## Abstract

The structure of a polyatomic molecule derived from observed spectroscopic moments of inertia differs appreciably from both the equilibrium stmature and the zero-point average structure. A perturbation expansion of the moments of inertia is derived here in a form which allows the vibrational displacements to be referred to any fixed configuration of the atoms as origin. A method for evaluating the expansion coefficlencs is given which proceeds "atom-by-atom." Linear WXYZ, branched WXYZ, and symmetric WXY ${ }_{3}$ moleculea are treated in detail.

Empirical data show that the anhamonicity of the vibrations gives rise to the most important of the corrections required to obtain the equilibrium structure. Except for a few molecules, the anharmonicity is not accurately known. It is shown, however, that the anhamonic contributions are completely absorbed (to a practical approximation). in displacing the average configuration from the equilibrium one. Therefore the moments of inertia for the zero-point average configuration of a molecule can be derived from the observed effective moments by applying corrections which depend only upon the hamonic part of the vibrational potential.

[^0]The traditional model of point masses connected by weightless rigid rods gives a remarkably good fit to the rotational spectra on most molecules: However, molecular vibrations make the "effective" moments of inertia obtained from a rigid rotor analysis differ appreciably from the moments for the equilibrium structure of the molecule. Even in the ground state, the contribution of zero-point vibrations to the effective moments is usually of the order of $1 \%$. This is far larger than experimental uncertainties in high resolution spectroscopy, particularly microwave spectroscopy, which commonly yields moments accurate to $0.002 \%$ or better.

Except for diatomic molecules and the simplest polyatomic molecules, "experimental determination of the vibrational contributions has not been reasible. Theoretical calculations have been forestalled by thelr complexity as well as lack of surficient information about vibrational potential functions. Some of the conceptual difficulties are evident in the discussions, ${ }^{1}$ enlivened by several wong conclusions, which led to Eckart's fomulation ${ }^{2}$ of the conditions necessary to define an internal axis system that would insure the maximum uncoupling of vibration and rotation. ${ }^{3}$ Wison and Howard ${ }^{4}$ carried out a perturbation treatment of the vibration-rotation coupling and showed that the rotational spectrum of most molecules (after allowance for centrifugal distortion) should be that of a fictitious rigid rotor. Wilson and Howard emphasized that the effective moments of inertia are not simply related either to the average of the instantaneous moments or to the average of their reciprocals, because of Coriolis forces and
other interactions, but this point has since often been overlooked. Nielsen, Dennison, and others extended the treatment and derived explicit expressions relating the effective moments to the equilibrium momente of inertia. 5 Unfortunately, the terms that are nearly always the most important in these relations involve the anhamonic part of the vibrational potential, which ls accurately known for only a few polyatomic molecules.

The problem of deriving equilibrium structures for polyatomic molecules has therefore remained intractable, and the general practice has been to make direct use of the efrective moments. The structures obtained are usually refered to as "rostructures." The inconsistencies in $r_{o}$ parameters caused by zepo-point vibrations are particulariy noticeable in microwave data for isotopic molecules, ${ }^{6}$ and attempts have been made to estinate their effect in a number of specific cases. ${ }^{7-11}$ Also, Costain ${ }^{12}$ has proposed a general procedure of analysus, in which Krattchman's equations 13 are used to detemine stmutures by fitting the dipferences of the effective moments of isocopic species rather chan the absolute values of the moments. Costain has designated the parameters obtained by this "substitution" method as the " $p_{s}$ structure." He has shown cases where remariably consistent $r_{s}$ parameters are obtained even when there is considerable variation in the $r_{o}$ parameters obtained by fitting different combinations of the absolute values of the moments. Pierce ${ }^{14}$ has discussed the use of second differences in cases where multiple isotopic substitutions are made. Although these semiempirical methods have given promising results, it has not been clear whether they make the optimum use of the data, and several
vexine problems reman, inolucing the dificuity or locating atoms near pronotpat axes, the means of allowine for "inextal defects," and the guesthon of the proper proceduxe for analyzine data when all atons have not been 1 fotopaceliy subatituted.

Another gustion when ss not yet resclved is the relation on

In the present study the am has been to examane these practical problens of atructure analysis from the viewponnt of che general theory of ytbration-motathon interartions. Mah of the physieal
 work anready extsting. 5 Howevers the avaitabie amacuscrons have ubualiy been ondented soward the Interpeetation of spetra rather then any specifle undembancing of problens ot struoture deteminatlong and we have tound it auvantageous to take an approach which discere tr many detalis In particular, the treatment is mocirica here so that the perturbation expentions are not rectricted to the egunibrivm contigurathon, but nay be resermed to any arbitraxily
chosen consiguration of the atoms. From this it is found that the moments of inerta for the average configuration of a molecule may be derived from the observed effective moments by applying corrections which depend only upon the hamonic part of the vibrational potential. ${ }^{17}$ Also, the calculations are simplified by a formulation which takes advantage of wilson's methods for vibrational analysis. 18 This paper outlines the derivations cogether with some qualitative conslderations. Applications to structure analysis are presented in succeeding papers on the calculation of average structures (Part II); inertial defects (Part III), and Isotopic substitution (Part IV).

## PREIIMINARY ANALYSIS OF SIMPLE CASES

The basis for approximations to be introduced in the general treatment can be illustrated most simply with diatomic and triatomic molecules:

## Diatomic Molecules

The vibrational average of any function of internuclear distance is readily obtained from a series expansion in $\xi=(r-r) / r_{e}$, the relative deviation from the equilibrium distance. Thus the average $n^{\text {th }}$ power of the bond distance is given by 19

$$
\begin{equation*}
\left\langle r^{n}\right\rangle^{1 / n}=k r_{e} \tag{I}
\end{equation*}
$$

where the scale factor is

$$
\begin{equation*}
\mathbb{k}=1+\langle\xi\rangle-\frac{1}{2}(1-n)\left\langle\xi^{2}\right\rangle+\cdots \tag{2}
\end{equation*}
$$

The corresponding correction terms for moments of inertia and rotational constants are given by

$$
\begin{align*}
& I=r^{2}=x^{2} I_{e}  \tag{3a}\\
& B=h / 8 \pi^{2} I=x^{-2} B_{e} \tag{3b}
\end{align*}
$$

In these formulas

$$
\begin{align*}
& \langle\xi\rangle=-a_{1}\left(3 B_{e} / \omega_{e}\right)\left(v+\frac{1}{2}\right)  \tag{4a}\\
& \left\langle\xi^{2}\right\rangle=\left(2 B_{e} / \omega_{e}\right)\left(v+\frac{1}{2}\right) \tag{4b}
\end{align*}
$$

where $\omega_{e}$ is the harmonic vibrational frequency and $a_{1}$ is $a$ (dinensionless) cubic anharmonic constant. ${ }^{20}$ In Eqs. (4) and elseWhere only terms Iinear in the vibrational quantum number are retained; this approximation is well justified empirically.

In Table I various kinds of average bond lengths are compared. For the ground vibrational state the direct average, $\langle r\rangle$, 1 essentially the same as the parameter $r_{g}(0)$ obtained from electron diffraction. ${ }^{21}$ This is always larger than the effective bond lentth, $r_{0}(n=-2$ average), obtained from rotational spectroscopy, which is in turn larger than Costain's substitution parancter, $T_{s}$. The inverse cube average, $\left\langle s^{-3}\right\rangle^{-1 / 3}$, appears in interaction constants measured in magnetic resonance ${ }^{19}$ or microwave maser ${ }^{22}$ experiments.

As indicated in Table $I$, the deviation of $\langle r\rangle$ from $r_{e}$ is due entirely to anharmonicity. Furthermore, Eq. (I) gives the same anharmonic contribution for any $\underline{n}^{\text {th }}$ power average. Any of these averages can therefore be derived from 〈r> by means of a correction which involves just the harmonic vibrational amplitude,

$$
\begin{equation*}
\left\langle r^{n}\right\rangle^{1 / n}=\langle r\rangle-\frac{1}{2}(1-n)\left\langle 5^{2}\right\rangle r_{e} \tag{5}
\end{equation*}
$$

This gives rise to the parallelism displayed in Fig. Is in which the value of $x-1$ for each bond length is plotted versus the anharmonic constant. The ordinate scale is marked in mitiples of $\left\langle\xi^{2}\right\rangle$; thus, for a typical ground state value of $\left\langle\hat{\xi}^{2}\right\rangle=10^{-3}$, each; division corresponds to an $0.1 \%$ deviation from $r_{e}$.

The anharmonic constant can be detemined from $\alpha_{e}$, the spectroscopic vibration-rotation interaction constant. Since

$$
\begin{equation*}
B_{v}=B_{e}-\left(v+\frac{1}{2}\right) \alpha_{e} \tag{6}
\end{equation*}
$$

- comparison with Eq. (3b) gives

$$
\begin{equation*}
\alpha_{e}=-\left(6 B_{e}^{2} / \omega_{e}\right)\left(1+\alpha_{1}\right) \tag{7}
\end{equation*}
$$

In structure analysis it is convenient to use instead a parameter $\epsilon$ which gives the correction to the effective moment of inertia,

$$
\begin{align*}
& I_{v}=K / B_{v}=I_{e}+\left(v+\frac{1}{2}\right) \epsilon  \tag{8}\\
& \epsilon=I_{e}\left(\alpha_{e} / B_{e}\right)=-\left(6 K / \omega_{e}\right)\left(I+a_{I}\right) \tag{9}
\end{align*}
$$

where $K=h / 8 \pi^{2}$. In terms of $\epsilon$, the scale factor for the effective bond length is

$$
\begin{equation*}
K=I+\frac{1}{2}\left(V+\frac{1}{2}\right)\left(\epsilon / I_{e}\right) \tag{10}
\end{equation*}
$$

The ratio of the anharmonic and harmonic vibrational contributions in Eq. (10) is just equal to the anharmonic constant,

$$
\begin{equation*}
\epsilon_{a} / \epsilon_{h}=a_{1} \tag{11}
\end{equation*}
$$

as seen from. Eq. (9). Since $a_{1}$ is between -2 and -4 for almost ail diatomic molecules, ${ }^{23}$ the anharmonic term predominates; however, the harmonic term 1 is of opposite sigen and compensates for about $25 \%$ to $50 \%$ of the anharmonic displacement. For the general $\underline{n}^{\text {th }}$ power average the ratio in Eq. (II) becomes $3 a_{1} /(1-n)$, so only for $n>1$ does the harmonic tem reinforce the anharmonic one. On the other hand only for large negative values of $n$ does the cancellation become substantially complete (at $n=-5$ for $a_{1}=-2 ;$ at $n=-11$ for $a_{1}=-4$ ).

The effect of vibrations on structures determined by isotopic differences ${ }^{12}$ is considered in Part IV, where it is shown that the scale factor for the $r_{s}$ bond length is

$$
\begin{equation*}
k=1+\frac{1}{2}\left(v+\frac{1}{2}\right)\left(\epsilon / I_{e}\right) I, \tag{12a}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{S}=\left(\mu / m_{1}\right)\left[1+\left(\mu_{1} / \mu\right)^{\frac{1}{2}}\right]^{-1}+\left(\mu / m_{2}\right)\left[1+\left(\mu_{2} / \mu\right)^{\frac{1}{2}}\right]^{-1} . \tag{1.2b}
\end{equation*}
$$

Here $m_{1}$ and $m_{2}$ denote the masses or the atoms in the parent molecule and $\mu_{1}, \mu_{2}$ the reduced masses of the isotopically substituted molecules. The factor faries only slightly with isotopic substitution. It approaches an upper limit of one-hale when both $\mu_{I}$ and $\mu_{2}$ differ negligibly from $\mu_{2}$ whereas $f=0.414$ for deuterium substitution in $\mathrm{H}_{2}$. As seen by comparing Egs. (10) and (12), the deviations from equilibrium

$$
\begin{aligned}
& I_{s}-r_{e}=f\left(I_{\mathrm{v}}-r_{e}\right) \\
& I_{s}-I_{e}=I\left(I_{\mathrm{v}}-I_{e}\right)
\end{aligned}
$$

are correspondingly less than those for the effective bond length. 12 Similariyg it is found that $\$_{s}$ will show about $50 \%$ less variation with isotopic species than does $r_{v^{*}}$ Howevers the use of isotopic differences does not alter the ratio of anharmonic and harmonic contributions, which is still given by Eq. (11).

## Triatomic Molecules

The effective moment of inertia for a linear triatomic molecule,

$$
I_{v}=I_{e}+\Sigma_{s}\left(v_{s}+\frac{1}{2} \alpha_{s}\right) \epsilon_{s},
$$

contains contributions from the symmetric ( $s=1$ ) and antisymetric ( $s=3$ ) stretching vibrational modes and from the doubly degenerate bending ( $s=2, d_{2}=2$ ) mode. These corrections may be written in a form

$$
\begin{equation*}
d_{\mathrm{s}} \epsilon_{\mathrm{s}}=-\left(6 \mathrm{~K} / \omega_{\mathrm{s}}\right)\left(\mathrm{H}_{\mathrm{s}}+A_{\mathrm{s}}\right) \tag{13}
\end{equation*}
$$

analogous to Eq. (9). The harmonic terms $H_{s}$ are readily evaluated from formulas given in Part II. However, except for a few cases, ${ }^{24}$ the anharmonic potential constants are not known sufficiently well to allow reliable values or the $A_{s}$ to be caiculated. Experimental values of some of the $\epsilon_{s}$ coefficients are available for several molecules and by subtracting calculated values of the harmonic contributions we have evaluated the $A_{S}$ terms. Table II iists the ratios

$$
\epsilon(\text { anharmonic }) / \epsilon(\text { hamonic })=A_{s} / H_{s}
$$

which were obtained. It is seen that for all the linear molecules the anharmonic contribution is dominant and opposite in sign to the harmonic contribution, just as for diatomic molecules. For the
symetric stretenirg mode, the ratio is roughly the same as that given by Eq. (II) for related diatomics. In most cases, however, the anharmonic contribution is enhanced considerably in the other modes ard in the total correction.

