels and the calcium-mobilizer purinergic P2Y1 receptor.

Results: Chronic exposure of INS-1E beta-cells, WT mice and human islets for 4 days to fructose induced AMPK phosphorylation (1.6-fold, $p<0.05$) and exaggerated insulin secretion in response to intermediate 8.3-11 mM glucose (1.6-fold, $p<0.05$). Correlating with AMPK activation, fructose pre-treatment in INS-1E beta-cells reduced intracellular ATP levels (-30%) without affecting mitochondrial respiration and caused translocation of KIR6.2 to the cell membrane. Stronger plasma membrane depolarization and faster cytosolic calcium oscillations were observed in the fructose-treated cells. Importantly, fructose exposure increased by 30% INS-1E extracellular ATP under stimulatory glucose conditions. This cellular ATP release, potentially mediated by pannexin1 channel, may activate purinergic P2Y receptors. Immunoblot and immunofluorescence analyses showed the presence of pannexin1 and P2Y1 in INS-1E cells and islets. Addition of the ecto-ATPase inhibitor ARL67156 or the P2Y agonist 2MeSADP to naive INS-1E cells and mouse or human islets potentiated insulin secretion stimulated by intermediate glucose, mimicking fructose pre-treatment. Conversely, the pannexin1 inhibitor mefloquin and the P2Y1 antagonist MRS2179 reversed the potentiated secretory response induced by fructose in INS-1E cells and human islets. These results were confirmed using Panx1-KO islets. Moreover, clearance of extracellular ATP and ADP by apyrase also inhibited fructose-potentiating effects.

Conclusion: Fructose treatment induced intracellular starving-like phenotype in INS-1E beta-cells and islets, resulting in AMPK activation and potentiation of intermediate GSIS. This effect was mediated by activation of purinergic P2Y receptors through increased release of cellular ATP by pannexin1 channel.

At low glucose arginine stimulates and sulfonylureas or K^+ depolarisation inhibit glucagon secretion by perifused mouse islets

E.-H. Frueh, I. Rustenbeck;
Institute of Pharmacology and Toxicology, TU Braunschweig, Braunschweig, Germany.

Background and aims: Like pancreatic beta-cells pancreatic alpha-cells release their peptide hormone by depolarization-triggered exocytosis and both alpha- and beta-cells express KATP channels. However, the sulfonylurea gliclazide has been described to directly inhibit glucagon release, which might explain its more favorable clinical results as compared to other sulfonylureas. Here, we have investigated the role of depolarizing stimuli and glucose on the interaction between alpha- and beta-cells within isolated islets.

Materials and methods: Batches of 50 freshly isolated NMRI mouse islets were perifused with a HEPES-buffered Krebs-Ringer medium (2 mg/ml BSA) saturated with 95% O_2 and 5% CO_2, which contained the respective secretagogues. The contents of insulin and of glucagon were determined by ELISA (Mercodia) from the same samples of the fractionated efflux.

Results: Decreasing the glucose concentration after 60 min of perifusion with 10 mM glucose to 1 mM led to a transient increase of glucagon secretion before the insulin secretion was diminished. Raising subsequently the glucose concentration from 1 to 30 mM increased the insulin secretion before the glucagon secretion was diminished. In the presence of 1 mM glucose 20 mM arginine had a moderate stimulatory effect on glucagon secretion but not on insulin secretion. Adding either 30 μM gliclazide or 500 μM tolbutamide or 15 mM KCl to the perifusion medium increased insulin secretion before it diminished glucagon secretion. The combined action of 20 mM arginine and 30 μM gliclazide in the presence of 1 mM glucose led to a simultaneous increase of glucagon and insulin release. This increase was modest and transient for glucagon, whereas the insulin secretion remained moderately elevated after an initial peak. Adding 1 μM of the α_2-adrenoceptor agonist clonidine in the continued presence of arginine and gliclazide suppressed insulin secretion and at the same time markedly increased glucagon secretion.

Conclusion: Stimulated secretion of glucagon appears to be an autonomous function of the alpha-cells, which can be abrogated by the paracrine effect of concomitantly stimulated insulin secretion. α_2-Adrenoceptor agonism inhibits insulin but not glucagon secretion. There is no evidence for a direct inhibitory effect of gliclazide on glucagon secretion.

Disclosure: **E. Frueh:** None.

Inhibition of fatty acid synthase impairs insulin secretion in islets from mice fed both a normal and high-fat diet

J.I. Real[1], C. Miranda[1], S.S. Ahmadi[1], P. Rorsman[1,2];
[1]Department of Physiology, University of Gothenburg, Gothenburg, Sweden, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Churchill Hospital, Oxford, UK.

Background and aims: NADPH is an important player in the antioxidant system. It has been proposed to be a mediator in glucose-stimulated insulin secretion in amplifying pathway from pancreatic β-cells. Here we investigate if secretory capacity is correlated with the redox state of the β-cells within intact islets. To address this we measured the acute effect of a FAS (fatty acid synthase) inhibitor - C75 - on insulin secretion, both in chow- and high fat diet (HFD)-fed mice and electrical activity.

Materials and methods: Insulin secretion was measured in isolated islets from chow and HFD (60% fat for 8 weeks) mice with or without C75 (150 μM), at 1 and 11 mM glucose. The membrane potential was recorded in the presence of 11 mM glucose from microdissected mouse islets, using high-resistance microelectrodes, at 11 mM glucose.

Results: C75 reduced insulin secretion at 11 mM glucose by >80 % ($p<0.001$) in both chow and HFD islets; basal insulin secretion was not affected by C75. These results show that FAS inhibition has similar effects under normal and diabetogenic (HFD) conditions in pancreatic β-cells. C75 hyperpolarized (20%; i.e. made more negative) the membrane potential during the inactive phase of the oscillatory electrical activity evoked by 11 mM glucose ($n=4$, $p<0.001$), an effect that peaked at 10-12min. Burst duration (active phase), increased burst frequency (+28%) and reduced the duration of the silent intervals between two successive bursts (-26%). In addition, C75 decreased spike amplitude as well as the threshold by 25% ($n=4$, $p<0.001$) and 17% ($n=4$, $p<0.05$), respectively. The latter parameter reflects a reduction in voltage threshold for action potential firing. Rather different results were obtained upon application of NADPH (150 μM), which increased the interburst potential by 13% ($n=4$, $p<0.001$) and increased burst duration by 45% without affecting the burst frequency or action potential amplitude.

Conclusion: These data are in agreement with the observation that C75 and NADPH have opposing effects on insulin secretion. These results suggest that the metabolic balance in β-cells 'jumps' between FAS and β-oxidation. By inhibiting FAS, pancreatic β-cells become less electrically active which lead to a decrease in insulin secretion. Our observations suggest that FAS inhibition has a deleterious effect on β-cell electrical activity and insulin secretion.

Dual amylin and calcitonin receptor agonists exert direct peripheral effects on beta cells, muscle and adipose tissue contributing to their beneficial effects on metabolism

K. Henriksen, S. Gydesen, A.T. Larsen, K.V. Andreassen, M.A. Karsdal;
Nordic Bioscience, Herlev, Denmark.

Background and aims: Dual amylin and calcitonin receptor agonists (DACRA) are novel candidates for treatment of obesity and type 2 diabetes due to their impressive effects on body weight, glucose control and insulin sensitivity. However, the mechanisms behind the DACRA-mediated metabolic improvements are unclear. Here we investigate in which tissue the DACRAs, KBP-042 and KBP-089, have direct effects

using a combination of in vivo activation and ex vivo cultures of healthy and diabetic adipose tissue, as well as pancreatic islets.
Materials and methods: To investigate DACRA mediated tissue activation in vivo, rats were treated with a single subcutaneous dose of KBP-042 (5 μg/kg) followed by collection of metabolic tissue and analysis of signaling pathways by western blot. To investigate whether DACRAs directly mediated secretory function of the pancreatic islets, we used isolated islets from healthy adult rats. The effect of various KBP-042 concentrations (0.1, 1, 10 and 100 nM) were tested on glucose stimulated insulin secretion (GSIS) and arginine induced insulin secretion (ASGS) in freshly isolated islets and islets, which were cultured under glucolipotoxic conditions (GLTX) (22 mM glucose and 500 μM palmitate) with islets cultured in 5.5 mM glucose media as controls. To explore whether DACRAs had direct effect on metabolic activity in adipose tissue, epididymal and perirenal fat pads were surgically removed from lean rats treated with cultured in the presence of KBP-089 and oxidation was measured using Alamar Blue.
Results: Administration of KBP-042 (5 μg/kg) acutely activated Akt signaling in both muscle and epididymal adipose tissue in vivo. We did not observe any differences in Erk and STAT3 signaling activation in muscle and adipose tissue from rats treated with KBP-042. KBP-042 dose-dependently reduced GSIS and ASGS in freshly isolated islets. In the islets cultured under glucolipotoxic conditions, GSIS was significantly attenuated compared to the islets cultured in normal control media. Impressively, KBP-042 was able to preserve the secretory function of the GLTX islets when co-cultured for 24 hours. The GSIS was dose-dependently higher in the islets, which had KBP-042 present during culturing. Finally, KBP-089 significantly increased the metabolic activity in both perirenal and epididymal adipose tissue, hence indicating an increased energy expenditure.
Conclusion: In conclusion, we show that KBP-042 preserves the secretory function in GLTX cultured islets. Furthermore, KBP-042 acutely activates Akt signaling in muscle and epididymal adipose tissue, indicating a beneficial metabolic effect of KBP directly in metabolic tissues, and finally, that KBP-089 might have a direct effect on mitochondrial oxidation. Thus, KBP-042 directly mediates activation in metabolic tissues and directly modulates pancreatic islets, which is highly promising and warrants for further studies.

Effect of ARHGAP21 reduction upon glucose-insulin homeostasis and body composition of diet-induced obesity in C57BL/6 mice

G.M. Soares[1], L. Zangerolamo[1], E.G. de Azevedo[1], S.O. Saad[2], A.C. Boschero[1], H.C. Barbosa-Sampaio[1];
[1]Department of Structural and Functional Biology, University of Campinas, [2]Haematology Centre, University of Campinas, Campinas, Brazil.

Background and aims: GTPase activating proteins (GAP) seems to impact glucose-insulin homeostasis. Inhibition of GAP ARHGAP2 in pancreatic islet from neonate mice, improves pancreatic beta cell function. However, the possible role of ARHGAP21 in glucose homeostasis remains unknown. Here we used an ARHGAP21 haplodeficient mice, aiming to explore the involvement of ARHGAP21 in glucose-insulin homeostasis.
Materials and methods: 30 days old C57BL/6 mice, controls and ARHGAP21 haplodeficient mice were fed on chow diet (Ctl and Het) or a high-fat diet (Ctl-HFD and Het-HFD) during 10 weeks. We analyzed body composition considering body weight gain during all experimental period and also measuring perigonadal fat content after euthanasia. We also evaluated the glucose-insulin homeostasis through glucose and insulin tolerance test, as well as assessing fasted glycemic and insulinemic levels. Further, we analyzed the pancreatic islet function and morphology focuses on pancreatic beta cell insulin secretion and size. To analyze the data we used the Student´s t-test. Data are mean ± SEM, and the difference between the groups were considered statistically significant if $P \leq 0.05$.
Results: We did not observe any difference between the Ctl and Het animals fed on chow diet. As expected, Ctl-HFD mice developed the deleterious effects inherent in the consumption of the high fat diet. Interestingly, Het-HFD animals did not become obese (34,96 g ± 0,83 Ctl-HFD x 28,93 g ± 1,07 Het-HFD) and had less accumulation of fat deposits (4,58 % body weight ± 0,25 Ctl-HFD x 2,66 % body weight ± 0,54 Het-HFD), which probably contributed to lower insulinemia of fasting (0,75 ng/μL ± 0,11 Ctl-HFD x 0,37 ng/μL ± 0,09 Het-HFD), insulin sensitivity (1,46 kITT ± 0,36 Ctl-HFD x 3,83 kITT ± 0,78 Het-HFD) and glucose tolerance (30194 AUC ± 1727 Ctl-HFD x 24111 AUC ± 1381 Het-HFD). As no compensation was required for the pancreas, these animals had lower insulin secretion (0,93 ng/μL ± 0,08 Ctl-HFD x 0,65 ng/μL ± 0,03 Het-HFD) and lower beta cell area (2470 square μm ± 64 Ctl-HFD x 1268 square μm ± 114 Het-HFD).
Conclusion: Taken together, our study indicates a possible role of ARHGAP21 in whole body metabolism, impacting on body weight gain, as well as glucose-insulin homeostasis in high fat diet-fed mice. The data suggest that GAP protein member as a potential candidate to prevent and treat obesity and related diseases.

The effect of islet culture on the biphasic pattern of fuel-induced insulin secretion

M. Morsi, T. Schulze, K. Reckers, I. Rustenbeck;
Institute of Pharmacology and Toxicology, University of Braunschweig, Braunschweig, Germany.

Background and aims: The insulin secretion pattern by mouse islets is reported to differ from that of human and rat islets in that a strong first phase is followed by an elevated plateau instead of a slowly ascending second phase. This has led to the argument that mouse islets or beta cells may not be a good experimental model. Here, we have tested the role of islet culture on shaping the kinetics of insulin secretion.
Materials and methods: Mouse islets were isolated by collagenase digestion and selected by hand-picking. The culture duration was 22 h in RPMI 1640 with 10% FCS. The glucose concentration was 5 mM throughout. The kinetics of secretion was measured by islet perifusion and ELISA of the fractionated efflux. The kinetics of the cytosolic Ca^{2+} concentration and of the NAD(P)H- and FAD-autofluorescence were measured by epifluorescence microscopy of perifused islets.
Results: Raising the glucose concentration from 0 to 30 mM produced a modest initial increase in insulin secretion (from 11 to 24 pg x $islet^{-1}$ x min^{-1}) of freshly isolated islets, which was followed by a continuous increase up to 95 pg x $islet^{-1}$ x min^{-1}. Using the same protocol with cultured islets 30 mM glucose generated a marked first phase (70 pg x $islet^{-1}$ x min^{-1}) which after 15 min receded back to a moderately elevated plateau (27 pg x $islet^{-1}$ x min^{-1}). When 10 mM α-ketoisocaproic was the stimulus, fresh islets responded with a prompt, strong and sustained secretion, whereas cultured islets generated a pattern which closely resembled that of 30 mM glucose. The kinetics of the NAD(P)H/FAD- autofluorescence differed in that the NAD(P)H-increase but not the FAD-decrease by 30 mM glucose occurred about 5 min earlier and was significantly larger in cultured islets, but the overall pattern was unchanged by the cell culture period. Similarly, the modest increase of the NAD(P)H/FAD- autofluorescence by KIC was markedly enhanced in cultured islets, but retained its overall pattern, in particular the sluggish decrease upon wash-out. Finally, $[Ca^{2+}]_i$ measurements showed that the resting values were lower after culture, but the square wave increase upon glucose

exposure and wash-out was visible with both, freshly isolated and cultured islets.
Conclusion: Since freshly isolated mouse islets show an ascending second phase with glucose and a fast and strong initial response with KIC, the uniform response pattern with a plateau after a marked first phase is shaped by the cell culture period. Cell culture may not simply relieve the stress of collagenase isolation but also leaves an imprint on the metabolic memory of the beta cell. The effect on the secretion kinetics is not reflected by the parameters of oxidative phosphorylation and $[Ca^{2+}]_i$ and may therefore be mediated by the signals of metabolic amplification.

Formation of peudoislets induces incretin responsiveness in incretin-unresponsive clonal beta cells: possible role of an amino acid transporter

N. Yokoi, M. Hashim, G. Gheni, H. Takahashi, S. Seino;
Division of Molecular and Metabolic Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.

Background and aims: Cell-to-cell interactions between pancreatic beta cells are essential for normal regulation of insulin secretion. We previously found that incretin responsiveness was induced by formation of pseudoislets (PIs) in otherwise incretin-unresponsive monolayer-cultured cells (MCCs). In this study, we tried to elucidate the mechanism of the induction of incretin responsiveness in PIs.
Materials and methods: PIs were formed from incretin-unresponsive mouse clonal beta cells (MIN6-K20) by seven-day culture on ultra-low attachment dishes. We examined morphology, contents of ATP, cAMP and insulin, and insulin secretion, and also performed RNA sequencing and metabolome analysis. We evaluated the effect of oxamic acid (OA), an inhibitor of the malate-aspartate shuttle, on glutamate production and insulin secretion. We also examined a possible role of amino acid transporters in insulin secretion from MCCs and islets of ob/ob mice, an animal model of obesity and diabetes.
Results: PIs showed well-developed mitochondria and increased contents of cellular metabolites, ATP, cAMP, and insulin. Both GLP-1 and GIP did potentiate insulin secretion from PIs in a concentration-dependent manner. OA treatment inhibited glutamate production by glucose and abolished incretin/cAMP-induced insulin secretion. Expression of a neutral amino acid transporter was markedly up-regulated in MCCs while it was down-regulated in PIs. Inhibition of the transporter increased cellular glutamate content and induced incretin responsiveness in MCCs. The inhibition also increased incretin-induced insulin secretion from islets of ob/ob mice.
Conclusion: Our study indicates that increased cellular metabolism by formation of PIs confers incretin responsiveness, in which down-regulation of an amino acid transporter contributes to the accumulation of cellular glutamate.

The selective serotonin reuptake inhibitor fluoxetine improves glucose homeostasis by promoting insulin secretion and maintaining functional beta cell mass

B. Liu[1], I. Ruz-Maldonado[1], M.G. Zariwala[2], G.C. Huang[1], M. Zhao[1], P.M. Jones[1], S.J. Persaud[1];
[1]Division of Diabetes and Nutritional Sciences, King's College London, [2]Faculty of Science and Technology, University of Westminster, London, UK.

Background and aims: Management of depression using the serotonin reuptake inhibitor fluoxetine has been reported to cause reductions in plasma glucose and glycated haemoglobin that are independent of changes in food intake and body weight. Fluoxetine reaches steady state concentrations in plasma of approximately 2μM. Its use at concentrations up to 75μM is reported to be cytotoxic in β-cell lines *in vitro*, but there is no information on whether physiologically relevant concentrations of fluoxetine play a role in regulating β-cell function and glucose homeostasis. This was investigated in the current study.
Materials and methods: MIN6 β-cells or isolated mouse islets were exposed to increasing concentrations of fluoxetine (0.1μM-10μM) for 24-72h. Cell viability was assessed by ATP quantification, β-cell proliferation was determined by quantifying BrdU incorporation and islet cell apoptosis was examined by measuring caspase 3/7 activities. Dynamic insulin secretion was quantified by radioimmunoassay after perifusion of isolated mouse and human islets in a physiological salt solution in the absence or presence of 1μM fluoxetine. In *in vivo* experiments, ob/ob mice were administered 4 doses of fluoxetine (10mg/kg body weight) or DMSO (vehicle) intraperitoneally over the course of 2 weeks prior to being subjected to intraperitoneal glucose tolerance tests following a single administration of glucose (2g/kg body weight) in the presence of fluoxetine or DMSO.
Results: While 24h exposure to 10μM fluoxetine significantly reduced ATP synthesis (control: 4,538,119±193,788 luminescence units; +10μM fluoxetine: 154,230±18,935 n=5; P<0.01) β-cell viability was not compromised by 0.1 and 1μM fluoxetine, even after incubation for 72h (0.1μM fluoxetine: 4,521,279±134,752; 1μM fluoxetine: 4,410,727 ±115,886; n=5; P>0.5). In perifusion experiments 1μM fluoxetine induced rapid and sustained potentiation of glucose-induced insulin secretion from mouse (AUC: 20mM glucose: 654±78; +1μM fluoxetine: 1202 ±108; n=4; P<0.05) and human (AUC: 20mM glucose: 1320±17; +1μM fluoxetine: 2567±73; n=4; P<0.01) islets. Furthermore, 1μM fluoxetine induced a 1.10±0.03 fold increase in BrdU incorporation (n=10; P<0.05) in MIN6 β-cells and a 38±9% reduction in caspase 3/7 activities in mouse islets (n=8; P<0.01). *In vivo* experiments indicated that intraperitoneal administration of fluoxetine improved glucose handling in ob/ob mice (blood glucose concentrations, control vs fluoxetine; T=0: 6.7±0.8mM vs 6.5±0.5; P>0.5; T=210min: 36.3±8.5mM vs 16.5±2.4; P<0.05; n=5).
Conclusion: These data demonstrate that physiologically relevant concentrations of fluoxetine are well tolerated by β-cells *in vitro* for at least 72 hours. Acute exposure to fluoxetine stimulated insulin secretion, increased β-cell proliferation and reduced apoptosis, while delivery to mice *in vivo* improved glucose tolerance. These data are consistent with a role for fluoxetine in regulating glucose homeostasis through direct effects at β-cells. Repurposing of fluoxetine thus represents a novel therapeutic strategy for the management of type 2 diabetes.

Mechanotransduction is involved in glucose-stimulated insulin secretion

Y. Ye, M. Barghouth, E. Zhang, E. Renström;
Lund University, Malmö, Sweden.

Background and aims: The consensus model for glucose-stimulated insulin secretion is incomplete, ion channels other than the K_{ATP} channel are needed for generating the glucose-dependent depolarization. Several reports indicate that glucose stimulation causes a slight increase in beta cell volume. Cell swelling increases membrane tension and such a mechanical signal can be transduced into electrical signals by mechanosensitive ion channels. Piezo1 and 2 were discovered as a new class of mechanosensitive channels and non-selectively allow passage of Ca^{2+}, K^+ and Na^+, which generates an overall depolarizing effect. These channels could provide the ion conductance missing in the beta-cell consensus model. Here we have explored the role of mechanotransduction in insulin secretion.
Materials and methods: RNA sequencing; qPCR; Western blot; ELISA; Ca^{2+} imaging
Results: PIEZO1 exhibited 20% increasingly altered expression in islets from individuals with known type 2-diabetes (T2D) (among the 7.6% most differentially expressed genes, p=0.012; non-diabetes: n=114, diabetes: n=17). PIEZO1 positively associated with INSULIN (R^2=0.33, p=6.1e-13, n=131). The mRNA expression level of Piezo1 in db/db mice showed similar tendency by increasing 82% (WT: 0.034 vs db/db: 0.062, p<0.05, n=5, 3, respectively). In contrast, prolonged (48h) glucose treatment in INS-1 832/13 cells significantly decreased the expression of Piezo1 by 65% comparing with 2.8 and 20mMG treatment (2.8mMG: 100%, 5mMG: 80.19%, 10mMG: 43%, 20mMG: 34%, n=3), as well as the protein level (2.8mMG: 1.2, 5mMG: 0.9, 10mMG: 0.7, 20mMG: 0.5, n=5). Insulin secretion was markedly inhibited in Piezo1-silenced cells (NC: 359 vs KDp1: 199, p <0.05, n=4), but not when Piezo2 was silenced (NC: 359 vs KDp2: 350, n=4). Piezo1-agonist Yoda1 (25 μM) stimulated insulin secretion at basal (2.8mMG; DMSO: 32.5 vs Yoda1: 64.7 ng insulin /mg protein /h, p<0.001) and stimulated conditions (16.7 mMG; DMSO: 318.4 vs Yoda1: 527.2 ng /mg /h, p<0.05, n=7). Percentage of secreted insulin was significantly suppressed by Piezo1 inhibitors at basal (2.8mMG; untreated: 0.57% vs GsMTx4: 0.4%, p<0.01, Ruthenium Red: 0.3%, p<0.0001) and stimulated conditions (16.7mMG; untreated: 5.9% vs GsMTx4: 3%, p<0.05, RR: 3.2%, p<0.05). Silencing of Piezo1 did not affect depolarization-evoked Ca^{2+} signaling (peaks; NC: 4.4 vs KDp1: 4.5, n= 29), when stimulated using a high-K^+ solution of the same osmolarity. By contrast, glucose-stimulated Ca^{2+}-signals were impaired by Piezo1 knockdown (glucose AUC; NC 829 vs KDp1: 642, p<0.0001, n= 46). Piezo1- agonist Yoda1 stimulated Ca^{2+} signals significantly (peaks; DMSO: 1.44 vs Yoda1: 2.58, p<0.0001, n=61).
Conclusion: We explore the involvement of mechanotransduction in the stimulus-secretion coupling of the pancreatic beta cell. Our findings suggest that: 1) Piezo1 current contributes to the basal depolarizing tone, in particular in INS-1 832/13 cells that have modest K_{ATP} currents and exhibit spontaneous action potentials also at basal glucose; 2) Piezo1 is part of the nutrient-sensing machinery of the beta-cell. These results rectify many of the shortcomings of the established consensus beta-cell model and offer strong support for mechanotransduction playing an important role in glucose stimulated insulin secretion, as well as being involved in determining the risk for T2D. Further experiments are underway to find the reason of upregulation of PIEZO1 expression in T2D and explore the regulation network of PIEZO1.

Knockdown of beta1-integrin affects exocytotic proteins and integrins expression in pancreatic beta cells

J. Li, R. Wang;
Physiology and Pharmacology, The University of Western Ontario, London, Canada.

Background and aims: The β1-integrin receptor provides a physical basis for cell-cell and cell-ECM contact and influences cell differentiation, migration, proliferation, function, and survival. *In vitro* functional blockade of β1-integrin results in inhibition of islet cell adhesion, islet architecture disruption, and a significant increase in islet cell death in both human and rodent systems. Mouse models of conditional postnatal β1-integrin deficiency in collagen I producing cells (β1KO) or beta-cells (MIPβ1KO) demonstrated a significant reduction in beta-cell mass with impaired glucose tolerance and insulin secretion. However, the role of beta-cell β1-integrin in the recruitment of exocytotic molecules that are required for insulin release and trafficking of other integrins expression remains to be determined. The aim of the current study is to examine whether loss of β1-integrin in beta-cells influences exocytotic protein recruitment and integrin expression in β1-integrin KO islets and cultured INS-1 cells.
Materials and methods: Adult pancreata and islets (10-12 weeks of age) were collected from both inducible β1KO or MIPβ1KO mice and their counterpart wild-type (WT) littermates. INS-1 cells were cultured on matrix-coated plates with or without an immunoneutralizing β1-integrin antibody treatment. Expression of exocytotic molecules and integrins in the islets and INS-1 cells were analyzed by quantitative RT-PCR and immunofluorescence.
Results: Both β1KO and MIPβ1KO mice displayed impaired glucose-stimulated insulin secretion (GSIS) and a concomitant reduction in Munc18-1, Snap25, and Vamp2 mRNA and protein levels, suggesting an important role for β1-integrin in the regulation of insulin exocytotic machinery. β1KO and MIPβ1KO islets also showed lower levels of α6 and αV integrins on beta-cell membranes compared to WT islets, and, since both α subunits are associated with β1 and other β subunits, indicates that integrin expression and trafficking to the plasma membrane may depend on exocytotic machinery. INS-1 cells cultured on matrix proteins had high adhesion to collagen I and IV matrices and increased exocytotic proteins expression, which correlated with enhanced insulin secretion at basal and GSIS. Blocking β1-integrin decreased INS-1 cell adhesion to the collagen I matrix and reduced the expression of Munc18-1 and SNARE proteins along with other integrins, resulting in significantly lower insulin secretion following GSIS.
Conclusion: We have found that beta-cell β1-integrin deficiency causes dysfunctional insulin secretion that is associated with the impaired recruitment of exocytotic proteins and other integrins. This observation suggests that β1-integrin on beta-cells is a crucial regulator of the exocytotic machinery, integrin expression and trafficking.

Role of StarD10 in beta cell physiology

G. Carrat[1], E. Haythorne[1], P. Chabosseau[1], D.J. Hodson[1,2], A. Tomas Catala[1], G.A. Rutter[1];
[1]Medicine, Imperial College London, London, [2]Institute of Biomedical Research, University of Birmingham, Birmingham, UK.

Background and aims: Risk alleles in the *STARD10* locus, associated with type 2 Diabetes (T2D), impair glucose-induced insulin secretion and are associated with decreased proinsulin:insulin ratios. We have recently shown that the T2D risk associated with variation at this locus was most probably mediated through reduction in *STARD10* expression in the β-cell. Here we investigate the mechanisms by which STARD10 could affect insulin secretion.
Materials and methods: Islets were isolated from StarD10$^{fl/fl}$-ins1-cre male mice (β*StarD10*KO). Electrophysiology was performed in perforated patch-clamp configuration, on dissociated islets. Correlation analysis of Ca^{2+} signalling was performed using a Pearson R coefficient. Transmission Electron Microscopy (EM) images were obtained from isolated islets after chemical fixation and sectioning using an ultramicrotome.

Results: We have previously shown a decrease in calcium signals induced by glucose in isolated islets of β*StarD10*KO. However, current clamp recordings of isolated β-cell from these animals showed no change in the membrane potentials in response to 3 and 17 mM glucose addition, compared to WT littermates (n=2 mice/genotype). We observed similar levels of cell-cell coordination as measured by correlation analysis of Ca^{2+} signalling in presence of 3 or 17 mM glucose or 10mM KCl. Interestingly, Transmission electron microscopy images of β-cell isolated from β*StarD10*KO mice exhibited altered dense core granule appearance. These animals showed a significant increase in granules showing a rod like structure (WT: 3.5 vs. KO: 13.5 % total granules; $p<0.5$) coupled with a reduction in granules showing the usual dense core, when compared to the WT littermates (WT: 84.2% vs. KO: 72.2%; $p<0.5$).
Conclusion: These data indicate a role of StarD10 in normal insulin crystallisation and granule dense core formation, potentially responsible, at least in part, for the defect in insulin secretion previously observed in islets of β*StarD10*KO mice. The rod like structure in the granules is reminiscent of the phenotype observed in *ZnT8*KO mice, suggesting a potential regulation of Zn transport by STARD10.

The HDAC inhibitor MC1568 rescues Hdac7-induced beta cell impairment by improving mitochondrial function
K. Bacos, M. Daneshpajooh, C. Ling;
Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: It is becoming increasingly clear that epigenetics contribute to beta-cell dysfunction in type 2 diabetes (T2D). For example, we recently showed that HDAC7 is upregulated in human pancreatic islets from donors with T2D, and overexpression of Hdac7 in rat islets and clonal beta-cells impaired insulin secretion and cell survival. We could further show that treating Hdac7-overexpressing cells with the HDAC inhibitor MC1568, or co-transfecting the cells with a siRNA targeting Hdac7, rescued the secretory impairment. These findings support the development of HDAC7 specific inhibitors for the possible use in treatment of T2D. The aim of the current study was to further investigate the mechanisms by which MC1568 improves beta-cell function.
Materials and methods: Hdac7 was overexpressed in 832/13 INS-1 beta-cells via plasmid transfection and the cells were treated with 1μM MC1568. Glucose-stimulated insulin secretion (GSIS) was determined by standard methods and mitochondrial function was determined by measurement of cellular ATP and oxygen consumption. beta-cell number and apoptosis were determined by crystal violet staining and measurement of Caspase-3/-7 activity, respectively.
Results: We could verify that Hdac7 overexpression results in impaired GSIS (~50% reduction, $p<0.05$) and this was completely reversed by treatment with MC1568. The inhibitor had no effect on GSIS from control transfected cells however. Hdac7 overexpression also resulted in reduced ATP levels at high glucose levels (~30% reduction, $p<0.05$) and impaired mitochondrial respiration (~25% reduction, $p<0.05$). Treatment with MC1568 normalized ATP levels and improved mitochondrial respiration in Hdac7 overexpressing cells, again without effect on control transfected cells. Lastly, treatment with MC1568 normalized the number of beta-cells in vitro via a complete rescue of Hdac7-induced apoptosis.
Conclusion: In summary, our data suggest that treating Hdac7 overexpressing beta-cells with MC1568 rescues insulin secretion via improving mitochondrial function. MC1568 also improves beta-cell survival. These data further support the development of HDAC7 specific inhibitors as novel therapeutics for T2D.

Expression of S561F CDKAL1 variant modifies the constitutive trafficking and affects insulin release in INS1E cells
E.S. Di Cairano[1], C. Cosentino[2], A. Galli[1], M.C. Proverbio[3], C. Battaglia[2], C. Perego[1];
[1]Dept of Pharmacological and Biomolecular Sciences, Università degli studi di Milano, [2]Department of Medical Biotechnology and Translational Medicine, Università degli studi di Milano, [3]Department of Pathophysiology and Transplantation, Università degli studi di Milano, Milano, Italy.

Background and aims: Congenital hyperinsulinism (CHI) is a rare disorder (OMIM#256450), characterized by hypoglycaemia due to inappropriate insulin secretion. A Whole Exome Sequencing (WES) analysis performed on CHI patients lacking mutations in ABCC8/KCNJ11 identified a polimorfism in the CDKAL transcript (S561F-CDKAL1 variant). CDKAL is a methylthiotransferase that modifies tRNA(Lys) to enhance translational fidelity of transcripts, including the one encoding proinsulin. Interestingly, CDKAL is a susceptibility gene for type 2 diabetes and CDKAL knock-out (cdkal1 -/-) mice showed impaired glucose homeostasis, thus indicating the protein involvement in beta-cell function. Aim of this work was to understand the impact of the CDKAL1 variant S561F on the insulin content, trafficking and release in pancreatic beta cells.
Materials and methods: Clonal INS1-E cells expressing Wild Type (WT) or S561F CDKAL1 were generated and used as a model to characterize S561F-CDKAL1 impact on beta cell function. The localization of the variant protein was monitored by immunofluorescence and insulin content and release were measured with ELISA. An acridine orange assay was performed to evaluate the constitutive and regulated trafficking and possible alterations in vesicle protein expression were evaluated by western blotting.
Results: Wild type CDKAL1 overexpressed in INS1-E cells localized in the reticular compartment. The S561F variant was similarly confined to the reticular compartment, although its localization was enriched in spot-like structures distributed in the perinuclear region. Insulin content was increased by overexpression of WT CDKAL1 (2 fold over INS1E, $p<0.05$) while it was decreased by S561F-CDKAL1 variant expression. Conversely, insulin release measured in overnight culture medium or in 30 minutes static incubation in normal glucose concentrations was increased in the S561F-CDKAL1 as compared to WT clones (2 to 4 folds increase over WT; $p<0.05$), thus suggesting a different insulin processing/secretion in the mutant CDKAL1. An acridina orange assay performed to measure the constitutive and regulated trafficking in INS1E cells revealed more basal exocytosis in S561F-CDKAL1 than WT clones. Interestingly, the basal release was not further increased by potassium chloride or high glucose. Western blotting experiments revealed up-regulation of proteins involved in the secretion machinery in mutant clones compared to WT.
Conclusion: The S561F-CDKAL1 variant expression leads to an increased basal insulin release in INS1E cell line. Such an increase is associated to a defect in the vesicle trafficking and correlates with altered expression of proteins involved in the secretory machinery , further studies are needed to clarify molecular mechanisms linking CDKAL to insulin processing and membrane trafficking. Our findings confirm the importance of CDKAL1 in insulin release and suggest a possible mechanism by which this variant can participate to the development of congenital hyperinsulinism.

A robust in vitro islet model: long-lived, standardised and glucose-responsive human islet microtissues
B. Yesildag, A. Neelakandhan, A. Biernath, O. Frey, S. Messner;
InSphero AG, Schlieren, Switzerland.

Background and aims: Inherent heterogeneity in pancreatic islet size, cellular composition and function as well as the short *ex vivo* lifespan of both intact and dispersed islets, pose a significant challenge for their use as an *in vitro* model system in diabetes research.
Materials and methods: To address this issue, we developed a standardized 3D islet model by controlled reaggregation of dispersed primary islet cells. Reaggregated islets - homogenous in size, cellular composition and tissue architecture - were cultured in 96-well-plates in a single islet per well format, enabling high-throughput data acquisition with low intra-assay variability.
Results: Our model displayed uniform, highly reproducible and robust glucose-regulated insulin and glucagon secretion across donors for more than 28 days in culture. In perifusion experiments, the step from 2.8 to 16.7 mM glucose induced biphasic insulin secretion with a prominent first phase (35-fold increase) and a sustained, pulsatile second phase (8-fold increase) potentiated by glucagon-like peptide 1, closely mimicking dynamic in vivo insulin secretion. Relative proportion of endocrine cells, quantified by morphometric analysis of tissue sections, closely reflected fractions found within the human pancreas (54.6% β, 35.5% α and 7.2% δ cells). Basal β-cell proliferation observed in reaggregated islets from multiple donors was comparable to previously described rates and was successfully increased with various stimulators. Long-term exposure to β-cell stress inducers, such as increased glucose, free fatty acid or cytokine concentrations, impaired β-cell function and/or islet viability. This impairment was partially restored upon removal of the stress inducer or addition of β-cell supportive compounds.
Conclusion: These results demonstrate that our model is suitable for high-throughput and long-term study of islet function and regeneration in health and disease.

In vitro amino acid restriction: a new tool to study protein malnutrition-induced beta cell programming predisposing the development of type 2 diabetes

L.M. Gonçalves[1], J.F. Vettorazzi[1], E.C. Vanzela[1], T.M. Batista[2], C.C. Zoppi[1], E.M. Carneiro[1];
[1]Structural and Functional Biology, University of Campinas - UNICAMP, Campinas, Brazil, [2]Joslin Diabetes Center, Boston, USA.

Background and aims: Malnutrition predisposes to develop obesity and diabetes. Protein malnutrition reduces pancreatic beta cell mass and proliferation as well as insulin secretion, calcium handling, and the content of proteins related to glucose metabolism and secretion machinery. To deepen the study of mechanisms involved in beta cell programming by protein malnutrition, we aimed to validate an *in vitro* model of amino acid restriction on INS-1E cell line and isolated mouse pancreatic islets.
Materials and methods: INS-1E cells and islets isolated from C57bl/6 mice (by collagenase) were treated for 48 hours in RPMI 1640 medium supplied with 5% FCS and 11 mmol/l glucose (INS-1E) or 10% FCS and 5.6 mmol/l glucose (islets), with 100% (Control - Ctl) or 25% (Malnutrition - Mnt) of amino acids solution (RPMI 1640 Amino Acid Solution 50x R7131 - Sigma) at 37°C in a humidified atmosphere of 95% O_2 and 5% CO_2. We evaluated insulin secretion (RIA), calcium handling (fura-2/AM), protein content (western blot) as well as gene expression (RT-PCR real- time) involved with apoptosis, beta cell metabolism and insulin secretion. Results were expressed as mean ± SEM. Statistical significance was determined using Two-tailed unpaired t-test. $p < 0.05$ was considered significant.
Results: The restriction of amino acid did not alter cleaved caspase 3 protein content (Ctl: 99.98±0.03 %; Mnt: 93.80±8.8 % P value: 0,618). Insulin secretion was reduced in both, INS-1E and islets treated with Mnt solution in presence of stimulatory glucose concentration (INS-1E: Ctl: 0.063±0.006 ng/μg*ml^{-1}; Mnt: 0.038±0.006 ng/μg*ml^{-1}; P value: 0,006. Islets: Ctl: 0.066±0.010 ng/islet*h; Mnt: 0.042±0.008 ng/islet*h; P value: 0,0477). The frequency of calcium oscillation in response to glucose (22.2 and 11 mmol/l) was increased both in Mnt-treated INS-1E and islets (INS-1E: Ctl: 4.486±0.4 oscillation/min; Mnt: 7.462±0.3 oscillation/min; P value: <0,001. Islets: Ctl: 2.778±0.7 oscillation/min; Mnt: 6.300±1.0 oscillation/min; P value: 0,0118). Amino acid restriction, in INS1-E cells, altered the protein content of Sirt 3 (Ctl: 99.9±0.01 %; Mnt: 78.75±8.8 %; P value: 0,0326), PKC (Ctl: 99.9±0.02 %; Mnt: 80.13±5.4 %; P value: 0,0034), phosho-Eif2alpha (Ctl: 99.9±0.03 %; Mnt: 173.8±22.7 %; P value: 0,0311) and Snap 25 (Ctl: 99.9±0.02 %; Mnt: 73.06±5.9 %; P value: 0,0005), proteins known to be modulated by protein malnutrition. Moreover, the expression of insulin gene was reduced in pancreatic islets exposed to amino acid restriction (Ctl: 0.998±0.002; Mnt: 0.787±0.033 relative quantification; P value: <0,001).
Conclusion: We validate a viable *in vitro* model of amino acid restriction in INS-1E cells and isolated mouse pancreatic islets. This model offers a new tool to investigate the mechanisms by which protein malnutrition impairs beta cell mass and function, favoring the development of type 2 diabetes.

Metabolism-secretion coupling and kinase array profiling reveal selective changes upon chronic hyperglycaemia and exposure to C16/C18: n fatty acids in INS-1E beta cells

L. Oberhauser, T. Brun, P. Maechler;
Department of Cell Physiology and Metabolism, University of Geneva Medical Center, Geneva, Switzerland.

Background and aims: Chronic exposure to elevated glucose levels and/or free fatty acids impairs beta-cell function, leading to insulin secretion defects and beta-cell death, potentially prompting diabetes. These effects, referred to as glucolipotoxicity, and mechanisms induced by saturated versus unsaturated fatty acids remain unclear. Using a semi-high throughput approach, we investigated the effects of chronic exposure of INS-1E beta-cells to saturated and unsaturated fatty acids, associated with high glucose, on mitochondrial function, glucose-stimulated calcium rise, kinetics of insulin secretion, and untargeted kinase activity.
Materials and methods: INS-1E beta-cells were cultured for 3 days at low 5.5 mM, standard 11.1 mM (control) and high 25 mM glucose in the presence or absence of BSA-complexed 0.4 mM saturated (palmitate), monounsaturated (oleate) or polyunsaturated (linoleate, linolenate) fatty acids. Metabolic fitness was determined by redox activity (MTT assay) and mitochondrial function by oxygen consumption rate (OCR), ATP generation, and proton leak (OCRs) using 96-well Seahorse monitoring. INS-1E beta-cell function was assessed by 96-well online measurements of both intracellular calcium (Fura-2) and kinetics of insulin secretion (luciferase-based C-peptide substitution) upon glucose stimulation. Kinase array (PamStation-12, 144 peptides per array) was used to profile phosphotyrosine (PT) and serine/threonine (ST) kinase activity.
Results: Metabolic fitness of the cells increased along with chronic high glucose. Chronic palmitate (C16:0) and polyunsaturated fatty acids, linoleate and linolenate (C18:2, C18:3), decreased the metabolic fitness of INS-1E cells by 30% at normal and high glucose, while oleate (C18:1) affected this parameter twice as less. Glucose-stimulated OCR was not changed by chronic high glucose, by fatty acids, or the combination of both. However, both palmitate and oleate decreased ATP production by increasing proton leak at high glucose. Palmitate and oleate were also the only fatty acids reducing markedly the calcium signal by nearly 90% against 60-70% for polyunsaturated fatty acids. These effects were not additive to glucotoxicity regarding the secretory function as palmitate and oleate did not alter further insulin secretion under glucotoxic conditions. However, oleate was deleterious at low and normal glucose culture conditions, while palmitate potentiated the secretory response. The different metabolic stresses affected mainly the activity of kinases involved in

signal transduction, cell cycle and stress response. When combined with high glucose, oleate specifically increased both PTK and STK activity in INS-1E beta-cells.

Conclusion: Under chronic high glucose, both the saturated fatty acid palmitate and the monounsaturated fatty acid oleate altered the first steps of metabolism-secretion coupling, while polyunsaturated did not. Such alterations were differently reproduced on the complete development of the secretory response, showing that the different fatty acids selectively affected the amplifying pathway, an observation made at any concentrations of glucose culture. Kinase activity profiling also provides new insight on the differential effects of metabolic stresses revealing a specific signature of glucose and fatty acids on kinase activity in INS-1E beta-cells.

Increased secretagogin secretion as a response to human beta cell stress

S.F. Hansson[1], A. Zhou[1], M. Sörhede Winzell[2], P. Davidsson[1]; [1]Translational Science, CVMD IMED, AstraZeneca, R&D, [2]Bioscience, CVMD IMED, AstraZeneca, R&D, Gothenburg, Sweden.

Background and aims: Therapies promoting the preservation and restoration of functional pancreatic β-cells are desirable for the treatment of type 2 diabetes mellitus (T2D). A challenge for the development of such therapies is the lack of biomarkers to assess changes in β-cell stress with therapeutic intervention. Secretagogin (SCGN) is a Ca^{2+} binding protein, expressed in endocrine cells, particularly in human islets. The exact function of SCGN is still unknown. A previous study has shown significantly elevated SCGN plasma levels in T2D compared to non-T2D individuals. We hypothesized that increased SCGN secretion in T2D individuals may reflect β-cell stress. The aim of this study was to evaluate SCGN as a potential biomarker of β-cell stress using human EndoC-βH1 cells, islets and pancreatic tissue, as well as human islet xenografts transplanted (Tx) mice, subjected to stress conditions.

Materials and methods: Human tissue and primary islets were purchased from Prodo Laboratories Inc. providing islets isolated from donor pancreases with consent from Organ Procurement Organizations. Human pancreatic tissue was double stained using mouse anti SCGN ab and guinea pig anti Insulin ab. Human islets were cultured for 24 hours and subjected to normal (5.8 mM) and high (22 mM) glucose conditions. EndoC-βH1 were transfected with SCGN and Scrambled siRNA oligos and stress was induced by either thapsigargin, tunicamycin or cytokine cocktail (IFN-γ, IL1-β, TNF-α) (n=4). To study human islet in vivo under stress, human islets (1000 IEQ) was transplanted under the kidney capsule to diabetic and non-diabetic nu/nu mice (n=7). At termination, plasma samples were collected. ELISA kits were used to quantify human SCGN, Insulin and C-peptide in plasma samples and culture media. Apoptosis activity was measured using Caspase-Glo 3/7 assay.

Results: Immunohistochemistry confirmed that SCGN co-localized with insulin in the β-cells of the human endocrine pancreas but also with the other islet cell type, while, exocrine pancreatic tissue had no SCGN expression. SCGN was not secreted merely in an insulin dependent manner as determined by correlation to the insulin or C-peptide release in EndoC-βH1 cells, human primary islets and plasma from Tx mice. However, secretion of SCGN from EndoC cells was significantly increased in response to all stressors, including cytokine cocktail (2662 ± 138 pg/mL, $p<0.0001$), tunicamycin (1932 ± 75 pg/mL, $p<0.0001$), thapsigargin (1689 ± 136 pg/mL, $p<0.0001$), compared with DMSO ctrl. (973 ± 17 pg/mL). Silencing of SCGN in EndoC β-cells, resulted in significantly increased apoptosis when induced by ER, but not by inflammatory stress, compared with cells treated with scrambled siRNA stress (tunicamycin 978 ± 12 RLU vs. 667 ± 24 RLU, $p<0.0001$; thapsigargin, 1277 ± 35 RLU vs. 1101 ± 29 RLU, $p = 0.003$; cytokine, 690 ± 84 RLU vs. 691 ± 78 RLU, $p = 0.99$; DMSO ctrl; 430 ± 33 RLU vs. 372 ± 53 RLU, $p = 0.2$). In plasma from Tx mice, hSCGN inversely correlated with hC-peptide levels, showing that a poor glycemic control was related to high levels of hSCGN ($r = -0.79$, $p = 0.036$). SCGN may be released to protect the islets from increased stress but ultimately the engraftment of islets failed.

Conclusion: This study showed for the first time that SCGN showed interesting features as a novel biomarker reflecting islet and/or β-cell stress. However, further mechanistic and T2D cohort studies will be required to confirm these findings.

Disclosure: **S.F. Hansson:** None.

PS 019 Beta cell signal transduction I

Complement components C3 and C5 improve islet beta cell function

P. Atanes, I. Ruz-Maldonado, A. Pingitore, P. Choudhary, G.C. Huang, S.J. Persaud, S. Amisten;
Diabetes Research Group, King's College London, London, UK.

Background and aims: The complement system represents one of the major effector mechanisms of the innate immune system. Complement components 3 and 5 (C3 and C5) play essential roles in the complement system, generating C3a and C5a peptides that act as chemotactic and inflammatory factors. These active peptides are mainly associated with immune responses, but there is some evidence that they also regulate glucose homeostasis. The aims of the current study were to determine the mRNA and protein expression of C3/C3a and C5/C5a in islets, and identify the effects of C3a and $C5a_1$ receptor activation on human and mouse islet secretory function and viability.
Materials and methods: The mRNA expression of genes encoding C3 and C5 proteins, as well as CFD and C2 (key elements in the complement system cascade for activation of C3 and C5), and C3a, $C5a_1$ and $C5a_2$ receptors was quantified by qPCR in human and mouse islets. Distribution of C3 and C5 proteins in human and mouse islets was determined by IHC, with insulin, glucagon and somatostatin co-staining. Effects of C3 and C5 proteins and receptor agonists sc-214644 (C3a) and 65121-ANA ($C5a_1$) and antagonists SB 290157 (C3a) and PMX 205 ($C5a_1$) on static and dynamic glucose-stimulated insulin secretion (GSIS) from human and mouse islets were measured by radioimmunoassay. Intracellular calcium and apoptosis were assessed by standard techniques. Activation of C3a and $C5a_1$ receptor was assessed using DiscoverX β-arrestin assays.
Results: C3 and C5 complement proteins and their receptors are expressed by human and mouse islets, and C3 and C5 are mainly co-localised in β- and α-cells. Complement proteins and receptor agonists potentiated GSIS from human islets (20mM glucose: 1.13±0.05 ng/islet/hour; +100nM C3: 1.50±0.10; +100nM C5: 1.49 ±0.08; +1μM C3a: 1.81±0.08; +1μM C5a: 1.87±0.12; p< 0.001) but GSIS was inhibited by 1μM SB 290157 (0.80 ±0.05) and 1μM PMX 205 (0.76±0.05). Similar effects were observed in mouse islets. Single cell microfluorimetry experiments indicated that 1μM C3a and $C5a_1$ receptor agonists increased intracellular calcium at 20mM glucose in mouse islets. C3a and $C5a_1$ receptor agonists also protected human islets against apoptosis induced by a pro-apoptotic cytokine cocktail (No cytokines control: 100±9.5%; cytokines control: 204±23.3%; 1μM C3a + cytokines: 115.0±7.4%; 1μM C5a + cytokines: 109.3±9.3%; p< 0.001) and palmitate (No palmitate control: 100±8.0%; palmitate control: 144± 4.3%; 1μM C3a + palmitate: 99.9± 8.0%; 1μM C5a + palmitate: 110.8± 7.5%; p< 0.001). Similar effects were observed in mouse islets. Conditioned media from islets exposed for 1 h to 5.5 and 20mM glucose stimulated C3a and $C5a_1$ receptor-mediated β-arrestin recruitment.
Conclusion: Our data reveal that C3 and C5 complement proteins and their receptors are expressed by human and mouse islets, and that islets secrete activating receptor ligands in a glucose-dependent manner. Activation of the C3a and $C5a_1$ receptor in islets results in potentiation of glucose-induced insulin secretion, protection against cytokine- or palmitate- induced apoptosis and increased intracellular calcium levels. These observations demonstrate a functional link between activation of components of the innate immune and improved human and mouse β-cell function, suggesting that low level chronic inflammation may improve glucose homeostasis through direct effects on β-cells.

The p66Shc protein mediates saturated fatty acid-induced insulin resistance in pancreatic beta cells

G. Biondi[1], A. Natalicchio[1], N. Marrano[1], R. Spagnuolo[1], R. Labarbuta[1], L. Dipaola[1], A. Cignarelli[1], P. Marchetti[2], S. Perrini[1], L. Laviola[1], F. Giorgino[1];
[1]Department of Emergency and Organ Transplantation, University of Bari Aldo Moro, Bari, [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy.

Background and aims: Insulin-secreting pancreatic beta-cells are a target for insulin that acts on cell growth, insulin biosynthesis and release. Prolonged exposure of beta-cells to high levels of saturated fatty acids (SFAs) impairs insulin signaling and the insulin-induced increase in proinsulin mRNA. The p66Shc protein is a redox sensor and radical oxygen species (ROS) producer and mediates obesity-induced insulin resistance in adipose tissue and endothelial cells. In this study, we explored the role of p66Shc in SFAs-induced insulin resistance of beta-cells.
Materials and methods: The effects of insulin on insulin biosynthesis and secretion were investigated in rat insulin-secreting INS-1E cells and in human pancreatic islets exposed to 0.5 mM palmitate for 24 h or left untreated. Insulin-induced insulin biosynthesis and secretion were evaluated by detection of insulin cellular content and C-peptide released in the medium, respectively, using specific ELISA kits. The role of p66Shc in palmitate-induced beta-cell insulin resistance was investigated in INS-1E cells both by siRNA-mediated p66Shc gene silencing and adenovirus-mediated p66Shc overexpression, respectively.
Results: When INS-1E cells and human islets were pretreated with 0.5 mM palmitate for 24 h the effects of insulin to augment insulin protein levels and to stimulate C-peptide secretion were abrogated. Under these conditions, we found that palmitate increased p66Shc mRNA and protein levels. The role of p66Shc in palmitate-induced beta-cell insulin resistance was thus investigated. Knockdown of p66Shc resulted in increased C-peptide levels both under basal conditions ($p<0.05$ vs vehicle) and following insulin stimulation ($p<0.05$ vs control), and restored the insulin-induced C-peptide secretion that was reduced by palmitate ($p<0.05$ vs vehicle). By contrast, overexpression of p66Shc inhibited insulin-induced C-peptide secretion under basal conditions and in the presence of palmitate ($p<0.05$ vs mock). Similarly, knockdown of the p66Shc protein restored the insulin-mediated increase in insulin content that was reduced by palmitate ($p<0.05$ vs vehicle), while p66Shc overexpression reduced it both under basal conditions and in the presence of palmitate ($p<0.05$ vs mock). Moreover, palmitate enhanced p70S6K phosphorylation on Thr389 and IRS-1 phosphorylation on Ser307, reducing IRS-1 protein levels due to its degradation, and impaired basal and insulin-stimulated AKT phosphorylation ($p<0.05$ vs control). However, following p66Shc protein knockdown, the effects of palmitate on p70S6K Thr389 and IRS-1 Ser307 phosphorylation were attenuated ($p<0.05$ vs vehicle). By contrast, p66Shc overexpression augmented IRS-1 Ser307 phosphorylation and reduced the ability of insulin to stimulate AKT phosphorylation both under basal conditions and in the presence of palmitate ($p<0.05$ vs mock).
Conclusion: The p66Shc protein plays an inhibitory role in insulin signaling, insulin-induced insulin biosynthesis and C-peptide secretion in beta-cells and mediates SFAs-induced insulin resistance.

Identification of Negr1 as an age-regulated gene in mouse islets with a role in glucose homeostasis

J. Mir-Coll[1,2], R. Fernández-Ruiz[1,3], B. Serra-Navarro[1,2], E.G. Ruano[1,3], A. García[1,3], Y. Esteban[1,3], R. Gomis[1,3], R. Gasa[1,3];
[1]IDIBAPS, [2]University of Barcelona, [3]CIBERDEM, Barcelona, Spain.

Background and aims: The restoration of a functional beta cell mass is a therapeutic target in diabetes. Thus, a deeper knowledge of the mechanisms governing beta cell proliferation is needed. The postnatal stage is a valuable context for the study of factors involved in the regulation of beta cell replication, since a significant expansion of the beta cell mass occurs during this period. Then, beta cell proliferation drops progressively and it is almost nonexistent during adulthood. In this study, we used high-

throughput RNA expression profiling in mouse islets of various ages in order to identify intrinsic factors involved in the decline of beta cell proliferation rates.
Materials and methods: We performed gene expression analysis in pancreatic islets isolated from 2, 4 and 20 week-old (WO) C57B/6J mice using Affymetrix GeneChip HT MG-430 PM Array Plate. We obtained *Negr1* Knockout (KO) mice and studied glucose tolerance and insulin resistance by i.p. glucose tolerance test (GTT) and insulin tolerance test (ITT). Hepatic glucose production was assessed by i.p. pyruvate tolerance test (PTT). Beta cell mass was quantified histologically by morphometry. RNA expression in islets from *Negr1* KO mice was assessed by qPCR.
Results: Microarray results revealed *Negr1* as one of the top upregulated genes with age in mouse islets. *Negr1* followed an opposed pattern of expression to that of the proliferation markers *Ki67* and *Pcna,* which were highly expressed in 2 WO islets and decreased progressively in 4 and 20 WO islets. We measured body weight, glycaemia and performed morphometric analysis of the pancreas in *Negr1* KO mice during the postnatal stage to establish whether these mice have a beta cell phenotype. As reported in previous literature, 4 WO *Negr1* KO mice presented lower body weight. Interestingly, at this age these mice also had lower glycaemia than controls (Ctrl vs KO: 145±4 mg/dl vs 120±5 mg/dl, $p<0.001$). Next, we analyzed glucose homeostasis in 8 WO *Negr1* KO mice. GTT showed that these mice had impaired glucose tolerance (AUC Ctrl vs KO: 9236±959 vs 13445±1079, $p<0.05$). On the other hand, ITT and PTT tests revealed no alterations in insulin resistance or hepatic glucose production in *Negr1* KO mice. Beta cell mass as determined by morphometric analysis was similar in 4 WO *Negr1* KO and littermate controls. Yet, when we assessed the expression of beta cell function and identity genes in isolated islets from this age, we found an increase in the expression of *Mafa* (Ctrl vs KO: 1±0.12 vs 1.9±0.25, $p<0.01$), a significant reduction in the levels of *G6pc2* (Ctrl vs KO: 1±0.09 vs 0.73±0.05, $p<0.001$) and *Slc2a2* (Ctrl vs KO: 1±0.06 vs 0.79±0.06, $p<0.05$).
Conclusion: Impaired glucose tolerance in the absence of insulin resistance and altered hepatic glucose production in *Negr1* KO mice suggests that *Negr1* has a role in the regulation of functional beta cell mass. At the molecular level, increased *Mafa* and decreased *G6pc2* islet gene expression might be involved in the *Negr1* KO phenotype. Intriguingly, *G6pc2* KO mice present lower fasting glycaemia, reduced body weight and slightly impaired glucose tolerance, a similar phenotype to that of *Negr1* KO mice. Further experiments including metabolic tests in high-fat diet fed mice and the study of the regenerative capacity of the beta cells in *Negr1* KO after STZ treatment are needed to describe in detail the role of *Negr1* in beta cells.

PKC-mediated control of glutamate signalling in islet of Langerhans in response to hyperglycaemia

C. Perego[1], S. Moretti[1], A. Galli[1], P. Marciani[1], F. Bertuzzi[2], F. Folli[3], E.S. Di Cairano[1];
[1]DiSFB Dept of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, [2]Niguarda Cà Granda Hospital, [3]Dept of Health Science, Università degli Studi di Milano, Milano, Italy.

Background and aims: Islets of Langerhans use a sophisticate system of paracrine and autocrine signals to synchronize their activities, among these is glutamate which controls hormone release and β-cell viability, by activating specific glutamate receptors. The extracellular glutamate concentration is shaped by the glutamate transporter GLT1 but the precise mechanisms by which it modulates islet functions is poorly understood. Aim of the proposed research was to verify the impact of acute changes of glucose concentrations on GLT1 function and glutamate signalling in the islet and to verify the molecular mechanisms of this modulation.
Materials and methods: Mouse βTC3 cells and human islets were incubated under different glucose concentrations (from 3 to 16.7 mmol/l glucose for up to 30 minutes), and the localization and activity of plasma membrane glutamate transporters was studied by in vivo imaging, Total internal reflection microscopy (TIRFM) and [3H]-Glutamate uptake. Hormone release was detected by means of ELISA assays.
Results: We found that the acute exposure of βTC3 cell lines human β-cells to high glucose concentrations caused the transporter relocalization in intracellular compartments (assessed by TIRFM). Accordingly, GLT1 transport activity, measured by [^{3}H]D-glutamate uptake, was inhibited by 25±5%. The GLT1 relocalization was prevented by inhibition of PKC activation, a kinase implicated in the control of vesicular trafficking and upregulated by high glucose, indicating that PKC controls the localization and/or activity of this transporter. In line with this possibility, PKC activation by TPA treatment caused a statistically significant reduction in the glutamate uptake. Accordingly, we found that βTC3 pre-treatment with the PKC inhibitor Bisindoleymide abolished the glutamate uptake down-regulation induced by 20 mM glucose incubation. Furthermore, no additive effects were observed when βTC3 cells, maintained in 20 mM glucose, were incubated with the PKC activator TPA
Conclusion: In the context of the islet physiology, glutamate is an important paracrine signals that positively modulate the somatostatin secretion. Being GLT1 the main regulator of extracellular glutamate concentration, its relocalization in intracellular compartments would potentiate the activation of glutamate receptors on δ-cells, thus stimulating the somatostatin release. Understanding the molecular mechanisms controlling glutamate release and clearance in islet of Langerhans may be important to control glucose homeostasis in health and disease.
Disclosure: **C. Perego:** None.

Pkcδ-induced glucagon secretion in alpha cells

F. Kei[1], M. Shiozaki[2], K. Utsunomiya[2];
[1]keifujimoto0902@gmail.com, Chiba, [2]keifujimoto0902@gmail.com, Tokyo, Japan.

Background and aims: Type 2 diabetes is known as "bi-hormonal disorder" due to dysregulated insulin and glucagon secretion. Although, protein kinase cδ (Pkcδ) associates with glucagon secretion in pancreatic α cells, the precise molecular mechanism of Pkcδ in α cells remains unclear. Agouti related peptide YY (PYY) hormone expresses in neuron, gut and pancreatic islet δ and PP cells which reduces glucagon secretion by bariatric surgery. To our knowledge, however, the association between Pkcδ and diabetes/PYY is unknown. Thus, the aim of this study is to elucidate Pkcδ-dependent glucagon secretion in pancreatic α cells.
Materials and methods: Glucagon secreting αTC1 cells were incubated with 11 and 25 mM glucose conditions, and subjected to diacylglycerol (DAG) EIISA analysis and western blotting for Pkcδ. Pkcδ was knocked down with shRNA for Pkcδ by using lentiviral vector in αTC1 cells. Pkcδ function was studied by pharmacological and genetic inhibitions by rottlerin and shPkcδ, respectively. Activation of Pkcδ was assessed by cleavage (catalytically active fragment, Pkcδ-CF) and phosphorylation for Pkcδ by western blot. Lentiviral vector harboring wild type (WT) and caspase-3-insesitive Pkcδ (Pkcδ-D327A) were infected to αTC1 cells. Neuropeptide Y 1 receptor (Npy1r) agonist PYY and antagonist BIBP-3226 were employed to evaluate Pkcδ-dependent glucagon secretion in αTC1 cells. Isolated mouse pancreatic islets were incubated with insulin antibody to neutralize insulin action. Glucose and Npy1r antagonist induced glucagon secretion were studied in the presence of insulin antibody with/without rottlerin in isolated islet.
Results: High glucose induced glucagon secretion accompanied with increased DAG production and Pkcδ activation in αTC1 cells. Pkcδ knockdown prevented glucose-induced glucagon secretion in αTC1 cells. Interestingly, high glucose condition resulted in cleavage of Pkcδ in αTC1 cells. Overexpression of caspase-3-insesitive Pkcδ (Pkcδ-

D327A) showed same glucagon secretion pattern compared to that of WT, indicating cleavage of Pkcδ is epiphenomenon regarding to glucagon secretion in αTC1 cells. Npy1r agonist PYY suppressed glucagon secretion in αTC1 cells. On the other hands, Npy1r antagonist increased glucagon secretion and DAG production in αTC1 cells. Analogous to high glucose condition, Npy1r antagonist activated Pkcδ. Isolated mouse pancreatic islets were used to further elucidate the molecular mechanism of Pkcδ. In ex vivo islet study, high glucose reduced glucagon secretion due to increased insulin secretion. Thus insulin antibody was supplemented to neutralize insulin action in isolated islet. Compared to control IgG antibody, presence of insulin antibody was resulted in augmented glucagon secretion in both euglycemia and high glucose conditions, confirming insulin as a suppressor of glucagon secretion. Analogous to αTC1 cells, high glucose and Npy1r agonist induced glucagon secretion in the presence of insulin antibody in islet cells. Furthermore, Pkcδ inhibitor rottlerin suppressed this phenomenon, indicating Pkcδ regulates glucagon secretion in α cells especially in insulinopenic high glucose condition and PYY-Npy1r pathway.
Conclusion: High glucose and suppression of PYY-Npy1r pathway induced glucagon secretion in α cells. Targeting dysregulated glucagon secretion via Pkcδ in diabetes (especially in insulinopenic type 1 diabetes) might be promising approach.

CD36 dependent Vav2, a guanine nucleotide exchange factor activation promotes inflammatory activation in pancreatic beta cells

S. Elumalai[1], U. Karunakaran[1], S. Chung[2], J. Moon[2], K. Won[2];
[1]Institute of Medical Science, Yeungnam University College of Medicine, [2]Department of Internal Medicine, Yeungnam University College of Medicine, Daegu, Republic of Korea.

Background and aims: Altered metabolism has been implicated in the pathogenesis of beta-cell failure in type 2 diabetes. Of them, many clinical studies have confirmed a positive correlation between plasma and tissue levels of several ceramide species play a major role in inflammatory and stress responses that induce type 2 diabetes. CD36, a class B scavenger receptor initiates the inflammatory signaling in adipocytes and macrophages in diet-induced obesity and in the pathogenesis of type 2 diabetes. Here we investigated the role of CD36 signaling and its impact for the beta-cell inflammation induced by ceramide.
Materials and methods: To address this question, we used INS-1, rat islets and human 1.1b4 pancreatic beta-cells with C2-ceramide (N-acetyl-sphingosine). NF-kB-p65 DNA-binding activity was measured by ELISA-based transcription factor assay. Gene expression was assessed by real-time RT-PCR. Apoptosis was determined by TUNEL In-Situ cell death detection kit. Rac1 activation was measured by non-radioactive Rac1 activation kit (Millipore). NADPH oxidase activity was measured by Lucigenin based chemiluminescence assay. Protein expression levels of Src, Vav2, TXNIP and insulin signaling were measured by western blot.
Results: Exposure of INS-1 and human 1.1b4 beta cells to C2-ceramide (50uM) induced a time dependent increase in Src mediated Vav2 tyrosine phosphorylation, which activates its GEF activity accompanied by expression of active Rac1-GTP ($p<0.05$). Rac1-GTP activation enhanced NADPH oxidase activity (5 fold $p< 0.001$) with a 4.5 fold ($p<0.005$) increase in ROS production. Further, NADPH oxidase activity potentiated C2-ceramide induced nuclear factor NF-kB transcriptional activity (3.5 fold $p<0.001$). This effect was associated with upregulation of TXNIP mRNA levels ($p<0.005$) and downregulation of Insulin ($p<0.05$) and PDX1 mRNA ($p<0.001$) levels. Interestingly, pharmacological inhibition of CD36 by Sulfo-N-succinimidyl oleate (SSO) blocked C2-ceramide induced Src activation and reduced Vav2 GEF activity by decreasing Vav2 tyrosine phosphorylation. Further, reduced expression of active Rac1-GTP resulted in decreased NADPH oxidase activity by ~ 50% ($p<0.005$). Under these same conditions, nuclear factor NF-kB transcriptional activity was strongly inhibited by 2 fold ($p<0.001$). Moreover, inhibition of CD36 downregulate TXNIP mRNA ($p<0.05$) and upregulate the levels of Insulin, PDX1 mRNA ($p<0.05$). Finally, inhibition of CD36 by SSO or Src activation by SU6656 (10uM) reduced INS-1 and human pancreatic 1.1b4 beta cell apoptosis.
Conclusion: Ceramide triggers the CD36 mediated upregulation of Vav2 guanine nucleotide exchange factor (GEF) activity by Src activation. This is associated with enhanced Rac1-GTP- NADPH oxidase activity and a rise in nuclear factor NF-kB transcriptional activity with cell apoptosis. Collectively, our results unveil a novel role of CD36 in early molecular events leading to the ceramide-induced pathogenesis of pancreatic beta-cell dysfunction and failure.

RNA-seq analysis of human islets exposed to gluco-lipotoxic conditions identifies transcriptomic changes associated with transient or persistent beta cell dysfunction

L. Marselli[1], M. Suleiman[1], Y. Bai[2], B. Rady[2], M. Bugliani[1], K. Belongie[2], S. Mossuto[1], I. Bakaj[2], F. Grano[1], S. Lee[2], U. Boggi[1], F. Filipponi[1], L. Norquay[2], A. Pocai[2], P. Marchetti[1];
[1]University of Pisa, Pisa, Italy, [2]Janssen R&D, Spring House, USA.

Background and aims: Several gluco-lipotoxic conditions (GLtox) reduce glucose-stimulated insulin secretion (GSIS) and promote beta cell death, which, in association with genetic predisposition, can lead to type 2 diabetes (T2D). We have previously observed that reversal of functional damage of human islets (HI) induced by GLtox occurred after removal of some, but not all, the tested deleterious conditions. Here we describe the transcriptome profile of HI with transient or persistent beta cell dysfunction induced by GLtox.
Materials and methods: For the purpose of the present study we used HI isolated from 8 non-diabetic organ donors (age, 70±11 yrs; gender, 4M/4F; BMI, 23.2±3.4 kg/m^2) cultured with/without 0.5 mM palmitate (P) or P + 22.2 mM glucose (P+G). Islets were studied basally (Bas), after 2 days (2d) of GLtox incubation and following 4 additional days in normal medium (wash-out, WO). Islet RNA (RIN ≥ 7.9) was sequenced by Illumina HiSeq2500; reads (≥198M/sample) were mapped using the OmicSoft Aligner.
Results: Compared to Bas values, GSIS decreased significantly at 2d with both P and P+G exposure. Normalization of GSIS was observed at WO vs 2d with P, but not with P+G. With P-exposed islets, RNA-seq analysis showed that the transcripts differentially (FDR<0.05) expressed were 161 (84 up and 77 downregulated) with 2d treated vs 2d control HI and 3,452 (1,733 up and 1,719 downregulated) with WO vs 2d treated HI. The comparison of 2d P-treated vs 2d untreated islets retrieved 35 pathways (DAVID version 6.8): 8 were upregulated (including Fatty acid metabolism and PPAR signalling) and 27 downregulated (including Cell adhesion molecules and Complement and coagulation cascades). In the comparison of WO vs 2d P-treated HI, 92 pathways were identified: 24 were upregulated (including: Synaptic vesicle cycle, MODY, Insulin secretion, ABC transporters, Insulin signalling, Calcium signalling) and 68 downregulated (including PI3K-Akt signalling, Hippo signalling, MAPK signalling, Notch signalling, Wnt signalling and Apoptosis). With P+G-exposed islets the transcripts regulated were 1,048 (572 up and 476 down) with 2d P+G-treated vs 2d control HI and 20 (4 up and 16 down) with WO vs 2d treated HI. The comparison of 2d P+G-treated vs 2d untreated islets indicated 57 pathways, of which 27 were upregulated (including TNF signaling pathway, Protein processing in ER, NF-kB signalling, Fatty acid biosynthesis and Adipocytokine signalling) and 30 downregulated (including Glutathione metabolism, Metabolic pathways, MODY and Glycolysis/Gluconeogenesis). Only minor changes were seen in the analysis of WO vs 2d P+G-treated HI.
Conclusion: At our experimental conditions, lipotoxicity (0.5 mM P) induced transient deterioration of GSIS from human islets; however,

lipo-glucotoxicity (0.5 P + 22.2 mM G) resulted in persistent functional damage. Different transcriptomic changes were found to associate with the two conditions, indicating pathways to be possibly targeted for prevention or reversal of GLtox-induced beta cell damage.

Somatostatin protects against palmitate-induced apoptosis and ER stress in pancreatic beta cells

A.C. Hauge-Evans[1], E.L. Damsteegt[1], Z. Hassan[2], P.M. Jones[2];
[1]Health Sciences Research Centre, University of Roehampton, London, [2]Diabetes Research Group, King's College London, London, UK.

Background and aims: Somatostatin (SST) released from pancreatic delta cells inhibits insulin secretion from pancreatic beta cells but little is known about the impact of the peptide on beta cell survival. Anti-proliferative and anti-apoptotic properties have been reported but protective effects of SST have also been observed in retinopathy, acute liver damage and in models of neurodegeneration. Here we investigate a potential role of SST in beta cell survival.
Materials and methods: mRNA expression was assessed by qPCR, beta cell proliferation by immunocytochemical measurements of BrdU incorporation and apoptosis by assessment of 3/7 caspase activity in MIN6 beta cells or by TUNEL in cells from dispersed mouse islets.
Results: MIN6 beta cells and primary mouse islets expressed mRNA for somatostatin receptor 2, which has previously been linked to apoptotic pathways. Pre-treatment of MIN6 cells for 48h with SST14 (10nM-1μM) dose-dependently reduced palmitate-induced 3/7 caspase activity in MIN6 cells (0.5mM palmitate, 20h; 10nM SST: 102±3% palmitate only; 100nM: 92±3, 1μM: 80±3; n=8, P<0.001) and in dispersed mouse islet cells (100 nM SST: 50±9% palmitate only, n=8, P<0.001). In contrast, SST14 (10nM-1μM) did not affect the proliferative rate of MIN6 cells (n=8, P>0.2). Consistent with previously-reported induction of ER-stress in beta cells by palmitate, the mRNA expression of heat shock protein 70 (*Hspa1a*) and the pro-apoptotic, ER stress-induced transcription factor, CHOP (*Ddit3)*, were up-regulated in MIN6 beta cells following 20h incubation with 0.5mM palmitate (301±80 and 313±76% control, respectively). 48h pre-treatment with 1μM SST14 decreased this effect by 27±5 and 15±3%, respectively (n=4, P<0.05). Prolonged (48h) incubation with 2% fetal bovine serum (FBS) similarly led to increased mRNA expression of *Ddit3* (194±20% control, P<0.05), and this was also reduced by SST14 (48h, 1μM: 53±3% 2% FBS only, n=4, P<0.05). Reduction of palmitate-induced 3/7 caspase activity by SST14 was not reversed by incubation in the presence of CYN154860, a SSTR2 antagonist (1μM SST: 71±2% palmitate only; 1μM SST + 100nM CYN: 72±2%; 1μM SST + 1μM CYN: 65±2; 1μM SST + 10μM CYN: 69±3, n=8, P>0.2). In addition, mRNA expression of SSTR2 was not affected by incubation with palmitate (20h) nor with 1 μM SST14 (48h, n=4, P>0.2).
Conclusion: These results suggest that SST14 partially protects against palmitate-induced apoptosis and ER stress and that this effect is not mediated via the SSTR2 receptor.

The mitochondrial Ca^{2+} uniporter (MCUa) is required for glucose-stimulated mitochondrial Ca^{2+} uptake and insulin secretion in mouse pancreatic beta cells

E.A. Haythorne[1], A. Martinez-Sanchez[1], R. Rizzuto[2], G.A. Rutter[1];
[1]Department of Medicine, Imperial College London, London, UK, [2]Department of Biomedical Sciences, University of Padova, Padova, Italy.

Background and aims: Oxidative metabolism is central to the stimulation of insulin secretion by glucose. Whether mitochondrial Ca^{2+} uptake in pancreatic β-cells potentiates this process, however, remains unclear. MCUa is believed to form the main route of entry for Ca^{2+} into the mitochondria. To test this hypothesis, we have generated β-cell specific MCUa knockout mice and assessed the impact of blocking mitochondrial Ca^{2+} uptake on β-cell function and whole body glucose homeostasis.
Materials and methods: C57BL6 mice bearing MCUa alleles with *floxP* sites flanking exons 11 and 12 were bred with mice bearing Cre recombinase inserted at the Ins1 locus (Ins1Cre). This strategy allowed highly β-cell selective deletion of both MCUa splice variants (KO). Mice bearing floxed MCUa alleles but lacking Cre recombinase were used as littermate controls (WT). Intraperitoneal glucose (1 g/kg) tolerance was measured every four weeks from eight weeks of age, and insulin sensitivity (0.75U/kg) was determined at 8-10 weeks of age. Glucose-stimulated insulin secretion (3 to 17 mM) was examined *in vitro* during perifusion at 37 °C in Krebs-bicarbonate medium. Adenovirus-mediated delivery of a targeted recombinant Ca^{2+} probe, R-GECO, and Fura-Red, were used respectively to record mitochondrial and cytosolic free Ca^{2+} changes in dissociated β-cells during fluorescence microscopy (Olympus IX81 microscope, 40x objective).
Results: Glucose (3 vs 17 mM)-stimulated mitochondrial Ca^{2+} uptake was markedly reduced in KO vs WT mice (AUC: WT, 24.06 ± 0.67 vs KO, 22.12 ± 0.42, $p<0.05$, $n=5$, 3 mice per genotype) while the cytosolic Ca^{2+} responses were unaffected. Glucose (3 vs 17 mM)-stimulated insulin secretion was also impaired from isolated islets of KO mice in comparison to littermate controls (AUC: WT, 0.035 ± 0.001 vs KO, 0.017 ± 0.005, $p<0.05$, $n=$ 3-4, 3 mice per genotype). Paradoxically, male KO mice displayed significantly improved glucose tolerance compared to WT mice at eight weeks of age (AUC: WT, 1329 ± 47.78 vs KO, 1113 ± 46.2 mmol/L*min, $p<0.01$, n=11-15). However, this difference normalised from twelve weeks of age. Body weight, fed and fasting glycaemia and insulin sensitivity did not differ significantly between genotypes.
Conclusion: MCUa is crucial in pancreatic β-cells to allow glucose-stimulated Ca^{2+} uptake by mitochondria and normal glucose-stimulated insulin secretion. These findings thus support the view that increases in mitochondrial matrix Ca^{2+} are required for a full activation of oxidative metabolism, the generation of increases in ATP/ADP and potentially of other mitochondrially-derived coupling factors in response to stimulation with glucose. The apparent compensatory mechanisms which allow maintained or improved insulin production in MCUa KO mice *in vivo* remain to be established.

Light-induced pancreatic beta cell proliferation through endogenous opsin signalling

E. Reichhart, A.-M. Tichy, H. Janovjak;
Synthetic Physiology, Institute of Science and Technology Austria, Klosterneuburg, Austria.

Background and aims: Diabetes is a disease characterized by the loss of function and number of pancreatic beta-cells with no available cure. A key therapeutic concept is based on regenerating beta-cell mass by islets transplantation or inducing proliferation of beta-cells by growth factors. These therapies, however, are either highly invasive or lead to non-specific induction of cell proliferation and thus linked to carcinogenic potential. Here we propose an alternative approach based on light induced proliferation of beta-cells that offers spatial and temporal precision.
Materials and methods: Using RT-PCR, we studied the expression of opsin proteins in rodent and human pancreatic islets. By using a nucleotide incorporation assay we analyzed the proliferative responses of cell lines, primary murine and primary human pancreatic islets to illumination with blue-green light. The activation of the major proliferative MAPK/Erk and anti-apoptotic PI3K-/Akt pathways after illumination

was assessed by Western blot. Furthermore, we optimized the illumination protocol regarding wavelength- and intensity-dependence for potent proliferative pathway activation.
Results: We found that several opsins, especially panopsin, and to lower levels melanopsin and rhodopsin, are present in rodent and human pancreatic islets. To test whether these opsins have a functional role, we analyzed the response of primary murine and human pancreatic islets to illumination with blue-green light. We determined the percentage of proliferating cells in islets and found increased proliferation after illumination relative to control groups. Illumination furthermore resulted in elevated activation of the major proliferative MAPK/Erk and anti-apoptotic PI3K/Akt pathways, as determined by Erk1/2 and Akt phosphorylation levels.
Conclusion: Taken together, our results show that pancreatic β-cell proliferation can be induced with high spatial and temporal precision using visible light, without addition of exogenous factors or gene transfer, indicating a potential mechanism for a novel therapeutic strategy.

Protective role of complement C3 against cytokine-mediated beta cell apoptosis

R.S. Dos Santos[1], L. Marroquí[1,2], F.A. Grieco[1], L. Marselli[3], S.R. Henz[4], P. Marchetti[3], R. Wernersson[4,5], D.L. Eizirik[1];
[1]ULB Center for Diabetes Research, Université Libre de Bruxelles, Brussels, Belgium, [2]Instituto de Bioingeniería, Universidad Miguel Hernández, Elche, Spain, [3]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [4]Intomics A/S, Lyngby, [5]Department of Bio and Health Informatics, Technical University of Denmark, Lyngby, Denmark.

Background and aims: Type 1 diabetes is a chronic autoimmune disease characterized by pancreatic islet inflammation and β-cell destruction by pro-inflammatory cytokines and other mediators. The complement system, a major component of the immune system, has been recently shown to also act in metabolic organs, such as liver, adipose tissue, and pancreas. In the present study we identified complement C3 as an important hub of a cytokine-modified complement network in human islets and characterized the role of C3 in β-cell survival.
Materials and methods: RNA sequencing and protein-protein interaction analyses of ten human islet preparations left untreated or treated with pro-inflammatory cytokines IL-1β + IFN-γ were used to identify gene networks modified by cytokines. INS-1E cells, primary rat β-cells, and dispersed human islets were transfected with small interfering RNAs targeting C3 (inhibition of >50%) and subsequently exposed to the same cytokines. Viability assays were performed by nuclear dyes (Hoechst/Propidium Iodide). C3, insulin and CXCL10 secretion were evaluated by ELISA kits. mRNA expression was evaluated by RT-PCR, and modulation of signaling pathways was assessed by Western blot analysis.
Results: C3 was identified as a key hub for a cytokine-regulated network containing 216 proteins. Proinflammatory cytokines induced C3 expression (>6 fold increase, n=4-9; $p<0.05$) and secretion (1.6-7 fold increase, n=6; $p<0.05$) in rodent β-cells and dispersed human islets. C3 inhibition did not modify insulin accumulation in the medium or insulin and PDX1 mRNA expression. On the other hand, C3 silencing exacerbated cytokine-induced inflammation, as evaluated by CCL2, CCL5 and CXCL10 expression and CXCL10 secretion (1.3-8 fold increase, n=4-6; $p<0.05$), and apoptosis both under basal conditions and upon cytokine exposure (1.5-2.0 fold increase, n=4; $p<0.05$). These effects were due to JNK activation and AKT inhibition, as shown by mechanistic experiments based on parallel inhibition (JNK) or up-regulation (AKT) of the downstream signaling molecules. Exogenous C3 addition protected against cytokine-induced β-cell death (30-40% protection, n=4-5; $p<0.05$) and partially rescued the effects of C3 inhibition.
Conclusion: Locally produced C3 is an important prosurvival protein in pancreatic β-cells and its deficiency renders β-cells vulnerable to inflammatory stress.

Localisation of a novel Mst1 inhibitor for the therapy of diabetes by MALDI imaging

K. Maedler[1], J. Oetjen[1], L. Hauberg-Lotte[1], S. Li[2], S. Yu[2], T. Baguley[2], M. Surakattula[2], A. Chatterjee[2], N. Rogers[2], W. Shen[2], M. Tremblay[2], K. Annamalai[1], A. Dobrowolski[1], B. Lupše[1], A. Ardestani[1];
[1]Centre for Biomolecular Interactions, University of Bremen, Bremen, Germany, [2]CALIBR, La Jolla, USA.

Background and aims: MALDI imaging mass spectrometry (MALDI-IMS), has been established for an unbiased protein distribution analysis in various organs including the mouse pancreas. In this study, we aimed to use MALDI-IMS for a specific localization identification of neratinib, a tyrosine kinase inhibitor, which was identified in a biochemical kinase inhibition screen as potent MST1 inhibitor. Neratinib is currently in Phase III clinical trials for breast cancer targeting Her2/EGFR dual kinases.
Materials and methods: Beta cell survival and protein expression upon neratinib exposure of human islets and INS-1E cells was analysed by western blotting. Glucose homeostasis was analysed by in-vivo GSIS in daily neratinib or vehicle injected multiple low-dose streptozotocin-induced and obese $Lepr^{db/db}$ mouse models of type 1 and type 2 diabetes. MALDI spectra from 10 μm cryo sections were recorded using a Bruker autofleX speed mass spectrometer.
Results: Neratinib inhibited activated MST1 and restored beta cell survival under multiple diabetogenic conditions in vitro (H_2O_2, high glucose and free fatty acid concentrations and inflammatory cytokines IL-1β and IFNγ) in human islets and INS-1E cells. In vivo, neratinib restored normoglycemia, beta cell function, survival and beta cell mass in type 1 (multiple low-dose streptozotocin-induced) and type 2 (obese diabetic $Lepr^{db/db}$) diabetic mice. In both models, daily intraperitoneal injections of neratinib over 30 days significantly reduced fasting glucose levels and improved glucose tolerance, the insulin/glucose ratio, and glucose-stimulated insulin secretion during a glucose tolerance test. The characteristic isotope distribution of neratinib could be detected by MALDI-IMS in single spectra of high neratinib intense regions in the pancreas 4h after neratinib injection in the mice, while no signal came from vehicle injected control mice. The pancreas was the organ with the highest neratinib specific peak intensity.
Conclusion: We show that neratinib, a novel inhibitor of MST1, can be localized in the pancreas after i.p. injection. It represents a robust proof-of-concept for MST1 inhibition therapy in vivo in rodent models of both type 1 and type 2 diabetes.

A novel human $CD3^+CD56^+$ regulatory subset: involvement in the pathogenesis of type 1 diabetes

M. Santopaolo[1], S. Bruzzaniti[2], V. Rubino[3], S. De Simone[2], A.T. Palatucci[4], A. Giovazzino[3], A. Franzese[3], E. Mozzillo[3], G. Terrazzano[4], G. Ruggiero[3], G. Matarese[1], M. Galgani[2];
[1]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università degli Studi di Napoli "Federico II", [2]Istituto per l'Endocrinologia e l'Oncologia Sperimentale "G. Salvatore", Consiglio Nazionale delle Ricerche, [3]Dipartimento di Scienze Mediche Traslazionali, Università degli Studi di Napoli, Naples, [4]Dipartimento di Scienze, Università degli Studi di Potenza, Potenza, Italy.

Background and aims: The key role of regulatory populations in the prevention of autoimmunity and immune mediated diseases has been largely shown. A number of observations indicates that normal peripheral blood of healthy individuals contains a small percentage of lymphocyte population co-expressing the CD56 and CD3 surface markers that characterize human natural killer (NK) and T cells, respectively. Although the biological hallmarks and functional properties of $CD3^+CD56^+$ cells are poor defined, experimental evidence associated this lymphocyte subset with different pathophysiological conditions. Recently we described that the absolute number of circulating $CD3^+CD56^+$ T at disease onset, associated with a higher β-cell activity in T1D one year later. Moreover, we found that number of $CD3^+CD56^+$ cells was reduced in T1D subjects. Overall, these findings suggest a possible regulatory role for this cell subset in T1D pathogenesis. We aim at investigating the functional properties, the precise role and the mechanism of action of $CD3^+CD56^+$ cells in both physiological and autoimmune diabetes.
Materials and methods: $CD3^+CD56^+$ cells were isolated from peripheral blood mononuclear cells (PBMCs) of human healthy subjects (HS) and T1D, by high-performance cell sorting. Phenotype and functional properties of human $CD3^+CD56^+$ cells was evaluated *in vitro*.
Results: In HS, we found that flow-sorted $CD3^+CD56^+$ cells inhibited proliferation, cytotoxicity and interferon (IFN)-gamma production of $CD8^+$ T cells activated via T cell receptor (TCR), both in autologous and allogeneic conditions. Furthermore, it has been observed that down-modulation of $CD8^+$ T cell effector functions required cell to cell contact and not associated with apoptosis induction. Finally, frequency and suppressive ability of $CD3^+CD56^+$ cells were reduced in T1D compared with HS.
Conclusion: Our data unveil a novel lymphocyte subset with regulatory properties that specifically modulate $CD8^+$ T cell response, which numbers and function were impaired in T1D. Our results are conceivable with the hypothesis that altered $CD3^+CD56^+$ number and activity may account for the deranged effector function of $CD8^+$ T lymphocytes, typical of T1D. Thus, monitoring and therapeutic manipulation of $CD3^+CD56^+$ cells may represent an innovative approach to restore immune-tolerance in autoimmunity.

Double insulin-glucagon positive pancreatic islet cells in type 1 diabetes and the role of cytokines

M. Bugliani[1], V. De Tata[1], C. Gysemans[2], M. Suleiman[1], M. Colli[3], S. Mossuto[1], F. Grano[1], C. Ippolito[1], U. Boggi[1], F. Filipponi[1], L. Marselli[1], A. Dolfi[1], C. Mathieu[2], D.L. Eizirik[3], P. Marchetti[1];
[1]University of Pisa, Pisa, Italy, [2]Katholieke Universiteit Leuven, Leuven, [3]Université Libre de Bruxelles, Bruxelles, Belgium.

Background and aims: Pancreatic islet cells double-positive for insulin and glucagon (DPIGc) have been described in subjects with type 2 diabetes or insulin resistance. Information on DPIGc in human type 1 diabetes (T1D) is limited. We explored the presence of DPIGc in islets of T1D organ donors and studied the effects of a pro-inflammatory milieu.
Materials and methods: Pancreas samples and/or isolated islets from 3 T1D (age: 45±25 yrs; BMI: 25.6±0.5 kg/m^2; duration of diabetes: 12±11 yrs) and 12 non-diabetic (ND; age: 54±19 yrs; BMI: 23.6±4.2 kg/m^2) multi-organ donors were used. Pancreas specimens collected from normoglycemic non-obese diabetic (NOD) mice (16 weeks of age), the human EndoC-βH1 cell line and the rodent INS-1E and MIN6 beta cell lines were also used in selected experiments. Immunofluorescence, confocal and electron microscopy (EM) assessments were performed with tissue samples. Isolated islets from ND were cultured up to 120h with or without the pro-inflammatory cytokines (cyt) IL-1β (50 U/ml) and IFN-γ (1,000 U/ml) and analysed by EM. Beta cell lines were exposed to cyt for 24h and glucagon gene expression was then determined by RNA-Seq and/or quantitative RT-PCR.
Results: Light microscopy studies revealed the presence of DPIGc in T1D pancreatic samples and also in NOD islets with insulitis (approximately 5% of endocrine cells), but these cells were seldom observed in ND individuals. By EM we found that DPIGc were 10±4% (out of 453 cells counted) in T1D and 1±2% (out of 538 cells) in ND islets ($p<0.01$). Cyt-exposed human islets showed a progressive and marked increase of DPIGc (3±2% at 24h, 31±11% at 120h), with decreased proportion of cells containing only insulin granules and an unchanged percentage of cells with only glucagon granules. No apoptotic DPIGc were observed. DPIGc persisted after 48h of cyt removal. On the other hand, cyt exposure did not increase glucagon gene expression in EndoC-βH1, INS-1E or MIN6 cells.
Conclusion: DPIGc are more common in T1D pancreatic islets, possibly deriving from beta cells as a consequence of the pro-inflammatory milieu.

Lack of direct effect of cyt on glucagon expression in beta cell lines suggests that factors derived from the islet microenvironment could play a role in DPIGc formation.

Low-grade inflammatory marker profile is mainly driven by adiposity-related characteristics in patients with LADA, type 1 and type 2 diabetes

E. Castelblanco[1,2], M. Hernández[3], A. Castelblanco[4], A. Esquerda[5], A. Mollo[6], A. Ramirez-Morros[1], J. Franch-Nadal[7,2], J.M. Fernández-Real[8,9], D. Mauricio[1,2];
[1]Institut Germans Trias i Pujol, Badalona, [2]CIBERDEM, ISCIII, Barcelona, [3]Department of Endocrinology and Nutrition, University Hospital Arnau de Vilanova and IRBLleida, Lleida, Spain, [4]Health Sciences Department, Navarra University Foundation, Neiva, Colombia, [5]Department of Laboratory Medicine, University Hospital Arnau de Vilanova and IRBLleida, Lleida, [6]Centre d'Atencio Primaria de Cervera, ICS, Cervera, [7]EAP Raval Sud, ICS, Red GEDAPS, IDIAP, Barcelona, [8]Department of Diabetes, Endocrinology and Nutrition, Hospital Dr Josep Trueta, IDIBGI, Girona, [9]CIBEROBN, ISCIII, Girona, Spain.

Background and aims: Patients with LADA (latent autoimmune diabetes in adults) share some characteristics with both classical type 1 (T1D) and type 2 diabetic (T2D) subjects. Previous work has shown that the clinical and metabolic characteristics of these subjects are perched between T1D and T2D patients. Recent work reported that, apart from the characteristics of the acquired immunology traits, patients with LADA are indistinguishable from T1D diabetic subjects in terms of innate immunity. The hypothesis of this study was that patients with LADA would also show a differential profile in terms of low-grade inflammatory mediators, according to the specific adiposity- and metabolic-related traits.
Materials and methods: Serum levels of adiponectin, sTNFRII (soluble TNF-receptor II), and IL-6 were measured using ELISA, and standard laboratory procedures were used to measure hsCRP (high-sensitivity C reactive protein) and leukocytes in patients with LADA (n=82), T1D (n=73) and T2D (n=442). Multiple logistic regression and lineal models were performed to analyze associations between T1D, LADA and T2D, inflammatory markers, and clinical-metabolic variables (age, sex, GAD antibodies, BMI, WHR), systolic-BP (SBP), diastolic-BP (DBP), glucose, HbA1c, triglycerides, HDL-cholesterol, LDL-cholesterol and total-cholesterol).
Results: The clinical and metabolic variables in patients with LADA were intermediate between T1D and T2D, except for fasting glucose (higher than in T2D). Further, only sex distribution (p=0.218) and total-cholesterol (p=0.580) showed no differences among groups. There were no significant differences in IL6 (p=0.607) among groups. Levels of adiponectin, leukocytes and hsCRP were not different between T1D and LADA; when comparing T2D and LADA, no differences were found for sTNFRII. In logistic regression models: age (p=0.008), DBP (p=0.047) and HDL-cholesterol (p=0.017) were independently associated with LADA and T1D model. In LADA and T2D model, the variables independently associated were age (p=0.044), BMI (p<0.0001), glucose (p=0.025) and HDL-cholesterol (p<0.001). No association of the type of diabetes with any of the cytokines studied was found. In linear regression model, BMI (p=0.009), DBP (p=0.001), HDL-cholesterol (p=0.003), triglycerides (p=0.038), adiponectin (p=0.031), IL6 (p=0.028) and leukocytes (p=0.007) were associated with GAD levels.
Conclusion: Although patients with LADA showed a differential profile of innate inflammatory markers when compared with T1D and T2D, these differences were explained mainly by adiposity-related inflammatory markers regardless of the type of diabetes.

Depletion of STAT6 attenuates the cytoprotective action of interleukin-13 in pancreatic beta cells

K.A. Leslie, M.A. Russell, S.J. Richardson, N.G. Morgan;
University of Exeter, Exeter, UK.

Background and aims: Administration of interleukin (IL)-13 prevents the development of diabetes in non-obese diabetic (NOD) mice and it also protects human and rodent pancreatic beta cells against the cytotoxic effects of pro-inflammatory cytokines. Thus, loss of IL-13 signalling may contribute to the demise of beta cells in type 1 diabetes. IL-13 signals through a cell surface receptor to promote the activation of Jak kinase signalling leading to the phosphorylation and activation of a transcription factor, STAT6. Importantly, we have found that STAT6 expression is diminished in the insulin containing beta cells of patients with Type 1 diabetes and we hypothesise that this may contribute to their loss. Here, we have examined the importance of Jak kinases and STAT6 in mediating the cytoprotective actions of IL-13 in beta cells.
Materials and methods: INS-1E cells were employed to investigate the actions of IL-13 in the presence and absence of various cytotoxic stimuli. Western blotting was used to investigate changes in total and phosphorylated-proteins, with cell viability studied by vital dye staining. Signalling via the Jak/STAT pathway was interrupted either by pharmacological inhibition or using STAT6 specific siRNA. Finally, gene expression studies were performed using a Jak/STAT specific RT-qPCR array, with results verified by primer specific qPCR.
Results: Treatment of INS-1E cells with IL-13 led to a rapid (within 15 minutes) increase in STAT6 phosphorylation at Tyr641 and protected the cells against a range of cytotoxic stimuli including; serum starvation (no serum: 46.4± 3.5% cell death, IL-13:28.0 ± 3.3%; $p < 0.001$), 0.25mM Palmitic acid (PA: 91.4 ± 1.5%, PA+IL-13: 75.1 ± 3.3%$p < 0.001$), and a pro-inflammatory cytokine cocktail (PICs (IL-1β, TNFα, IFNγ and IL-6): 64.7 ± 4.3%, PICs+IL-13: 47.4 ± 2.2% $p < 0.001$). Pharmacological intervention with a selective Jak kinase inhibitor, P6, reversed the cytoprotection by IL-13 (no serum: 30.0 ± 1.3%, IL-13: 16.9±0.8%, IL-13+P6: 30.3±1.3%; $p < 0.001$). To confirm the involvement of STAT6 in this response, siRNA mediated knockdown was used. STAT6 knockdown was achieved efficiently (75%; $p<0.05$) and sustained for 5 days. Depletion of STAT6 did not, itself, alter INS-1E cell viability directly (scrambled control: 11.3 ± 1.7%, siRNA alone: 14.3 ± 2.7%, $p>0.05$) but it markedly diminished the cytoprotective actions of IL-13: (no serum + scrambled siRNA: 27.96 ± 3.3%; no serum + STAT6 siRNA: 42.01 ± 2.6%; $p<0.005$). Analysis of gene expression by RT-qPCR array revealed that IL-13 caused the up regulation of multiple genes and, among these, the largest increase was in a gene encoding SIRPα (also called SHPS-1). This response was attenuated by STAT6 knockdown ($p<0.001$).
Conclusion: These findings demonstrate that phosphorylation and activation of STAT6 is required to mediate the cytoprotective effects of IL-13 in beta cells and reveal that this is accompanied by increased transcription of a previously unrecognised STAT6 target gene in beta cells, SIRPα. The data lend weight to the hypothesis that a reduction in STAT6 activation may contribute to beta cell loss during the progression of type 1 diabetes. Therapeutic targeting of this pathway may therefore be a novel means to reduce β-cell loss.

Background and aims: Autoreactive T cells are a hallmark of type 1 diabetes (T1D) pathogenesis and represent key mediators of islet autoimmunity. Insulitic lesions from both T1D donors and NOD mice are enriched with CD8+ Tcells which lead to beta-cell destruction. Previous studies demonstrated that the human leukocyte antigen (HLA)-A2-restricted zinc transporter 8 $(ZnT8)_{186\text{-}194}$ beta-cell epitope is preferentially targeted by interferon-γ-producing CD8+ T cells in T1D patients. Although such autoimmune reactivity in T1D has been previously reported, information is lacking about the pancreatic localization of such $ZnT8_{186\text{-}194}$-reactive CD8+ Tcell in T1D. Therefore, the aim of this study was to identify $ZnT8_{186\text{-}194}$-reactive cells in the pancreas of T1D donors using HLA-A2 multimer (MMr) immunostaining.
Materials and methods: The in-situ MMr immunohistochemical detection method used herein has been previously reported and validated. OCT frozen pancreatic sections from n=4 T1D, n=4 islet-specific autoantibodies positive (aAb+) and n=4 islet-specific autoantibodies negative (CTR) non-diabetic donors were obtained from the nPOD network. PE (Phycoerythrin)-coupled $ZnT8_{186\text{-}194}$MMrs recognizing autoreactive CD8+ T cells were loaded at 1μg/section and incubated at 4°C overnight. Rabbit anti-PE and Goat anti-Rabbit-HRP were used in order to detect MMr binding.
Results: We investigated whether $ZnT8_{186\text{-}194}$-reactive cells were detected in pancreata from nPOD donors. Sections from all 4 T1D cases analyzed and from 2 of 4 aAb+ cases displayed $ZnT8_{186\text{-}194}$ MMr+ cells, while all sections from CTR cases were negative. $ZnT8_{186\text{-}194}$ MMr+ cells were found scattered either within islets or the exocrine tissue. MMr+ cell count per each section analyzed revealed an increased number of positive cells in T1D cases and aAb+ cases compared with CTR; moreover, an increased number of MMr+ cells were found in islets of T1D cases compared with aAb+ donors. Parallel staining of sections with control MMrs loaded with an irrelevant MelanA peptide did not detect any positive cells, confirming ZnT8 specificity.
Conclusion: We detected for the first time the presence of $ZnT8_{186\text{-}194}$-reactive cells in the pancreas of T1D donors, thus suggesting an unprecedented role for these cells in destructive insulitis during autoimmune diabetes.

Increased expression of CO- and NO-producing enzymes in beta cells of obese mice with incipient diabetes

I.M. Al-Amily, I. Lundquist, A. Salehi;
CRC, Malmö, Sweden.

Background and aims: Our previous observations suggested that carbon monoxide (CO) and nitric oxide (NO) serve as positive and negative modulators, respectively, of pancreatic β-cell function. Here we studied the expression levels of the CO-producing enzymes heme oxygenase 1 (HO-1) and 2 (HO-2) in relation to the nitric oxide (NO) producing enzymes NO synthase 1 (NOS-1) and 2 (NOS-2) in two different animal models with a distinct diabetic phenotype *i.e. ob/ob* and *db/db* at the age of 6 weeks (prediabetic normoglycemic stage) and at 12 weeks (initial hyperglycemic stage) to elucidate a possible role for these enzymes in the early development of spontaneous obese diabetes.
Materials and methods: Fluorescence microscopic analysis of β-cell protein expression levels of the different enzymes in relation to the prevailing plasma levels of glucose and insulin at the different stages of diabetes development. Lean control mice were included. Each group consisted of 6-12 mice.
Results: At 6 weeks the basal plasma levels of glucose were essentially within the normal range in all three groups, while the insulin levels were greatly enhanced in both *db/db* and *ob/ob*. Plasma glucose, controls 7.6 ±0.5 mmol/l vs *db/db* 9.4±0.5 mmol/l and *ob/ob* 9.1±0.6 mmol/l. Plasma insulin, controls 11.1±1.6 pmol/l vs *db/db* 18.1±2.9 pmol/l and *ob/ob* 17.8±3.1 pmol/l ($p<0.05$). β-Cell protein expression of the two NOS-enzymes, especially NOS-2, was extremely high in *db/db* and very low in *ob/ob*. NOS-1 protein expression in controls 93.3±7.2 vs *db/db* 215 ±16.7 and *ob/ob* 97.5±18 (intensity/μm^2) ($p<0.001$ vs *db/db*). NOS-2 intensity/μm^2 was 0.1±0.04 in controls, 167±22.9 in *db/db* and 11.1±3.5 in *ob/ob*, ($p<0.001$ *db/db* vs *ob/ob*). HO-1 was 0.6±0.03 in controls but highly increased in *db/db* (210±22.8) vs *ob/ob* (24.1±5.6) ($p<0.001$). HO-2 was stable in each group although slightly depressed in *ob/ob*. All fluorescence parameters were essentially the same at 12 weeks. The plasma levels of glucose and insulin were now very high in both diabetic groups. Plasma glucose, controls 7.8±0.6 mmol/l vs *db/db* 19.1±0.7 mmol/l and *ob/ob* 18.8±0.9 mmol/l ($p<0.001$). Plasma insulin, controls 17.1±0.7 vs *db/db* 33±1.7 and *ob/ob* 205.8±25.4 ($p<0.001$) for both.
Conclusion: The results suggest that the early development of β-cell demise in *db/db* mice is imposed by a marked increase in the expression of the NOS-enzymes, especially NOS-2. The increase in HO-1 expression seems not to be satisfactory as an antioxidant/antistress factor in *db/db* mice. The leptin-deficient *ob/ob* mice do not react with increased NOS expression and activity, a fact that might be of great importance for their undamaged β-cells and insulin oversecretion throughout their life time.
Disclosure: **I.M. Al-Amily:** None.

Exendin-4 prevents palmitate-induced cell death via modulation of autophagy in INS-1 cells

K. Ahn, J. Ahn, I.-J. Cho, Y.-C. Hwang, I.-K. Jeong, H.-Y. Chung;
Department of Endocrinology and Metabolism, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.

Background and aims: Western diets composed of saturated free fatty acids have been considered as environmental factor contributing to the pathogenesis of type 2 diabetes mellitus (T2DM). Exendin-4 (Ex-4), a glucagon-like peptide-1 receptor agonists (GLP-1 RAs), is an effective therapeutic agent for T2DM and has been proven to protect pancreatic β-cells. Autophagy is essential for the maintenance of β-cell function and mass. Recently, increasing attention is being focused on the effect of autophagy in T2DM. However, the effects of GLP-1 RAs on β-cell functions associated with autophagy also remain elusive. The aim of this *in vitro* study was to evaluate whether GLP-1 RAs can modulate autophagy in β-cells.
Materials and methods: INS-1 cells were treated with 0.5 mM palmitate (PA) and the resultant cell death was measured using MTT assay. Changes in autophagic signaling were measured using autophagy markers like microtubule-associated protein light chain 3 (LC3)-II and p62. To establish the function of Ex-4 on inhibition of autophagy, INS-1 cells were transfected with siRNA against mTOR and raptor, followed by treatment with PA and Ex-4.
Results: Enhanced autophagosome formation was observed upon exposure of INS-1 cells to 0.5 mM PA for 6 h. Treatment with Ex-4 improved the survival of INS-1 cells treated with PA, and reduced the levels of LC II. These findings indicate that autophagy could be activated in PA-treated INS-1 cells, and suggest that Ex-4 might play a protective role in PA-induced cell death through the reduction of excessive autophagy. Knockdown of mTOR and raptor reduced the protective action of Ex-4 against PA-induced cell death, suggesting that mTOR and raptor activation are involved in Ex-4 mediated protection from excessive autophagy in β-cells.
Conclusion: The results of the present study improve the current understanding of mechanisms involved in the protective effects of Ex-4 on pancreatic β-cells and provide evidence for the prevention of β-cell autophagy in clinical practice.
Disclosure: **K. Ahn:** None.

Beta cells exposed to sera from obese diabetic patients undergoing improved glycaemic control exhibit enhanced survival and diminished formation of reactive oxygen species

M. Nemecz[1], A. Constantin[1], M. Dumitrescu[1], N. Alexandru[1], A. Picu[2], B. Smeu[3], G. Tanko[1], M. Simionescu[1];
[1]Institute of Cellular Biology and Pathology "N.Simionescu", [2]Institute of Diabetes, Nutrition and Metabolic Diseases "Prof. Dr N. Paulescu", [3]Ponderas Hospital, Bucharest, Romania.

Background and aims: Pancreatic β-cells are highly vulnerable and react to plasma alterations and to the oxidative stress, common conditions in type 2 diabetes mellitus (T2DM) and obesity. Oxidative stress promotes the expression and activation of different matrix metalloproteinases (MMPs) involved in many cellular functions, including proliferation and apoptosis. We aimed at understanding whether factors present in the sera of (1) obese patients with T2DM and of (2) comparable patients that underwent severe weight loss and improved glycemic control affect differentially beta cells characteristics.
Materials and methods: Forty obese T2DM patients were assigned to two groups according to their treatments: (1) intensive medication for diabetes, and (2) laparoscopic sleeve gastrectomy. Serum samples collected from these patients at baseline (0 month) and 6 months after the beginning of the study were subjected to biochemical assays (the content of 8-hydroxy-2'-deoxyguanosine as an oxidative stress biomarker, and hormones, like leptin and adiponectin) and in vitro studies. For the latter, confluent human insulin-secreting 1.1B4 β-cells were chronically exposed to 10% serum samples from the two groups of patients, collected at 0 and 6 months. After 72 h, the following parameters were investigated: (i) gene and protein expression of MMP2 and MMP9 (by quantitative Real Time-PCR and Western blot, respectively), (ii) production of reactive oxygen species (ROS, estimated with DCFH-DA assay), (iii) cellular viability, proliferation and apoptosis (using MTT assay, xCELLigence system, and flow cytometry after annexin V-FITC/propidium iodide staining), and (iv) the presence of insulin (by immunohistochemistry).
Results: Patients: glucose homeostasis was significantly improved in all patients subjected to gastrectomy and only in a few diabetes-treated patients. In addition, all these patients presented significantly decreased serum levels of 8-hydroxy-2'-deoxyguanosine and leptin, whereas the adiponectin level was increased. Cells: compared to β-cells incubated with sera obtained at the beginning of the study, the β-cells exposed to sera collected after 6 months from patients who succeeded to improve their glycemic control exhibited: (i) increased cell proliferation (32%, $p<0.05$); (ii) decreased ROS production (40%, $p<0.01$) and enhanced protein expression of SOD2, indicating an increased antioxidant capacity; (iii) diminished gene expression of MMP2 and MMP9 (30%, and 7%, respectively, $p<0.05$) and (iv) increased intracellular stored insulin.
Conclusion: Together, these findings indicate that factors present in the obese T2DM patients' sera are injurious for pancreatic β-cells whereas the sera of patients who attained an improved glycemic control, diminished leptin and increased adiponectin levels are not detrimental to cells and modulate molecular mechanisms that enhance their antioxidant capacity (decreased MMP2/MMP9 and increased SOD2 expression) and promote cell survival. These results may facilitate the design of future strategies targeted to protect the β- cells and optimize the treatment of obesity T2DM.

PS 021 Experimental and clinical immunology of type 1 diabetes

443

The macrophage stimulatory activity of the autoantigenic proinsulin B-chain peptide B11-23 is mediated by the 70 kDa heat shock protein DnaK

V. Burkart[1,2], E. Blasius[1], E. Gülden[1], C. Habich[1];
[1]Institute for Clinical Diabetology, Düsseldorf, [2]German Center for Diabetes Research (DZD), München-Neuherberg, Germany.

Background and aims: Autologous insulin represents a dominant antigen in the development of immune reactivity against pancreatic beta cells and in the pathogenesis of type 1 diabetes. Under stress conditions as they occur during inflammatory processes, proteins increasingly associate with heat shock proteins (Hsp). Proteins/peptides bound to Hsp exhibit increased immunogenicity. By chaperoning autologous peptides, Hsp may contribute to the development of autoimmunity. As innate immune cells play an important role in the initiation of beta cell-directed immunity, we hypothesized that Hsp70, a prominent member of the HSP family, and (prepro-)insulin-derived peptides synergize in the activation of macrophages.
Materials and methods: Interactions of the 70 kDa Hsp analogue DnaK with preproinsulin-derived peptides (13 amino acids long) were assessed by competition binding assays. Cultivated cells of the monocyte/macrophage lines J774A.1 and MM6 were exposed to various concentrations of DnaK, to proinsulin-derived 13mer peptides or to combinations of DnaK and the 13mer peptides. The release of inflammatory mediators was quantified by ELISA and multiplex technology.
Results: In a screening assay, a set of overlapping 13mer peptides spanning the entire amino acid sequence of preproinsulin was tested for DnaK binding. A DnaK-binding region was identified in each of the functional preproinsulin domains, i.e. in the signal peptide, the C-peptide and the A- and B-chain. Highest DnaK affinity (K'_d 2.2 ± 0.4 μM) was observed for the B-chain core region B11-23, which had previously been identified as dominant target of (auto-)immune reactivity in type 1 diabetes. Exposure of cultivated macrophages to combinations of 10 μg/ml B11-23 and 1 μg/ml DnaK induced the release of higher levels of tumor necrosis factor α (TNFα) and interleukin 6 (IL-6) from J774A.1 (446±143 pg/ml TNFα; 35±12 pg/ml IL-6; all $p<0.05$)) and MM6 cells (757±110 pg/ml TNFα; 572±42 pg/ml IL-6; all $p<0.01$)) than the individual reagents alone (<122 pg/ml TNFα; <10 pg/ml IL-6). Combinations of DnaK and the peptide B18-30 from the C-terminal region of the B-chain had no significant effects on cytokine release. Binding assays showed a 17.5 fold higher DnaK affinity of B11-23 than B18-30 ($p<0.001$). In a screening approach, macrophage activity, as assessed by the release of inflammatory mediators, remained unaffected by DnaK in the absence or presence of a wide panel of other 13mer peptides of the proinsulin A- and B-chains and the C-peptide.
Conclusion: We conclude that the particular macrophage-stimulating potential of combinations of Hsp70 and B11-23 may contribute to the immunodominance of this insulin peptide in the development of beta cell-directed autoimmunity.

Are any differences in the clinical manifestation and the prevalence of ZnT8-ab and other antibodies depending on age at onset diabetes type 1 in adults?

A. Rogowicz-Frontczak, S. Pilacinski, B. Wierusz-Wysocka, D. Zozulinska-Ziolkiewicz;
Department of Internal Medicine and Diabetes, Medical University in Poznan, Poznan, Poland.

Background and aims: Autoimmune diabetes is a common form of diabetes in childhood and adolescence but it could appear at any age. The aim of the study was to assess the prevalence of diabetes-associated autoantibodies, including zinc transporter 8 antibodies (ZnT8-ab), anti-thyroid antibodies and clinical manifestation of type 1 diabetes (T1DM) (age <35years) and latent autoimmune diabetes LADA (age >35years) at onset of disease.
Materials and methods: The study comprised 119 patients, 66 T1DM (women/men: 18/48; mean age: 26±5 years), LADA (women/men: 19/34; age: 43±8 years). Diabetes was diagnosed based on WHO criteria. To confirm autoimmune diabetes origin autoantibodies were tested: GAD-ab, IA2-ab, ICA, ZnT8-ab, screening for thyroid peroxidase antibodies (ATPO) was performed.
Results: On disease onset there were no differences in BMI, glycaemia, HbA1c value, ketones in the urine, blood pH and TSH between T1DM and LADA patients (p>0,05). In LADA higher C-peptide level (1,2±0,7 vs 1,0±0,5 pmol/ml, p=0,03) was observed. The prevalence of GAD-ab, IA2-ab, ZnT8-ab was similar in both study groups (p>0,05). ICA had been reported more often in T1DM ((81,8 vs 43,3 %, p=0.0007) but ATPO in LADA (35,8 vs 21.2 %, p=0.04). The titres of diabetes-associated antibodies GAD-ab, IA2-ab and ICA were higher in T1DM than in LADA [(691,3±984,4vs280,3±294IU/ml, p=0.004), (731,4 ±1150,2vs 162,4±432,3U/ml, p=0.0001), (254,4±396,0vs49,1±79,1JDF, p=0.0003)]. The prevalence of multiple autoantibody positivity differed significantly between T1DM and LADA. The prevalence of single autoantibody positivity was rare in T1DM (4.5%; ICA only). Commonly, T1DM were positive for two (27.3%), three (40.9%) or four (19,6%) autoantibodies. Conversely, LADA often presented one (30.2%) antibodies (81.2% GAD-ab, 12,5 % IA2-ab and 6,3 % ICA). The number of positive autoantibodies was related to younger age (Rs -0,23), lower C-peptide (Rs -0,28) and higher titres of all antibodies (p<0,05). 45% T1DM and 34 % LADA subjects were positive for ZnT8-ab. ZnT8-ab positive subjects had lower C-peptide level (0,9±0,5vs1,1±0,7pmol/ml, p=0,03) and higher titre of IA2-ab (705,4±1046,2 vs 326,5±846,2U/ml, p=0.03), in T1DM group higher titre of ATPO (97,5±244,4 vs 11,0±34,1U/ml, p=0.04).
Conclusion: Adults classified as T1DM and LADA differ the β-cell function and severity of autoimmune process at the diabetes diagnosis. LADA patients are more prevalent to ATPO. ZnT8-ab positivity is common but not increases the sensitivity for diagnosis of autoimmune diabetes in adults. ZnT8-ab positivity was related to lower β -cell function and higher titre of autoantibodies.
Disclosure: **A. Rogowicz-Frontczak:** None.

Prevalence and diagnostic value of zinc transporter 8 antibodies in Bulgarian population with type 1 diabetes

N. Chakarova, G. Grozeva, R. Dimova, T. Tankova, I. Atanassova;
Diabetology, Clinical Center of Endocrinology, Medical University, Sofia, Sofia, Bulgaria.

Background and aims: Zinc transporter 8 (ZnT8) is the most recently recognized autoantigen involved in the pathogenesis of type 1 diabetes. The assessment of ZnT8 antibodies (ZnT8-Ab) has become available in Bulgaria in the past two years. To that moment there is no data for the prevalence and diagnostic value of this new immunologic marker for Bulgarian population of type 1 diabetes patients. The aim of the study is to investigate the prevalence and diagnostic value of ZnT8-Ab in a Bulgarian population of type 1 diabetes patients.
Materials and methods: 75 patients (45 males and 30 females), of mean age 37.2 ±11.4 years and mean BMI 23.4±4.3 kg/m^2, of up to 5 years duration of the disease were investigated. In 48% of the patients diabetes was newly-diagnosed or of less than a year duration. Antibodies to glutamic acid decarboxylase (GAD 65-Ab), antibodies to thyrosin phosphatase (IA 2-Ab) and ZnT8-Ab were assessed by a quantitative immunoenzyme assay ELISA. The diagnosis of idiopathic type 1 diabetes was established in antibody negative patients with the additional performance of insulin secretion stimulatory test - venous glucose tolerance test with assessment of immunorective insulin, confirming insulinopenia. Statistical analysis of data was performed with SPSS vs. 21 applying descriptive analysis, chi-square test and logistic regression - stepwise forward method.
Results: One or more of the investigated antibodies were detected in 85.7% of the participants, ZnT8-Ab being the second most prevalent - in 45.7% of the group, following GAD 65-Ab - 77.1% and exceeding the prevalence of IA-2-Ab - 34.3%. Triple negative were 14.3% of the participants. Positive to ZnT8 only were 2.9% which accounts for 16.6% of the cases of idiopathic type 1 diabetes. ZnT8-Ab were significantly more prevalent in the subgroup with newly-diagnosed diabetes and diabetes of less than a year duration - 63.6%, (p=0.04). The assessment of the classical combination GAD 65-Ab + IA-2-Ab identified 83% of type 1 diabetes cases (F=[2,3] 43.4, p<0.001, r=0.462). The use of ZnT8-Ab instead of IA 2-Ab as a second immunologic marker identified more cases of type 1 diabetes - 87% (F=[2,3] 46.6, p<0.001, r=0.486), and the combination of all the three antibodies led to the diagnosis of 92% of the type 1 diabetes cases (F=[3,3] 50.7, p=0.043, r=0.515).
Conclusion: In Bulgarian population of adult patients with autoimmune diabetes ZnT8-Ab is the second most prevalent antibody and the second in diagnostic importance after GAD 65-Ab. The assessment of ZnT8-Ab in addition to GAD 65-Ab and IA 2-Ab reduces the cases of idiopathic type 1 diabetes and the use of ZnT8-Ab as a second immunologic marker in addition to GAD 65-Ab outweighs the established combination of GAD 65-Ab+IA 2-Ab.

The role of autoimmune markers in the development of microvascular complication in patients with diabetes

J. Litwińczuk-Hajduk[1], M. Kowrach[1], M. Rabijewski[1], P. Piatkiewicz[1], J. Cielecka-Kuszyk[2];
[1]Department of Internal Diseases, Diabetology and Endocrinology, Second Faculty of Medicine, Medical, [2]National Institute of Public Health, National Institute of Hygiene, Warsaw, Poland.

Background and aims: The available literature contains little data on the prevalence of autoimmune markers other than antibodies against islet antigens in patients with diabetes. The aim of this study was to evaluate the prevalence of antinuclear antibodies (ANA), anti-neutrophil cytoplasmic antibodies (ANCA), antiparietal cell antibodies (APCA), anti-smooth muscle antibodies (ASMA) in patients with type 1 and type 2 diabetes. Another objective of the study was to assess the correlation between their presence and the degree of metabolic control in both studied groups.
Materials and methods: The study included 100 patients aged 25-75 years, with a body mass index (BMI) in the range of 20-30 kg / m2, hospitalized in the Department of Internal Diseases, Diabetology and Endocrinology, with previously diagnosed diabetes who were assigned to one of two 50 subjects' groups (Table 1). In all study participants performed a panel of biochemical tests - fasting blood glucose, HbA1c, lipid profile, liver enzymes, uric acid, serum creatinine, eGFR by MDRD, microalbuminuria. For the determination of antibodies by indirect immunofluorescence techniques were used (Wistar Cmd). In addition, all patients were examined for neurological diabetic neuropathy and fundus examination.
Results: The presence of ANA antibodies were found in 12 patients (24%) with type 1 and 11 patients (22%) with type 2 diabetes. In the patients with type 1 diabetes, there was a correlation between the presence of anti-ANA and the prevalence of diabetic polyneuropathy. No such relationship was observed in patients with type 2 diabetes. In both type 1 and 2 diabetes, there were no relationships between the presence of these antibodies and the presence of diabetic retinopathy and microalbuminuria. The presence of anti-p-ANCA has been found in 16

patients (32%) with type 1 diabetes and 14 patients (28%) of type 2 diabetes, c- ANCA in 5 (10%) and 2 (4%) subjects. In the group of patients with type 1 diabetes, albuminuria was significantly more frequent in patients with ANCA autoantibodies (41% vs 6%). In the case of neuropathy in patients with type 1 diabetes, the incidence reached 41% versus 15%. APCA occurred with equal frequency in both groups with type 1 and with type 2 diabetes -10%. The presence of APCA was associated with the occurrence of peripheral neuropathy, both in subjects with type 1 diabetes and type 2 diabetes.

Conclusion: Identification of ANA and APCA in patients with type 1 diabetes may be a marker used to isolate a group of patients with the risk of developing diabetic neuropathy. The presence of ANCA antibodies in patients with type 1 diabetes may indicate an increased risk of microangiopathic complications. ASMA antibody does not appear to be significant in the diagnosis of diabetes and its chronic complications.

PARAMETER	TYPE 1 DIABETES average (±SD)	TYPE 2 DIABETES average (±SD)

Response to IL-2 signalling is specifically impaired in type 1 diabetes

B. Prietl[1,2], S. Kofler[3], S. Stanzer[4], H. Brezinsek[5], J. Münzker[1], T. Pieber[1,2], H. Sourij[1];
[1]Division of Endocrinology and Diabetology, Medical University of Graz, [2]CBmed, Graz, [3]FH JOANNEUM, University of Applied Sciences, Graz, [4]Division of Oncology, Medical University of Graz, [5]Division of Rheumatology and Clinical Immunology, Medical University of Graz, Graz, Austria.

Background and aims: The response to interleukin-2 (IL-2) is essential for the stability and function of regulatory T cells (Tregs) in vivo. Impaired IL-2 receptor signaling might play a crucial role in the decreased function of Tregs in autoimmunity but might also contribute to the highly increased suppressive capacity of Tregs in cancer. In this study we aimed to examine differences in the phosphorylation of STAT5 as a downstream measure of IL-2 signaling in type 1 diabetes (T1D), rheumatoid arthritis (RA), colo-rectal cancer (CRC) and healthy controls.

Materials and methods: Phosphorylation of STAT5 was examined in patients with T1D, RA, and CRC (10 participants in each group), and in 10 healthy controls. Freshly drawn whole blood samples were stimulated with increasing amounts of IL-2 [0, 0.5, 1, 5, 10 U/ml] for 30 minutes. The expression of phosphorylated STAT5 (pSTAT5) in Tregs was analysed by a multi-parameter FACS staining.

Results: Tregs from T1D patients showed significantly decreased levels of pSTAT5 when compared to healthy controls after stimulation with 0.5 U IL-2 (mean fluorescence intensity MFI: 896 ± 502 vs 3435 ± 1035, p<0.001) and after stimulation with 1 U IL-2/ml (MFI: 1095 ± 942 vs 3835 ± 1415, p=0.004). Tregs from RA patients showed decreased levels after stimulation with 0.5 U IL-2/ml (p=0.043) but not after stimulation with 1U IL-2/ml when compared to healthy controls. No significant differences between cells from CRC patients and controls were found. Stimulation with 5 or 10 U IL-2/ml led to comparable levels of pSTAT5 in all investigated samples.

Conclusion: The response of Tregs towards low doses of IL-2 is highly significantly decreased in Tregs from T1D patients. This might contribute to the loss of tolerance in autoimmunity, such as T1D and RA, whereas low dose IL2 signaling seems not to be involved in the increased suppressive capacity of Tregs from CRC patients.

Inflammation mediates the deleterious effect of pancreatic ductal cells on human islet transplantation

S. Marín[1,2], E. Estilles[1,2], C. García[1], N. Téllez[1,2], M. Nacher[1,2], E. Montanya[1,2];
[1]Diabetes Lab., IDIBELL, University of Barcelona, University Hospital of Bellvitge, L'Hospitalet de Llobregat, [2]CIBERDEM, Barcelona, Spain.

Background and aims: We have recently reported that pancreatic ductal cells have a negative impact on the metabolic evolution and grafted beta cell mass in experimental human islet transplantation. Ductal cells produce cytokines that may be detrimental to islet survival, but they also release angiogenic and growth factors that could improve islet survival and engraftment. The aim of this study was to investigate the mechanisms involved in the deleterious effect of pancreatic ductal cells on human islet transplantation.

Materials and methods: Pancreases of cadaveric organ donors were processed for islet isolation and ductal cells were purified from the exocrine fraction. Pancreatic ductal cells clustered into pancreatospheres (DPS) after 3 day-culture in suspension. Human islets were cultured with/without DPS. Glucose-stimulated insulin secretion (GSIS) (ELISA), β-cell apoptosis (TUNEL) and gene expression (RT-qPCR) of inflammation mediators (*il-1β*, *il1ra*, *nlrp3*, *cxcl11*), macrophages (*cd68*, *cd206*), angiogenic factors (*vegfa*), hypoxia (*hif1a*) and growth factors (*igf2*) was determined after 48 hours in culture. Supernatants were collected after 24, 48 and 72 hours. Eight-hundred human islets (Tx Group) or 800 human islets + 600 DPS (Co-Tx Group) were transplanted under the kidney capsule of immunodeficient mice and gene expression was determined in grafts harvested on day 3 after transplantation.

Results: After 48 hours in culture, β-cell apoptosis was similar in islets cultured with/without DPS (Islets: 0.74 ± 0.31%; Islets + DPS: 0.66 ± 0.22%). GSIS was significantly reduced in islets cultured with DPS (stimulation index, Islets: 6.41 ± 1.14; Islets + DPS: 4.40 ± 0.54; p<0.05). *il-1β* and *cxcl11* gene expression was increased in islets cultured with DPS (p<0.05). IL-1β was detected in 12% and 40% of samples after 48 and 72 hours in culture respectively in islets + DPS preparations, whereas it was not detected at any time in islets cultured in the absence of DPS. *il1ra* expression was increased in islets cultured with DPS although the difference did not reach statistical significance. *igf2* expression was almost undetectable in DPS. Macrophage markers, as well as *nlrp3* and *vegfa* expression were similar in islets cultured with/without DPS. Grafts showed similar gene expression profiles than islets cultured with/without DPS. *il-1β* and *il1ra* expression was increased in Co-Tx grafts (p<0.01), while gene expression of macrophages, angiogenic factors, hypoxia and growth factors was similar in Tx and Co-Tx grafts.

Conclusion: Enrichment of human islet cell preparations with ductal cells has a negative impact on beta cell function. The inflammation induced by pancreatic ductal cells may mediate the deleterious effect of ductal cells on islet transplantation outcome.

The type 1 diabetes candidate gene DEXI modulates virus-induced beta cell dysfunction via regulation of type I interferons

I. Santin[1,2], R.S. Dos Santos[3], L. Marroquí[3], A. Castellanos-Rubio[4], T. Velayos[1,2], A. Jauregi-Miguel[4], D.L. Eizirik[3], L. Castaño[1,2];

[1]Research Group in Endocrinology and Diabetes, BioCruces Health Research Institute, UPV-EHU, Barakaldo, [2]Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders, Barakaldo, Spain, [3]ULB Center for Diabetes Research, Brussels, Belgium, [4]Immunogenetics Research Laboratory, University of the Basque Country, Leioa, Spain.

Background and aims: The chromosome 16p13 region has been associated with several autoimmune diseases, including type 1 diabetes (T1D), and CLEC16A has been proposed as the most likely candidate gene in the region. However recent findings suggest that autoimmune-disease associated SNPs in intron 19 of CLEC16A regulate expression of a neighboring gene, namely DEXI. This suggests that DEXI is the real etiologic gene in the region, potentially playing a role in the pathogenesis of T1D. Against this background, in this work we analyzed the role of DEXI in pancreatic β cell inflammation and death driven by viral infections.
Materials and methods: DEXI was inhibited or overexpressed in rat and human β cells by respectively transfection with specific siRNAs targeting DEXI (inhibition of >70 %) or with adenoviral vectors encoding DEXI (>200-fold increase). Subsequently cells were exposed to a synthetic analog of viral dsRNA (polyinosinic-polycytidylic acid; PIC) or infected with the coxsackie virus B5 (CVB5). Cell viability was evaluated by Hoechst-Propidium iodide staining. Expression of pro-inflammatory chemokines and type I interferons (IFNs) was determined by RT-PCR, and the STAT1 signaling pathway was evaluated by measuring ISRE reporter activity and STAT1 phosphorylation. Cellular localization of DEXI was analyzed in cell fractions by Western blot and interacting partners of DEXI were determined by co-immunoprecipitation experiments. Chemokine expression was also evaluated in DEXI-inhibited cells created by the CRISPR-Cas9 editing technique.
Results: DEXI knockdown protected β cells against PIC- or CVB5-induced apoptosis (30% and 70% protection, respectively; $p<0.001$; n=3-5). Inhibition of DEXI decreased PIC-induced CXCL9, CCL5 and CXCL1 expression in rat and human β cells (by 35-75%, $p<0.01$; n=4-5). In addition, DEXI inhibition decreased PIC-induced STAT1 signaling, as evidenced by decreased phosphorylation of STAT1 and reduced ISRE reporter activation (70% reduction; $p<0.001$; n=4). The decrease in STAT1 signaling may be explained by a significant decrease in PIC-induced IFNβ in DEXI-inhibited β cells. In a mirror image of these experiments, DEXI overexpression increased STAT1 and chemokine expression upon PIC exposure ($p<0.05$; n=3). The function of the protein encoded by DEXI is presently unknown, but bioinformatics analysis predicted the presence of transcription factor-related motifs in its sequence. In line with this, we observed that DEXI is apparently bound to the nuclear chromatin in pancreatic β cells, suggesting a role in transcriptional regulation.
Conclusion: Viral dsRNA up-regulates DEXI in pancreatic β cells, leading to activation of type I IFN signaling, and resulting in increased β cell inflammation and death via STAT1 upregulation. These observations suggest that DEXI, a potential candidate gene for T1D, may act via regulation of local cell innate immune responses in the pancreatic islets.

Therapeutic effects of co-transplanted angiogenic bone marrow-derived spheroids in the intraportal islet transplantation

B.-J. Oh[1], J.-M. Choi[1], S.-M. Jin[1], Y.-S. Kwon[1], G. Kim[1], Y.-C. Hwang[2], J.-H. Kim[1];
[1]Division of Endocrinology and Metabolism, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, [2]Division of Endocrinology, Kyung Hee University School of Medicine, Seoul, Republic of Korea.

Background and aims: We have applied a strategy for co-transplanting accessory cells that possesses higher angiogenic or paracrine activities to islet transplantation. We recently reported that co-transplantation of bone marrow-derived spheroids (BM-spheroid) formed using 3-dimension culture from BM-derived mononuclear cells (BM-MNCs) enhanced therapeutic efficacy of islet in a marginal mass renal subcapsular islet transplantation model. In the present study, we investigated whether co-transplantation of islets with BM-spheroid can improve intraportal islet transplantation outcome in syngeneic mice and assessed the safety and the feasibility of co-transplantation of islets with BM-spheroid in nonhuman primate (NHP) intraportal islet allotransplantation.
Materials and methods: Mice was induced with streptozotocin (STZ) administered intraperitoneally at 180 mg/kg in a citrate buffer solution and cynomolgus monkeys received simultaneous subtotal pancreatectomy and 60-80 mg/kg streptozotocin (STZ) injections to induce diabetes. The efficacy of intraportally co-transplanted BM-spheroids was investigated using a syngeneic marginal mass (300 islets) transplantation in mice, and allogeneic marginal mass (20,000 IEQ per recipient's body weigh in kg) NHP islets were co-transplanted with NHP recipient's autologous BM-spheroids in parallel with immunosuppressive agents after islet infusion. The morphology of intraportally transplanted islet, revascularization of islets and iron-labeled BM-spheroids were examined by immunohistochemistry.
Results: In mice models, portal-spheroid co-transplantation with islets improved the post-transplant outcomes in terms of glucose tolerance, serum insulin levels, and diabetes reversal rate when compared with islet alone. The area of grafted endocrine tissue and vascularization of individual islets within the graft-bearing liver was significantly higher in the spheroid group compared to the islets alone. In NHPs model, post-transplant blood glucose levels were maintained within the target without administration of exogenous insulin only in BM-spheroid group. There were few islets in the recipient's liver in islet alone, whereas more islets were present in BM-spheroid. In both mice and NHPs models, iron-labeled BM-spheroids revealed visible hypointense spots in in vivo MRI, and those of tissue ex vivo MRI corresponded with Prussian blue-positive cells.
Conclusion: Our results suggest that intraportal co-transplantation of BM-spheroids presents a promising strategy for improving the efficacy of islet transplantation. In addition, NHP results suggest the clinical feasibility of intraportal co-transplantation of allogeneic islets and autologous BM-spheroids.

The impact of pro-inflammatory cytokines on the regulatory landscape of the pancreatic beta cells

M. Ramos-Rodríguez[1], H. Raurell-Vila[1], J. Juan-Mateu[2], J.-V. Turatsinze[2], D.L. Eizirik[2], L. Pasquali[1,3];
[1]Endocrine Regulatory Genomics, PMPPC-IGTP, Badalona, Spain, [2]ULB Center for Diabetes Research and Welbio, Medical Faculty, Université Libre de Bruxelles (ULB), Brussels, Belgium, [3]CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

Background and aims: Type 1 Diabetes (T1D) develops as a consequence of genetic predisposition and environmental factors that, combined, trigger an autoimmune assault against the pancreatic β-cells provoking local inflammation (insulitis) and progressive loss of β-cells due to apoptosis. During early insulitis, inflammation contributes to both the primary induction and secondary amplification of the immune assault with inflammatory mediators contributing to the functional suppression and apoptosis of β-cells. The precise mechanisms by which autoimmunity is triggered and aggravated in T1D remain to be clarified. We here seek to elucidate the role of epigenetic gene regulation and its interaction with T1D genetics in the context of the autoimmune mediators that may contribute β-cell death.

Materials and methods: Human insulin-producing EndoC-βH1 cells were exposed to proinflammatory cytokines (IL-1β and IFN-γ) for 48h. RNA-seq in 5 independent cell preparations was assessed to identify transcriptional changes; ATAC-seq in 3 paired replicates and ChIP-seq of H3K27ac were performed under similar experimental conditions to map chromatin remodelling and infer active regulatory elements in each condition.
Results: We found dramatic changes in both gene expression (~1,200 genes differentially regulated, log2FC> 1.5) and chromatin remodeling (~2,000 regions differentially opened, log2FC >1.5). Integration of changes in chromatin accessibility and H3K27ac enrichment unmasked ~4,000 cytokine-induced regulatory elements linked to differential expression of their target genes ($p < 0.001$). Analysis of the sequence composition of the dynamic regulatory landscape unmasked a central role of IRF (motif present in ~70% induced regulatory elements) together with islet-specific transcription factors (NeuroD1, Pdx1 and INSM1) pointing to the activation of specific regulatory networks. Finally, integration of our data with published GWAS studies revealed an enrichment ($P<0.05$) of cytokine induced chromatin remodelling sites at T1D loci.
Conclusion: The present data shows that exposure to proinflammatory cytokines causes profound changes in β-cells gene expression and regulatory landscape. Such changes unmask the activation of specific cis regulatory networks enriched in T1D associated loci, opening the avenue to the identification of new T1D candidate genes acting at the β-cell level.

Everolimus suppress insulin secretion independently of its anti-proliferative or cytotoxic effects reveald by clinical case and in vitro study

L. Suzuki, T. Miyatsuka, M. Himuro, M. Miura, R. Nishio, H. Goto, T. Uchida, A. Kanazawa, H. Watada;
Metabolism and Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background and aims: Everolimus, an orally administered mammalian target of rapamycin (mTOR) inhibitor, has been widely used as immunosuppressive and anti-cancer agents. Although it has been reported that everolimus can control hypoglycemia in patients with insulinoma, the underlying cellular mechanisms still remain to be elucidated.
Materials and methods: Here we report the case of a patient with metastatic insulinoma and refractory hypoglycemia that can be successfully controlled with everolimus. In addition, we established *in vitro* experimental models to investigate the effects of everolimus in insulinoma cell line MIN6 and human iPS cell-derived insulin-producing cells.
Results: A 53-year-old woman was admitted to the hospital for the control of refractory hypoglycemia. She had been diagnosed as primary pancreatic insulinoma at the age of 47 and a tumor resection was performed. Although there was no obvious metastatic lesion identified, she was treated with everolimus for prevention of recurrent severe hypoglycemia. In the first laboratory test, three days after the initial everolimus administration, substantial decrease in insulin secretion (IRI (μU/ml)/plasma glucose (mg/dl), 0.138 to 0.066) was observed and there was no hypoglycemic event after that. After the everolimus was administered for five weeks, it was discontinued since drug-induced lung injury was suspected. Notably, two days after the everolinus discontinuation, more than two-fold increase in serum insulin (IRI/PG 0.078→0.162) was observed. Thus, according to rapid decrease in insulin secretion after everolimus administration and reverse response just after its discontinuation, we hypothesized that everolimus can directly suppress insulin secretion on β cells, independently of its anti-tumor effects. To address this question, we examined glucose-stimulated insulin secretion (GSIS) in MIN6 cells treated with everolimus. Everolimus had no effect on basal insulin secretion with lower glucose concentration (2.8mM). On the other hand, insulin secretion at high glucose concentration (16.7mM) was significantly suppressed by everolimus (48% lower than control, $p<0.0001$). Since there was no significant changes in total insulin content and the number of EdU-positive cells, everolimus is likely to inhibit GSIS independently of its cytotoxic or anti-proliferative effects. Furthermore, everolimus suppressed insulin secretion in human iPS-derived insulin-producing cells.
Conclusion: Both the clinical case that we experienced and *in vitro* experiments with MIN6 cells and human iPS-derived insulin producing cells suggest that everolimus directly suppresses insulin secretion independently of its anti-proliferative or cytotoxic effects, which could reflect at least part of its therapeutic effect.

Impact of Prolylhydroxylases proteins on survival, function and angiogenesis in pancreatic islets: A target to improve islets graft?

A. Langlois, W. Bietiger, C. Peronet, C. Sookhareea, C. Mura, E. Maillard, M. Pinget, S. Sigrist, K. Bouzakri;
DIATECH, EA 7294, Centre Européen d'Etude du Diabète, Université de Strasbourg, Strasbourg, France.

Background and aims: Islet number dramatically drops during the whole process of transplantation leading to high requirement in islets (>10,000 IEQ/kg) to reverse diabetes. For instance, 70% of the transplanted islets are destroyed within the first few days after transplantation, partly due to a poor revascularization. The aim of this project was to enhance angiogenesis from grafted islets targeting hypoxia pathway involving Hypoxia Inducible Factor-1α (HIF-1α). Angiogenesis is mainly triggered by the target genes of HIF-1α which require the prevention of its degradation to dimerize and translocate into the nucleus. The degradation being taken in charge by the Prolylhydroxylases, inhibition of those proteins could be an interesting approach to increase vascularization of the graft.
Materials and methods: The study was realized on rat pancreatic islets. After islet dissociation using Trypsin 0.5%, cells were transfected (Lipofectamine RNAiMax) with 50 nM of siRNA specific against PHD1, 2 or 3 for 4h. Then, after 3 days of islets reformation, viability was determined using FDA/PI staining. Functionality was assessed by glucose stimulation insulin and glucagon secretion (ELISA kit). PHDs and HIF-1α protein expressions were analyzed by western blotting. Finally, the secretion of VEGF was determined in the conditioned medium by Elisa test. Conditions were compared to following controls: untreated dissociated islets, undissociated islets, islets with lipovector alone and islets lipofected with siNUL. Statistics were performed using non parametric test (Mann Whitney). Data were reported as mean ± SEM for the indicated number of replicates and a p value of <0.05 was considered statistically significant.
Results: Islet viability was improved with siPHD1 or siPHD2 *versus* siNUL (siPHD1: 93 ± 1 %, siPHD2: 92 ± 2 % *vs* siNUL: 84 ± 2 %; $p<0.05$; n = 6). Regarding protein expression, PHD3 was up regulated by siPHD1 and siPHD2 (siPHD1: 230 ± 38 % and siPHD2: 250 ± 25 % of PHD3 expression *versus* CTL; $p<0.001$; n = 5), whereas no difference was observed with siPHD3 as compared to CTL. Moreover, siPHDs did not affect PHD1 expression in comparison to CTL and no PHD2 expression was detected. Furthermore, HIF-1α was significantly up regulated *versus* CTL using siPHD2 (254 ± 112 %; $p<0.01$; n = 7) and siPHD3 (188 ± 60 %; $p<0.01$; n = 12).VEGF secretion, major event for triggering angiogenesis, was increased by siPHD1 (siPHD1: 289 ± 121 % of secreted VEGF *versus* CTL; $p<0.05$; n = 15). Islet functionality was improved by siPHD1 with the restauration of glucose stimulation insulin response (2.8 mM glucose: 0.45 ± 0.12 %, 16.7 mM glucose: 1.60 ± 0.68 % of total insulin content; $p<0.05$; n = 9) *versus* siNUL (2.8 mM glucose: 2.65 ± 1 %, 16.7 mM glucose: 2.31 ± 0.78 % of total insulin content; n = 9). No significant results were obtained by the inhibition of both PHD2 and 3 isoforms. Finally, a physiological glucagon secretion in basal condition was observed with siPHD1, 2 and 3 (CTL: 0.78 ± 0.49 %; siPHD1: 0.56 ± 0.20 %, siPHD2:1.83 ± 0.81 %, siPHD3: 0.73 ± 0.21 % of total glucagon content) *versus* siNUL: 7.43 ± 3.37 % of total glucagon content; $p<0.05$; n = 6).
Conclusion: This work showed that PHDs, and more specifically isoform 1, are involved in glycemia regulation and angiogenesis. Consequently, targeting PHDs pathway could be a promising approach to improve islet survival, function and revascularization during transplantation.

Progression of diabetic complications in patients with type 1 diabetes

A. Glazunova[1], M. Arutyunova[1], M. Shamkhalova[1], M. Shestakova[1,2], Y. Moysyuk[3], A. Pinchuk[4], I. Dmitriev[4], S. Arzumanov[5], I. Dedov[1];
[1]Diabetes Institution, Endocrinology Research Centre, [2]I.M. Sechenov First Moscow State Medical University, [3]Transplantation Institution, Moscow regional research clinical Institute n.a. M.F. Vladimirsky, [4]Transplantation Institution, State Budget Institution of Moscow Health "Research Institute of Emergency Care, N.V. Sklifosofskiy Moscow Health Department ", [5]Transplantation Institution, Federal Research Centre of Urology, Moscow, Russian Federation.