This pattern does not hold for $\mathrm{H}_{2} \mathrm{O}$, especially in the bending mode. As yet there is virtualiy no information available for other nonlinear triatomic molecules.

Unilke the diatomic case, in isotopic differences the ratio of contributions from $A_{S}$ and $H_{S}$ does not remain constant. orten it is widely different for different modes. Again the anhamonicity nearly always gives the doninait contribution, as shown in Part IV.

Figure 2 indicates the relative contribution of the stretching and bending modes. Data is included ror all polyatomic molecules. for which the equilibrium moment of inertia is known. It is found that the contributions from bending are usually opposite in sign to those from stretching, but somewhat smaller in magnitude. Consequently, the total correction,

$$
\epsilon=\Sigma_{s} \dot{a}_{s} \epsilon_{s},
$$

(shown by the solid points) in most cases falls substantially below the dashed line, which gives the corrections due to stretching alone. Another comparison (shown by open points) with the sum of stretching terms is obtained by assigning to each bond the observed $\epsilon_{s}$ value for the corresponding diatomic nolecule. Except for $\mathrm{C}_{2} \mathrm{H}_{2}$, HCN , and $\mathrm{H}_{2} \mathrm{O}$, this proves to be a considerable underestimate, An example in which the contribution from bending outweighs that from stretching is the a-axis principal monent of inertia of $\mathrm{H}_{2} \mathrm{O}$.

For a inear, symmetric $\mathrm{XY}_{2}$ molecules it is Peasible to express the $n^{t h}$ power average of the bond distance, $\left\langle r^{n}\right\rangle^{1 / n}$, and the vibrationrotation parameters of Eq. (I3) as explicit functions of the force; constants, atomic masses, and geometry. The results are collected $\ddagger n$ Table III. As indicated, the quadratic and cubic force constants refer to internal displacement coordinates, and symmetry allows oniy certain terms to appear in the potential enerey. ${ }^{18}$ For the symmetric stretching mode, the form of the vibrational parameter. $\lambda_{1}$ and the coffricients $H_{1}$ and $A_{1}$ is the same as in the diatomic case; however, this is not so for the other modes. The calculation of $\left\langle r^{n}\right\rangle^{1 / n}$ starts from the relation

$$
2 r=2 r_{e}+S_{1}+S_{3}
$$

Up to terms linear in $v+\frac{1}{2}$, the only normal coordinate which enters is the symmetric stretch, proportional to $S_{1}+S_{3}$, and the vibrational averages may be evaluated as indicated in Eqs. (34) and (35) and Appendix C. It is found that Eqs. (I) (3) and (5) still hold, but $\xi$ is replaced by $\frac{1}{2}\left(S_{1}+S_{3}\right)$ and the averages in Eq. (4) take the values given in Table III.

- From these results, it is readily shown that the effective rotational constant $B_{v}$ is not simply the vibrational average, 〈B>. The lateer is given by

$$
\langle B\rangle=K\left\langle I^{-1}\right\rangle=(K / 2 m)\left\langle r^{-2}\right\rangle
$$

where $m$ is the mass of the $Y$ aton. From Tables I and III, we find

$$
\begin{equation*}
\left\langle i^{n}\right\rangle^{1 / n}=\langle s\rangle-(1-n)\left(B_{e} / \omega_{1}\right)\left(v_{I}+\frac{1}{2}\right) \tag{14}
\end{equation*}
$$

The effective bond length, however, is given by

$$
r_{v}=x r_{e}=\left(I_{v} / 2 m\right)^{1 / 2}
$$

with

$$
k=1+\frac{1}{2} \sum_{s}\left(v_{s}+\frac{1}{2} \alpha_{s}\right)\left(\epsilon_{s} / I_{e}\right)
$$

as in Eq. (10), Thus we find

$$
\begin{equation*}
r_{V}=\langle r\rangle-\Sigma_{\mathrm{S}}\left(3 B_{\mathrm{e}} / \omega_{\mathrm{S}}\right) \mathrm{H}_{\mathrm{S}}\left(\mathrm{~V}_{\mathrm{S}}+\frac{1}{2}\right) \tag{15}
\end{equation*}
$$

so that $r_{V}$ has terms involving $H_{2}$ and $H_{3}$ not present in $\left\langle r^{-2}\right\rangle-1 / 2$. As" shown for the general case in Eq. (26) and Appendix B, these "extra" terms arise from Corfolis interactions. Only for diatomic molecules is the effective rotational constant simply proportional to $\left\langle I^{-1}\right\rangle$ 。

In EqS. (14) and (15) it is again found, however, that any of the $n^{t h}$ power average bond lengths may be computed from the effective bond length without knowledge of the anharmonic force constants, Just as in Eq. (5) for the diatomic case.

Table IV gives a detailed analysis of the contributions to $I_{0}-I_{e}$ for $\mathrm{CO}_{2}$. It is seen that the Coriolis terms $\mathrm{H}_{2}$ and $\mathrm{H}_{3}$ are comparable to $H_{I}$. Another typical feature, found for all the inear triatomic molecules of Fig. 2, is the substantial cancellation which occurs between bending and stretching and between harmonic and anharmonic terms.

## GENERAL FORMULATION

The results found for the diatomic and linear $X_{2}$ molecules suggest that even in a polyatomic molecule the main effect of vibrational anhamonicity is to displace the average configuration of the atoms from the equilibrium one. We shall confirm this by deriving relations between the effective moments of inertia obtained from spectroscopy and the moments that correspond to various configurations of the atoms. Although a perturbation treathent parallel to the usual one ${ }^{5}$ gives the same results, another approach, patterned aiter the treatment of diatomics, is used here to simplify the formulation.

## CoordInates and Hamiltonian

The positions of the atoms are specified by vectors $x_{i}$ whose Cartesian components ( $\alpha_{i}, \beta_{i}, \gamma_{i}$ ) are referred to a set or axes moving with the molecule (the so-called molecule-fixed axes). A standard configuration or the atoms, which need not be the equilibrium configuration but should not diffex greatly from it, 26 is defined by a set of coordinates $\left(\alpha_{i}^{*}, \beta_{i}^{*}, \gamma_{i}^{*}\right)$. Vibrational displacements from the standard configuration are described by nomal coordinates $Q_{s}$, which are derined in terms of the increments

$$
5 \alpha_{i}=\alpha_{i}-\alpha_{i}^{*}
$$

etc. The increments are not all independent, but must atisfy the Eckart conditions.

$$
\begin{align*}
& \Sigma_{1} m_{i} \delta \alpha_{i}=0  \tag{16}\\
& \Sigma_{i} m_{1}\left(\alpha_{i}^{*} \delta \beta_{1}-\beta_{1}^{*} \delta \alpha\right)=0_{2} \tag{17}
\end{align*}
$$

etc. These sir conditions serve both to define the molecule-fixed axis system and to complete the transformation equations which relate the $3 N$ atomio displacements to the $3 N-6$ noxmal coordinates. 2,18

$$
\begin{equation*}
0 \alpha_{i}=m_{i}^{-1 / 2} \Sigma_{s} \ell_{i s}^{(\alpha)} Q_{s} \tag{18a}
\end{equation*}
$$

and

$$
\begin{equation*}
Q_{s}=\Sigma_{\alpha} \Sigma_{i} m_{i}^{1 / 2} 2_{Q i}(\alpha)_{0 \alpha_{i}} \tag{18b}
\end{equation*}
$$

The mass adjustment makes the transfomation orthonomal, so that

$$
\begin{equation*}
\Sigma_{i} \Sigma_{\alpha} l_{i s}^{(\alpha)} l_{i t}^{(\alpha)}=\delta_{s t} \tag{19}
\end{equation*}
$$

We shall consider later a method of evaluating the transformation coefincients, as our final results will be expressed in terms of them.

The potential energy associated with the vibrational displacements is expanded as

$$
\begin{equation*}
2 V=\Sigma_{s} V_{s} Q_{s}+\Sigma_{s} \lambda_{s} Q_{s}^{2}+\Sigma_{s} k_{s s s} Q_{s}^{3}+3 \Sigma_{s} \Sigma_{i} k_{s s} Q_{s}^{2} Q_{t}+\cdots \tag{20}
\end{equation*}
$$

Unless the standard configuration is the equilibrium one, the coefficients of the Inear terms will not vanish. In any case, however, the normal coordinates can be chosen to eliminate cross tems in the quadratic part of the potential energy. Furthermore, We can relate the coefrictents in (20) to the usual parameters, Which refer to an expansion about the equilibrium configuration. As shown in Eq. (42), for practical purposes the vibration frequencies and cubic constants are unchanged and the coefficient of the lineax term takes the form

$$
\begin{equation*}
\mathrm{V}_{\mathrm{S}}=-3\left[\sigma_{\mathrm{sS}}\left\langle\mathrm{Q}_{\mathrm{s}}^{2}\right\rangle+\Sigma_{\mathrm{c}} \sigma_{\mathrm{tS}}\left\langle Q_{\mathrm{c}}^{2}\right\rangle\right] \tag{21}
\end{equation*}
$$

Where the constants $\sigma_{s s}$ and $\sigma_{t s}$ are a linear combination of $\lambda_{s}, k_{\text {sss }}$, and $k_{t \in s}$.

The Hamiltonian for vibration and rotation may be written as

$$
\begin{equation*}
2 \mathrm{H}=m^{\dagger} I^{-1} m+(P-p)^{\dagger}(P-\underset{\sim}{p})+2 V \tag{22}
\end{equation*}
$$

as shown in Appendix A. (See Table $V$ for notation.) If the molecule were vibrating but not rotating, only the terms ${ }^{18}$

$$
\begin{equation*}
2 t_{\mathrm{Vib}}={\underset{\sim}{P}}^{\dagger} \underset{\sim}{P}+2 V \tag{23}
\end{equation*}
$$

would remaing whereas if the molecule were "rrozen" in the standard configuration, only the kinetic energy of rigid rotation would appear,

$$
\begin{equation*}
2 H_{r i g 1 d}=m_{n}^{\dagger}\left(I_{\sim}^{\mu l}\right)^{*} \underset{\sim}{m} \tag{24}
\end{equation*}
$$

This involves just the inverse of the moment of inertia tensor for the standard configuration and since principal axes are used

$$
\begin{align*}
& I_{\alpha}^{*}=\Sigma_{1} m_{1}\left(\beta_{i}^{* 2}+\gamma_{1}^{* 2}\right)  \tag{25a}\\
& I_{\alpha \beta}^{*}=-\Sigma_{i} m_{1} \alpha_{i}^{*} \beta_{1}^{*}=0 \tag{25b}
\end{align*}
$$

In the vibrating molecule additional contributions to the rotational energy arise in two ways. One is the dependence of the moments of Inertia of the distorted molecule on the nomal coordinates. This can be evaluated by a straightrorward vibrational average, using the eigenfunctions $\psi_{\text {vin }}$ associated with (23). The other contributions come from the terms involving $P$ in (22). As shown in Appendix $A$, the operator $P$ is proportional to $\underset{\sim}{m}$ and represents the part of
the vibrational momentum that arises from comiolis forces in the rotating molecule. A second order perturbation treatment of these Coriolis interactions therefore yields tems quadratic in m which contribute to the effective moments of inertia. Hence the effective moments are given by

$$
\begin{equation*}
I_{V}=\left\langle I^{-1}\right\rangle^{-I}+\text { Coriolis terms } \tag{26}
\end{equation*}
$$

The vibrational average of ${\underset{\sim}{I}}^{-1}$ is evaluated in the next section and the Corlolis terms are treated in Appendix B.

The result of this perturbation treatment is to replace (22) With an effective rotational Hamiltonian,

$$
\begin{equation*}
H_{\text {rot }}=m_{\sim}^{\dagger} \underset{\sim}{B} m_{\sim}=\Sigma_{\alpha} \Sigma_{\beta} B_{\alpha \beta} m_{\alpha} m_{\beta} \tag{27}
\end{equation*}
$$

in which the rotational constants take the fom

$$
\begin{equation*}
B_{\alpha \beta}=\left(K / I_{\alpha}^{*}\right) \delta_{\alpha \beta}-\Sigma_{s}\left(v_{S}+\frac{1}{2} \alpha_{S}\right) \alpha_{S}^{\alpha \beta} \tag{28}
\end{equation*}
$$

The vibration-rotation interactions 27 thus contribute both diagonal and nondiagonal terms to the effective moment of inertia tensor, whose elements may be written as

$$
\begin{equation*}
I_{\alpha \beta}^{V}=I_{\alpha}^{*} \delta_{\alpha \beta}+\Sigma_{S}\left(V_{S}+\frac{1}{2} \alpha_{G}\right) \epsilon_{S}^{\alpha \beta} \tag{29}
\end{equation*}
$$

where

$$
\epsilon_{\sigma}^{\alpha \beta}=\left(I_{\alpha} I_{\beta} / K\right) \alpha_{\sigma}^{\alpha \beta}
$$

as found by inverting (27). The calculation indicated in (26) will provide expressions for the coefficients $\epsilon_{S}^{\alpha \beta}$ as functions of the molecular geometry, atomic masses, and potential energy paraneters.