Background and aims: Evaluation of the effect of simultaneous transplantation of kidney and pancreas (SPK) on the dynamics of the manifestations of late complications of diabetes mellitus (DM).
Materials and methods: The study included 21 patients with T1DM after successful SPK. Posttransplantation period at the time of inclusion of patients was 11 months [8;18]. 14 people received standard triple immunosuppressive therapy during the study period, 7 patients canceled steroid therapy after 6 months. The average age was 34 years old [31;40], duration of T1DM 22 years [20,5;28], the duration of diabetic nephropathy10 years[8;14,5]. Donors of SPK were young 29 [25; 33] and transplant cold ischemia time was 8[7;10]hours. Follow-up period was 4,2 years [3,6;4,3]. Kidney transplant dysfunction markers: Cystatin C (serum, urine); NGAL, KIM-1, podocin, nephrin, IL-18, IP-10 (urine), TGF-β1, MMP-9, VEGF-A, OPN (serum) were defined.
Results: Patients with SPK functioning graft pancreas - 93.75% and kidney -100% of cases. According to a continuous glucose monitoring system using «iPRO2» euglycemia (glycemia(mmol/l)3,9-8,9-89%, lower than 3,9-11%, higher than 8,9-0%) was marked during the 6 days. HbA1c (before study 9.1% [8,7; 11] then decreased to 5.7% [5,55; 5,9], p<0.0001), insulin 12.5 mkE/ml [11,4; 15,3], basal C-peptide - 2.02 ng/ml [1,07; 2,77]; GFR was 87.6[70;94.4] ml/min/1.73 m^2; albuminuria - 2,6[0,6;5,9]mg/g, parathormone - 78[62,3;73,5] pg/ml, blood pressure 110[105; 122] mm Hg/70[64; 80] mm Hg, Hb - 116 g/l[109;128,5]. High level and a negative associated of blood cystatin C with GFR (r = - 0,36, p<0.05) and positive with albuminuria (r=0,40, p<0,05), as well as a direct link of podocin urine-with blood creatinine (r = 0,35, p<0.05) and NGAL with albuminuria (r = 0,35, p<0.05) in patients after transplantation were defined. Association between podocin with MMP-9 (r = 0,46, p<0,05) and NGAL (r = 0,33, p<0,05) indicated correlation of renal microstructures stress factors . In control terms in 10% of cases noted the need for vitrectomy and additional sessions of photocoagulation of the retina about diabetic retinopathy (20%); newly diagnosed cataract (81.25%), secondary cataracts (25%), glaucoma (25%), macular edema (12.5 %). 35% have ulcers of the lower extremities, 4 patients - manifestation of Charcot's osteoarthropathy, 2 patients underwent amputation with resection of the metatarsal bones, the osteomyelitis in the framework of the diabetic foot syndrome. In connection with the development of stenosing atherosclerosis of vessels of lower extremities, one patient underwent balloon angioplasty and stenting.
Conclusion: Despite the euglycemia and renal function normalization after SPK the progression of diabetic complications and high levels of renal graft dysfunction biomarkers were observed. This fact indicates the need of further monitoring and treatment in this category of patients.

Cardiovascular autonomic function after simultaneous pancreas-kidney and kidney-alone transplantation in patients with diabetes

H. Paajanen[1], M. Bordino[1], A. Sandelin[1], A. Ekstrand[1], M. Lempinen[2], C. Forsblom[1], L. Bernardi[1], P.-H. Groop[1];
[1]Abdominal Center Nephrology, University of Helsinki and Helsinki University Hospital, Folkhälsan Institute of Genetics, Folkhälsan Research Center, [2]Abdominal Center Transplantation and Liver

Surgery, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background and aims: Cardiovascular autonomic dysfunction (CAD) is a common and severe complication of diabetes. Likewise, end-stage renal disease (ESRD) can lead to the development of CAD as dysglycemia as well as uremia both are contributing factors in the etiology of CAD. Moreover, CAD can also be caused by tissue hypoxia. CAD leads to sympathetic nervous system overactivity as well as to a decrease in baroreflex sensitivity (BRS) and heart rate variability (HRV). Kidney-alone (KA) transplantation corrects uremia but simultaneous pancreas-kidney (SPK) transplantation also leads to normalization of blood glucose. The aim of the study was to examine whether CAD is improved at an early stage after KA or after SPK transplantation in patients with diabetes and ESRD. In addition, we wanted to investigate whether tissue hypoxia is improved after transplantation.
Materials and methods: We studied cardiovascular autonomic function in 56 ESRD patients, but only those with diabetes were included in this analysis. Thus 10 patients undergoing KA (59.9 [57.6-67.4] years, median (IQR); 7 men) and 13 undergoing SPK transplantation (36.5 [34.2-49.3] years; 11 men) were selected. BRS, HRV (standard deviation of heart period) and tissue oxygenation (NIRS) were measured before and after (KA 5.9 [3.9-7.2], SPK 3.9 [2.9-7.5] months) transplantation. All SPK and 3 KA patients had type 1 diabetes, while 7 KA patients had type 2 diabetes. In addition, 55 healthy controls (38.3 [32.9-51.0] years, 33 men) were studied.
Results: Before transplantation the autonomic function tests BRS and HRV were reduced but tissue oxygenation was similar in the KA group (BRS 2.1 [1.5-3.2], HRV 4.9 [3.8-5.9], NIRS 62.9 [62.5-62.9]) compared to the SPK group (BRS 2.6 [1.3-4.7], HRV 8.3 [4.7-10.4], NIRS 62.3 [61.9-62.8]). Compared to controls, all values were lower in the KA and SPK groups (controls: BRS 11.7 [8.7-19.3], HRV 28.5 [21.8-39.9], NIRS 65.6 [64.7-66.7]; $p<0.005$). Age-adjusted HRV improved in KA patients after transplantation (7.1 [5.1-8.1]; $p<0.05$). Both BRS and HRV improved in the type 2 diabetic KA patients after transplantation (BRS from 2.1 [1.4-3.0] to 2.6 [1.9-4.0], HRV from 5.2 [2.9-5.8] to 5.3 [4.3-5.9]; $p<0.05$). Furthermore, there was a trend of improvement of age-adjusted BRS, age-adjusted HRV and NIRS in the SPK group after transplantation (BRS 3.9 [2.6-7.6], HRV 9.4 [4.7-11.2], NIRS 64.2 [62.6-65.5]; $p\leq0.1$). Although the improvement in tissue oxygenation after transplantation was not significant between the different groups, it was significant when the data were pooled (NIRS, [n=20], from 62.3 [61.8-62.8] to 64.2 [62.4-66.0]; $p<0.05$).
Conclusion: Diabetic cardiovascular autonomic dysfunction improved early after KA transplantation and after SPK there was a trend of improvement. The data suggest that change in tissue oxygenation and thus relief of tissue hypoxia could play a role in the improvement of cardiovascular autonomic function after transplantation.

Comparaison of metabolic results and complications of procedures for pancreas or islet grafts in the two years following transplantation: a single centre experience

O. Villard[1], S. Delmas[2], P. Benhamou[3], T. Berney[4], J. Brun[5], G. Mourad[2], M.-A. Pierredon[6], F. Panaro[7], A. Wojtusciszyn[1];
[1]Endocrinologie-Diabétologie, CHU Lapeyronie Montpellier, [2]Néphrologie, CHU Lapeyronie Montpellier, Montpellier, [3]Endocrinologie-Diabétologie, CHU Grenoble Alpes, Grenoble, France, [4]Chirurgie digestive, Hopitaux Universitaires Genève, Genève, Switzerland, [5]Physiologie Clinique, CHU Lapeyronie Montpellier, [6]Imagerie Médicale, CHU Saint Eloi Montpellier, [7]Chirurgie digestive et Transplantation, CHU Saint Eloi Montpellier, Montpellier, France.

Background and aims: The restoration of pancreatic beta-cell function, through allogeneic transplantation of pancreas (PT) or islets (IT), can be proposed for selected patients with type 1 diabetes. Results of IT continuously improved from the Edmonton protocol and are almost at the level of those of PT. We compared metabolic results and complications of these 2 techniques, obtained in the 2 years following the first transplantation in patients grafted by one of these techniques in our center.
Materials and methods: Twenty PT (10F/10M) patients (17 received simultaneously a renal transplant) were compared to 14 IT (9F/5M): 3 after a pancreatic transplant failure, 2 after a renal transplant and 9 with an IT alone. Islets transplanted patients' data were taken from GRAGIL and TRIMECO trials and pancreatic transplanted patients were followed at 3, 6 and 12 months by the diabetologist in our center. Data were collected prospectively and expressed as mean. Comparison were made using t-test.
Results: At the time of transplantation, PT recipients were younger than IT (respectively mean age 39 and 49 yrs, $p=0.01$). The 2 groups were similar according to duration of diabetes, BMI, HbA1c and insulin requirements before graft. Nine PT and 12 IT recipients were followed up at 2years. Both grafts significantly reduced HbA1c: median with IQ of 5.3% [5.0; 5.6] and 6% [5.6;6.3] at 1year post-graft, and 6.0% [5.7;7.5] and 6.6% [5.9;7.3] at 2 years, for PT and IT respectively. Insulin-independence in PT often occurs very early after surgery and is estimated at 94%, 81% and 67% respectively at 6 months, 1 and 2 years post-graft. In IT, insulin-independence is estimated at 62%, 69% and 75% after completion of the second or even third islet infusion. Among 31 islet infusions performed, 8 perihepatic hematomas (7 patients), 1 transfusion and 1 radiological embolization occured. Complications occurred in 18 out of 20 PT patients: 6 hemodynamic shocks, 4 pulmonary embolisms, 17 anemias with need of transfusion and 6 sepsis. Early re-surgery (in first 15 days) was necessary in 7 PT (35%): 2 pancreatic venous thrombosis, 1 renal transplantectomy, 4 peri-anastomotic hemorrhages. We report 3 later surgeries: 2 drainages of pancreatic abscess and 1 evisceration. A loss of graft was observed in 4 PT and 3 IT. The iatrogenicity of immunosuppressive drug is comparable between the 2 groups.
Conclusion: Both graft types improved all metabolic parameters in all patients at 2 years post transplantation. These results are observed very early in PT, delayed at 6 months in IT to finally be comparable on the rate of insulin-independence at 2 years. IT remains minimally invasive. PT is associated with severe morbidity with 30% life threatening complications, all favorable at 3 months. Each procedure therefore retains its indications, which must be strictly reserved for patients for whom the benefit/risk balance remains positive.

One world inside another: co-encapsulation of beta cells and nanoparticles containing GLP-1 improves insulin secretion in alginate-based bioartificial pancreas

J. Crisóstomo;
Laboratory of Physiology, IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal.

Background and aims: The bioartificial pancreas presents a promising methodology to treat diabetes: cells are commonly entrapped in alginate hydrogels, being able to secrete insulin properly while being protected from the immune system. However, this method is still associated with a high rate of graft failure caused by poorly functioning cells. In the present work, we developed a novel model based on the co-encapsulation of beta cells with nanoparticles containing glucagon like peptide-1 (GLP-1) on alginate hydrogels, allowing its delivery and action in the specific target, the beta cells.
Materials and methods: Poly(lactide-co-glycolide) (PLGA) was used to produce nanoparticles containing GLP-1 through a modified solvent emulsification-evaporation method, based on the water-in-oil-in-water

(w/o/w) double emulsion technique. Nanoparticles were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). GLP-1 association and release were calculated using a GLP-1 EIA commercial kit. INS-1E beta cells were maintained in culture and, for encapsulation, $5x10^6$/mL were mixed only with 2wt% alginate (Alg 0) or also with nanoparticles (Alg GLP-1) and extruded under a coaxial nitrogen flow using a VarJ1 Encapsulation Unit to a calcium bath for crosslinking. Cellular metabolic activity was assessed by Resazurin and levels of insulin were measured by an insulin ELISA commercial kit after glucose-stimulated insulin secretion assay.

Results: The produced PLGA nanoparticles had an average size of 169.3 ± 3.24 nm, a polydispersity index of 0.05 ± 0.01 and an average zeta-potential of -24.3 ± 3.94 mV. PLGA nanoparticles induced a very low grade of cytotoxicity, decreasing 12% of INS-1E metabolic activity ($p<0.05$) only at a PLGA concentration of 10 mg/ml after 48h of exposure. The average association efficiency of GLP-1 was 65.4% ± 11.5 and the in vitro release test showed a gradual increase of GLP-1 release during time, reaching 71% ± 0.0 after 7 days. Comparing to cells encapsulated in the absence of nanoparticles (Alg 0), the co-encapsulation of nanoparticles containing GLP-1 with INS-1E cells in alginate hydrogels (Alg GLP-1) increased cellular metabolic activity at all timepoints ($p<0.001$ at days 1 and 4 and $p<0.05$ at day 7). The capacity of beta cells to secrete insulin also increased in the presence of nanoparticles: comparing 2mM and 20mM of glucose stimuli, insulin secretion increased 1.8-fold and 5.7-fold ($p<0.001$) in conditions Alg 0 and Alg GLP-1, respectively.

Conclusion: Our results reveal a promising approach to ensure the proper delivery and action of GLP-1 in encapsulated beta cells, leading to a marked increase of insulin secretion. More experiments are required to better characterize this novel model, which can effectively contribute to bioartificial pancreas success.

Continuous glucose monitoring in a mouse model of islet transplantation

A.L.F. Austin[1], R. Rabe[1], M. Nandi[2], P.M. Jones[1], J. Bowe[1], A.J.F. King[1];
[1]Diabetes and Nutritional Sciences Division, King's College London, [2]Pharmaceutical Sciences Institute, King's College London, London, UK.

Background and aims: Blood glucose concentrations are an important end-point in diabetes research utilising mouse models of diabetes. Typically glucose is measured using a glucometer at a frequency of once a day or less often. However, the accuracy of this measurement could potentially be affected by blood glucose fluctuations. Using continuous blood glucose monitoring in unrestrained mice we measured blood glucose fluctuations in mice in the normoglycaemic condition, after streptozotocin injection to induce hyperglycaemia and after islet transplantation. The aim of this study was to measure fluctuations in blood glucose in mice in different states of hyperglycaemia to determine the extent and timings of blood glucose fluctuations.

Materials and methods: Five male C57Bl/6 mice were implanted with continuous glucose telemetry devices with blood glucose measured in the carotid artery in accordance with manufacturer's instructions. Continuous blood glucose monitoring started seven days after probe implantation, with averages reported every 10 seconds. After five days of baseline measurements the mice were injected with 180mg/kg streptozotocin (STZ) to induce diabetes. Five days later, 200 C57Bl/6 islets were implanted under the kidney capsule and animals were maintained for a further 14 days. The light/dark cycle was 12 hours with lights on at 7am and off at 7pm.

Results: In normoglycaemic mice, average day time blood glucose was lower than average night time blood glucose (8.2±0.2 mmol/l vs 8.6 ±0.1mmol/l; $p<0.05$, paired t-test, n=5). Average daily excursions (from lowest to highest measurement) were 5.0±1.2mmol/l. STZ injection led to a rapid peak in blood glucose within 3.0±0.6 hours (18.6±0.4 mmol/l), which was followed by a nadir at an average time of 10.5±0.7 hours after injection (3.6±0.2 mmol/l). Blood glucose concentrations then increased and persistent hyperglycaemia (>16.7 mmol/l) was reached at an average of 40.2±9.0 hours after STZ injection. After islet transplantation, all mice had reduced blood glucose concentrations ($p<0.01$, paired t-test, n=5). Average day time blood glucose was lower than night time blood glucose (12.6±0.6 mmol/l vs 15.5±0.6 mmol/l, P=0.0003, two way repeated measure ANOVA, n=5). Considerable glucose excursions were present throughout the day and night with larger fluctuations at night (median: 9.2mmol/l vs 10.1mmol/l respectively, $p<0.05$, Wilcoxon Rank Sum Test, n=5). Nonetheless, daytime fluctuations were considerable with blood glucose changing rapidly between 7am and 10am (Figure 1), which is a common time to measure blood glucose in mice.

Conclusion: Using continuous glucose monitoring it is clear that blood glucose excursions are considerable in mice. While average day time blood glucose concentrations are lower than night time, fluctuations throughout the day could mean that a single blood glucose measurement may misrepresent the overall glycaemic control of the mouse.

Pancreatic extracellular matrix: novel microencapsulation platform for diabetes cell-based therapy

M. Machluf, L. Baruch, S. Krishtul;
Technion - Israel Institute of Technology, Haifa, Israel.

Background and aims: Encapsulation of pancreatic islets has been investigated for over three decades, aiming to improve islet transplantation outcomes in diabetic patients. Nevertheless, major hurdles impede this approach from reaching the clinic, mainly the limited longevity of the isolated pancreatic islets. Growing understanding of the interactions between cells and their surrounding tissue has led, in the recent years, to componential and structural mimicking of the islets' natural microenvironment, their extracellular matrix (ECM). We previously demonstrated ECM-based encapsulation of human mesenchymal stem cells and liver cells, which were induced to transdifferentiate into insulin producing cells. While this platform resulted in significant amelioration in hyperglycemia and provided a proof of concept for ECM-microencapsulation, we believe the full potential of our platform can be revealed upon addressing

the ECM-microencapsulation of pancreatic islets, naturally secreting substantial doses of insulin in a glucose regulated manner. The overall aim of our study was, therefore, to develop an ECM-based microencapsulation platform for the entrapment of pancreatic islets, to maximize their long term survival and function, while isolating and protecting them from the host immune system.

Materials and methods: We used porcine pancreatic ECM which was decellularized using unique physical, enzymatic and chemical process, and enzymatically solubilized. This solubilized ECM was reassembled into microcapsules of ECM hydrogel, entrapping freshly isolated murine islets.

Results: The unique ECM-microencapsulation platform was optimized to support the long-term viability and function of islets (Fig. 1). Microcapsule size, ECM concentration and islets density were addressed. Hence, upon ECM-microencapsulation the islets remained viable and secreted insulin in a glucose-regulated manner for more than four weeks, indicating at the potential of this platform in overcoming islets' natural poor survival rates post isolation. Islets cultured on ECM gel, adhered to its fibers and remodeled it, revealing a crosstalk between the cells and the ECM, and proving the gel's bioactivity.

Conclusion: Overall, our unique ECM-microencapsulation platform provides pancreatic islets a microenvironment that is permissive for long term survival and insulin secretion, and can therefore, be considered as a prospective platform for beta cell replacement therapy.

RAGE-binding peptide (RBP) as a novel anti-HMGB1 therapy for improving islet transplant survival

S.-H. Ihm[1], H.-J. Hwang[1], M.-G. Choi[1], M. Lee[2], J. Ihm[3];
[1]Internal Medicine, College of Medicine, Hallym University, Chuncheon, [2]Bioengineering, College of Engineering, Hanyang University, Seoul, [3]Chemistry, College of Natural Sciences, Kyonggi University, Suwon, Republic of Korea.

Background and aims: The receptor for advanced glycation end products (RAGE) is a multi-ligand cell surface receptor and is involved in a wide range of inflammatory and degenerative disorders by engaging diverse ligands, including high-mobility group protein B1 (HMGB1). HMGB1 protein released from transplanted islets can trigger innate immune rejection and accelerate the injury to transplanted islets. Therefore, anti-HMGB1 therapy might be a candidate for further improving the outcomes of islet transplantation. In this study, we evaluated whether the blocking of HMGB1/RAGE signaling pathways with novel RAGE-binding peptide (RBP), which is derived from RAGE binding domain (amino-acids 150-183 segment) of HMGB1, can protect islet cells from HMGB1-induced damage in vitro and enhance survival of mouse islet grafts in vivo.

Materials and methods: RBP was overexpressed in bacteria and purified by consecutive chromatographies. INS-1 cells or isolated mouse islets were treated with RBP (5 μg/mL) added in culture media and then treated with HMGB1 (2.5 μg/mL). Intracellular ROS generation in INS-1 cells was measured with H_2DCFDA staining. To assess RAGE expression, INS-1 cells were incubated with rabbit anti-RAGE antibody and FITC-conjugated secondary antibody. Expression of inflammatory cytokine genes was assessed by RT-PCR. Apoptosis was measured in INS-1 and islet cells using Cell-APOPercentage™ Apoptosis Assay. A suboptimal mass of control or RBP-treated syngeneic islets were transplanted intraportally into the liver of streptozotocin-induced diabetic mice. After transplantation, non-fasting blood glucose levels were measured 3 days per week for 30 days.

Results: In INS-1 cells, RBP treatment significantly reduced HMGB1-induced intracellular ROS production, RAGE expression, and apoptotic cell death. In mouse islets, IL-1β and IFN-γ gene expression was highly upregulated after exposure to HMGB1 and RBP-pretreatment reduced IL-1β and IFN-γ gene expression. Islet cells were also protected from HMGB1-induced apoptosis with RBP treatment. Diabetic mice transplanted with a suboptimal mass of RBP-treated islets into the liver became normoglycemic in 50% of the recipients at 30 days post-transplant, whereas none of the mice transplanted with control islets was normoglycemic ($P < 0.05$).

Conclusion: This study shows that RBP suppresses HMGB1/RAGE pathway-dependent proinflammatory and proapototic activation of islets and enhances islet cell survival during the early post-transplant period, and preserved islet mass and functions over time in the transplants. In conclusion, RBP treatment might be a novel anti-HMGB1 therapy to improve the outcome of clinical islet transplantation.

Dynamic molecular changes of porcine neonatal pancreatic cell clusters in culture and after transplantation

W.-C. Li[1,2], C.-Y. Chen[3], P.-C. Huang[1], T.-Y. Kuo[1], Y.-T. Hsieh[1], H.-Y. Chia[2], C.-W. Kao[3], J.-H. Juang[3];
[1]Institute of Oral Biology, School of Dentistry, National Yang-Ming University, [2]Department of Dentistry, School of Dentistry, National Yang-Ming University, Taipei, [3]Division of Endocrinology and Metabolism, Chang Gung University and Memorial Hospital, Taoyuan, Taiwan.

Background and aims: It takes more than 8 weeks to achieve normoglycemia in diabetic nude mice after transplantation (Tx) of isolated porcine neonatal pancreatic cell clusters (NPCCs). The ductal epithelium is primarily detected in NPCC grafts suggesting that initial grafts exhibit progenitor-like phenotype. To further clarify the cell identity of NPCCs grafts, we examined the molecular profile of NPCCs from 1-day neonatal pigs before and after Tx.

Materials and methods: Pancreases obtained from 1-day-old neonatal pigs were cut into fragments, digested by collagenase and maintained in culture. Six and twelve hundred NPCCs were transplanted under the kidney capsule of nondiabetic and diabetic nude mice, respectively. The

mRNA expression of insulin, glucagon and carboxypeptidase B (CPB) in isolated NPCCs were detected by semi-quantitative RT-PCR. NPCC cultures and grafts were fixed, sectioned and quantitatively stained for insulin, glucagon, somatostatin, pancreatic polypeptide, PDX-1, SOX-9 and Ki67.

Results: During 4-day NPCC culture, endocrine insulin and glucagon mRNAs increased while mRNA expression of exocrine amylase and CPB decreased gradually. Soon after NPCC isolation, $Pdx1^{+}$/$Insulin^{-}$ (78.7±1.7% after isolation vs. 51.9±3.1% in 1-day-old pig pancreas) and $Sox9^{+}$ (67.1±3.5% after isolation vs. 6.8±0.7% in 1-day-old pig pancreas) pancreatic progenitors dramatically increased. Moreover, dual-hormonal progenitor-like cells including $insulin^{+}$/$glucagon^{+}$, $insulin^{+}$/$somatostatin^{+}$ and $insulin^{+}$/pancreatic $polypeptide^{+}$ were observed. After Tx, $insulin^{+}$ cells increased whereas $Pdx1^{+}$ and $Sox9^{+}$ progenitors were downregulated in both non-diabetic and streptozotocin-induced diabetic recipient mice over 2 months. Strikingly, it was found that significant higher percentage of $insulin^{+}$ cells were only detected in 9-day (5.24 ±0.42% in diabetic grafts vs. 3.48±0.39% in nondiabetic grafts) and 16-day grafts (5.84±0.68% in diabetic grafts vs. 4.48±0.57% in nondiabetic grafts), but not in 23-day, 30-day and 60-day grafts, indicating that hyperglycemia could facilitated NPCC-derived β cells early post-Tx. Further mechanistic analysis showed that increased diabetes mediated NPCC derived β cells post-Tx is not through an enhanced replication of β cells but via upregulated neogeneic differentiation based on the detection of $insulin^{+}$ cells budding out from $Pdx1^{+}$/$Sox9^{+}$ progenitors in NPCCs grafts. Interestingly, significant decrease of $Sox9^{+}$ progenitors was detected 16 days post-Tx in diabetic grafts (14.14±2.27% in diabetic grafts vs. 49.67±2.63% in non-diabetic grafts); unlike $Sox9^{+}$ cells, $Pdx1^{+}$ precursors between diabetic and nondiabetic grafts do not show significant difference until 60 days post-Tx (33.72±4.52% in diabetic grafts vs. 54.59±6.21% in nondiabetic grafts) implying that distinct NPCC-derived progenitor populations differentially fuel new β cells post-Tx.

Conclusion: In conclusion, our results demonstrated that islet precursors could be activated during NPCC isolation while NPCC progenitors maintained their pluripotency in culture and in early stage post-Tx while neogenesis underlies hyperglycemia mediated graft β cell maturation.

Impact of diabetes on human pancreatic and bone marrow vascular network

G. Graiani[1,2], C.A.M. Lagrasta[1], A. Zecca[1,2], B. Lorusso[1], D. Madeddu[1], P. Crafa[1], R. Vilella[1], C. Mangiaracina[1], A. Falco[1], C. Frati[1], R. Fioretzaki[1], F. Quaini[1,2];
[1]University of Parma, [2]Azienda Ospedaliero-Universitaria di Parma, Parma, Italy.

Background and aims: The variability in tissue response to chronic hyperglycaemia makes it difficult to sustain a unified hypothesis on diabetes associated multiorgan failure. A significant literature exists on the functional impairment of circulating and bone marrow endothelial progenitor cells as a feature of diabetes. However, whether this phenomenon results in an unbalance between injury and repair s is poorly described. Thus, a morphometric analysis of the vascular network on pancreatic and bone marrow tissues in response to diabetes was carried out.

Materials and methods: The effects of type 2 diabetes on different vascular compartments was investigated in 20 patients and compared to 20 normoglycemic subjects. The number and distribution of capillaries, venules, arterioles and lymphatics were determined by immunohistochemistry in pancreatic and bone marrow tissues obtained by the same patients.

Results: Capillary and venules density were significantly reduced in pancreatic insulae, whereas no changes were observed in exocrine parenchyma. However, the reduction in functional parenchyma as a result of diabetes tended to decrease vessels/cells ratio compared to control parenchyma. Similarly, capillary and sinusoids density was significantly reduced in diabetic bone marrow parenchymal and paratrabecular areas when compared to non diabetic cases ($p<0.05$). Compared to controls, lymphatic vessels were also significantly reduced in diabetic pancreas ($p<0.05$) while arteriolar density was unaffected. Interestingly, $CD34^{pos}$ progenitor cells were significantly reduced ($p<0.01$) in both bone marrow and pancreas of diabetic patients compared to controls.

Conclusion: Rearrangement of the blood and lymphatic network and reduction in $CD34^{pos}$ progenitors concur in multiple tissues with diabetes. Although we did not established whether this was a consequence or a cause of diabetes associated multiorgan damage, our approach may offer new insights on the understanding of the diabetic paradox of a tissue specific angiopathy.

Dietary influence on GLP-1 dependent effects in the liver and adipose tissue

S. Folie, K. Salzmann, S. Kaser;
Internal Medicine 1 Innsbruck, Innsbruck, Austria.

Background and aims: Besides its well-known systemic effects on glucose homeostasis by modulating insulin and glucagon secretion glucagon-like-peptide 1 (GLP-1) also affects energy metabolism in various tissues such as the myocardium, liver or adipose tissue. In the pancreatic β-cells GLP-1 exerts its metabolic effects by activating GLP-1 receptor (GLP1R). In other tissues mode of action is less clear: both, GLP1R dependent and GLP1R independent mechanisms have been proposed. In previous studies, incretin mimetic exendin-4 was found to increase sirtuin 1 (Sirt1) expression via nicotinamide phosphoribosyltransferase (Nampt) in hepatocytes thereby improving fatty liver disease in high fat diet fed mice. Aim of this study was to investigate whether GLP-1 dependent effects in the liver and the adipose tissue are influenced by dietary intake.
Materials and methods: Six weeks old male C57BL/6J mice were fed either a fructose-rich (HFru), high fat diet (HFD), mixed high sucrose and high fat diet (HSHFD) or standard diet (SD) for 10 weeks. Glucose tolerance and insulin sensitivity was estimated by oral glucose tolerance test and intraperitoneal insulin sensitivity test. NAMPT and SIRT1 mRNA expressions were determined in livers and visceral adipose tissue samples by fluorescence based real time PCR.
Results: After 10 weeks of feeding HFD (45.12g) and HSHFD (40.13g) but nor HFru (28.76g) fed mice gained significantly more weight than SD (29.54g) mice. The Glucose tolerance as well as insulin sensitivity was significantly impaired in HFD and HSHFD and worsened in HFru mice compared with SD mice. In the liver NAMPT expression was highly upregulated in mice fed a HFD and downregulated in mice fed with HFruD or HSHFD when compared to SD. Hepatic SIRT1 expression tended to be lower in mice fed any carbohydrate-rich diet and was tendentially higher in HFD fed mice. Conversely, NAMPT expression was not relevantly influenced by dietary intake in the visceral adipose tissue, while SIRT1 expression was significantly reduced in HFD and HSHFD fed mice.
Conclusion: In summary we found that dietary intake influences GLP-1 effector proteins and enzymes in a tissue-specific manner. From our data we hypothesize that GLP-1 receptor agonist therapy might be especially beneficial in patients with high dietary carbohydrate intake due to marked downregulation of hepatic NAMPT expression in this setting.

The anti-diabetic role of heat shock protein 72 in mouse model of type 2 diabetes

T. Kondo[1], S. Kitano[1], R. Goto[1], K. Ono[1], M. Igata[1], J. Kawashima[1], H. Motoshima[1], T. Matsumura[1], H. Kai[2], E. Araki[1];
[1]Metabolic Medicine, Kumamoto University, [2]Molecular Medicine, Kumamoto University, Kumamoto, Japan.

Background and aims: Cell stresses, such as endoplasmic reticulum stress or oxidative stress is one of the key mediators in pathophysiology of type 2 diabetes. Molecular chaperone, which modulate protein folding and/or assembly and protect cells from those stresses, may be a favorable target for diabetic treatment. Heat shock protein (HSP) 72 is a major inducible heat shock protein against heat, ultraviolet, heavy metals or infection, and serves to protect cells from those cellular stress signals. Induction of HSP72 by pharmacologic agent or mild electrical stimulation with heat shock improves glucose intolerance in diabetic model mice. In this study, we investigated glucose metabolism in whole body HSP72 deficient (KO) mice to explore the roles of HSP72 in diabetes.
Materials and methods: Male HSP72 KO mice or control mice were subjected to a high-fat diet (HFD) regimen for 16 weeks. Metabolic parameter and pathophysiological examination were performed. HSP72 was overexpressed in HSP72 whole body knockout by lenti-virus system to investigate the role of HSP72 in liver.
Results: KO mice showed significantly higher body weight after 10 weeks of HFD (KO: 36.9 g v.s. control: 33.4 g). Fasting blood glucose was significantly elevated after 11 weeks of HFD (KO: 143.3 mg/dL v.s. control: 115.5 mg/dL). Random fed blood glucose and food intake were comparable. Upon glucose challenge test, blood glucose levels at any time points measured were higher in KO mice. On insulin tolerance test, KO mice exhibited insulin resistant phenotype. Visceral fat mass was increased and hepatic steatosis was obvious in KO mice. Upon insulin stimulation, phosphorylation of Akt was decreased by approximately 50% in KO liver, with increased activation of c-jun N-terminal kinase. Hepatic gluconeogenesis was not suppressed in KO mice. When adding back to HSP72 expression in liver by lenti-viral system on HFD fed KO mice, fasting blood glucose was reversed compared to control mice on HFD.
Conclusion: Deficiency of HSP72 leads to increased visceral adiposity, hepatic insulin resistance, glucose intolerance and fatty liver. As induction of HSP72 in liver is beneficial to treat diabetes, our observations strongly indicate the abundance of HSP72 in liver is critical in diabetic pathophysiology.

From mouse and man: the insulin-degrading enzyme gene governs insulin clearance and drives glucose intolerance and NAFLD development

D.O. Borges[1], R.S. Patarrão[1], J.F. Raposo[1,2], F.O. Martins[1,3], M. Martins[1], R.T. Ribeiro[2], L. Gardete-Correia[2], R. Duarte[2,4], J.M. Boavida[2], I. Correia[2,4], R. Andrade[2], J.L. Medina[4], J. Costa[5], C.P. Gonçalves[5], M.P. Macedo[1,3];
[1]NOVA Medical School, CEDOC, [2]APDP-ERC, Lisbon, [3]Department of Medical Sciences, University of Aveiro, Aveiro, [4]Sociedade Portuguesa de Diabetologia, Lisbon, [5]Instituto Gulbenkian de Ciência, Oeiras, Portugal.

Background and aims: The liver removes 60 to 40% of the circulating insulin that is secreted by the pancreas and reaches the portal vein, a process called Insulin Clearance (IC). IC is a key regulator of peripheral levels of insulin, insulin sensitivity and is associated to metabolic conditions such as Type 2 Diabetes (T2D) and non-alcoholic fatty liver disease (NAFLD). We have previously found that IC impairments in prediabetic individuals were related to a dysmetabolic condition that suggests an inhibition of Insulin Degrading Enzyme (IDE) by increased levels of nitric oxide produced at the post prandial state. Using a human cohort and IDE knockout (IDE-KO) mice we aimed to ascertain if IC is dependent on the IDE gene and test if genetically determined IC impairments contribute to metabolic impairments such as NAFLD and glucose intolerance induced by hypercaloric diets.
Materials and methods: IDE-KO mice with six weeks of age were exposed to a hypercaloric regimen or to standard chow diet and compared to age and sex matched wild type controls. The mice were monitored during 12 weeks of diet exposure by an Oral Glucose Tolerance Tests (OGTT) performed at 4, 8 and 12 weeks. Glucose levels were measured at fasting and at 15, 30, 60 and 120 minutes after a glucose challenge. Serum was obtained at the same time points for IC estimation (Area under the curve (AUC) c-peptide/AUC insulin). In parallel, we evaluated glucose tolerance and IC in the PREVDIAB2 cohort, a collection of 1,088 individuals from the Portuguese population that underwent OGTT analyzed at 0, 30 and 120 min after the glucose challenge. Fatty liver index (FLI) was estimated using validated methodology. Studies of genetic

association in IDE-KIF11-HHEX genomic region were performed using quantitative trait locus (QTL) analysis.
Results: We found that IDE-KO mice show an IC reduction, supporting the notion that the IDE gene is a key regulator of IC. At all time points analyzed and regardless of sex and diet regimen being aggravated with the diet, the IDE-KO mice presented higher levels of glucose intolerance when compared with wild type controls as measured by increased area under the curve of the glucose excursions during OGTT. Genetic association analysis in the PREVADIAB2 cohort identified that 3 SNP variants in the IDE-KIFF11 intergenic region and a SNP located in the upstream region of the IDE gene that are associated with reduced IC and increased liver fibrosis index (NAFLD Fibrosis Score) (0.008<P-value<0.030). Interestingly, subjects with high FLI (FLI>60) showed reduced IC during the OGTT.
Conclusion: Together these results revealed that the IDE gene is critical for the IC mechanism and support the notion that IC impairments governed by the IDE gene are associated with glucose intolerance and NAFLD development. Furthermore, the finding that the 3 SNP variants in the IDE-KIFF11 intergenic region and a SNP located in the upstream region of the IDE gene controls IC provide an explanation for the involvement of this genomic region in Prediabetes/T2D genetic susceptibility.

Alterations in adenosine metabolism and adenosine receptor expression are associated with insulin resistance

I.B. Martins[1], M.J. Ribeiro[1], B.F. Melo[1], T. Rodrigues[2], J.F. Sacramento[1], R. Seiça[2], P. Matafome[2], S.V. Conde[1];
[1]CEDOC, NOVA Medical School, Lisbon, [2]Laboratorio de Fisiologia, IBILI, Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal.

Background and aims: Type 2 diabetes *mellitus* (T2D) is a metabolic chronic disease that is characterized by hyperglycemia concomitantly with insulin resistance and abnormal insulin secretion. Adenosine is a key extracellular signaling molecule that regulates tissue homeostasis through its action in A_1, A_{2A}, A_{2B} and A_3 receptors. It is consensual that in the liver, skeletal muscle and adipose tissue the adenosinergic system is crucial in the regulation of glucose homeostasis/insulin action and in the pathophysiology of T2D. However, remains to clarify which modifications in the adenosinergic system are associated with insulin resistance and with glucose intolerance. Herein we have investigated if alterations in adenosine metabolism and in the expression of adenosine receptors in insulin sensitive tissues, namely liver, adipose tissue and skeletal muscle, are associated with insulin resistance.
Materials and methods: The experiments were performed in 9 - 20 weeks male *Wistar* rats (200-450g). Two groups of rats were used: a control group and the high sucrose (HSu) group. The Hsu group was obtained by submitting the animals to 35% sucrose in drinking water for 4 weeks. Animals were anesthetized and the insulin sensitive-tissues, liver, visceral adipose tissue and soleus muscle were collected. For adenosine release and production, the tissues were incubated during 10, 30 and 60 minutes, in the presence of EHNA (adenosine desaminase inhibitor, 25 μM) and NBTI (equilibrative nucleoside transport inhibitor, 5 μM). The adenosine present in the tissues and in the incubation medium was measured by HPLC. Also, the expression of A_1, A_{2A} and A_{2B} adenosine receptors expression in these tissues was investigated by Western-blot.
Results: In *Soleus* muscle HSu diet significantly increased adenosine production by 102, 141 and 56% and adenosine release by 40, 53 and 80% (for 10, 30 and 60 min of incubation, respectively). In the adipose tissue Hsu diet increased significantly adenosine release by 281.33%, 163.64% and 220.22% after 10, 30 and 60 minutes of incubation, without changing significantly adenosine production. In the liver, Hsu diet did not modify nor the release or the production of adenosine in any of the times of incubation tested. In *Soleus* muscle, HSu diet increased by 40%, 48% and 20%, respectively, the expression of A_1, A_{2A} and A_{2B} receptors. On the other hand, Hsu diet in the adipose tissue, A_1 receptors decreased by 28%, although without statistical significance and A2A receptors decreased by 45%, without altering the expression of A2B receptors. In the liver, Hsu diet decreased by 29.29% A_{2A} receptor expression and increased by 73% A_{2B} expression, without affecting the expression of A_1 receptors.
Conclusion: We can conclude that alterations in the metabolism of adenosine and in the expression of adenosine receptors mainly in the skeletal muscle and the adipose tissue are associated with insulin resistance.

Obesity induced microRNA-222 impairs insulin signalling through the repression of IRS-1 expression in hepatocytes

K. Ono, M. Igata, T. Kondo, S. Kitano, Y. Takaki, S. Hanatani, R. Rieko, T. Senokuchi, J. Kawashima, N. Furukawa, E. Araki;
Department of Metabolic Medicine, Kumamoto University, Kumamoto, Japan.

Background and aims: MicroRNAs (miRNAs) are short non-coding RNAs that post-transcriptionally regulate gene expression, and have been shown to participate in various cellular processes. Several miRNAs have recently been reported to implicate in glucose metabolism, but roles of miRNAs in insulin resistant states, such as obesity or type 2 diabetes, are largely unknown. In this study, we focused on miR-222, whose expression was increased in the livers of high-fat diet fed mice, and investigated the effect of miR-222 on gene expression and insulin signaling in liver.
Materials and methods: MiR-222 expression levels were measured in the livers of HFD-fed mice by real-time quantitative PCR. To examine the role of miR-222 on insulin signaling, hepatocytes were overexpressed with miR-222 and stimulated with insulin. Insulin-stimulated Akt phosphorylation and expression of gluconeogenuc genes were evaluated. In silico analysis, miR-222 potentially binds to the 3' UTR of the IRS-1 gene, a key insulin signaling molecule. To confirm the direct interaction between miR-222 and 3' UTR of IRS-1 gene, a dual-luciferase assay was perfomed.
Results: MiR-222 expressions were upregulated in the livers of HFD-fed mice. Overexpression of miR-222 in primary mouse hepatocytes attenuated protein levels of IRS1 and insulin-induced Akt phosphorylation. In accordance with reduced Akt phosphorylation, Pck1 mRNA was increased. Direct interaction between miR-222 and 3'UTR of IRS-1 gene was confirmed by luciferase assay.
Conclusion: This study demonstrates that hepatic miR-222 is upregulated in an insulin resistant state, which in turn impairs insulin signaling through the repression of IRS-1 expression. These findings suggests that miR-222 could be a novel target for the treatment of obesity associated metabolic disorders.

Metabolic effects of a mixture of low-dose pollutants in a mouse model of estrogen deficiency

B. Julien, C. Pinteur, N. Vega, E. Labaronne, H. Vidal, D. Naville, B. Le Magueresse-Battistoni;
CarMeN Laboratory, Inserm U1060, INRA U1397, Université Claude Bernard Lyon 1, Charles Mérieux Medical School, Oullins, France.

Background and aims: Solid evidences have demonstrated that environmental pollutants contribute to the etiology of obesity and related metabolic disorders. Using a model of lifelong exposure to a mixture of low-dose pollutants, we recently observed aggravation of glucose intolerance

and hepatic insulin resistance of adult females but not of males fed a high-fat high-sucrose diet (HFSD). Conversely, lifelong exposure to the pollutant mixture induced alleviation of glucose intolerance and enhanced insulin sensitivity of immature female mice also HFSD-fed (all occurring in the absence of body weight changes). Thus, we hypothesized that the mixture of pollutants may induce estrogeno-mimetic activities. Indeed, it is well established that estrogens protect females against metabolic disorders at physiological levels but that insulin resistance develops following overstimulation of estrogen receptors or in conditions of estrogen deficiency. To further validate our hypothesis, we evaluated if the mixture of pollutants could reduce the deleterious metabolic effects induced by ovariectomy.

Materials and methods: This study has been carried out along the "Principles of laboratory animal care" (NIH Publication no. 85-23, revised 1985). C57BL/6J female mice were exposed from preconception until adulthood to a HFSD containing (HFp) or not (HF0) a mixture of persistent organic (TCDD, PCB 153) and short-lived (BPA, DEHP) pollutants, each used in the range of its tolerable daily intake reference dose. At 5 weeks of age, mice underwent ovariectomy (OVX) or were sham-operated, generating a total of 4 groups (HF0-sham/HF0-OVX/HFp-sham/HFp-OVX). Weight and food intake were weekly recorded. Several blood parameters, glucose tolerance, plasma lipids and hepatic expression of estrogen receptor α (Esr1) were measured.

Results: OVX resulted in body weight increase with no modification of food intake. Mice fed HFSD showed glucose intolerance and high plasma insulin levels which worsened in OVX mice. Pollutant exposure did not impact body weight, food intake or plasma insulin levels. However, it resulted in a decrease in plasma triglyceride level (0.71 ±0.019 mM *vs* 0.83±0.033 mM; p=0.008) and improvement of glucose tolerance in OVX females. In addition, fasting plasma insulin levels measured at the peak of response after the injection of glucose during the GTT (i.e. 15 minutes) were 1.6-fold higher in HFp-OVX mice than in HF0-OVX mice. This effect was not observed with sham mice. Thus, and although the *p*value=0.06, it may explain alleviation of glucose tolerance by pollutants in OVX conditions. Furthermore, in HFp-OVX mice, the mixture of pollutants led to a 1.4-fold increase in the expression of Esr1 gene (p=0.038) as compared to non-exposed mice that underwent OVX.

Conclusion: Collectively, these results illustrate the cocktail effect resulting from exposure to a mixture of environmental pollutants, each used at a dose supposedly without effect. Consistently with our working hypothesis on the estrogeno-mimetic activity of the mixture of pollutants, we observed beneficial metabolic effects of the pollutant mixture in conditions of estrogen deficiency. Because of the very low doses of pollutants used in mixture, these findings may have strong implications in terms of understanding the potential role of environmental contaminants in the development of metabolic diseases.

Estradiol enhances insulin sensitivity in malnourished mice through estrogen receptor alpha

M. García-Arévalo, E. Lorza-Gil, N.C. Leite, J.F. Vettorazzi, A.C. Boschero, E.M. Carneiro;
Instituto de Biologia and OCRC- UNICAMP, Campinas, Brazil.

Background and aims: Malnourished mice develop increased insulin sensitivity in peripheral tissues and a low insulin secretion by beta cells. Estradiol is a steroid hormone involved in the control of energy balance and glucose homeostasis. The aim of this study was to assess the role of estradiol on glucose homeostasis of malnourished mice.

Materials and methods: To develop the malnutrition model, post-weaned Swiss male mice were fed with low protein diet (6%) during 8 weeks. The insulin hypersensitivity is a characteristic of protein malnutrition. We characterized the malnourishment phenotype through analyses of the body weight, insulin, protein and albumin plasma levels. We analyzed the insulin sensitivity and the effect of 10μg/Kg E2 on it by hyperinsulinemic-euglycemic clamp assay. Western blot was performed to study the insulin pathway in the liver, adipose tissue and, skeletal muscle. Data are expressed as mean ± SEM and statistical significance was determined using two-tailed T-test.

Results: Malnourishment phenotype was confirmed by a lower body weight (control: 41.23±30.64g; LP: 36.30.83±0.38g; p-value: 0.0001), lower plasma levels of insulin (control: 2.94±0.51ng/mL; LP:1.20 ±0.18ng/mL; p-value: 0.002), albumin (control: 2.16±0.07g/dL; LP: 1.92±0.07g/dL; p-value: 0.02) and protein (control: 5.61±0.23g/dL; LP: 4.86±0. 19g/dL; p-value: 0.02). The hypersensitivity to insulin was demonstrated by an increased in glucose infusion in LP group compared with control (control 0.57±0.08mL/min; LP 0.89±0.1mL/min; p-value: 0.005) by a hyperinsulinemic-euglycemic clamp. The stimulation with of 10μg/Kg E2, in the clamp, showed a statistically significant increase in glucose infusion rate in LP group compared with control (control: 0.65 ±0.06mL/min; LP: 1.25±0.12mL/min; p-value: 0.005). This date indicates enhanced insulin sensitivity in LP mice. In addition, estradiol increased the glucose uptake on peripheral tissues (control: 16.33±1.6mg/Kg/min; LP: 36.18±4.2mg/Kg/min; p-value: 0.006). To verify whether these effects were produced by estrogen receptors (ER), mice were treated with ICI 182,780 and MPP, estrogen receptor antagonists, during 4 days. In these mice, the effect of estradiol on glucose infusion and uptake were absent (glucose infusion rate: $LP_{vehicle}$:0.78±0.16mL/min; $LP_{estradiol}$: 0.84 ±0.23mgL/min; glucose uptake: $LP_{vehicle}$: 21.6±4.6mg/Kg/min; $LP_{estradiol}$: 23.4±6.4mg/Kg/min). MPP, an ER alpha antagonist, also prevented the effect of estradiol to enhance insulin sensitivity (glucose infusion rate: $LP_{vehicle}$:1.63±0.19mL/min; $LP_{estradiol}$: 1.05±0.14mgL/min; glucose uptake: $LP_{vehicle}$: 37.94±6.62mg/Kg/min; $LP_{estradiol}$: 26.48 ±2.58mg/Kg/min). We observed an increased activity of insulin pathway, represented by a higher AKT phosphorylation in muscle tissue.

Conclusion: We conclude that the effect of estradiol enhanced the insulin sensitivity on malnourished mice was produced by estrogen receptor alpha, through an increased AKT phosphorylation in muscle.

Beta cell insulin resistance dynamics are different in various animal models

M. Paschen, I. Valladolid Acebes, T. Moede, B. Leibiger, I.B. Leibiger, P.-O. Berggren;
Karolinska Institutet, Stockholm, Sweden.

Background and aims: β-cell failure is central to the development of type 2 diabetes (T2DM). Since the pancreatic β-cell itself is a target for insulin action, β-cell insulin resistance can contribute to β-cell dysfunction. So far β-cell insulin resistance has not been studied in vivo in the context of insulin resistance in other tissues. Here, we used a recently by us developed method that allows specific monitoring of β-cell insulin resistance dynamics in vivo in various genetic and dietary animal models in the context of glucose tolerance, whole body and liver insulin resistance.

Materials and methods: As genetic models for insulin resistance we used ob/ob mice and NZO mice. For diet-induced insulin resistance, C57BL/6J mice were used. Here, mice were treated for 8 weeks with one of the following diets: High-Sucrose-Diet (HSD), High-Fat-Diet (HFD), High-Fat-High-Sucrose Diet (HFHSD) or High-Fat-High-Fructose-Diet (HFHFrD). To monitor β-cell insulin resistance isolated islets of Langerhans were transduced with the β-cell insulin resistance biosensor. This biosensor is based on GFP labelled FoxO1 that changes its position from the cytoplasm to the nucleus in case of insulin resistance. For each model and imaging time point the biosensor allows us to

calculate a relative β-cell insulin resistance index (rβIRI). This index represents the ratio of nuclear to cytoplasmic FoxO1-GFP localization normalized to the control (ob-control or C57BL/6J fed a control diet). Transduced islets were transplanted into the anterior chamber of the eye of mice and imaged by confocal microscopy at distinct time points from 4 weeks after transplantation on. Additionally glucose-, insulin and pyruvate-tolerance tests were performed.

Results: Ob/ob mice are β-cell-, whole-body- and liver insulin resistant at young age (3 months of age (moa); ob-control: rβIRI = 1 ± 0.02; obob: rβIRI = 1.24 ± 0.03; p<0.001). These mice recover from their insulin resistance at older age (10 moa; ob-control: rβIRI = 1.11 ± 0.02, obob: rβIRI = 1.12 ± 0.02; n.s.). NZO mice are β-cell and whole-body insulin resistant from 3 moa (NZO: rβIR = 1.2 ± 0.02; ob-control: rβIRI = 1 ± 0.02; p<0.001) to 6 moa, but did not develop liver insulin resistance. Differences were also seen in diet-induced animal models. While a HSD did not change any of the measured parameters, both a HFD and HFHFrD led to the development of whole-body and liver insulin resistance. Only feeding of a HFHSD resulted in the development of β-cell insulin resistance (after 8 weeks of treatment: Control: rβIRI = 1.04 ± 0.02; HFHSD: rβIRI = 1.18 ± 0.04 p<0.01). This occurred together with whole-body insulin resistance, but not liver insulin resistance. All types of insulin resistances were paralleled by impaired glucose tolerance.

Conclusion: This study shows that different insulin resistance dynamics exist in different models of insulin resistance. Furthermore, we provide evidence for diet-depend differences in T2DM development. Thus, the presented mouse models can be used to study different insulin resistance and T2DM development patterns and lay the ground for the investigation of the underlying molecular mechanisms. This will help to develop novel treatment and prevention strategies to counteract diabetes.

Activation of pregnane X receptor modulates glucose homeostasis in healthy and obese mice

M. Karpale[1], O. Kummu[1], F. Hassani[1], J. Rysä[2], H. Jukka[1];
[1]Research Unit of Biomedicine, University of Oulu, Oulu, [2]Faculty of Health Sciences, University of Eastern Finland, Kuopio, Finland.

Background and aims: The pregnane X receptor (PXR; gene name NR1I2) is a ligand-activated nuclear receptor expressed mainly in the liver and intestine. Its activation leads to induction of drug-metabolism related genes as it acts as a regulator of xenobiotic metabolism. Multiple prescription drugs, environmental pollutants and pesticides are PXR ligands. Recent studies have revealed an additional role of PXR as a regulator of glucose metabolism. In clinical studies, PXR agonists have been shown to impair postprandial glucose tolerance. Also, statins with PXR-activating properties are known to induce hyperglycemia and they have been linked to the prevalence of type 2 diabetes (T2D). The link between exposure to environmental pollutants and T2D is also well established. In mouse experiments, PXR knock-out has been shown to protect from high fat diet-induced impairment of glucose metabolism but PXR activation has also been reported to have a protective effect against high fat diet. To further evaluate and characterize the effect of PXR activation, we administered a selective PXR agonist to both healthy and obese wildtype mice and also to PXR knockout (PXR-KO) mice, and evaluated glucose and insulin tolerance.

Materials and methods: C57BL/6 mice and PXR-KO mice were administered selective murine PXR agonist, pregnenolone-16α-carbonitrile (PCN), 50 mg/kg or vehicle control once a day i.p. for 4 days. Then, the mice were fasted for 12 hours for OGTT or 6 hours for insulin tolerance test (ITT). For OGTT mice were given orally 2 g/kg D-glucose. For ITT, mice were administered 1 U/kg human insulin i.p. The mice were anesthetized with fentanyl-fluanisone and midazolam and blood glucose was monitored for 2 hours. For high fat diet (HFD) experiment, mice were fed high fat diet (Envigo td.06414, 60% of calories from fat) for 15 weeks and weight gain was followed weekly. On week 15, the mice were treated with PCN (n=8/group) or vehicle control and OGTT was conducted. Student's T test was used for statistical analysis for glucose AUC values.

Results: PXR activation by 4-day administration of PCN impaired postprandial glucose tolerance in wildtype mice (P=0.015; n=6) compared to vehicle group (n=6) but not in PXR-KO mice (n=10/group), clearly indicating that the effect of PCN on glucose tolerance is mediated by PXR. However, ITT performed with wildtype mice did not show impairment in insulin sensitivity after PXR-activation, suggesting that detrimental effect of PXR activation arise from diminished insulin secretion. After blood glucose started to rise after insulin administration, from 30 to 120 minutes, PCN treated mice had significantly lower blood glucose level compared to vehicle controls (P=0.001) suggesting inhibition of gluconeogenesis, which has been reported earlier. Interestingly, in obese wildtype mice fed with high-fat diet, the acute PXR-activation improved oral glucose tolerance (P=0.026) showing that PXR-activation possess multifaceted functions on glucose metabolism.

Conclusion: Our results demonstrate that PXR activation impaired postprandial glucose tolerance in healthy mice but improved glucose tolerance after high fat diet, and insulin sensitivity was not affected in healthy mice. PXR activation exhibit clear but complex roles in glucose metabolism possibly providing mechanical link between prevalence of T2D, drugs and environmental chemicals.

Method considerations when estimating insulin sensitivity in streptozotocin-induced diabetic and normal Göttingen minipigs

T.P. Ludvigsen[1], B.Ø. Christoffersen[1], J. Bæklund[2,3], K. Kristensen[3], J.J. Fels[4], V. Manfè[4], J. Kildegaard[1];
[1]Metabolic Disease Research, Novo Nordisk A/S, Måløv, [2]Department of Drug Design and Pharmacology, University of Copenhagen, Copenhagen, [3]Non-Clinical Development, Novo Nordisk A/S, Måløv, [4]Discovery Technology, Novo Nordisk A/S, Måløv, Denmark.

Background and aims: The gold standard for assessing insulin sensitivity in both pre-clinical and clinical studies is the euglycemic hyperinsulinemic clamp. Indices of insulin resistance can also be obtained from glucose tolerance tests, such as the frequently sampled intravenous glucose tolerance test (FSIVGTT). Comparing normal and insulin-depleted individuals is not trivial and the aim of the present study was to evaluate methods for estimating insulin sensitivity in normal and insulin-dependent STZ-induced diabetic minipigs, using different *in vivo* methods.

Materials and methods: Female Göttingen minipigs with (DIA, *n*=6) or without (NORM, *n*=6) STZ-induced insulin-dependent diabetes, were clamped at euglycemia, using a constant i.v. infusion rate of insulin aspart at 0.5, 2, 8 or 16 pmol/kg/min, with or without i.v. insulin bolus or an insulin pre-infusion. Animals were clamped up to 300 min with glucose infusion rates (GIR) adjusted every 15 min from plasma glucose (PG) measurements. In addition, a 2 hour FSIVGTT was performed in both groups dosing a porcine insulin bolus in DIA (0.4 nmol/kg) at t=20 min. PG, insulin exposure, C-peptide, glucagon and endogenous insulin were assessed regularly during both tests. For the clamp, steady state (SS) GIR, insulin infusion rates and plasma insulin exposure across groups were used to fit sigmoidal dose response curves with maximum GIR fixed at 30 mg/kg/min. From the FSIVGTT, insulin sensitivity was estimated by minimal modelling (S_I).

Results: DIA had lower bodyweight (25.2 kg±0.4 (mean±SD) vs. 27.4 ±0.4, p<0.05) and higher fasting PG (16.4 mmol/L±1.4 vs. 3.2±0.4, p<0.05) compared to NORM. In the clamp, a pre-infusion of 180 min

(8 pmol/kg/min) and a dose level of 16 pmol/kg/min were necessary to ensure PG target at SS. An i.v. insulin bolus and i.v. infusion rates of 8 pmol/kg/min or less, was not consistently sufficient for all animals to reach SS and target PG. At comparable insulin infusion rates (8 pmol/kg/min), GIR in DIA was significantly different ($p<0.05$) compared to NORM (1.9 mg/kg/min±0.4 vs 11.9±1.8). In a fitted dose-response curve of GIR to infusion rate, the ED_{50} in DIA was 29 pmol/kg/min compared to NORM ED_{50} of 9.8 pmol/kg/min. S_I was $1.50*10^{-04}$ mL/(min*μU)±$1.02*10^{-04}$ in DIA and $4.75*10^{-04}$±$2.22*10^{-04}$ in NORM.

Conclusion: In this study, optimization of the euglycemic hyperinsulinemic clamp protocol in STZ-induced insulin-dependent diabetic minipigs compared to normal animals was explored. An insulin pre-infusion rate for 180 min (at 8 pmol/kg/min) and an infusion rate of 16 pmol/kg/min were necessary to ensure PG target at SS. Also, data from both tests indicated that DIA had a different response to insulin compared to NORM. However, the pre-hepatic contributions in NORM and the difference in FSIVGTT insulin-profiles exemplifies the challenges in comparing NORM and DIA and this should be taken into account when evaluating insulin sensitivity across the groups. Overall, characterizing the insulin sensitivity and potentially understanding the mechanisms behind the difference of DIA and NORM is an important step towards a better study design and use of the models in the pre-clinical part of drug development.

Absence of Cannabinoid 1 receptor (CB1) in skeletal muscle in mice causes increased lean muscle mass and enhanced insulin action

I. González-Mariscal, R.A. Montoro, J.M. Egan;
National Institute of Health, Baltimore, USA.

Background and aims: Type 2 diabetes mellitus is characterized by deficient insulin secretion and reduced insulin action. We previously reported that inhibiting the cannabinoid 1 receptor (CB1) improves both insulin secretion and insulin action in pancreatic beta cells. Skeletal muscle plays an important role in metabolism because it is responsible for the majority of glucose uptake in the fed state, especially in humans. Therefore, we developed a specific skeletal muscle CB1 knockout (Skm-$CB1^{-/-}$) mouse to determine what role, if any, CB1 plays in skeletal muscle.

Materials and methods: We infused 8-week old Skm-$CB1^{-/-}$ and control Skm-$CB1^{+/+}$ littermates with S961 (insulin receptor blocker) for 6 days to induce acute insulin resistance during which we monitored blood glucose and plasma insulin. We also fed 6-to-8-week old Skm-$CB1^{-/-}$ and Skm-$CB1^{+/+}$ male mice either a standard diet (SD), or a high fat/high sugar diet (HFHS) for 15 weeks to induce chronic insulin resistance. We measured body weight and blood glucose levels throughout the study, and performed an intraperitoneal insulin tolerance tests (ITT) prior to sacrifice. We measured metabolic parameters utilizing CLAMS system, and body composition by nuclear magnetic resonance (NMR) at the end of the study. We evaluated physical performance by placing the mice on a rotarod and a treadmill, and by grip strength test prior to sacrifice. At the end of the study, we cryopreserved muscles for protein extraction and for histological analysis.

Results: S961 induced a 2.8-fold increase in blood glucose (BG) and 30-fold increase in plasma insulin (PI) in Skm-$CB1^{+/+}$ mice, but 1.7-fold and 15-fold respectively in Skm-$CB1^{-/-}$ mice. SD-Skm-$CB1^{-/-}$ had a 1.6-fold increase in endurance only in the rotarod, compared to SD-Skm-$CB1^{+/+}$ mice. After 15 weeks on HFHS body weight and BG were similar in both strains, but circulating PI levels were 25% lower in HFHS-Skm-$CB1^{-/-}$ mice and they were more insulin sensitive based on ITT than HFHS-Skm-$CB1^{+/+}$ mice. Additionally, the respiratory exchange ratio of HFHS-Skm-$CB1^{-/-}$ was significantly lower than in HFHS-Skm-$CB1^{+/+}$ mice, suggesting that Skm-$CB1^{-/-}$ mice are more reliant on fatty acid than glucose metabolism. The lean/fat ratio was significantly higher and the mass of gastrocnemius, soleus, and quadriceps was greater in HFHS-Skm-$CB1^{-/-}$ mice compared to HFHS-Skm-$CB1^{+/+}$ mice. Physical performance tests showed that HFHS-Skm-$CB1^{-/-}$ had greater endurance than HFHS-Skm-$CB1^{+/+}$ mice. Protein array performed on gastrocnemius protein extracts revealed a change in phosphorylation of downstream targets of the insulin receptor pathway.

Conclusion: Absence of CB1 specifically in skeletal muscle increases insulin sensitivity in mouse models of both acute and chronic insulin resistance. Absence of CB1 in skeletal muscle also leads to increased lean/fat ratio, increased muscle mass and improved mouse endurance in physical performance tests. These results collectively show that CB1 is involved in regulating muscle mass and insulin sensitivity, and consequently physical performance.

KBP-089 improves glucose control and reduces liver steatosis, inflammation and fibrosis stage in high fat, high cholesterol fed rats

S. Gydesen, S.J. Daniels, A.T. Larsen, M.A. Karsdal, K. Henriksen;
Nordic Bioscience, Herlev, Denmark.

Background and aims: Insulin sensitizers such as the different PPAR agonists have shown promise as therapies for nonalcoholic steatohepatitis

(NASH), and while these agents have proven efficacious with regards to hepatic histology and glucose control - their use is limited by the conservative beneficial effects and the undesired side effects associated with their use, namely weight gain. Here we present a highly potent dual amylin- and calcitonin receptor agonist (DACRA), KBP-089, which is able to induce substantial weight loss and improve glucose control and insulin sensitivity. Here we evaluate the effect on body weight, glucose control as well as different hepatic features of NASH in rats.

Materials and methods: 6 week old rats received a high fat diet (HFD) for 8 weeks to induce obesity followed by a high fat, high cholesterol and cholate diet (HFCC) for 56 days. After HFD, the rats were significantly obese ($p<0.01$). The rats were assigned into treatment groups receiving either vehicle (saline) or KBP-089 in four doses. All the rats were escalated weekly starting from the lowest dose 0.625 μg/kg and to 1.25, 2.5 and 5.0 $\mu g \cdot kg^{-1}$, respectively. We evaluated the livers using the NAFLD activity score (NAS). The blinded histological assessment of NAS was performed on Masson's Trichrome and Sirius Red stained terminal hepatic tissue from vehicle and KBP-089 E5 μg/kg treated HFCC rats.

Results: KBP-089 induced and sustained a significant vehicle-corrected weight loss - 16.5% in the group receiving the highest dose - and reduced overall adiposity. Importantly, treatment with KBP-089 improved glucose tolerance and enhanced insulin action during and oral glucose tolerance test, resulting in significantly reduced AUC values for both glucose and insulin. Additionally, KBP-089 treatment reduced total triglyceride and AST levels, albeit no difference was observed in ALT levels. At the histological level, KBP-089 impressively reduced both the combined NAFLD activity score and HFCC induced fibrosis stage. Finally, KBP-089 improved insulin action during an oral glucose tolerance test. After 8 weeks of treatment, the HFCC diet induced hepatomegaly was dose-dependently reduced by KBP-089; a reduction, which was equalized when normalized to the individual body weight. The HFCC feeding induced massive lipid accumulation, ballooning and inflammation in the vehicle livers. Notably, after treatment with KBP-089 for 8 weeks, this inappropriate storage of lipids, ballooning, and inflammation were reduced by treatment with KBP-089, hence significantly reducing NAS. Finally, KBP-089 significantly reduced the fibrosis stage in HFCC rats by approximately 60%.

Conclusion: In conclusion, KBP-089 is a weight reducing agent that is well tolerated when introduced by dose escalation. Importantly, KBP-089 enhances glucose tolerance and insulin action and improves hepatic features of NASH, hence revealing the potential of KBP-089 as a therapeutic target in the treatment of T2D and NASH.

Bromocriptine changes adipocyte lipid metabolism improving insulin sensitivity in obese diabetic rats

P. Matafome[1,2], D. Marques[1], A.S. Santos[1], T. Rodrigues[1], J. Sacramento[3], B. Melo[3], R. Seiça[1], S.V. Conde[3];
[1]Faculty of Medicine, University of Coimbra, [2]Coimbra Health School, Polythecnique Institute of Coimbra, Coimbra, [3]Faculty of Medical Sciences, New University of Lisbon, Lisbon, Portugal.

Background and aims: Alterations of adipocyte lipid metabolism in obesity is associated with the development of adipose tissue dysfunction and insulin resistance, ultimately leading to type 2 diabetes (T2D). Bromocriptine, a D2 dopamine receptor agonist, has been shown to be a promising therapeutic strategy in the treatment of T2D, leading to a significant reduction of glycemia. However, its role in modulating the mechanisms of insulin resistance is not known. Thus, our main goal was to assess the therapeutic usefulness of bromocriptine in modulating the mechanisms of lipid and glucose metabolism in periepididymal adipose tissue, as well as the insulin sensitivity in obese type 2 diabetic rats.

Materials and methods: We studied male Wistar rats fed a standard diet (group 1) and non-obese type 2 diabetic Goto-Kakizaki (GK) rats divided into 4 groups: a group fed the standard diet (group 2), a group of obese GK rats induced by a high-fat high-sucrose diet (group 3), a group of obese GK rats treated with bromocriptine 10mg/Kg/day for 30 days (group 4) and a group of obese GK rats treated with the vehicle (group 5) (n=8/group). The glycemic and lipid profiles were assessed and an insulin tolerance test was performed. Moreover, insulin receptor pathway and lipid oxidation, synthesis and storage pathways were also assessed.

Results: Obese GK rats had impaired insulin tolerance, fasting hyperglycemia and higher cholesterol and triglycerides levels than their lean controls. Bromocriptine treatment improved insulin sensitivity and fasting glycemia. Furthermore, despite no alteration were observed in insulin receptor activation, bromocriptine dramatically increased dopaminergic signaling and GLUT4 levels in periepididymal adipose tissue. Regarding the mechanisms involved in lipid metabolism, bromocriptine increased the activation of AMPK, important for lipid oxidation, and caused a downregulation of ACC, FAS and HSL, key enzymes in fatty acid synthesis pathways.

Conclusion: Although the mechanisms still need future investigation, our results show that bromocriptine changes adipose tissue lipid metabolism, also increasing GLUT4 levels. Such events are involved in improving fasting glycemia and insulin sensitivity, suggesting that bromocriptine may be a promising therapeutic strategy in T2D.

Bilateral electrical modulation of carotid sinus nerve improves glucose homeostasis in rodent type 2 diabetes model

S.V. Conde[1], J.F. Sacramento[1], D. Chew[2], B.F. Melo[1], M. Donega[2], W. Dopson[2], A. Robinson[2], J. Prieto-lloret[1], S. Patel[2], B. Holisnski[2], N. Ramnarain[2], V. Pikov[2], M.P. Guarino[1,3];
[1]CEDOC, Faculty of Medical Sciences, Lisbon, Portugal, [2]Galvani Bioelectronics, Stevenage, UK, [3]Escola Superior de Saude de Leiria, Leiria, Portugal.

Background and aims: Bilateral abolishment of carotid body (CB) activity, through surgical resection of the carotid sinus nerve (CSN), restores insulin sensitivity and glucose tolerance in prediabetes and early-phase type 2 diabetes animal models by positively impacting on increased liver and visceral adipose tissue glucose uptake. Application of a high frequency alternating current (HFAC) onto the CSN inhibits action potential propagation through the nerve and was used to study the effect of an electrical, reversible, CSN neuromodulation upon glucose metabolism in a diet-induced early stage type 2 diabetes animal model.

Materials and methods: Rats were fed either a chow or high-fat-high sucrose (HFHSu) diet (60% lipid-rich diet plus 35% sucrose drinking water) during 14 weeks. HFHSu fed rats developed insulin and glucose intolerance. Neural interfaces were bilaterally implanted in the CSNs and attached through a head cap and tether to an external pulse generator. The rats were then randomized to electrical neuromodulation or no neuromodulation groups. Blocking parameters were defined by testing the effect of acute CSN blocking in the response to hypoxia (10% O_2+ 90% N_2, 1 min). Insulin sensitivity was evaluated through an insulin tolerance test and glucose tolerance by an oral glucose tolerance test throughout the duration of the study. Fasting glycemia, insulinemia, ventilatory responses and behavior were also monitored.

Results: HFAC neuromodulation of the CSN, applied continuously over 9 weeks restored insulin sensitivity (K_{ITT} HFHSu sham=2.56±0.41 %glucose /min; K_{ITT} HFHSu CSN electrical block= 5.01±0.52 %glucose/min) and glucose tolerance (AUC HFHSu sham=1278±20.36 mmol/lxmin; AUC HFHSu CSN electrical block=1054.15±62.64 mmol/lxmin) in early-stage type 2 diabetes rat models. Upon cessation of the electrical stimulus, the insulin resistance and glucose intolerance returned within 5 weeks. HFAC neuromodulation of the CSN in chow fed rats decreased basal ventilation and the ventilatory response to hypoxia but behavioral

alterations were not observed. The ventilatory responses were reversible upon cessation of the electrical stimulus.
Conclusion: The present study shows that high frequency block of the CSN improves metabolic control in early-stage type 2 diabetes animal models representing a potential therapeutic tool for the treatment of type 2 diabetes.

Diet-specific effects of apolipoprotein A5 on glucose metabolim

C. Ress[1,2], J. Dobner[2], K. Rufinatscha[2], S. Folie[2], K. Salzmann[2,1], G. Staudacher[1], B. Staels[3], E. Rubin[4], H. Tilg[1], S. Kaser[2,1];
[1]Department of Medicine 1, Medical University Innsbruck, [2]Christian Doppler Laboratory for Metabolic Crosstalk, Innsbruck, Austria, [3]Institut Pasteur de Lille-Université Lille Nord de France, Lille, France, [4]DOE Joint Genome Institute, Berkeley, USA.

Background and aims: Apolipoprotein A5 (ApoA5) is a liver-derived protein with major impact on triglyceride metabolism that has also been found to determine ectopic lipid accumulation in high fat diet fed mice. While its extracellular effects on lipoprotein lipase activity are well understood, cellular effects have not been clearly identified yet. In this study we set out to clearly define diet-specific effects of apoA5 in glucose metabolism.
Materials and methods: Male, apoA5 knockout (apoA5$^{(-/-)}$) and wildtype (wt) mice were fed with different metabolically harmful diets (high fat diet (HFD), high fructose diet (HFruD), mixed high sucrose and high fat diet (HSHFD) or standard diet (STD) for 10 weeks. Characterization of all mice included performance of oral glucose tolerance test (GTT) and intraperitoneal insulin tolerance test (ITT) calculated as glucose area under the curve.
Results: Body weight was comparable in apoA5$^{(-/-)}$ and wt mice in any diet group. Glucose area under the curve during oral glucose tolerance test was significantly lower in HFruD fed apoA5$^{(-/-)}$ mice when compared to HFruD fed wt mice. In any other diet group, glucose tolerance was similar in apoA5 deficient and wildtype mice. In accordance with results from the oral glucose tolerance test, insulin sensitivity estimated by an intraperitoneal insulin tolerance test was significantly higher in HFruD fed apoA5$^{(-/-)}$ mice than in wt littermates, while insulin sensitivity was comparable in apoA5 deficient and wt mice after HFD, HSHFD or SD feeding. As expected, serum triglyceride levels were significantly higher in all apoA5$^{(-/-)}$ mice than in wt mice.
Conclusion: In our studies apoA5 deficiency was associated with improved glucose tolerance and insulin sensitivity in high fructose but not in high fat or mixed high sucrose and high fat diet fed mice. From these results we hypothesize that apoA5 is critically involved in pathogenesis of metabolic disturbances caused by high fructose intake and thus warrants further investigation as novel treatment target in diet-induced metabolic disease.

Hepatocyte-specific Shp1 deletion increases the beneficial effect of rosiglitazone in diet-induced obese mice

K. Bellmann[1], L. Sales Gomez[2], M.-P. Forest[1], M.-H. Lavallée-Bourget[1], R. Junges Moreira[1], M. Schwab[1], Y. Deshaies[1], M. Sola-Penna[2], A. Marette[1];
[1]Centre de Recherche de l'Institut Universitaire de Cardiologie et Pneumologie de Québec, Quebec, Canada, [2]Department of Pharmaceutical Biotechnology, UFRJ, Rio de Janeiro, Brazil.

Background and aims: The protein-tyrosine phosphatase Shp1 plays a critical role in the development of obesity-linked insulin resistance. Hepatocyte-specific deletion of Shp1 in mice ameliorates liver glucose homeostasis and hepatic lipid metabolism. While Shp1 hepatocyte-specific knockout mice (*Ptpn6*$^{H\text{-}KO}$) fed a high-fat diet (HFD) develop increased hepatic steatosis compared to their wild-type littermates (*Ptpn6*$^{fl/fl}$) on the same diet their livers exhibit a reduced inflammatory profile and less hepatocellular damage. Interestingly, we found that peroxisome proliferator-activated receptor gamma (PPARγ) expression and activity was increased in the livers of *Ptpn6*$^{H\text{-}KO}$ mice suggesting a new role for Shp1 in the regulation of PPARγ and the control of hepatic lipid metabolism. Thus, the aim of the present study was to determine whether increasing hepatic PPARγ activity in the liver of the *Ptpn6*$^{H\text{-}KO}$ mice using rosiglitazone (RSG) treatment could further improve hepatic glucose and lipid homeostasis as well as the inflammatory profile in these mice lacking hepatocyte Shp1.
Materials and methods: *Ptpn6*$^{H\text{-}KO}$ and *Ptpn6*$^{fl/fl}$ mice were kept on a standard or HFD (55% kcal fat) for 18 weeks starting at 8 weeks of age. During the last 4 weeks animals were treated with a very low dose of RSG (0.3 mg/kg/day), which aims at mainly targeting the liver to avoid confounding effects on the liver due to rosiglitazone acting on adipose tissue. Oral glucose tolerance tests (oGTT) were performed before and at the end of RSG treatment. At 18 weeks mice were sacrificed for further plasma and tissue analyses.
Results: RSG treatment improved glucose tolerance more in high-fat fed *Ptpn6*$^{H\text{-}KO}$ mice as compared to *Ptpn6*$^{fl/fl}$ littermates. Glucose-induced insulin response during oGTT was not affected. Insulin-induced Akt phosphorylation was increased in RSG-treated *Ptpn6*$^{H\text{-}KO}$ and *Ptpn6*$^{fl/fl}$ mice on HFD compared to untreated HFD mice. Liver weight and hepatic triglyceride levels were increased by RSG in both *Ptpn6*$^{fl/fl}$ and *Ptpn6*$^{H\text{-}KO}$ mice on HFD. Despite this increase in hepatic steatosis, we observed a stronger increase in IL-10 expression in RSG treated *Ptpn6*$^{H\text{-}KO}$ mice than in the *Ptpn6*$^{fl/fl}$ mice without any changes in TNFα or IL-1β levels or macrophage infiltration based on determination of F4/80 levels. Interestingly, RSG treatment did not affect any of the fat pad weights nor did it alter adiponectin level in mice of both genotypes on HFD confirming that the low dose of RSG mainly affected the liver.
Conclusion: Our data suggest that hepatic invalidation of Shp1 increased the beneficial effect of RSG on glucose tolerance, which is associated with increased production of anti-inflammatory IL-10 in the liver of HFD-fed obese mice.

Liver-specific ablation of insulin-degrading enzyme causes hepatic insulin resistance and glucose intolerance, without effect on insulin clearance in mice

P. Villa-Perez[1], P. Cidad[1], C.D. Lobaton[1], A. Moreno[1], M. Leissring[2], I. Cozar-Castellano[1], G. Perdomo[3];
[1]Instituto de Biologia y Genetica Molecular, Valladolid, Spain, [2]University of California Irvine, Irvine, USA, [3]Ciencias de la Salud, Universidad de Burgos, Burgos, Spain.

Background and aims: Insulin-degrading enzyme (IDE) is a ubiquitously expressed zinc-metalloprotease that is one of the principal enzymes implicated in the degradation and clearance of insulin, in addition to glucagon, amylin and the amyloid-ß protein (Aß). Several polymorphisms of IDE are associated with risk for type 2 diabetes (T2D) in humans, whereas hepatic insulin clearance is reduced in T2D patients. Although strongly implicated in insulin clearance in vivo, the role of IDE specifically in the liver—the principal site of plasma insulin clearance—remains unclear. The aim of this study is to decipher the role of IDE on hepatic insulin signaling and its impact on whole-body glucose metabolism and insulin clearance.
Materials and methods: To ablate IDE selectively in hepatocytes, mice homozygous for a floxed *IDE* allele were intercrossed with albumin-Cre

mice (hereafter L-IDE-KO). Metabolic studies were performed in 3-month-old male mice for fasting and non-fasting glucose, insulin, triglycerides, and body weight. Likewise, intraperitoneal glucose and insulin tolerance tests, and hepatic plasma insulin clearance were assessed. To analyze hepatic insulin signaling, fasted mice were injected intraperitoneally with insulin (0.75U/Kg) for 10 min. Afterwards, mice were sacrificed and liver (or skeletal muscle) tissues analyzed by western blot for total and phosphorylated levels of the insulin receptor (IR), and protein kinase B (AKT1 and AKT2). Glucagon, Aβ40 and amylin levels were assessed by ELISA.

Results: L-IDE-KO fasting and non-fasting plasma glucose levels were higher (~20%) than control mice. These changes were not associated with augmented food intake or body weight. Of note, fasting and non-fasting plasma insulin levels were similar between control and L-IDE-KO mice. In parallel, L-IDE-KO showed glucose intolerance and insulin resistance. Surprisingly, hepatic plasma insulin clearance was similar between L-IDE-KO and control mice. Plasma amylin and Aβ40 levels remained unchanged between control and L-IDE-KO mice, whereas non-fasting plasma glucagon levels showed a ~50% non-statistically significant increase in L-IDE-KO mice compared to control mice. Hepatic insulin resistance in the L-IDE-KO mouse was associated with reduced plasma membrane IR levels (~30%), as well as reduced phosphorylation levels (~55%). Consistently, phosphorylation of AKT1 and AKT2 were reduced by ~45% at both Ser473 and Thr308 residues. Finally, muscle insulin signaling (phosphorylation of AKT) was unaffected by hepatic ablation of IDE.

Conclusion: We have revealed a new role for IDE in the regulation of hepatic insulin signaling. Our data suggest that IDE might be a key player in hepatic insulin resistance. We hypothesize that IDE regulates IR recycling to plasma membrane, and its activity, in response to insulin stimulation in hepatocytes. Finally, our data demonstrate that IDE is not necessary for hepatic plasma insulin clearance.

Febuxostat improves skeletal muscle insulin resistance via upregulating skeletal muscle PGC-1α expression in high fat diet fed male Wistar rats

C. Moriya, H. Satoh, H. Watada;
Department of Metabolism and Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background and aims: Hyperuricemia is closely associated with various metabolic disorders such as diabetes, hypertension, dyslipidemia, and cardiovascular diseases. Xanthine oxidoreductase (XOR) is a key enzyme known to catalyze purines to uric acid. Febuxostat is an orally-active, potent, non-purine, selective XOR inhibitor. However, the effect of febuxostat on glucose and insulin metabolism has not been fully elucidated. In current study, we investigated the effect of febuxostat on insulin sensitivity in male Wistar rats, whereby insulin sensitivity was measured directly using the hyperinsulinemic-euglycemic glucose clamp studies (at 25 mU/kg/min insulin infusion rate) after an 8 hour fast.

Materials and methods: Male Wistar rats were fed normal chow diet (NCD), or 60% high fat diet (HFD) containing with either febuxostat (~4 mg/kg/day) or not, for 4 weeks. Euglycemic-hyperinsulinemic clamp studies were performed after an 8-hour fast. All procedures were performed in accordance with the Guide for Care and Use of Laboratory Animals of the NIH and were approved by the Animal Subjects Committee of our institute.

Results: In the NCD fed rats, during the clamp studies, the glucose infusion rate (GIR), the clamp hepatic glucose output (cHGO) and insulin-stimulated glucose disposal rate (IS-GDR) were no significant changes between two groups. On the other hand, in the HFD fed rats, the GIR and IS-GDR were significantly increased by 12% and 17%, respectively, in febuxostat group compared to in the HFD fed control group. But cHGO was no significant change between two groups. Consistent with the clamp data, the insulin-stimulated phosphorylation of Akt and AMPK were significantly increased by 90% and 53%, respectively, in skeletal muscle of HFD fed febuxostat treated HFD fed rats. Furthermore, peroxisome proliferator-activated receptor-γ coactivator (PGC)-1α expression in skeletal muscle, which is a key regulator of mitochondrial content and function, was significantly increased by 2 folds in HFD fed febuxostat treated rats compared to the HFD fed control rats, as assayed by real-time qRT-PCR.

Conclusion: Our findings demonstrated that febuxostat had beneficial effects on skeletal muscle insulin sensitivity in an insulin resistant state.

A_2 adenosine receptors mediate chronic caffeine effects on insulin sensitivity

J.F. Sacramento[1], M.J. Ribeiro[1], T. Rodrigues[2], P. Matafome[2], M.P. Guarino[1,3], R. Seiça[2], S.V. Conde[1];
[1]CEDOC, NOVA Medical School|Faculdade Ciências Médicas, Universidade Nova de Lisboa, Lisbon, [2]Laboratório de Fisiologia, IBILI, Faculdade de Medicina, Universidade de Coimbra, Coimbra, [3]Escola Superior de Saúde de Leiria, Instituto Politécnico de Leiria, Leiria, Portugal.

Background and aims: Several epidemiological studies showed that chronic caffeine intake decreased the risk of type 2 diabetes, and our group demonstrated that chronic caffeine intake prevents the development of insulin resistance in diet-induced insulin resistance rats. Caffeine has several cellular mechanisms of action, being the antagonist of adenosine receptors the only attained with human coffee consumption. The aim of this work is to unravel the subtypes of adenosine receptors involved on the effects of chronic caffeine intake on insulin sensitivity and the mechanism behind this effect.

Materials and methods: Two groups of Wistar Rats of both sexes (9-12weeks) were used. The control group fed a sham diet and the high-sucrose (HSu) group fed 35% sucrose in drinking water during 28 days. The control and HSu animals were randomly divided into three subgroups that were submitted to the i.p. administration of DPCPX (A_1 antagonist, 0.4mg/kg), SCH58261 (A_{2A} antagonist, 0.5mg/kg) and MRS1754 (A_{2B} antagonist, 9.5μg/kg), respectively, in the last 15 days of the diet. Insulin sensitivity was assessed through an insulin tolerance test. Blood pressure, visceral and total fat were measured. Skeletal muscle, adipose tissue and liver were collected to evaluate, by western blot, alterations in the expression of Glut4, Glut2 and, A_1, A_2A and A_2B adenosine receptors.

Results: In control animals, SCH58261 and MRS1754 decreased insulin sensitivity by 20.40 and 41.45%, respectively. HSu diet decreased insulin sensitivity to 2.41±0.18 %glucose/min from a control value of 4.16±0.28 %glucose/min, an effect that was increased by SCH58261 and MRS1754 administration by 36.92 and 54.32%, respectively. In HSu group, MRS1754 increased total fat and DPCPX reversed visceral fat to control values. HSu animals showed an increase in blood pressure, an effect that was decreased by DPCPX and SCH58261, and completely restored by MRS1754. In skeletal muscle from control animals, DPCPX and SCH58261 administration increased A_1 and A_2A expression by 39.27 and 24.32%, respectively. Moreover, A_1, A_2A and A_2B expression was increased in HSu group, an effect that was restored only by SCH58261 and MRS1754. In liver, A_2A expression is increased in HSu group, an effect that was restored by SCH58261. Moreover, A_2B expression decreased in HSu animals, an effect that was restored by MRS1754. In adipose tissue, SCH58261 increased A_2A expression and DPCPX decreased A_1 expression in HSu animals. Additionally, Glut4 expression in skeletal muscle from control animals decreased with DPCPX and SCH58261 administration.

Conclusion: The effects of chronic caffeine intake on insulin sensitivity are mediated mainly by A_{2A} and A_{2B} adenosine receptors. Additionally, an effect of A_1 adenosine receptors on visceral fat can also account for the effects of the chronic caffeine intake on insulin sensitivity.

Cystathionine beta synthase deficiency impairs in vivo insulin secretion in mice

C. Cruciani-Guglielmacci[1], S. Migrenne-Li[1], J. Denom[1], K. Meneyrol[1], F. Daubigney[1], H. le Stunff[1], M. Ibberson[2], B. Thorens[3], N. Janel[1], C. Magnan[1]; [1]Physiology, University Paris-Diderot, Paris, France, [2]Swiss Institute of Bioinformatics, Lausanne, [3]Center for Integrative Genomics, Lausanne, Switzerland.

Background and aims: Cystathionine beta synthase (CBS) catalyzes the first step of the transsulfuration pathway form homocysteine to cystathionine, and its deficiency lead to hyperhomocysteinemia (HHcy) in humans and rodents. Although it has been shown that hyperhomocysteinemia promotes insulin resistance by inducing endoplasmic reticulum stress in adipose tissue, and upregulating resistin, scarce information is available about its effect on insulin secretion, and the overall link between CBS activity and the setting of type 2 diabetes is still unknown. We recently established a multiparameter systems-based approach to identified new islet-expressed genes associated with islet functions in mice. Among these genes, we identified CBS whose expression in islet is positively correlated with in vivo insulin secretion. We postulated that a CBS deficiency would be associated with decreased insulin secretion.

Materials and methods: We used a mouse model heterozygous for CBS (CBS+/-) which presents a mild HHcy. Another group of CBS+/- mice, and controls, was supplemented with methionine in drinking water to increase mild to intermediate HHcy, the latter were also submitted to a high-fat diet. We characterized the mice for their food intake, body weight gain, body composition, glucose homeostasis, plasma homocysteine level and CBS activity.

Results: CBS+/- mice without methionine supplementation present a mild glucose intolerance without any change in body weight or insulin sensitivity; they display a significant decrease in basal insulinaemia. Under methionine supplementation, CBS+/- mice have lower body weight and less fat mass than their wild-type controls, under both chow diet and high-fat diet, and these features are not accompanied with changes in food intake. CBS+/- mice show a glucose intolerance due to a defect in insulin secretion in both basal and glucose stimulated conditions (CBS+/- basal insulin secretion in ng/ml : 0,74 ± 0,06 vs. 1,14 ± 0,07 in controls, $p<0.05$; CBS+/- glucose stimulated insulin secretion 1,68 ± 0,07 vs. 2,95 ± 0,12, $p<0.001$). CBS+/- mice with methionine also present a slight improvement in insulin sensitivity after in vivo insulin tolerance test.

Conclusion: We report here that CBS+/- mice with methionine supplementation are leaner under chow diet and protected against high-fat diet induced body weight gain, however they present a glucose intolerance due to insufficient insulin secretion. Whether this defect is due to a direct control of CBS on insulin secretion needs to be further investigated.

Impaired beta cell function and glucose sensitivity in Chinese individuals with young-onset type 2 diabetes

E. Chow[1], A.O. Luk[1], L.L. Lim[2], R. Ozaki[1], B. Fan[2], A.P. Kong[2], R.C. Ma[2], A. Mari[3], E. Ferrannini[4], J.C.N. Chan[2];
[1]Medicine and Therapeutics, Phase 1 Clinical Trial Centre, Chinese University of Hong Kong, [2]Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, Hong Kong, [3]CNR Institute of Neurosciences, [4]CNR Institute of Clinical Physiology, Padua, Italy.

Background and aims: Young-onset type 2 diabetes (YOD) under the age of 40 years occurs in one in five patients with diabetes in Asia. We hypothesise this is driven mainly by beta cell dysfunction, however, detailed physiological studies in Chinese patients are lacking. The aim of this study is to evaluate beta cell function, beta cell glucose sensitivity and insulin sensitivity using the hyperglycaemic clamp in YOD patients with early disease and normal controls.
Materials and methods: We studied 10 YOD patients of Chinese ethnicity (Mean±SD age 36±6 years, BMI 25.7±3.6 kg/m^2, disease duration 2.9±1.5 years) and 10 age- and BMI- matched subjects with normal glucose tolerance and no family history of diabetes . First- and second- phase insulin were evaluated using a two-hour hyperglycaemic (12 mmol/L) clamp. Insulin secretion rates were determined by C-peptide deconvolution. Glucose sensitivity was calculated as the ratio of incremental second-phase insulin secretion to the increment in glycaemia. Insulin sensitivity index (ISI) was calculated as the glucose infusion rate divided by the plasma insulin at steady state.
Results: Basal insulin secretion rate was lower in YOD participants than control subjects (64 [51] *vs* 82 [36] pmol·min^{-1}·m^{-2}, median [IQR], p=0.02). First-phase insulin secretion was reduced by 74% in YOD participants compared to normal subjects (98 [95] *vs* 624 [261] pmol·min^{-1}·m^{-2}, p=0.001) and second-phase insulin secretion was reduced by 64% (227 [158] *vs* 627 [306] pmol·min^{-1}·m^{-2}, p=0.001). Glucose sensitivity was markedly impaired in YOD as compared to controls (24.4 [18.3] *vs* 77.5 [38.0] pmol·min^{-1}·m^{-2}·mM^{-1}, p=0.001) whilst ISI was similar in both groups (22 [39] *vs* 18 [21] mg·kg^{-1}·min^{-1}·pmol^{-1}).
Conclusion: Chinese individuals with YOD display marked deficiency in insulin secretion and beta cell glucose sensitivity even with short duration of disease. While early insulin treatment may slow down the progression of beta cell dysfunction, early detection of these subjects through screening is important to prevent delayed intervention.

55P0251, a novel molecule developed from a herbal backbone structure with potent anti-hyperglycaemic activity in rodents: An imidazoline-like mechanism of action?

C. Fürnsinn[1], Z. Lehner[1], K. Stadlbauer[1], B. Brunmair[1], I. Adorjan[2], T. Scherer[1], A. Luger[1], L. Bauer[2];
[1]Dept. Med. III, Div. Endocrinol. Metab., Medical University of Vienna, [2]55pharma Drug Discovery and Development AG, Vienna, Austria.

Background and aims: 55P0251 is a novel compound, which we have developed from a molecular backbone structure derived from multiflorine, a compound found in herbal remedies. 55P0251 has distinct anti-hyperglycaemic, but not hypoglycaemic, activity in rodents, which we have attributed to amplification of glucose-stimulated insulin secretion. In preceding experiments, we excluded that 55P0251 acts via mechanisms exploited by established anti-diabetic drugs, including that it did not affect the K_{ATP} channel or the GLP-1 system. Here, we describe further efforts to track down its molecular target and mechanism of action.
Materials and methods: The effects of 55P0251 and its corresponding enantiomer, 55P0250, were examined in a comparative manner in mice. Oral glucose tolerance tests (OGTT), insulin release from perifused pancreatic islets, and oxygen saturation of tail blood were examined. The α_2-adrenoceptor agonist UK14,304 (UK) was used to sort out the potential role of the sympathetic nervous system.
Results: *In vivo*, 55P0251 showed much more pronounced glucose lowering activity than its corresponding enantiomer 55P0250 (AUC in the OGTT, mol/l*min: vehicle, 1.71±0.04; 45mg/kg 55P0251, 1.10±0.03, p<0.0001 vs vehicle; 45mg/kg 55P0250, 1.54±0.06, p=0.03 vs vehicle; enantiomer comparison, p<0.0001). *In vitro*, the two enantiomers augmented glucose-induced insulin release to a similar extent in the absence of adrenergic stimulation (insulin released from perifused islets during 30min of glucose stimulation, pmol/islet: vehicle, 160±30; 500µmol/l 55P0251, 346±69, p=0.02 vs vehicle; 500µmol/l 55P0250, 493±48, p<0.001 vs vehicle; enantiomer comparison, ns), but 55P0251 was clearly superior in counteracting adrenergic inhibition of insulin release by 1µmol/l UK (pmol/islet: UK alone, 52±13; UK+250µmol/l 55P0251, 169±18, p=0.0008 vs UK; 250µmol/l UK+55P0250, 42±14, ns vs UK; enantiomer comparison, p=0.0006). This pattern hinted at sympathetic antagonism of 55P0251, but not 55P0250, which was supported by corresponding interaction with the α_{2A}-adrenoceptor (% inhibition in the binding assay: 10µmol/l 55P0251, -73%; 10µmol/l 55P0250, -1%). α_{2A}-antagonistic activity of 55P0251 *in vivo* was confirmed by increased oxygen saturation of tail blood (indicative of thermoregulatory vasodilation), as it was likewise induced by established α_{2A}-antagonists (vehicle, 64.9±2.0%; 0.5mg/kg yohimbine, 86.5±0.9%; 1mg/kg efaroxan, 85.2 ±3.6%; 90mg/kg 55P0251, 83.4±2.5%; p<0.0001 vs vehicle each). 55P0250 had no such effect (vehicle, 52.4±1.6%, vs 90mg/kg 55P0250, 56.7±2.9%; ns). Accordingly, a low dose of 55P0251 counteracted hyperglycaemia induced by injection of the α_2-agonist UK (AUC of glucose excursion caused by 0.1mg/kg UK: UK alone, 2.22±0.08; vs UK+1.4mg/kg 55P0251, 1.82±0.16; p<0.05).
Conclusion: The novel glucose lowering agent 55P0251 obviously carries α_{2A}-antagonistic properties, which contribute to its effects on insulin release and blood glucose. At high concentrations, 55P0251 appears to amplify glucose-stimulated insulin release via a second mechanism of action that is also addressed by its corresponding enantiomer 55P0250. The observed dual mode of action of 55P0251 is reminiscent of what has been ascribed to imidazolines.

Sphingomyelin synthase 2 deficiency impairs insulin secretion in pancreatic beta cells

H. Zhou, Y. Gong, P. Yang, Y. Ma, Z. Fu, Y. Zhou, J. Fu, X. Zhu, T. Yang; the First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background and aims: Sphingomyelin synthase 2 (SMS2), which mainly located in the plasma membrane and the Golgi, is known to synthesis

sphingomyelin from substrate ceramide. Previous work demonstrated that plasma membrane sphingomyelin content reduction resulted from knocking out SMS2 improved whole-body insulin sensitivity. Meanwhile, we also noted that serum insulin level in SMS2-KO mice significantly decreased both at fasting and feeding status, but its role in insulin secretion remains unclear.

Materials and methods: We performed experiments on SMS2 whole-body knock out mice. Glucose tolerance test and insulin tolerance test were conducted. Islets number, size and density analysis were based on pancreas HE staining. Islets were isolated for glucose stimulated insulin secretion test, glucose uptake test, RNA extraction, as well as for getting single beta cells for further patch clamp and Immunofluorescence staining. SPSS 19.0 was used for statistics analysis.

Results: First, we validated that lower serum insulin level in SMS2-KO mice upon 2g/kg glucose challenge via intraperitoneal injection. The results were further confirmed by *ex vivo* glucose stimulated insulin secretion test, showing significant insulin secretion capacity in the isolated islets from SMS2 deficient mice when treated with 16.7mmol/L glucose solution. Then, our work indicated the lower insulin concentration was not owing to changes in the number or size of the islets, beta cell proliferation or apoptosis, the ratio between alpha and beta cells or proinsulin synthesis. Thus we came to the hypothesis, SMS2 is fundamental to pancreatic beta cell insulin secretion, which get strongly supported by patch clamp on single beta cells, presenting with almost 2-fold decrease of functional insulin release pool size in SMS2-KO mice. Transmission electron microscopy was applied to observe ultra-structure within beta cells. Insulin granules in SMS2 null group seemed to be smaller in size, lower density and less mature. Meanwhile, glucose response is crucial to beta cell function, and GLUT2 on the plasma membrane is the glucose transporter in beta cell, serving as the first-line glucose sensor. We found that glucose uptake was dramatically decreased, along with less detectable GLUT2 protein in SMS2-KO beta cells. Since SMS2 KO could directly lead to decline in sphingomyelin content on the plasma membrane, anchored membrane protein such as GLUT2 would be influenced by local lipid composition changes.

Conclusion: Herein, we reported insulin secretion got impaired in SMS2 deficient mice, and changes in GLUT2 on the membrane may account for the decrease in glucose stimulated insulin secretion capacity.

Metabolic consequences of residual beta cell function during the early years after diagnosis of type 2 diabetes

S.V. Zhyzhneuskaya[1], A. Al-Mrabeh[1], C. Peters[1], A. Barnes[1], K.G. Hollingsworth[1], B.S. Aribisala[2], H. Pilkington[3], M. Lean[4], R. Taylor[1]; [1]Magnetic Resonance Centre, Newcastle University, Newcastle upon Tyne, UK, [2]Computer Science Department, Lagos University, Lagos, Nigeria, [3]Clinical Research Ageing Unit, Newcastle University, Newcastle upon Tyne, [4]School of Medicine, Dentistry and Nursing, Glasgow University, Glasgow, UK.

Background and aims: Beta cell function in the years following diagnosis of type 2 diabetes is a major therapeutic target, and understanding the metabolic effects of residual function is important. The Direct Remission Clinical Trial (DiRECT) is a controlled trial of weight loss versus conventional therapy for people with early Type 2 Diabetes. We report the characteristics of a subgroup at baseline who had detailed insulin secretion and metabolic assessments.

Materials and methods: Participants were studied during current therapy. 95 participants underwent detailed metabolic testing and complete data was obtained on n=89. Insulin secretion was assessed by the Stepped Insulin Secretion Test with Arginine (SISTA) after an overnight fast and during 2.8 mmol/l increments in plasma glucose. A deconvolution method was used to reconstruct insulin secretion rates from C-peptide concentrations and calculate the 6 minute incremental insulin secretion response. Fasting very low density lipoprotein triglyceride (VLDL-TG) production rate and pool size was measured by a non-isotopic competitive blocking method. 3-point Dixon Magnetic Resonance Imaging was used to estimate the liver and the pancreatic fat. Data are shown as mean ± SD or median with range.

Results: This subgroup of DiRECT was representative of the United Kingdom type 2 diabetes population with early type 2 Diabetes: 57% male; 53.1±7.8 years; 99.5±16.2 kg; BMI 34.4±4.2 kg/m^2, diabetes duration 2.9±1.7 years. Fasting plasma glucose (FPG) was 8.4±2.6 mmol/l with fasting plasma insulin (FPI) 92±57 pmol/l. Liver fat was markedly elevated at 14.7±9.8%. Mean pancreatic fat was also elevated at 8.3 ±2.3%. The production rate of VLDL1-TG was 545±179 mg/kg/day with VLDL1-TG pool size of 2291±1645mg. Fasting NEFA was 0.61±0.20 mmol/l and 0.31±0.13mmol/l at 70min of the SISTA. Liver fat positively correlated with VLDL1-TG production rate (R=0.43; p<0.0001), VLDL1-TG pool size (R=0.31; p=0.003), FPI (R=0.52; p<0.0001), and FPG (R=0.35; p=0.001).The median first phase insulin secretion was 0.138 nmol/min/m^2 (range -0.068 to +0.321).Total cohort first phase insulin response correlated negatively with FPG (R=-0.35; p<0.001). This correlation was much stronger in males (R=-0.54; p<0.0001). FPI correlated negatively with fasting NEFA in the whole cohort (R=-0.23; p=0.015). The first phase insulin response was independent of age, duration of the diabetes, liver fat and VLDL1-TG pool size.

Conclusion: In this cohort of people with short duration type 2 diabetes, median first phase insulin response was low although a wide range of responses were observed. This was associated with fasting plasma glucose control, reflecting the importance of beta cell function for overall control in the early years of type 2 diabetes. There was no correlation between first phase insulin response and duration within the first 6 years of diabetes. Liver fat was nearly 3 times over the upper limit of the population normal range. The data provide new insight into the consequences of beta cell dysfunction in early type 2 diabetes and form a baseline from which the effect of the weight loss intervention of DiRECT can be measured.

Beta cell secretory responses to oral ethanol and isoethanolaemic i.v. ethanol in healthy subjects

A.R. Lanng, L.S. Gasbjerg, N.C. Bergmann, T. Vilsbøll, F.K. Knop; Center of Diabetes Research, University of Copenhagen, Hellerup, Denmark.

Background and aims: The macronutrients glucose, protein and fat are well known stimulators of the secretion of the incretin hormones glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) from the enteroendocrine K and L cells, respectively, and thus elicit what is denominated the incretin effect; i.e. a greater insulin response after oral vs i.v. administration. Ethanol can also be considered an energy-rich macronutrient, but it is not known whether oral administration of ethanol elicits an incretin effect. The aim of this study was to investigate a possible incretin effect of ethanol.

Materials and methods: In a double-blinded, cross-over design, we subjected 12 fasted healthy men (age 25.3±3.9 (mean±SD) years; BMI 22.6±2.6 kg/m^2) to intragastrically instilled (0.70 g ethanol per kg body weight in a 20% (v/w) solution infused over 5 minutes) and isoethanolaemic i.v. infusion of ethanol (0.70 g ethanol per kg body weight in a 20% (v/w) solution infused over 45 minutes to mimic the plasma ethanol curve from the 'oral' day), respectively, on two separate experimental days. Blood was sampled repeatedly

during both experimental days. The primary endpoint was change in serum insulin levels. Secondary endpoints included plasma/serum responses of glucose and C-peptide during the two ethanol administration forms.

Results: Isoethanoleamia during the two ethanol administration forms was obtained (mean peak plasma ethanol concentrations were reached after 45 minutes during both ethanol administration forms and amounted to 1.8±0.3 (i.v.) and 1.7±0.4 g/l (p=0.22). Plasma glucose levels did not differ between the two days. No increment in serum insulin was observed during the 'oral' ethanol load and a decrease in insulin levels was observed during the isoethanolaemic i.v. infusion (Figure 1). Thus, serum insulin responses (as assessed by incremental $AUC_{0\text{-}180\ min}$) were significantly lower on the i.v. day compared to the day of intragastric administration (-1,478±520 vs -33±652 pmol/l × min (mean±SEM), p=0.05) (Figure 1). No difference between serum C-peptide responses between the two days was observed.

Conclusion: We show that - in contrast to other macronutrients - 'oral' ethanol does not promote an insulin response and that isoethanolaemic i.v. infusion of ethanol decreases serum insulin concentrations. As serum C-peptide concentrations were similar during the two ethanol.

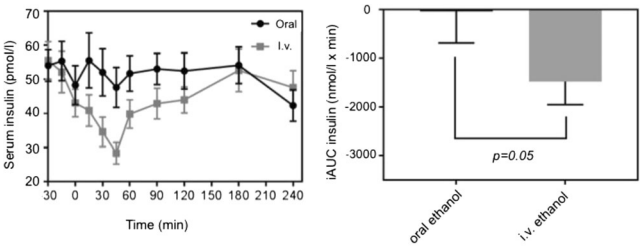

Figure 1. Serum insulin levels after ethanol administered 'orally' (i.e. via an intragastric tube) vs intravenously. iAUC: incremental area under the curve

ERK7 is a novel regulator of insulin secretion and lipid metabolism in Drosophila melanogaster

K. Hasygar, R. Hynynen, K. Kokki, V. Hietakangas;
Department of Biosciences/Institute of Biotechnology, University of Helsinki, Helsinki, Finland.

Background and aims: Mitogen Activated Protein Kinases (MAPKs) are Ser/Thr kinases which regulate a wide variety of cellular processes. Although this family is very well studied, some of the members like ERK7 (ERK8/MAPK15) are poorly characterized. ERK7 is an atypical MAP kinase which was shown to be activated by amino acid and serum starvation in *Drosophila* S2 cells. We have developed *in vivo Drosophila* models to further characterize its role in the regulation of insulin sensitivity and lipid metabolism.

Materials and methods: dILP2-Gal4; UAS-GFP driver line was used for Insulin Producing Cells (IPC) specific genetic manipulations. CG-Gal4 was used for fat body (fly counterpart of liver and adipose tissue) specific experiments. RNAi lines and p53 overexpression lines were obtained from VDRC, Austria and Bloomington Stock Center, USA. CRISPR/cas9 technique was employed to generate ERK7 mutants. qRT-PCR assays were used to measure mRNA levels of insulin like peptides and lipogenic genes. Immunostainings using anti-dILP2 antibody were used to assess secretion of insulin like peptides. Gas chromatography was used for quantitative lipidomics.

Results: We hereby show that ERK7 is an important regulator of insulin secretion and lipid metabolism in *Drosophila*. We observed that upon starvation, ERK7 is expressed in median neurosecretory cells (IPCs) which regulate larval growth by secreting insulin-like peptides (dILPs) in diet-dependent manner. We demonstrate that overexpression of ERK7 in IPCs strongly inhibits dILP secretion which consequently impairs larval development. We also identify p53 as an upstream activator of ERK7 in IPCs. Further, we establish that ERK7 function in IPCs is necessary for efficient starvation response. Finally, we also demonstrate that ERK7 has important metabolic functions outside IPCs. We show that ERK7 function in lipogenic tissues of *Drosophila* is important for normal lipid homeostasis. ERK7 expression in fat body (fly counterpart of liver and adipose tissue) disturbs lipid metabolism and leads to insulin resistance. To further explore ERK7 functions, we have generated ERK7 mutants which display obese phenotypes. RNA sequencing of the mutants has revealed a crucial role for ERK7 in lipid metabolism and insulin sensitivity. Hence, we aim to characterize ERK7 as a potential link between diet, diabetes and obesity.

Conclusion: ERK7 regulates insulin secretion in diet dependent manner. In addition, it has a crucial role in modulating insulin sensitivity and lipid metabolism in peripheral adipose tissue.

Sex difference in the effect of foetal exposure to maternal diabetes on insulin secretion

J.-F. Gautier[1], L.S. Fetita[1], F. Mauvais-Jarvis[2], F. Ibrahim[3], R. Porcher[3], C. Abi Khalil[4], G. Velho[5], S.-P. Choukem[1], S. Hadjadj[6], E. Larger[7], R. Roussel[4], P. Boudou[3], E. Ravussin[8], M. Marre[4], J.-P. Riveline[1];
[1]University Paris 7, Lariboisiere Hospital, Paris, France, [2]Tulane University, New Orleans, USA, [3]Saint-Louis Hospital, Paris, [4]Bichat Hospital, Paris, [5]INSERM UMRS 1138, Paris, [6]CHU, Poitiers, [7]Cochin Hospital, Paris, France, [8]Penington Center, Baton Rouge, USA.

Background and aims: We previously showed that foetal exposure to maternal type 1 diabetes (T1D) is associated with altered glucose-stimulated insulin secretion in adult offspring. Here, we investigated whether this β-cell defect displays a gender dimorphism.

Materials and methods: Twenty nine adult non-diabetic offspring of T1D mothers (ODMs) were compared to 29 non-diabetic offspring of T1D fathers (ODFs). We measured insulin secretion in response to oral glucose and to I.V. glucose ramping followed by I.V. arginine. Insulin sensitivity and body composition were assessed by a euglycemic hyperinsulinemic clamps and dual-energy X-ray absorptiometry respectively.

Results: There was no significant difference between ODMs and ODFs with respect to age (mean (sd): 26.2 (6.1) yrs vs. 25.9 (6.2); p=0.82), female gender (55% vs. 52%), anthropometric variables, routine lab tests and insulin sensitivity (M value: 11.5 (2.9) mg/kg.min vs. 11.7 (2.5); p=0.75). In response to oral glucose, males and females ODMs displayed a reduced early insulin secretion (median (IQR)): 6.0 (3.8 to 9.4) and 9.3 (7.3 to 13.1) μU/mmol vs. 10.4 (5.9 to 14.2) and 13.3 (7.6 to 25.9); p=0.035. In contrast, in response to graded I.V. glucose infusion, a significant interaction (p=0.03) between group and offspring gender was found for the slope of insulin secretion rate against plasma glucose indicating that only females ODMs, but not males, exhibited decreased insulin secretion. There was no defect in response to combined I.V. arginine and glucose suggesting that males and females ODMs exhibit a functional β-cell defect rather than a reduced β-cell mass.

Conclusion: Foetal exposure to maternal type 1 diabetes predisposes to β-cell dysfunction in adult male and female offspring. This β-cell defect is characterized by a sexual dimorphism following I.V. glucose stimulation.

Impaired beta cell function and reduced incretin effect following surgical acute beta cell loss in humans

V.A. Sun[1], T. Mezza[1], F. Cinti[1], C.M.A. Cefalo[1], S. Moffa[1], G. Sorice[1], F. Impronta[1], A. Mari[2], A. Giaccari[1];
[1]Università Cattolica del Sacro Cuore, Rome, [2]CNR, Padua, Italy.

Background and aims: Pancreaticoduodenectomy (PD) causes acute beta-cell loss (~50%) and a compensatory increase in GLP-1 secretion. In this study we explored the effects of PD on quantitative and qualitative parameters of insulin secretion.
Materials and methods: We studied insulin secretion, β cell glucose sensitivity (GS) and incretin effect in 13 non-diabetic patients, (10 F/8 M, 51±15 yrs., BMI 27.9±5.3 kg/m2), before and after PD, using a 2-h hyperglycemic clamp (HC) + arginine and a mixed meal test (MMT). Beta cell-GS was calculated as the ratio of insulin secretion and glucose increments (HC) or modeling (MTT). Incretin effect was estimated as the ratio of GS during MTT and HC and the potentiation factor of several potentiating mechanisms.
Results: As expected, PD caused a significant reduction in total insulin secretion rate, (77.3±6.68 before surgery vs. 37.3±4.90 nmol·m-2 after surgery, nmol·m-2,p<0.001), basal insulin secretion rate, (101±9.82 before surgery vs. 60.2±6.62 pmol·min-1·m-2 after surgery, p<0.01), incremental first phase, (- 58%, p<0.01) second phase, (- 33%, p<0.04) as well as in arginine-stimulated insulin secretion (1919±330.5 before surgery vs. 648.7±244.1pmol/L after surgery, p=0.01). GS was reduced by 38% during HC and by 78% during MMT. Consequently, the incretin effect also decreased significantly following PD (2.87±0.47 before surgery vs. 1.11 ±0.17 after surgery, p<0.01), while no change was observed in the potentiation factor evaluated during MMT (PF before surgery 1.30±0.18 vs. after surgery 1.47±0.22, p=0.58).
Conclusion: These data suggest that acute beta-cell loss determines not only quantitative, but also qualitative alterations of residual beta-cell mass. Further, impaired β-cell GS during MTT following PD may be driven by the decreased incretin effect. The previously observed increased GLP1 secretion following PD does not seem to fully compensate for the reduced incretin effect. Our data are in favor of a pivotal role of the incretin effect (even more than incretin concentration) on the dysregulation of beta-cell responsiveness.

Insulin sensitivity, beta cell function and hepatic insulin extraction: associations with adiposity and family history of type 2 diabetes in admixed adolescents

A.C.J. Vasques[1], D.F. Camilo[1], K. Hayashi[1], A. Tura[2], C.C. Silva[1], M.P. Zambon[3], M.A.G. Antônio[3], B. Geloneze[1];
[1]Laboratory of Investigation on Metabolism and Diabetes (LIMED), University of Campinas, Campinas, Brazil, [2]Metabolic Unit, CNR Institute of Neuroscience, Padova, Italy, [3]Department of Pediatrics, University of Campinas, Campinas, Brazil.

Background and aims: Beta-cell dysfunction and insulin resistance have different manifestations across racial/ethnic groups and there is lack of knowledge regarding the pathophysiology of type 2 diabetes mellitus (T2DM) for ethnic admixed adolescents. The Brazilian people are one of the most admixed populations in the world, which is the result of five centuries of interethnic crosses of peoples from three continents. We aimed to investigate the influence of adiposity and family history of T2DM on aspects of insulin sensitivity, beta-cell function and hepatic extraction of insulin in Brazilian normoglycemic adolescents.
Materials and methods: 82 adolescents (41 girls) underwent the 120-min. hyperglycemic clamp. The insulin sensitivity index was adjusted for free fat mass. Insulin secretion and beta-cell function parameters were obtained from C-peptide deconvolution. The hepatic insulin extraction and the disposition index, which represents the beta-cell function relative to insulin sensitivity, were calculated. The nutritional status was classified based on BMI for age according to the Centers for Disease Control and Prevention growth charts.
Results: After adjusting for pubertal stage, both lean and overweight/obese adolescents had similar glycemic profile (HbA_{1c}: 5.1 ± 0.1 vs. 5.2 ± 0.1%; p = 0.621) and similar disposition index (952 ± 134 vs. 757 ± 90 mg.kg.min*100 per pmol; p = 0.234), respectively. Overweight/obese adolescents had about 1/3 of the insulin sensitivity of lean adolescents (1.1 ± 0.2 *vs.* 3.4 ± 0.3 mg.kg.min.pmol*1000), which was compensated by an increase around 2.5 times in basal (130 ± 7 *vs.* 52 ± 10 pmol.l.min) and total insulin secretion (85839 ± 5076 *vs.* 34407 ± 7273 pmol), and in first (8136 ± 577 *vs*. 3456 ± 827 pmol) and second (69493 ± 4240 *vs*. 27916 ± 6075 pmol) phases of insulin secretion; respectively (p < 0.001 for all). This increase was accompanied by a mean reduction in hepatic insulin extraction of 35% (33 ± 4 *vs.* 51 ± 5 %; p = 0.013), and an increase in beta-cell glucose sensitivity by 2.7 times (86 ± 7 *vs.* 32 ± 10 pmol.min_mmol.l; p = 0.001), respectively. The presence of positive family history of T2DM was not associated with derangements in insulin sensitivity, beta-cells function and hepatic insulin extraction.
Conclusion: In an admixed sample of Brazilian adolescents, the hyperglycemic clamp test demonstrated a strong influence of adiposity and no direct influence of family history of T2DM in different aspects of glucose metabolism.

Specific GLUT2 invalidation in enteroendocrine cells: impact on glucose homeostasis and enteroendocrine cell plasticity in mice

A. Grosfeld[1], L. Choï[1], C. Schmitt[1], C. Osinski[1], G. Guillemain[1,2], B. Blondeau[1,2], A. Leturque[1], P. Serradas[1];
[1]UPMC, UMRS 1138, Centre de recherche des Cordeliers, [2]Present address UMRS 938, Centre de recherche Saint-Antoine, Paris, France.

Background and aims: The role of glucose transporter GLUT2 in the intestine has been partially uncovered. We have recently published that intestinal GLUT2 invalidation in all epithelial cells leads to a delayed tissue distribution of glucose and reveals unexpected roles in gut homeostasis, including a reduced density of glucagon-like peptide-1 (GLP-1) positive cells. Because GLUT2 is not only located at the membrane of enterocytes but also in enteroendocrine cells, we wanted to understand the specific role of enteroendocrine cells in GLUT2-mediated control of glucose homeostasis and enteroendocrine cell plasticity.
Materials and methods: To address this question, we generated an inducible GLUT2 deficient mouse model specifically in enteroendocrine cells ($GLUT2^{\Delta IEEC}$) by breeding GLUT2 floxed mice with Ngn3-CreERTm mice (gift from G. Gradwohl). GLUT2 invalidation was induced by tamoxifen gavages at 2-months of age (4 days at 1mg/mouse/day). Body weight gain, oral glucose tolerance test (2g/Kg), plasma insulin and GLP-1 measurements were performed 4 weeks after enteroendocrine GLUT2 invalidation. Intestinal GLP-1 content was determined in the jejunum, the ileum and the colon 4 weeks after GLUT2 invalidation.
Results: Body weight gain was similar in $GLUT2^{\Delta IEEC}$ and control mice. Unexpectedly, glucose tolerance was improved in $GLUT2^{\Delta IEEC}$ as compared to control mice (AUC 9241 ± 1191 *vs.* 12472 ± 1006 mg/dL per 120 min., P<0.05). In accordance with this result, we found that basal and glucose-induced plasma insulin was increased in $GLUT2^{\Delta IEEC}$ as compared to control mice (at basal state 0.48 ± 0.07 vs. 0.33 ± 0.03 ng/mL, P<0.05; at 30 min. 0.58 ± 0.04 vs. 0.45 ± 0.04 ng/mL, P<0.05). GLUT2 invalidation in enteroendocrine cells led to a decreased GLP-1 content in all intestinal segments compared to control mice (jejunum 30 ± 2 *vs.* 54 ± 2 pmol/g tissue, P<0.01; ileum 60 ± 3 *vs.* 85 ± 3 pmol/g tissue, P<0.01; colon 106 ± 6 *vs.* 142 ± 11 pmol/g tissue, P<0.05). The impaired intestinal GLP-1 content in $GLUT2^{\Delta IEEC}$ did not alter basal and stimulated plasma GLP-1 (before and 10 min after oral glucose load). We are currently working on the appropriate cell-sorting strategy to demonstrate specific GLUT2 invalidation in enteroendocrine cells.
Conclusion: Our data revealed a new role of GLUT2 on endocrine cell plasticity in the gut but also on glucose homeostasis independently of plasma GLP-1 level.

Effect of high insulin levels and hyperglycaemia on valvular interstitial cells

J.I. Selig[1], D.M. Ouwens[2,3], P. Akhyari[1], A. Lichtenberg[1], M. Barth[1];
[1]Department of Cardiovascular Surgery, University Hospital of the Heinrich-Heine-University Düsseldorf, Medical Faculty, [2]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, [3]German Center for Diabetes Research, München-Neuherberg, Germany.

Background and aims: Type 2 diabetes (T2D) is a risk factor for the development of calcific aortic valve disease (CAVD). During CAVD, fibrosis, ECM remodeling and finally calcification of the valve cusps take place. Despite the high incidence of T2D and CAVD, knowledge about the effect of a diabetic environment on cellular mechanisms in the valve is limited. In a previous study, we demonstrated that valvular interstitial cells (VIC) are sensitive to insulin and become insulin resistant in response to chronically elevated insulin levels. In this study, diabetic conditions like hyperglycemia and insulin resistance were simulated in vitro to gain better insight in the degeneration of VIC and processes leading to fibrosis and remodeling.
Materials and methods: Primary VIC, isolated from ovine aortic valves, were cultured for 6 d in normal (100 mg/dl; NG) and high glucose (450 mg/dl; HG) medium to simulate hyperglycemic conditions. Additionally, cells were treated with insulin (100 nM) to mimic an environment with increased insulin levels and decreased insulin sensitivity. Cell count was determined every second day and glucose concentration in the supernatant was measured daily in order to describe the metabolic activity of VIC. Degenerative processes and remodeling of the ECM were investigated by gene expression analyses of marker genes, e.g. alpha smooth muscle actin (aSMA) and collagen type I (COL1A1). Calcium accumulation, which occurs during severe degeneration, was quantified with a calcium assay. Data were collected in independent experiments using VIC from six individual sheep and are expressed as mean ± SEM.
Results: At the end of cultivation time, the cell count of insulin-treated VIC under NG conditions was significantly increased compared to NG or HG VIC (NG insulin 1.56 ± 0.16 $x10^6$; NG 1.15 ± 0.09 $x10^6$, p = 0.024; HG 1.08 ± 0.16 $x10^6$, p = 0.005). The glucose concentration in the supernatant decreased under NG conditions significantly at 5 d (NG 51 ± 8 mg/dl, NG insulin 48 ± 7 mg/dl, p < 0.0001) and 6 d (NG 55 ± 10 mg/dl, NG insulin 40 ± 11 mg/dl, p < 0.0001) compared to fresh medium. In contrast, the glucose concentration in HG medium was stable, independent of time point or treatment group. Gene expression analyses showed a significantly decreased aSMA expression after insulin treatment in NG medium (0.53 ± 0.1 fold of NG, p = 0.024) and a similar trend in HG medium (HG 0.97 ± 0.11, HG insulin 0.70 ± 0.13, p = 0.505), whereby HG alone had no effect (p > 0.999). The COL1A1 transcription was increased by trend after insulin treatment (1.83 ± 0.17 fold of NG, p = 0.158) and also under hyperglycemia (1.92 ± 0.43 fold of NG, p = 0.195), whereas the combination of both treatments had an additive effect (2.40 ± 0.66 fold of NG, p = 0.065). However, calcium accumulation was not affected by diabetes-like conditions.
Conclusion: Insulin leads to an increased proliferation rate of VIC and a reduced activation phenotype with decreased aSMA transcription. When further supplemented with hyperglycemia, core markers of ECM remodeling are altered by high insulin levels, representing an in vitro effect mimicking the clinically observed correlation of T2D and CAVD. All in all, the herein presented *in vitro* model may facilitate the investigation of T2D and CAVD in more detail.

Mid51 regulates not only mitochondrial viability but also glucose-stimulated-insulin secretion in pancreatic beta cells

J. Schultz, R. Waterstradt, S. Baltrusch;
Institut of Medical Biochemistry and Molecular Biology, Rostock, Germany.

Background and aims: The quality of mitochondria is maintained through fusion and fission events that alternate. This dynamic is important for pancreatic beta cells function. Mitochondrial fission is finalized by the dynamin-related protein 1 (Drp1), which is able to constrict mitochondria. The mitochondrial membrane protein Mid51 has been proposed to act as a receptor that can recruit Drp1 from the cytosol to the outer mitochondrial membrane. Several studies suggest that Mid51 promotes mitochondrial fusion by inactivation of Drp1. However, this mechanism remains to be firmly established. Therefore, the aim of this study was to investigate

changes in mitochondrial dynamics, autophagy and cellular function after overexpression of Mid51 in beta cells.

Materials and methods: Overexpression of Mid51 in MIN6 cells was achieved using the pcDNA expression vector. Mid51 gene expression was determined by quantitative RT-PCR. Mid51 protein content and distribution was analysed using western blots and immunofluorescence. Glucose-stimulated insulin secretion was analysed by ELISA. Cellular oxygen consumption was measured with a Clark-type O_2 micro sensor. Confocal microscopy was used to investigate mitochondrial membrane potential, mitochondrial morphology and formation of auotphagosomes after staining with TMRE, MitoTracker Green and a LC3 marker, respectively.

Results: Overexpression of Mid51 resulted in significant enhanced gene and protein expression compared to control transfected MIN6 cells. Control cells showed a homogenous mitochondrial network structure. In contrast, cells with enhanced expression of Mid51 exhibited fragmentation of mitochondria with perinuclear cluster formation. Both, the mitochondrial membrane potential and oxygen consumption were significantly reduced in cells overexpressing Mid51 compared to control transfected cells. Whereas the control transfected cells respond normal after stimulation with 25 mmol/l glucose we found an impairment of glucose-stimulated insulin secretion after overexpression of Mid51. LC3 expression analyses indicated deficits in the regulation of autophagy in cells with enhanced Mid51 level.

Conclusion: Our results suggest that Mid51 is important for regulation of mitochondrial function e.g. membrane potential and oxygen consumption and eventually to maintain glucose-stimulated insulin secretion in MIN6 cells. Because enhanced Mid51 expression disturbed the mitochondrial live cycle and autophagy the protein is likely to be a key player of mitochondrial viability. Future work is important to elucidate if changes in expression and regulation of Mid51 contributes to the development of beta-cell dysfunction in type 2 diabetes.

The interaction between vitamin D and renin-angiotensin system in the determination of hepatic metabolism in human HepG2 cells under insulin-resistant state

T.P. Wong, D. Zhang, P.S. Leung;
School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background and aims: Vitamin D deficiency or hypovitaminosis D is associated with increased risks of insulin resistance, type 2 diabetes mellitus (T2DM) and its related non-alcoholic fatty liver disease (NAFLD); meanwhile, inappropriate activation of the hepatic renin-angiotensin system (RAS) leads to the liver dysfunction and increased risk of T2DM, such as abnormalities in lipid and glucose metabolism. Our previous findings show that calcitriol (an active metabolite of vitamin D) reduces hepatic triglyceride accumulation and glucose output in diabetic db/db mice and human hepatocellular cell HepG2 under insulin-resistant conditions. Notwithstanding the existence of this finding, the protective action of vitamin D in regulating the activation of hepatic RAS-induced metabolic abnormalities under insulin resistance remains unquestionable. The present study was, therefore, designed to investigate the effects of calcitriol on the expression and function of the RAS components in HepG2 and primary hepatocytes under insulin-resistance state.

Materials and methods: Human hepatocellular cell line HepG2 and isolated c57/BL6J mouse hepatocytes were used as in vitro and ex vivo models, respectively. To mimic T2DM-related insulin-resistance, HepG2 cells and isolated primary hepatocytes were cultured in high-glucose plus high-insulin conditions (30mM glucose; 100nM insulin). Male T2DM db/db mice were also used for in vivo studies. In vitro, ex vivo and in vivo effects of calcitriol on the expression and function of the hepatic RAS components (angiotensin II/ACE/AT1/AT2 receptors and angiotensin 7/ACE2/Mas receptor axes) were then examined.

Results: As expected, major RAS components (e.g. angiotensinogen, AT1/AT2/Mas receptors, and ACE/ACE2) were expressed in the HepG2 and isolated hepatocyte cells. Interestingly, our preliminary data showed that high-glucose plus high-insulin culture conditions significantly upregulated the expression of the key RAS components, notably the AT1 receptor in HepG2 cells. More interestingly, the treatment with different concentrations of calcitriol (0.1-10nM) significantly suppressed the inappropriate activation of the AT1 receptor expression under insulin-resistant conditions in a dose dependent manner (1.66 ± 0.17 vs 0.70 ± 0.09, $p<0.01$), of which these inhibitory effects on AT1 receptor were observed from 4 to 6 hour-calcitriol treatment. In corroboration with the HepG2 cells, similar results on the protective effects of calcitriol were also observed in the isolated hepatocytes.

Conclusion: These data indicate that hormonal vitamin D (calcitriol) has modulatory action on the inappropriate upregulation of the hepatic RAS under insulin-resistant conditions in HepG2 cells, and that potential vitamin D supplementation might provide a cost-effective measure for improving hepatic metabolic dysfunction in T2DM and related NAFLD.

Novel small molecules targeting lipid phosphatase SHIP2: new treatments for type 2 diabetes

Z. Polianskyte-Prause[1], T.A. Tolvanen[1], S. Lindfors[1], K. Kon[2], H. Wang[1], V. Dumont[1], P.-H. Groop[3,4], T. Wada[2], H. Tsuneki[2], T. Sasaoka[2], S. Lehtonen[1];
[1]Department of Pathology, University of Helsinki, Helsinki, Finland, [2]Department of Clinical Pharmacology, University of Toyama, Toyama, Japan, [3]University of Helsinki, [4]Abdominal Center Nephrology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background and aims: Lipid phosphatase SH2 domain-containing inositol 5′-phoshatase 2 (SHIP2), a negative regulator of the insulin signaling pathway, is upregulated in muscle, adipose and kidney tissue in experimental models of diabetes, and its inhibition leads to improved insulin sensitivity. Thus, SHIP2 is a potential therapeutic target molecule for the treatment of insulin resistance in type 2 diabetes and diabetic kidney disease. However, to date only a few chemical compounds possessing an inhibitory effect on SHIP2 are known.

Materials and methods: To identify new molecules that inhibit SHIP2 more efficiently than the known inhibitors and possess more favorable properties to be eligible drug candidates, we performed in silico structure-based virtual screening of small molecule chemical libraries. The most potent candidates were validated by biological screening and analyzed using cultured cells, diabetic db/db mice and mice overexpressing SHIP2.

Results: We identified 379 potential SHIP2 inhibitor candidates that had more favorable interaction energies than the previously described SHIP2 inhibitor, AS1949490, and four of them had IC_{50} values lower than 10 μmol. Interestingly, virtual screening revealed anti-diabetic drug, metformin, and compound 118 among these molecules as potential SHIP2 inhibitors. We found that compound 118 (IC_{50} value of 0.75 μmol) and metformin (IC_{50} value of 6.1 μmol) inhibit the catalytic activity of the recombinant SHIP2 phosphatase domain by 100% and 39%, correspondingly. In addition, compound 118 inhibits the catalytic activity of SHIP2 in cultured myotubes and podocytes, and in skeletal muscle and kidney of SHIP2 overexpressing mice more efficiently than metformin. We also observed that, opposite to metformin, compound 118 ameliorates impaired glucose tolerance in SHIP2 overexpressing mice.

Conclusion: Compound 118 inhibits the activity of SHIP2 in vitro and in vivo and ameliorates peripheral insulin resistance. Furthermore, compound 118 has higher SHIP2 inhibition potential than the well-known drug, metformin. This highlights the potential of SHIP2 as a drug target and provides an avenue to identify and design novel molecules, which can be used to develop new insulin sensitizers for future clinical trials.

Identification of basolateral, not luminal, orientation of insulin and IGF1 receptors in gut epithelia

C.E. Stidsen, B. Ballarín-González, S.T. Buckley, S.G. Schéele, J. Ahnfeldt-Rønne, H. Hvid, B.F. Hansen, E. Nishimura;
Global Research, Novo Nordisk A/S, Maaloev, Denmark.

Background and aims: Due to the robust barrier properties of the gastrointestinal tract, appreciable amounts of insulin are expected to remain unabsorbed following oral administration. Given this, it is critical to understand the orientation of the insulin and insulin-like growth factor 1 receptors (InsR and IGF1R, respectively) expressed on the intestinal epithelia, as these might potentially interact with the insulin present in the intestinal lumen.
Materials and methods: We investigated the expression and distribution of InsR and IGF1R in the gastrointestinal tract of mice and rats by means of Western blotting, quantitative PCR (qPCR) and immunohistochemical (IHC) analyses. Furthermore, we assessed InsR- and IGF1R-mediated signalling by Surefire analysis in in vitro systems of intestinal epithelial or goblet-cell function (i.e. Caco-2, T84 and HT29-MTX-E12 cell monolayers). In addition, insulin-mediated signalling was investigated in rat intestinal tissue mounted in Ussing chambers.
Results: Western blot analysis demonstrated relatively low levels of both receptors in the duodenum, jejunum and ileum of the animals, with receptor expression gradually increasing from the proximal to the more distal regions of the small intestine. Maximal receptor levels were observed in the ascending and transverse sections of the colon which, normalised to tissue weight, expressed approximately 50-75% of the InsR found in liver tissue. qPCR analysis of rat intestinal tissue confirmed the described receptor distribution and supported the observations from the Western blot analyses suggesting similar or higher levels of InsR compared to IGF1R for most of the intestinal regions. Apical stimulation of the cell monolayers with either human insulin (HI) or insulin-like growth factor 1 (IGF1) did not result in significant InsR or IGF1R activation. In contrast, application of the ligands on the basolateral side induced the phosphorylation of their respective receptors in a concentration-dependent manner and with EC50 values in the low nanomolar range. Reflecting the activation of the receptors, basolateral (but not apical) administration of HI or IGF1 resulted in a clear phosphorylation of protein kinase B (Akt). Similarly, basolateral exposure of an insulin analogue (modified to withstand enzymatic degradation) to rat colonic mucosa mounted in Ussing chambers induced a significant increase in Akt phosphorylation compared to that of apically-treated tissue ($p<0.05$). Visualisation of the InsR in murine intestinal samples by means of IHC analyses further confirmed the localisation of the InsR in the basolateral membrane.
Conclusion: Collectively, these results indicate a wide expression of InsR and IGF1R throughout the gastrointestinal tract with a clear basolateral orientation of receptors in the intestinal epithelia which essentially renders these receptors inaccessible to any unabsorbed insulin that may be present in the intestinal lumen following oral dosing of insulin.

Calcineurin is involved in the regulation of human adipocyte glucose uptake

A.R.G. Fonseca[1,2], E. Carvalho[1,3], J.W. Eriksson[2], M.J. Pereira[2];
[1]Center for Neuroscience and Cell Biology, Coimbra, Portugal, [2]Department of Medical Sciences, University of Uppsala, Uppsala, Sweden, [3]Department of Geriatrics, University of Arkansas for Medical Sciences, Little Rock, USA.

Background and aims: Calcineurin inhibitors (CNIs), e.g. tacrolimus (Tac), are the cornerstone immunosuppressive therapy used after transplantation to prevent graft rejection. They are associated with metabolic side effects, like dyslipidemia, insulin resistance (IR) and development of diabetes mellitus (DM). CNIs inhibit lipid storage and expression of lipogenic genes in adipose tissue (AT), contributing to the development of dyslipidemia and IR. CNIs also reduce glucose uptake (GU) by reducing the amount of glucose transporter type 4 (GLUT4) on the cell surface via increased internalization in white AT and muscle cells, without altering the total levels of GLUT4 or insulin signaling. Our aim was to investigate possible pathways involved in the decrease of GLUT4 in the plasma membrane and consequent reduction of GU induced by CNIs in human subcutaneous AT (SAT).
Materials and methods: Human SAT biopsies were obtained by needle aspiration from the lower part of the abdomen from nondiabetic subjects (34 females/11 males, HbA1c 34±3.3 mmol/mol, BMI 26.7±4.7 Kg/m^2, mean ±SD). Adipocytes isolated with collagenase were treated for 75 min or 20 h (short- and long-term) with Tac (100 nM), cyclosporine A (CsA, 100 nM), deltamethrin (Delt, 1 μM), okadaic acid (OA, 250 nM), actinomycin D (ActD, 5 μg/ml) or cycloheximide (CH, 25 μM) and the GU was measured in the absence (basal) and in the presence of 25 and 1000 μU/ml insulin for 1h, using D-[U-^{14}C] glucose. The concentration of each drug used did not decrease the cell viability. AT incubated for 20 h with Tac (100 nM) was used to analyse the expression of genes involved in GLUT4 translocation with a PCR array. Top- and down- regulated genes and genes that were statistically different between control and Tac treatment were validated by standard qRT-PCR.
Results: Short- and long-term incubation with Tac, CsA and Delt decreased both basal and insulin-dependent GU in adipocytes to the same extent (about 16% and 34%, respectively, $p<0.05$) and without additive effects when co-incubated. This suggests that the effects of CNIs on GU are due to calcineurin inhibition. OA, used at a concentration (250 nM) that does not inhibit calcineurin but inhibits protein phosphatases 1 and 2A, increased the GU in adipocytes to 154% ($p<0.01$). Thus, the decrease in GU observed with CNIs is specific to calcineurin inhibition and not due to a general phosphatase inhibition. The inhibition of gene transcription by ActD and protein translation by CH also reduced GU by about 45% and 52%, respectively, $p<0.05$, but no Tac effects were seen when gene transcription and protein translation were inhibited. However, the expression of genes involved in GLUT4 translocation was not affected by Tac, suggesting that the GU reduction induced by CNIs may be due to effects on other genes, or protein amount or activation.
Conclusion: The specific inhibition of calcineurin, but not of other protein phosphatases 1 and 2A, decreases GU in subcutaneous adipocytes. This effect requires gene transcription and/or protein synthesis, but not gene expression of well-known genes involved in GLUT4 trafficking and cytoskeleton function. These data suggest that inhibition of calcineurin can contribute to impaired glucose handling in peripheral tissues, as reported with calcineurin therapy in organ-transplanted patients.

The role of GLUT4 in the kidney proximal tubule in blood glucose control and kidney function

L.A. Gallo[1,2], M.R. Gandhi[1,2], E.D. Abel[3], I. Rubera[4], M. Tauc[4], J.M. Forbes[1,5];

[1]Mater Research Institute-University of Queensland, Woolloongabba, [2]School of Biomedical Sciences, The University of Queensland, St Lucia, Australia, [3]Department of Medicine, Carver College of Medicine, University of Iowa, Iowa City, USA, [4]Laboratoire de Physio-Médecine Moléculaire, Centre National de la Recherche Scientifique, Nice, France, [5]Mater Clinical School of Medicine, The University of Queensland, South Brisbane, Australia.

Background and aims: The contribution of the kidneys to blood glucose control has become increasingly recognized. This includes both endogenous glucose production in fasting states and the reabsorption of filtered glucose; the latter being the target of novel type 2 diabetes drug class, sodium-dependent glucose transporter (SGLT)-2 inhibitors. Our laboratory has identified the presence of the insulin-sensitive glucose transporter, GLUT4, in kidney proximal tubule cells. We aimed to ascertain the role of this transporter in blood glucose control and kidney function.
Materials and methods: Proximal tubule cell-specific GLUT4 knockout mice (GLUT4 KO) were generated by breeding GLUT4 floxed mice with iL1-sglt2-cre mice and compared to wildtype littermates (WT). Twenty-week old male and female mice were studied (n=11-16/group). An oral glucose tolerance was performed and kidney function determined using 24 h urine collections.
Results: Male mice lacking the GLUT4 transporter in renal proximal tubule cells had elevated blood glucose levels in both fed (12.4 ± 0.8 vs 10.5 ± 0.3 mmol.l-1) and fasted (10.7 ± 0.7 vs 9.1 ± 0.3 mmol.l-1) states, and impaired glucose tolerance during the OGTT (AUGC: 2,145 ± 201 vs 1,691 ± 72 mmol.l-1 x 120 min) compared to WT littermates ($p<0.05$). There was a trend ($p=0.06$) for reduced urine flow rate (1.3 ± 0.2 vs 1.9 ± 0.2 ml.24h-1) and smaller kidneys (368 ± 10 vs 411 ± 18 mg) in these male GLUT4 KO mice compared to WT. There were no differences in food or water consumption between groups. Conversely, in female mice, deletion of the GLUT4 transporter from kidney proximal tubule cells did not affect blood glucose levels, kidney weight, or urine production.
Conclusion: These findings highlight sex-specific differences in the role of proximal tubule GLUT4 in whole-body glucose homeostasis and urine formation. This may have implications for therapeutic targeting of renal glucose reabsorption in the treatment of type 2 diabetes. Further assessment of peripheral insulin sensitivity, kidney handling of glucose, and overall kidney function is ongoing.

Estrogens modulate glucose homeostasis by increasing glucagon-like peptide -1 secretion for L and alpha cells

S. Handgraaf, R. Dusaulcy, F. Visentin, J. Philippe, Y. Gosmain; HUG Geneva, Geneva, Switzerland.

Background and aims: The implication of estrogens and their associated signalling pathways on metabolism have generated much interest. Clinical and experimental data indicate a beneficial effect on energy and glucose homeostasis associated with improved insulin-sensitivity and positive effects on insulin secretion. The aim of our study is to investigate the impact of estrogen on proglucagon-producing cells, pancreatic alpha- and enteroendocrine L-cells.
Materials and methods: To study the consequences of sexual hormone deprivation, adult female mice from the transgenic GLU-Venus x INS-Cherry mouse strain were ovariectomized (ovx), or sham operated. Conversely, the effects of estrogens were studied in ovx mice after administration of 17β-estradiol (E_2, 80μg/kg), or vehicle for 48 hours. The direct effects of E2 were investigated on primary sorted alpha- and beta-cells from ovx mice or on GLUTag cell line, treated during 48 hours with E_2 (10^{-8}mol/l), or with the estrogen receptor beta agonist Diarylpropionitrile (DPN, 10^{-8}mol/l), for the GLUTag cells only.
Results: Ovx mice exhibited alteration of glucose tolerance during OGTT (29.2 ± 6.0% increase of the area under the curve (AUC)) but not during IPGTT associated to decreased GLP-1 secretion (0.49 ± 0.04 pmol/l and 0.29 ± 0.04 pmol/l for sham and ovx mice respectively, at 5 min after glucose load), an effect that can be reversed by E_2-treatment. E_2 increases insulin (+104.9 ± 32.5%) and decreases glucagon (-63.7 ± 10.5%) pancreatic content and secretion while increasing pancreatic and small intestinal GLP-1 contents. E2 directly acts on alpha-cells to decrease glucagon and increases GLP-1 secretions and contents. Studies on intestinal cells from ovx mice and on the GLUTag cell line showed that E_2 was able to increase intestinal GLP-1 content and secretion. Moreover, by the use of the highly selective estrogen receptor beta agonist, the Diarylpropionitrile (DPN) at the concentration of 10^{-8}mol/l, we could determine that the impact of estradiol on intestinal GLP-1 content and secretion is mainly mediated trough the activation of the estrogen receptor beta.
Conclusion: E_2 has not only beneficial direct actions on insulin and glucagon secretion, but also increases GLP-1 secretion from both intestinal L and pancreatic alpha-cells, highlighting the potential of the estrogenic pathway to reduce type 2 diabetes.

Glucose-dependent insulinotropic polypeptide (GIP) deficiency improves obesity but worsens bone loss in ovariectomised mice

Y. Kanemaru[1,2], N. Harada[1,2], S. Simazu-Kuwahara[1], Y. Ueda[1], S. Yamane[1], Y. Murata[1], T.J. Kieffer[3,2], N. Inagaki[1,2];
[1]Diabetes, Endocrinology and Nutrition, Kyoto University, [2]JSPS Core-to-Core Program, A. Advanced Research Networks, Kyoto, Japan, [3]Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

Background and aims: Ovarian hormone deficiency such as menopause induces osteoporosis and increases the risk of obesity and insulin resistance. Glucose-dependent insulinotropic polypeptide (GIP) is a gut hormone released from enteroendocrine K-cells after food intake and enhances insulin secretion through GIP receptor (GIPR) expressed in pancreatic β-cells. GIPR is also expressed in adipose and bone tissue. GIP deficiency protected the mice from high fat diet-induced obesity and

insulin resistance. Moreover, GIP deficiency showed reduced bone volume. In this study, we assessed the contribution of GIP in ovariectomy (OVX)-induced obesity, insulin resistance, and osteoporosis.

Materials and methods: GIP deficiency in C57BL/6 mice was produced by insertion of a sequence coding green fluorescent protein (GFP) into the preproGIP gene. Homozygous mice ($GIP^{gfp/gfp}$) have a complete absence of circulating GIP while plasma GIP levels are reduced in heterozygous ($GIP^{gfp/+}$) mice. Female wild-type (WT) C57BL/6 mice served as controls. At the age of 8 weeks, ovariectomies (OVX) were performed on WT, $GIP^{gfp/+}$, and $GIP^{gfp/gfp}$ mice, with a subgroup of WT mice given a sham operation. Mice were weighed weekly during experiments. At 20-30 weeks of age, oral glucose tolerance tests and insulin tolerance tests were performed. Fat mass, energy expenditure, and locomotor activity were measured at 25 weeks of age. At 16 weeks of age, bone analysis was performed by micro-computed tomography. Plasma osteocalcin levels were measured by ELISA.

Results: Weight gain following OVX was substantially reduced In in $GIP^{gfp/gfp}$ mice and the associated increase in subcutaneous and visceral fat mass was completely prevented by the elimination of GIP. The OVX-induced increase in food intake and decreases in locomotor activity and energy expenditure were not significantly altered in $GIP^{gfp/+}$ or $GIP^{gfp/gfp}$ mice. OVX lead to glucose intolerance in WT mice but glucose tolerance in $GIP^{gfp/gfp}$-OVX mice was similar to WT controls given sham surgery. Insulin sensitivity remained similar among all groups. Cancellous bone mineral density was reduced in WT mice by OVX, but the reduction was even greater in $GIP^{gfp/gfp}$-OVX mice and GIP depletion also promoted reduced bone cortical thickness, in association with reduced plasma osteocalcin levels.

Conclusion: GIP deficiency ameliorates excess weight gain and adiposity after ovariectomy but enhances ovariectomy-induced osteoporosis, particularly in cancellous bone by suppressing bone formation.