## Vibrational Averages

The componenta of the instantaneous moment of inertia tensor nay be expanded as

$$
\begin{equation*}
I_{\alpha \beta}=I_{\alpha}^{*} \delta_{\alpha \beta}+\Sigma_{S} E_{S}^{\alpha \beta_{Q}}+\Sigma_{s} \Sigma_{\delta} A_{S t}^{\alpha \beta_{S}} Q_{t}+\cdots, \tag{30}
\end{equation*}
$$

Where the coefficients

$$
\begin{aligned}
& a_{s}^{\alpha \beta}=\left(\partial I_{\alpha \beta} \partial Q_{s}\right)_{*} \\
& A_{s t}^{\alpha \beta}=\left(\partial^{2} I_{\alpha \beta} / \partial Q_{s} \partial Q_{t}\right)_{*}
\end{aligned}
$$

are evaluated in terms of the transformation relations (18) as indicated in Eq. (48). The corresponding expansion of the inverse moment of inertia tensor is given by

$$
\begin{align*}
\left(I^{-1}\right)_{\alpha \beta} & =\delta_{\alpha \beta} / I_{\alpha}^{*}-\Sigma_{s} z_{s}^{\alpha \beta_{Q}} \\
& -\Sigma_{s} \Sigma_{t}\left[A_{s i}^{\alpha \beta}-\Sigma_{\gamma} \alpha_{s}^{\alpha \gamma} \alpha_{s}^{\beta \gamma} / I_{\gamma}\right] Q_{s} Q_{\psi}+\cdots \tag{31}
\end{align*}
$$

In the vibrational average there is no mixing of the contributions from the various parts of (31) and the Coriolis tems of Appendix $B_{2}$ as long as only terns Inear in $v_{G}+\frac{1}{2}$ are retained. The cross terms $\left\langle Q_{S} Q_{t}\right\rangle$ also do not contribute in this order of approximation. Thus, after averaging and re-inverting (31) we have

$$
\begin{align*}
\left\langle\left(I^{-1}\right)_{\alpha \beta}\right\rangle^{-1} & =I_{\alpha}^{*} \delta_{\alpha \beta}+\Sigma_{s} a_{s}^{\alpha \beta}\left\langle Q_{s}\right\rangle \\
& +\Sigma_{s}\left[A_{s S}^{\alpha \beta}-\Sigma_{\gamma} a_{s}^{\alpha \gamma_{2} \beta \gamma} / I_{\gamma}\right]\left\langle Q_{s}^{2}\right\rangle+\cdots \tag{32}
\end{align*}
$$

To this we must add the Coriolys contributions from Eq. (B6),

$$
\begin{equation*}
-4 \Sigma_{s} \Sigma_{t}\left[\zeta_{s t}^{\alpha} \rho_{s t}^{\beta} \lambda_{s} /\left(\lambda_{s}-\lambda_{t}\right)\right]\left\langle Q_{s}^{2}\right\rangle, \tag{33}
\end{equation*}
$$

in order to obtain the effective moment of inertia. The requisite vibrational averages are given by

$$
\begin{equation*}
\left\langle Q_{s}\right\rangle=-\frac{3}{2}\left[\left(k_{s s s}-\sigma_{s s}\right)\left\langle Q_{s}^{2}\right\rangle+\Sigma_{t}\left(k_{t t s}-\sigma_{t s}\right)\left\langle Q_{t}^{2}\right\rangle / \lambda_{s}\right. \tag{34}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle Q_{s}^{2}\right\rangle=\left(2 \mathrm{~K} / \omega_{s}\right)\left(v_{s}+\frac{1}{2} \alpha_{s}\right), \tag{35}
\end{equation*}
$$

as, shown in Appendix c. When (34) is substituted into (32), there results a double sum over the nondiagonal cubic constants. However, this may be rearranged to make a common factor of $\left\langle Q_{S}^{2}\right\rangle$ appear in all the terms. Thus we obtain

$$
\begin{align*}
& \epsilon_{\mathbb{S}}^{\alpha \beta}(\text { har })=\left(2 K / \omega_{s}\right)\left[A_{s s}^{\alpha \beta}-\Sigma_{\gamma}{ }^{\alpha} \gamma_{a} \beta \gamma^{2} / I_{\gamma}-\Delta \Sigma_{t} \zeta_{s t}^{\alpha} \xi_{s t}^{\beta} \lambda_{s} /\left(\lambda_{s}-\lambda_{t}\right)\right]  \tag{36}\\
& (36)  \tag{37}\\
& \epsilon_{s}^{\alpha \beta}(\text { anhar })=\left(-3 K / \omega_{s}\right)\left[a_{s}^{\alpha \beta}\left(k_{s s s}-\sigma_{s s}\right) / \lambda_{s}+\Sigma_{t} a_{t}^{\alpha \beta}\left(k_{s s t}-\sigma_{s t}\right) / \lambda_{t}\right]
\end{align*}
$$

as the general formulas for the "harmonic" and "anharmonic" parts of the coefficients in Eq. (29). By comparison with (30) and (3I) it is seen that the first term in $\epsilon_{S}$ (har) represents a direct average over the instantaneous moment of inertia, 〈I>; the second term arises because it is the reciprocal moment which is actually averaged; and the third term accounts for the Coriolis contributions. 28 The two latter effects do not enter $\varepsilon_{s}$ (anhar), however. These formulas enable us to relate the moments of inertia for any choice of the standard configuration to the observed effective moments.

## Compartson of Equilibrium and Average Configurations

When the equilibrium configuration is the standard, $\sigma_{s s}=\sigma_{s t}=0$ and the formulas (36) and (37) become equivalent to the results derived by Nielsen. ${ }^{5}$ When the average configuration is taken as the standard. we shall find that

$$
\begin{equation*}
\epsilon_{\mathrm{s}}^{\alpha \beta}(\operatorname{anh} a r)=0 . \tag{38}
\end{equation*}
$$

In the following comparisons, we indicate by an overhead bar quantities which refer to the equilibrium configuration as the standard. Thus from (18) we have

$$
\alpha_{1}-\bar{\alpha}_{i}=m_{i}^{-1 / 2} \Sigma_{s} \bar{t}_{i s}^{\alpha} \bar{Q}_{s},
$$

and these nomal coordinates of course differ somewhat from those used when the average configuration is the standard. The displacement of the average configuration from the equilibrium one is therefore given by

$$
\begin{align*}
\alpha_{i}^{*}-\bar{\alpha}_{i} & =\left\langle\alpha_{i}-\bar{\alpha}_{i}\right\rangle \\
& =m_{i}^{-1 / 2} \sum_{s} \bar{\ell}_{i s}^{(\alpha)}\left\langle\bar{Q}_{s}\right\rangle \tag{39}
\end{align*}
$$

Here the wavefunction $\mathbb{W}_{\text {vib }}$ to be used in the vibrational average also refers to the equilibrium configuration as the standard. From (39) we see that a displacement from the average configuration may be expressed as

$$
\alpha_{i}-\alpha_{i}^{*}=m_{i}^{-1 / 2} \Sigma_{s} \bar{\nu}_{i s}^{\alpha}\left[\bar{Q}_{s}-\left\langle\bar{Q}_{s}\right\rangle\right]
$$

so that a comparison with (18) establishes the relations

$$
\begin{equation*}
Q_{s}=\Sigma_{t} T_{s t}\left[\bar{Q}_{t}-\left\langle\bar{Q}_{t}\right\rangle\right] \tag{ion}
\end{equation*}
$$

and

$$
\widetilde{Q}_{S}=\left\langle\bar{Q}_{S}\right\rangle+\Sigma_{t} T_{S t} Q_{t},
$$

where

$$
\begin{equation*}
T_{s t}=\Sigma_{i} \Sigma_{\alpha}\left(e_{i s}^{\alpha} \bar{l}_{i t}^{\alpha}\right) \tag{41a}
\end{equation*}
$$

From Eggs. ( 40 ) we can derive corresponding relations between the coefficients that appear in the expansion of the potential energy. For example, the linear term in Eq. (20) involves

$$
\frac{1}{2} V_{s}=\left(\partial V / \partial Q_{s}\right)_{n}=\Sigma_{t}\left(\partial V / \partial Q_{t}\right)_{*} \cdot T_{t s}
$$

and

$$
\left(\partial V / \partial \bar{Q}_{t}\right)_{*}=\bar{\lambda}_{t}\left\langle\bar{Q}_{t}\right\rangle+\frac{3 \bar{x}^{2}}{\bar{x}_{t t t}}\left\langle\bar{Q}_{t}\right\rangle^{2}+\cdots
$$

Only the first term in this derivative need be retained, as the others will be at least quadratic functions of $\left(v+\frac{1}{2}\right)$. Furthermore, the difference between the two sets of transformation coefficients is so slight that (41) may be approximated by

$$
\begin{equation*}
T_{s t}=T_{t s}=\delta_{s t} \tag{4ib}
\end{equation*}
$$

The result then reduces to

$$
\begin{equation*}
V_{s}=-3\left[\bar{k}_{s s s}\left\langle\bar{Q}_{s}^{2}\right\rangle+\Sigma_{t} \bar{x}_{t t s}\left\langle\bar{Q}_{t}^{2}\right\rangle\right] \tag{42a}
\end{equation*}
$$

after introducing (34) with $\vec{\sigma}_{s s}=\bar{\sigma}_{t s}=0$. In the same way we ind

$$
\begin{align*}
& \lambda_{s}=\left(\partial^{2} \mathrm{~V} / \partial Q_{\mathrm{s}}^{2}\right)_{\%}=\bar{\lambda}_{s}+\cdots  \tag{42b}\\
& k_{s S S}=\bar{T}_{s s s}+\cdots, \tag{42c}
\end{align*}
$$

efc. The vibration Prequencies and cubic constants can be taken to be the same for both configurations, since in the effective

Hamiltonian of Eg. (27) the corrections thereby omitted would not show up in the terms proportional to $\left(v+\frac{1}{2}\right)$. For the same reason we can omit the bars from the quantitses in (42). Thus we obtain the form given in Eq. (21) and find that

$$
\begin{equation*}
\sigma_{S S}=k_{s s s}, \quad \sigma_{t s}=k_{t t s} \tag{43}
\end{equation*}
$$

when the standard is the average configuration. Substitution of these resules in the general Eqs. (34) and (37) then leads to (38). This demonstrates that (up to terms Innear in $\dot{\mathrm{v}}+\frac{1}{2}$ ) only the harmonic part of the vibrational potential is required in order to calculate the moments of Inertia for the average structure from the observed efrective moments. Such calculations are glven for several molecules in Part II of this series.

A similar derivation shows that other choices for the standard conifigurationwould again lead to Eq, (21) with Eqs. (43) replaced by expressions analogous to those found in Table I for the diatomic case.

## CALCULATION OF PARANETERS

The numerical evaluation of the vibration-rotation parameters In EgS. (36) and (37) requires, in adaition to the potential constants, a calculation of the coefficients, $a_{S}^{\alpha \beta}$ and $A_{S S}^{\alpha \beta}$, in the expansion of the moment of inertia and the Coriolis constants, $\zeta_{s i t}^{\alpha}$. These quantities" may be expressed in terms of the transformation coefficients $\ell_{\text {is }}^{(\alpha)}$ which define the normal coordinates. ${ }^{5}$ As seen from Eq. (18), the
coefficients can be witten as derivatives,

$$
\begin{equation*}
m_{i}^{-1 / 2} \sum_{i S}^{(\alpha)}=\left(\partial \alpha_{1} / \partial Q_{S}\right) * \tag{44a}
\end{equation*}
$$

but proper account must be taken of the Eckart conditions (since there are $3 N$ displacement coordinates $\delta \alpha_{1}$ and only $3 N-6$ normal coordinates $Q_{s}$. . This gives rise to a number of useful relations involving the parameters $a_{s}^{\alpha \beta}, A_{s s}^{\alpha \beta}$, and $\xi_{s t}^{\alpha}$, which have been fully developed by Meal and Polo 29 and by Oka and Morino. 30 Particularly convenient is the general relation, 30

$$
\left[A_{s S}^{\alpha \beta}-\Sigma_{\gamma} a_{s}^{\alpha \gamma} a^{\beta \gamma} / I_{\gamma}\right]=4 \Sigma_{t} \zeta_{s t}^{\alpha} \zeta_{s t}^{\beta}-3 A_{S S}^{\alpha \beta}
$$

Which enables us to rewrite Eq. (36) as

$$
\begin{equation*}
\epsilon_{S}^{\alpha \beta}(\text { har })=\left(-6 K / \omega_{S}\right)\left[A_{S S}^{\alpha \beta}-\frac{\left.\hbar_{S} \Sigma_{t} \xi_{S t}^{\alpha} \xi_{S t}^{\beta} \lambda_{t} /\left(\lambda_{t}-\lambda_{S}\right)\right] . . . .}{}\right. \tag{45}
\end{equation*}
$$

The parameters $A_{S S}^{\alpha B}$ are unity on zero for several simple types of molecules (including the linear $X Y_{2}, X Y$, and $X_{2} Y_{2}$ molecules, out-ofplane axis of bent $X Y_{2}$, and tetrahedral $X X_{4}$ ). Furthemore, the methods derived by Meal and polo oftcen circumvent much or all of the normal coordinate anaysis in calculating the coriolis constants. 29 Thus, as illustrated in part II, there are several cases of interest In which $\epsilon_{G}^{\alpha \beta}$ (har) can be evaluated without a normal coordinate analysis.

- We shall outline a convenient method of obtaining the $d_{i s}^{(a)}$ coefficients for more general cases. 31 This will be used to derive formulas for some examples (linear $W X Y Z$, branched WXYZ, and symmetric $\mathrm{XYZ}_{3}$ molecules) and to treat a model in which several of the vibrations are regarded as "frozen stiff."

## Derlvatives Subject to Eckart Conditions

The derivatives in (44a) ane to be evaluated at the standard conflguration and are peferred to the principal axes mystem of (25), An arbitrary set of increments in the coordinates,

$$
\delta{\underset{\sim}{i}}_{i}^{p}=\left(\delta \alpha_{i}^{1}, \delta \beta_{i}^{1}, \delta \gamma_{i}^{1}\right)_{,}
$$

Would not in general satisfy the Eckart conditions (16) and (17), since the distorted configuration (when viewed from the original molecule-fixed system) would have its center of mass displaced along the a-axis by an amount

$$
\begin{equation*}
\delta \tau_{\alpha}=\Sigma_{i} m_{i} \delta \alpha_{i}^{\prime} / M \tag{46a}
\end{equation*}
$$

and would be rotated through an angle

$$
\begin{equation*}
\delta v_{\gamma}=\Sigma_{i} m_{i}\left(\alpha_{i}^{*} \delta \beta_{i}^{\prime}-\beta_{i}^{*} \delta \alpha_{i}^{\prime}\right) / I_{\gamma}^{*} \tag{46b}
\end{equation*}
$$

about the $\gamma$-axis. However, any such set of displacements can be converted into a set

$$
\delta \underset{\sim}{r} i=\left(\delta \alpha_{i}, \delta \beta_{i}, \delta \gamma_{i}\right)
$$

Which does satisfy the Eckart conditions by subtracting the appropriate rigid translations and rigid rotations of the whole nolecule. 33 rrom Eqs. (46) we find

$$
\begin{equation*}
\delta \alpha_{1}=\delta \alpha_{i}^{1}-\delta \tau_{\alpha}-\left(\gamma_{i}^{*} \delta \vartheta_{\beta}-\beta_{i}^{*} \delta v_{\gamma}\right) \tag{47}
\end{equation*}
$$

The freecom which this formulation allows in the choice of the primed displacements is an important advantage. Thus, a comparison with (18) now shows that the derivatives in (4sa) are given by.

$$
\begin{equation*}
\delta \alpha_{1 s}=\left(\partial \alpha_{1} / \partial Q_{s}\right)_{\%} \tag{44.B}
\end{equation*}
$$

Where $\delta \alpha_{\text {is }}$ denotes the increment computed from (47) by choosing a set of primed displacements such that $Q_{S}=1$ and all other normal coordinates ( $t \neq s$ ) vanish. We shall refer to such a set or displacements $\delta r^{\dagger}$ as an "expanston of normal mode $Q_{s}$ "

Before presenting a scheme for constructing the special set of increments, let us note that this leads to a very simple formulation of the vibration-rotation coefficients. Substitution of (44b) into Nielsen's definitions ${ }^{5}$ gives

$$
\begin{align*}
& a_{S}^{\alpha \alpha}=2 \Sigma_{i} m_{i}\left(\beta_{i}^{*} \delta \beta_{i s}+\gamma_{i}^{*} \delta \gamma_{i s}\right)  \tag{48a}\\
& a_{S}^{\alpha \beta}=-\Sigma_{i} m_{i}\left(\alpha_{i}^{*} \delta \beta_{i S}+\beta_{i}^{*} \delta \alpha_{i s}\right)  \tag{48b}\\
& A_{S S}^{\alpha \alpha}=\Sigma_{i} m_{i}\left[\left(\delta \beta_{i S}\right)^{2}+\left(\delta \gamma_{i s}\right)^{2}\right]  \tag{48c}\\
& A_{G S}^{\alpha \beta}=-\sum_{i} m_{i} \delta \alpha_{i S} \delta \beta_{i S}  \tag{48d}\\
& \zeta_{S t}^{\alpha}=\sum_{i} m_{i}\left(\delta \beta_{i s} \delta \gamma_{i t}-\delta \gamma_{i s} \delta \beta_{i t}\right) \tag{49}
\end{align*}
$$

These expressions may also be obtained directly from Eq. (18) and (A1I) of Appendix A. From Eq. (30) we find that the moment of inertia components comesponding to the expanded configuration specified by (44) are given by ${ }^{34}$

$$
I_{\alpha \beta}\left({\underset{\sim}{r}}^{*}+\delta{\underset{\sim i}{ }}^{r_{i S}}\right)=I_{\alpha \beta}\left({\underset{\sim}{i}}_{*}^{*}\right)+a_{\alpha}^{\alpha \beta}+A_{s S}^{\alpha \beta}
$$

where $I_{\alpha \beta}\left({\underset{\sim}{r}}_{i}^{*}\right)=I_{\alpha}^{*} \delta_{\alpha \beta}$, as given by (25). This may be coneirmed by inspection of (48). Also we see that

$$
\begin{equation*}
A_{S S}^{\alpha \beta}=I_{\alpha \beta}\left(\delta r_{i S}\right) \tag{50}
\end{equation*}
$$

and therefore

$$
\begin{equation*}
a_{s}^{\alpha \beta}=I_{\alpha \beta}\left(r_{\sim 1}^{*}+\delta{\underset{\sim}{r}}_{1 s}\right)-I_{\alpha \beta}(\delta{\underset{\sim}{r}})-I_{\alpha \beta}\left(r_{i}^{*}\right) . \tag{51}
\end{equation*}
$$

Although the coriolis constants are not conviently expressed in terms of moments of inertia, there are already avallable several formulations well sulted to numerical calculation, ${ }^{29}$ The vector form,

$$
\begin{equation*}
\xi_{s t}=\Sigma_{1} m_{i}\left(\delta{\underset{\sim}{r}}_{1 s} \times \delta{\underset{\sim}{1}}\right), \tag{52}
\end{equation*}
$$

Is orten userul in taentifying which of the components of gst will be near unity or zero. Also we note that the relation

$$
\begin{equation*}
\Sigma_{1} m_{i} \delta r_{1 s} \cdot \delta r_{i t}=\delta_{s t} \tag{53}
\end{equation*}
$$

Implied by the orthogonality condition (19) is frequently useful.

## Construction of Normal Mode Expansions

The expansion of a mode can be readily evaluated in terms of the customary internal coordinates $S_{k}$, which measure deviations of the bond lengths and angles from their values for the standard configuration. A normal coordinate analysis ${ }^{18}$ provides the transformation equations,

$$
\begin{equation*}
s_{k}=\Sigma_{t} I_{k t} Q_{t} \tag{54}
\end{equation*}
$$

The molecular configuration corresponding to $Q_{S}=1$, with other $Q_{C}=$ 0 , is therefore given by

$$
\begin{equation*}
s_{k}=L_{k s}, k=1,2, \ldots, 3 N-6 \tag{55}
\end{equation*}
$$

By means of a method borrowed from statistical mechanics, 35,36 we may derive from (55) the SN Cartesian displacements that comprise the expansion of the mode. This method, which will be described

Whth the ate of tis: 3, cenerates the displacements atom-by-atom. In Fig. 3 (a) we ctart with the atoma in the standara conflgurationg Whth coordinates $\left(\alpha_{1}^{*} \theta_{2}^{*} \gamma_{1}^{*}\right.$. Any atom may be chosen as the mast one $(1=1)$ and the others numbered ir suceession, The Intemal coordinates are also spechied: $S_{1}$ La taken as the $1-2$ bond buetch, $S_{2}$ as the $2-3$ bond stretch, $S_{3}$ as the $1-2-3$ angle bend, ete. Since the six extra degwees of freedom thet appean in the Careesian traneeription of (55) ane leter to be elimanated by use of Ec. (A7), we can begin with atom 1 as a fixed oricin and asso fix the orientation of the I-2 bona and $1-2-3$ plane. Next. in Fie. 3 (b) the displacement of atorn 2 as obtained by whinting it (anc all those "beyond") a distance tis alone the $1-2$ bond dinection. For atom 3 the displacenent is determined by two intemal coordinates. Therefores in Fig, 3 (f) we firet pull aton 3 and those weyond ft outwayda a dintance Ligs parallel to the $2-3$ bond for, 19 Les is negative, we push then inwardsly and then change the $1-2 w 3$ bond angle by shinting aton 3 a atstance $x_{23}^{*} L_{3 s}$ perpenomeulaw to the $2-3$ bond. In the same
 the latex atoms, which will each involve three internal coordinates. 37 The axpay of displacements thus obtained does nots of courses give a unicue expanaton of the mode (as a diferent order of numbering will Iead to difrerent reaultsy. Apter the tranclations and motations are removed by use on Eq. (47), however. the description of the atstorted confleuration becones unigues this final set of
 of mode $\mathrm{a}_{5}{ }^{\circ}$

It should be emphasized that the customary 18 internal coordinates $S_{k}$ adopted here are defined so that they transform linearly to Cartesian and to normal coordinates. Consequently, only for infinitesmal amplitudes of vibration does the stretching coordinates $S_{2}$, for example, measure the increment in the instantaneous distance between atoms 2 and 3. The $S_{2}$ coordinate actually represents the projection of the true instantaneous displacement of the atoms onto the original direction of the undisplaced $2-3$ bond. 38 This is why bending displacements take the form lilustrated in Fig. 3(c). To maintain the projection constant, we have to make the "bending" motion perpendicular to the bond: whereas, if instead the actual $2-3$ distance had to be preserved, we would need co swing atom 3 along an arc or length $\left(r_{23}^{*}+I_{2 s}\right) I_{3 s}$ about atom 2 . Since the displacements Iks are generally quite large, these two operations give appreciably different results and it is important to use the first procedure. In this we do not presume the linear relations of Eqs. (18) and (54) to be valid beyond small amplitude vibrations. Rather, in deriving relationships between the transfomation coefficients, we use the Inear melations merely as definitions of the coefficients, which must remain the same regardleas of the size of the displacements. 39 An analytic form for the expansion of a mode is readily obtained. The Inearity of the transformations allows us to write

$$
\begin{equation*}
\delta r_{i s}^{\prime}=\Sigma_{k} p_{i k} L_{k S} \tag{56}
\end{equation*}
$$

Where the $\mathrm{g}_{\mathrm{ik}}$ are displacement vectors, each chosen so that the Increment in a particular coordinate $S_{k}$ is unyty while all other Internal coordinates remain fixed at their values for the standard
configuration, Such vectors have already been introduced into viorational analysis by polo. ${ }^{\circ}$ He points out that these vectors fom a set reciprocal to W11son! $s^{18}$ well-known $s_{\sim}$-vectors,

$$
\Sigma_{1 S_{1 k}}, Q_{i l}=\delta_{1 k},
$$

and the p-vectors are often simply proportional to the g-vectors. Formal conmon types of internal coordinates polo has listed formulas rof the $\rho$-vectors, expressed in terms of unit vectors parallel and perpendicular to the bonds of the undistorted molecule. In practice (56) is guite convenient, since most normal coordinates contain significant contributions from oniy a few internal coordinates. A good approximation can usually be obtained by taking no more than three of the transformation coefficients $I_{k s}$ as nonzero. Furthermore, most of the internal coordinates are defined in terms of bonds and angles involving just 2,3 , or 4 atoms.

For symnetrical molecules, the calculations are simplified by use of symmetry coordinates fomed from linear combinations of the Internal coortinates. ${ }^{18,41}$ If the sets of $\mathcal{L}_{i k}$ vectors are chosen to have the appropriate symmetry, vibrations or each symmetry species can be considered separately. Also, the Eckart corrections in Eq. (47) vanish unless the corresponding translation or rotation has the sane symmetry as the vibrational mode.

To find the appropriate $\mathcal{Q}_{\text {ik }}$ vectors we have to displace the symmetrically equivalent atoms simultaneously, rather than proceeding atom-by-atom, but this is usually simple to do (as illustrated below). Whenever a symetry species contains only one vibration, the Eckart expansion of that mode will depend only on the atomic masses
and moleoular geometry. In this case Eq. (54) reduces to ${ }^{42}$

$$
\delta_{k}=\alpha_{k s} Q_{s}
$$

and the transformation coefficient,

$$
\begin{equation*}
s_{k s}=\left(F_{k k}\right)^{1 / 2} \tag{57}
\end{equation*}
$$

Involves just a diagonal element of Wilson's p-matrix. When there same are two or more vibrations of the/symmetry, the transformation coefficients also involve the vibrational force constants and must be found by solving a secular equation. 18 . other points which arise In the calculation of normal mode expansions wlll be bought out in the course of deriving formulas for some examples.

## EXAMPIES

## Linear WXYZ Molecule

If we choose the $z$-axis along the molecular axis, then for any linear molecule the following quantities all vanish:

$$
\delta x_{i s}{ }^{3} \delta y_{i s} ; \delta \tau_{x s}, \delta \tau_{y s}{ }^{\circ} \delta v_{x s}, \delta v_{y s}{ }^{2} \delta v_{z s^{2}}
$$

for the stretching vibrations and

$$
\theta z_{i s} ; \delta t_{z s} ; \delta v_{Z s}
$$

for the bending vibrations. Fig. 4 shows the numbering of atoms and coordinates. We may consider the stretches and bends separately since they are in different symmetry species. The stretching coordinates are defined by

$$
\begin{align*}
& S_{1}=\delta z_{2}-\delta z_{1} \\
& S_{3}=\delta z_{3}-\delta z_{2}  \tag{58}\\
& S_{5}=\delta z_{4}-\delta z_{3}
\end{align*}
$$

Therefore we find the expansion to be

$$
\begin{aligned}
& \delta z_{I s}=0 \\
& \delta z_{2 s}^{\prime}=I_{1 s} \\
& \delta z_{3 s}=L_{1 s}+I_{3 s} \\
& \delta z_{4 s}=I_{I s}+I_{3 s}+I_{5 s}
\end{aligned}
$$

for any one of the three stretching normal modes. After accounting for the Eckarc conditions by use of (47), we have

$$
\begin{equation*}
\delta z_{i s}=\left[\left(m_{2}-M 0_{11}\right) L_{i s}-\left(m_{3}+m_{L}\right) L_{3 s}-m_{E} L_{5 s}\right] / M \tag{59a}
\end{equation*}
$$

for $i=1,2$ and

$$
\begin{equation*}
\delta z_{i s}=\left[m_{1} I_{1 s}+\left(m_{1}+m_{2}\right) I_{3 s}-\left(m_{4}-M_{i 4}\right) I_{5 s}\right] / M \tag{59b}
\end{equation*}
$$

for $i=3,4$. These results are readily visualized; for example, When the I-2 bond is stretched an amount $I_{1 s}$. We find atom $I$ moves to the Iett a distance

$$
\left[I-\left(m_{1} / M\right)\right] \Sigma_{1 s}=\left[\left(m_{2}+m_{3}+m_{4}\right) / M\right] \Sigma_{1 s}
$$

and the other three atoms shift to the right a distance

$$
\left(m_{1} / \mathrm{N}\right) \mathrm{L}_{1 s^{\circ}}
$$

The bending coordinates in the xz plane are defined by

$$
\begin{align*}
& S_{2 x}=\left(\delta x_{2}-\delta x_{1}\right) / r_{12}+\left(\delta x_{2}-\delta x_{3}\right) / r_{23}  \tag{60a}\\
& S_{4 x}=\left(\delta x_{3}-\delta x_{2}\right) / r_{23}+\left(\delta x_{3}-\delta x_{4}\right) / r_{34} \tag{60~b}
\end{align*}
$$

and analogous expressions (with $x$ replaced by $y$ ) hold for the yz plane. The simplest way to obtain an expansion of a bending mode is to set all displacements equal to zero except

$$
\begin{equation*}
\delta x_{1 S}=-r_{12} I_{2 S}, \delta x_{4 S}=-r_{34} L_{4 S} \tag{61}
\end{equation*}
$$

The Eckart expansion is then found to be

$$
\begin{align*}
\delta \mathrm{x}_{i s} & =\left(\frac{m_{1}-M \delta_{i 1}}{M}+\frac{m_{1} z_{1} z_{i}}{I}\right) r_{12} I_{2 s} \\
& +\left(\frac{m_{4}-M D_{i 4}}{M}+\frac{m_{4} z_{4} z_{i}}{I}\right) r_{34} I_{L S} \tag{62a}
\end{align*}
$$

for $i=1,2,3,4$. These formulas can be readily specialized to simpler cases or extended to an even longer string of atoms.