The nuclear receptor FXR decreases enteroendocrine L cell response to gut microbiota metabolites, the short chain fatty acids

S. Ducastel, V. Touche, M.-S. Trabelsi, B. Staels, S. Lestavel;
INSERM U1011, Lille, France.

Background and aims: Diabetes mellitus involves many metabolic disorders including a decrease in incretin effect. One of the incretine hormones, Glucagon-Like Peptide-1 (GLP-1), is produced and secreted by enteroendocrine L cells which represent 1% of the intestinal epithelial cells. We have recently shown that bile acid nuclear receptor Farnesoid X Receptor (FXR) activation in enteroendocrine L cells decreases glucose-induced ChREBP-dependant proglucagon (GLP-1 precursor) gene transcription. By inhibiting glycolysis pathway, FXR also decreases glucose-induced GLP-1 secretion. We hypothesize that FXR could globally decrease L cell response to other GLP-1 secretagogues. The aim of this study is thus to investigate the role of FXR in the L cell response to short chain fatty acids (SCFA) which are metabolites produced by the gut microbiota via fermentation of non digestible polysaccharides. Indeed, in addition to their contribution of 5 to 10% of the daily energetic resources, SCFA are also signalling molecules as they bind to the transmembrane receptor FFAR2, thereby promoting GLP-1 secretion by L cells.

Materials and methods: FXR was activated *in vitro* in the murine cell line GLUTag, in the human cell line NCI-H716 and *in vivo* in C57Bl6/J mice by the synthetic agonist GW4064. GLP-1 secretion tests (ELISA) in response to natural (propionate and butyrate) and synthetic FFAR2 agonists were performed *in vitro* in GLUTag and in NCI-H716 and *ex vivo* on murine colonic explants. FFAR2 mRNA levels were evaluated by qPCR in colon from mice treated with GW4064, from KO FXR mice and from mice treated with colesevelam, a bile acid sequestrant, which display a drastic down regulation of intestinal FXR transcriptional activity.

Results: *In vivo* FXR activation decreases FFAR2 mRNA levels and the subsequent *ex vivo* colonic GLP-1 secretion in response to butyrate. As a mirror effect, FXR KO and colesevelam treated mice exhibit increased colonic FFAR2 mRNA levels. Moreover, *in vitro,* both in GLUTag and NCI-H716 cells, FXR activation decreases GLP-1 secretion in response to butyrate and to synthetic agonists of FFAR2 which is, at least in GLUTag cells, in parallel to a decrease in proglucagon and FFAR2 mRNA levels.

Conclusion: FXR activation decreases L cell response to SCFA in terms of GLP-1 secretion at least in part via the decrease of proglucagon and FFAR2 mRNA expression. Inhibiting FXR in intestine, pharmacologically or by modulating the bile acid pool, leading to an increased L cell response to various nutrients, may be a promising approach in Type 2 Diabetes therapies.

Inhibition of hepatic bile acid uptake prolongs bile acid signalling leading to reduced adiposity, increased thermogenesis and enhanced intestinal GLP-1 secretion

J.M. Donkers[1], S.F.J. van de Graaf[1,2];
[1]Tytgat Institute for Liver and Intestinal Research, AMC, Amsterdam, Netherlands, [2]Department of Gastroenterology and Hepatology, AMC, Amsterdam, Netherlands.

Background and aims: Bile acids, known for their facilitating role in fat absorption, are now also recognized as signalling molecules that regulate glucose metabolism, inflammation, and energy expenditure via activation of their receptors FXR and TGR5. Hepatic uptake of bile acids is mediated by the sodium taurocholate co-transporting polypeptide (NTCP, *SLC10A1*) and different members of the organic anion-transporting polypeptide (OATP) family. Here, we propose that (partially) inhibiting hepatic bile acid transport will delay hepatic clearance of bile acids from portal and peripheral blood, thereby prolonging bile acid signalling and ameliorate metabolic diseases such as diabetes.

Materials and methods: To investigate the effect of prolonged bile acid signalling *in vivo*, NTCP deficient mice (*Slc10a1* knockout) were studied in a diet-induced-obesity (DIO) setting. Also, short and long term effects of pharmacological inhibition of NTCP were studied in OATP1a/1b/– KO mice (that lack all NTCP-independent bile acid uptake). The SGBS pre-adipocyte cell line was used as an *in vitro* model of human adipocytes to study bile acid signalling in fat tissue, while the GLUTag cell line was used to investigate bile acid-induced intestinal L-cell GLP-1 secretion.

Results: NTCP inhibition *in vivo* showed decreased clearance of serum bile acid in both lean and DIO mice. Both male and female NTCP KO mice displayed partial protection against deleterious effects of a high fat diet compared with their wild type counterparts. In this setting, NTCP KO mice had a lower body weight, reduced liver adiposity, and decreased size of white adipose tissue storage depots. Treatment of the OATP1a/1b/– KO mice with a specific NTCP inhibitor resulted in rapid reduction of body weight (~15 % within 3 weeks). They also showed increased serum GLP-1 levels, as well as an increase in body temperature. Importantly, no detrimental effects of NTCP inhibition were seen on plasma ALT levels or liver histology, while plasma bile acid concentrations significantly increased. Stimulation of SGBS cells, a model of human brown adipocytes, with the bile acid TCDCA or a specific TGR5 agonist (TG-1005) for 2 hours, induced a significant upregulation of thermogenesis related genes UCP-1, Dio2, and PGC1α. Injection of the same compounds increased the capacity of mitochondria to use uncoupled respiration within 15 minutes. The same bile acid TCDCA and TGR-5 agonist TG-1005 showed an significant increase in GLP-1 secretion by GLUTag cells, 2 hours after stimulation.

Conclusion: Both long-term and short-term studies in mouse models affected in their BA transport capacity point towards an improved metabolic state upon reduced hepatic bile acid uptake. *In vitro* research confirms that conjugated bile acids execute their beneficial effects in adipocytes and intestinal GLP-1 secretion most likely via TGR5.

The intestinotrophic effects of glucagon-like peptide 1 and 2 are not important for the metabolic effects of bariatric surgery

P. Wismann[1], P. Barkholt[1], N. Vrang[1], L.L. Baggio[2], J.A. Koehler[2], D.J. Drucker[2], D.A. Sandoval[3], J. Jelsing[1];
[1]Gubra, Hørsholm, Denmark, [2]Lunenfeld-Tanenbaum Research Institute, Toronto, Canada, [3]University of Michigan, Ann Arbor, USA.

Background and aims: The prevalence of obesity and related comorbidities is reaching pandemic proportions. Today, the most effective obesity treatments are glucagon-like peptide 1 (GLP-1) analogs and bariatric surgery, respectively. Interestingly, the anti-obesity treatment effects of both intervention paradigms have been associated with adaptive growth responses in the gut. The objective of this study was to evaluate the intestinotrophic effects of glucagon-like peptides and the importance of this mechanism in bariatric surgery.

Materials and methods: *In situ* hybridization was used to provide a detailed and comparative anatomical map on the local distribution of GLP-1 receptor (*Glp1r*), GLP-2 receptor (*Glp2r*) and preproglucagon (*Gcg*) mRNA expression throughout the mouse gastrointestinal tract. Gut development in GLP-1R-, GLP-2R- or GCG-deficient mice was compared to their corresponding wild-type (WT) controls, and intestinotrophic effects of GLP-1 and GLP-2 analogs was assessed in WT mice. Lastly, gut volume was determined in a mouse model of vertical sleeve gastrectomy (VSG).

Results: Comparison of *Glp1r*, *Glp2r* and *Gcg* mRNA expression indicated a widespread, but distinct, distribution of these three transcripts throughout all compartments of the mouse gastrointestinal tract. While mice null for *Glp1r* or *Gcg* showed normal intestinal morphology ($Glp1r^{-/-}$ 688±37 mm^3 vs. WT 700±31 mm^3, p=0.81 and $Gcg^{-/-}$ 944 ±43mm^3 vs. WT 938±44mm^3, p=0.92), $Glp2r^{-/-}$ mice exhibited a slight reduction in small intestinal mucosa volume (13±3.7%, 547±10 mm^3 vs 475±20 mm^3, p=0.01). Pharmacological treatment with GLP-1 and GLP-2 analogs markedly increased gut volume (70±6.5% increase, p=0.001 GLP-1+GLP-2 combination vs. vehicle treatment). In contrast, VSG surgery had no effect on intestinal morphology (small intestine volume VSG 885±82 mm^3 vs. sham 879±44 mm^3, p=0.95).

Conclusion: The present study indicates that the endogenous preproglucagon system does not play an essential role in normal gut development in the mouse. Similarly, increased circulating GLP-1 levels in VSG-treated mice could not be coupled to changes in intestinal morphometry. We conclude that pharmacological treatment with long-acting GLP-1 and GLP-2 analogs enhanced gut growth in the mouse, and that intestinotrophic effects of GLP-1 and GLP-2 are revealed upon supraphysiological stimulation of their cognate receptors only.

Development of an antagonistic GLP1R antibody to block GLP-1 signalling in vivo

E.K. Biggs[1,2], L. Liang[2], J. Naylor[2], R. Collier[3], D. Hornigold[2], P. Ravn[4], D. Baker[2], M. Coghlan[2], F. Reimann[1], F.M. Gribble[1];
[1]Institute of Metabolic Science, University of Cambridge, [2]Department of Cardiovascular and Metabolic Disease, MedImmune, [3]In vivo Sciences - UK, AstraZeneca, [4]Department of Antibody Discovery and Protein Engineering, MedImmune, Cambridge, UK.

Background and aims: Glucagon like peptide-1 (GLP-1) and GLP-1 mimetics enhance glucose-dependent insulin secretion by binding to GLP-1 receptors (GLP1R) on pancreatic beta cells. Despite the therapeutic success of GLP-1 mimetics for the treatment of type 2 diabetes, several clinical effects of GLP-1 remain unexplained at a mechanistic level, particularly in extra-pancreatic tissues such as the cardiovascular system. The objective of this study was to generate and characterise a monoclonal antagonistic antibody for the GLP1R that can be used to block GLP1R signalling in vivo.

Materials and methods: A naïve phage display selection strategy was used for isolation of single chain variable fragments (ScFv) that bound to GLP1R. The first two rounds were soluble selections on biotinylated human GLP1R extracellular domain, the third round was a cell surface selection using CHO cells overexpressing mouse GLP1R. This led to the isolation of 18 ScFv clones for functional analysis. The clone with the highest affinity, Glp1R0017, was converted into a human IgG1 and characterised further. In vitro antagonistic activity was assessed in a number of assays; a cAMP based HTRF assay in GLP1R overexpressing cell lines, a live cell cAMP imaging assay using INS-1 832/3 cells transfected with the Epac2-camps probe, and an insulin secretion assay in INS-1 832/3 cells. Glp1R0017 was further tested in immunostaining of mouse pancreas, and the ability of Glp1R0017 to block GLP1R in vivo was assessed by intraperitoneal glucose tolerance tests (ipGTT) in C57/Bl6 mice (n=8 per group).

Results: Naïve phage display led to the selection of Glp1R0017. Glp1R0017 was found to be antagonistic against mouse, human, rat, cyno and dog GLP1R with IC_{50} values of 5.2 nM, 43.3 nM, 5.3 nM, 9.0 nM and 11.7 nM, respectively. This antagonistic activity was specific to GLP1R; no antagonistic activity was found in cells overexpressing the glucose dependent insulinotropic peptide receptor (GIPR), GLP-2 receptor or glucagon receptor. INS-1 832/3 imaging experiments, measuring cAMP changes in real time, showed that GLP-1 stimulated cAMP was reduced 2.8 fold after 15 minute pre-incubation of cells with Glp1R0017 ($p<0.001$). Also in INS-1 832/3 cells, Glp1R0017 reduced insulin secretion stimulated by GLP-1 from 1.4 fold to 0.8 fold ($p<0.001$). Immunostaining of mouse pancreas tissue with Glp1R0017 showed specific staining in the islets of Langerhans, not observed in GLP1R KO tissue. In vivo, Glp1R0017 reversed the glucose-lowering effect of liraglutide during ipGTT in mice.

Conclusion: Glp1R0017 is a monoclonal antagonistic antibody to the GLP1R that blocks GLP-1 actions on pancreatic beta cells, including elevation of cAMP and insulin secretion. In vivo inhibition of GLP1R has also been demonstrated by ipGTT. This antibody holds the potential to investigate the physiological importance of GLP1R signalling in extra-pancreatic tissues where less is known about the cellular targets and signalling pathways activated by GLP-1.

Exploring the autophagy mechanism in pancreatic alpha cell

M. Himuro[1], T. Miyatsuka[1], L. Suzuki[1], M. Koike[2], C. Shiota[3], G.K. Gittes[4], Y. Fujitani[5], H. Watada[1];
[1]Department of Metabolism and Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, [2]Department of Cell Biology and Neuroscience, Juntendo University Graduate School of Medicine, Tokyo, Japan, [3]Vanderbilt University, Nashville, [4]University of Pittsburgh, Pittsburgh, USA, [5]Gunma University, Institute for Molecular and Cellular Regulation, Gunma, Japan.

Background and aims: It has been reported that autophagy plays a pivotal role in intracellular quality control through degradation of subcellular damaged organelles and components. While autophagy has been demonstrated to play an essential role in β-cell homeostasis, it remains to be elucidated how the cellular autophagy affects the homeostasis and function of glucagon-secreting α cells, another type of pancreatic endocrine cells.
Materials and methods: In order to generate a mutant mouse model lacking Atg7, a key molecule for autophagosome formation, specifically in α cells (αAtg7KO), we crossed the *Atg7*$^{flox/flox}$ mice with the *Gcg-CreERTM* mice that induce Cre-mediated recombination under the control of the glucagon (*Gcg*) locus.
Results: When the αAtg7KO mouse was administered tamoxifen at the age of four weeks, accumulation of p62 was observed specifically in α cells, suggesting that α-cell autophagy was specifically disrupted as designed. Histological analysis revealed that the number of α cells was increased in αAtg7KO mice compared to control littermates, and multilayered glucagon-positive cells were observed in the islets of αAtg7KO mice. On the other hand, metabolic parameters such as body weight, blood glucose levels and glucose tolerance were comparable between αAtg7KO mice and control littermates. In addition, there was almost no difference in serum glucagon levels between the groups.
Conclusion: These findings suggest that α-cell autophagy plays a role in regulating α-cell mass and islet formation. Further investigation would be needed to investigate underlying mechanisms of this phenotype.

Islet amyloid induces beta cell dysfunction in mice independent of toll-like receptor 2 signalling

H.C. Denroche[1], I.W. Suen[1], K. Yau[2], C. Verchere[1,2];
[1]Surgery, University of British Columbia, [2]Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada.

Background and aims: Islet amyloid, formed by the aggregation of beta cell-derived islet amyloid polypeptide (IAPP), is thought to contribute to beta cell dysfunction in type 2 diabetes, however the mechanism is unclear. IAPP aggregates recruit macrophages to pancreatic islets and induce secretion of pro-inflammatory cytokines, contributing to islet inflammation and impaired beta cell function in mice. *In vitro,* the induction of pro-inflammatory cytokine expression by IAPP aggregates is mediated by toll-like receptor 2 (TLR2) and its downstream adaptor molecule Myeloid Differentiation Primary Response Gene 88 (MyD88). We hypothesized that IAPP aggregates induce beta cell dysfunction and subsequent diabetes development through TLR2-dependent signalling.
Materials and methods: To test this, we examined the impact of TLR2 or MyD88 deletion on islet amyloid induced islet inflammation and beta cell dysfunction in mice. As rodent IAPP does not aggregate to form islet amyloid, we utilised mice expressing the human form of IAPP in beta cells (hIAPP Tg/0 mice), which develop islet amyloid, islet inflammation, and diabetes. We first crossed hIAPP Tg/0 mice with *Tlr2*$^{-/-}$ mice to generate *Tlr2*$^{-/-}$ hIAPP Tg/0 and *Trl2*$^{+/+}$ hIAPP Tg/0 mice, as well as hIAPP 0/0 littermate controls. As IAPP aggregates could induce islet inflammation through redundant TLR pathways, many of which signal through MyD88, we next generated hIAPP Tg/0 mice with myeloid-specific deletion of MyD88 by crossing hIAPP Tg/0 mice with *Myd88*$^{flox/flox}$ *Lysm*$^{cre/+}$ mice.
Results: *Tlr2*$^{+/+}$ hIAPP Tg/0 mice were significantly hyperglycemic and glucose intolerant relative to hIAPP 0/0 littermate controls on high fat diet. Surprisingly, *Tlr2*$^{-/-}$ hIAPP Tg/0 mice did not have attenuated hyperglycemia relative to *Trl2*$^{+/+}$ hIAPP Tg/0 mice (18.8 ± 2.0 vs 16.0 ± 1.4 mmol/L at 18 weeks, n=6-11, p=0.4) nor improved glucose tolerance. Beta cell function was impaired in both *Tlr2*$^{-/-}$ hIAPP Tg/0 and *Trl2*$^{+/+}$ hIAPP Tg/0 mice, evidenced by ~5 fold reductions of plasma insulin levels and ~2 fold increases in proinsulin: insulin ratios compared to their respective hIAPP 0/0 controls. Furthermore, inflammatory markers were elevated in islets of both *Tlr2*$^{-/-}$ hIAPP Tg/0 and *Trl2*$^{+/+}$ hIAPP Tg/0 relative to hIAPP 0/0 controls, revealing that deletion of TLR2 did not resolve islet amyloid induced islet inflammation. Deletion of MyD88 in myeloid cells yielded similar results. *Myd88*$^{flox/flox}$ *Lysm*$^{cre/+}$ hIAPP Tg/0 and *Myd88*$^{flox/flox}$ *Lysm*$^{+/+}$ hIAPP Tg/0 mice displayed similar levels of hyperglycemia (20.5 ± 2.3 vs 19.6 ± 1.9 mmol/l at 22 weeks, n=10) compared to their respective hIAPP 0/0 controls (11.4 ± 1.4 and 11.5 ± 0.9 mmol/l at 22 weeks, n=5-8) on high fat diet. Relative to hIAPP 0/0 controls, hIAPP Tg/0 mice also had impaired glucose tolerance and reduced plasma insulin regardless of myeloid MyD88 deletion.
Conclusion: While TLR2 and MyD88 are necessary for the proinflammatory response to IAPP aggregates *in vitro*, these data demonstrate that deletion of TLR2 signalling pathway components does not resolve islet amyloid induced inflammation or beta cell dysfunction in mice, indicating that alternate innate signalling pathways likely contribute to the inflammatory and deleterious effect of islet amyloid *in vivo*.

Influence of meal olfactory and visual stimuli on GLP-1 plasma concentration in healthy volunteers

E.A. Shestakova[1,2], I.A. Sklyanik[1], E.D. Dedova[2], L.V. Nikankina[1], M.V. Shestakova[1,2], I.I. Dedov[1,2];
[1]Endocrinology Research Centre, [2]Lomonosov Moscow State University, Moscow, Russian Federation.

Background and aims: Food ingestion is well known to induce a rapid increase in plasma glucagon-like peptide-1 (GLP-1) level much faster than food reaches the distal intestine where GLP-1 is produced. The aim of the study is to investigate whether the olfactory and visual alimentary stimuli can provoke the plasma GLP-1 rise before meal.
Materials and methods: 13 healthy volunteers (5 men and 8 women) 21-22 years old with a mean BMI 21,70 kg/m2 (18,74 - 25,45 kg/m2) without DM and metabolic disorders had highly caloric delicious breakfast. Venous plasma glucose, insulin and GLP-1 were examined twice at fasting state (-5', 0' min), then twice (10'and 20' min) when smelling and looking at food (not eating), and then twice after the start of the meal (30' and 120' min). Data analyzed by descriptive statistics.
Results: Baseline characteristics: HbA1c 4,97% ±0,26% mean waist-hip ratio 0,77 ± 0,05, mean HOMA-IR 1,46 ± 0,69. All participants had normal glucose tolerance. Mean fasting glucose was 4,62 mmol/l (min 3,90; max 5,22 mmol/l), glucose at 120' 4,84 mmol/l (min 3,90; max 6,28 mmol/l). No increase in insulin level in response to olfactory and visual stimuli was observed. Seven participants (54%) had GLP-1 plasma level increased from baseline in average by 33,2% in 10 minutes after they started smelling and watching the food. The increase in plasma GLP-1 was associated with higher BMI (Figure) and waist-hip ratio. The meal-stimulated GLP-1 peak was observed at 30 min of the study as expected. The other 6 volunteers showed no increase or slightly decrease in GLP-1 plasma level at 10' min of smelling and watching the meal, while the meal-stimulated GLP-1 peak was also observed at 30 min.
Conclusion: We found that increase in GLP-1 concentration in half of the healthy volunteers is starting before food ingestion at the stage of smelling and watching the food, mostly in participants with higher BMI. These visual and olfactory stimuli might activate central neurotransmitters that provoke the GLP-1 secretion in distal intestine. Heterogeneity of the GLP-1 response to such stimuli needs further investigation. Figure. Increase in plasma GLP-1 (%) from baseline to min 10 of visual and olfactory alimentary stimuli in healthy volunteers. The results of participants are ranged from higher (1)(25,4 kg/m2) to lower (13) (18,7 kg/m2) BMI

Plasma proneurotensin and diabetes risk in Iraqi immigrants and native Swedes. The MEDIM population based study

L. Bennet[1,2], A. Fawad[1], J. Struck[2], A. Bergmann[2], O. Melander[1];
[1]Department of Clinical Sciences, Lund University, Malmö, Sweden, [2]Sphingotec, Hennigsdorf, Germany.

Background and aims: Proneurotensin has recently been shown to predict type 2 diabetes and cardiovascular morbidity and mortality. Type 2 diabetes is highly prevalent in Middle Eastern populations that represent the largest non-European immigrant group in Sweden today. The aim of this study was to investigate differences across ethnicities in proneurotensin and its associations with type 2 diabetes risk.
Materials and methods: The MEDIM study is a population-based, cross-sectional study conducted 2010-2012 in the general community, City of Malmö, Sweden. Residents 30 to 75 years of age born in either Iraq or Sweden were invited from the census register. Anthropometrics and fasting plasma samples were collected and oral glucose tolerance tests performed.
Results: Iraqi born individuals had significantly higher fasting proneurotensin concentration than Swedish born (137.5 vs 119.8 pmol/L, $p<0.001$), irrespective of age, sex or body mass index (BMI). Insulin sensitivity index and insulin secretion respectively, displayed stronger associations with proneurotensin within the Iraqi than within the Swedish born population as reflected by significant interactions between country of birth and proneurotensin ($P_{interaction\ ISI}=0.050$; $P_{interaction\ DI}=0.007$). Iraqi born participants within the highest tertile of proneurotensin had almost five times the odds of having type 2 diabetes as compared to Swedes within the lowest tertile of proneurotensin.
Conclusion: This study reports that the Iraqi immigrant population compared to the native Swedish population have higher levels of proneurotensin irrespective of age, sex or body mass index. In this study the effect of proneurotensin on insulin secretion and action is modified by ethnic background in that the associations between proneurotensin and insulin action and secretion are stronger in Iraqi immigrants than in native Swedes. Our data indicate that part of the excess diabetes risk in the Middle Eastern immigrant population as compared to the native Caucasian population, can be explained by higher levels of proneurotensin.

Differences in glucose and insulin metabolism after Roux-en-Y gastric bypass and sleeve gastrectomy

M.S. Svane[1,2], K.N. Bojsen-Møller[1,2], C. Martinussen[1,2], V.B. Kristiansen[3], G. van Hall[4], J.J. Holst[2], S. Madsbad[1,2];
[1]Dept. of Endocrinology, Copenhagen University Hospital Hvidovre, Hvidovre, [2]NNF Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, [3]Dept. of Surgical Gastroenterology, Copenhagen University Hospital Hvidovre, Hvidovre, [4]Dept. of Clinical Metabolomics, Rigshospitalet, Copenhagen, Denmark.

Background and aims: The two surgical procedures Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy (SG) induce major and sustainable weight losses and result in improved glycaemic control in patients with pre-operative type 2 diabetes. The mechanism behind these beneficial effects has been suggested to be related for the two procedures, but many details remain to be elucidated. We therefore compared postprandial glucose metabolism after similar weight losses in SG and RYGB operated subjects as well as in obese controls (CON).

Materials and methods: In a cross sectional design 12 SG operated subjects (1.8±0.4 [mean±SD] years post SG), 12 RYGB operated subjects (2.2±0.4 years post RYGB) and 12 obese CON subjects were included and underwent a 4-hour liquid mixed meal test (400 kcal, 50 E% carbohydrate, 35 E% fat, 15 E% protein). All subjects had normal glucose tolerance (HbA1c<48 mmol/mol and fasting plasma glucose (PG) <6.1 mmol/L) and the groups were matched on BMI (SG: 33.4±8 kg/m2, RYGB: 33.5±7, CON: 33.4±6, ANOVA p=0.99), age (SG: 42.8±11 years, RYGB: 43.0±7, CON: 44.9±12, p=0.86), and sex (3/9 (men/women) in all groups). Surgical groups were also matched on post-operative weight loss (Pre-operative BMI: SG: 44.0±7 vs. RYGB 44.1±8, p=0.96).
Results: Fasting PG was similar in the two surgical groups (SG: 5.1 mmol/L vs. RYGB: 4.9, p=0.23), but was higher in CON subjects (5.3, p<0.01 vs. RYGB). Postprandial glucose excursions differed between all 3 groups and were largest after RYGB with numerically higher peak (p=0.08 vs SG, p<0.01 vs. CON) and lower nadir (p=0.02 vs. SG and <0.01 vs CON) (Δmax-min plasma glucose: SG: 5.6±1.5 mmol/L, RYGB: 7.2 ± 1.6, CON: 4.3±1.5, nadir PG: SG: 4.3±0.5, RYGB: 3.8 ±0.6, CON: 4.4±0.4), whereas iAUC of PG was comparable between groups (ANOVA p=0.77). Peak of insulin was also greatly exaggerated after RYGB (p<0.01 vs. SG and CON), but was comparable after SG and CON (p=0.42). In contrast, iAUC of insulin did not differ between the groups (ANOVA p=0.41). Postprandial lactate followed the PG excursions (Peak lactate: SG: 1.8±0.2, RYGB 2.1±0.2, CON: 1.4 ±0.3, ANOVA p<0.01). Insulin clearance was larger in both surgical groups (C-peptide/Insulin: SG: 25 (20;27) [median (IQR)], RYGB: 21 (15;23), CON: 13 (11;19)). Insulin secretion related to insulin resistance (Disposition Index (Insulinogenic index * 1/HOMA-IR): SG: 162 (119;202), RYGB: 199 (127;323), CON 89 (57;118)) was comparable between RYGB and SG (p=0.26), but higher when compared with CON subjects (p<0.05 vs. both SG and RYGB).
Conclusion: Postprandial glucose metabolism after RYGB and SG differs with respect to glucose excursions, nadir of glucose and peak of insulin despite similar iAUC of both glucose and insulin. The metabolic fate of ingested glucose also differs significantly after RYGB and SG with larger postprandial lactate formation after RYGB, suggesting that differential mechanisms underlie the improved glycaemic control in the two surgical situations. In contrast, beta cell function in relation to the ambient insulin resistance was similarly improved after SG and RYGB.

Weight loss by two different diets increases the postprandial response of GLP-1 but only the Paleolithic diet increases the postprandial response of GIP

J. Otten[1], M. Ryberg[1], C. Mellberg[1], B. Lindahl[2], C. Larsson[3], J. Juul Holst[4], T. Olsson[1];
[1]Department of Medicine, Umeå University, [2]Department of Public Health and Clinical Medicine, Umeå University, Umeå, [3]University of Gothenburg, Gothenburg, Sweden, [4]University of Copenhagen, Copenhagen, Denmark.

Background and aims: Weight loss by diet intervention has shown conflicting results on postprandial levels of glucagon-like peptide 1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP). We therefore investigated a Paleolithic diet (PD) and a prudent control diet according to the Nordic nutrition recommendations (CD) and aimed to compare the effect of the two diets on postprandial levels of GLP-1 and GIP.
Materials and methods: Seventy healthy, obese, postmenopausal women were randomized to either the PD or the CD. In the PD group participants were advised to eat vegetables, fruit, lean meat, fish, nuts and eggs. Cereals, dairy products, added sugar and salt were excluded. With the CD participants were advised to increase their intake of whole grain, fruit, vegetables and fish. Dairy products and meat were supposed to be low fat. Both diets were without calorie restriction. Plasma levels of GLP-1 and GIP were measured after ingestion of 75 g glucose at baseline and after 6 and 24 months of diet intervention. The incremental area under the curve (iAUC) of GLP-1 and GIP was calculated during 120 min after glucose intake.
Results: The PD group showed a more pronounced weight reduction after 6 months (9.2 ± 4.2 kg (mean±SD)) and 24 months (8.1 ± 5.6 kg) compared to the CD group (4.7 ± 4.2 kg at 6 months and 4.9 ± 4.8 kg at 24 months; P<0.001 and P<0.05 for the difference between groups at 6 months and 24 months). For the PD group the iAUC of GLP-1 increased by 34 % after 6 months and by 45 % after 24 months compared to baseline. For the CD group the iAUC of GLP-1 increased by 11 % after 6 months and by 59 % after 24 months. For the PD group the iAUC of GIP increased by 23 % after 6 months compared to baseline but decreased by 3 % in the CD group (P<0.05 for the difference between groups).
Conclusion: Postprandial levels of GLP-1 increased through diet-induced weight loss by the Paleolithic diet and the control diet. The postprandial GIP response increased through weight loss by the Paleolithic diet but not by the control diet.
Clinical Trial Registration Number: Dnr 05-098M

Acute lowering of circulating fatty acids does not improve the incretin effect in patients with type 2 diabetes

V.B. Chueire[1], B.D. Astiarraga[2], A.L. Souza[1], R. Pereira-Moreira[1], S. Rodovalho[3], S. Monte Alegre[1], A. Tura[4], A. Mari[4], E. Ferrannini[5], E. Muscelli[1];
[1]Department of Internal Medicine, State University of Campinas, Campinas, Brazil, [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [3]Department of Internal Medicine, Catholic University of Campinas, Campinas, Brazil, [4]CNR Institute of Neuroscience, Padua, [5]CNR Institute of Clinical Physiology, Pisa, Italy.

Background and aims: Plasma glucose is the main stimulus for insulin secretion (IS), but non-esterified fatty acids (NEFA) and the incretin hormones (mainly, GLP-1 and GIP) also are important modulators of IS. The incretin effect (IE) accounts for the ~40-80% higher IS after oral ingestion compared to intravenous glucose. Palmitate impairs IE by downregulating GLP-1 receptor signaling in beta-cell lines and isolated mouse islets. Insulin resistance and defective IE are common in T2DM. Thus, increased NEFA levels could impact beta-cell function through an impairment of IE. Our aim was to test whether an acute NEFA reduction induced by acipimox (ACP, a potent inhibitor of lipolysis) improves IE in T2DM.
Materials and methods: Thirteen patients (10F/3M; 54.8±7.6 years, mean±SD; BMI = 32.8±5.6 kg/m^2; HbA_{1c} = 7.24±0.48 %) received a 3-hour OGTT (75 g) and a 3-hour isoglycaemic glucose infusion (IV) on separate days. Both tests were repeated after ACP ingestion (200 mg two hours before and 1hour after starting glucose administration). C-peptide deconvolution was used to calculate IS rates, and mathematical modelling to quantitate beta-cell function and IE. The main parameters are insulin secretion rate (ISR); glucose sensitivity (ßGS), *i.e.,* the slope of the IS/glucose dose-response curve; glucose-induced potentiation (P_{GLU}), a time-dependent modulation of the dose-response; and incretin-induced potentiation (P_{INCR}) calculated as the fold IS increment during OGTT compared to IV glucose.
Results: On the OGTT, ACP decreased NEFA OGTT-area-under-curve (AUC) by 55±14% (64±28 *vs* 27±9 mol·L^{-1}·h^{-1}, p<0.01). Fasting glycaemia, OGTT and IV glucose AUCs were similar before and after ACP, while ACP decreased incremental OGTT-glucose AUC (744±163 *vs* 902± 262 mol·L^{-1}·3h^{-1}, p<0.05). ISR was lower during IV than OGTT

both in the control (58±19 *vs* 70±23 nmol·m^{-2}; p<0.01) and ACP studies (53±15 *vs* 64±20 nmol·m^{-2}, p<0.01). ACP reduced ISR (64±20 *vs* 70±23 nmol·m^{-2}, p<0.05) and did not change ßGS (32±11 *vs* 26±9 pmol·min^{-1}·m^{-2}·mM^{-1}), P_{INCR} (1.17±0.14 *vs* 1.12±0.19 fold), P_{GLU} or plasma glucagon and GIP (all p=ns). In contrast, ACP improved insulin sensitivity, estimated as the oral glucose sensitivity index, OGIS (326±44 *vs* 291±60 ml·min^{-1}·m^{-2}, p<0.05). Changes in ISR were directly related to changes in NEFA (rho=0.62, p=0.03) and inversely related to OGIS (rho= -0.73, p=0.01).

Conclusion: In patients with type 2 diabetes, acute pharmacological NEFA reduction lowers glycaemia and enhances insulin sensitivity but does not improve the incretin effect.

Glucagon response in patients with type 1 diabetes during meal-related hypoglycaemia and hyperinsulinaemic, hypoglycaemic clamp conditions

J. Muenzker[1], S. Zenz[1], O. Moser[2], M. Motschnig[1], A. Puffing[1], H. Elsayed[1], P. Baumann[3], H.-P. Schadler[3], T.R. Pieber[1,3], H. Sourij[1], J. Mader[1];

[1]Endocrinology and Diabetology, Medical University of Graz, Graz, Austria, [2]Diabetes Research Group, Swansea University, Swansea, UK, [3]Health, Joanneum Research GmbH, Graz, Austria.

Background and aims: It has been suggested that in long-standing, C-peptide negative type 1 diabetes not only insulin secretion is disturbed but also counter-regulatory response to hypoglycaemia and in particular adequate glucagon secretion is blunted. Glucagon response to hypoglycaemia was tested in a hypoglycaemic clamp setting (clamp) vs. mimicking real-life hypoglycaemia conditions by using a n increased insulin to carbohydrate ratio and exercise challenge (real-life) in C-peptide positive (CP+) vs. C-peptide negative (CP-) subjects with T1D.

Materials and methods: Data from one clamp study and three real-life studies were pooled. In the clamp study 21 (10 CP+, 11 CP-) subjects underwent a hyperinsulinemic, hypoglycaemic clamp (target 3.5mmol/L) after an overnight stabilisation phase at 5.5mmol/L ± 10%. In the real-life studies 27 subjects (9CP+, 18CP-) were investigated at the research centre and received standardised meals with 180% of their regular short-acting insulin dose. Glucagon response during hypoglycaemia was defined as the area under the glucagon curve during the first hypoglycaemic episode (≤3.5 mmol/L). In both experiments, glucose was measured every 5min (Super GL glucose analyser); glucagon samples were collected using P800 (BD) blood tubes and analysis was performed via specific sandwich ELISA (Mercodia). The area under the curve (AUC) for glucagon was calculated using the trapezoidal method. CP+ was defined as C-peptide concentrations ≥0.05 nmol/L.

Results: Baseline characteristics are given in Table 1. During real-life both CP+ and CP- patients had significantly higher AUC-glucagon levels as compared to clamp (CP+: p=0.0146 and CP-: p=0.0022, respectively). During clamp, CP+ patients showed a higher glucagon response (AUC-glucagon) compared to CP- patients (p=0.0074). This finding was not observed in the real-life setting.

Conclusion: Patients during the real-life experiment had overall higher glucagon response than patients undergoing the clamp experiment. CP+ showed a higher glucagon response compared to CP- during hypoglycaemic clamp conditions, but not during real-life conditions. Whether this is due to differences in the patient population investigated (e.g. difference in diabetes duration between clamp and real-life population) or due to the differences in hypoglycaemia induced glucagon stimulation remains to be elucidated.

	Clamp		Real-life	
	CP+ (n=10)	CP- (n=11)	CP+ (n=9)	CP- (n=18)
Age (a)	39.6 ± 12.8	38.3 ± 12.4	32.5 ± 13.7	31.3 ± 9.5

Insulin resistance and beta cell function in pregnancies after gastric bypass surgery

C.S. Göbl[1], L. Bozkurt[2], M. Leutner[2], L. Andrei[1], L. Fahr[1], P. Husslein[1], W. Eppel[1], A. Tura[3], A. Kautzky-Willer[2];

[1]Department of Obstetrics and Gynecology, Division of Obstetrics and Feto-Maternal Medicine, Medical University of Vienna, [2]Department of Internal Medicine III, Div. of Endocrinology and Metabolism, Unit of Gender Medicine, Medical University of Vienna, Vienna, Austria, [3]Metabolic Unit, Institute of Neuroscience, National Research Council, Padova, Italy.

Background and aims: Obesity has become a major health care concern, related to impaired quality of life and increased risk for metabolic disorders. Surgical interventions are provided already in younger populations at reproductive age if conservative strategies fail to derive satisfactory weight reduction. Previous studies have shown altered glucose kinetics in pregnancies following gastric bypass surgery, however, the pathophysiological alterations beyond these observations are not fully discovered.

Materials and methods: A total of 64 females (26 with history of gastric bypass (RYGB), 19 obese and 19 normal weight controls) were consecutively recruited among women visiting our pregnancy outpatient department between April 2014 to February 2016. A detailed metabolic characterization of the study population was performed between 24 and 28 weeks of gestation including an extended 3h-75g-OGTT as well as a short frequently sampled intravenous glucose tolerance test (IVGTT) to provide estimates of insulin sensitivity and insulin secretion.

Results: We found major alterations in glucose kinetics during the OGTT including an early rise of plasma glucose followed by hypoglycemia in 86% of RYGB women. This was accompanied by increased insulin, C-peptide and glucagon concentrations after oral glucose load. IVGTT data suggested improved insulin sensitivity (CSI in RYGB vs. obese vs. normal weight: 2.31 vs. 0.81 vs. 3.72 (10^{-4} min^{-1} [µU/ml]$^{-1}$, p<0.001) and reduced acute insulin response to intravenous glucose (ΔAIRG: 81.9 vs. 149.7 vs. 89.2 µU/ml). Hence, the disposition index (CSI×ΔAIRG) was improved in pregnancies after RYGB as compared to obese women but subtle alterations in β-cell function were observed in RYGB vs. normal weight controls. We further evaluated data on glucose disposal in n=15 RYGB and n=15 controls, which were matched for their actual BMI and found improved insulin sensitivity in the RYGB subgroup.

Conclusion: Pregnancies after gastric bypass surgery are affected by altered postprandial glucose insulin and C-peptide dynamics, associated with higher glycemic variability. Insulin sensitivity is improved, however, subtle alterations in β-cell function were still observed in pregnancies following bariatric surgery. Longitudinal studies are at need to assess potential consequences for fetal development and pregnancy outcome.

Glucagon-like peptide-1 (GLP-1) has no effect on peripheral vasodilation but augments coronary microcirculatory flow in humans

S.J. Clarke[1], J.P. Giblett[2], T. Zhao[2], A. Hubsch[3], L. Yang[3], D. Dutka[1], J. Cheriyan[3], S.P. Hoole[2];

[1]Cardiovascular Medicine, University of Cambridge, [2]Interventional Cardiology, Papworth Hospital NHS Trust, [3]Clinical Pharmacology, University of Cambridge, Cambridge, UK.

Background and aims: We have previously demonstrated that GLP-1 (7-36) improves post-ischemic left ventricular contractility (stunning) induced by coronary balloon occlusion in humans. The mechanism for this cardioprotection is elusive; GLP-1 receptors are not expressed on human myocardium. We hypothesised that GLP-1 (7-36) mediated vasodilatation may be responsible either by dilating coronary arteries, or dilating the peripheral circulation, or both.
Materials and methods: 10 patients requiring left anterior descending coronary artery stenting were recruited to undergo a forearm bloodflow study, and a coronary microcirculation study. On the first visit we gave a local intra-arterial infusion of 5 incremental doses of GLP-1 (7-36) (0.0375, 0.075, 0.15, 0.3, and 0.6pmol/kg/min) for 6 minutes each and assessed forearm bloodflow using standard plethysmography technique. On the second visit, we recorded paired coronary haemodynamic measures (Pd, Pa, transit time (T_{mn}) at rest and during maximal adenosine hyperaemia) at baseline (10 minutes after stent implantation) and after a 20-minute continuous infusion of GLP-1 (7-36) at 1.2pmol/kg/min. We calculated Fractional Flow Reserve (FFR), Basal Microcirculatory Resistance, Index of Microcirculatory Resistance (IMR), Coronary Flow Reserve (CFR), and Coronary Collateral Flow Index (CFI_p).
Results: The results are shown in Table 1 and illustrate that there was no significant effect of GLP-1 on absolute change in forearm bloodflow (1.838 to 1.909, p=0.78), forearm bloodflow ratio (1.152 to 0.974, p=0.19), or percentage change in forearm bloodflow ratio (-14.372%, p=0.2) from baseline to the top dose of 0.6pmol/kg/min. There were no significant effects of GLP-1 on FFR (0.87 vs. 0.89, p=0.68), IMR (17.8 vs. 21.2, p=0.61), CFR (4.4 vs. 3.2, p=0.40) or CFI_p(0.11 vs. 0.14 p=0.32). Resting T_{mn} was faster following GLP-1 (0.97 vs. 0.68, p=0.02) and this was responsible for lowering basal microcirculatory resistance (BMR) (82.4 vs. 55.5, p=0.02).
Conclusion: We did not observe any dilation in peripheral vessels with GLP-1. Therefore it is unlikely that increasing left ventricular ejection fraction by reducing afterload contributes to the mechanism of cardioprotection in humans. GLP-1 appears to act as a coronary microcirculatory vasodilator in humans. Augmenting microcirculatory flow opens stretch-activated calcium channels in adjacent cardiac myocytes, increasing intracellular calcium, which in turn enhances contractility, a mechanism known as the Gregg effect.

The glucagon-like peptide-1 receptor agonist lixisenatide reduces postprandial glucose excursions in totally pancreatectomised patients

C.T.B. Juel[1], A. Lund[1], C.P. Hansen[2], J. Storkholm[2], N. Wewer Albrechtsen[3], J. Holst[3], T. Vilsbøll[4], F.K. Knop[1];
[1]Center for Diabetes Research, Hellerup/Copenhagen, [2]Department of Gastrointestinal Surgery, Rigshospitalet, University of Copenhagen, Copenhagen, [3]NNF Center for Basic Metabolic Research and Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [4]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, Denmark.

Background and aims: The extrapancreatic effects of glucagon-like peptide-1 (GLP-1) have been difficult to disentangle. Treatment of diabetes secondary to total pancreatectomy remains a challenge. We investigated the effects of the GLP-1 receptor agonist, lixisenatide, on postprandial glucose metabolism in totally pancreatectomised patients.
Materials and methods: In a double-blinded, randomised, cross-over study, we recruited 12 totally pancreatectomised patients (3 women; age: 65.0±9.5 [mean±SD] years; BMI: 22.9±3.9 kg/m^2) and 12 control subjects (4 women; age 64.4±7.6 years; BMI: 24.0±2.9 kg/m^2). Both groups were examined during two 3-hour liquid mixed meal tests (with 1.5 g paracetamol for evaluation of gastric emptying) after single-dose injection of 20 μg of lixisenatide or placebo, respectively. Patients received their regular dose of basal insulin the night before each experimental day; no insulin was given during the meal tests. Blood was sampled for measurements of plasma/serum concentrations of glucose, glucagon, C-peptide and paracetamol.
Results: Compared to placebo**,** lixisenatide significantly reduced postprandial plasma glucose excursions in totally pancreatectomised patients (AUC±SEM: 2,715±179 vs 3,473±177 mmol/l × min, p=0.006) and controls (AUC: 814±14 vs 1,152±57 mmol/l × min, p<0.0001) (figure 1). In totally pancreatectomised patients, C-peptide was undetectable in plasma and lixisenatide significantly reduced gastric emptying as well as postprandial glucagon responses (AUC: 620±162 vs 1,479±271 pmol/l × min, p=0.003). In the control subjects, lixisenatide reduced postprandial plasma C-peptide responses (AUC: 105±19 vs. 261±34 nmol/l × min, p=<0.001) and decelerated gastric emptying significantly whereas postprandial glucagon responses were unaffected (AUC: 1,283±159 vs 1,253 ±225 pmol/l × min, p=0.879).
Conclusion: The GLP-1 receptor agonist lixisenatide reduces postprandial plasma glucose excursions in totally pancreatectomised patients. The mode of action seems to involve deceleration of gastric emptying and reduced postprandial responses of gut-derived glucagon.

Early exercise performance predicts late-onset development of type 2 diabetes in New Zealand obese mice

C.A. Springer, A. Chadt, H. Al-Hasani;
Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Leibniz Institute for Diabetes Research at Heinrich Heine University Düsseldorf; German Center for Diabetes Research (DZD), Düsseldorf, Germany.

Background and aims: Regular exercise training improves insulin sensitivity and glycaemia. However, individuals with type-2 diabetes (T2D) may largely differ in their response to exercise and subsequent improvements in glycaemic control, implicating that the genetic background affects the ability to respond to exercise. Our aim was to investigate on the molecular level exercise-induced alterations in glucose homeostasis in an established polygenic mouse model for T2D, the inbred New Zealand Obese (NZO) mouse strain.
Materials and methods: NZO mice were fed a high-fat diet with 30 % fat from calories after weaning. At week 6 of life, mice were subjected to a 6-weeks chronic interval training on treadmills, or kept as sedentary controls. Endurance capacity was assessed by acute running tests before and after the training intervention. Fasting (6h) plasma glucose levels (FPG) and glucose tolerance tests (GTT) were determined to evaluate glycaemic control. Liver and skeletal muscle triglycerides were determined using a colorimetric assay. Statistical analysis was performed using student's t-test and two-way ANOVA.
Results: At 6 weeks of age, all NZO mice were normoglycaemic (90-100 mg/dl FPG). At 12 weeks, approx. 50% of the mice had developed diabetes (FPG ≥300 mg/dl) in both the trained (11/19) and sedentary (13/26) group, respectively. However, after six weeks of chronic interval training, NZO mice showed improved physical condition, measured by increased time to exhaustion during an acute running test (trained vs sedentary; 13.7 ± 0.5 min vs 11.5 ± 0.4 min, n = 5-19, $p<0.05$). Post-hoc analysis of the acute running tests revealed that diabetic (T2D) mice showed significantly reduced endurance capacity compared to non-diabetic (ND) mice, even before the training (14.1 ± 0.4 min vs 16.7 ± 0.6 min, n = 8-11, $p<0.001$). Furthermore, only ND mice significantly improved their glucose tolerance (trained vs sedentary; AUC 46790 ± 2982 vs 71370 ± 4907, n = 8-12, $p<0.01$), whereas T2D mice remained glucose intolerant (trained vs sedentary; AUC 129300 ± 2633 vs 127500 ± 2465, n = 7-9) in an i.p.GTT, despite the training. Liver triglycerides were increased after chronic interval training, both in ND (trained vs sedentary; 33.5 ± 1.7 μg/mg liver vs 26.7 ± 1.7 μg/mg liver, n = 6, $p<0.05$) and T2D (trained vs sedentary; 37.5 ± 2.3 μg/mg liver vs 31.5 ± 1.4 μg/mg liver, n = 6-7, $p=0.06$) mice. In contrast, skeletal muscle triglycerides only tended to be reduced after chronic exercise in ND and T2D mice.
Conclusion: NZO mice, a polygenic model for early onset obesity and type 2 diabetes, show a heterogeneous response to chronic exercise training with respect to glycaemia. While our results demonstrate that regular training is able to improve exercise performance in NZO mice, an improvement of glycaemic control is observed only in a subgroup of the animals. In fact, we identified reduced endurance capacity as an efficient predictor for the development of T2D, indicating that metabolic programming of non-responder NZO mice has already occurred at a very early age and may not be reversed by acute exercise training. Furthermore, elevated liver fat content indicates abnormal lipid storage and distribution in the NZO model that is not improved by exercise training. Future studies will focus on the identification of epigenetic and metabolic factors that determine the response to exercise.

High physical activity levels are associated with better glycaemic control in patients with type 1 diabetes

S. Murillo, L. Brugnara, A. Novials;
Diabetes and Obesity Research Laboratory, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Barcelona, Spain.

Background and aims: The beneficial effects of exercise on metabolic control of patients with type 1 Diabetes (T1D) are still controversial. The aim of this work was to study PA levels and the relationship with glycaemic control and health-related parameters, as body composition and nutritional habits in adults with T1D.
Materials and methods: We included 182 patients with T1D and 185 controls without diabetes between 18 and 50 years old. We assessed PA levels using IPAQ questionnaire, classifying individuals as low (inactive), moderate or high PA levels. Also, we analysed cardiorespiratory fitness by gas analysis exchange (VO2/VCO2) during a maximal incremental exercise test on a cycle-ergometer, obtaining the maximum oxygen consumption (VO_{2max}).We collected medical history that included clinical records and nutrition analyses using a 4days dietary register. Body composition was calculated using dual energy X-ray absorptiometry (DXA). Glycaemic control was established as the last value of HbA1c. We studied values of HbA1c, VO_{2max}, body composition and nutritional habits in relation of PA levels in T1D and control groups.
Results: Patients with T1D and control subjects presented no differences on age, BMI or total PA levels. Patients with T1D present lower levels of cardiorespiratory fitness (VO_{2max}: 30.1±11.1 vs 33.5±11.8 mlO_2/kg/min; $p<0.01$) compared with control group as well as lower amounts of carbohydrates intake (185.9±62.7g vs 212.1±70.1g;$p<0.05$). Regarding T1D individuals, inactive patients had similar values of HbA_{1c} than those with high PA levels (7.8±1.2 vs 7.6±1.4,$p=0.5$). However, analysing just a group of the more trained ones (more than 5 training sessions a week), they showed lower levels of HbA1c than those classified as inactive (7.2±1 vs 8.0±1.3,$p<0.05$).
Conclusion: Subjects with T1D show significant differences in cardiorespiratory fitness and nutrition habits compared to controls. Also, we found a favourable relationship between physical activity levels and glycaemic control, but only in those individuals with higher levels of physical activity.

Associations of physical activity intensity levels and cardiorespiratory fitness with glucose-induced GLP-1 responses: the ADDITTION-PRO study

S.S. Torekov[1], C. Janus[1], H. Amadid[2], D. Vistisen[2], D. Witte[3], A. Jonsson[1], T. Lauritzen[3], S. Brage[4], O. Pedersen[1], A.-L. Bjerregaard[3], T. Hansen[1], J. Holst[1], M. Jørgensen[2], K. Færch[2];
[1]University of Copenhagen, Copenhagen, [2]Steno Diabetes Center Copenhagen, Gentofte, [3]Aarhus University, Aarhus, Denmark, [4]Cambridge University, Cambridge, UK.

Background and aims: Physical activity and cardiorespiratory fitness may affect the secretion of the gut hormone GLP-1 whose involvement in glucose- and appetite regulation is well-established. However, little is known about the role of physical activity levels during daily living on GLP-1 secretion. Therefore, we examined the association of physical activity intensity levels, including sleep and sedentary time, and fitness with GLP-1 responses to an oral glucose tolerance test.
Materials and methods: We analysed cross-sectional data from 1,326 individuals from the Danish ADDITION-PRO study without known diabetes (53% men, mean age 66.0 years). Circulating GLP-1 levels were

measured at 0, 30, and 120 minutes during a 75-g oral glucose tolerance test. Physical activity was measured using a combined heart rate and movement sensor during 7 days. The intensity of physical activity was classified using metabolic equivalents (METs). The cardiorespiratory fitness level was estimated by an 8-min step test in combination with heart rate measurement. Associations between physical activity measures as explanatory variables and GLP-1 response as outcome were examined by linear regression analysis adjusted for age and sex (model 1), and further adjusted for insulin sensitivity and BMI (model 2). Moderate-to-vigorous physical activity (MVPA) (hours/day) and sedentary time (hours/day) were further adjusted for overall daily physical activity energy expenditure (PAEE) in both models. This was in order for an increase in MVPA to be at the expense of a decrease in a less intensive activity.

Results: The total area under the curve (AUC) for GLP-1 was 10.3-12.7% lower for every hour increase in physical activity spent in moderate-to-vigorous intensity (MVPA) compared to light intensity activity, independent of obesity and insulin sensitivity (See Table 1.). Furthermore, a lower total GLP-1 response with increasing fitness levels was observed, independent of obesity and insulin sensitivity (See Table 1.). PAEE, sedentary and sleep time did not influence the total GLP-1 response to glucose (See Table 1.).

Conclusion: The results suggest that individuals who spend physically active hours at moderate-to-vigorous intensity have lower total GLP-1 response compared to individuals who spend physically active hours at light intensity independent of obesity status and insulin sensitivity. Perspectives: A better understanding of how physical activity is associated with GLP-1 response to oral glucose will be a powerful tool in developing more successful strategies for prevention and management of type 2 diabetes and obesity.

Ghrelin is related to the maintenance of the exercise pattern synchronised with circadian clock under the condition of constant darkness

H. Mifune[1], Y. Tajiri[2], Y. Sakai[1], T. Sato[3], M. Kojima[3];
[1]Kurume University School of Medicine, [2]Division of Endocrinology and Metabolism, Kurume University School of Medicine, [3]Molecular Genetics, Life Science Institute, Kurume University, Kurume, Japan.

Background and aims: We previously reported a bimodal diurnal rhythm of ghrelin with its peaks at the beginning and at the end of the dark period concomitant with a simultaneous increases of voluntary exercise in the wild type (WT) mice. Those accelerations of exercise were attenuated in the ghrelin knockout (GKO) mice, suggesting the relevance of ghrelin surge to the motivation for voluntary exercise (52nd EASD annual meeting). However, the pattern of voluntary exercise was quite similar between WT and GKO mice. It has not been elucidated whether the exercise pattern is synchronized with circadian clock and whether it is entrained by light on-off or ghrelin surge which has been considered to be necessary for the entrainment of circadian rhythm to 24 h daily rhythm. In the present study, we investigated the exercise pattern in WT and GKO mice under constant darkness to evaluate the relevance of circadian clock and ghrelin independently.

Materials and methods: Eight-week-old male WT and GKO mice were individually housed in cages equipped with running wheels under a 12 h light: 12 h dark cycle (L/D, light on 7:00-19:00) at a controlled ambient temperature with ad libitum access to food and water. The number of revolutions was acquired every 15 minutes. At 15 weeks of age, mice were subjected to wheel running under constant dark conditions (D/D) and kept for the next 60 days to measure the circadian rhythmicity of voluntary exercise. At 23 weeks old, light was turned on at 7:00 and the L/D condition was resumed for the next 10 days in order to ascertain whether re-entrainment appeared or not in either group of mice.

Results: A marked increase of wheel-running activity was observed both at the beginning and at the end of dark period in either WT or GKO mice under L/D condition. Under D/D condition, shorter circadian periods than 24 h were observed in both WT and GKO mice with no difference between both groups. In WT mice the wheel-running activity as voluntary exercise was synchronized with circadian rhythmicity with the repetition of clear peaks of exercise and no exercise. In contrast, the exercise pattern was quite different and acrophase of voluntary exercise was unclear and dispersed in GKO mice. Both WT and GKO mice were re-entrained after the resumption of L/D condition (Figure).

Conclusion: It was demonstrated that ghrelin in itself is not relevant to the maintenance of the exercise pattern under L/D condition because of the immediate re-entrainment in either WT or GKO mice. In contrast, it is plausible that ghrelin is related to the maintenance of the exercise pattern synchronized with circadian clock under D/D condition. Thus it is conceivable that the role of ghrelin in voluntary exercise is different between under L/D and D/D condition, that is the relevance to the motivation for exercise under L/D and to the maintenance of exercise pattern under D/D.

Hypothalamic regulation is involved in the AMPK activation in skeletal muscles during physical exercise

L. Miyamoto, G. Tomokawa, Y. Matsuda, M. Yamane, K. Takenokuma, R. Oonishi, K. Tsuchiya;
Medical Pharmacology, Inst. of Biomedical Sciences, The University of Tokushima Graduate School, Tokushima, Japan.

Background and aims: Physical exercise is a potent stimulator of AMPK activation in skeletal muscles. AMPK has been believed to play pivotal roles in metabolic changes in contracting skeletal muscles, as we demonstrated that pharmacological activation of AMPK causes alterations in metabolome quite similar to those in contracting skeletal muscles. The AMPK activation has been considered to be due to local consumption of ATP by muscle contraction. On the other hand, we have demonstrated that leptin activates AMPK in liver as well as skeletal muscles through central pathways. Thus, we investigated possible involvement of the central regulation in the AMPK activation by physical exercise.
Materials and methods: Male ddY mice were forced to swim in the current water pool for 30 or 60 min following to treatment with various blockers. Neonatally monosodium glutamate-treated mice (MSG-mice), whose hypothalamic neurons were damaged, were also evaluated. Gastrocnemius and biceps muscles were isolated just after the exercise and isoform-specific AMPK activities were determined by immunoprecipitation and canonical kinase assay.
Results: The swimming exercise evoked alpha2 isoform-specific AMPK activation in the skeletal muscles with increase in phosphorylation level of Thr172 residue of alpha subunit. In contrast, we did not find AMPK alpha2 activation after swimming exercise in the MSG-mice. Chemical sympathectomy by guanethidine treatment almost completely inhibited the swimming-induced AMPK activation. While pretreatment of propranolol, a blocker against beta-adrenoreceptors, did not affect it, the AMPK activation was completely inhibited by prazosin, an alpha1-adrenoreceptor antagonist. Administration of propranolol or prazosin slightly decreased basal plasma lactate levels, but we confirmed that these treatment did not affect change in the plasma lactate levels during the swimming exercise.
Conclusion: Our observations suggest that physical exercise causes isoform-specific activation of AMPK alpha2 in skeletal muscles primarily via hypothalamus-sympathetic nervous systems with alpha1-adrenoreceptors. Suppression of the AMPK activation in MSG-mice suggested involvement of hypothalamic neurons, however, the MSG-mice exhibited obesity. Thus, intensity of exercise might be different between control and MSG-mice. Therefore, we determined the effects of sympathetic blockers. Guanethidine-induced chemical sympathectomy as well as prazosin administration completely blocked the AMPK activation after swimming, suggesting that alpha1 receptor-dependent sympathetic control should be more important for AMPK activation we observed than local ATP consumption by muscle contraction itself. These treatments did not affect rise in plasma lactate levels by swimming, which suggests no difference in the exercise intensity. In conclusion, AMPK activation in skeletal muscles during physical exercise should not be simply due to local changes in energy status by ATP consumption. Systemic regulations including hypothalamic pathways should play significant roles in the AMPK activation and its downstream metabolic alterations during physical exercise.

Poor glycaemic control is associated with altered physiological responses during cardio-pulmonary exercise testing in type 1 diabetes

O. Moser[1], O. McCarthy[1], R. Deere[1], M.L. Eckstein[1], S.C. Bain[1], H.L. Haahr[2], E. Zijlstra[3], T. Heise[3], R.M. Bracken[1];
[1]Swansea University, Swansea, UK, [2]Novo Nordisk A/S, Søborg, Denmark, [3]Profil, Neuss, Germany.

Background and aims: There is equivocal research detailing functional capacity impairment in people with type 1 diabetes compared to those without the condition. It is unclear where the mechanistic basis for impairment may lie but it has been shown in some studies to involve cardiovascular, pulmonary and/or musculoskeletal systems, with glycaemic control suggested to play a role. Cardio-pulmonary exercise (CPX) testing provides assessment of the integrative responses of cardiovascular, pulmonary and musculoskeletal systems during sub-maximal and maximal exercise intensities. It is non-invasive and highly sensitive and can be used to determine the location of fatigue of cardiovascular or respiration origin. Little work has assessed the impact of glycaemic control on physiological markers during acute CPX testing in type 1 diabetes. This study sought to measure changes in sub-maximal and peak cardio-pulmonary physiological markers in response to cardio-pulmonary exercise testing and determine the impact of glycaemic control on exercise responses.
Materials and methods: Following ethical approval and after informed consent sixty-four patients with type 1 diabetes (age: 34.7±7.7 years; 13 females; length of diabetes: 17.1±9 years; HbA_{1c}: 7.81±0.95 % (61.9±13.1 mmol/mol) performed a cardio-pulmonary cycle ergometer exercise test until maximum volitional exhaustion (female/male; start: 30/40 watts, increase: 30/40 watts every 3 min). Data were averaged every 10 s and expressed as absolute and relative physiological and power values. Metabolic oxidative data were determined using principles of stoichiometry. Pearson's product moment correlations (r) were used to explore relationships between glycaemic control and physiological and performance markers, with $P \leq 0.05$.
Results: Peak physiological parameters were heart rate (HR_{peak}) 185±11 bpm, maximum oxygen uptake (VO_{2max}) 36.7±5.2 $ml.kg^{-1}.min^{-1}$ and power output (P_{peak}) 230±46 watts. Total exercise time was found at 21.2±2.9 min. HbA_{1c} was associated with several markers at the sub-maximal threshold of the heart rate turn point (HRTP); namely, exercise time (r=-0.23, P=0.07), P_{HRTP} (watts) adjusted for body mass (kg) (r=-0.24, P=0.06), O_2 uptake at P_{HRTP} (r=-0.31, P=0.01). Furthermore, HbA_{1c} was correlated to the carbohydrate oxidation rate at HRTP when expressed relative to percentage of VO_{2max} (r=-0.27, P=0.02). HbA_{1c} was also related to the time to exhaustion (r=-0.30, P=0.01), P_{peak} (watts) adjusted for body mass (kg) (r=-0.25, P=0.04), O_2 uptake at P_{peak} (r=-0.24, P=0.06) and HR_{peak} (r=0.29, P=0.02).
Conclusion: Our data demonstrate an efficacious role for cardio-pulmonary exercise testing in a large group of type 1 diabetes patients in determining performance capacity. This study found an important influence of glycaemic control on acute exercise tolerance during cardio-pulmonary exercise testing in type 1 diabetes. Higher HbA_{1c} values were related to lower economy of O_2 use at sub-maximal work rates that translated to shorter exercise test duration and higher peak heart rates. The influence of glycaemic control on cardio-respiratory responses and exercise tolerance in type 1 diabetes warrants further investigation.

Evaluation of invasive versus non-invasive thresholds during cardio-pulmonary exercise testing in patients with type 1 diabetes

M.L. Eckstein[1], O. Moser[1], G. Tschakert[2], A. Mueller[2], W. Groeschl[2], G. Koehler[3], O. McCarthy[1], R.M. Bracken[1], P. Hofmann[2];
[1]Swansea University, Swansea, UK, [2]University of Graz, [3]Medical University of Graz, Graz, Austria.

Background and aims: Cardio-pulmonary exercise (CPX) testing protocols with small stage-to-stage increments can be used to determine two thresholds defining three phases of metabolism. The second threshold such as the second ventilatory threshold (VT2) or the second lactate turn

point (LTP_2) serve as upper limits for endurance training. Both methods are expensive, complex, time consuming or invasive. As a non-invasive technique, the dynamics of the heart rate to performance curve (HRPC) can be used to identify a heart rate turn point (HRTP) because the HRPC deviates near to maximum effort, which allows detecting the HRTP. This point was shown to be related to LTP_2 in healthy individuals. As it is currently not known if the HRTP is in congruence with LTP_2 in patients with type 1 diabetes (T1D) this method was investigated as it might offer a useful and easy to apply non-invasive detection method for the upper limit of sustainable endurance exercise.

Materials and methods: 14 male subjects were recruited for this study (7 T1D patients/7 healthy individuals). T1D patients and healthy individuals' characteristics were: BMI 23.9 ± 2.5 vs. 23.4 ± 1.8 kg/m^2, age 25.3 ± 5.3 vs. 23.4 ± 4.1 years and HbA_{1c} 7.4 (57) ± 0.6 % (6.3 mmol.mol^{-1}) and duration of diabetes 16.9 ± 8.1 years. All subjects performed CPX test on a cycle ergometer (start 40 watts, increase 20 W.min^{-1}). Both lactate turn points (LTP_1/LTP_2) were identified by a computer-aided linear regression break point analysis from the power output (P) and lactate concentration relationship, and HRTP was defined as the point of intersection of two regression lines in the HRPC between LTP_1 and P_{max} with minimal standard deviation of the two straight lines. Pulmonary gas-exchange variables were measured continuously. Lactate concentration (LA), heart rate (HR), oxygen uptake (VO_2), carbohydrate oxidation rate (CHOoxi) and P were compared between HRTP and LTP_2 via ANOVA, post-hoc testing and Pearson's product moment correlations (r), with P≤0.05.

Results: Starting blood glucose prior the CPX testing was 10.58 ± 3.42 mmol.l^{-1} in T1D. HRTP and LTP_2 were significantly associated for physiological variables and P for both T1D patients (r=0.94) and healthy individuals (r=0.91) (p<0.01). Mean differences and confidence intervals for HRTP and LTP_2 were found for LA at -0.30 mmol.l^{-1} (-0.35 to 0.05, p=0.08), HR -1.71 b.min^{-1} (-4.86 to 1.43, p=0.23), VO_2 -1.61 ml.kg^{-1}.min^{-1} (-4.64 to 1.40, p=0.23), CHOoxi 0.23 g.min^{-1} (-0.59 to 1.05, p=0.51) and P -6.57 W (-14.67-1.52, p=0.09) for T1D patients. Similar results were found for healthy controls for LA at 0.21 mmol.l^{-1} (-0.41 to 0.84, p=0.43), HR -0.14 b.min^{-1} (-2.72 to 2.44, p=0.89), VO_2 -0.34 ml.kg^{-1}.min^{-1} (-1.64 to 0.95, p=0.53), CHOoxi 0.36 g.min^{-1} (-0.27 to 1.01, p= 0.21) and P 0.57 W (-6.09 to 7.23, p=0.84).

Conclusion: Comparable to healthy individuals the HRTP is an easy to apply non-invasive method to determine the upper limit for endurance exercise in T1D patients which is equivalent to lactate derived thresholds. Furthermore, no expensive and sophisticated equipment is needed and anxious patients with fear of breathlessness do not need to wear a constricting facemask.

The role of glucagon in gastrointestinal-mediated glucose-disposal and incretin effect in patients with type 2 diabetes and normal glucose tolerant individuals

E. Nielsen-Hannerup[1], S. Hædersdal[1], A. Lund[1], H.E.G. Maagensen[1], J.J. Holst[2], F.K. Knop[1,3], T. Vilsbøll[1,4];

[1]Center for Diabetes Research, Gentofte Hospital, University of Copenhagen, Hellerup, [2]NFF Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [3]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [4]Steno Diabetes Center Copenhagen, University of Copenhagen, Gentofte, Denmark.

Background and aims: Gastrointestinal-mediated glucose-disposal (GIGD) after OGTT reflects the percentage of glucose disposal caused by the oral route. GIGD is reduced in patients with type 2 diabetes (T2D) because of a reduced incretin effect, but possibly also due to OGTT-induced hyperglucagonaemia. Utilising the glucagon receptor antagonist (GRA) LY2409021, we investigated the effect of glucagon on GIGD, incretin effect and plasma glucose.

Materials and methods: In a double-blinded, randomised, cross-over study, 10 patients with T2D (male/female: 5/5; age: 57.1±4.1 [mean ±SEM] years; BMI: 33.0±1.7 kg/m^2; fasting plasma glucose: 8.1 ±0.3 mmol/l; HbA1c: 46.2±1.9 mmol/mol) and 10 gender, age and BMI-matched controls (male/female: 5/5; age: 57.4±4.0 years; BMI: 31.8±1.3 kg/m^2; fasting plasma glucose: 5.6±0.1 mmol/l; HbA1c: 33.9±0.9 mmol/mol) underwent two 50 g-OGTTs with preceding single-dose administration of 100 mg GRA and placebo, respectively, and two corresponding isoglycaemic i.v. glucose infusions (IIGIs).

Results: Compared to placebo, GRA reduced fasting plasma glucose by 2.4±0.4 mmol/l (p=0.0001) in T2D patients and by 0.6±0.04 mmol/l (p<0.0001) in controls. Plasma glucose excursions during OGTT assessed by baseline-subtracted AUC were greater with GRA compared to placebo in both groups (T2D: 998±64 vs. 694±66 pmol/l × min, p=0.0004; controls: 307±40 vs. 209±44 pmol/l × min, p=0.005). No differences were observed between GRA and placebo on GIGD or the incretin effect.

Conclusion: Fasting plasma glucose was lowered by LY2409021 in patients with T2D and controls, but baseline-subtracted plasma glucose excursions increased with GRA in both groups. GIGD and incretin effect are unaffected by glucagon receptor antagonism.

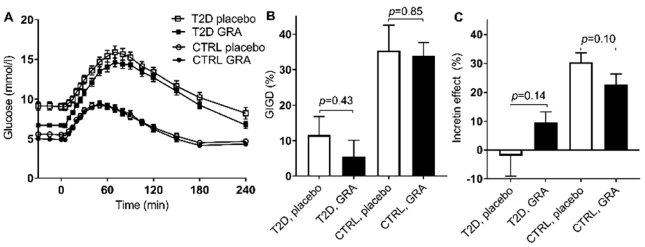

Figure 1. Plasma glucose excursions (A) during 50 g-OGTT, gastrointestinal-mediated glucose disposal (GIGD) (B) and incretin effect (C) after single-dose administration of glucagon receptor antagonist (GRA) and placebo in patients with type 2 diabetes (T2D) and controls (CTRL). Data are means±SEM

Novel approach to estimate glucagon turnover in humans: use of ^{13}C glucagon

A. Basu[1], L. Hinshaw[1], K. Johnson[2], D. McCormick[2], J. Reid[3], M. Slama[1], R. Basu[1];
[1]Endocrinology, Metabolism and Nutrition, [2]Biochemistry and Molecular Biology, [3]Pharmacology, Mayo Clinic College of Medicine, Rochester, USA.

Background and aims: Unlike the C-peptide model used to estimate insulin secretion, there are currently no available methods to measure glucagon secretion and kinetics in humans. A better understanding of these parameters could lead to valuable insights into future research into dysregulation of pancreatic alpha cell function in diabetes. Translationally, this knowledge could further inform the development of multi-hormone algorithms for closed loop control in T1D.
Materials and methods: In order to do so, we applied the isotope dilution approach by synthesizing a non-radioactive, ^{13}C labeled glucagon isotope (FF-glucagon; Phe 6 $^{13}C_9$, ^{15}N; Phe 22 $^{13}C_9$,^{15}N) that was reproducibly detectable in plasma (LOD: 5 pg/ml) by nanoLCMS/MS. To estimate post-absorptive glucagon turnover, we conducted a pilot study in 8 non-diabetic (ND) (age 31.1±10.8 yrs., BMI 22.9±4.5kg/m^2; HbA1c 5.0±0.1%) and 2 type 1 diabetes (T1D) (age 32.8±13.2 yrs., BMI 28.8 ±5.5kg/m^2; HbA1c 6.6±0.1%) subjects with normal liver and kidney functions. Subjects were admitted at 6 PM to the Clinical Research Trials Unit, consumed a standard meal at 7 PM and remained NPO except water for the rest of the study. Insulin was infused in T1D subjects to maintain euglycemia. FF-glucagon was infused intravenously for 2 hours starting at 7 AM at a constant rate to achieve steady plasma enrichment. The heated hand vein method was used to collect blood periodically to measure glucose, insulin, glucagon concentrations and FF-glucagon enrichment. Glucagon concentration (native + FF-glucagon) was measured by a radioimmunoassay (Millipore) and FF-glucagon enrichment by nanoLCMS/MS.
Results: Plasma glucose (4.8±0.3 mM), insulin (24.4±12.3 pM) and glucagon (20.9±4.4 pM) concentrations did not change during and after cessation of FF-glucagon infusion. A stable tracer-tracee ratio (TTR) enabled measurement of Glucagon kinetics with the steady-state equation: $Ra_{glucagon} = ([F_{FF\text{-}glucagon}/TTR] - F_{FF\text{-}glucagon})$, where $Ra_{glucagon}$ = rate of systemic post-hepatic glucagon appearance; $F_{FF\text{-}glucagon}$ = rate of infusion of FF-glucagon and TTR = Ratio of FF-glucagon to total glucagon. $Ra_{glucagon}$ was 0.18±.02 pM/kg/min in ND and 0.32±.04pM/kg/min in T1D; glucagon clearance was 11.5±3.3 ml/kg in ND and 11.1±4.5 ml/kg in T1D.
Conclusion: The results provide proof of concept that the method works and hints that the inappropriately elevated plasma glucagon concentrations observed frequently in T1D could be due to increased systemic glucagon appearance rather than due to altered glucagon clearance. We believe this represents the first report of a novel method to measure in vivo glucagon kinetics in humans.

Glucagon elimination is increased in patients with type 2 diabetes

A.B. Lund[1], M.F. Grøndahl[1], J.I. Bagger[1], J.J. Holst[2,3], M. Christensen[1,4], T. Vilsbøll[1,2], F.K. Knop[1,2];
[1]Center for Diabetes Research, [2]Novo Nordisk Foundation Center for Metabolic Research, [3]Department of Biomedical Sciences, [4]Department of Clinical Medicine, Copenhagen, Denmark.

Background and aims: Type 2 diabetes (T2D) is characterised by hyperglucagonaemia, which contributes significantly to the hyperglycaemic state of the disease. The aetiology behind the hyperglucagonaemia is complex and thought to involve hypersecretion of glucagon from the pancreas. However, no study has so far investigated whether a decreased metabolic clearance rate of glucagon could contribute to hyperglucagonaemia in patients with T2D
Materials and methods: Glucagon was infused intravenously (4 ng/kg/min) for 1 hour in 16 patients with T2D (age [mean±SD]: 59±8 years, BMI: 31±6 kg/m^2, HbA1c: 52±16 mmol/mol (6.9±1.4%), estimated glomerular filtration rate (eGFR): 89±12 ml/min/1.73 m^2) and 16 age, gender and BMI-matched non-diabetic controls (age: 59±9 years, BMI: 31±6 kg/m^2, HbA_{1c}: 34±4 mmol/mol (5.3±0.4%), eGFR: 83±13 ml/min/1.73 m^2). Plasma glucagon was measured frequently before, during and after the 1-hour infusion (Figure 1).
Results: Compared to controls, metabolic clearance rate of glucagon was higher (40.6±2.7 [mean±SEM] vs. 29.7±1.2 ml/kg/min, p=0.002) and elimination $t_{½}$ of glucagon was lower in the T2D patients (4.4±0.3 vs. 5.5±0.4 minutes, p=0.02).
Conclusion: From these accurate estimates of the metabolic clearance rate and $t_{½}$ of glucagon in patients with T2D and matched non-diabetic controls, we conclude that glucagon elimination is increased in our cohort of patients with T2D, suggesting that increased secretion rather than diminished metabolic clearance rate of glucagon contributes to the hyperglucagonaemic state of T2D.

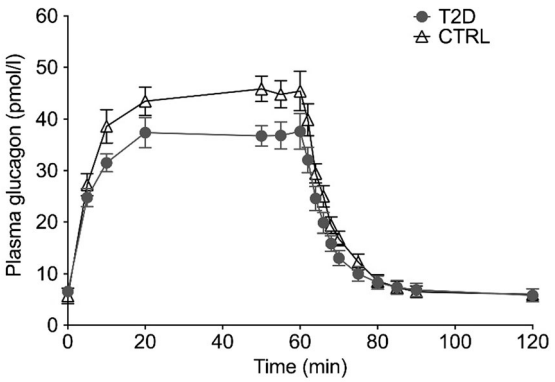

Figure 1. Plasma glucagon (mean±SEM) following infusion of glucagon (4 ng/kg/min) from 0-60 minutes in 16 patients with type 2 diabetes (T2D) and 16 matched non-diabetic control subjects (CTRL)

Baicalin attenuates glucose intolerance by modulating pancreatic hormones in high-fat induced obese diabetic mice

J. You, J. Kim, K. Park, S. Lee, M. Kim, J. Nam, J. Park, C. Ahn, K. Kim; Yonsei University, Seoul, Republic of Korea.

Background and aims: Baicalin, a naturally occurring flavonoid found in in the genus *Scutellaria*, was originally known as an allosteric modulator of the benzodiazepine sites of the γ-aminobutyric acid A receptor ($GABA_AR$) producing anxiolytic effects in mice without sedative or myorelaxant effects. Baicalin has been recently shown to exert metabolic effects by attenuating hyperglycemia-induced mitochondrial damage in 훽;-cells in diabetic rats, high-fat diet- (HFD-) induced body weight gain, and lipid deposits in the liver and systemic inflammation in mice. This study investigated the effects of baicalin on islet functions and diabetic status in HFD-induced obese diabetic mice.
Materials and methods: C57BL/6 mice were grouped into normal control, HF control, HF sham, and 4 different baicalin dose-administered groups (25, 50, 100, and 150 mg/kg). HFD containing 60% fat and water were fed ad libitum for 24 weeks. Designated doses of baicalin or 0.9%

saline were administered intraperitoneally 5d/wk. Body weight (BW) and conventional glucose homeostasis parameters (FPG, FPI, AUC-glucose, AUC-insulin, and etc.) were monitored; in addition, ex vivo glucose-stimulated insulin secretion (GSIS) and glucagon secretion (GSGS) with isolated islets were performed.
Results: Baicalin attenuated HFD-induced hyperglycemia in dose-dependent manner without affecting BW. Insulin secretion in response to high glucose stimulation (16.7mM) was significantly higher in islets isolated from the groups administered 50, 100, 150 mg/kg baicalin compared to HF control; glucagon secretion was significantly suppressed by high glucose stimulation in islets from the same groups.
Conclusion: This study showed that baicalin had positive effects on glycemic control by regulating secretion of insulin and glucagon, possibly through $GABA_AR$ mediation.
Disclosure: **J. You:** None.

NADPH as a metabolic coupling factor: A player in glucagon secretion?

C. Miranda[1], S.S. Ahmadi[1], J.I. Real[1], P. Rorsman[1,2];
[1]Department of Physiology, Gothenburg University, Gothenburg, Sweden, [2]Oxford Centre for Diabetes, University of Oxford, Churchill Hospital, Oxford, UK.

Background and aims: NADPH is an important coupling factor in the mechanisms controlling insulin secretion by pancreatic β-cells where stimulus-secretion coupling largely depends on mitochondrial activity. It has been reported that in β-cells, NADPH plays an important role in the amplifying pathway of insulin secretion in response to elevated $[Ca^{2+}]_i$. In α-cells, both intrinsic and paracrine mechanisms have been postulated. The causes of glucagon hypersecretion in type-2 diabetes (T2D) are only beginning to be elucidated. The aim of this study is to access the role of NADPH in the metabolism and pathophysiology of α-cells using both αTC1 clone 6 cell line and intact mouse islets.
Materials and methods: Expression was down regulated by small interfering RNA of four NADPH generating enzymes in αTC1 clone 6 cells: isocitrate dehydrogenase-1(IDH-1), the mitochondrial form IDH-2, Malic enzyme 1 and the mitochondrial form Malic enzyme 3 (ME3). C75 was used to inhibit Fatty acid synthase (FAS) in attempt to increase the levels of NADPH. Glucagon secretion was measured in isolated mouse islets from chow- and high fat diet (HFD) -fed C57/bl6-J mice for 8 weeks. Islets were pretreated with C75 (150 μM) in DMSO 2 hours prior to secretion experiment.
Results: siRNA downregulation of ME3 by 50% resulted in decreased levels of NADPH by 50% and reduced glucagon gene expression by 67%. After knockdown of ME3, glucagon secretion was increased in 30% and C75 treatment more than doubled glucagon secretion at 1 mM glucose (to 158 ±40 pmol/l from 65±19 pmol/l; n=6, p<0.05) in HFD mouse islets but was ineffective in islets from mice fed the control diet. Glucagon secretion at 11 mM glucose was also increased 2.5-fold (n=6, p<0.05).
Conclusion: These results suggest that (1) both ME3 and FAS are involved in α-cell regulation and (2) that C75 may have deleterious effects on islet function under diabetogenic conditions, exacerbating hyperglucagonemia.

Endogenous progestogen steroid hormone modifies the positive association between total estradiol and type 2 diabetes risk in postmenopausal women: a prospective study

M. Taulant[1], E. Asllanaj[1], M. Glisic[1], A.M. Ikram[1], J.S.E. Laven[2], O.H. Franco[1];
[1]Epidemiology, Erasmus MC, [2]Department of Obstetrics and Gynaecology, Erasmus MC, Rotterdam, Netherlands.

Background and aims: Recent evidence indicates that higher levels of endogenous estradiol might be associated with increased risk of type 2 diabetes (T2D) in postmenopausal women. It is not known whether progesterone attenuates the deleterious effects of estrogen on T2D. We analyzed whether endogenous estradiol levels were associated with T2D risk in postmenopausal women and whether this association was modified by the levels of the endogenous progestogen steroid hormone.
Materials and methods: This study was embedded in the Rotterdam Study, a prospective follow-up study among subjects aged ≥45 years (n= 3117). At baseline, total estradiol and 17-hydroxyprogesterone levels were measured. T2D events were diagnosed on the basis of medical records and glucose measurements from Rotterdam Study visits. Multivariable adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated using Cox regression models.
Results: During a median follow-up of 11.1 years, we identified 384 incident cases of T2D. Total estradiol was associated with increased risk of T2D (3rd tertile vs. 1st tertile: RR: 1.42; 95%CIs=1.02 -2.00, P-trend=0.04). A significant interaction between total estradiol and 17-hydroxyprogesterone was found (*P-interaction* =0.02). After stratification by median 17-hydroxyprogesterone, an increased risk of T2D was observed for total estradiol only in subjects with levels of 17-hydroxyprogesterone lower than median (3rd tertile vs.1st tertile: HR = 1.99, 95% CI=1.22-3.24, *P*-trend=0.007). No association was observed in subjects with levels of 17-hydroxyprogesterone higher than median (3rd tertile vs.1st tertile: HR = 1.05, 95% CI=0.67-1.36, *P*-trend=0.88).
Conclusion: These findings suggest that high levels of endogenous estradiol levels increase T2D risk in postmenopausal women, but this risk may be reduced by high levels of 17-hydroxyprogesterone.
Disclosure: **M. Taulant:** None.

Dysregulated iron homeostasis in type 2 diabetes

S. Altamura[1], S. Kopf[2], K. Müdder[1], P. Nawroth[2], M. Muckenthaler[1];
[1]Department of Pediatric Oncology, Hematology and Immunology, University of Heidelberg, [2]Department of Internal Medicine I and Clinical Chemistry, University of Heidelberg, Heidelberg, Germany.

Background and aims: Iron and diabetes are strictly related. This is clinically evident in patients affected by hereditary hemochromatosis, in which the prevalence of diabetes is about 20%. On the other side, recent studies demonstrate that in diabetic patients plasma iron and/or ferritin levels could be prognostic factors for the development of the disease. The aim of this study is to understand the molecular mechanisms that cause diabetic iron overload and to elucidate the role of increased iron levels in the pathogenesis of diabetes and in the generation of the diabetic late complications.
Materials and methods: Patients with diabetes mellitus type 2 (T2DM) from the HEIDIS cohort were analysed for systemic iron parameters and hepcidin expression. Lepr(db/db) mice were used as a model of T2DM to identify the mechanisms by which diabetes affects iron homeostasis. Tissue iron content and distribution have been assessed in histology while alterations in the expression of iron-related genes have been analysed in qRT-PCR and western blot. Systemic iron content and hepcidin levels have been measured using the BDA method and with a specific ELISA. To assess how increased iron levels affect the pathogenesis of diabetes, Lepr(db/db) mice have been mated with the FpnC326S mouse model of hereditary hemochromatosis type 4 and diabetic and iron parameters have been measured.
Results: 115 T2DM patients and 26 healthy controls were analyzed for systemic iron parameters. CRP>2 was used as exclusion criteria to avoid inflammatory interferences. Diabetic patients show a significant increase in serum iron content (p=0,035), transferrin saturation (p=0,025) and

ferritin levels (p=0.01). Serum hepcidin levels were inappropriately low (p<0,0001) explaining the elevated systemic iron levels. To study how diabetes affects iron homeostasis, we analyzed the Lepr(db/db) mouse model of T2DM. 10-week old mice show the hallmarks of the early T2DM: obesity, hyperglycemia, hyperinsulinemia and increased HbA1c. Consistent with the patients, these mice have elevated serum iron, transferrin saturation and ferritin levels while circulating hepcidin is significantly reduced. Analysis of the liver revealed an overall iron deficiency despite the elevated systemic iron content and the increased TfR1 mRNA expression. Interestingly, the hepatic levels of the iron storage protein ferritin are unchanged. Molecular analysis revealed the typical BMP/SMAD activation pattern that mediates hepcidin upregulation upon systemic iron overload. FpnC326S/Lepr(db/db) hemochromatotic diabetic mice show a similar phenotype when compared to hemochromatotic non-diabetic controls, having a 1,5-fold increase in systemic iron levels and a decrease in non-heme liver iron content.

Conclusion: This study revealed that hepcidin levels are inappropriately decreased both in patients and in Lepr(db/db) mouse model of T2DM, causing elevated systemic iron levels. T2DM causes a lack of systemic iron uptake by the liver, generating hepatic iron deficiency. This phenotype persists in hemochromatotic/diabetic mice, which show decreased hepatic iron content and increased systemic iron levels compared to hemochromatotic non-diabetic mice. Experiments are ongoing to identify the consequences of increased systemic iron content in organs affected by the diabetic late complications.

Analysis of heterogeneity of individual donor and islet glucagon responses to glucose stimulated hormone secretion and drug therapy

M. Chetboun[1], C. Saponaro[1], V. Gmyr[1,2], E. Moerman[1,2], N. Delalleau[1,2], J. Thevenet[1,2], G. Pasquetti[1], F. Pattou[1,2], J. Kerr-Conte[1,2], C. Bonner[1,3];

[1]Inserm UMR 1190, [2]University of Lille 2, [3]Institut Pasteur de Lille, Lille, France.

Background and aims: Human islets have become a critical resource for researchers studying islet physiology and hormone secretion. Notably, donor islet heterogeneity influences the development of diabetes and its response to treatment, and often poses a high risk of data reproducibility and misinterpretation compared to rodent islets. Dapagliflozin (an SGLT2 inhibitor) has been shown to elevate plasma glucagon levels independent of the action of insulin. The aim of this study was to determine the reproducibility of human islet cultures in response to glucose and drug treatment across a large number of donors.

Materials and methods: Human islets were isolated from deceased non-diabetic donors. Islet preparations were treated in quadruplicate with 1 mM or 6 mM glucose, with or without dapagliflozin (12 μM) for 1h. Healthy male C57BL/6J mice were treated with one-shot dapagliflozin (10 mg/kg of body weight *n= 30*) or vehicle (*n=30*) after an overnight fast. Glucagon secretion was measured by ELISA.

Results: Islets from 26 donors (BMI range, age range, HbA1c range) were studied. Mean glucagon secretion was 6,06±5,70% of content (range 16,17% to 0,27%) at 1mM and decreased to 3,68±3,56% of content (range 12,37% to 0,23%) at 6mM. However, donor effect was a major determinant of glucagon secretion (p<0.0001). When analyzed with two-way ANOVA, dapagliflozin significantly induced glucagon secretion at 6mM to 6,16±5,58% of content (range 22,99% to 0,42%), (p<0.0001, dapagliflozin / donor interaction). Sample size analysis predicted that for 80% power with 5% significance as a measure of sensitivity, the minimal sample size required to draw firm conclusion is n=10 human islet donors. *In vivo*, *dapagliflozin consistently and significantly induced glucagon secretion in C57BL/6J* mice (vehicle vs. dapagliflozin; p<0,0001).

Conclusion: The use of human islet cultures for drug testing is recommended in conjunction with adequately powered group sizes for dependable preclinical testing of new therapeutic drugs.

What happens to glucose metabolism if we combine fructose and prednisolone intake? It is never too late to repair bad habits

A. Rafacho, C. dos Santos, J.S. da Silva, H.S. Brunetta;
Physiological Sciences, Federal University of Santa Catarina, Florianópolis, Brazil.

Background and aims: It is well known that regular ingestion of fructose and continuous treatment with glucocorticoid (GC), separately, causes diabetogenic effects. Thus, we sought to evaluate the impact of a combination of fructose and prednisolone ingestion on glucose and lipid homeostasis as well as the impact of the interruption of this combined treatment.
Materials and methods: Male Wistar rats were divided into five groups as follows: control (C) group, fructose (F) group (20% fructose in the drinking water), prednisolone (P) group (12.5 μg/mL prednisolone in the drinking water), fructose plus prednisolone (FP) group (a combination of fructose and prednisolone in the drinking water as for F and P groups) for 90 consecutive days. Half of the rats (group R) from the FP group were maintained for 90 more days with a discontinuation of fructose and prednisolone to monitor the parameters.
Results: The FP and P groups exhibited reduced body weight gain even though they had comparable caloric intake with the C and F groups (n=10, p<0.05). The combination of fructose and GC intake rendered rats hypertriacylglyceridemic from the fourth week of treatment until the end of treatment (n=10, p<0.05). The FP group also developed increased abdominal adiposity, reduced insulin sensitivity, hyperinsulinemia, increased circulating uric acid, and impaired hepatic redox balance with increased hepatic triacylglycerol content (n=10, p<0.05). No major impact on fasting glycemia or glucose tolerance was observed in the FP group. This metabolic phenotype observed in the FP group was accompanied by an increase in the fat accumulation in the liver and by augmented beta cell mass per body mass (n=8-10, p<0.05). In addition, the combination of fructose and GC treatment led to a decrease in the total protein kinase B (PKB) content in the liver and to a reduction in the phosphorylated 5' AMP-activated protein kinase (AMPK) content in the adipose tissue (n=6, p<0.05). Quantification of several proteins involved with the proinflammatory pathway showed no alteration caused by the combination of fructose and GC intake. Interruption of fructose and prednisolone ingestion was satisfactory for the improvement of body weight gain and the normalization of circulating triacylglycerol and uric acid in the R group. Cessation of treatments also led to normalization of the peripheral insulin sensitivity, fat accumulation and redox state in the liver (n=7-14, p<0.05). Finally, protein content of PKB in the liver and phosphorylated AMPK in the adipose tissue were all improved in the R group (n=6, p<0.05).
Conclusion: We conclude that combination of fructose and prednisolone intake impairs the body growth and induces a metabolic syndrome-like phenotype. We also conclude that the removal of fructose and GC from water ameliorates practically all metabolic adverse effects. These findings point to the risk of associating GC-based therapies with a regular intake of sweetened beverages and draws attention to the plasticity of the organism and the benefits of removing the causal factors, whenever possible.

Pyruvate dehydrogenase kinase as a regulator of hepatic gluconeogenesis

J.-H. Jeon[1], B.-Y. Park[1], E.-H. Kim[2], I.-K. Lee[3];
[1]Kyungpook National University Hospital, [2]Department of Internal Medicine, Daegu Fatima Hospital, Daegu, [3]Department of Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea.

Background and aims: Hepatic gluconeogenesis is delicately controlled by fasting and feeding. In fasting or diabetes, for example, gluconeogenic genes are transcriptionally activated by upregulation of cAMP-PKA-CREB signaling pathway. Pyruvate dehydrogenase (PDC), a gatekeeper determining the fate of pyruvate by catalyzing it into acetyl CoA, becomes inactivate when phosphorylated by pyruvate dehydrogenase kinase (PDK). It was previously known that inhibition of PDK4 in the muscle increases pyruvate oxidation thereby limit availability of substrate utilized for gluconeogenesis in the liver. However, the role of PDK4 in the liver is less studied.
Materials and methods: Mice were treated with either adenovirus carrying PDK4 or GFP intravenously, and their pyruvate tolerance and mRNA expression of gluconeogenic genes were examined. PDK inhibitor dichloroacetate was treated to evaluate the pharmacologic effect on hepatic gluconeogenesis. After hepatic PDK4 was knocked down by injecting adenovirus carrying shPDK4, hepatic glucose production was examined by pyruvate tolerance test and gluconeogenic gene expression was evaluated by qPCR.
Results: PDK4 overexpression in the liver was sufficient to upregulate PEPCK, G6Pase mRNA expression and increase blood glucose levels as well as hepatic glucose production in normal mice via augmenting PKA-CREB signaling pathway, whereas knockdown of hepatic PDK4 by adenoviral shPDK4 infection in diet-induced obesity mice decreased blood glucose level and hepatic glucose production. Mice treated with PDK inhibitor dichloroacetate in the long-term also exhibited attenuated gluconeogenic gene expression and gluconeogenesis, thus their blood glucose levels became normalized.
Conclusion: Collectively, we propose the novel and critical role of hepatic PDK4 which inhibits gluconeogenesis by counteracting glucagon signals. This finding strengthens the possibility of PDK4 as an ideal target against diabetes where glucagon signaling is pathologically stimulated.

The impact of a meal with high fructose content on glycaemic control and hepatic gluconeogenesis

C. Barosa[1], R. Ribeiro[2,3], R. Andrade[3], J.G. Jones[1,3], J. Raposo[3];
[1]Center for Neurosciences and Cell Biology, UC-Biotech, Cantanhede, [2]CEDOC-NMS|FCM Chronic Diseases Research Center, Faculty of Medical Sciences of Lisbon, Nova Medical School, Lisboa, [3]Associação Protetora dos Diabéticos de Portugal, Lisboa, Portugal.

Background and aims: Over the past 3 decades there has been a massive increase in the intake of high-fructose corn syrup (HCFS) in Western countries. HFCS, which consists of 55% fructose and 45% glucose, is implicated in the surge of glucose intolerance, insulin resistance, Type 2 Diabetes and fatty liver disease over the same period. Paradoxically, fructose per se is traditionally regarded as being beneficial for diabetic subjects, since it is described as having a low glycemic index. Our objective was to characterize the kinetics metabolic profile of glycemic control in healthy subjects following ingestion of a meal containing 50 grams of fructose and glucose in proportion to that of HFCS (55% fructose/45% glucose- HF) and compare to ingestion of a load with catalytic levels of fructose (5% fructose/95% glucose- LF) - which has previously been shown to have beneficial effects on glycemic control and glucose disposal in diabetic subjects.
Materials and methods: Seven overnight fasted subjects were given a meal consisting of 50 g 55% fructose/45% glucose and powdered whey protein dissolved in 330 ml water having ingested ^2H_2O to 0.3% body water 2 hr before the meal. 0.5g Paracetamol was ingested 1 hr before and

1 hr after the meal. Plasma glucose was sampled periodically with a glucometer and a 30 ml sample was collected at 180 min post-load for analysis of ^{2}H enrichment by ^{2}H NMR. Urine was also sampled from 120-240 min for paracetamol glucuronide (PG) and body water enrichments. Four of the subjects repeated the study with 50 g 5% fructose/95% glucose. The contribution of glucose absorption and gluconeogenesis to plasma glucose levels was estimated from the enrichment of glucose hydrogen 5 relative to body water (H5/BW). The contributions of direct and indirect pathways of hepatic glycogen synthesis were determined from PG H5/BW.

Results: Glycemic excursions were identical for HF and LF loads. However, H5/BW was significantly higher for HF compared to LF (0.51±0.03 vs. 0.29±0.01) translating to a significantly higher fractional contribution of gluconeogenesis to plasma glucose levels (51±3% vs. 29 ±3%). In addition, HF had a tendency for higher indirect pathway contributions to glycogen synthesis compared to LF (56±3% vs. 44±3%).

Conclusion: High-fructose sugar formulations presents the liver with both fructose and glucose with the conversion of fructose to gluconeogenic precursors being relatively uncontrolled. Our data indicate that plasma glucose excursions have a higher gluconeogenic component following ingestion of a carbohydrate load with fructose/glucose proportions resembling HFCS. Nevertheless, glycemic control is maintained by healthy subjects presumably through hepatic autoregulation.

Glucose tolerance in adolescents with obesity

A.A. Chylińska-Frątczak;
Departament of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Łódź, Poland.

Background and aims: Prevalence of obesity in children and adolescents is growing and currently affects about 20% of the world population. Childhood obesity is associated with glucose intolerance. dyslipidemia and hypertension. The aim of the study was to assess the glucose metabolism in the adolescents with obesity.

Materials and methods: 151 patients with obesity aged 9-18 years. BMI>95pc. without any additional diseases and drugs affecting metabolic parameters were included in the study. Height. body weight. waist circumference. BMI were measured; pubertal maturity to Tanner stage criteria were assessed. HbA1c were measured and 2-hours OGTT (glucose and insulin) was performed in all children. Insulin resistance was determined by HOMA-IR. In the second stage of the study. in 46 adolescents 4-hours OGTT and Mixed Meal Tolerance Test (glucose and insulin) were performed and continuous glucose monitoring system CGM (iPro-Medtronic) were submitted to 5-6 days.

Results: Among 151 patients (66 girls. 85 boys. at the age of 13.5 ±1; 2.5 years) BMI 30 ±4.5kg/m^{2}. BMI z-score 2.1 ± 0.3. waist circumference 96.4 ±10.6cm. 13.2% (20 children) was in the prepubertal period. Based on OGTT impaired fasting glucose was found in 4 patients (2.6%), glucose intolerance in 25 patients (16.5%) and diabetes in 2 patients (1.3%). HbA1c was 5.3 ±0.3%. HOMA-IR was 3.8 ± 2.1. In 53 children (35.1%) insulin resistance was found. A positive correlation (R = 0.25; p = 0.0025) between HOMA-IR and BMI z-score was observed. Hyperinsulinemia was present in 103 patients (68.2%). Comparing 4-hours OGTT and MMTT lower glycemic values were observed at all time points after consuming a standardized meal than in the OGTT. However the mean value of insulin was statistically higher in 15 and 30 minute of the test in MMTT than in OGTT. In CGM the mean glycemic value was 101.3 mg/dl. 98.64% of glucose readings were in the range of 70-140 mg/dl. Only 0.91% of the readings were above 140 mg/dl and 0.45% of readings were below 70mg/dl. The mean glycaemia value at night was 95.9 mg/dl. A positive correlation (R = 0.36; p = 0.013) between HOMA-IR and mean of nighttime glycaemia was observed.

Conclusion: With the rise in obesity insulin resistance increases, which leads to higher glycaemia at night. Mixed meal stimulates higher insulin secretion than glucose in the first 30 minutes after ingestion.

Impact of dietary carbohydrate composition on metabolic benefits of low protein-high carbohydrate diets

J.A. Wali[1,2], T. Pulpitel[1], M. Kabede[1], T. Dodgson[1], G. Pinget[1], B. Yau[1], D. Wahl[1], S.M. Solon-Biet[1], G.J. Cooney[1], V.C. Cogger[1], D.G. Le Couteur[1,2], S.J. Simpson[1];
[1]Charles Perkins Centre, University of Sydney, [2]Ageing and Alzheimer's Institute, New South Wales Health, Sydney, Australia.

Background and aims: Nutrition is the major modifiable factor that influences health and lifespan, but the relationship is complex and poorly understood. Recent research using Geometric Framework (GF), a state-space nutritional modelling method, showed that 'low protein-high carbohydrate' (LPHC) diets generate the best cardio-metabolic health and lifespan outcomes (Solon-Biet 2014). This seems at odds with advice to reduce intake of simple carbohydrates because there is evidence that they promote metabolic disease. However, the discrepancy may relate to the fact that the LPHC diets used starch derived *complex* carbohydrates. Therefore, we aimed to evaluate which *types* of carbohydrate contribute to the benefits of LPHC diets.

Materials and methods: Male C57BL/6 mice (n=300; 8 wk old) were fed ad libitum one of 15 isocaloric LPHC diets composed of differing percentages of low protein (5, 10 and 15%) and high carbohydrate (75, 70 and 65%), while the fat was fixed at 20%. Diets were further factored by systematically changing the sucrose-starch ratios (20/80, 35/65, 50/50, 65/35, 80/20) in their carbohydrate component. This feeding array allows examination of the impact of each individual food component (protein, sucrose and starch) and their interactions using GF methodology. Food intake and body weights were monitored fortnightly, parameters of metabolic health were assessed after 5-6 and 13-14 wks, and tissues were harvested after 18 wks on diets. For data analysis by GF, means/mouse/cage or data/mouse were used (as appropriate), using thin-plate spline procedures in R, constructed upon nutrient axes for sucrose, starch and protein across diet composition and nutrient intake spaces.

Results: GF analysis showed that mouse weights were markedly affected by protein intake and peaked on a combination of increased protein-high starch consumption. In contrast, energy intake increased on lower protein-high starch diets and declined with an increase in dietary protein and sucrose content. Water intake was negatively regulated by dietary protein and increased with sucrose ingestion. Glucose tolerance and insulin concentrations were adversely affected by protein intake, but surprisingly, moderate sucrose intake did not impair glucose homeostasis, while extreme consumption paradoxically improved insulin sensitivity due at least in part to decreased food intake on very high sucrose diets. Consistently, adiposity increased with protein and starch intake, but high sucrose consumption reduced body fat and consequently led to increased % lean mass. On the contrary, liver fat was maximum on low protein diets with no effect of sucrose intake. Circulating concentrations of triglyceride and urea increased with protein consumption but increased sucrose intake did not induce hypertriglyceridemia or hyperuremia. Similarly, weights of liver, kidney and pancreas and glucose stimulated insulin secretion from the islets increased with protein intake, but the source of dietary carbohydrate did not have remarkable effects on these measurements.

Conclusion: Our work suggests that in the context of LPHC diets, protein intake is the major determinant of the metabolic phenotype, while compared to starch, very high sucrose intake paradoxically improves parameters of metabolic health in this setting.

Modelling postprandial absorption of complex carbohydrates

M. Schiavon[1], C. Dalla Man[1], R.E. Carter[2], L. Hinshaw[2], M. Slama[2], M. Persson[2], R. Basu[2], A. Basu[2], C. Cobelli[1];
[1]University of Padova, Padova, Italy, [2]Mayo Clinic, Rochester, USA.

Background and aims: We have previously developed a novel isotope dilution method to estimate complex carbohydrate metabolism in humans that exploits the natural abundance of ^{13}C contained within the ingested polysaccharide (PS). With this technique, it is possible to estimate the systemic appearance of meal carbohydrates (Ra_{meal}), a surrogate for rate of carbohydrate absorption. The aim of this analysis was: 1) to assess the reproducibility of the method, 2) to model the dynamics of complex carbohydrates vs. simple carbohydrates absorption.
Materials and methods: Sixteen healthy subjects (9M, age, 33±2 y, BMI 23±1 kg/m^2; mean±SE) were randomized into two matched groups. Each subject was studied at a Clinical Research Trials Unit on three occasions in random order: once with simple carbohydrates (glucose; G) as Jell-O (labeled with [^{13}C]glucose), and twice (to assess reproducibility) with [^{13}C]PS containing mixed meals, with either sorghum (S) or rice (R) as the complex carbohydrate. All meals had ~50g carbohydrates and similar macronutrient composition amounting to a 600 calorie mixed meal. In addition, [6-^3H]glucose was infused for 360 min to enable model independent estimation of Ra_{meal}. The model of glucose absorption assumes that the stomach is described by two compartments, representing the solid and the liquid phase, while the gut is described by one compartment. In addition the grinding rate of the stomach and the absorption rate from the gut are assumed to be constant, while gastric emptying depends on the total amount of carbohydrates in the stomach. The model estimates the amount of carbohydrates in the stomach and thus the gastric retention (GR) as percentage of the ingested carbohydrates. The time when GR reaches 50% ($T_{50\%}$) and the GR at t=60 min (GR_{60min}) were calculated. Reproducibility of the results was assessed using intra-class correlation (ICC) analyses. ICC>0.9 was considered to be a robust representation of reproducibility. Differences among model parameters were assessed with the Wilcoxon signed rank test ($p<0.05$ was considered statistically significant).
Results: Data suggests that rice is more reproducible than sorghum for iAUC of Ra_{meal}: ICC^R=0.93 (95% CI: 0.66-0.99) vs ICC^S=0.66 (95% CI: 0.66-0.87). Average GR profiles are reported in Figure 1. $T_{50\%}$ and GR_{60min} were both significantly higher in R and S than in G: $T_{50\%}{}^R$=122±13 min (visit 2: 108±7 min) vs. $T_{50\%}{}^G$=42±10 min (p=0.0156); $T_{50\%}{}^S$=118±7 min (visit 2: 110±7 min) vs. $T_{50\%}{}^G$=43±7 min (p=0.0156); $GR_{60min}{}^R$=72±4% (visit 2: 71±3%) vs. $GR_{60min}{}^G$=39±7% (p=0.0156); $GR_{60min}{}^S$=76±2% (visit 2: 70±3%) vs. $GR_{60min}{}^G$=41±4% (p=0.0156). Finally, the model does not highlight any difference in gut absorption.
Conclusion: Rice provided more reproducible results for Ra_{meal} than sorghum and is thus more suitable for in future clinical research studies on PS metabolism. The higher GR estimated with complex vs. simple carbohydrates is likely responsible for the delayed Ra_{meal}.

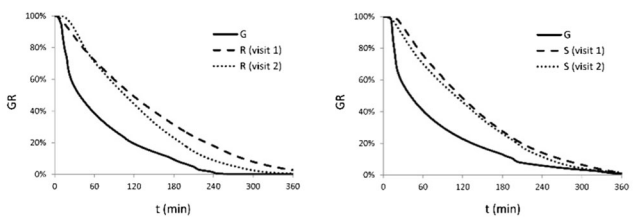

Figure 1: Left panel: Gastric Retention (GR) as percentage of the ingested dose for G (solid) and R (visit 1, dashed) and R (visit 2, dotted line). Right panel: Gastric Retention (GR) as percentage of the ingested dose for G (solid) and S (visit 1, dashed) and S (visit 2, dotted line).

Toxicological impact of high fructose intake on gut microbiota and liver/intestine integrity: Any differences between solid and liquid formulations?

R. Mastrocola[1], A.S. Cento[1], F. Chiazza[2], I. Ferrocino[3], V. Bitonto[4], D. Nigro[1], G. Querio[2], K. Rantsiou[3], J.C. Cutrin[4], M. Aragno[1], E. Liberto[2], E. Masini[5], C. Cordero[2], L. Cocolin[3], M. Collino[2];
[1]Clinical and Biological Sciences, University of Turin, [2]Drug Science and Technology, University of Turin, [3]Agricultural, Forest and Food Sciences, University of Turin, [4]Molecular Biotechnology and Health Sciences, University of Turin, Turin, [5]Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy.

Background and aims: We previously demonstrated the deleterious effects of fructose feeding on liver through production of advanced glycation end products (AGEs) and the induction of hepatic steatosis and inflammation. Moreover, it has been reported that high fructose intake alters microbiota composition, resulting in reduced bacterial diversity and altered expression of genes involved in specific metabolic pathways. A recent paper demonstrated that liquid high-sugar compared to solid high-sugar diets differentially modulate intestinal sugar transporters and hormone expression. To date, however, the peculiar effects of fructose intake in different forms, liquid or solid, on intestinal integrity and microbiota, and hepatic outcomes, have never been investigated.
Materials and methods: For this aim, C57 mice were fed a standard diet (SD) plus water to drink, a standard diet plus 60% fructose syrup (L-Fr), or a 60% fructose solid diet plus water (S-Fr), for 12 weeks. At the end of protocol, analysis on liver lipogenesis, fibrosis, and inflammation and on intestinal absorption, AGEs accumulation, and integrity were performed by western blotting, biochemical and histological analysis. Gut microbiota population has been characterized by metagenomic sequencing.
Results: L-Fr intake induced higher levels of hepatosteatosis (liver TG: +80% vs. SD, +33% vs. S-Fr, $p<0.05$), with greater activation of the lipogenic SCAP/SREBP signaling, and of markers of fibrosis, than the S-Fr. In contrast, S-Fr evoked a stronger local AGEs accumulation, RAGE expression, and barrier injury in the ileum intestinal mucosa, leading to higher concentration of LPS in the portal plasma (+300% vs. SD, +210% vs. L-Fr, $p<0.05$). This effect was associated to a stronger activation of the LPS-dependent pro-inflammatory pathway NLRP3 inflammasome in the liver of S-Fr mice than of L-Fr mice. Interestingly, the local accumulation of fructose in the intestine led to alterations of the gut microbiota composition depending on the fructose formulation, with increase in the saccharides metabolizing *Lactobacillus* genus in the L-Fr, and increased colonization by populations related to intestinal inflammation and barrier disruption, such as *Clostridium*, in the S-Fr group.
Conclusion: These results suggest that consumption of fructose under different forms, liquid or solid, has a different impact on intestinal mucosa, thus differently affecting liver homeostasis. We hypothesize that the liquid fructose is more rapidly absorbed by intestine and metabolized by the liver to produce considerable amounts of lipids. In contrast, the solid form might be slowly absorbed by enterocytes producing glycated proteins and affecting barrier integrity, with developing of systemic inflammation. Such alterations of intestinal integrity and microbial population, also found in diabetic and obese individuals, might predispose to the development of chronic metabolic and inflammatory diseases.

Metabolic profile of the women after gestational diabetes

M. Zurawska-Klis, M. Kosinski, K. Cypryk;

Department of Diabetology and Metabolic Diseases, Medical University of Lodz, Lodz, Poland.

Background and aims: The data from the many studies indicate that GDM is associated with an increased risk of metabolic disorders in later life. The aim of our study was to evaluate the incidence of metabolic disturbances after GDM and to analyze their determinants.
Materials and methods: 144 women with GDM treated in Outpatient Department of Diabetes in Lodz between 2013 and 2016 were initially included in the study. Patients were examined toward metabolic disturbances at 3 and 18 months after delivery. Anthropometric data including BMI, waist and hips circumference, suprailiac, subscapula and biceps skinfolds were analyzed. Body composition was examined with the use of *Tanita* analyzer. Glucose and insulin concentrations in oral glucose tolerance test (OGTT) were evaluated, and the indices of insulin resistance and beta cell function were calculated based on HOMA2 IR, HOMA2 %S, HOMA2 B and QUICKI methods. Haemoglobin A_{1c}, C-reactive protein (CRP), total, LDL and HDL cholesterol and triglycerides concentrations were also measured.
Results: 95 and 68 women attended follow-up visit at 3 and 18 months after delivery, respectively. Normal OGTT result was shown in 82 and 46 women, impaired fasting glucose (IFG) was detected in 6 and 15 patients, impaired glucose tolerance (IGT) in 9 and 5 patients, and diabetes mellitus (DM) was diagnosed in 1 and 1 subjects after 3 and 18 months postpartum, respectively. 3 months after delivery, in a group of healthy women, compared to a group with any glucose disturbances (IFG and/or IGT or DM), significantly lower waist and hip circumference, thinner biceps, suprailiac and subscapula skinfold, as well as lower body weight (all $p < 0.001$), BMI ($p < 0.01$), fat percent ($p < 0.05$), visceral fat ($p < 0.01$) and index of obesity ($p< 0.001$) were noted. Lower CRP ($p < 0.05$) and triglycerides concentration ($p < 0.01$), as well as lower HOMA2 IR ($p < 0.01$), higher HOMA2% S ($p < 0.01$) and higher QUICKI ($p < 0.05$) were also observed in this group. Other parameters did not differ significantly between the groups ($p > 0.05$). 18 months after delivery, in a group of healthy subjects, compared to a group with abnormal OGTT results, significantly lower waist circumference ($p < 0.05$) and fat percent ($p < 0.005$) were shown. Other parameters did not differ significantly between the groups. A significant correlation between the presence of any disturbances in OGTT and waist circumference ($r = 0.266$, $p < 0.05$) and fat percent ($r = 0.293$, $p < 0.05$) was noted.
Conclusion: In the women after GDM less favorable metabolic profile and higher CRP concentration are connected with persistent carbohydrate disturbances shortly after delivery. 18 months postpartum however, most of the differences in the metabolic profile between the studied groups disappeared, and the metabolic disturbances that persisted postpartum in a longer perspective correlated with waist circumferenceand the fat percent only.

Leptin therapy alters the hepatic transcriptome, the proteome, and the metabolome to suppress amino acid utilisation in diabetic rodents
M.M. Kwon[1], A. McAfee[2], J.N.C. Toews[1], R.K. Baker[1], L.J. Foster[2], T.J. Kieffer[1];
[1]Department of Cellular and Physiological Sciences, University of British Columbia, [2]Department of Biochemistry and Molecular Biology, University of British Columbia, Vancouver, Canada.

Background and aims: Leptin lowers blood glucose levels in diabetic rodents and the typically observed hypoglycemia with fasting suggests suppressed glucose production may be the mechanism. Since the liver is a major site for glucose production, we used an un-biased multi-omics approach to characterize leptin-induced changes in liver.
Materials and methods: We administered leptin or vehicle by pumps to streptozotocin (STZ)-diabetic mice and collected the liver on day 4 for transcriptomics analysis by RNA-sequencing, and proteomics and metabolomics analysis by mass spectrometry. Enrichment analysis independently pointed towards suppressed utilization of amino acids. Thus, we examined amino acid utilization in leptin-treated STZ-mice and non-diabetic controls by performing alanine tolerance tests and pyruvate tolerance tests as a comparison. To further assess the role of suppressed alanine metabolism, we overexpressed the gene responsible for alanine catabolism, glutamic pyruvate transaminase (*Gpt*), in the liver of STZ-diabetic mice by hydrodynamic gene delivery then tested the efficacy of leptin therapy on day 4 post plasmid injection.
Results: Leptin treatment downregulated 993 genes in the liver, including genes involved in amino acid catabolism. Proteomics similarly revealed that proteins involved in amino acid catabolism were downregulated. Metabolites involved in protein biosynthesis and amino acid metabolism were upregulated, suggesting a global build up of amino acids in the liver of leptin-treated STZ-mice. To assess amino acid utilization, STZ-mice were treated with leptin, which normalized blood glucose levels (22.1 ±0.5 vs 6.7±0.7 mM day -1 and day 3), then STZ-leptin and non-diabetic groups were fasted to the point of mild hypoglycemia and injected with alanine or pyruvate on day 4. Alanine did not increase blood glucose levels in leptin-treated STZ-mice (6.0±0.5 vs 6.4±0.4 mM at 0 and 30 minutes), and hypoglycemia worsened (3.9±0.6 mM at 90 minutes). In contrast, pyruvate increased blood glucose levels in leptin-treated STZ-mice (6.5±0.5 vs 9.9±1.8 mM at 0 and 30 minutes). In non-diabetic controls with mild hypoglycemia, blood glucose levels were increased with both alanine (4.7±0.1 vs 6.9±0.4 mM at 0 and 30 minutes) and pyruvate (4.5±0.2 vs 11.1±0.3 mM at 0 and 30 minutes). *Gpt* transcript levels were downregulated by ~2 fold in leptin-treated STZ-mice compared to diabetic controls on day 4 ($p<0.0001$). Administration of plasmid encoding *Gpt* to STZ-mice for overexpression of GPT in the liver did not alter blood glucose (24.1±0.7 vs 24.3±0.7 mM on day 3). Leptin similarly lowered blood glucose levels in mice with hepatic *Gpt* overexpression (10.6±2.5 mM) and controls (9.0±1.1 mM) by day 5 post leptin therapy.
Conclusion: Leptin alters the hepatic transcriptome, the proteome, and the metabolome, to suppress amino acid catabolism. Leptin-treated STZ-mice cannot utilize alanine to produce glucose but their ability to utilize pyruvate, a product of alanine breakdown, remains intact. Overexpression of *Gpt* is insufficient to block leptin action, suggesting that leptin-induced downregulation of *Gpt* alone does not drive the anti-diabetic actions of leptin.

ERO1Lβ is a key regulator of the endoplasmic reticulum stress resolution in pancreatic beta cells
D. Amadio, C. Ämmälä, F. Chimienti;
Bioscience Diabetes, Cardiovascular and Metabolic Diseases, Innovative Medicines and Early Developm, AstraZeneca, Mölndal, Sweden.

Background and aims: Type 2 diabetes (T2D) is characterized by pancreatic beta-cell failure that lead to uncontrolled glucose homeostasis. A relevant contribution to beta-cell loss in type 2 diabetes is endoplasmic reticulum (ER) stress induced by accumulation of misfolded proteins. The unfolded protein response (UPR) is an adaptive response inducing attenuation of protein translation and degradation of misfolded protein in order to alleviate ER stress and prevent beta-cell death. ERO1LB, a disulfide oxidoreductase whose expression is highly enriched in the ER of pancreatic beta-cells, contributes to correct disulfide bonds formation and proper insulin folding. Here we investigated the capacity of ERO1LB to protect against palmitate-induced ER stress and its ability to rescue proper beta-cell function. Furthermore, we aimed to characterize the role of ERO1LB in the UPR signaling pathway response to understand the potential as a therapeutic target for the treatment of T2D.

Materials and methods: To simulate the acute and chronic effect of ER-stress in beta-cells, we examined short (2 days) and longterm (7 days) effects of palmitate-induced ER stress on ERO1LB expression and compared it to classical inducers of ER stress. We further characterized the beta-cell response to a glucose challenge (GSIS) after short and long palmitate exposure, and correlated these results with the activation of UPR, monitored by RT-qPCR, Western Blot and ImmunoFluorescence analysis. Folding capacity assays and measurements of ER Ca^{2+} levels were used to gain insight into the functional and mechanicistic role of ERO1LB protein in a mouse beta-cell line (MIN6). By using overexpression approaches we investigate the ability of ERO1LB to alleviate beta-cells from ER stress induced by glucolipotoxicity condition.
Results: We show that beta cells exposed to chronic lipotoxicity, a condition often present in obese T2D patients with chronically elevated circulating fatty acid levels, induces ER-stress and activates strong UPR response. In our ER stress model we observed a significant increased proinsulin/insulin ratio only after longterm palmitate treatment, as well as activation of the three different arms of the UPR response in a time-dependent manner (PERK, then ATF6 and IRE1α). Decreased ER Ca^{2+} levels and protein folding capacity were also observed in presence of palmitate. ERO1LB is upregulated by short palmitate exposure whereas long palmitate treatment induces a decrease in ERO1LB levels, similar to what has been observed in islets from T2D. Overexpression of ERO1LB in MIN6 cells alleviated the induction of ER stress, and restored appropriate proinsulin folding. This suggests ERO1LB is important for maintaining a sustained insulin folding capacity.
Conclusion: Our data showes that ERO1LB is able to prevent lipotoxicity induced ER-stress by interfering with UPR activation, and suggest that ERO1LB has the ability to rescue beta-cell from ER stress induced loss of function. These findings confirm an important role for ERO1LB in maintaining proper insulin folding and beta-cell function. Thus, ERO1LB is a potential candidate target for novel treatments for T2D.

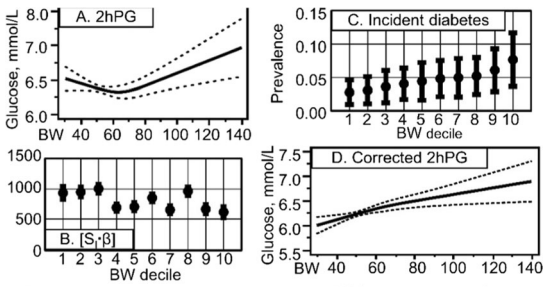
Critical assessment of postchallenge hyperglycaemia in subjects with low body weight

T. Sakuma[1], K. Yamashita[2], M. Shimodaira[3], K. Hirabayashi[2], H. Koike[2], T. Shimbo[4], T. Aizawa[2];
[1]Ina Central Hospital, Ina, [2]Aizawa Hospital, Matsumoto, [3]Iida Municipal Hospital, Iida, [4]Ohta Nishinouchi Hospital, Fukushima, Japan.

Background and aims: Post-challenge hyperglycaemia (PCH) in the 75-g OGTT due to low glucose volume (G_V) is theoretically possible in subjects with low body weight (LBW) because G_V is a function of BW. The present study aimed to critically evaluate this issue.
Materials and methods: Data from 11,411 non-diabetic subjects (Matsumoto cohort; male-to-female ratio, 7,077:4,334; mean age, 52.6 years; BW, 63.3 kg) were analysed. Among these subjects, 5,282 were followed up for a mean of 5.3 years. All participants underwent a standard 75-g OGTT and HbA1c evaluation, and glucose tolerance was determined using the ADA definition. In an independent group of non-diabetic subjects (Iida cohort; n = 1,537; male-to-female ratio, 950:587; mean age, 52.8 years; BW, 62.7 kg), insulin sensitivity (S_I, 1/HOMA-IR), β (Stumvoll 1st phase), and the index of whole body insulin action (a product of the two variables) were determined. Considering BW or BW decile as an explanatory variable, multiple correlation analysis, analysis of covariance, or logistic regression analysis was performed with adjustment for age, sex, and percentage body fat. The possible non-linear effect of BW was evaluated using cubic spline fitting. In subjects with BW ≤ 59 kg, correction of 2-h plasma glucose (2hPG) in proportion to reduced estimated extracellular water (ECW, a surrogate of G_V) was attempted, i.e., $2hPG_{corr}$ = fasting plasma glucose (FPG) + (ECF/16.1 [males] or 15.1 [females]) · δPG_{2h}. ECF denotes the estimated ECW in a given individual, and 16.1 and 15.1 were ECF values of males and females, respectively, with BW of 59 kg.
Results: BW, across the entire range, was positively correlated with FPG ($p < 0.01$). In contrast, BW was correlated in a skewed J-shape fashion with all post-challenge glucose values, such as 1hPG, 2hPG (Panel A), δPG_{1h}, and δPG_{2h}, with inflections at around 60 kg (p for non-linearity <0.01, for each). The prevalence of impaired glucose tolerance (IGT) as a function of BW was also J-shaped. S_I significantly increased as BW decreased (p for trend <0.01), and there was no significant BW-related trend for β. As a result, insulin action ($S_I \cdot \beta$) tended to be high with LBW (Panel B, p for trend = 0.09). On follow-up, diabetes developed less frequently in subjects with LBW (Panel C). Analysis in IGT subgroup showed essentially the same results. Correcting 2hPG mitigated the J-shape correlation between BW and 2hPG (Panel D).
Conclusion: PCH against BW showed a J-shape distribution. However, insulin action was not impaired in subjects with increased prevalence of PCH at the lower end of BW. Of note, despite a high prevalence of PCH, the future development of diabetes was less frequent in LBW subjects than in their heavier counterparts. Correcting 2hPG on the basis of the estimated ECW mitigated the J-shape for 2hPG. PCH, especially IGT, in subjects with BW ≤ 59 kg may be, in part, due to reduced G_V rather than impaired glucose metabolism.



Panels A, B and D, estimated means and 95%CIs at the mean of covariates;Panel C, mean and SD of p obtained by logistic regression.

The lipid peroxidation by-product 4-hydroxy-2-hexenal impairs insulin sensitivity in skeletal muscle

L. Sardón Puig[1], C.O. Soulage[2], M. Guichardant[2], M. Lagarde[2], N.J. Pillon[1]; [1]Karolinska Institutet, Stockholm, Sweden, [2]Univ Lyon, INSA-Lyon, INSERM UMR 1060, INRA UMR 1397, CarMeN, Villeurbanne, France.

Background and aims: Oxidative stress is involved in the pathophysiology of many chronic diseases and in particular contributes to the development of insulin resistance and its progression towards type 2 diabetes. The peroxidation of cell membrane phospholipids associated with oxidative stress produces deleterious reactive species, including hydroxy-alkenals. Peroxidation of omega-6 polyunsaturated fatty acids leads to the production of 4-hydroxy-2-nonenal (4-HNE), while 4-hydroxy-2-hexenal (4-HHE) is generated during the oxidation of omega-3 polyunsaturated fatty acids. These lipid aldehydes exhibit potent electrophilic properties making them able to make covalent adducts with amino phospholipids such as phosphatidylethanolamine, proteins and nucleotides. Because of their relative stability and high reactivity, these aldehydes are thought to interfere with crucial physiological processes such as cell cycle, apoptosis or metabolic pathways. Only a handful of studies have shown activation of stress signalling pathways by 4-HHE, but the data about its pathophysiological effects remains scarce. Especially, the putative role of 4-HHE in the development of insulin resistance has not been investigated. The aim of the present study was to investigate the effect of 4-HHE in the development of insulin resistance.
Materials and methods: 4-HHE concentration was measured in plasma from humans and rats by GC-MS. Insulin resistance was estimated in healthy rats using hyperinsulinemic euglycemic clamps. In L6 muscle cells and 3T3 adipocytes, glucose uptake was measured using 2-deoxy-D-glucose and signalling pathways by western blotting. Intracellular glutathione was measured using fluorimetric assay kit and boosted using 3H-1,2-dithiole-3-thione (D3T).
Results: In T2D subjects, plasma 4-HHE was twice the level of healthy volunteers. Circulating levels of 4-HHE were elevated in Zucker Fatty diabetic rats. During hyperinsulinemic euglycemic clamps in rats, acute intravenous injection of 4-HHE significantly altered whole body insulin sensitivity and decreased glucose infusion rate. In vitro, 4-HHE impaired insulin-stimulated glucose uptake and signaling (PKB/Akt and IRS1) in L6 muscle cells. 4-HHE induced carbonylation of cell proteins and reduced glutathione concentration. Increasing intracellular glutathione pools using D3T prevented 4-HHE-induced carbonyl stress and insulin resistance.
Conclusion: These results demonstrate that 4-HHE is produced under diabetic conditions and blunts insulin action. 4-HHE may therefore play a causal role in the pathophysiology of T2D and lipid peroxidation might constitute a potential therapeutic target to taper oxidative stress-induced insulin resistance.

Association of circulating betatrophin levels with insulin resistance in polycystic ovary syndrome: cross-sectional and interventional studies

M. Yang[1], L. Li[1], G. Yang[2]; [1]Key Laboratory of Diagnostic Medicine of Ministry of Education, School of Laboratory Medicine, Chongqing Medical University, Chongqing, [2]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China.

Background and aims: Betatrophinis a secreted protein of 198 amino acids that is highly conserved in all mammalian species. Polycystic ovary syndrome (PCOS) is characterized by heterogeneity in phenotypic manifestations mainly related to reproductive and hormone aberrations and metabolic disturbances. IR is the most significant and highly prevalent parameter among PCOS women, while IR is associated with T2DM and obesity. Recent studies have demonstrated the relationship between betatrophin and insulin resistance (IR) inT2DM, but the reports were inconsistent. Furthermore, the physiological role of betatrophin remains poorly understood. The aim of this study was to investigate the association of betatrophin with IR in PCOS women and explore the physiological role of betatrophin*in vivo* and *in vitro*.
Materials and methods: Plasma betatrophin levels were measured with ELISA. Insulin sensitivity was assessed with EHC. Gene expressions at mRNA and protein levels were determined with qRT-PCR and Western blotting. Influences of insulin, metformin, rosiglitazone and over- or knockdown-expression of betatrophin were analyzed ex vivo.
Results: PCOS women had higher betatrophin levels compared with the controls ($P<0.01$). Circulating betatrophin was positively correlated with BMI, WHR, TG, TC, LDL-C, AUC glucose, AUC insulin, LH, FAI and HOMA-IR but negatively with M-value. Metformin treatment in newly diagnosed PCOS women led to a reduction of betatrophin levels. Insulin stimulation in hepatocytes increased betatrophin expression, but not promoted its secretion. Metformin or rosiglitazone led to a reduction of betatrophin expression in insulin-stimulated hepatocytes. In hepatocytes/macrophages co-culture systems, betatrophin expressions were significantly increased, whereas this increase was eliminated by rosiglitazone. In hepatocytes, overexpression and knockdown of betatrophin decreased and increased insulin-stimulated InsR, AKT and IRS-1 phosphorylation respectively. Serum from metformin-treated PCOS women decreased betatrophin expression and reinforced insulin signals.
Conclusion: The present study provide the first evidence indicating a significant increase of circulating betatrophin in untreated PCOS patients and different effects of elevated insulin on betatrophin*in vivo* or *in vitro*. We also present novel data suggesting that metformin or rosiglitazone treatment, possibly *via* a direct effect and/or an indirect effect of improved insulin sensitivity, decreases circulating levels and expression of betatrophin *in vivo* or *in vitro*. In addition, over-expression and knockdown of betatrophin impair and improve insulin signaling in hepatocytes, respectively. Finally, serum from metformin-treated PCOS women decreases betatrophin expression and reinforces insulin signal transduction in hepatocytes. Therefore, betatrophin is a useful marker of IR in PCOS.

Insulin resistance in hepatitis C virus infection: relative contribution from liver vs extrahepatic sites

D. Gomes[1], G. Gastaldi[2], P. Schneiter[3], L. Tappy[3], S. Clément[4], F. Negro[5];

[1]Pathology and Immunology, University Hospital of Geneva, [2]Division of Endocrinology, University Hospital of Geneva, Geneva, [3]Physiology, University of Lausanne, Lausanne, [4]Clinical Pathology, University Hospital of Geneva, Geneva, [5]Division of Gastroenterology and Hepatology, University Hospital of Geneva, Geneva, Switzerland.

Background and aims: Chronic hepatitis C (CHC) has been associated with the development of metabolic disorders, such as insulin resistance (IR). Albeit hepatitis C virus (HCV) infects only hepatocytes, peripheral IR is also observed in HCV infected patients. In the present study, we are interested to (1) identify the putative liver-derived inducers of IR in extrahepatic tissues (i.e. muscle and adipose tissue), and (2) elucidate the underlying molecular mechanisms.
Materials and methods: CHC genotype 3a patients were treated with an interferon-free regimen (ledipasvir/sofosbuvir combined with ribavirin). These patients underwent a 2-step euglycemic hyperinsulinemic clamp with tracers, together with indirect calorimetry measurement, to measure IR at start and after 6 weeks of antiviral therapy. Blood and adipose and muscle tissue biopsy samples were collected at the same time points. *In vitro*, human primary adipocytes were treated with the collected sera. Insulin signaling and lipid/glucose metabolism were investigated by immunoblot and RT-PCR. Insulin-stimulated glucose uptake was assessed by incubating cells with [1,2-3H(N)]-2-deoxy-D-glucose.
Results: As of today, 13 patients have been enrolled, and complete viral suppression was achieved in 10/10 who received 6 weeks of therapy. Clamp analyses have been completed in 6 patients: all exhibited a significant improvement of the peripheral insulin sensitivity (p=0.0004), whereas no difference was observed in insulin-mediated lipolysis suppression, as measured by non-esterified fatty acid levels. Treatment of adipocytes with sera from virally-suppressed patients increased the insulin ability to promote glucose uptake and to induce Akt phosphorylation compared to exposure to sera collected before treatment. No difference in the expression of lipid metabolism genes was observed.
Conclusion: Taken together, these data indicate that HCV clearance might result into an improved peripheral insulin sensitivity. Clarification of the role of skeletal muscle in the systemic IR, and identification of liver-derived circulating factors potentially involved in the regulation of peripheral insulin sensitivity (metabolome analysis) are underway.

Type 2 diabetes prevention through hormone sensitive lipase inhibition: elongase ELOVL6 at the center of attention

P. Morigny[1], M. Houssier[1], E. Mouisel[1], A. Mairal[1], S. Caspar-Bauguil[1], G. Tavernier[1], S. Virtue[2], H. Guillou[3], V. Stich[4], P. Arner[5], M. Rydén[5], A. Vidal-Puig[2], H. Vidal[6], C. Postic[7], D. Langin[1];
[1]Inserm UMR1048, Institut des Maladies Métaboliques et Cardiovasculaires, Toulouse, France, [2]Metabolic Research Laboratories, University of Cambridge, Cambridge, UK, [3]INRA, UMR 1331, TOXALIM, Toulouse, France, [4]Department of Sport Medicine, Third Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [5]Department of Medicine, Karolinska Institutet, Huddinge, Sweden, [6]CarMeN Laboratory, InsermU1060, INRA U1397, Université Lyon 1, INSA Lyon, Oullins, [7]CNRS UMR 8104, Institut Cochin, Paris, France.

Background and aims: Hormone sensitive lipase (HSL) is an enzyme expressed in adipose tissue where it hydrolyzes triglycerides into fatty acids. We previously demonstrated the protective effect of HSL inhibition on the development of insulin resistance in obese HSL haploinsufficient mice. However, the mechanisms involved in the improvement of insulin sensitivity were still unclear. In this study, we demonstrate the prominent role of adipocyte de novo lipogenesis (DNL i.e glucose-derived fatty acid synthesis) and of the Elongation of Very-Long-Chain Fatty Acids protein 6 (ELOVL6) in the beneficial effect induced by HSL inhibition.
Materials and methods: Human hMADS adipocytes (human multipotent adipose-derived stem cells) were used for in vitro studies. Murine models of HSL, elongase ELOVL6 and Carbohydrate Responsive Element Binding Protein (ChREBP) transcription factor deficiency were employed for in vivo studies. Human data were obtained from patients with differing obese and metabolic status and from morbidly obese subjects undergoing a bariatric surgery.
Results: Robust induction of DNL was observed in parallel with better activation of insulin signaling in human adipocytes with siRNA-induced HSL knockdown. A strong elevation of the expression and activity of elongase ELOVL6, one of the enzymes of DNL, was measured in vitro and in vivo during genetic and pharmacologic HSL inhibition. Increased ELOVL6 activity was responsible for a shift in fatty acid composition leading to an accumulation of the C18-fatty acid oleate in triglycerides and phospholipids. Concomitant knockdown of HSL and ELOVL6 reversed oleate accumulation and the improvement of insulin signaling observed in HSL-inhibited adipocytes. The beneficial effect of ELOVL6 was triggered by an increased oleate content in phospholipids and a higher plasma membrane fluidity. In human subcutaneous adipose tissue, ELOVL6 gene expression was reduced during insulin resistance and restored after a bariatric surgery-induced weight loss, showing a close association between ELOVL6 and insulin sensitivity. In vitro and in vivo, the DNL-transcriptional factor ChREBP exerts a strong and specific control on ELOVL6 expression. Dual HSL-ChREBP inhibition mirrored ELOVL6 deletion on fatty acid profile and insulin signaling.
Conclusion: In this study, we demontrate that HSL inhibition protects from insulin resistance. HSL inhibition promotes ChREBP activity and induces ELOVL6 which modulation of plasma membrane fatty acid composition and fluidity improves insulin signaling.

Effect of insulin on renal maximum glucose transport capacity in healthy volunteers and patients with type 2 diabetes

E. Muscelli[1], R. Pereira-Moreira[1], M. Seghieri[2], B.D. Astiarraga[2], A.L. Souza[1], V.B. Chueire[1], S. Monte Alegre[1], A. Solini[2], E. Ferrannini[3];
[1]Department of Internal Medicine, State University of Campinas, Campinas, Brazil, [2]Department of Clinical and Experimental Medicine, University of Pisa, [3]CNR Institute of Clinical Physiology, Pisa, Italy.

Background and aims: Most studies, though not all, indicate that the maximum glucose transport capacity of the proximal tubule (Tm_G) is increased in patients with type 2 diabetes (T2D). Furthermore, one old study from 1951 suggested that insulinization may reduce Tm_G. In contrast, in human embryonic kidney 293T cells insulin increases the activity of transfected human SGLT2. To assess these issues *de novo*, we examined the effect of physiological hyperinsulinaemia on Tm_G and urinary glucose excretion (UGE) in healthy subjects (NGT) and T2D patients under steady-state conditions of plasma glucose and insulin concentrations.
Materials and methods: Nine T2D (5F/4M; 55±5 years, mean±SD; BMI=28.1±5.3 kg/m^2; HbA_{1c}=7.6±0.6 %) and 7 NGT participants (1F/6M; 36±8 years; BMI=24.9±4.7 kg/m^2) received a 7-hour constant somatostatin infusion (400 μg/h) and a variable glucose infusion designed to achieve steady-state glycaemias of ~22 mmol/L in 1 hour and to maintain this level for the next 3 hours (CT period). Then, a constant insulin infusion (1 mU·min^{-1}·kg^{-1}) was started and maintained for an additional 3 hours (INS period) while clamping glycaemia at CT levels with the use of an *ad hoc* algorithm. Urines were collected separately for the two study periods for the measurement of glucose and creatinine.

Results: Plasma glucose plateaus were similar across group and study period (CT=21.7±0.2 *vs* INS=21.5±5.2 mmol/L in T2D; 22.8±2.1 *vs* 23.0 ±3.6 mmol/L in NGT, all *p*=ns). Exogenous glucose infusion rate (GIR) was similar in T2D and NGT during the CT period (30±7 *vs* 30±15 $\mu mol \cdot kg^{-1} \cdot min^{-1}$; *p*=ns); during the INS period, GIR rose much higher in NGT than T2D (128±20 *vs* 69±29 $\mu mol \cdot kg^{-1} \cdot min^{-1}$, *p*<0.0001). Creatinine clearance was similar between groups and study periods (144±25 and 140±31 $ml \cdot min^{-1}$, CT *vs* INS in T2D; 158±39 and 169 ±28, CT *vs* INS in NGT, all *p*=ns). During the CT period, UGE was significantly lower in T2D than in NGT (486 [309] *vs* 706 [347] $\mu mol \cdot min^{-1}$, median and [IQR], *p*=0.03) whereas fractional glucose excretion (FE_G) was similar (17±5% and 22±7%, respectively; *p*=ns). During the INS period, both UGE and FE_G rose above CT levels in NGT (to 1,155 [547] $\mu mol \cdot min^{-1}$ and 32±12%, respectively, *p*<0.03 for both *vs* CT), whereas they were unchanged in T2D (at 531 [319] $\mu mol \cdot min^{-1}$ and 18±6%, respectively, *p*=ns). In the pooled data of T2D and NGT participants, FE_G was positively associated with GIR during the INS period (*r*=0.63, *p*=0.02).
Conclusion: Acute physiological hyperinsulinaemia during steady-state hyperglycaemia increases urinary glucose excretion in NGT subjects. This insulin effect is impaired in patients with type 2 diabetes, and may be related to insulin resistance.

Three days low-carbohydrate/high-fat diet increases insulin clearance in non-obese healthy men

R. Suzuki, Y. Tamura, S. Kakehi, K. Takeno, Y. Sakurai, T. Funayama, Y. Furukawa, H. Kaga, D. Sugimoto, S. Kadowaki, Y. Someya, A. Kanazawa, R. Kawamori, H. Watada;
Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background and aims: It has been reported that 1-wk overfeeding impairs insulin sensitivity and elevates insulin level, and the latter is partly induced by impaired metabolic clearance rate of insulin (MCRI). Thus, MCRI is considered as a regulatory factor to maintain euglycemia during short term dietary change. However, the effect of low-carbohydrate/high-fat (LCHF) diet on MCRI has not been elucidated.
Materials and methods: To clarify the effect of 3-day LCHF diet, we studied 48 non-obese healthy men (BMI; 22.6±2.5 kg/m^2). Each subject consumed a 3-day control diet, which was followed by a 3-day eucaloric LCHF diet (20% carbohydrate, 20% protein, 60% fat). After the completion of both diet protocols, we performed hyperinsulinemic euglycemic clamp (insulin infusion rate (IIR) = 100 mU/m^2 per min) to evaluate glucose infusion rate (GIR) and MCRI, calculated as a ratio of IIR to steady state serum insulin (SS_{SI}).
Results: The 3-day LCHF diet increased MCRI (497.4±71.4 ml/min per m^2 to 540.1±85.0 ml/min per m^2, P < 0.05); however, the individual changes were highly variable. To further investigate the role of MCRI, we divided the subject into high-responder (HR) and low-responder (LR) based on the median %change of MCRI by LCHF diet. At baseline, HR group showed higher GIR level compared with LR group (13.0±1.9 vs. 11.8±2.0 mg/kg FFM per min, P<0.05), while MCRI and SS_{SI} levels were comparable. After LCHF diet, MCRI was increased (481.9±58.8 to 582.5±90.8 ml/min per m^2, P<0.001) and SS_{SI} was decreased (210.2 ±23.3 μU/mL to 175.1±23.5 μU/mL, P<0.001) in HR group, but those were not altered in LR group. In parallel with decreased SS_{SI}, GIR was decreased in HR group (from 13.0±1.9 to 11.7±2.4 mg/kg FFM per min, P=0.003) after LCHF diet, but not in LR group.
Conclusion: In conclusion, MCRI was increased after 3-day LCHF diet; however, the effect was highly variable. The decreased GIR after LCHF diet in HR group may be partly due to decreased SS_{SI} and contribute to maintain euglycemia during low-carbohydrate availability in insulin sensitive subjects.
Disclosure: **R. Suzuki:** None.

Effect of liver transplantation on beta cell function and insulin sensitivity and clearance in cirrhotic patients. A 2 years-FU study

V. Grancini[1], M. Boselli[2], M. Lunati[1], E. Palmieri[1], V. Resi[1], A. Gaglio[1], G. Pugliese[3], R. Bonadonna[4], E. Orsi[1];
[1]Endocrinology, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico di Milano, Milano, [2]Division of Endocrinology, Diabetology and Metabolic Diseases, University of Verona, Verona, [3]Department of Clinical and Molecular Medicine, "La Sapienza" University, Rome, [4]Division of Endocrinology and Metabolic Diseases, University of Parma, and Azienda Ospedaliera Universitaria, Parma, Italy.

Background and aims: Abnormalities of glucose (G) homeostasis are common in cirrhotic patients and may improve after liver transplantation (LT). Aim of the study was to assess the impact of LT on beta cell function (BCF) and insulin (I) sensitivity/clearance.
Materials and methods: 89 cirrhotic patients were studied before and 3, 6, 12, 24 months after LT by a frequently sampled OGTT, which was analyzed by well established mathematical models and provided 4 key outputs: 1. derivative control (DC: I secreted in response to the rate of plasma G increase; units: $[pmol \cdot m^{-2}$ BSA$]/[mM \cdot min^{-1}]$) and 2. proportional control (PC: the stimulus-response curve linking G per se to I secretion rate) of BCF from the G/C-peptide curves; 3. OGIS (units: $ml \cdot min^{-1} \cdot m^{-2}$ BSA), a robust index of I sensitivity, from the G/I curves; 4. I Clearance (units: $L \cdot min^{-1} \cdot m^{-2}$ BSA) from the combined analysis of G/C-peptide/I curves
Results: After LT, 26 patients recovered from DM (regressors, R), 15 did not (non-regressors, NR), 4 developed DM, and 44 stayed non-diabetic. Before LT, R group was similar to NR group, but for higher I sensitivity (OGIS 373.65±91.85 VS 316.51±82.82, p=0.048). In all groups I clearance increased (p<0.03) from 1.3±0.2 (before LT) to 1.9±0.1, 1.8±0.1, 1.7 ±0.2 and 1.6±0.1 before and 3, 6, 12, 24 months after LT, respectively. In the R group, the trajectories over time of I sensitivity (from 367±92 to 435 ±62 to 432±73 to 423±54 to 449±62) and DC of BCF (from 522±142 to 965±282 to 1207±238 to 1572±360 to 1309±287) showed significant improvements in the R group only (p=0.0001 and p=0.001, respectively). A declining trajectory over time of PC of BCF was detected in the NR group (p<0.05-0.01).
Conclusion: LT brings about a generalized increase in I clearance and is associated to regression of DM in ~30% of patients. Our data ascribe this beneficial change in G homeostasis to improvements in both I sensitivity and specific facets of BCF

Plasma soluble leptin receptor predicts insulin sensitivity in humans

C. Sommer[1], S. Lee[2], H.L. Gulseth[1], J. Jensen[3], C.A. Drevon[2], K.I. Birkeland[2];
[1]Oslo University Hospital, [2]University of Oslo, [3]Norwegian School of Sport Sciences, Oslo, Norway.