Usually there are many possible alternative choices for the primed displacements. The corresponding formulas for the Eckart expansions will sometimes look quite different, but the various alternatives will give identical numerical results. The bending mode of a linear XXZ molecule provides a convenient example of this. (In applying the forgoing results, we disregard the fourth atom and set $I_{4 s}=I_{5 s}=0$. ) From Eq. (60) we see that Inscead of the choice given in (61) we could set all displacements equal to zero except

$$
\delta x_{2 S}^{*}=R I_{2 s},
$$

where $R=r_{12} r_{23} /\left(r_{12}+r_{23}\right)$. This leads to

$$
\begin{equation*}
\delta x_{1 s}=-\left(\frac{m_{2}-M 0_{i 2}}{M}+\frac{m_{2} z_{2}^{2}}{I}\right) R I_{2 s} \tag{62b}
\end{equation*}
$$

$i=1,2,3$, instead of Eq. (62a). However, the center of mass condition, $\sum_{i} m_{i} z_{i}=0$, cogether with the definitions $r_{i j}=z_{j}-z_{i}$, yields the relations

$$
\begin{aligned}
& 1 z_{3}=\left(m_{1} r_{13}+m_{2} r_{23}\right) \\
& I=-\left(m_{1} z_{1} r_{13}+m_{2} z_{2} r_{23}\right)
\end{aligned}
$$

(and others obtained by cyclic permutation of subscripts) and from these we see that Eq. (62b) is actually Identical to (62a).

To illustrate the use of symmetry coordinates, we may consider a linear $X_{2} Y_{2}$ molecule such as acetylene. Table VI gives the delinttions of the symmetry coordinates, as obtained by the usual methods. 18 The species which have nonvanishing Eokart corrections are found from the character table of the $D_{\text {oh }}$ group. According to Eq. (55), we need to find displacements such that ${ }^{42} \delta_{k}=\dot{\delta}_{k s}$. By inspection of Table VI and Eq. (58) we see that for the two $\Sigma_{g}^{t}$ modes the appropriate displacements are

$$
\begin{align*}
& -\delta z_{1 s}=\delta z_{4 \mathrm{~s}}=2^{-1 / 2} \mathcal{L}_{1 \mathrm{~s}}+\frac{1}{2} \mathcal{L}_{2 \mathrm{~s}}  \tag{63}\\
& -\delta z_{2 \mathrm{~s}}=\delta z_{3 \mathrm{~s}}=\frac{1}{2} \delta_{2 \mathrm{~s}}
\end{align*}
$$

and no Echart corrections enter for this symmetry species. For the $\Sigma_{\hat{u}}^{+}$mode,

$$
\begin{align*}
& \delta z_{1 S}^{1}=\delta z_{4 s}^{\prime}=-2^{-1 / 2} \mathcal{L}_{3 s}  \tag{64}\\
& \delta z_{2 s}^{\prime}=\delta z_{3 s}=0
\end{align*}
$$

and after subtracting the translational correction of Eq. (47) we find the Eckart expansion is

$$
\begin{align*}
& \delta z_{I s}=\delta z_{\Delta s}=2^{1 / 2}\left(m_{2} / M\right) \delta_{3 s}  \tag{65}\\
& \delta z_{2 s}=\delta z_{3 s}=-2^{1 / 2}\left(m_{1} / M\right) \delta_{3 s}
\end{align*}
$$

From Eq. (60) we obtain results of the same form as (64) but with $z$ replaced by $x$, for the $x$-component of the $H_{u}$ mode; the results for
the $\Pi_{g}$ mode also have this fom except that the sign of ox is reversed. Thus we find the following Eckart expansions for the bending vibrations:

$$
\begin{align*}
& -6 x_{1 s}=\delta x_{4 s}=2^{1 / 2}\left(m_{1} z_{2}^{2} / I\right) r \mathcal{L}_{4 s} \\
& \delta x_{2 s}=-6 x_{3 s}=2^{1 / 2}\left(m_{1} z_{1} z_{2} / I\right) r \delta_{4 s} \tag{66}
\end{align*}
$$

for the $\Pi_{g}$ species and

$$
\begin{align*}
& 6 x_{1 s}=\delta x_{4 S}=-2^{1 / 2}\left(m_{C} / M\right) r \alpha_{5 s} \\
& 6 x_{2 s}=\delta x_{3 s}=2^{1 / 2}\left(m_{1} / M\right) r \&_{5 s} \tag{67}
\end{align*}
$$

Sor the $H_{\text {u }}$ secles. only the $\Sigma_{\mathrm{g}}^{+}$nodes require the solution of a secular equation; for the others the chs coefrictents can be evaluated from Eq. (57) and the b-natrix elements in Table VI.

## Branched WXYZ Molecule

When expressed in the vector notation of Eq. (56), the procedure indicated in Fig. 3 yielas

$$
\begin{align*}
& \operatorname{Dr}_{\sim}^{n} \text { Is }=0 \\
& \delta_{\sim}^{2} 2_{2}^{1}={\underset{\sim}{1}} L_{15}  \tag{68}\\
& \delta r_{\sim}^{\prime}{ }_{3 s}=\delta r_{2 s}^{\prime}+e_{23} I_{29}+\left(e_{6} \times{\underset{\sim}{23}}^{e_{23}}\right)_{23} I_{3 s},
\end{align*}
$$

Where

$$
\begin{equation*}
e_{0}=\left(e_{21} x e_{23}\right) \csc \phi_{123} \tag{69}
\end{equation*}
$$

is a unit vector nomal to the plane of the $1-2-3$ angle. Addition of a fourth atom introduces the three new internal coordinates shown in Fig. 5(a). If the standard configuration of the molecule is planar,
we rind

$$
\begin{equation*}
\sigma_{\sim}^{r}{ }_{4 S}=\delta_{\sim}^{r}{ }_{2 S}+e_{24} I_{4 S}+\left(e_{\sim} x e_{24}\right) r_{24} I_{5 S}+e_{0} r_{24} I_{6 S} \tag{70}
\end{equation*}
$$

This follows from Eq. (56) and the three $\mathrm{P}_{4 \mathrm{k}}$ vectors pictured in Fig: 5(b). The $p$ vectors for the $2-4$ bond stretch and $1-2-4$ angle bend if are analogous to. those in (68); that for the out-of-plane bend is perpendicular to the plane and of length $r^{\circ} 24^{*}$. If the molecule is nonplanar, the last two terms in (70) are replaced by ${ }^{43}$

$$
\begin{equation*}
e_{\sigma} \cdot \csc y_{143^{r}}^{24} I_{5 s}+\left(e_{24} x e_{2}\right) r_{24} I_{65} . \tag{79}
\end{equation*}
$$

Here $\psi_{143}$ is the dihedral angle between the 1-2-4 and 3-2-4 planes; $e_{0}$ is given by (69) with the subscript 1 replaced by 4 ; and $e{ }_{\sim}$ is a unit vector parallel to the $1-2-3$ plane and perpendicular to the $2-4$ bond: The $e_{4 k}$ vectors are show h in Fig. $5(c)$. Note that the p-vector for the 1-2-4 angle bend no longer lies in the plane of the angle but now is normal to the plane of the adjacent $3-2-4$ angle: its length is also increased by the factor csc $\psi_{143}$.

Except when treating the elmplest molecules, we have found it expedient to first evaluate the primed displacements numerically and then use Eq. (55), rather than derive analytic formulas for the Eckart expansions. For any planar molecule (with the out-of-plane axis taken as the z-direction), the $C_{s}$ group character table shows that the following quantities vanish:

$$
\delta z_{\mathrm{is}} ; \delta \tau_{z \mathrm{~s}} ; \delta v_{\mathrm{XS}}, \delta v_{\mathrm{ys}}{ }^{2}
$$

for the in-plane vibrations and

$$
\delta x_{i s}, \delta y_{i s} ; \delta \tau_{x s}, \delta \tau_{y x} ; \delta v_{z s}{ }^{2}
$$

for the out-of-plane vibrations. As a planar molecule of four atoms has only one out-of-plane mode $(s=6)$, in this case it id preferable to work with the Eckart expansion, which is given by

$$
\begin{equation*}
\delta z_{16}=\left[\left(\delta_{i 4}-\frac{m_{4}}{M}\right)-\left(\frac{m_{4} x_{i} x_{4}}{I_{y}}+\frac{m_{4} y_{1} y_{4}}{I_{x}}\right)\right] r_{24} I_{66} \tag{72}
\end{equation*}
$$

for $1=1,2,3,4$.
In applying Eq. (56) to symmetrical molecules, we may take advantage of the fact that the symmetry coordinates are defined by an orthogonal transformation of the internal coordinates, $\underset{\sim}{\mathcal{E}}=\underset{\sim}{S}$. In most cases $1 t$ is easy to choose the $p$-vectors for the internal coordinates so that under the group operations they transform in the same way as the internal coordinates. Then by simply forming the linear combinations dictated by the transformation $\mathbb{U}$, we can construct the appropriate $\rho_{\text {pk }}$ vectors for each symmetry coordinate.

A planar $W X Y_{2}$ molecule such as formaldehyde offers a simple example for this method. The symmetry coordinates are given in Table VII. The coordinate $S_{5}^{\prime}$ is the increment in the $3-2-4$ angle; to bring out the symmetry it is used in preference to the coordinate $s_{3}$ shown in Fig. 5(a). The connection with the previous description is obtained from the redundancy relation,

$$
\begin{equation*}
s_{3}+s_{5}+s_{5}^{1}=0 \tag{73}
\end{equation*}
$$

By definition, the efik vectors for a symmetry coordinate, for example,

$$
\delta_{4}=2^{-1 / 2}\left(S_{1}-S_{2}\right)
$$

must make $\mathcal{S}_{4}=1$ while the other symmetry coordinates remain zero. If we find the $p$-vectors for $S_{1}$ and $-S_{2}$ in the way already illustrated, the sum of these will give

$$
\delta_{4}=2^{-1 / 2}(1+1)=2^{1 / 2}
$$

Hence, to get the desired result we merely have to renormalize the sum by dividing through by $2^{1 / 2}$. The orthogonality of the transformation guarantees that this procedure will alter only $⿻_{4}$. The complete expansion generated from Table VII in this way is

$$
\begin{align*}
& \underset{\sim 2 S}{ }=0 \\
& \operatorname{or}_{\sim}^{1}=e_{\sim 24^{2}} \mathcal{L}_{3 s}+e_{\sim} \phi_{6 s} \tag{74}
\end{align*}
$$

for $i=1$ (upper sign) and $i=3$ (lower sign).
This molecule is simple enough to make explicit formulation of the Eckart expansion worthwhile. The results can be tidily written by defining the quantities

$$
\begin{aligned}
& X_{k \ell}=\sin \alpha \delta_{k N}-r \cos \alpha \mathcal{L}_{\ell s} \\
& Y_{k \ell}=\cos \alpha \delta_{k s}+r \sin \alpha \mathcal{L}_{\ell s}
\end{aligned}
$$

Where $\alpha$ is one-half of the 1-2-3 angle. The components of the displacements parallel to the symmetry axis are, for the $A_{1}$ species:

$$
\begin{equation*}
\delta y_{i s}=2^{1 / 2}\left(m_{1} / M\right) Y_{12}+\left[\delta_{i 4}-\left(m_{4} / M\right)\right] \delta_{3 s} \tag{75a}
\end{equation*}
$$

$i=2,4$ and

$$
\delta y_{i s}=\delta y_{3 s}=-2^{-1 / 2}\left[\left(m_{2}+m_{4}\right) / M\right] Y_{12}-\left(m_{4} / M\right) \&_{3 s}
$$

for the $B_{1}$ species:

$$
\begin{align*}
& \delta y_{2 s}=\delta y_{4 s}=0  \tag{75b}\\
& \delta y_{1 s}=-\delta y_{3 s}=-2^{-1 / 2}\left[\left(1-\frac{2 m_{1} x_{1}^{2}}{I_{z}}\right) y_{45}+\frac{2 m_{1} x_{1} y_{1}}{I_{z}} x_{45}\right]
\end{align*}
$$

The perpendicular components are, for the $A_{1}$ species:

$$
\begin{align*}
& \delta x_{2 s}=\delta x_{4 s}=0 \\
& \delta x_{1 s}=-\delta x_{3 s}=-2^{-1 / 2} x_{12} \tag{75c}
\end{align*}
$$

and for the $B_{1}$ species:

$$
\begin{equation*}
\delta x_{i s}=2^{1 / 2}\left[\left(\frac{m_{1}}{m_{1}}+\frac{m_{1} y_{1} y_{i}}{I_{z}}\right) x_{45}-\frac{m_{1} x_{1} y_{1}}{I_{z}} Y_{45}\right] \tag{75d}
\end{equation*}
$$

$i=2,4$ and

$$
\delta x_{1 s}=\delta x_{3 s}=-2^{-1 / 2}\left[\left(\frac{m_{2}+m_{4}}{M}-\frac{2 m_{1} y_{1}^{2}}{I_{2}}\right) x_{45}+\frac{2 m_{1} x_{1} y_{1}}{I_{2}} y_{45}\right]
$$

Only the $B_{2}$ species has out-or-plane components and the formulas for these are included in Eq. (72).

- To obtain the results for a bent $X Y_{2}$ molecule from the forgoing, we discard terms involving $\mathcal{L}_{3 \mathrm{~s}}, \mathcal{L}_{5 s}, \mathcal{L}_{6 \mathrm{~s}}$, and $\mathrm{m}_{4}$. In addition, however, we must readjust the normalization of $\mathcal{L}_{2 s^{\prime}}$. On substituting Eq. (73) inco Table VII we see that

$$
\&_{2}=-2^{-1 / 2} S_{3}
$$

and since $\mathscr{F}_{2}^{1}=S_{3}$ is the proper symmetry coordinate for a bent $X Y_{2}$ molecule, we need to replace $\mathcal{L}_{2 s}$ by

$$
\mathcal{L}_{2 s}^{\prime}=-2^{1 / Z^{2}} \mathcal{L}_{2 s}
$$

## Symmetric $\mathrm{WXX}_{3}$ Molecule

Typical molecules of this type are the methyl halides, $\mathrm{CH}_{3} \mathrm{X}$. The $H$ atoms are numbered $1,2,3$; the $C$ atom 4 ; the $X$ atom 5 . Bonds and angles are denoted by R for CX . $r_{i}$ for $\mathrm{CH}_{i}$, $\alpha_{i}$ for $\mathrm{HjCH}_{\mathrm{k}}$, and $B_{i}$ for $\mathrm{XCH}_{1}$. The general, nontetrahedral model will be considered. 44 The symmetry coordinates for the $A_{1}$ species are ${ }^{45}$

$$
\begin{aligned}
\delta_{1} & =\Delta R \\
\delta_{2} & =3^{-1 / 2}\left(\Delta r_{1}+\Delta r_{2}+\Delta r_{3}\right) \\
\delta_{3} & =6^{-1 / 2_{f}}\left[\Delta \alpha_{1}+\Delta \alpha_{2}+\Delta \alpha_{3}-\gamma\left(\Delta \beta_{1}+\Delta \beta_{2}+\Delta \beta_{3}\right)\right] \\
& =(2 / 3)^{1 / 2_{f}}\left(\Delta \alpha_{1}+\Delta \alpha_{2}+\Delta \alpha_{3}\right)
\end{aligned}
$$

Where the second form for $\mathscr{S}_{3}$ is obtained by use of the redundancy condition. The parameters $f$ and $\gamma$, which are equal to unity for the tetrahedral case, are defined by

$$
f:=2^{1 / 2}\left(1+\gamma^{2}\right)^{-1 / 2}
$$

and

$$
\gamma=-3^{1 / 2} \cos \beta \sec \frac{1}{2^{2}} \alpha
$$

The coordinates for the degenerate $E$ species consist of pairs, eguivalent except for orientation.

$$
\mathscr{X}_{4 x}=6^{-1 / 2}\left(2 \Delta r_{1}-\Delta r_{2}-\Delta r_{3}\right)
$$

and

$$
8_{4 y}=2^{-1 / 2}\left(\Delta r_{2}-\Delta r_{3}\right)
$$

and the two remaining pairs or coordinates, $\delta_{5}$ and $\delta_{6}$, are derined by replacing $\Delta r_{i}$ by $\Delta \alpha_{i}$ and $\Delta \beta_{i}$, respectively.

The form of the p-vectors for the internal coordinates has been illustrated in the previous examples. However, here we must take some care to start with a set which transforms under the group openations in the same way as the internal coordinates. As in Figs. 3(c) and 5 (b) and Eq. (68), to increase $\Delta r_{i}$ and $\Delta \beta_{i}$ by unity we shift atom $H_{1}$ by

$$
\begin{align*}
& e_{\text {ir }}={\underset{\sim}{A L i}}  \tag{76}\\
& \mathscr{R}_{i \beta}=\left[\left({\underset{\sim}{e}}_{45} \times{\underset{\sim}{e}}_{e_{i 1}}\right) \times{\underset{\sim}{e}}_{41}\right] r \csc \beta . \tag{77}
\end{align*}
$$

These vectors obviously transform properly already, since they lie In the $\mathrm{XCH}_{i}$ symmetry planes. On the other hand, for $\Delta \alpha_{i}$ the $p$-vector used in Fig. 5(c) and Eq. (71) would move either $H_{j}$ or $H_{k}$ in an unsymmetrical fashion. Therefore, to increase $\Delta \alpha_{i}$ by unity, we shift both atoms by half the usual distance and thus maintain symmetry with respect to the $\mathrm{XCH}_{i}$ plane.

$$
\begin{align*}
& {\underset{\sim}{j}}\left(\Delta \alpha_{i}\right)=\frac{1}{2}\left({\underset{\sim}{e}}_{41} \times{\underset{\sim}{e}}_{4 j}\right) r \csc \psi \csc \alpha  \tag{78a}\\
& \rho_{N K}\left(\Delta \alpha_{i}\right)=\frac{1}{2}\left({\underset{\sim}{e}}_{e_{k K}} x \underset{\sim}{e}{ }_{4 i}\right) r \csc \psi \csc \alpha \tag{78b}
\end{align*}
$$

where i, j, $k=1,2,3$ in cyclic order and $v$ is the dihedral angle between successive $H_{i} C X$ and $H_{j} C X$ planes.

The p-vectors for the symmetry coordinates may now be constructed by the method illustrated with formaldehyde. For example, as the vector for $\&_{6 X}$ we take

$$
\mathbb{N}_{X}\left(2 \rho_{I \beta}-\rho_{2 \beta}-\rho_{3 \beta}\right)
$$

This combination of displacements gives

$$
\delta_{6 x}=N_{x} 6^{-1 / 2}(2+1+1)
$$

(since the $\ell_{i \beta}$ are defined so that $\Delta \beta_{i}=1$ ) and therefore the normalization constant is assigned the value

$$
N_{X}=\frac{1}{2}(3 / 2)^{1 / 2}
$$

For the $\delta_{3}$ coordinate, the use of Eggs. (78) leads to

$$
N_{3} \Sigma_{i}\left[\rho_{i}\left(\Delta \alpha_{j}\right)+\underline{p}_{i}\left(\Delta \alpha_{k}\right)\right],
$$

where $i=1,2,3$ and $N_{3}=6^{-1 / 2} / \mathrm{i}$. Thus in this case the displacement of each $H$ atom must be obtained by addition of two vectors; it is readily shown that the resultant lies in the $\mathrm{XCH}_{i 1}$ plane and is given by*

$$
\begin{equation*}
\underline{e}_{i}\left(\Delta \alpha_{j}\right)+\underline{q}_{i}\left(\Delta \alpha_{k}\right)=-\underline{q}_{i \beta} / \gamma, \tag{79}
\end{equation*}
$$

in conformity with the redundancy relation.
The expansion obtained for the $A_{1}$ modes is
$(1=1,2,3)$ where $N_{2}=3^{-1 / 2}$ and $N_{3}^{\prime}=-6^{-1 / 2} / \gamma 1$.
For the $\mathrm{E}_{\mathrm{X}}$ components of the degenerate modes,

$$
\begin{align*}
& \delta r_{i s}^{\prime}=N_{x}\left[-e_{4 i} \alpha_{4 s}+\rho_{i \beta}\left(\delta_{5 s} / \gamma-\mathcal{L}_{6 s}\right)+3 \rho_{i \alpha^{\prime}} \alpha_{5 s}\right] \tag{80b}
\end{align*}
$$

and $i=2,3$. For the $E_{y}$ components,

$$
\begin{align*}
& \operatorname{\delta r}_{1 S}=N_{y}\left[\rho_{1}\left(\Delta \alpha_{2}\right)-\rho_{1}\left(\Delta \alpha_{3}\right)\right]{L_{5}} \\
& \dot{\sim}_{1 S}= \pm N_{y}\left[e_{41} \mathcal{L}_{4 S}+\rho_{1 \beta}\left(\alpha_{5 S} / \gamma+\mathcal{L}_{6 s}\right)\right]+\rho_{1 \alpha} \mathcal{L}_{5 s} \tag{800}
\end{align*}
$$

with $i=2$ (plus sign), $i=3$ (minus sign), and $N_{y}=2^{-1 / 2}$, $P_{i \alpha}$ denotes $\rho_{i}\left(\Delta \alpha_{1}\right)$, and the relation (79) has been used to simplify some terms. Atoms 4 and 5 have zero displacements.

Cartesian expressions for the $e_{41}$ and $\rho_{1 B}$ vectors are obtained easily, but those for the $\rho_{i}\left(\Delta \alpha_{j}\right)$ vectors are rather awkward. It is only necessary, however, to evaluate the components of $\underset{\sim}{p}=\rho_{2}\left(\Delta a_{1}\right)$, which are

$$
\begin{align*}
& \rho_{X}=-\frac{1}{2} r \csc \psi \sin \psi^{\prime} \cos \beta \\
& \rho_{y}^{\prime}=-\frac{1}{2} r \operatorname{coc} \psi \cos \psi  \tag{81}\\
& \rho_{z}=\frac{1}{2} r \csc \psi \sin \psi^{\prime} \sin \beta_{2}
\end{align*}
$$

Where $\psi^{\prime}$ is the dihedral angle between a $X_{10 H}$ plane and the adjacent $H_{1} \mathrm{CH}$ plane. The z-axis points along the $4-5$ bond and the $x$-axis lies in the $\mathrm{XCH}_{\mathrm{I}}$ plane. By reversing the sign of the $y$-component in ( 81 ) $\rho_{3}\left(A \alpha_{1}\right)$ is obtained and the relation

$$
\rho_{1}\left(\Delta \alpha_{j}\right)=\rho_{j}\left(\Delta \alpha_{1}\right)
$$

then provides the other coordinates that enter Eqs. (80). In terms of interbond angles, the dihedral angles are given by

$$
\begin{aligned}
& \cos \psi=\left(\cos \alpha+\cos ^{2} \beta\right) / \sin ^{2} \beta \\
& \cos \psi=\cos \beta(1-\cos \alpha) /(\sin \alpha \sin \beta)
\end{aligned}
$$

The Eckart correction for the $A_{1}$ modes involves just translation along the symmetry axis,

$$
\delta \tau_{2}=m_{5} \alpha_{1 s}-3 m_{1}\left(\cos \beta N_{2} \alpha_{2 s}+r \sin \beta N_{3}^{1} \delta_{3 s}\right)
$$

For the degenerate modes, the nonzero corrections are $\delta \tau_{x}$, $\delta v_{y}$ for $E_{x}$ and $\delta \tau_{y}, \delta v_{x}$ for $E_{y}$.

The expressions given above may also be applied to symmetric pyrimidal $\mathrm{XX}_{3}$ molecules. Terms arising from $\ell_{1}, \delta_{6}$, and $m_{4}$ are discarded; $\delta_{3}$ is renomalized and accordingly $N_{3}=N_{3}^{1}=3^{-1 / 2}$. It is convenient to retain the angles $\beta_{1}$, which are now defined with reference to the symmetry axis.

## "Partly Frozen" Model; Group Vibrations

The one or two normal modes of lowest frequency are often found to contribute the dominant tems to Vibration-rotation interactions. Examples which have been well characterized experimentally include the corsional oscillations of methyl groups, 46 the "warping" vibrations of planar rings, 47 and (as shown in part III) a large class of inertial defects. Molecular models in which various parts are regarded as rigid have given good results for such cases. The form of EqS. (47) and (56) makes it easy to derive a "partly frozen" approximation for any type of molecule. To freeze an atom, its displacement ${\underset{\sim}{r}}_{i}^{\prime}$ is merely set equal to zero. In contrast to previous examples in which parts of a molecule were discarded, here the masses of the frozen atoms still enter, by way of the $M$ and $I_{\alpha}$ elements in the Eckart corrections. When all the atoms involved in an internal coordinate are frozen, the coefficients for that cocrdinate vanish
(For all $s$ ). Moreover, the values of the $\mathcal{L}_{\mathrm{ks}}$ for other coordinates are in seneral altered somewhat. These coefficients are most conveniently determined from a reduced vibrational secular equation involving the ${\underset{\sim}{a}}^{-1}$ elements for the unfrozen coorainates. 48 Fortunately, however, a matrix inversion can be avoided since polo has derived the relation ${ }^{40}$

$$
\begin{equation*}
\left(G^{-1}\right)_{k k}=\Sigma_{1} m_{i}\left(\rho_{i k}\right)^{2} \tag{82}
\end{equation*}
$$

Here the Eckart corrections are to be included in the pik and the sum must be extended over all the atoms (including the frozen ones).

The simolest example to consider has a single atom $m_{1}$ vibrating against the center of mass of a group. This is a uaeful approximation for the $\mathrm{C}-\mathrm{I}$ stretch in $\mathrm{CH}_{3} \mathrm{I}$. Eq, (47) requires that

$$
\begin{aligned}
& \delta{\underset{\sim}{I S}}=e_{\sim} I_{G}^{I} \\
& \delta r_{i s}=-\left(m_{1} / m_{g}\right) \delta r_{I S}
\end{aligned}
$$

Where $i=2, \ldots, N, m_{g}=\Sigma_{i} m_{i}$ is the mass of the group, and

$$
L=\left[m_{1} m_{\mathrm{g}} /\left(m_{1}+m_{\mathrm{C}}\right)\right]^{-1 / 2}
$$

Although L has the same form as for a diatomic molecule, the contributions to the vibration-rotation parameters also involve (via the elg factor) the direction cosines between the principal axes and the line joining $m_{1}$ to the center of mass.