Background and aims: Soluble leptin receptor (sOb-R) concentration is inversely associated with risk of type 2 diabetes (T2D) and gestational diabetes (GDM) in humans, but little is known about the underlying mechanisms. Both T2D and GDM are characterized by insulin resistance in combination with beta-cell dysfunction. Insulin resistance and leptin resistance usually appear simultaneously, and insulin and leptin signaling share many of the same signaling pathways. sOb-R is formed by ectodomain shedding of membrane-bound leptin receptors, and the sOb-R concentration may reflect leptin sensitivity. The aim of this study was to explore the association between sOb-R and insulin sensitivity.
Materials and methods: MyoGlu was a clinical trial of 26 sedentary men (13 with impaired glucose metabolism [IGM] and 13 controls) aged

40-65 years, showing that a 12-week exercise intervention increased insulin sensitivity by 30%. Insulin sensitivity was measured as the total glucose infusion rate (GIR) during a hyperinsulinemic euglycemic clamp. Plasma sOb-R and leptin were measured with ELISA kits. Global gene expression was quantified using high throughput mRNA sequencing from muscle and adipose tissue biopsies. Pathway analyses were performed based on correlations between sOb-R and gene expression in muscle and adipose tissue.

Results: At baseline, IGM men had higher total body fat (mean ± SD; 14.2 ± 0.9 vs. 7.8 ± 0.6 L, p < 0.001), lower GIR (4.2 ± 0.5 vs. 7.6±0.4 mg/kg/min, p < 0.001) and lower sOb-R (4.4 ± 0.2 vs. 5.6 ± 0.4 ng/mL, p = 0.016) than controls. Baseline sOb-R was strongly correlated with baseline GIR (linear regression coefficient β [95 % CI]: 1.19 [0.57-1.82] mg/kg/min per increment increase in sOb-R, p= 0.001). This association was weakened but persisted after adjustment for age, IGM status, total body fat and plasma leptin concentration (0.67 [0.09-1.24], p = 0.026).In contrast to insulin sensitivity, sOb-R did not change following the intervention (5.0 ± 1.3 vs 5.1 ± 1.2, p = 0.20). However, baseline sOb-R was positively associated with change in GIR (Figure 1). The association was strengthened after adjustment for IGM status, age, baseline GIR, total body fat and plasma leptin concentration (0.75 [0.17-1.33] mg/kg/min, p = 0.014). In pathway analyses of both adipose tissue and skeletal muscle, sOb-R was positively correlated with increased metabolism (e.g. oxidative phosphorylation, branched chain amino acid degradation and PPAR signaling) and negatively correlated with inflammatory pathways (e.g. chemokine, B and T cell receptor signaling pathways).

Conclusion: Plasma sOb-R was positively correlated with insulin sensitivity, and predicted change in GIR following a 12-week exercise intervention, independently of covariates. High plasma sOb-R was correlated with upregulation of genes related to increased metabolism. These findings may partly explain the observed inverse association between sOb-R and risk of GDM and T2D.

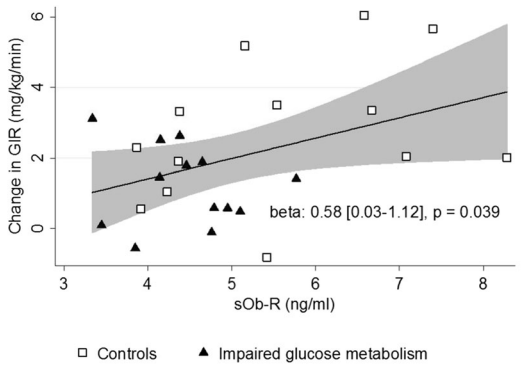

Figure 1. Crude relationship between baseline sOb-R and change in glucose infusion rate (GIR) following a 12-week exercise intervention in men with impaired glucose metabolism and controls. Linear prediction (full line) with 95 % CI (grey area).

Higher insulin sensitivity in recent-onset latent autoimmune diabetes of adults compared with recent-onset type 2 diabetes

O.P. Zaharia[1,2], K. Bódis[1,2], Y. Karusheva[1,2], D.F. Markgraf[1,2], N.C. Schloot[1], P. Bobrov[3,2], K. Strassburger[3,2], V. Burkart[1,2], K. Müssig[1,4], J. Szendroedi[1,4], M. Roden[1,4];
[1]Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich Heine University, Düsseldorf, [2]German Center for Diabetes Research (DZD), München-Neuherberg, [3]Institute for Biometrics and Epidemiology, German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich Heine University, Düsseldorf, [4]Department of Endocrinology and Diabetology, Medical Faculty, Heinrich Heine University, Düsseldorf, Germany.

Background and aims: Latent autoimmune diabetes of adults (LADA) exhibits features of both type 1 diabetes (T1D: islet-cell antibodies), and type 2 diabetes (T2D: late onset and initial insulin-independence). However, less is known about the key abnormalities of T1D and T2D, insulin sensitivity and beta-cell function, in humans with LADA. This study aimed to compare the metabolic phenotype of persons with recent-onset (disease duration <1 year) LADA, T1D, T2D and nondiabetic humans (CON).

Materials and methods: We compared sex-, age- and BMI-matched participants of the German Diabetes Study: LADA: n[m/f]=42[26/16], age 50.5±9.5 years, BMI 27.9±5.3 kg/m^2 ; T1D: n[m/f]=42[26/16], 47.9±7.8 years, 26.3±4.6 kg/m^2 ; T2D: n[m/f]=42[26/16], 50.6±9.9 years, 28.4±4.9 kg/m^2 and CON: n[m/f]=42[26/16], 50.3±10.6 years, 27.6±4.6 kg/m^2. LADA was diagnosed by age >30 years at manifestation, positivity for glutamic acid decarboxylase (GAD) autoantibody and/or islet-cell antibodies (ICA) and >6 months of an initial insulin-free period. All participants underwent glucagon tests and IVGTT to assess insulin secretion and hyperinsulinemic-euglycemic clamp tests, to assess insulin sensitivity (M). Data were analyzed using generalized ANOVA, taking the matched design into consideration and adjusted for age, sex and BMI.

Results: Glycemic control in LADA was better than in T1D (HbA1c: 6.6 ±1.1 % [49±12 mmol/mol] vs. 7.1±1.6 % [54±18 mmol/mol], p<0.05), but similar to T2D (6.6±1.1 % [49±12 mmol/mol] vs. 6.5±0.8 % [48±8 mmol/mol]) and lower than in CON (6.6±1.1 % [49±12 mmol/mol] vs. 5.3±0.3 % [34±4 mmol/mol], p<0.05). Beta-cell function, as assessed from both C-peptide and insulin rise following glucagon stimulation, was 66% higher in LADA than in T1D, but 33% lower than in T2D and 95% lower than in CON (all p<0.05). Total C-peptide secretion during IVGTT was 3.1 times higher in LADA compared to T1D (84.0±67.2 vs. 27.0±26.6 ng/ml), 17% lower than in T2D (98.5±59.1 ng/ml) and 2.4 times lower than in CON (200.7±68.4 ng/ml) (all p<0.05). Insulin sensitivity in LADA was comparable to T1D (8.2±2.9 and 8.3±3.2 mg/kg*min), 15% higher than in T2D (7.0±2.1 mg/kg*min, p<0.05), but 26% lower than in CON (10.3±3.1 mg/kg*min, p<0.05).

Conclusion: Persons with recent-onset LADA feature similar whole-body insulin sensitivity as T1D and similar beta-cell function as T2D, placing these patients as a metabolically hybrid phenotype between T1D and T2D.

Effect of calcidiol on insulin resistance and beta cell function in subjects with pre-diabetes

E. Maddaloni, R. Strollo, P. Pozzilli, N. Napoli;
University Campus Bio-Medico, Rome, Italy.

Background and aims: Several studies have evaluated extraskeletal effects played by vitamin D on metabolic outcomes but data are not consistent and little evidence is available for calcidiol [25(OH)D]. Aim of this study was to evaluate the effect of calcidiol supplementation on insulin resistance, β-cell function and markers of inflammation and oxidative stress in subjects with pre-diabetes.
Materials and methods: We carried out a double blind placebo-controlled clinical trial enrolling a total of 150 subjects with IGT, IFG (defined by ADA criteria) and 25(OH)D <20 ng/ml, followed up for 6 months. Subjects were either assigned (50 per group) to 1) daily supplementation of 50 mcg of calcidiol (Arm A); 2) 25mcg of calcidiol (arm B); 3) placebo (Arm C). ISOGTT index was used to test insulin resistance while ISSI-2 index was used for beta-cell function. Other parameters included: HbA1c, 25(OH)D, calcium, phosphorus, PTHi, lipid panel, Hs-CRP, TNFα, IL-6, sRAGE
Results: At baseline. subjects were (mean ±SD) 63.8± 2.1 old , BMI of 27.4±1.2; serum glucose 115.1±8.4, HBa1c 6.4±0.6, 25(OH)D 16.3±2.5. There were significant associations of 25(OH)D with ISOGTT (β=0.35; 95% CI, 0.14, 0.46) and β-cell function (ISSI-2; β = 0.15; 95% CI, 0.02, 0.28).At six months, 25(OH)D increased up to 48 ± 3 ng/mL in the A arm (P<0.01) and to 36 ± 5 ng/mL in the B arm (P<0.01); no significant changes in the C arm. Subjects in Arm A had a lower risk of dysglycemia (HR = 0.85, 95% CI, 0.75-0.97 per SD increase) while no significant effects were observed in the Arms B or C. Both ISOGTT and ISSI-2 were improved in Arm A (P<0.05) while no significant changes were observed in Arm B or placebo. Serum levels of sRAGE decreased in Arm A [median 1354 (1069-1680) pg/ml (P<0.01), as compared with levels at study entry, but not in Arms B or C. No significant differences were observed for CRP, IL6, TNFα or lipid panel.
Conclusion: Our finding indicate that high doses of calcidiol improved indices of glucose homeostasis in prediabetic subjects and decreased circulating sRAGE levels, suggesting a positive effect also on oxidative stress.

Circadian misalignment induces insulin resistance and elevated glucose and FFA levels: a randomised crossover trial

J. Wefers[1], D. van Moorsel[2,1], J. Hansen[1], N. Connell[1], B. Havekes[2,1], F.A. Scheer[3,4], J. Hoeks[1], N.C. Schaper[2], E. Phielix[1], M.K.C. Hesselink[1], P. Schrauwen[1];
[1]Department of Human Biology and Human Movement Sciences, NUTRIM, Maastricht University Medical Center, [2]Department of Internal Medicine, Devision of Endocrinology, Maastricht University Medical Center, Maastricht, Netherlands, [3]Medical Chronobiology Program, Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Boston, [4]Division of Sleep Medicine, Harvard Medical School, Boston, USA.

Background and aims: Circadian misalignment, such as in shift work, has been associated with obesity and insulin resistance. Recently, we demonstrated a day-night rhythm in human skeletal muscle mitochondrial function. It is tempting to suggest that a reduced or a shifted rhythm of mitochondrial function might be involved in the development of insulin resistance by circadian misalignment. However, direct effects of circadian misalignment on peripheral insulin sensitivity have never been investigated.
Materials and methods: Fourteen healthy young lean men (age 22.4 ± 2.8 years; BMI 22.3 ± 2.1 kg/m2 [mean ± SD]) participated in a randomized cross-over study to determine the influence of controlled circadian misalignment on insulin sensitivity, assessed by hyperinsulinemic two-step euglycemic clamping. Participants were studied after a 3-day control period and after a 3.5-day misalignment period performed by a 12-rapid shift in a respiration chamber, isolated from time cues. Whole body indirect calorimetry was performed to assess resting metabolic rate and substrate oxidation. In addition, sleeping metabolic rate (SMR) was measured with whole room indirect calorimetry. Glucose, FFA and triglyceride levels were determined in plasma samples after an overnight fast (either at 7 AM or 7 PM).
Results: Circadian misalignment resulted in a significant decrease in insulin stimulated glucose disposal (Glucose infusion rate: 8.7 ± 1.8 vs. 7.8 ± 1.2 mg/kg/min; control *vs.* misalignment; p=0.04). Fasting glucose and FFA levels were higher in circadian misalignment (Glucose: 5.0 ± 0.2 vs. 5.2 ± 0.2 mmol/l; control *vs.* misalignment; p=0.01; FFA: 390 ± 174 vs. 525 ± 179 μmol/l; control *vs.* misalignment; p=0.006). In addition, participants had higher SMR in circadian misalignment (4.94 ± 0.48 vs. 5.14 ± 0.57 kJ/min; control *vs.* misalignment), while resting metabolic rate tended to increase (5.06 ± 0.58 *vs.* 5.33 ± 0.63 kJ/min; control *vs.* misalignment; p=0.08).
Conclusion: Controlled circadian misalignment leads to decreased peripheral insulin sensitivity, higher glucose and FFA levels and higher SMR. Our findings support a causal role of circadian misalignment in the development of obesity and type 2 diabetes mellitus. Further analysis - including markers of mitochondrial metabolism - is currently ongoing.

A randomised cross-over study of the acute effects of running 5 km on glucose, insulin and troponin T

F.H. Nyström, B. Keselman, S. Nyberg, M. Vergara;
Department of Medical and Health Sciences, Faculty of Medicine and Health Sciences, Linköping University, Linköping, Sweden.

Background and aims: We aimed to study the impact by running 5 km, at maximal speed, on the normal variations of metabolic variables related to glucose, insulin, insulin sensitivity and metabolic rate.
Materials and methods: Five women and 12 men 25.7±5.2 years of age with a body-mass-index of 22.5±2.3 kg/m^2 where recruited to run 5 km at individual maximal speed in the morning, and to a corresponding day of rest, followed by standardized breakfast and lunch meals. Blood sampling and measurement of indirect calorimetry were done before and after meals. The participants were randomized regarding the order of the two trial-days in this cross-over study.
Results: Glucose, cortisol and metabolic rate were higher on race-days compared with days without exercise (ANOVA repeated measures, p=0.030, p=0.007 and p=0.008, respectively) while insulin levels or insulin sensitivity did not show such statistical differences (p=0.31 and p=0.14, respectively). When analyzing specific time-points we found that glucose increased from 5.01±0.37 mmol/l to 6.36 ± 1.3 mmol/l, p= 0.001, by running, while serum insulin concomitantly increased from 42±21 to 90±54 pmol/l, p= 0.003. In accordance, the QUICKI index of serum sensitivity, $1/(\log_{10}\text{insulin}+\log_{10}\text{glucose})$, was lowered by the race, p< 0.0001. Serum cortisol levels increased from 408±137 nmol/l to 644±171 nmol/l, p= 0.001, by the races while serum glucagon was unaffected. Troponin T was detectable post-race in 12 out of the 17 participants and reached or surpassed the clinical reference

level of 15 ng/l in three subjects. Post-race electrocardiograms displayed no pathologies.
Conclusion: Relatively short running-races can apparently induce a temporary reduction in insulin sensitivity that is not fully compensated by concomitantly increased insulin secretion intended to ensure euglycemia. Since also Troponin T was detected in plasma in a majority of the participants, our data suggest that it is possible to induce considerable metabolic stress by running merely 5 km, when striving for maximal speed.

Differences in C-peptide levels in gestational diabetes with or without previous bariatric surgery indicate improved insulin sensitivity

J. Dereke[1], P. Katra[1], C. Nilsson[1,2], H. Strevens[3], U. Moll[4], M. Landin-Olsson[1,4], D. Ursing[4], M. Hillman[1];
[1]Clinical Sciences, Lund University, Lund, [2]Department of Paediatrics, Helsingborg Hospital, Helsingborg, [3]Department of Gynaecology and Obstetrics, Skåne University Hospital, Lund, [4]Department of Endocrinology, Skåne University Hospital, Lund, Sweden.

Background and aims: Bariatric surgery (BS) is an increasingly common method to combat obesity. It has been shown that bariatric surgery before pregnancy decreases the risk of developing gestational diabetes mellitus (GDM). However, some women do develop GDM despite weight loss surgery, and this patients group has not been studied extensively before. The aim of this study was to investigate the insulin secretion in patients with GDM with and without prior BS and pregnant women without diabetes who had undergone BS prior to pregnancy.
Materials and methods: All study participants were recruited at a University Hospital. Serum samples from all groups were collected either in the 1st or 3rd trimester of gestation. Patients with GDM (GDM: n=521) were recruited in 2009 - 2017 following a 2h 75 g OGTT. GDM patients that had undergone BS prior to pregnancy (BS-GDM: n=54) were diagnosed 2011 - 2016 following a 3-day plasma glucose monitoring, consisting of 7 capillary blood glucose tests per day (fasting and before and after each meal). The diagnostic criteria for GDM was 2 or more glucose values >8mmol/L. Pregnant women without diabetes that had undergone BS prior to pregnancy (BS-controls: n=34) were recruited 2015 - 2017. The study has been approved by the Regional Ethics Review Board in Lund, Sweden (2014/78, 2014/746). C-peptide levels were analysed in serum that had been frozen within 3 days of sample collection using a commercially available ELISA. Data is reported as median followed by [interquartile range]. Mann-Whitney U-test was used to compared median ranks between the groups. Effect size (ES) was calculated using eta^2 and $p<0.05$ was considered as statistically significant.
Results: The results of this study showed that BS-GDM women had lower C-peptide levels (0.59 [0.39-1.0] ng/mL) than women with GDM and no surgery (1.0 [0.61-1.7] ng/mL; ES=0.20, p<0.0001). There was a trend towards a difference between the groups of BS-GDM and BS-controls (0.44 [0.34-0.67] ng/mL, ES=0.20 p=0.066). There was also a difference between the BS-controls and GDM (ES=0.24, p<0.0001). BMI was highest in the BS-controls (29.9 [27.0-31.0] kg/m^2), followed by the BS-GDM group (26.5 [24.9-29.9] kg/m^2, ES=0.19, p=0.097). The women with GDM had the lowest BMI values, (25.8 [22.4-30.5] kg/m^2), significantly lower than the BS-controls (ES=0.12, p=0.0073), but not the BS-GDM women, (ES=0.075, p=0.091), although there was a trend.
Conclusion: In conclusion, women that have undergone BS and subsequently developed GDM have lower C-peptide levels than women with GDM who have not undergone surgery despite the trend towards higher BMI in the BS-GDM group. This could indicate an improved insulin sensitivity in these women, possibly related to metabolic changes caused by BS.

Low oxidation of branched-chain amino acids in people with type 2 diabetes may underlie increased systemic levels

E. Phielix[1], M. de Ligt[1], L. Bilet[1], T. van de Weijer[1,2], V.B. Schrauwen[1,2], M. Hesselink[1], P. Schrauwen[1];
[1]Human Biology and Human Movement Sciences, Maastricht University, [2]Radiology, Maastricht University Medical Centre, Maastricht, Netherlands.

Background and aims: Recent studies implicate that circulating branched-chain amino acids (BCAA) can be involved in the development of insulin resistance, likewise BCAA are elevated in humans at risk to develop type 2 diabetes (T2DM). In the present study we sought to investigate whether systemic BCAA levels differ between patients with T2DM, first-degree relatives (FDR) and control participants (CON), and if BCAA are associated with key metabolic parameters like insulin sensitivity, metabolic flexibility, mitochondrial function and intrahepatic lipid (IHL) content. Also, we investigated whether a low oxidation of BCAA underlies elevated systemic levels of BCAA.
Materials and methods: In total 15 patients with T2DM, 13 FDR and 17 CON (age within 50-65 years) were matched for BMI (31±1, 30±1 and 32±1 kg/m^2, respectively). Hyperinsulinemic-euglycemic clamps combined with D2-glucose and indirect calorimetry were performed to determine whole body insulin sensitivity (ΔRd: μmol/kg/min) and metabolic flexibility (ΔRQ: μmol/kg/min). Proton magnetic resonance spectroscopy (^{1}H-MRS) was used to determine intrahepatic lipid (IHL) content (%) and high-resolution respirometry in vastus lateralis muscle tissue to examine ex vivo mitochondrial function (O_2- flux: pmol/mg wet weight/s). In a sub-group of n=5 T2DM and n=5 CON, clamps were combined with 1-^{13}C leucine isotope to determine leucine oxidation under baseline and insulin stimulated conditions.
Results: Circulating BCAA were higher in T2DM vs. CON and FDR (543 ± 14 vs. 453 ± 16 and 480 ± 18 μmol/l; p<0.05). Negative correlations were found between fasting BCAA plasma levels and ΔRd (r=-0.41; p<0.05), ΔRQ (r=-0.43; p<0.05) and mitochondrial O_2-flux (state 3: r=-0.39; p<0.01 and state u: r=-0.48; p<0.001). In addition, a strong positive correlation was found between BCAA and IHL (r=0.35; p<0.05). Interestingly, leucine oxidation was lower in T2DM vs. CON both at baseline as well as during insulin stimulation (baseline: 0.23 ± 0.02 vs. 0.32 ± 0.02 μmol/kg/min, p<0.05; insulin-stimulated: 0.38 ± 0.03 vs. 0.44 ± 0.02 μmol/kg/min, p<0.05).
Conclusion: BCAA strongly associates with key metabolic parameters and are elevated in patients with T2DM. In patients with T2DM a blunted BCAA oxidation during baseline and insulin stimulation possibly underlies elevated systemic BCAA levels. Our results suggest that altered metabolism of BCAAs is part of the insulin resistant phenotype.

Glucose homeostasis and whole-body insulin resistance improved 4 weeks after gastric bypass surgery in type 2 diabetes, whereas adipose tissue metabolism was unchanged

P. Katsogiannos[1], G.J. Boersma[1], M.J. Pereira[1], P. Lundkvist[1], M. Sundbom[2], J.W. Eriksson[1];
[1]Clinical Diabetes and Metabolism, Department of Medical Sciences, Uppsala University, [2]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden.

Background and aims: Gastric bypass (GBP) surgery used in severe obesity has also shown beneficial effects to prevent or treat type 2 diabetes (T2D). Markedly improved insulin sensitivity, beta-cell function and reduced hepatic glucose production, visceral and hepatic fat have been reported. Our aim was to explore short-term effects following GBP on glucose tolerance, insulin sensitivity and beta-cell function as well as on adipose tissue metabolic function.
Materials and methods: The data presented are part of a larger study including T2D subjects with BMI 30-45 randomized to either GBP or standard-of-care medical treatment (2:1). For this pilot study, 7 subjects randomized to GBP (age 58.3 ± 9.1; M/F 3/4, diabetes duration 4.1 ± 0.7 yr) were included in the analyses. They were assessed pre-surgery, and 4 weeks post-surgery as follows: 1) oral glucose tolerance test (OGTT) to assess insulin resistance and glucose tolerance, 2) an iv arginine (5g) challenge to assess beta-cell capacity, and 3) adipose tissue biopsies to measure glucose uptake, lipolysis and insulin action in isolated adipocytes.
Results: The in-vivo measurements showed that 4 weeks after surgery, subjects had lower fasting glucose and insulin levels, and glucose levels at 60 and 120 mins of the OGTT were reduced ($p<0.01$). Insulin sensitivity assessed with the Matsuda index was increased ($p< 0.05$). There were no differences pre- and post-GBP in either the disposition index or the insulinogenic index. During arginine challenge insulin levels were consistently lower post-GBP ($p<0.01$). However, the relative peak insulin response to arginine was increased post-GBP ($p<0.05$). In-vitro studies of isolated adipocytes did not show any significant changes in either basal or isoprenaline-stimulated lipolysis rates or glucose uptake, and neither was there any change in the effects of insulin (0.1-1000 μU/mL). However, adipocyte size was significantly decreased 4 weeks post-GBP ($p<0.01$). The first subjects (n=4) of the control group did not display any consistent anthropometric or metabolic changes during a 24-wk follow-up.
Conclusion: These obese patients with type 2 diabetes had a clear improvement in insulin sensitivity and glycemic control already 4 weeks after GBP, but this was not accompanied with any changes in glucose uptake and lipolysis rates or insulin sensitivity in adipose tissue. Therefore, we hypothesize that the mechanisms for rapid improvement of diabetes after GBP occur mainly in other tissues than adipose, like skeletal muscle, liver, and CNS, and that they could involve neuroendocrine pathways and incretin hormones. This will be addressed in the onward analyses of this study.

Sam68 mediates insulin and leptin signalling in granulosa cells and is downregulated in polycystic ovary syndrome patients

V. Sanchez-Margalet[1], T. Vilariño-García[1], A. Perez-Perez[1], E. Santamaria-Lopez[2], N. Prados-Nodd[3], M. Fernandez-Sanchez[3];
[1]Medical Biochemistry and Molecular Biology, and Immunology, Virgen Macarena University Hospital, [2]Medical Biochemistry and Molecular Biology, and Immunology, Instituto Valenciano de Infertilidad, [3]Instituto Valenciano de Infertilidad, Seville, Spain.

Background and aims: Sam68, an RNA-binding protein that participate in signal transduction is expressed in granulosa cells. The Sam68 knockout female mice are subfertile, and present ovulation problems. We have previously found that Sam68 may be recruited to insulin and leptin receptors in different systems including granulosa cells, and Sam68 expression is induced by both insulin and leptin stimulation. In order to assess the relevance of Sam68 in leptin and insulin receptor signaling in granulosa cells, we planned to study the effect of either downregulation or overexpression of Sam68 in the activation of PI3K and MAPK signaling pathways by insulin or leptin. We then wanted to check whether Sam68 expression was altered in granulosa cells from patients with polycystic ovary syndrome, where both insulin and leptin resistance have previously been observed.
Materials and methods: Granulosa cells from control (25) and polycystic ovary syndrome women (25) were obtained obtained as a waste product from follicles recollected getting oocytes for in vitro fecundation, after informed written consent. Downregulation of Sam68 expression was achieved using siRNA method, and Sam68 overexpression was performed using an expression plasmid vector containing the Sam68 cDNA. Signaling was studied by immunoblot of the phosphorylated proteins. The bands obtained in the blots were scanned and analyzed after nrmaization by the PCBAS 2.0 program. The expression level of Sam68, and leptin and insulin receptors are quantified by qPCR and confirmed by immunoblot. Statistical significance was assessed by analysis of variance followed by Bonferroni's post hoc tests. P-value of <0.05 was considered to be statistically significant.
Results: Sam68 down-regulation by Sam68 siRNA prevents the leptin- and insulin-dependent activation of PI3K and MAPK pathways in granulosa cells, whereas overexpression of Sam68 potentiates the activation of PI3K and MAPK pathways in response to leptin or insulin. Moreover, Granulosa cells from polycystic ovary syndrome subjects have significant lower expression of Sam68 than granulosa cells from control women.
Conclusion: Sam68 is necessary for fully activation of leptin and insuln signaling in human granulosa cells, and Sam68 expression is downregulated in granulosa from polycystic ovary syndrome patients. Thus, Sam68 may be an important element in the ovarian insulin and leptin resistance, and may mediate the decreased fertility in women with polycystic ovary syndrome. Therefore, Sam68 could be considered a new target for therapy.

Putative miRNA biomarkers of insulin resistance and the effect of metformin: data from the CAMERA trial

T. ALRamah[1], K. Pinel[1], D. Preiss[2], N. Sattar[1], J. Logue[1], P. Welsh[1];
[1]University of Glasgow, Glasgow, [2]University of Oxford, Oxford, England, UK.

Background and aims: Several circulating miRNAs have been reported to be associated with insulin resistance (IR) and are considered as potential diagnostic biomarkers, although studies have generally been limited by small size. It is also not clear whether these associations are causal. We aimed to 1) validate cross sectional associations of targeted miRNAs within a large study and 2) to explore the effect of metformin on these miRNAs.
Materials and methods: The CAMERA study was a randomised, placebo-controlled double-blinded trial performed in Glasgow, UK (2009-2012). 173 patients aged 35-75 on statins with coronary heart disease and large waist circumferences (but without diabetes) were randomly assigned to metformin or placebo (1:1) and followed for 18 months. miRNAs were extracted from 308 paired stored samples from 154 participants (taken at baseline and after 18 months of treatment). The expressions of mir-221, 222, 144, 155, 192 and 193b (targeted based on previous literature) were measured using real time quantitative polymerase chain reaction (RT-qPCR). Samples from each patient were run simultaneously. Spike-in of cel-miR-39 was used as a quality control. We

used linear regression of CT values for cross sectional analyses, and the $2^{-\Delta\Delta CT}$ method to investigate the randomised effect of metformin.
Results: In cross sectional analysis at baseline, mir-144 showed the strongest association with markers of insulin sensitivity: in models adjusting for age and sex, for every unit increase in HOMA-IR, mir-144 was 10.2% (95% CI 2.5% - 17.2%, p<0.05) lower and for a 1 mmol/L increase in fasting plasma glucose (FPG), mir-144 was 34.9% (95% CI 15.1% - 50%, p<0.01) lower. Other miRNAs showed variable associations with markers of insulin resistance and glycaemia, but no miRNA was associated with BMI. Mir-192 and 193b showed strong associations with liver enzymes. For every 10-unit increase in ALT, mir-192 was 24.7% (95% CI 16.5% - 32.2%, p<0.001 lower while mir-193b was 34.9% (95% CI 28.8% - 40.1%, p<0.001) lower. For every 10-unit increase in GGT, mir-192 (95% CI 2.7% - 8.6%, p<0.001) was 6% lower and mir-193b was 8% (95% CI 5.4% - 10.5%, p<0.001) lower. Adjustment for body fat did not attenuate these associations. Over 18 months, metformin reduced weight by 3.3 kg, FPG by 0.3 mmol/L and HOMA-IR by 0.81 units versus placebo. However, metformin showed no effect on the expression of mir-221, 222, 144, 155, 192 and 193b (p=0.91, 0.51, 0.25, 0.97, 0.89 and 0.69 respectively). From observational data, this effect would be expected to translate into an ~8% increase in miRNA-144, which may not be of clinical relevance.
Conclusion: In this, one of the first studies to investigate the effect of a randomised intervention on miRNA expression, we observed broadly expected cross-sectional associations of targeted miRNAs with biomarkers of metabolic risk in a non-diabetic population with coronary heart disease but without diabetes. These data support the putative utilities of miRNAs as reproducible biomarkers, but more RCTs should explore the effect of interventions on their expression.

Adipose tissue lipolytic inhibition enhances the glucoregulatory properties of exercise in type 2 diabetes patients

K. Verboven[1,2], D. Hansen[1,3], J.-W. van Dijk[4], L.J.C. van Loon[2,4];
[1]Rehabilitation Research Center, Hasselt University, Hasselt, Belgium, [2]Human Biology and Movement Sciences, Maastricht University Medical Centre+, Maastricht, Netherlands, [3]Jessa Hospital, Hasselt, Belgium, [4]HAN University of Applied Sciences, Nijmegen, Netherlands.

Background and aims: Exercise combined with adipose tissue lipolytic inhibition augments intramuscular lipid and glycogen use in type 2 diabetes mellitus (T2DM) patients. The present study investigates the impact of adipose tissue lipolytic inhibition during exercise on subsequent postprandial glycemic control in T2DM patients.
Materials and methods: Fourteen male T2DM patients (age: 65±2 years, HbA_{1c} 6.7±0.1%) participated in a double-blind placebo-controlled randomized cross-over study in which subjects performed 60 min of endurance-type exercise (at 45% W_{peak}) after being administered 250 mg of an nicotinic acid analog (acipimox; ACP) or a placebo (PLA). A control experiment was included in which no exercise was performed (CON). Plasma samples were obtained before, during and for up to 7.5 h after exercise.
Results: Sixty min of exercise at 73±6 W did not significantly lower circulating plasma glucose and insulin excursions in PLA when compared with CON (P=0.300 and 0.778 for glucose and insulin, respectively). Acipimox administration strongly reduced circulating plasma FFA concentrations during exercise (175±13 vs 535±47 and 637±58 mmol/L in the ACP vs CON and PLA, respectively; P<0.001). Circulating plasma glucose (tAUC, 3500±124 vs 3794±172 and 3946±183 mmol/L/450min) and insulin (tAUC, 76±7 vs 106±13 and 103±13 nmol/L/450min) excursions were substantially lower during 7.5 h of recovery from exercise (*i.e.* postprandially) in ACP when compared with either CON or PLA (P<0.05 and <0.001, respectively).
Conclusion: Exercise with adipose tissue lipolytic inhibition improves postprandial blood glucose regulation and thus clinical efficacy as compared to exercise alone in male T2DM patients.

The effects of feeding a sodium caseinate derived hydrolysate on glycaemic control and insulin sensitivity following an oral lipid load

E.B. Kennedy[1], E. Meaney[1], L.A. Shakerdi[2], A.B. Nongonierma[3], R.J. Fitzgerald[3], C.W. Le Roux[2], H.M. Roche[1];
[1]Nutrigenomics Research Group, UCD Conway Institute, UCD Institute of Food and Health, University College Dublin, [2]Diabetes Complications Research Centre, UCD Conway Institute, School of Medicine and Medical Sciences, University College Dublin, Dublin, [3]Department of Life Sciences and Food for Health Ireland (FHI), University of Limerick, Limerick, Ireland.

Background and aims: Obesity with its associated state of chronic low-grade inflammation with dysregulated metabolism is a major driver of insulin resistance (IR). Dysregulated postprandial insulin and glucose responses, which are hallmarks of IR, are among the main therapeutic targets. Intake of casein and casein derived hydrolysates are associated with increased insulin secretion and reduced glucose levels. Certain casein hydrolysates are also associated with reductions in metabolic inflammation and improvements in insulin signaling. The current study addressed the hypothesis that a sodium caseinate (NaCas) derived bioactive hydrolysate could improve glycaemic control in an obese insulin resistant cohort, using an oral lipid load combined with a hyperinsulinemic euglycaemic clamp technique, using an acute metabolic challenge approach.
Materials and methods: Six obese male volunteers participated in this randomized cross-over controlled trial. Following an overnight fast, participants received an oral lipid load (100 mL soyabean oil) to induce IR. After 2 hours volunteers completed a 4 hour hyperinsulinemic-euglycaemic clamp (30 mU/m^2/min) combined with either 12g sodium caseinate (NaCas), 12g NaCas derived bioactive hydrolysate or a water control (Figure 1). Glucose, insulin, triacylglycerol (TAG), non-esterified fatty acids (NEFA), C-peptide, GIP and GLP-1 responses were determined after the oral lipid load, with or without oral administration of the NaCas derived hydrolysate versus NaCas control and water. Data analyzed by repeated measures ANOVA using SPSS statistical software.
Results: Administration of the NaCas derived hydrolysate did not improve whole-body insulin sensitivity following an oral lipid load, compared to the native NaCas or water controls. Consumption of the NaCas derived hydrolysate did not alter glucose metabolism as measured by glucose, insulin and C-peptide concentrations, compared to NaCas or water controls. NEFA concentrations decreased by 36% following the NaCas derived hydrolysate while triglycerides increased by 30% compared to baseline, however this was not significantly different from the NaCas or water controls.
Conclusion: Ingestion of 12g NaCas or NaCas derived hydrolysate did not improve insulin sensitivity compared to a water control in obese, insulin resistant males following an oral lipid load. Despite the promising finding that NaCas increases insulin secretion and improves insulin signaling this does extend to improved insulin sensitivity in the current study.

Exenatide LAR decreases cIMT and improves flow mediated dilation similarly in obese and non-obese patients with type 2 diabetes: an 8-month prospective study

G. Castellino[1], C. Mannina[1], A.M. Patti[1], R. Galletta[1], R. Chianetta[1], D. Nikolic[1], R.V. Giglio[1], R. Citarrella[1], A.A. Rizvi[2], G. Montalto[1], M. Rizzo[1,2];
[1]Biomedical Department of Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy, [2]Division of Endocrinology, Diabetes and Metabolism, University of South Carolina, School of Medicine, Columbia, USA.

Background and aims: The increasing prevalence of type 2 diabetes (T2DM) may be explained by increased rate of obesity. Treatment with GLP-1RA, exenatide once-weekly (long-acting release, LAR), after 3 and 5 years, led to sustained body weight loss. Here we investigated whether exenatide LAR may exert different effects on several cardio-metabolic parameters in obese vs. non-obese T2DM patients.
Materials and methods: Sixty subjects with T2DM (41 men and 19 women; 60±10 yrs) naïve to incretin-based therapies, and treated with exenatide LAR as add-on to metformin (from 1500 up to 3000 mg/day) for 8 months, were included in this prospective study. The presence of a previous major cardiovascular event, as well as moderate and severe renal and liver function were the main exclusion criteria. Fasting blood samples were collected at baseline and after 8 months for routine biochemical analysis. The cohort of patients was subdivided in 2 groups: 1) those with body mass index (BMI) ≥30 (n=31) and 2) those with BMI <30 (n=29). The fatty liver index (FLI) was calculated in each subgroup. cIMT was assessed by B-mode real-time ultrasound, while endothelial function by flow mediated dilation (FMD) of the brachial artery.
Results: Statistical analysis was performed using paired t-test and ANOVA. After 8 months of exenatide therapy, improvements in all investigated parameters were seen in both groups (Table). In addition, alanine and aspartate transaminases (AST and ALT) significantly improved in obese patients only (AST: from 22.3±8.0 to 18.4±4.3 U/L, p=0.006 in obese vs. from 22.1±10.2 to 20.7±8.5 U/L, p=0.340 in non-obese; ALT: from 30.1±14.4 to 24.2±12.8 U/L, p=0.004 in obese vs. from 27.9±17.2 to 26.7±18.1 U/L, p=0.609 in non-obese). FLI improved only in obese patients (Table).
Conclusion: This is the first study reporting that exenatide LAR provides significant and equally beneficial cardio-metabolic control, reducing cIMT and improving FMD, in both obese and non-obese T2DM patients. Greater weight loss, decrease in waist circumference and improvement in hepatic parameters were seen in obese vs overweight patients. Whether exenatide LAR use is associated with sustained decrease in obesity rates, in addition to its benefits cardio-metabolic parameters, remains to be established by future studies.

Improvement in flow-mediated dilatation and proinflammatory cytokines with exenatide LAR occurred independently of baseline carotid IMT in patients with type 2 diabetes

A.M. Patti[1], C. Mannina[1], G. Castellino[1], R. Catalfio[1], R.V. Giglio[1], D. Nikolic[1], R. Chianetta[1], R. Citarrella[1], G. Montalto[1], A.A. Rizvi[2], M. Rizzo[1,2]; [1]Biomedical Department of Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy, [2]Division of Endocrinology, Diabetes and Metabolism, University of South Carolina, School of Medicine, Columbia, USA.

Background and aims: The effect of exenatide once-weekly (long-acting release, LAR) on carotid intima-media thickness (cIMT), a surrogate marker of early, subclinical atherosclerosis, is still unknown. We aimed to investigate: 1) whether exenatide LAR may have different effects on cIMT, depending on the value at baseline, and 2) whether this effect is associated with the exenatide modulation of cardio-metabolic parameters, including cytokines potentially involved in endothelial function.

Materials and methods: Sixty subjects with type 2 diabetes (41 men and 19 women; 60±10 yrs) naïve to incretin-based therapies, and treated with exenatide LAR as add-on to metformin (from 1500 up to 3000 mg/day) for 8 months, were included in this prospective study. Exclusion criteria included the presence of a previous major cardiovascular (CV) event, as well as moderate and severe renal and liver function. Fasting blood samples were collected at baseline and after 8 months for routine biochemical analysis. The cohort of patients was subdivided in 2 groups: 1) those with cIMT ≤0.9 mm (considered as a normal value; n=27) and 2) those with cIMT >0.9 mm (considered as an abnormal value; n=33). cIMT was assessed by B-mode real-time ultrasound, while endothelial function was assessed by flow mediated dilation (FMD) of the brachial artery. Cytokines were measured by multiplex analysis using Luminex Magpix®.

Results: Statistical analysis was performed by paired t-test and ANOVA. After 8 months of exenatide therapy, improvements in the majority of assessed cardio-metabolic parameters were seen in both groups of patients (Table). However, improved lipid profile was seen in patients with abnormal cIMT only. Several cytokines improved in the abnormal cIMT group: a decrease was seen in plasminogen activator inhibitor-1 (PAI-1) (from 2.8 ±1.6 to 1.4±0.7 ng/ml; p=0.022), p-selectin (from 11.42±6.8 to 7.1±3.9 ng/ml, p=0.002), interleukins (IL)-2 and 1-B (from 9.3±5.0 to 5.8±2.2 pg/ml, p=0.001 and from 1.2±0.6 to 0.9±0.2 pg/ml, p=0.041, respectively), while a cell adhesion molecule with a key role in endothelial function, L-selectin, increased (from 0.49±0.16 to 0.59±0.23 μg/ml, p=0.018).

Conclusion: This study shows that, in patients with type-2 diabetes, exenatide LAR improves several cardio-metabolic parameters and such effects seem to not be impacted by early, subclinical atherosclerosis. The improvements in investigated cytokines seen only in patients with an abnormal cIMT levels at baseline may, at least in part, explain further protective effects of exenatide in those patients. Whether this finding may be associated with CV prevention remains to be established by future studies.

Dulaglutide protects beta cells against cytokine stress by anti-oxidative, anti-inflammatory pathways and modification of membrane remodelling

G. Kreutter[1], A. El Habhab[1], M. Kassem[1], L. Amoura[1], F. Zobairi[1], F. Toti[1], G. Ubeaud-Sequier[1], L. Kessler[1,2]; [1]EA 7293 Stress vasculaire et tissulaire en transplantation, [2]DIabetologia-Endocrinology, Hospital University of Strasbourg, Strasbourg, France.

Background and aims: Inflammation and oxidative stress are major actors in type 2 diabetes. They prompt pancreatic cell dysfunction associated with membrane remodeling and the release of noxious microparticles (MPs) with pro-apoptotic, pro-inflammatory and pro-coagulant effects. MP are plasma membrane vesicles and procoagulant circulating biomarkers of cell stress and organ damage. In vitro, MPs shed from cytokine or oxidative stress-stimulated β cells act as cellular effectors prompting tissue factor (TF) expression, cytokine release, apoptosis and reducing insulin secretion We investigated whether Dulaglutide (Dula), a GLP-1 analog, could prevent cytokine-driven β cell dysfunction.

Materials and methods: Rin-m5F rat β cells and freshly isolated rat islets were submitted for 24 hours to cytokines (cyt: 1000 IU/ml TNF-α, 50 IU/ml IL1β 1000 IU/ml INF-γ) in the presence of Dula (0.05-1μM). GLP1R-dependent effects were inhibited by 200 nM exendin9-39 (Ex), a GLP1R antagonist. Apoptosis was measured by Propidium Iodide / Annexin 5 staining, MP release by prothrombinase assay, insulin secretion by ELISA. TF activity at β cell surface was measured by tenase assay and reported as fM per 50'000 cells. Islet total ROS amount was quantified by DiHydroEthidium staining and mitochondrial ROS by the MITOSOX fluorescent probe. Inflammatory pathway was explored by study NF-KB pathway by Western blot analysis.

Results: Dula (1-0,05 μM) significantly reduced β cell apoptosis induced by cytokines in a concentration-dependent manner (Cytokines: 17% ± 1 vs Dula 1μM: 8 % ± 1% ; 0.2 μM: 13 %± 1,; 0.05 μM 14% ± 1, vs. p <0.01, n = 4) and 1μM Dula completely abolished the apoptotic response (untreated cells : 8% ± 1). Cell pretreatment with the receptor antagonist GLP1R for 1 hour caused a sharp decline in the protective effect of Dula, indicating a GLP1 receptor-R dependent cytoprotection (Apoptosis: Cyt 17 % ± 1; Dula 1 μM: 9% ± 2; Dula + Exendin: 14 % ± 1, n = 4). Dulaglutide (1μM) limited the release of MP in the supernatant of cytokine- treated and untreated cells (untreated: 8.5 nM± 0.3; Untrd + Dula: 6.3 nM ± 0.5 ; Cyt: 12.2 nM ± 0.5, Cyt + Dula: 10, 6 nM± 0.1; p <0.01, n = 4) and was also dependent on GLP1R (cyt+ Dula +Exe: 12.8 nM ± 0.7, p <0.01, n = 4). Dulaglutide (1μM) decreased TF activity induced by cytokines at β cell surface (Untrd: 95 f. ± .11, Cyt: 211 f. ± 27, cyt+ Dula: 113 ± 5, p <0.05). However, the inhibitory effect of Dula on TF activity seemed independent of the GLP1-R (Cyt+ Dula+ Exendin: 95 fM± 20, p <0.05). Dulaglutide (1μM) decreased the amount of total ROS in islets by 50 % and mitochondrial ROS by 40 % (n=4, p<0.05). Western blot confirmed that expression of ratio pIKB/IKB is altered in cells submitted to cytokine stress and restored by pretreatment with dulaglutide.

Conclusion: Dulaglutide exerts cytoprotection on β cell by drastic reduction of apoptosis and by limiting inflammatory response through GLP-1R dependent- and non-dependent GLP1R pathways prompting membrane remodeling and microparticles release. Cytoprotection against oxidative stress was also obtained in isolated islets. Further studies are ongoing to characterize the underlying signalling pathways. The cytoprotective effect of Dulaglutide on islets will be further investigated in murine models of T2D.

Changes in lipid concentrations in patients with type 2 diabetes on once-weekly dulaglutide 1.5 mg: post hoc pooled analysis of the AWARD trials

I. Pavo[1], L.-E. García-Pérez[1], Y. Tao[1], V.T. Thieu[1], N.A. Sattar[2];
[1]Eli Lilly and Company, Indianapolis, USA, [2]Institute of Cardiovascular and Medical Sciences Glasgow, Glasgow, UK.

Background and aims: Glucagon-like peptide (GLP)-1 receptor agonists may improve lipid profiles in patients (pts) with type 2 diabetes (T2D), but few large scale studies exist.
Materials and methods: A post hoc, pooled analysis of 5 studies (AWARD 1, 2, 3, 5 and 6) of once-weekly dulaglutide (DU) 1.5 mg added to oral glucose lowering agents was conducted to evaluate the magnitude of the lipid changes. Associations between lipid changes and baseline covariates were analysed in a multivariable model.
Results: A total of 1424 pts were included: mean (SD) age was 55.6 y (9.9), diabetes duration 6.9 y (5.6), BMI 32.6 kg/m^2 (5.3) and HbA1c 63.9 (12.0) mmol/mol [8% (1.1)], with 683 (48%) on lipid lowering agents (LLAs, 91% statins). DU 1.5-mg treatment for 6 months resulted in modest changes in Total-C and LDL-C (Table). Greater reduction in LDL-C was observed in males (by 0.12 mmol/L vs. females, p<.001) and those on LLAs (by 0.11 mmol/L vs. pts without LLAs, p=.003). Similar associations were observed for Total-C. In addition, pts with higher baseline Total-C, LDL-C and triglycerides had more marked reduction in the respective indices (p<.001 for all) at 6 months.
Conclusion: Treatment with DU 1.5 mg in pts with T2D resulted in modest but statistically significant decreases in Total-C and LDL-C. Preliminary data suggest that these lipid changes are greater in males and those on statin therapy. The clinical relevance of these changes requires further investigation.

Mean Change in Lipids from Baseline to 6 Months with Once-Weekly DU 1.5 mg

Lipid	Baseline (mmol/L) Mean (SD)	Δ From Baseline (mmol/L) LSM (95% CI)	Δ From Baseline (%) LSM (95% CI)	p-value
Total-C	4.7 (1.1)	−0.13 (−0.21, −0.05)	−2.8 (−4.5, −1.0)	.002
LDL-C	2.6 (0.9)	−0.11 (−0.18, −0.04)	−4.2 (−6.9, −1.5)	.002
HDL-C	1.2 (0.3)	0.03 (−0.02, 0.09)	2.6 (−1.9, 7.1)	.26

3-month results for GOAL-RCT: a randomised trial comparing colesevelam vs ezetimibe in type 2 diabetes

H.S. Bajaj[1], R. Brown[2], D. Jiandani[2], K. Venn[2], A. Jain[2], H. Al-Asaad[2], H. Khandwala[2], O. Steen[2], S. Abdel-Salam[2], R. Aronson[2];
[1]LMC Diabetes & Endocrinology, Brampton, [2]LMC Diabetes and Endocrinology, Toronto, Canada.

Background and aims: Lipid-lowering therapies are often added to statin drugs in patients with type 2 diabetes (T2D) who fail to achieve target LDL cholesterol. Our objective was to compare the efficacy and safety of two second-line LDL lowering options: colesevelam (COL) vs. ezetimibe (EZE) in T2D.
Materials and methods: GOAL-RCT is the first randomized controlled trial comparing COL vs. EZE (NCT02682680). The 6-month, open-label, randomized, parallel-group, multicentre trial enrolled 200 patients with T2D who had uncontrolled A1c (7 - 10%) and LDL cholesterol (>2 mmol/L); and randomized them to either COL (3.75g daily) or EZE (10 mg daily) in a 1:1 ratio. The randomization was stratified for use of Sodium glucose co-transporter 2 inhibitors (SGLT2i). T2D medications as well as statin dose were unchanged during the trial. The primary outcome was the proportion of patients achieving A1c ≤7.0% and LDL ≤2 mmol/L. We present the protocol-specified 3-month results for the randomized trial.
Results: GOAL-RCT enrolled 200 subjects with comparable baseline characteristics: mean age 59 ± 10 years, mean A1c 8.0% and mean LDL 2.5 mmol/L. T2D therapies included metformin (88%), insulin (85%), Dipeptidyl peptidase-4 inhibitor (63%), and SGLT2i (52%). 97% of the enrolled subjects were on statin medications. Table 1 outlines the main results for the trial at 3 months. Three month data were available for 85 COL patients and 98 EZE patients. The proportion of patients achieving A1c ≤7.0% and LDL ≤ 2 mmol/L in the COL arm (14%) was non-inferior to the proportion in the EZE arm (9%) (p <0.01 for non-inferiority; p = 0.28 for superiority). The COL arm had a lesser reduction in both LDL (-0.28 vs -0.65 mmol/L; p<0.01) and non-HDL (-0.32 vs -0.74, P<0.01) but a greater reduction in A1c (-0.4% vs. 0%; p<0.01) compared to EZE, respectively. No significant differences were noted between fasting plasma glucose, triglycerides, HDL and CRP levels. Fifteen COL patients and 6 EZE patients discontinued study treatment (7 and 5 subjects due to adverse effects, respectively). SGLT2i was used by 104 patients, with retrospective analysis suggesting a historical rise in LDL from pre-SGLT2i use of 0.27 mmol/L, a 12% increase (p=0.01). Following randomization, within this SGLT2i subgroup, the COL arm had a lesser reduction in LDL (-0.29 vs -0.81 mmol/l; p=0.05), and a greater reduction in A1c (-0.3% vs. +0.1%; p=0.05) compared to EZE, respectively.
Conclusion: When used in combination with statin therapy, the proportion of patients with T2D achieving A1c ≤7.0% and LDL ≤2 mmol/L was similar for COL and EZE at 3 months. EZE produced greater reductions in both LDL and non-HDL cholesterol whereas only COL led to reduction in A1c.

Table 1 – Comparison of clinical efficacy parameters at 3 months between colesevelam and ezetimibe among subjects with type 2 diabetes

	colesevelam (n=85)		ezetimibe (n=98)		Between-group difference (95% CI) (ezetimibe as reference)
Proportion achieving A1c ≤ 7.0% and LDL ≤2.0 mmol/L	14.0%		9.2%		-5.1% (-13.8 to 3.6%)
Proportion achieving A1c ≤ 7.0%	35.3%		14.3%		-20.0% (-33.7% to -7.8%)
Proportion achieving LDL ≤ 2 mmol/L	43.5%		69.4%		25.9% (10.8% to 39.7%)
	Baseline	3 month Δ	Baseline	3 month Δ	Between-group difference (95% CI)
A1c (%)	8.0 ± 0.9	-0.4 ± 0.92	8.0 ± 0.8	0.0 ± 0.7	-0.4* (-0.6 to -0.1)
LDL (mmol/L)	2.54 ± 0.66	-0.28 ± 0.85	2.50 ± 0.56	-0.65 ± 0.80	0.37* (0.12 to 0.61)
Non-HDL (mmol/L)	3.34 ± 0.78	-0.32 ± 0.98	3.19 ± 0.73	-0.74 ± 0.99	0.42* (0.12 to 0.70)

* significant difference between groups (P<0.05).

The effects of lobeglitazone on glycaemic control and lipid metabolism in high-fat diet-induced diabetic mice

H. Kim[1], N. Cho[1], E. Han[1], J.-H. Park[2], H. Cho[1];
[1]Department of Endocrinology, Internal Medicine, Keimyung University DongSan Medical Center, [2]Department of Physiology, Keimyung University School of Medicine, Daegu, Republic of Korea.

Background and aims: The aim of this study was to compare the effects of lobeglitazone, a novel peroxisome proliferator-activated receptor-γ agonist, on glycemic control and lipid metabolism with pioglitazone in mice with type 2 diabetes. We also determined the effects of lobeglitazone and pioglitazone on glucose uptake, translocation of GLUT4 and AMPK activity in 3T3L-1 adipocytes.
Materials and methods: 4-week-old C57BL/6 mice were treated with a high-fat diet for 8 weeks. After 8 weeks of high-fat diet, lobeglitazone or pioglitazone was administered once daily by oral gavage for 6 weeks.
Results: Low-dose lobeglitazone (1 mg/kg) improved fasting blood glucose and insulin levels, HOMA-IR index, and blood triglyceride levels while low-dose pioglitazone did not. In 3T3L-1 cells, low-dose lobeglitazone (1 μM) significantly increased cellular glucose uptake and, GLUT4 translocation. Pioglitzone exhibited similar effects at only high dose treatment (10 μM). High-dose lobeglitazone (10 μM) increased total cellular GLUT4 protein content while pioglitazone did not. In subcutaneous fat and 3T3L-1 cells, relative mRNA expression levels for lipid synthesis were increased in both lobeglitazone and pioglitazone-treated groups compared to vehicle-treated group, but mRNA expression levels of β-oxidation-related genes and the energy expenditure-related genes were significantly increased in lobeglitazone-treated group compared to pioglitazone-treated group. In addition, lobegitazone treatment significantly increased phosphorylation of the AMP-activated protein kinase compared to pioglitazone treatment in 3T3L-1 cells.
Conclusion: These results indicate that low-dose treatment of lobeglitazone might be enough to improve glucose intolerance while pioglitazone dose not. In addition, lobeglitazone could improve lipid metabolism by stimulating β-oxidation and the energy expenditure through activation of AMPK in adipocyte.

DPP4 inhibition by linagliptin prevents the development of heart failure with preserved ejection fraction in the metabolic syndrome ZSF1 rats

S. Heymans[1], I. Cuijpers[1], A.-P. Papageorgiou[1], P. Carai[1], T. Klein[2];
[1]Maastricht University Medical Centre, Maastricht, Netherlands, [2]Boehringer Ingelheim Pharma GmbH & Co, Biberach, Germany.

Background and aims: Heart failure with preserved ejection fraction (HFpEF) is the most common HF phenotype. HFpEF is highly prevalent in elderly women and frequently accompanied by a cluster of comorbidities, including obesity, type 2 diabetes mellitus, arterial hypertension, chronic obstructive pulmonary disease (COPD), renal insufficiencies and anaemia. Currently, the pathophysiology underlying HFpEF is not fully elucidated resulting in the absence of prevention and treatment strategies. As the anti-diabetic drug Linagliptin, a dipeptidyl peptidase 4 (DPP-4) inhibitor, has been shown to have cardioprotective effects (e.g. improvement of diastolic dysfunction and cardiac inflammation), we hypothesized that Linagliptin could protect against HFpEF development (hypertrophy, inflammation, fibrosis and diastolic dysfunction) in a chronic metabolic risk-induced HFpEF animal model.
Materials and methods: Sixteen weeks old obese ZSF-1 rats received Linagliptin supplemented diet (83 mg/kg; n=7) or placebo chow (n=7) for four weeks, while hypertensive non-diabetic Lean ZSF-1 rats, which do not develop HFpEF, served as non-diseased controls (n=5).
Results: Linagliptin significantly reduced plasma DPP4 activity by 81.9% and elevated active glucagon-like peptide 1 (aGLP1; inhibited by DPP4) by 271.3% in obese ZSF1 rats proving its therapeutic potential. In line, Linagliptin significantly diminished the fasting glucose levels by 33.5% in diabetic obese ZSF1 rats. Importantly, Linagliptin decreased cardiac hypertrophy as reflected by a significantly diminished left ventricular weight to tibia length (-9%) and a trend towards reduced cardiomyocyte size (-16.2%; p=0.05) in obese ZSF1 rats. Moreover, Linagliptin improved left ventricular diastolic dysfunction as reflected by a 24.1% reduction in deceleration time, an indicator of left ventricular stiffness, in obese ZSF1 rats. In addition to reducing cardiac hypertrophy and improving diastolic function, Linagliptin significantly cardiac leukocyte infiltration, while inducing a trend towards reduced systemic (pro-inflammatory) monocyte levels (-33.9%; p=0.08) in obese ZSF1 rats suggesting that Linagliptin has an anti-inflammatory effect both systemic and cardiac. Furthermore, Linagliptin significantly reduced perivascular fibrosis (-27.7%) and elevated the coronary capillary density (+52.8%) in obese ZSF1 rats proposing a vascular effect. In addition, Linagliptin ameliorated the MetS phenotype as reflected by significantly diminished total body weight (-11.5%), %), spleen (-18.1%), kidney (-19.7%), liver (-34.9%) weight to tibia length and plasma triglycerides (-51.8%) and non-HDL cholesterol levels (-31.2%), while elevating plasma HDL levels (+75.0%) in obese ZSF1 rats.
Conclusion: The anti-diabetic drug Linagliptin diminished cardiac hypertrophy, inflammation, capillary rarefaction and overall diastolic dysfunction in a rat model for diabetes-, obesity- and hypertension-induced chronic HFpEF. In addition, Linagliptin ameliorated the MetS phenotype as reflected by diminished total body and relative organ weight, systemic inflammation, hyperglycaemia, and Therefore, Linagliptin could be a novel treatment for HFpEF.

Exposure to maternal obesity differentially impacts pancreatic islet function in male and female offspring

L.M. Nicholas, L.C. Kusinski, D.S. Fernandez-Twinn, S.E. Ozanne; University of Cambridge, Cambridge, UK.

Background and aims: Studies have shown that not only does current obesity increase the risk of developing type 2 diabetes (T2D), but obesity during pregnancy can increase the risk of T2D in the offspring. Abnormalities in β-cell function are critical in defining the risk and development of T2D; a defining event in T2D pathogenesis is when functionally impaired β-cells can no longer compensate for insulin resistance in peripheral tissues. In contrast, sustained β-cell adaptation is capable of preventing T2D even in the face of severe insulin resistance. The aim of this study was, therefore, to elucidate whether exposure to maternal obesity (MO) during pregnancy and lactation programs changes in pancreatic islets and whether these changes are different between male and female offspring.

Materials and methods: Mice were generated using a well-established mouse model of MO. Briefly, female mice were fed ad libitum either a chow diet or highly palatable energy-rich obesogenic diet prior to and throughout pregnancy and lactation. Offspring were weaned onto a chow diet and remained on this diet until 8 weeks of age. At this age, offspring had normal body weight thus allowing the investigation of the impact of MO independently of offspring obesity. Pancreatic islets were isolated from male and female offspring. Islets were stimulated with low (2.8mM) and high (16.7mM) glucose ex vivo and insulin and proinsulin secretion as well as content was determined by ELISA. Insulin secretion was also determined upon stimulation with leucine/glutamine (Leu/Gtn; mitochondrial fuel) and potassium chloride (KCl). Mitochondrial (mt) respiration was assessed using Seahorse XF24. Expression of Ins1, Ins2, Tfam and mt encoded genes in islets was determined by qRT-PCR. Data were analysed using an unpaired t-test. A probability level of 5% was taken to be significant.

Results: Glucose-stimulated insulin secretion from islets was increased ($P<0.05$) in both male and female offspring exposed to MO. In females but not males, this was primarily due to increased mt metabolism and exocytotic capacity of islets as reflected by increased Leu/Gtn ($P<0.01$) and KCl-stimulated ($P<0.05$) insulin secretion. Furthermore, islets from female offspring displayed increased mt respiration in response to glucose ($P<0.01$) as well as increased ATP turnover ($P<0.01$). Expression of mt encoded genes mt-Nd5 ($P<0.01$), Cyb ($P<0.001$) and Co1 ($P<0.05$) was increased but the mt transcription factor Tfam was unchanged. Ins1 ($P<0.01$) and Ins2 ($P=0.06$) gene expression was also increased in these islets. In contrast, both mt respiration ($P=0.057$) and ATP turnover ($P<0.05$) were decreased in islets from male offspring. Expression of mt genes and Tfam was unchanged whilst Ins1 expression was increased ($P<0.01$) in these islets. Whilst islet insulin and proinsulin content was unaffected in male offspring exposed to MO, islet proinsulin:insulin content ($P<0.05$) was decreased in female offspring.

Conclusion: Compensatory changes are present in the islets of female offspring exposed to MO that are not present in male offspring. This study is the first to demonstrate sexual dimorphism in the programming of altered pancreatic islet function in the offspring in response to the chronic hyperglycemic environment of MO and may explain differences in time course of the development of offspring glucose intolerance.

Reduced insulin causes weight loss without affecting glucose homeostasis

M.M. Page[1], S. Skovsø[1], H. Cen[1], D.A. Dionne[1], A.P. Chiu[2], D.F. Hutchinson[1], G.E. Lim[3], M. Szabat[1], B. Rodrigues[2], J.D. Johnson[1]; [1]Department of Cellular and Physiological Sciences, University of British Columbia, [2]Pharmaceutical Sciences, University of British Columbia, Vancouver, [3]Centre de Recherche du Centre Hospitalier de l'Université de Montreal and Department of Medicine, University of Montreal, Montreal, Canada.

Background and aims: Obesity is an epidemic affecting more than 500 million people worldwide. Furthermore, it is a risk factor to several diseases, including diabetes, heart disease, stroke and cancer. Obesity is commonly associated with basal hyperinsulinemia and insulin resistance, but the cause and effect relationship between obesity, hyperinsulinemia, insulin resistance and type 2 diabetes remains to be fully elucidated. Some evidence suggests a causal role for hyperinsulinemia in obesity, independently of insulin resistance. Drugs that block hyperinsulinemia have been reported to cause weight loss in humans, but this remains controversial and has been suggested that such drugs work independently of insulin. We previously reported that both life-long and early life transient suppression of basal hyperinsulinemia in mice resulted in protection from diet-induced obesity. These results provide evidence that hyperinsulinemia can play a causal role in mammalian obesity, however it is still unclear whether insulin reduction in adult, obese mice would result in weight loss. To address this critical therapeutic question, we developed a mouse model of acute 50% deletion of the *Ins2* gene.

Materials and methods: We generated an inducible, beta-cell specific insulin gene heterozygous mice ($Pdx1^{CreER}$:$Ins1^{-/-}$:$Ins2^{fl/+}$) to test the hypothesis that diet-induced obesity can be lowered by simply reducing pancreatic insulin production, which would indicate that long-term developmental reprogramming of the insulin system is not required to protect mammals from obesity. Low (10%), moderate (25%) and high fat (58% fat) diets were initiated in male mice at 6 weeks of age. Following 12 weeks on the respective diets, test and littermate control mice were injected with tamoxifen resulting in the inducible loss of one *Ins2* allele in test mice.

Results: Following 12 weeks on a high fat diet, all mice weighed approximately 40 grams. Remarkably, inducible reduction of pancreatic *Ins2* gene dosage in tamoxifen-injected $Pdx1^{CreER}$:$Ins1^{-/-}$:$Ins2^{fl/+}$ mice resulted in a rapid 5% weight loss within 5 weeks. This effect was only noted in mice fed a high fat diet (HFD) and the weight loss observed in these mice was due primarily to significantly reduced gonadal (control 3.3±0.3g vs test 2.2±0.2g; $p<0.05$) and perirenal (control 0.8±0.1g vs test 0.6±0.1g; $p<0.05$) fat mass. Protein levels of the lipodystrophy gene PTRF were ~50% lower ($p<0.05$) and an ~35% reduction in LPL protein levels ($p=0.06$) in the test mice compared to controls, suggesting impaired lipid storage. Weight loss appeared to be unaffected by food intake and was not associated with glucose intolerance in these mice. Furthermore, transcriptional sequencing revealed slight but significant down regulations in several innate immune related genes within gonadal adipose tissue isolated from test mice compared to controls.

Conclusion: Together, these data provide the first evidence in any organism that obesity can be reversed by acutely reducing the production and circulation of insulin. Our results have profound implications for nutritional guidelines and therapeutic efforts to combat obesity.

Mutation of OXPHOS NADH-dehydrogenase subunit 2 improves age-dependent adaption of energy metabolism in liver tissue

M. Wietzke, S. Schröder, S.E. Baltrusch, M. Tiedge;

Institute of Biochemistry and Medical Molecular Biology, Rostock, Germany.

Background and aims: The mitochondrial genome of the conplastic B6-mt^{ALR} mouse strain is characterized by a mtDNA encoded *ND2* mutation in complex I of the respiratory chain. OXPHOS mutations in liver are linked to obesity, liver steatosis and diabetes. Liver from B6-mt^{ALR} mouse showed high levels of ROS production only at late life but without susceptibility to hepatosteatosis. In this study we investigated the effect of the mutation on basic parameters of hepatocellular energy metabolism, response to nutrient challenge and AMPK activation in the course of aging.
Materials and methods: Conplastic B6-mt^{AKR} (AKR, control) and B6-mt^{ALR} (ALR, *ND2* mutation) mice were monitored over a period up to 24 months. At defined time-points liver tissue was analysed by Western blot analysis for AMPK activation. Hepatocytes were isolated at the age of 3, 6 and 12 months. In cultured hepatocytes ATP and ADP levels were measured by a luminescence assay. Glucose-induced changes of the ATP/ADP ratios were monitored after transfection of the hepatocytes with the ATP sensor Perceval.
Results: ATP and ADP level were higher in isolated hepatocytes of ALR mice at the age of 3 up to 12 month compared to control mice. Nucleotide levels remained unchanged during aging in the AKR control strain. In contrast to that the mutant strain exhibit significant increased ATP (4.4 vs. 10.9 nmol/mg Protein) and ADP (1.8 vs. 4.5 nmol/mg Protein) amounts at the age of 3 month. Thus, the *ND2* mutation was associated with an increased OXPHOS activity. There was also a lower fat accumulation in liver tissue in ALR compared to AKR mice. The data are in line with higher pAMPK/AMPK ratios in liver of ALR compared to the AKR mice at the age of 3 months. Challenge of isolated hepatocytes by 25 mM glucose resulted in different adaptation of the ATP/ADP ratios (ALR vs. AKR: 3 month, 0.56 AUC vs. 0.35 AUC; 12 month, 0.39 AUC vs. 0.14 AUC, $p < 0.05$) measured after Perceval transfection. Changes of ATP/ADP ratios decreased with aging in hepatocytes but were always lower in liver from ALR mice.
Conclusion: In conplastic ALR mice the mtND2 mutation in complex I of the respiratory chain favored better hepatic energy supply and nutrient sensing during aging. Despite of ROS generation the improved hepatic energy metabolism and AMPK activation in the liver suggesting a protective role against hepatosteatosis in the pathogenesis of diabetes.

The loss of the corepressor GPS2 favors "unhealthy" adipose tissue expansion in obesity leading toward the development of type 2 diabetes

K. Drareni[1], S. Barilla[2], F. Alzaid[1], R. Ballaire[1,2], E. Treuter[2], N. Venteclef[1];
[1]Cordeliers Research Center, Paris, France, [2]Karolinska Institute, Stockholm, Sweden.

Background and aims: Type 2 diabetes (T2D) and insulin resistance are associated with adipose tissue dysfunction. Adipocyte hypertrophy, i.e. the enlargement of pre-existing fat cells, is thought to increase T2D development independent of the level of obesity per se. Many human studies demonstrate that increased fat cell size is a significant predictor of altered blood lipid profiles and glucose-insulin homeostasis independent of adiposity indices. However, the explanation of why individual (obese and some non-obese) humans differ in their susceptibility to develop dysfunctional adipose tissue and adipocyte hypertrophy are still an issue that is currently not sufficiently addressed. Our recent work discovered the deregulation of the transcriptional coregulator GPS2 (G-Protein Pathway Suppressor 2, core subunit of the HDAC3/SMRT corepressor complex), in adipocytes, which may contribute to the development of insulin resistance and T2D in mice and humans.
Materials and methods: In order to identify the functions of GPS2 in adipocytes, we have generated adipocyte specific Knock-Out (AKO) mice. The WT and AKO mice were fed with a high fat diet and subjected to metabolic and transcriptomic analyses. These in vivo observations were complemented by in vitro experiments to decipher GPS2 actions
Results: Our data suggest that adipocyte-specific GPS2 knockout mice are predisposed to adipocyte hypertrophy, leading upon high fat diet to the rapid development of adipose tissue dysfunction and glucose intolerance. Indeed, the specific loss of GPS2 in adipocytes leads to an epigenomic reprogramming that favors inflammation, inadequate angiogenic remodeling and dysregulation of lipid oxydation.
Conclusion: GPS2 seems to play a protective role in adipocyte, influencing energy metabolism and limiting the progression of obesity towards insulin resistance and T2D. Hence maintaining GPS2 function is essential to have a healthy adipose tissue expansion during obesity.

Lack of B1 kinin receptor improves glucose metabolism in mice fed with cafeteria diet

P.E. Correia[1], C.B. Gomes[2], V.A. Bandeira[2], T. Marten[2], P. Merello[1], C.C. Barros[2], F. Gerchman[1];
[1]Endocrinoly Division, Federal University of Rio Grande do Sul, Porto Alegre, [2]Federal University of Pelotas, Pelotas, Brazil.

Background and aims: Previously studies have shown that the kinin B1 receptor (B1R), which is involved in inflammatory regulation, activates metabolic processes that modulate weight regulation and glucose homeostasis. Deletion of this receptor in a transgenic mice model resulted in protection for weight gain in mice submitted to a high fat diet in comparison with wild type controls. As a result, this model may be appropriated to test the effect of a cafeteria diet, which has a composition more related to the one consumed in the modern Western society and related to the development of obesity and diabetes. The aim of this study is to investigate whether the genetic deletion of kinin B1 receptor (B1RKO) might influence in the glucose metabolism of mice submitted to cafeteria diet (CAF).
Materials and methods: Two months old male C57Bl/6 wild-type (WT; 24.2 to 28.6 g) or B1RKO mice (21 to 28.6 g) were fed with standard chow (SC: 65% CHO, 22 % PTN, 10 % LIP) or cafeteria diet (CAF: 63% CHO, 12% PTN, 35% LIP) ad libitum for 14 weeks (WT-SC n= 7; 8 B1RKO-SC n= 8; WT-CAF n=7; B1RKO-CAF n = 10). Food intake was evaluated daily and the mice where weighed weekly. For body weight gain (WG), weight was assessed at baseline ($Weight_0$) and after 14 weeks ($Weight_{final}$) and expressed as the % of WG. After 8 hours fasting, glycemia was measured before and after the intraperitoneal injection of 1g/kg (live weight) of glucose in 10% solution, at times -15, 0, 15, 30 60 and 120 min. Glucose tolerance was assessed by the comparison of the area under curve (AUC) for glucose of each group. Two days later, for the Insulin Tolerance Test (ITT), regular insulin (1UI/kg - live weight) was injected intraperitoneally after 2 hours fasting to measure glycemia at 0, 5, 20 and 30 min and estimate insulin sensitivity as the calculation of the glucose decline relative up to 30 min relative to glycemia at 5 min and presented as the glucose decay constant (Kitt; %/min). Values are expressed as mean ± SEM. $P < 0.05$ was considered statistically significant.
Results: While the groups differ for relative weight gain (B1RK0-Caf 73.63 ± 16.10 ,WT-Caf 45.69 ± 16.95, B1RKO-SC 32.56 ± 5.63 , WT-SC 27.01 ± 5.39 mean ± SE % of WG; Diet p = < 0.0001, Genotype p = 0.0005 , Diet vs. Genotype p = 0.0140), B1RKO mice had similar percentage of perirenal and epidimal fat mass when fed with the same diet as the WT controls. However, WT mice had an increased glucose response as showed in the glucose tolerance test (AUC= 46996 ± 2969 vs. 36776 ± 2634; WT vs. B1RKO respectively; p= 0,016 ; and 50768 ± 2874 vs.