As another example, consider the symmetric bend $\omega_{2}$ for planar $W_{X Y}$ or bent $X Y Y_{2}$ molecules. This mode often accounts for most of the inertial defect, as shown in Part III. If the stretching vibrations of an $\mathrm{XY}_{2}$ molecule are frozen, the secular equation reduces to

$$
F_{22}-\lambda\left(G^{-1}\right)_{22}=0,
$$

where $F_{22}$ is the bending force constant and 40

$$
\left(G^{-1}\right)_{22}=\frac{1}{2} m_{Y^{r}}^{2}\left[1-2\left(m_{Y} / M\right) \sin ^{2} \alpha\right] .
$$

Eqs. (75a) and (75c) yield the same result for a $\mathrm{WXY}_{2}$ molecule, except that the factor of $\frac{1}{2}$ is replaced by unity because of the change in normalization of $\mathscr{X}_{2}$. The corresponding values of

$$
\delta_{22}=\left(\sigma^{-1}\right)_{22}^{-1 / 2}
$$

are used in Eqs. (75), with the other $\kappa_{k s}=0$, in order to calculate the vibration-rotation constants for this model.

- Vibrational irequencies characteristic of a particular functional group appear in many molecules. From Eq. (45) it is seen that the contributions of these group frequencies to $\epsilon$ (harmonic) can be considered separately, provided that the Coriolis constants $\zeta_{\text {st }}$ connecting the group and framework vibrations are sufficiently small. Even when this does not hold the calculations can often be simplified by use of the treatment of group frequencies recently presented by King and Crawford. ${ }^{49}$

## APPENDIX A

## VIBRATION-ROTATION HAMILTONIAN

Previous treatments ${ }^{5}$ have all been based on Eckart's expression for the classical kinetic energy,
and the Hamiltonian derived from this by Wilson and Howard, 4

$$
\begin{equation*}
2 \dot{H}=(\underset{\sim}{m}-\underset{\sim}{m})^{\dagger} \mu(\underset{\sim}{m}-\underset{\sim}{m})+{\underset{\sim}{p}}^{+} \underset{\sim}{p}+2 V \tag{AZ}
\end{equation*}
$$

where

$$
\begin{align*}
& \underset{\sim}{m}=\underset{\sim}{B C} \\
& \underset{\sim}{\mu} \underset{\sim}{p}=(\underset{\sim}{A}-\underset{\sim}{B C}  \tag{A3}\\
& -1 \\
& \underset{\sim}{B})^{+1}
\end{align*}
$$

Here the matrix A is $\underset{\sim}{I}$, the moment of inertia tensor, and for the usual choice of normal coordinates $\underset{\sim}{C}$ is just $\underset{\sim}{E}$, the unit matrix. The matrix $\underset{\sim}{B}$ involves the Coriolis coupling coefficients and is a linear function of the normal coordinates. The fact that the matrix $\underset{\sim}{\mu}$ is not merely the inverse of the monent of inertia tensor has complicated the fomulation and interpretation of vibration-rotation perturbations. This difficulty can be avoided by expressing the Hamiltonian in another form,

$$
\begin{equation*}
2 H=\underset{\sim}{r^{\top}}{\underset{\sim}{A}}^{-1} m+(\underset{\sim}{P}-\underset{\sim}{p})^{\dagger_{R}}{ }_{\sim}^{1}(\underset{\sim}{P}-\underset{\sim}{P})+2 V \tag{A5}
\end{equation*}
$$

where

$$
\begin{align*}
& \underset{\sim}{P}={\underset{\sim}{B}}^{\dagger^{A}}{ }_{\sim}^{-1} \underset{\sim}{m}  \tag{A6}\\
& \underset{\sim}{R}=\underset{\sim}{C}-{\underset{\sim}{B}}^{\dagger}{\underset{\sim}{A}}^{-1} \underset{\sim}{B} \tag{A7}
\end{align*}
$$

The derivation proceeds from (A1) and the definitions

$$
m_{\alpha}=\partial T / \partial \omega_{\alpha} \text { and } P_{S}=\partial T / \partial \dot{Q}_{S}
$$

Which yiela:

$$
\begin{align*}
& \underset{\sim}{M}=\underset{\sim}{A} \underset{\sim}{~}+\underset{\sim}{B} \dot{Q}  \tag{A8a}\\
& \underset{\sim}{P}=\underset{\sim}{B}+\underset{\sim}{\omega}+\underset{\sim}{C} \tag{A8~b}
\end{align*}
$$

Thus the total angular momentum mof the vibrating rotor contains a contribution from the intemal motion; likewise, the vibrational momentun $\underset{\sim}{P}$ includes contributions dependent on the velocity of overall rotation. For a rigid rotor the quantity

$$
m^{\dagger} I^{-1} m
$$

would be equal to twice the kinecic energy ( $Q=0$ ); for the vibrating rotor we find

$$
\begin{equation*}
\left.2 T-m_{\sim}^{\dagger}{\underset{\sim}{I}}^{-1} m=\underset{\sim}{\dot{Q}}+\underset{\sim}{C}-{\underset{\sim}{B}}^{\dagger}{\underset{\sim}{I}}^{-1} \underset{\sim}{B}\right] \underset{\sim}{Q} \tag{A9}
\end{equation*}
$$

The matrix $\underset{\sim}{R}$, detined by the terms within square brackets, may be regarded as a reduced mass natrix associated with the vibrations. This suggests that we write

$$
\begin{equation*}
\underset{\sim}{P}=\underset{\sim}{R} \dot{\sim} \dot{\sim}+\underset{\sim}{P} \tag{A10}
\end{equation*}
$$

In which $P$ represents the part of the total vibrational momentum that arises from the rotation (via Coriolis interaction). A comparison of (AB) With (AIO) shows that $\underset{\sim}{P}$ must be defined as in (A6). Substitution of (AIO) into (A9) then yields the desired form of (A5).

As shown by Eckart, ${ }^{2}$ the elements of the matrices $\underset{\sim}{A}(3 \times 3), \underset{\sim}{B}$ $(3 x 3 N-6)$ and $\underset{\sim}{C}(3 N-6 \times 3 N-6)$ are defined by

$$
\begin{align*}
& A_{\alpha \beta}=\Sigma_{i} m_{i}\left[r_{i}^{\delta_{\alpha}} \alpha \beta-\alpha_{i} \beta_{i}\right]_{*} \\
& B_{\alpha S}=\Sigma_{i} m_{i}\left[\alpha_{i}\left(\partial \beta_{i} / \partial Q_{s}\right)-\beta_{i}\left(\partial \alpha_{i} / \partial Q_{s}\right)\right]_{*}  \tag{A1I}\\
& C_{Q t}=\Sigma_{\alpha i} m_{i}\left(\partial \alpha_{i} \partial Q_{s}\right)_{*}\left(\partial \alpha_{i} / \partial Q_{t}\right)_{*}
\end{align*}
$$

It may be remarked that these expressions and the Hamiltonian forms (A2) or (A5) are quite general, and still hold (i) when the nomal coordinates are replaced by any set of internal coordinates; (1i) When a configuration other than the equilibrium one is chosen as the standard: and (iii) whether or not Eckart's second condition, Eq. (17), is applied. If internal coordinates are used the $\underset{\sim}{C}$ matrix becomes Wilson $\mathrm{s}^{-1}$ matrix. ${ }^{-18}$ When the second Eckart condition is imposed, the $\underset{\sim}{B}$ matrix becomes a linear function of the nomal coordinates. Accordingly $\underset{\sim}{R}$ and $\underset{\sim}{P}$ as well as $\underset{\sim}{I}$ are quadratically dependent on the nomal coordinates. However, for a treatment in Which only the vibrationmotation interactions conrect to terms inncar in $\left(v_{s}+\frac{1}{2}\right)$ are required, it is sufficient to use just the leading terms

$$
\begin{align*}
& \underset{\sim}{R}=\underset{\sim}{E}+\cdots  \tag{A12}\\
& \underset{\sim}{P}=\sum_{\sim} \mathcal{S}^{\alpha}{\underset{\sim}{Q}}_{\sim} / I_{\alpha}+\ldots
\end{align*}
$$

This is the case dealt with in the text and in Appendix. B.

- To obtain the corresponding quantum mechanical Hamiltonian, it is necessary to evaluate the proper Iaplacian operator. This is awhard since the coefificients of the momenta are not constants and the rotational momenta used are not conjugate to any coordinates. It has been verified that the procedures used by Wilson and Howard, 4,18
can be applied to (A5) With $\underset{\sim}{m}$ and $\underset{\sim}{P}-\underset{\sim}{~}$ taken as the quantum mechanical operators. EThe result has a form analogous to Eq. (10), p. 280, of peference 18 , with the determinant of ${\underset{\sim}{-1}}^{-1}$ replacine that of $\left.\underset{\sim}{\mu}.\right]$ However, in the perturbation treatment what is actually used is an expansion of the Hamiltonian up to terms quacratic in $Q$ and $P$. It is found that to this order the correct results are obtalned by merely symetrizing products such as $P_{S} Q_{S}$ in the classical Hamilconian.

## APPENDIX B

TREATMENT OF CORTOLIS TERMS

The perturbation treatment of the Hamiltonian given in (A5) conveniently separates into two parts. In the text the contributions from the leading term have been evaluated by simply calculating the vibrational average of the inverse moment of inertia. Here we shall derive the additional contributions that arise from the second tem and involve the Coriolis constants. In the approximation represented by Eq. (29) of the text, only those terms proportional to both $\underset{\sim}{m} \dagger$ and to $\left(v_{s}+\frac{1}{2}\right)$ will contribute to the effective moment of ineria. Contributions of this form are contained in the term

$$
\begin{equation*}
{\underset{\sim}{1}}^{\dagger} p \tag{B1}
\end{equation*}
$$

and in the cross term

$$
\begin{equation*}
-\left(P_{\sim}^{\dagger} \underset{\sim}{R}+\underset{\sim}{p} \underset{\sim}{\rho}\right) \tag{B2}
\end{equation*}
$$

According to (A13), the term (BI) can be averaged directly to give

$$
\begin{equation*}
\left\langle Q_{S}^{2}>\xi_{s t}^{\alpha} \zeta_{s t}^{\beta} m_{\alpha} m_{\beta} / I_{\alpha} I_{\beta}\right. \tag{B3}
\end{equation*}
$$

where $s, t, \alpha$, and $\beta$ are all summed over. (For convenience the summation variables have been reshuffled to putis first.) The cross term (B2) rust be evaluated as a second order perturbation since it has only nondiagonal vibrational matrix elements,

$$
\begin{align*}
& \left\langle v_{s} v_{t} \mid v_{s}+1, v_{t}+1\right\rangle=z(-1 K)\left(\omega_{s}-\omega_{t}\right)\left[\left(v_{s}+1\right)\left(v_{t}+1\right) / \omega_{s} \omega_{t}\right]^{1 / 2}  \tag{B4a}\\
& \left\langle v_{s} v_{t} \mid v_{s}+1, v_{t}-1\right\rangle=z(-1 K)\left(\omega_{s}+\omega_{t}\right)\left[\left(v_{s}+1\right) v_{t} / \omega_{s} \omega_{t}\right]^{1 / 2} \tag{BAb}
\end{align*}
$$

with

$$
z=\Sigma_{\alpha} \varphi_{s t}^{\alpha} \alpha / I_{\alpha}
$$

The two terms in (B2), one with $\zeta_{s t} P_{s} Q_{t}$ and the other with $\zeta_{t s} P_{t} Q_{s}$, have been combined using the relation $\zeta_{t s}=-\zeta_{s t}$. The second order perturbation sum reduces to the same form as (B3) with one more factor

$$
\begin{equation*}
\left(3 \lambda_{S}+\lambda_{t}\right) /\left(\lambda_{s}-\lambda_{t}\right) \tag{B5}
\end{equation*}
$$

The total Coriolls contribution to the effective rotational Hamiltonian of Eq. (27) thus contains the factor

$$
1+\left(5 \lambda_{s}+\lambda_{t}\right) /\left(\lambda_{s}-\lambda_{t}\right)=4 \lambda_{s} /\left(\lambda_{s}-\lambda_{t}\right)
$$

and in the coefficients of Eq. (36) appears as

In the effective moments of Inertia for the ground state ( $v_{S}=v_{t}=\ldots=0$ ) pairs of terms $\epsilon_{s}$ and $\epsilon_{t}$ may be added together to give

$$
\begin{equation*}
\frac{K}{\omega_{s}} \frac{\lambda_{s}}{\lambda_{s}-\lambda_{t}}+\frac{K}{\omega_{t}} \frac{\lambda_{t}}{\lambda_{t}-\lambda_{s}}=\frac{K}{\omega_{s}+\omega_{t}} \tag{B7}
\end{equation*}
$$

This shows that "resonant" Coriolis perturbations will not appear in the ground vibrational state.

It should be mentioned that other coriolis effects ${ }^{59}$, are present for degenerate vibrations. These show up in separate tems involving the angular momentum of the degenerate vibrations, and therefore are not regarded as part of the effective moment of inertia. Thus in the forgoing the constants $\zeta_{\mathrm{St}}$ which connect different components of a degenerate vibration are ignored. There are, however, useful relations between (B6) and the coefficients associated with the degenerate Coriolis perturbations. 25,30

## APPENDIX C

## ANHARIVONIC VIBRATIONAL AVERAGES

In our treatment the innear and cubic terms in the potential function of Eq. (20) are regarded as the primary perturbations. The first-order perturbed vibrational waverunction obtained fromeq. (23) is then used to average the interaction terms in the kinetic energy, a procedure equivalent to a second-order perturbation treatment of the Hamitonian. ${ }^{50}$ As shown in the text, the calculation reduces just to evaluating

$$
\begin{equation*}
\left\langle Q^{n}\right\rangle=\left\langle\psi_{v i b}\right| Q_{\mathrm{s}}^{n}\left|\psi_{\mathrm{vib}}\right\rangle \tag{CI}
\end{equation*}
$$

Fon $n=1,2$. Only an approximation which yields the leading terms, proportional to the vibrational quantum numbers, is required.

In $\psi_{v i b}=\psi_{h}+\psi_{a}$ the unperturbed or "harmonic" part is the product of harmonic oscillator functions, one for each normal mode:

$$
\begin{equation*}
\left.v_{\mathrm{h}}=\left|v_{\mathrm{s}}>\pi_{t}\right| v_{\mathrm{t}}\right\rangle \tag{c2}
\end{equation*}
$$

(where $t=s$ ) for a given vibrational state with quantum numbers $v_{1}, \ldots, v_{S}, \ldots, v_{3 N-6}$. The "anharmonic" part $v_{a}$ consists of a linear combination of many nondiagonal terms in which one or more of the vibrational quantum numbers differ from those in $\psi_{h}$. However, the only terms which enter in the evaluation of (Cl) are of the type

$$
\begin{equation*}
\left.v_{\mathrm{a}}=\left[A_{+}\left|v_{\mathrm{s}}+1\right\rangle+A_{-}\left|v_{\mathrm{S}}-1\right\rangle\right] \Pi_{t} v_{\hat{t}}\right\rangle \tag{c3}
\end{equation*}
$$

The coefricients

$$
A_{ \pm}=\left\langle v_{S}\right| v_{S}\left|v_{S} \pm 1\right\rangle /\left(\mp h \omega_{S}\right)
$$

are formed from matrix elements of those perturbation terms that are in near or cubic functions of the $s^{\text {th }}$ normal coordinates,

$$
V_{s}=\frac{1}{2} V_{s} Q_{s}+\frac{1}{2} k_{s s s} Q_{s}^{3}+\frac{3}{2} \Sigma_{t} k_{t t s} Q_{t}^{2} Q_{s}
$$

When $v_{s}$ is even (or odd), $\psi_{h}$ is an even (or odd) function of $Q_{s}$ and $V_{a}$ is an odd (or even) function. Therefore in (CI) we find

$$
\left\langle Q_{s}\right\rangle=\left\langle\psi_{h}\right| Q_{s}\left|\psi_{a}\right\rangle+\left\langle\psi_{a}\right| Q_{s}\left|\psi_{h}\right\rangle
$$

and

$$
\left\langle Q_{s}^{2}\right\rangle=\left\langle\psi_{h}\right| Q_{s}^{2}\left|\psi_{h}\right\rangle+\left\langle\psi_{a}\right| Q_{s}^{2}\left|\psi_{a}\right\rangle
$$

The anharmonic part of $\left\langle Q_{S}^{2}\right\rangle$ is dropped, since it contains only terms at least quadratic in $v+\frac{1}{2}$. Thus we are left with just the result for a simple harmonic oscillator,

$$
\left\langle Q_{s}^{2}\right\rangle=\left(2 \mathrm{~K} / \omega_{s}\right)\left(v_{s}+\frac{1}{2}\right)
$$

The two terms in $\left\langle Q_{S}\right\rangle$ are equal and we ind

$$
\left\langle Q_{S}\right\rangle=2\left[A_{+}\left\langle v_{S}\right| Q_{S}\left|v_{S}+I\right\rangle+A_{-}\left\langle v_{S}\right| Q_{S}\left|v_{S}-1\right\rangle\right] .
$$

After introducing the harmonic oscillator matrix elements and the relation $K / \omega_{S}=\frac{1}{2}\left(h \omega_{S} / \lambda_{S}\right)$, we can reduce this to

$$
\begin{equation*}
\left\langle Q_{S}\right\rangle=-\frac{3}{2}\left[k_{s s s}\left\langle Q_{S}^{2}\right\rangle+\Sigma_{t} k_{t t s}\left\langle Q_{t}^{2}\right\rangle+\frac{1}{3} V_{s}\right] / \lambda_{s} \tag{C4}
\end{equation*}
$$

This becomes Eq. (34) of the text when (21) is taken into account.
It is interesting to note that if we separate the potential energy into harmonic and inharmonic parts,

$$
\begin{aligned}
& 2 V_{h}=\Sigma_{s} \lambda_{s} Q_{S}^{2} \\
& 2 V_{a}=\Sigma_{s} V_{s} Q_{s}+\Sigma_{s} k_{s s s} Q_{s}^{3}+\cdots
\end{aligned}
$$

then (C4) is equivalent to the condition

$$
\lambda_{\mathrm{s}}\left\langle Q_{\mathrm{s}}\right\rangle=\left\langle\partial V_{\mathrm{h}} / \partial Q_{\mathrm{s}}\right\rangle=-\left\langle\partial V_{\mathrm{a}} / \partial Q_{\mathrm{s}}\right\rangle
$$

or

$$
\left\langle\partial V / \partial Q_{S}\right\rangle=0 .
$$

(Again, just terms linear in $v+\frac{1}{2}$ are retained.)
Often it is convenient to express the potential energy in terms of internal coordinates rather than normal coordinates, by use of Eq. (54). When transforming results from one basis to the other, it again proves useful to consider the expansion of a mode, as the following relations hold:

$$
\begin{align*}
\lambda_{s} & =2 v_{h}(\ddagger) \\
k_{s s s} & =2 v_{a}(\ddagger) \\
\xi_{s s t} & =2\left(\partial v_{a} / \partial Q_{t}\right)_{\ddagger}  \tag{C5}\\
& =2 \Sigma_{k}\left(\partial V_{a} / \partial s_{k}\right)_{\neq} I_{k t}
\end{align*}
$$

Here the symbol "t" indicates that the function is evaluated at the configuration specified in Eq. (55).

30. A matrix method has been given in references 30 and 38 ,

$$
\underset{\sim}{\mathcal{A}}={\underset{\sim}{M}}^{-1 / 2}{\underset{\sim}{B}}^{\dagger}{\underset{\sim}{G}}^{-1} \underset{\sim}{U}{\underset{\sim}{U}}^{\dagger}
$$

where $\underset{\sim}{M}$ is a diagonal matrix with elements $m_{i}$ and the other matrices are defined in reference 18.
32. In Eqs. (46) and elsewhere we write expressions corresponding to just one coordinate direction; the others can be obtained by cyclic permutations of $\alpha, \beta, \gamma$.
33. D. Kivelson and E. B. Wilson, J. Chem. Phys. 21, 1229 (1953). For other applications of Eq. (47) see references 40 and J. M. Dowling, R. Gold, and A. M. Meister, J. Molec. Spect. 1, 265 (1957); 2, 9, 411 (1958).
34. The coordinates obtained by use of Eq. (47) are referred to the center of mass of the expanded configuration, but not to its principal axes. In practice the contributions with $\alpha \neq \beta$ can often be neglected.
35. K. S. Pitzer, J. Chem. Phys, 8, 711 (1940).

36, D. R. Herschbach, H. S. Johnston, and D. Rapp, J. Chem. Phys. 31, 1652 (1959).
37. The procedure is particularly convenient for computing nachines. R. H. Schwendeman, J. Molec. Spect. 6, 301 (1961) has described a program for moment of inertia calculations which can be adapted to evaluate Eqs. (50) and (51).
38. This has been pointed out by pliva in reference 24. Fe has derived a treatment of triatomic molecules in which the internal coordinates are defined by che general noninear relations. The distinction is also important in the analysis of vibrational effects in electron diffraction; see Y. Morino and E. Hirotag J. Chem. Phys. 23, 737 (1955).
39. Similar considerations are Involved in the derivation of Eqs. (48) and (49).
40. S. R. Polo, J. Chem. Phys. 24, I133 (1956).
41. For symmetrical molecules certain of the coefficients in Eqs. (48) and (49) must vanish, according to rules summarized in rererence 30 .
42. Quantities which refer to symmetry coordinates will be distinguished by script letters.

43: Eq. (7I) may be derived by combining Eq. (A5) of reference 40 With Eq. (26a) of reference 36 ; in the latter the last subscript should read "o" rather than " $\gamma$ ".
44: The tetranedral case has been discussed briefly by Folo in refecence 40 . His results agree with ours but are considerably different in form, aince he treats symmetry coordinates differently.
45: The vibrational analysis of the nontetrahedral model is treated by G. W. Bethke and M. K. Wilson; J. Chem. Phys. 26, 1118 (I957) and W. T. King, I. M. Malls; and B. L. Crawford, ibide's 27. 455 (1957).

& \left.\left.H_{1}=1, H_{2}=\left(3 \lambda_{2}+\lambda_{3}\right) / \lambda_{3}-\lambda_{2}\right), H_{3}=\left(3 \lambda_{3}+\lambda_{2}\right) / \lambda_{3}-\lambda_{2}\right) \\
& A_{1}=r\left(F_{111}+3 F_{113}\right) /\left(F_{11}+F_{13}\right), A_{2}=\left(\lambda_{2} / \lambda_{1}\right)\left(4 r_{122} / F_{22}\right) \\
& \left\langle A_{3}=\left(\lambda_{3} / \lambda_{1}\right) r\left(F_{111}-F_{113}\right) /\left(F_{11}-F_{13}\right)\right. \\
& \langle\xi\rangle=-\left(3 B_{e} / \omega_{1}\right)\left[A_{1}\left(V_{1}+\frac{1}{2}\right)+\frac{1}{2}\left(\omega_{1} / \omega_{2}\right) A_{2}\left(V_{2}+1\right)+\left(\omega_{1} / \omega_{3}\right) A_{2}\left(V_{3}+\frac{1}{2}\right)\right] \\
& \langle\xi\rangle=\left(2 B_{e} / \omega_{1}\right)\left(V_{1}+\frac{1}{2}\right)
\end{aligned}
$$

${ }^{a} S_{1}=\delta r_{X Y} ; S_{2}=\delta ; S_{3}=\delta r_{X Y} ; \xi=\frac{1}{2}\left(S_{1}+S_{3}\right)$. Mas of $X$ atom is $M$, of $Y$ atom $m$, and $\mu=2 m M /(2 m+M)$.

Table IV. Víbration-rotation parameters for $\mathrm{CO}_{2} \cdot$.a

|  |  |  |  |
| :---: | :---: | :---: | ---: |
| Mode | Harmonic | Anharmonic | Total |
| 1 | -0.0747 | 0.213 | 0.139 |
| $2,2^{\prime}$ | 0.0673 | -0.234 | -0.167 |
| 3 | -0.0470 | 0.386 | 0.339 |
| Sum | -0.0544 | 0.365 | 0.311 |

$a_{\text {The }}$ tabulated quantities are the contributions to $\frac{1}{2} \epsilon=I_{0}-I_{e}$ (in amu $A^{2}$ units). Data used is from C. P. Courtoy [Can. J. Phys. 35, 608 (1957)]: $B_{e}=0.39162_{5}$, $\alpha_{1}=0.00126, \alpha_{2}=-0.00076, \alpha_{3}=0.003088$, $\omega_{1}=1354.9, \omega_{2}=673.02, \omega_{3}=2396.4$ (a11 in $\mathrm{cm}^{-1}$ units).

Table V. Notation and units.

$$
\begin{aligned}
& \alpha_{1}, \beta_{1}, \gamma_{1}=\text { coordinates of ito atom with respect to } \\
& \text { principal axis system, chosen from } x, y, z \text { in } \\
& \text { cyclic order ( } \AA \text { ). } \\
& Q_{s}=\text { normal coordinates }\left(g^{1 / 2} m o l e^{-1 / 2} \AA\right) \\
& P_{S} \cdot .=\text { total vibrational momentum associated with } \\
& s^{\text {th }} \text { normal coordinate } \\
& P_{S} \quad=\text { part of vibrational momentum which asses } \\
& \text { from Coriolis interaction, defined in Eq. } \\
& \text { (A6) of Appendix A. } \\
& m_{\alpha}:=\text { componerits of total angular momentum along } \\
& \text { the principal axes } \\
& \omega_{\mathrm{S}} \quad=\text { harmonic vibrational frequency }\left(\mathrm{cm}^{-1}\right) \\
& \lambda_{\mathrm{s}}=4 \pi^{2} \mathrm{c}^{2} \mathrm{~m}_{\mathrm{H}} \omega_{\mathrm{s}}^{2}=5.8893 \times 10^{-7} \omega_{\mathrm{S}}^{2}\left(10^{5} \text { dynes } \mathrm{cm}^{-1} \mathrm{~g}^{-1} \mathrm{~mole}\right) \\
& k_{\text {set }}=\text { cubic enharmonic vibrational constant ( } 10^{-11} \\
& \text { exes } \left.E^{-3 / 2} \operatorname{mole} e^{3 / 2} \AA^{-3}\right) \\
& K=\mathrm{h} / 8 \pi^{2}=16.863 \mathrm{~g} \mathrm{~mole} e^{-1} \AA^{2} \mathrm{~cm}^{-1}
\end{aligned}
$$

Table vI. Symmetry analysis for a linear $X_{2} Y_{2}$ molecule. a

$a_{\text {Here }} r=r_{12}=r_{34} ; R=r_{23} ; m_{1}=m_{4} ; m_{2}=m_{3}$. The nondiagonal element $火_{12}$ for the $\Sigma_{g}^{+}$modes has the value $-2 / m_{2}$.

Table VI. Symmetry coordinates for a planar Wy molecule. ${ }^{2}$

Fig. 1. Relative deviations from re for various types of average bond lengths as a function of the anharmonic constant. Ordinate scale is in multiples of the mean square harmonic vibrational amplitude.

Fig. 2. Comparison of vibrational contributions to effective moment of inertia. Abscissa and dashed line show sum of corrections for stretching modes. Solid circles show total correction, the sum of bending and stretching terms. Open circles show sum obtained by assigning to each bond the observed correction for the corresponding diatomic molecule.

Flg. 3. Construction of a normal mode expansion.
Fig. 4. Internal coordinates for a linear WXYZ molecule.
Fig. 5. Internal coordinates and displacement vectors for a branched WXYZ molecule.