33004 ± 2737 Caf vs. SC respectively; p= 0001), suggesting that B1RKO mice had a better tolerance to a glucose load. No interaction was found when compared diet vs. genotype in the AUC of GTT. When analyzing mice fed with Caf, in the WT group there was a stronger positive correlation between glucose response in the GTT test with the percentage of weight gain (r= 0,821; p= 0,023), while weight gain in the B1RKO group was not related with glucose response during GTT test (r= 0,667; p= 0,071 . In the insulin tolerance test no differences were found between groups.

Conclusion: Mice lacking B1kinin receptor presented a higher glucose uptake despite the highest weight gain. Take together these results, it shows that there was a dissociation between the weight gain and glucose metabolism in obese B1RKO mice when submitted to Cafeteria Diet.

Single-gene congenic strain reveals the effect of Zbtb16 gene on dexamethasone-induced insulin resistance and dyslipidaemia

L. Sedova[1], M. Krupkova[1], F. Liska[1], D. Krenova[1], V. Kren[1], L. Kazdova[2], O. Seda[1];
[1]Institute of Biology and Medical Genetics, Charles University, [2]Center for Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Background and aims: Glucocorticoid treatment is often accompanied with substantial side-effects, including dyslipidemia, diabetes or obesity. The genetic basis of the interindividual differences in response to glucocorticoids received only limited attention so far. By combining two distinct inbred models of metabolic syndorme, the spontaneously hypertensive rat (SHR) and the polydactylous rat (PD), we have previously isolated an apparently pleiotropic locus on rat chromosome 8 affecting major features of metabolic syndrome. We have established a congenic model SHR.PD5 differing from SHR by a 788kb segment of chromosome 8 of the PD origin containing 7 genes. SHR.PD5 is particularly sensitive to dexamethasone-induced insulin resistance and dyslipidemia. The differential segment contains a glucocorticoid-response gene, Zbtb16. To distinguish the effects of Zbtb16 from other candidate genes, we developed a single-gene congenic subline containing only the Zbtb16 gene and a subline containing 6 remaining genes but not the Zbtb16 gene.

Materials and methods: Adult male rats of SHR.PD(Zbtb16) and PD5(-Zbtb16) strains were fed standard diet (STD) and subsequently treated with dexamethasone in drinking water (0.026 mg/ml) for 3 days. We contrasted their morphometric and metabolic profiles (including oral glucose tolerance test, triacylglycerol content in liver and muscle). Insulin sensitivity of skeletal muscle and adipose tissue was determined by assessment of basal and insulin- stimulated radioactivelly-labeled glucose incorporation into glycogen (isolated soleus muscle) or total lipids of visceral adipose tissue. Isolated genomic DNA was amplified by PCR with specific primers, PCR fragments were analyzed by electrophoresis and sequenced directly using PCR primers and the BigDye Terminator v1.1 cycle sequencing kit.

Results: The single-gene SHR.PD(Zbtb16) congenic subline carries a differential segment spanning 254 kb and contains only the Zbtb16 gene. There is one missense SNP in the Plzf as well as a 3kb deletion of the highly conserved noncoding sequence in intron 2 of Zbtb16 in the congenic subline. The second congenic strain PD5(-Zbtb16) carries in its differential segment the same genes as the original SHR.PD5 strain, i.e. Htr3a, Htr3b, Usp28, Zw10, Tmprss5, and part of Drd2 (promoter, first noncoding exon, and part of the first intron). We identified 2 non-synonymous amino-acid substitutions (H364R in Htr3b and T76S in Usp28). SHR.PD(Zbtb16) showed higher body weight compared to PD5(-Zbtb16) (287±7 vs. 265±4 g, p=0.030), higher glucose levels throughout the first 60 minutes of OGTT (no differences in insulin throughout the test), higher level of serum TG (2.08±0.13 vs. 1.64 ±0.10 mmol/l, p=0.015) but lower content of TG in liver (4.95±0.55 vs. 6.48±0.37 μmol/g, p=0.026). While the insulin sensitivity of the adipose tissue was comparable, both baseline and insulin-induced sensitivity of skeletal muscle tissue was significantly lower in SHR.PD(Zbtb16).

Conclusion: Using the minimal congenic strain approach, we have established the substantial role of Zbtb16 gene in dexamethasone-induced insulin resistance and dyslipidemia.

AT2R protect against changes in mitochondrial function in early stages of STZ diabetes

S.C. Hoffmann[1], T. Micakovic[1], M. Papagiannarou[1], H.-J. Gröne[2];
[1]ZMF, University Heidelberg, Mannheim, [2]Department of Cellular and Molecular Pathology, DKFZ, Mannheim, Germany.

Background and aims: Diabetic nephropathy (DN) is associated with structural and functional changes of mitochondria and largely influenced by angiotensin II (AngII). The AngII type 2 receptor (AT2R) often counteract the classic AngII effects which are mainly transmitted via the AT1R. The present study addressed the hypothesis, that the AT2R protects mitochondria during DN

Materials and methods: Transgenic rats (TGR) overexpressing the AT2R in renal tubular epithelial cells for more than 30-fold and wildtype littermates (WT) were either untreated or subjected to STZ-diabetes (35 mg/kg body weight) for 7 months and 21 days, respectively. In addition to kidney function and histology, in 21-day STZ-diabetic rats function of isolated mitochondria and expression profile in renal cortex was determined. Co-localization of AT2Rs with a mitochondrial marker was demonstrated by immunohistochemistry (IHC) and confocal microscopy. For quantification, receptor binding studies using radiolabeled 125I[Sar1,Ile8]-Ang II as a ligand were performed on highly pure mitochondrial fractions, which were validated by electron microscopy and western blot analysis.

Results: 7-months of STZ diabetes induced albuminuria in WT but not in TGR. Early STZ diabetes (21-days) did not alter the kidney function. However, increased lipid and glycogen deposits and changes in mitochondrial structure were observed. Isolated mitochondria exhibited increased oxygen consumption and superoxide production, which was blunted in transgenic mitochondria in parallel to enhanced ATP production. Thus, AT2R improved bioenergetics of renal mitochondria in early diabetes. The gene expression profile of renal cortex was differently altered in WT and TGR. Pathway analysis indicated that in TGR important pathways were regulated in a protective manner when compared with WT rats. Oxidative phosphorylation was highly up regulated and fatty acid degradation by β-oxidation as well as fatty acid metabolism and anaerobic glycolysis were significantly down regulated in diabetic TGR relative to diabetic WT rats. Western blotting revealed an increased expression of all 5 ETC complexes in diabetic TGR when compared to controls and diabetic WT rats. Further, we evidenced the existence of high affine mitochondrial AT2R, their density constitutes 60 % of the AT2R density on the cell membrane.

Conclusion: The AT2R protect against DN already at very early stages of diabetes by improving the bioenergetic efficiency of mitochondrial respiration and by a modification of the diabetes induced alterations in the renal expression profile, which seems to allow the cell to switch from preferred FA oxidation to glucose oxidation and as such preventing the harmful "modified Warburg effect ". These protective actions seem to be transmitted at least partly by mitochondrial AT2R.

BACE2 suppression prevents weight gain in mice fed with high-fat diet

G. Alcarraz-Vizán[1,2], C. Castaño[1,2], A. Fernández-Pérez[3,2], J. Viegas[4,1], P. Macedo[4], M. Vallejo[3,2], M. Párrizas[1,2], J.-M. Servitja[1,2], A. Novials[1,2]; [1]Diabetes and Obesity Laboratory, IDIBAPS, Barcelona, [2]Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Madrid, Spain, [3]Instituto de Investigaciones Biomédicas Alberto Sols. Consejo Superior de Investigaciones Científicas/Universidad Autónoma de Madrid, Madrid, Spain, [4]CEDOC - Chronic Diseases Research Center, NOVA Medical, Universidade Nova de Lisboa, Lisbon, Portugal.

Background and aims: BACE2 (β-site APP-cleaving enzyme 2) is a protease that may play a role in the development of Alzheimer's disease (AD). However, besides the brain, it has also been localized in the pancreas, where it seems to play a physiological role. Nevertheless, despite the potential link between AD and glucose homoeostasis deregulation in humans and rodents, the involvement of BACE2 in metabolic disturbances such as insulin resistance and obesity, has not been explored. Therefore, the aim of the present study was to investigate the effect of BACE2 on whole-body glucose metabolism.

Materials and methods: BACE2-deficient (BACE2-KO) mice and their respective controls were used to analyze the phenotype after 16 weeks of high-fat diet (HFD) feeding. Insulin tolerance test (ITT), glucose tolerance test (GTT) and indirect calorimetry were performed to evaluate metabolic phenotype. mRNA expression of relevant genes from hypothalamus, liver and white adipose tissue was analyzed by quantitative PCR.

Results: BACE2-KO mice fed with HFD showed a 32% reduction in body weight ($p<0.05$), with respect to their wild type counterparts that was accompanied by better glucose homeostasis (28% decrease in the area under curve of GTT, $p<0.01$) and a good insulin sensitivity. Interestingly, BACE2-KO animals in regular diet presented a low respiratory exchange ratio ($p<0.05$) close to the groups of animals fed with HFD. BACE2-KO animals fed with HFD did not show changes in the expression of any of the hypothalamic neuropeptides studied with respect to the animals fed with regular diet. Moreover, regardless the diet, BACE2-KO mice showed an upregulation of the insulin signaling pathway in liver ($p<0.01$) and alterations of fatty acid metabolism markers in liver and white adipose tissue. Furthermore, white adipose tissue from BACE2-KO animals in HFD presented a weight reduction of 25% ($p<0.01$) and a lower expression of the inflammation marker *Ccl2*.

Conclusion: In summary, these results indicate that the absence of BACE2 seems to protect against HFD effects. Thus, targeting BACE2 may represent a good therapeutic strategy to ameliorate the pathological effects of obesity.

Glucose and insulin regulate cholesterol uptake, SR-BI and mRNA levels of genes involved in intestinal lipid transport in polarised CaCo-2 cells

M.N. Fuentes[1], V.A. Cortés[2]; [1]Dep Nutrition Diabetes and Metabolism, Pontificia Universidad Catolica de Chile, [2]Department of Nutrition, Diabetes and Metabolism, Pontificia Universidad Católica de Chile, Santiago, Chile.

Background and aims: Diabetic patients have higher and longer post prandial excursion of triglyceride-rich lipoproteins, suggesting abnormal lipid handling at the intestinal level. The aim of this study was to determine the effects of insulin and glucose stimulation on cholesterol uptake and mRNA levels of genes involved in the transport of lipids in a cellular model of intestinal epithelium.

Materials and methods: CaCo-2 cells (ATCC HTB-37) were grown to 80% confluence and then subcultured into 6-well plates with Transwell inserts to induce polarized differentiation. Cells were stimulated with insulin (100 nM) and/or glucose (5 or 25 mM). mRNA levels were quantified by qRT-PCR using Taqman technology. Individual mRNAs were normalized to GAPDH mRNA levels and expressed as fold-change using the $\Delta\Delta$Ct method. Cholesterol uptake was estimated by the amount of NBD-cholesterol taken up by cells in a plate reader (excitation/emission = 485/535 nm). Polarized CaCo-2 cells were fixed with 4% paraformaldehyde and nuclei (H33342), cholesterol (NBD), neutral lipids (BODIPY), SR-BI and Villin were detected by confocal immunofluorescence. Results were expressed as average ± SD of 6 independent experiments. Statistical significance of the differences was determined by one-way ANOVA and Tukey's multiple comparison test.

Results: In polarized CaCo-2 cells, 25 mM glucose increased the mRNA levels of ChREBP, NPC1L1 and ABCA1 (fold-change to vehicle treated cells: 10.9±3.7, 5.8±2.5, 3.5±1.2, respectively, $p < 0.05$), whereas 100 nM insulin increased the mRNA levels of SREBP1c, ABCA1 and SR-BI (fold change to vehicle treated cells: 7.2±2.8, 2.2±0.9, 13.0±1.4, respectively, $p < 0.05$). The abundance of SR-BI was increased by 100 nM insulin in whole cell protein extracts and confocal analysis showed higher levels of SR-BI exclusively at the apical side of CaCo-2 cells. Glucose treatment did not modify SR-BI levels nor its subcellular localization. Cholesterol uptake was increased by 100 nM insulin and 25 mM glucose separately (fold-change to vehicle treated cells: 1.9±0.3 and 1.2±0.2, respectively) but it was even higher with the combined treatment (fold-change: 2.32±0.6). The abundance of lipid droplets and NBD-cholesterol content was increased by 100 nM insulin, preferentially at the basolateral side of the cells. Glucose did not change the abundance nor the subcellular localization of lipid droplets in polarized CaCo-2 cells.

Conclusion: Glucose increases ChREBP, NPC1L1 and ABCA1, whereas insulin increases SREBP1c, ABCA1 and SR-BI, at the mRNA level in polarized CaCo-2 cells. Insulin, but not glucose, increases SR-BI in the apical surface of CaCo-2 cells and increases cholesterol cholesterol uptake and neutral lipids content, at basolateral side, in CaCo-2 cells. These results suggest that insulin promotes cholesterol uptake and intracellular lipid store in a polarized cell model of intestinal epithelium, possibly by increasing SR-BI levels at the apical surface.

Effects of fatty acids on GLP-1-producing cells

S. Ntika[1], K. Thombare[1], X. Wang[1,2], C. Krizhanovskii[1,3]; [1]Preclinical and Clinical Research, Sodertalje Hospital, Södertälje, [2]Medical Cell Biology, Uppsala University, Uppsala, [3]Molecular Medicine and Surgery (MMK), Karolinska Institute, Stockholm, Sweden.

Background and aims: Fatty acids acutely stimulate GLP-1 secretion from L-cells *in vivo*. However, a high fat diet has been shown to reduce the density of L-cells in the mouse intestine and a positive correlation has been indicated between L-cell number and GLP-1 secretion. Thus, the mechanism of fatty acid-stimulated GLP-1 secretion, potential effects of long term exposure to elevated levels of different fatty acid species, and underlying mechanisms are not fully understood. In the present study, we sought to determine how long-term exposure to saturated (16:0) and unsaturated (18:1) fatty acids, by direct effects on GLP-1-producing cells, alter function and viability, and the underlying mechanisms.
Materials and methods: GLP-1-secreting GLUTag cells were cultured in the presence/absence of saturated (16:0) and unsaturated (18:1) fatty acids (0.125 mmol/L) for 48 h, followed by analyses of viability and apoptosis, as well as involvement of fatty acid oxidation, free fatty acid receptors (FFAR1) and ceramide synthesis. In addition, effects on the expression of proglucagon, prohormone convertase 1/3 (PC1/3), free fatty acid receptors (FFAR1/2), sodium glucose co-transporter (SGLT) and subsequent secretory response were determined.
Results: Saturated (16:0) and unsaturated (18:1) fatty acids exerted opposing effects on the induction of apoptosis (1.4-fold increase in caspase-3 activity and DNA fragmentation by palmitate versus a 0.3-fold reduction in caspase-3 activity and 0.5-fold reduction in DNA fragmentation in response to oleate; $p<0.01$). Further, co-incubation with oleate abolished the effect of palmitate on caspase-3 activity and DNA fragmentation. Palmitate-induced apoptosis was associated with increased ceramide content and co-incubation with Fumonisin B1 abolished this lipoapoptosis. Oleate, on the other hand, reduced ceramide content, and – unlike palmitate – upregulated FFAR1/2, evoking a 2-fold increase in FFAR1-mediated GLP-1 secretion following acute exposure to 0.125 mmol/L palmitate; ($p<0.05$).
Conclusion: Saturated (16:0), but not unsaturated (18:1), fatty acids induce ceramide-mediated apoptosis of GLP-1-producing cells. Further, unsaturated fatty acids confer lipoprotection, enhancing viability and function of GLP-1-secreting cells. These data provide potential mechanistic insight contributing to reduced L-cell mass following a high fat diet and differential effects of saturated and unsaturated fatty acids on GLP-1 secretion *in vivo*.

Contribution of obese adipose tissue-derived stem cells to hepato-or breast-carcinoma inflammation, through promotion of Th17 cells and activation of IL-1b by monocytes

M. Chehimi[1], L. Delort[2], M. Robert[3], H. Vidal[1], F. Caldefie-Chezet[2], A. Eljaafari[1,3];
[1]Inserm U1060 CARMEN, Lyon, [2]Ecrein UMR 1019 INRA-UdA, Clermont-Ferrand, [3]Hospices Civils de Lyon, Lyon, France.

Background and aims: As opposed with lean adipose tissues (AT), obese AT are heavily infiltrated with variety of inflammatory cells such as macrophages and Th17 cells. Obesity-mediated chronic low-grade inflammation is known to contribute to tumor progression in various cancers, including hepatic and breast cancers. Because we have previously demonstrated, using co-culture experiments, that obese AT-derived stem cells (obASC) contribute to AT inflammation through promotion of Th17 cells, and activation of IL-1β-secreting monocytes, we postulated herein that such inflammatory environment could contribute to tumor progression in cancer-suffering obese patients.
Materials and methods: Human ASC were isolated from AT of obese donors. Mononuclear cells (MNC) were collected from healthy blood donors. Co-cultures of obASC and MNC were activated for 48 hours with phytohemagglutinin A (PHA), a T cell mitogen, or not. Conditionned media (CM) were collected, and added for 24h to cultures of HuH7 (hepatocarinoma cell line) or of two breast carcinoma cell lines, i.e MCF-7, or MDA-MB-231. Levels of inflammatory or angiogenic gene expression were evaluated by qRT-PCR. Expression of CXCR4 (a marker of invasiveness) was measured by flow cytometry in the HuH7 cell line.
Results: CM from PHA-activated-obASC/MNC co-cultures enhanced IL-1β, IL-8 and VEGFα mRNA expression in HuH7 cells by 1942.2, 45.7 and 6.1 -fold, respectively, as compared with no treatment. A putative effect of CM on HuH7 invasiveness was supported by a 2- and 3-fold increase in MMP-9, and CXCR4 expression, respectively. In addition, IL-1β, IL-8 and VEGF-α mRNA expression were increased by 34.3, 33.2, and 2.97 fold respectively in MCF-7 cells, and by 85.8, 52.0 , and 1.34 fold respectively, in MDA-MB-231 cells. These results indicated thus a differential sensitivity of cancer cell lines to CM from PHA-activated-obASC/MNC co-cultures, with a preponderant increase of IL-1β mRNA levels in hepatocarcinoma cells versus a similar increase of IL-1β and IL-8 gene expression in breast carcinoma cells.
Conclusion: Our results suggest that in cancer-suffering obese patients, interaction of obASC with AT-infiltrating immune cells contribute to the establishment of an inflammatory environment, propitious to tumor inflammation and/or tumor migration. Whether this inflammation could occur through propagation of obese AT inflammatory environment towards tumors, or through migration of ASC inside tumors and then interaction with tumor infiltrating immune cells, remain to be explored.

Adipose-derived stem cell extracellular vesicles induce inflammatory phenotype in T cells from type 1 and type 2 diabetes patients

E. Favaro[1], T. Lopatina[1], S. Occhipinti[1], R. Romagnoli[2], M. Giovarelli[1], M. Porta[1], G. Camussi[1], M. Zanone[1];
[1]Medical Science, University of Turin, [2]Surgical Science, University of Turin, Torino, Italy.

Background and aims: The concept of immune-mediated inflammatory disease is established for type 1 diabetes, but recent evidence indicates type 2 diabetes as an auto-inflammatory disease, with signs of insulitis as well. Adipose tissue is the largest endocrine organ with immune function and adipocyte dysfunction correlates with the development of insulin-resistance type 2 diabetes and with impaired micro- and macrovascular function. On the other hand, studies in animal models of type 1 diabetes reveal that adipocyte dysfunction and high levels of inflammatory cytokines can directly play a role in the onset and progression of the type 1 diabetes. Angiogenesis and cell therapy studies indicate that adipose-derived stem cells (ASCs) hold promise amongst stem cells of mesenchymal lineage, acting through paracrine mechanisms possibly involving the release of extracellular vesicles (EVs), a recognised integral component of the cellular network. Paralleling previous in vitro studies using EVs derived from bone-marrow mesenchymal stem cells (MSCs) indicated the promotion of an anti-inflammatory T cell response. We evaluated whether EVs derived from ASCs may effect inflammatory response in type 1 and type 2 diabetes, acting on T cell.
Materials and methods: EVs were purified from heterologous human adipose mesenchymal stem cells (ASCs) obtained from healthy donors by differential centrifugation. Protein array and gene array analysis showed high expression of some pro-inflammatory factors such as IFN-γ, IL-1, IL-17 and IL-6 and microRNA miR-126 in EVs. PBMCs were obtained from 6 patients with recent onset type 1 diabetes and 6 patients with long standing type 2 diabetes on metformin. Cultures were established with PBMCs and ASC-EVs for 48 hours in type 1 and type 2 diabetic patients. Responses to GAD65 stimulation were assessed by IFN-γ ELISPOT analysis in type 1 patients. Levels of cytokines were measured in the supernatant by ELISA and by intracellular flow cytometry analyses. T helper 17 (Th17) analysis was performed by flow cytometry analyses.

Results: ASC-EVs were internalised by PBMCs, as assessed by confocal microscopy and flow cytometry analyses. ASC-EVs increased IFN-γ spots in GAD65-stimulated PBMCs obtained from type 1 diabetes. Moreover, ASC-EVs increased levels of IFN-γ, IL-6, IL-10, TNF-α, IL-1-β in PBMCs obtained from type 1 and type 2 diabetes. Furthermore, ASC-EVs increased the number of Th17 cells and the levels of IL-17.
Conclusion: ASC-EVs appear to lack the antigen and non-antigen specific anti-inflammatory effects of MSCs, and induce a pro-inflammatory phenotype in T cells. In the context of type 1 diabetes, ASC-EVs may contribute to increased levels of cytokines thus inducing β cell death, inhibit insulin production and possibly contributing to the loss of self-tolerance. In type 2 diabetes may contribute lipotoxicity and exacerbate inflammation, also in the context of pancreatic islets.

Studying the proliferation and differentiation of human adipose stem cells: the effects of glucagon

G. Cantini, A. Di Franco, E. Mannucci, M. Luconi;
University of Florence, Florence, Italy.

Background and aims: Obesity is associated with an increase in the fat mass and dysfunctions of the white adipose tissue. Most of the drugs used for the treatment of obesity has limited efficacy in term of stable weight loss: moreover, relevant side effects limit de facto their clinical use. Therefore, a new pharmacological approach based on the use of drugs directly targeting the adipose tissue might be of interest. Glucagon-like peptide 1 (GLP-1) receptor agonists, such as liraglutide, are currently used for the treatment of type 2 diabetes and have been recently proposed as potential anti-obesity drugs, due to their relevant effects on weight loss. Among the products of the expression of the pro-glucagon gene, also glucagon, a key factor in the glucose homeostasis, seems to act on the adipose tissue, promoting lipolysis and energy expenditure. In the present study, we assessed the activity of glucagon in a human adipose stem cell (ASC) model in vitro.
Materials and methods: We assessed the effects of glucagon on ASC proliferation by direct cell count and cytofluorimetric analysis, adipogenesis by specific intracellular lipid staining and apoptosis by cytofluorimetric analysis of annexin V.
Results: We previously demonstrated that both liraglutide and native GLP-1 interfere with proliferation and differentiation ability of human adipose stem cells (ASC). In the present study, we assessed the in vitro effect of glucagon on the same cell model. Glucagon significantly inhibits ASC proliferation, in a dose and time-dependent manner, with a maximum effect at 3 days of culture (14.0%, 25.2% and 37.1%, $p<0.01$ for 1-10-100nM glucagon, respectively). The decrease in cell proliferation in the presence of glucagon is not associated with the activation of apoptosis, unlike what it has previously been observed with liraglutide and GLP-1. Moreover, addition of increasing doses of glucagon (1-10-100nM) inhibits in vitro-induced adipogenesis, lowering intracellular lipid accumulation, similarly to the effects obtained with liraglutide and GLP-1 (-28.82% and -10.2%, $p<0.05$ respectively).
Conclusion: This is the first study that shows glucagon's effects on human adipose cell precursors. Our findings demonstrate that glucagon has an inhibitory action on the proliferation and differentiation ability of these cells. Further preclinical studies are necessary to better elucidate glucagon's action on the body weight and clarify the molecular mechanisms underlying the effects of glucagon and GLP-1 receptor agonists at cellular level.

Adipose tissue derived stem cells proliferation ability in obese patients with early stage of type 2 diabetes

A. Witkowska[1], A. Skubis[2], B. Sikora[2], W. Kiełek[3], B. Jendrysik[3], E. Wojtyna[4], G. Wystrychowski[1], U. Mazurek[2], J. Gumprecht[1];
[1]Department of Internal Medicine, Diabetology and Nephrology, Medical University of Silesia, Zabrze, [2]Department of Molecular Biology, Medical University of Silesia, Sosnowiec, [3]VenoMed, Lubliniec, Poland, [4]University of Silesia, Katowice, Poland.

Background and aims: Adipose tissue derived stem cells (ADSCs) emerge as applicable and promising biological material for cell therapy of obesity, diabetes and associated complications. ADSCs are able to differentiate into brown adipose tissue or insulin-producing β-cells. On the other hand, some studies revealed lower ability of survival, regeneration and differentiation of ADSCs isolated from patients with long term type 2 diabetes with cardiovascular complications. It appears, therefore, important to define the group of diabetic patients that would still potentially benefit from autologous ADSCs treatment. The aim of our study was to assess the proliferation ability of ADSCs obtained from obese patients at early stage of type 2 diabetes with no cardiovascular complications.
Materials and methods: Peripheral adipose tissue was acquired by lipoaspiration from 9 obese patients with type 2 diabetes (3M and 6F; aged 45,3±12 years, diabetes duration 4,8±3,3 years, BMI median 39, HOMA-IR median 9,6) treated with metformin, and from 11 healthy control patients (4M and 7F; aged 41,4±16 years, BMI median 26, HOMA-IR median 1,3). The phenotype of ADSCs from each patient was confirmed by flow cytometry with the use of antibodies targeted against CD90, CD105, CD73 (positive markers). The cocktail of antibodies targeted against CD45, CD34, CD11b, CD79α and HLA-DR was used for negative markers analysis to fully confirm the identity of cells. Proliferation ability of ADSCs was measured by LDH, WST-1 and Sulforhodamine B (SRB) assays after 72h cultivation and also assessed by gene expression analysis of histone H3 and Ki67 with the use of RT-qPCR. For statistical analysis the Mann-Whitney U test was used ($\alpha=0.05$).
Results: The expressions of histone H3 and Ki67 were significantly upregulated in ADSCs obtained from patients with diabetes as compared with controls (both $p<0.001$; Fig. 1). In addition, the SRB assay revealed higher density of cellular protein content in the diabetic group ($p<0,05$).
Conclusion: Our results revealed higher proliferation ability of ADSCs obtained from obese patients with short term type 2 diabetes than from healthy subjects. While intriguing and promising, this outcome requires further, larger studies to elucidate its nature and verify its clinical significance.

Protective effect of Resveratrol against cardiac and endothelial dysfunctions of type 2 diabetic female GK rat heart submitted to ischaemia-reperfusion injury

M. Desrois[1], N. Fourny[1], C. Lan[1], E. Sérée[2], L. Pechere[3], M. Bernard[1]; [1]Aix-Marseille Univ, CNRS, CRMBM, [2]Aix-Marseille Univ, UMR Inserm 1062/INRA 1260, NORT, [3]YVERY Sarl, Marseille, France.

Background and aims: Type 2 diabetic women have greater risk of mortality by cardiovascular (CV) disease than non-diabetic women. Particularly, type 2 diabetes (T2D) doubles the risk of myocardial infarction in women, but involved mechanisms are still not clear. Today anti-diabetic treatments allow a reduction in blood glucose but do not decrease patient's CV mortality, this is why new treatments need to be found. Resveratrol (RSV) is a polyphenol found in grapes reported to be beneficial on oxidative stress, endothelial dysfunction and inflammation involved in CV complications of T2D. Consequently we have investigated the effect of RSV on the tolerance to ischemia-reperfusion (IR) injury of type 2 diabetic female Goto-Kakizaki (GK) rat hearts by using multiparametric approach allowing simultaneous measurement of cardiac function, energy metabolism and endothelial function.
Materials and methods: 8-month-old female GK (FGK) rats and their age-matched respective controls female Wistar (FW, n=11) were used. FGK were divided in three groups: one without treatment (FGK-0, n=14) ; one with RSV (FGK-RSV, n=8) at the dose of 1 mg/kg/day in drinking water during 8 weeks ; and one with Placebo (FGK-P, n=9). Then, isolated rat hearts were perfused with 0.4 Mm palmitate, 3% albumin, 11 mM glucose, 3U/L insulin, 0.8 mM lactate and 0.2 mM pyruvate for 24 minutes before switching to 1.2 mM palmitate during 32 minutes low-flow (0.5 mL/min/g wet wt) ischemia. Next, flow was restored with 0.4 mM palmitate buffer for 32 minutes. High-energy phosphates and intracellular pH were measured during the experimental course by ^{31}P magnetic resonance spectroscopy with simultaneous measurement of contractile function. Coronary flow was measured before and after ischemia. Glucose and free fatty acids (FFA) were measured in plasma. Nitric oxide and Sirtuin pathways were studied in freeze-clamped tissues at the end of experiments. Creatine kinase and lactate dehydrogenase activities were also used as markers of myocardial damage.
Results: Glucose was significantly higher in FGK vs. FW ($p<0.0001$) while FFA were similar in the four groups. Heart to body weight ratio was also significantly higher in FGK vs. FW indicating cardiac hypertrophy ($p<0.0001$). Before ischemia, Rate Pressure Product (RPP), index of cardiac performance, was significantly lower in FGK vs. FW ($p<0.0001$), indicating an impaired cardiac function that was not improved by treatment with RSV. During reperfusion, RPP was significantly lower in FGK-0 and in FGK-P vs. FW ($p<0.001$), whereas RSV treatment completely restored cardiac function during reperfusion in FGK-RSV (ns vs. FW). Moreover, baseline coronary flow was similar in the four groups but during reperfusion, coronary flow was impaired in FGK-0 and FGK-P groups vs. FW (respectively $p<0.001$ and $p<0.01$), whereas RSV significantly re-established coronary flow in FGK-RSV to control values (ns vs. FW).
Conclusion: Female type 2 diabetic GK rat hearts exhibit greater sensitivity to IR injury characterized by a decrease of cardiac and endothelial functions. Oral 8-weeks treatment with RSV improved myocardial performance and coronary flow during reperfusion. Consequently, RSV might be an interesting therapeutic approach to improve survival to myocardial IR injury of type 2 diabetic women.

HIF1 complex in the hypothalamus: role in the development of obesity

J.M. Gaspar, N.F. Mendes, F. Corrêa-da-Silva, L.A. Velloso; Laboratory of Cell Signaling, University of Campinas, Obesity and Comorbidities Research Center, Campinas, Brazil.

Background and aims: The balance between food intake and energy expenditure is mainly regulated by the hypothalamus. Dysregulation of this process is critical for the development of obesity. Hypoxia-inducible factor-1 (HIF1) is a transcription factor that activates several genes in response to hypoxia or other harmful conditions. Besides its importance in hypoxia conditions, HIF1 complex also plays a role in the regulation of glucose and energy homeostasis. Dysregulation of HIF1 complex could also be involved in the development of obesity and type 2 diabetes. Previously, it was reported that HIF1 can regulate the expression of POMC modulating food intake. In this work, we hypothesize that the consumption of high fat diet alters the expression of HIF1 in the hypothalamus with changes in the expression of neuronal POMC, and consequently altering the neuronal pathways that control food intake. Our main purpose was to analyze the expression profile of HIF1 in hypothalamus and evaluate whether high fat diet feeding changes the expression of this transcription factor. We also inhibited HIF1 in the arcuate nucleus to evaluate changes on high-fat diet consumption and body composition.
Materials and methods: We used male, 8-week old C57Bl6 mice, fed on chow or a high-fat diet for 1, 3, 7, 14 or 28 days. The expressions of HIF-1α and HIF-1β were measured by PCR and western blot and their hypothalamic distribution were evaluated by fluorescence microscopy. Inhibition of HIF-1β in arcuate nucleus of hypothalamus was performed using stereotaxic injection of shRNA lentiviral particles and animals were grouped under chow or high-fat diet for 14 days. Body mass, food intake and glycemia were evaluated throughout the experiments.
Results: HIF-1α and HIF-1β were mainly localized in the arcuate nucleus of the hypothalamus, and they were colocalized with POMC and with ACTH, but not with AgRP. These results indicate that HIF-1α and HIF-1β were only present in POMC neurons. As expected, we also observed that both proteins were colocalized with microglia and glial cell markers. The expression of mRNA of HIF-1α and HIF-1β significantly decreased after 3 and 7 days of high-fat feeding, returning to baseline levels after 14 and 28 days. However, the protein levels of HIF-1α significantly increased after 7, 14 and 28 days on high-fat diet consumption, with a decreased in the protein levels of VHL (E3ligase) which indicates an increase in HIF-1α stabilization. Mice with inhibition of HIF-1β in the arcuate nucleus and fed on chow, had an increase in body mass compared with control animals. This effect was more pronounced when animals were maintained on high-fat diet. However, food intake and glycemia were not affected by the inhibition of HIF-1β.
Conclusion: In summary, HIF1 complex is mainly expressed in POMC neurons in the arcuate nucleus of the hypothalamus. Although the mRNA expression of HIF-1α and HIF-1β decreased with high-fat diet feeding, its protein levels are increased indicating an increase in HIF-1α stabilization. These results point to a dysregulation of hypothalamic HIF1 complex associated with the consumption of high-fat diet, which can, at least in part, impact on changes in body mass. The increase in body mass without change in caloric intake in mice with hypothalamic inhibition of HIF complex, suggest that HIF1 complex could be involved in the regulation of energy expenditure. The role of HIF1 complex in the regulation of energy expenditure will be addressed in future studies.

The role of the liver in the adaptibility to high dietary lipid intake in C57BL/6J mice

J. Hansikova, O. Horakova, M. Svobodova, P. Kucharikova, M. Rombaldova, O. Kuda, M. Rossmeisl, J. Kopecky;

Department of Adipose Tissue, Institute of Physiology of the Czech Academy of Sciences, Prague, Czech Republic.

Background and aims: Exposure to an 'obesogenic' environment results in body weight gain (BWG), which is however quite variable among individuals. While obesity and related insulin resistance are linked to changes in lipid metabolism in the liver, the differences in mitochondrial energy efficiency may also represent a substantial cause of the variability in BWG. Our previous study has revealed heterogeneous responses to obesogenic high-fat diet (HFD) in C57BL/6J (B/6J) mice. In spite of the identical genetic background, large variations in BWG, glycemic control and lipid profiles were observed. Therefore, B/6J mice represent a suitable model for studying the mechanisms underlying the propensity to obesity and associated disorders. In this study, B/6J mice were used to examine the adaptability of liver metabolism to HFD feeding and its dependence on gender.
Materials and methods: Both male and female B/6J mice (n=30 per gender) were fed HFD (lipids ~32 wt %) for 12 weeks, while BWG and changes in glucose tolerance were assessed. At the end of HFD intervention, liver samples were collected for further analyses. Mitochondrial metabolism was characterized in liver homogenates using Seahorse XF24. Levels of acylcarnitines (AC) were quantified by FIA-ESI MS/MS. Hepatic gene expression was analyzed by qPCR. Within each gender, mice with either the lowest (LG, low gainers) or the highest (HG, high gainers) BWG (n=8 per group) were selected for comparisons. Data evaluation was performed using t-test ($p< 0.05$). Both univariate (Spearman pairwise correlations) and multivariate (PLS-DA) statistical analyses were used to examine relationship between measured variables. Data are presented as mean±SE or fold change.
Results: BWG significantly differed between LG and HG group in both males (LG, 2.8±0.8 vs HG, 14.7±1.0 g) and females (LG, 5.4±0.6 vs. HG, 15.8±0.7 g). Despite higher overall BWG in females, only in males a strong relationship between BWG and obesity-related metabolic disturbances such as fasting blood glucose (r_s=0.86) and hepatic lipid content (r_s=0.61) was observed. Gene expression analysis identified changes related to BWG (e.g. upregulation of *Srebp-1c* and downregulation of *Pepck* in HG as compared to LG), which were similar in both genders. In contrast, only in males, propensity to obesity was associated with a decrease in expression of genes related to lipid catabolism (*Atgl*, 1.5-fold; *Crat*, 1.5-fold; *Vlcad* 1.2-fold in HG as compared to LG). Moreover, liver AC profiles, primarily reflecting catabolism of fatty acids, distinguished HG and LG groups in males but not in females, while the most discriminant metabolites were C20:4; C0; C5-OH; C3 and C5. In females, HG group exhibited upregulation of lipogenic genes, namely *Fasn* (1.4-fold) and *Hmgcs-1* (1.7-fold) in comparison to LG, which is not associated with increase of intrahepatic triglyceride content. Only in females, ADP-stimulated respiration in liver increased with BWG (1.3-fold), while the maximal respiration capacity remained unchanged.
Conclusion: Our results document that female B/6J mice are less susceptible to HFD-induced impairment of glucose homeostasis when compared with male mice. This difference is not caused by BWG, which is lower in male mice. Hepatic metabolism could be involved, since HFD-fed females exert relatively high adaptability of both the lipogenesis and mitochondrial oxidative phosphorylation in the liver.

Differential contribution of glucose to triglyceride lipogenesis in visceral adipose tissue and liver following glucose/fructose supplementation

J.G. Jones[1], J. Silva[2], C. Marques[1], I. Viegas[1], F. Martins[2], M.P. Macedo[2];
[1]Metabolic Control, Center for Neurosciences and Cell Biology, Coimbra, [2]MEDIR- Metabolic DIseases Research Group, CEDOC, Chronic Diseases Research Center, Lisbon, Portugal.

Background and aims: Sugar consists of glucose and fructose monosaccharides which can both be utilized for triglyceride (TG) synthesis via *de-novo* lipogenesis (DNL) and high sugar intake is implicated in the development of non-alcoholic fatty liver disease (NAFLD). Under these conditions, increased liver TG (L-TG) is also strongly associated with expansion of visceral adipose tissue TG (VAT-TG). While DNL is considered to play a major in elevated L-TG, its contribution to VAT-TG is less clear. Liver and VAT are considered to have different capacities for utilizing glucose and fructose hence we hypothesized that they would contribute differently to the synthesis of new fatty acids in each tissue. We used a combination of deuterated water (^2H_2O) and [U-^{13}C]glucose to monitor the specific contribution of the glucose component of a glucose/fructose mixture to TG-fatty synthesis in VAT and liver.
Materials and methods: Five adult male C57BL/6 mice were kept on a 12/12h dark/light cycle and fed with standard chow and drinking water supplemented with 17.5% glucose and 17.5% fructose (w/v) for 24 weeks. At the start of the final night, mice were injected with 3g/100g body weight 99.9% ^2H_2O and the drinking water was replaced with 17.5% fructose and 17.5% glucose enriched to 50% with [U-^{13}C]glucose and 5% ^2H_2O. Mice were then allowed to feed naturally overnight. At the end of the dark period, mice were sacrificed, VAT and livers were freeze-clamped and VAT-TG and L-TG extracted and purified. Triglyceride positional ^{2}H enrichments and ^{13}C isotopomers were measured by ^{2}H and ^{13}C NMR. These data were integrated to yield the specific contribution of [U-^{13}C]glucose to the newly-synthesized FA components of VAT-TG and L-TG.
Results: In liver, [U-^{13}C]glucose contributed 9±3%, of newly-synthesized oleate, 10±3% of newly-formed palmitoleate and 19±5% of newly-synthesized C16 and C18 saturated fatty acids (SFA). In VAT, [U-^{13}C]glucose contributed 16±4% of newly synthesized oleate ($p<0.02$ *vs.* liver); 23±5% of newly-synthesized palmitoleate ($p<0.04$ *vs.* liver) and 57±10% of newly-synthesized SFA ($p<0.02$ *vs.* liver).
Conclusion: We demonstrate that in mice whose diet was supplemented with equimolar amounts of glucose and fructose in the drinking water, the glucose component was utilized to a greater degree for the synthesis of TG-fatty acids in VAT compared to the liver. This could reflect increased competition of the unlabeled dietary fructose for supplying lipogenic carbons in liver compared to VAT. Also, given that VAT supplies fatty acids to the liver, these data indicate that a portion of L-TG derived from [U-^{13}C]glucose may in fact been synthesized in VAT.

A dietary switch from saturated to monounsaturated fat is protective against metabolic dysregulation, hyperinsulinaemia and beta cell dysfunction

J.C. Ralston[1], M.-S. Nguyen-Tu[2], C.L. Lyons[1], A.M. Murphy[1], A.A. Cooke[1], A. Falvey[1], O.M. Finucane[1], G.A. Rutter[2], H.M. Roche[1];
[1]University College Dublin, Dublin, Ireland, [2]Department of Medicine, Imperial College London, London, UK.

Background and aims: Saturated fatty acids (SFA) promote metabolic-inflammation and insulin resistance. Conversely, feeding a high-fat diet (HFD) enriched with monounsaturated fatty acids (MUFA), rather than SFA-HFD, induces less IL-1β mediated inflammation, insulin resistance and hyperinsulinemia. The purpose of this study was to determine if switching from a SFA-enriched HFD to a MUFA-HFD affected pancreatic islet function.
Materials and methods: Male C57BL/6 mice were fed one of three diets: 1) a low fat diet for 32 weeks (LFD; 10% kcal), 2) a SFA-enriched HFD for 32 weeks (SFA-HFD; 45% kcal) or 3) a SFA-enriched diet for 16 weeks followed by a MUFA-enriched diet for a further 16 weeks (MUFA-HFD; 45% kcal). In vivo glucose-stimulated (1.5g/kg) insulin secretion response was examined at baseline and

following the diet, where plasma insulin was obtained via tail vein bleed and analyzed by ELISA. HOMA-IR and HOMA-%β were calculated from fasting glucose and insulin levels. Pancreatic islets were isolated and gene expression was examined by real time RT-PCR with β-actin as the housekeeping gene. Glucose-stimulated insulin secretion from isolated islets was measured by ELISA. Pancreatic immunostaining assessed macrophage infiltration, insulin and IL-1β expression. Data was analyzed by 1-way or 2-way ANOVA, where appropriate with Bonferroni post-hoc comparisons.

Results: MUFA-HFD mice displayed attenuated hyperinsulinemia compared to the SFA-HFD group ($p<0.001$). Whilst HOMA-IR was elevated by both HFDs, the degree of insulin resistance was significantly lower following the MUFA-HFD at 20, 24 and 32 weeks. The insulin stimulatory index from islets isolated after the SFA-HFD was significantly (~50%) lower, compared to LFD mice. This decline was partially reduced in MUFA-HFD mice. Immunostaining demonstrated elevated pancreatic macrophage infiltration and IL-1β content in SFA-HFD mice compared to MUFA-HFD and LFD mice. Interestingly, markers of β-cell development and function (e.g., Nkx6.1, Pdk1, insulin) were significantly reduced (36%, 15% and 27%, respectively) in SFA-HFD mice compared to LFD and MUFA-HFD mice. Additionally, Ampk mRNA expression was reduced in islets isolated following the SFA-HFD but maintained in MUFA-HFD islets, which coincided with a 57% reduction in IL-1β in MUFA-HFD islets compared to both LFD and SFA-HFD fed mice. Expression of the disallowed gene Ldha was unaltered by diet.

Conclusion: While SFA-HFD mice may have somewhat compensated for the dietary challenge through hyperinsulinemia, our results suggest that a SFA-HFD induces the early-stages of islet and β-cell dysfunction. Importantly, switching to a MUFA-HFD partially prevented pancreatic dysfunction, further highlighting the importance of the type of dietary fat for overall health.

Differential fractional synthetic and elongation rates of hepatic saturated fatty acids and oleate from dietary [U-13C]glucose in healthy mice

J. Silva[1], F. Martins[1], C. Marques[2], M.P. Macedo[1], I. Viegas[2], J. Jones[3,4]; [1]CEDOC, Chronic Diseases Research Center, Lisbon, [2]Center for Neurosciences and Cell Biology, Coimbra, [3]Center for Neurosciences, University of Coimbra, Coimbra, [4]APDP, Lisbon, Portugal.

Background and aims: Diet-derived glucose and fructose are considered to be potent lipogenic substrates and may explain the association between increased sugar intake and soaring NAFLD incidence rates. However, there is little information on the precise contributions of these substrates to hepatic de novo lipogenesis. Current stable-isotope tracer methods quantify the fractional synthetic and elongation rates (FSR, FER) of liver fatty acids (FA) from all precursors but cannot resolve contributions from individual substrates. We combined deuterated water (^2H_2O) and [U-^{13}C]glucose to measure FSR and FER from this substrate under natural feeding conditions.

Materials and methods: At the start of the dark period in a 12h/12h dark/light cycle, four adult male C57/BL6 mice fed with standard chow were given an intraperitoneal injection of 99.9% ^2H_2O/0.9% NaCl to raise body water ^{2}H-enrichment to 3.5%. The drinking water was supplemented with 5% ^2H_2O, 17.5% w/w unlabeled fructose and 17.5% w/w glucose enriched to 50% with [U-^{13}C]glucose. Animals were allowed to feed naturally overnight and then sacrificed at the end of the dark cycle. Livers were freeze-clamped and triglycerides were extracted and purified from other lipid species and analyzed for ^{2}H and ^{13}C-enrichment by ^{2}H and ^{13}C NMR at 11.7T and 14.1T, respectively.

Results: ^{2}H-enrichment analysis indicated that the fraction of newly-synthesized FA from all lipogensis precursors was 33 ± 6% (mean ± S.D.). ^{13}C NMR provided resolved signals for methyl and carboxyl carbons of oleate, and saturated FA (palmitate + stearate) as well as their position in the glyceryl esterification sites (1,3-flanking or central). [U-^{13}C]glucose accounted for 18 ± 3% of newly-synthesized saturated FA, but only 9 ± 2% of newly synthesized oleate ($p<0.01$ *vs.* SFA). Its contribution to the elongation of saturated FA was negligible (0 ± 2%) while it made small but significant contribution to oleate formation via elongation (5 ± 2%, $p = 0.016$ *vs.* SFA). The distribution of FA between the glyceryl 1,3-flanking and central esterification sites was highly non-homogenous with oleate being the principal fatty acid occupying the center site, while the 1,3-sites were occupied by a ~40/60 mixture of oleate and SFA.

Conclusion: The integration of ^2H_2O and ^{13}C-enriched substrates coupled to ^{2}H/^{13}C-NMR analysis of triglyceride allows contributions of specific substrates to fatty acid synthesis and elongation rates to be determined. Glucose, in the presence of fructose, contributed different FSR and FER for oleate and SFA. Moreover, these FA were not evenly distributed among the glyceryl sites.

The role of small intestine in differential metabolic effects of various lipid forms of dietary n-3 fatty acids

P. Kucharikova[1], E.M. van Schothorst[2], J. Hansikova[1], J. Keijer[2], J. Kopecky[1], M. Rossmeisl[1], O. Horakova[1]; [1]Department of Adipose Tissue Biology, Institute of Physiology of the Czech Academy of Sciences, Prague, Czech Republic, [2]Human and Animal Physiology, Wageningen University, Wageningen, Netherlands.

Background and aims: *n-3* polyunsaturated fatty acids (Omega-3) are known to exert hypolipidemic and anti-inflammatory effects. Previous studies have suggested that metabolic responses to Omega-3 depend on the lipid form of their administration, with phospholipids showing better efficacy than triacylglycerols, especially with regard to the effect on glucose homeostasis. The aim of this study was to investigate in dietary obese mice, whether this difference in efficacy might result already from changes in cellular and metabolic processes at the level of small intestine.

Materials and methods: Four groups of male C57BL/6NCrl mice were fed for 8 weeks a corn oil-based high-fat diet (cHF; lipids ~35% wt/wt), as well as cHF diet supplemented with Omega-3 (~30g EPA+DHA/kg diet) in the form of fish oil (i.e. triacylglycerols; TG diet) or Krill oil (i.e. phospholipids; PL-H diet). Moreover, Krill oil was also supplemented in the amount matching that of fish oil in the TG diet (i.e. PL-L diet), thus containing only ~10g EPA+DHA/kg diet. At week 7 of the study mice underwent intraperitoneal glucose tolerance test. At the end, total RNA was isolated from samples of small intestine, reverse transcribed, and hybridized to SurePrint G3 Mouse Gene Expression v2 8x60K Microarrays (Agilent).

Results: Mice in the PL-H group gained less body weight when compared to cHF (PL-H, 5.8±1 vs. cHF, 14.4±0.6 g; $p<0.05$ by ANOVA) and both PL groups had improved glucose tolerance assessed as incremental area under the glucose curve (AUC; PL-H, 899±77 vs. PL-L, 2260±193 *vs*. cHF, 2670±186 mmol/180min; $p<0.05$ vs. cHF for both PL groups). Blood glucose levels in the fed state were decreased only in PL-H group (PL-H, 9.43±0.42 vs. cHF, 11.98±0.81 mmol/l; $p<0.05$). In the small intestine, the most regulated pathways, as compared to cHF, included: (i) lipid metabolism (all groups), (ii) cytoskeleton remodeling (TG and PL-L), (iii) leptin signaling and macrophage regulation (TG), (iv) gastrin and VEGF signaling and immune response signaling pathways including NFkB and IL-16 (PL-L), and (v) peroxisomal fatty acid oxidation, retinol and glutathione metabolism and ketone bodies biosynthesis (PL-H).

Conclusion: Dietary Omega-3 efficiently regulated intestinal lipid metabolism and cellular processes depending on their lipid form. Our findings support the idea that changes of intestinal lipid metabolism might underlie differential metabolic efficacy of various lipid forms of Omega-3 at the whole-body level.

Vitamin-D improves insulin sensitivity in high fat diet induced diabetic mice by downregulating fetuin-A gene expression

S. Ali Mondal[1], S. Mukherjee[2], S. Chatterjee[2], M. Basu[1], S. Bhattacharya[2], S. Mukhopadhyay[1];
[1]Department of Endocrinology and Metabolism, IPGME&R, Kolkata, West Bengal, [2]Department of Zoology, Visva-Bharati University, Santiniketan, India.

Background and aims: Vitamin-D(VD) deficiency is associated with a chronic low grade inflammation (metaflammation) in adipose tissue that leads to insulin resistance. While VD supplementation improves insulin sensitivity and may prevent progression from prediabetes to T2DM, the underlying mechanism by which VD ameliorates insulin resistance(IR) is not clear. Fetuin-A (FetA), a hepato-adipokine expressed through NF-kB pathway, induces adipose tissue inflammation and IR by proinflammatory polarization of resident macrophages that leads to production of inflammatory cytokines. Our recent unpublished data shows a significant inverse correlation between serum levels of fetA and VD in insulin resistant human subjects with various degrees of glucose intolerance. This observation prompted us to check whether VD has any regulatory influence on FetA gene expression that might impact insulin sensitivity.
Materials and methods: In the in vitro study, preincubated hepatocytes isolated from Balb/c mice (n=6) for 1hr with incremental doses of calcitriol (50, 75 & 100 nM), followed by addition of FFA (0.75mM) for 4hrs by keeping one positive control(only palmitate) & one negative control(only vehicle). For the in vivo study, three groups of high fat diet treated (HFD) Balb/c mice were taken (n=6). Group-A comprised of six HFD mice treated with intraperitoneal injection of 25-hydroxy cholecalciferol (25OHD) at a dose of 5 μg/kg body weight every third day for 9 weeks. Group-B comprised of six HFD mice not treated with 25OHD& a third group of Balb/c mice treated with standard diet (Group-C). Insulin sensitivity was assessed from all the three groups of mice by oral glucose tolerance test (OGTT), insulin tolerance test (ITT) and ^{14}C-2-DOG uptake. Gene expression and protein levels of FetA, proinflammatory cytokines and insulin signaling molecules were determined by qPCR and immunoblot analysis from all the groups. NF-kB binding to FetA promoter was determined by ChIP and promoter-reporter activity assay.
Results: VD treatment of hepatocytes abrogated palmitate induced increase in the mRNA ($p<0.01$) and protein levels of FetA and proinflammatory cytokines as revealed by qPCR analysis and immunoblot respectively. VD induced FetA suppression in group A appeared to be due to NFκB deactivation as evidenced by immunofluorescenece and immunoblot analysis. VD markedly reduced phosphorylated NFκB levels in HFD mice (Group A). ChIP assay and NFκB promoter-reporter activity analysis showed, hepatocytes and adipocytes isolated from mice belonging to Group A have greater depletion in Fet-A and proinflammatory cytokine expression compared to Group B. VD also significantly augmented adiponectin gene expression ($p<0.01$) and protein levels in adipocytes isolated from Group A mice. The rise in plasma adiponectin levels($p<0.01$) was associated with improved insulin sensitivity, leading to significant reduction in serum levels of triacylglcerol, nonesterified fatty acids (NEFA) and cholesterol in Group A mice.
Conclusion: Our investigation shows VD induced down regulation of Fet A gene through NF-Kb pathway resulted in significant improvement in insulin sensitivity, probably due to upregulation of adiponectin and suppression of anti inflammatory cytokines in VD treated HFD mice.

Dietary fat oxidation is elevated in middle-aged type 2 diabetes

F.B. Stephens[1], C.J. Gaffney[1], P. Mansell[2], P.L. Greenhaff[3], K. Tsintzas[3];
[1]Sport and Health Sciences, University of Exeter, Exeter, [2]Diabetes and Endocrinolgy, Nottingham University Hospitals NHS Trust, Nottingham, [3]Life Sciences, University of Nottingham, Nottingham, UK.

Background and aims: Older individuals have increased delivery of endogenous fat to skeletal muscle, which may predispose to insulin resistance if fat oxidation is reduced. Likewise, insulin resistance increases the delivery and storage of dietary and endogenous fat in skeletal muscle. The aim of the present study was to investigate the effect of type 2 diabetes (T2D) and age on dietary fat oxidation.
Materials and methods: Seven middle age (46.0 ± 1.1 y) and seven older (63.4 ± 0.6 y) patients with T2D (metformin and/or diet control for 4.8 ± 1.1 y) were matched with seven middle age (46.1 ± 2.9 y) normoglycaemic controls for BMI (31.1 ± 1.5; 29.6 ± 1.1; 29.6 ± 1.3 kg/m^2, respectively), % body fat by DXA (28.5 ± 2.3; 28.2 ± 4.0; ± 30.6 ± 1.2 %, respectively), and habitual physical activity (measured and self-reported). Subjects were prescribed a eucaloric diet (Henry equation) for 72 h preceding a fasted oral glucose tolerance test (OGTT). During this time, interstitial glucose was continuously measured using a subcutaneous probe. Twenty-four h before the OGTT, subjects consumed a meal replacement drink (330 kcal: 44g carbohydrate, 11g fat, and 14g protein) containing 15 mg/kg [$^2H_{31}$]palmitate and 0.2 g/kg [^{18}O]water and were asked to collect all passed urine for the following 10 h. Indirect calorimetry was performed to determine respiratory exchange ratio (RER) before and at the end of the 120 min OGTT. Blood samples were taken every 15 min throughout the OGTT for measurement of blood glucose, serum insulin and free fatty acid (FFA) concentration. Urine samples were analysed for ^{2}H/^{1}H and ^{18}O/^{16}O isotope ratios by infrared spectroscopy in order to determine dietary fat oxidation and total body water, respectively. Two-way and one-way ANOVA was used to detect any differences in the blood and urine measurements, respectively. Data are presented as mean ± SEM.
Results: Average blood glucose during the OGTT was greater ($P<0.001$) in T2D (11.9 ± 0.9 and 10.7 ± 0.8 mmol/L for middle age and older, respectively) than control (7.6 ± 0.5 mmol/L), and average serum insulin was almost half (50.3 ± 5.05 mIU/L and 56.0 ± 7.15 mIU/L vs. 93.9 ± 11.5 mIU/L, respectively; $P=0.09$). Average 24 h interstitial glucose was also higher in T2D (9.9 ± 0.18 and 7.6 ± 0.14 mmol/L for middle age and older, respectively) compared to control (6.4 ± 0.07; $P<0.001$). There was a trend ($P=0.08$) for 10 h dietary fat oxidation to be greater in middle age T2D (22.6 ± 1.6 % recovery of dose) than older T2D (13.9 ± 3.3 %) and control (13.4 ± 2.7 %). Furthermore, fasting plasma FFA in middle age T2D (0.39 ± 0.05 mmol/L) was lower ($P=0.05$) than older T2D (0.48 ± 0.05 mmol/L) and control (0.49 ± 0.05 mmol/L), but higher ($P<0.05$) at the end of the OGTT (0.10 ± 0.03 vs. 0.05 ± 0.01 and 0.04 ± 0.01 mmol/L, respectively). RER increased during the OGTT in all groups ($P<0.001$) from similar fasted values (0.74 ± 0.05, 0.75 ± 0.04, and 0.74 ± 0.03 for controls, middle age T2D, and older T2D, respectively) to similar fed values (0.82 ± 0.03, 0.83 ± 0.02, and 0.84 ± 0.03, respectively).
Conclusion: Despite similar fasting fat oxidation, dietary fat oxidation was increased in middle age T2D compared to age matched controls. Combined with an inability to suppress plasma FFA with feeding, this suggests excessive postprandial fat delivery to skeletal muscle in T2D. The lower dietary fat oxidation in older T2D does not appear to exacerbate insulin resistance.

Higher serum levels of omentin-1 are associated with increases in glycaemia and incident type 2 diabetes: KORA F4/FF4 study

C. Herder[1,2], J.M. Kannenberg[1,2], C. Niersmann[1,2], C. Huth[2,3], M. Carstensen-Kirberg[1,2], C. Wittenbecher[2,4], M. Schulze[2,4], M. Blüher[5,2], W. Rathmann[1,2], A. Peters[2,3], M. Roden[1,6], C. Meisinger[3], B. Thorand[2,3]; [1]German Diabetes Center, Düsseldorf, [2]German Center for Diabetes Research (DZD), München-Neuherberg, [3]Helmholtz Zentrum München, Neuherberg, [4]German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, [5]University of Leipzig, Leipzig, [6]Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany.

Background and aims: Cross-sectional studies found that higher levels of the novel adipokine omentin-1 were associated with higher adiponectin and lower levels of risk factors for type 2 diabetes, but its relevance for incident type 2 diabetes is currently not understood. Therefore, this study investigated the associations between serum omentin-1, changes in glycaemia (fasting glucose, 2-hour glucose, HbA1c) and incident type 2 diabetes and compared them with adiponectin.
Materials and methods: The study was based on the population-based Cooperative Health Research in the Region of Augsburg (KORA) F4/FF4 cohort. Associations of baseline serum omentin-1 and adiponectin with changes in glycaemia were assessed in 471 non-diabetic participants, associations between both adipokines and incident type 2 diabetes in 76 cases and 430 non-cases (follow-up 6.5 years). Multivariable linear and logistic regression models were adjusted for multiple potential confounders.
Results: Higher serum levels of omentin-1 were associated with increases in fasting glucose, 2-hour glucose and HbA1c (all $p<0.001$) and with incident type 2 diabetes (adjusted OR (95% CI) 1.40 (1.03; 1.90) per SD of log2-transformed omentin-1; $p=0.032$). These associations were independent of potential confounders including adiponectin. In contrast, adiponectin levels showed inverse associations with changes in 2-hour glucose ($p=0.046$) and HbA1c ($p=0.041$), and were also inversely associated with the risk of type 2 diabetes (OR (95% CI) 0.60 (0.42; 0.85) per SD of log2-transformed of adiponectin; $p=0.004$).
Conclusion: Thus, the direction of the longitudinal associations between omentin-1 and glycaemia differed markedly from the direction observed in previous cross-sectional studies. It can be hypothesised that elevated omentin-1 levels at baseline indicating a higher risk of type 2 diabetes are the results of a counterregulatory mechanism in the face of metabolic and/or proinflammatory risk factors of type 2 diabetes.

Inverse association between fasting insulin levels and postprandial changes of plasma asprosin concentration in patients with type 2 diabetes

S. Tokumoto, E. Okamura, M. Abe, S. Honjo, A. Hamasaki;
Centre for Diabetes and Endocrinology, Tazuke Kofukai Foundation, Medical Research Institute, Kitano, Osaka, Japan.

Background and aims: Asprosin, a fasting-induced protein secreted by adipose tissue, has recently been discovered as a glucogenic hormone that promotes hepatic glucose release in mice and humans. While circulating Asprosin levels are reported to physiologically decrease after feeding, the pathophysiological role of Asprosin in patients with glucose intolerance remains poorly understood. The aim of this study was to evaluate the relationship between Asprosin postprandial concentration kinetics and other biomarkers.
Materials and methods: 11 healthy subjects and 23 type 2 diabetes mellitus (T2DM) patients underwent a 2-h meal tolerance test in the morning after an overnight fast; the meal consisted of 460 kcal of total caloric load with 56.5 g of carbohydrates, 18 g of protein and 18 g of fat. Blood samples were collected immediately before and 2 hrs after meals. HbA1c, fasting plasma glucose (FPG), total cholesterol, triacylglycerol, and other biomarkers were measured in all subjects. Plasma Asprosin levels was determined by enzyme-linked immunosorbent assay according to the manufacturer's protocol (Eiaab, Catalogue No.E15190h). Correlations were evaluated by Spearman's rank test. P values <0.05 were considered statistically significant.
Results: Fasting Asprosin levels in healthy subjects were significantly less than those in T2DM patients ($p < 0.05$). In T2DM patients, postprandial reduction of Asprosin levels showed a significant negative association with fasting insulin levels ($r = -0.41$ $p < 0.05$). No significant correlation was found between Asprosin levels and other biomarkers including FPG.
Conclusion: To our knowledge, this is the first report of a negative correlation of fasting insulin levels with postprandial reduction in Asprosin levels and higher fasting Asprosin levels in T2DM patients than healthy controls. Our results suggest that insulin resistance could be associated with the regulation of circulating Asprosin levels.

Background and aims: Syndecan 4 (SDC4) is a membrane-bound extracellular matrix protein relevant for inflammation, focal adhesion, and LDL-uptake. We recently showed that tumor necrosis factor (TNF) is highly upregulated in the subcutaneous adipose tissue one year after bariatric surgery, in the context of increased lipolysis, whereas other inflammatory cytokines were downregulated. Since TNF was described to induce SDC4 in an endothelial-like cell line, we wanted to investigate whether TNF and lipolysis may influence SDC4 expression in the adipose tissue after weight-loss.
Materials and methods: We analyzed subcutaneous adipose tissue (SAT) gene expression from 31 non-diabetic morbidly obese patients (BMI>40 kg/m^2) shortly before and one year after bariatric surgery and compared these to a lean control group. Genes relevant to lipid metabolism, insulin sensitivity and inflammation were analyzed by RT-qPCR. Independent predictors were determined by regression analysis. Primary adipocytes were stimulated in vitro for 24 hours and SDC4 gene expression was determined.
Results: Compared to the lean group, SDC4 was upregulated by 170 % ($p<0.05$) before and by 2000 % ($p<0.001$) one year after bariatric surgery. TNF expression and serum TNF were positive predictors for the postoperative SDC4 expression. Furthermore, TNF significantly upregulated SDC4 expression in cultured preadipocytes.
Conclusion: The TNF-induced upregulation of SDC4 in SAT from patients one year after bariatric surgery points to an important role of SDC4 and TNF in the context of weight-loss and lipolysis.

The role of acyl ghrelin in human visceral adipose tissue in relation to the LXR-ABC pathway and the metabolic state

R. Churm[1], S. Caplin[2], J.D. Barry[2], J.S. Davies[1], J.W. Stephens[1], S.L. Prior[1];

[1]Diabetes Research Group, Swansea University, [2]Welsh Institute of Metabolic & Obesity Surgery, Morriston Hospital, Swansea, UK.

Background and aims: Peroxisome proliferator-activated receptor gamma (PPAR-γ) induces the removal of cellular lipids by high density lipoproteins via the activation of liver X receptor isoform β (LXRβ) and in turn ATP binding cassette G1 (ABCG1). Centrally acting acyl ghrelin has been implicated as having a detrimental effect on the transcription of the PPAR-LXR-ABC pathway, resulting in increased white adipose tissue depots. However, the relationship between ghrelin, lipid retention and lipid biosynthesis genes are disputed amongst published studies. Visceral adiposity increases hepatic free fatty acid oxidation which has been implemented in triggering insulin resistance and increased glucose output. The aim of the present study was to clarify and translate contradictory theories about acyl ghrelin as a mediator of lipid homeostasis and insulin resistance within human visceral adipose tissue (hVAT).

Materials and methods: 30 hVAT biopsies taken from the greater omentum and EDTA blood samples were collected during routine abdominal surgery (Non-obese (NO)=10, Obese (O)=10 and Obese with Type 2 diabetes (OT2D)=10). RNA extracted from hVAT underwent Real Time PCR and analysed using the $2^{-\Delta\Delta CT}$ gene expression method, normalised against a β-actin housekeeper. Lipid profiles were analysed in fasted plasma samples via a standard colorimetric assay. Acyl ghrelin was measure in plasma samples that were treated with a protease inhibitor, 4-(2-aminoethyl)benzenesulfonyl fluoride hydrochloride, using a human ghrelin ELISA.

Results: Samples were split into two arms for data analysis to enable investigation of metabolic state (i) obesity effect ([OT2D+O] v NO) and (ii)diabetes effect ([O+NO] v OT2D. The analysis of obesity effect gene expression data indicates no overall gene expression alterations. However, analysis of the diabetes effect data indicates a marked down-regulation in LXRβ, ABCG1 and ghrelin (2.2, 2.2 and 2.1-fold change, respectively). Fasted acyl ghrelin levels were significantly decreased in OT2D samples compared to both O (OT2D v O: 228.5 [98-439] pg/mL v 515.5 [309-701] pg/mL, $p<0.05$) and NO individuals (OT2D v NO: 228.5 [98-439] pg/mL v 467.2 [326-508] pg/mL, $p<0.05$). Plasma acyl ghrelin was negatively correlated with plasma glucose levels ($r_s(29)=-0.37$, $p<0.05$) and body weight ($r_s(29)=-0.42$, $p<0.05$). A positive correlation was demonstrated between plasma acyl ghrelin levels with total cholesterol ($r_s(29)= 0.38$, $p<0.05$) and LDL ($r_s(29)= 0.39$, $p<0.05$).

Conclusion: Correlation of acyl ghrelin with key lipid profile markers allows us to determine that in a low acyl ghrelin environment there is a decrease in plasma lipid profiles and a decline in expression of the LXR-ABC pathway. OT2D had a significantly decreased level of circulating ghrelin, which was dependent upon plasma glucose levels and independent of octanyol modification genes. With increased endogenous glucose levels present in OT2D already being shown to increase cellular lipid concentrations, data suggests that the cellular export mechanism to counterbalance this lipid increase is being stalled due to a decline in acyl ghrelin levels. These findings correspond to the observed low plasma lipid concentrations due to hypertrophy trapping lipids within the cell and lowering the rate of release into the circulation independent of statin usage.

Background and aims: Human whole abdominal subcutaneous adipose tissue (WSAT) is divided by Scarpa's fascia in two putative metabolically distinct subdepots, referred to as deep (DSAT) and superficial (SSAT) adipose tissue layers. Previous studies showed that whole body insulin sensitivity (IS) correlates negatively with abdominal DSAT/WSAT thickness and positively with both muscle mitochondrial function and lipogenesis in WSAT of glucose-tolerant humans (CON). This study aimed to characterize differences between the two WSAT layers by assessment of SSAT/WSAT thickness, mitochondrial activity/efficiency and stearic-to-palmitic acid ratio (18:0/16:0), as marker of lipogenesis, in SAT of male patients with type 2 diabetes (T2D).

Materials and methods: We included 14 T2D and compared them to 14 CON matched for body mass index (BMI), age and WSAT thickness (32 ±1 kg/m^2, 53±2 yrs, 29±2 mm vs. 31±1 kg/m^2, 53±2 yrs, 27±3 mm). All participants underwent euglycemic-hyperinsulinemic clamp tests to assess M-values, as a measure for IS, as well as ultrasound imaging of SSAT and DSAT thickness at the level of rectus abdominis muscle, validated by single-slice magnetic resonance imaging. Ultrasound guided biopsies were performed to obtain targeted samples of SSAT and DSAT to assess 18:0/16:0 by gas chromatography-mass spectrometry. Furthermore, maximal mitochondrial oxidative capacity and mitochondrial efficiency, reflected by respiratory control ratio (RCR=state 3/state 4), was assessed via high-resolution respirometry in biopsy samples of both depots.

Results: T2D had lower 18:0/16:0 in SSAT than CON (0.15±0.01 vs. 0.18±0.01, $p<0.05$). The comparison of both depots in T2D showed lower 18:0/16:0 in SSAT than in DSAT (0.15±0.01 vs. 0.17±0.01, $p<0.01$). IS was 41% lower and SSAT/WSAT thickness was 33% lower in T2D compared to CON ($p<0.001$ respectively). However, 18:0/16:0 and SSAT/WSAT did not correlate with M-value. RCR, as marker of mitochondrial efficiency, was 33% lower in SSAT of T2D compared to SSAT of CON ($p<0.001$). Furthermore, maximal oxidative capacity of SSAT correlated positively with M-value ($r=0.80$, $p<0.001$) in CON upon adjustment for age and BMI, whereas maximal oxidative capacity was similar in both depots.

Conclusion: In T2D abdominal WSAT is composed of two distinct subdepots. The decrease of SSAT thickness, mitochondrial efficiency and stearic-to-palmitic acid ratio in T2D compared to CON point the presence of an unfavorable subphenotype in SSAT of T2D.

Differences in abdominal and femoral adipose tissue oxygen tension contribute to the adipose tissue phenotype in overweight and obese women

M.A.A. Vogel[1], J.W.E. Jocken[1], H. Sell[2], N. Hoebers[1], Y. Essers[1], K. Rouschop[3], M. Čajlaković[4], E.E. Blaak[1], G.H. Goossens[1];

Background and aims: Upper and lower-body adipose tissue (AT) depots exhibit opposing associations with obesity-related cardiometabolic diseases. AT oxygen tension (pO_2) may be a key player in AT dysfunction. We compared *in vivo* abdominal (ABD) and femoral (FEM) subcutaneous AT pO_2 in overweight/obese women, and investigated *in vitro*

depot-specific effects of physiological AT pO_2 on adipocyte metabolism and inflammation.

Materials and methods: ABD and FEM subcutaneous AT pO_2 were assessed in 8 well-phenotyped overweight/obese (BMI 34.4±1.6 kg/m^2) post-menopausal women with impaired glucose metabolism using an optochemical measurement system. AT blood flow (ATBF) was measured (^{133}Xe wash-out), and ABD and FEM AT biopsies were collected to determine adipocyte morphology and AT gene expression. The effects of prolonged exposure (14d) to physiological human AT pO_2 on adipogenic differentiation, adipokine expression/secretion, mitochondrial respiration and glucose uptake was investigated in differentiated human multipotent adipose-derived stem cells, derived from the same individuals.

Results: AT pO_2 was significantly higher in ABD than FEM AT (62.7 ±6.6 vs. 50.0±4.5 mmHg, P=0.013), whereas ATBF was comparable between depots (1.8±0.3 vs. 2.8±0.5 ml•100g tissue^{-1}•min^{-1}, respectively, P=0.122). Oxygen consumption was significantly lower in differentiated ABD than FEM human adipocytes for all pO_2 exposure regimens. Low physiological pO_2 (5% O_2) significantly decreased pro-inflammatory gene expression, increased basal glucose uptake and altered adipokine secretion in differentiated ABD and FEM adipocytes.

Conclusion: We demonstrated for the first time that AT pO2 is higher in ABD than FEM subcutaneous AT in overweight/obese women, likely due to lower oxygen consumption in ABD adipocytes. Moreover, physiological pO2 exposure markedly affects adipocyte functionality in a depot-independent manner, suggesting that altered pO2 may contribute to AT dysfunction in human obesity.
