General character skeleton

Deformation by human skeleton

Challenges

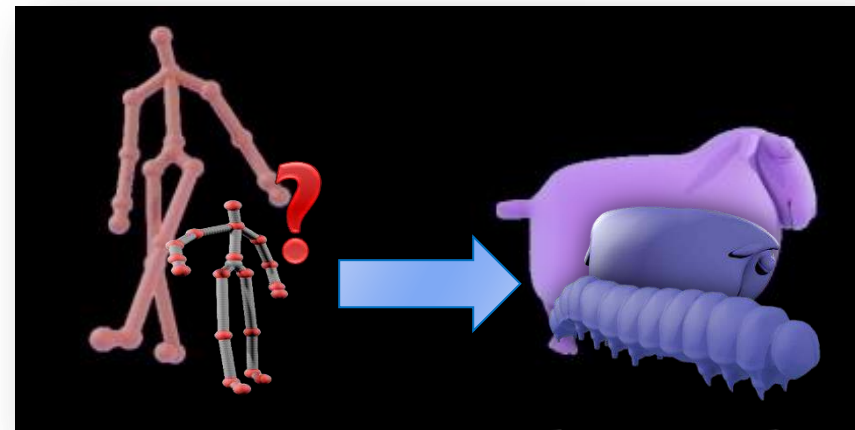

Existing approaches

- ▶ Skeleton based body control
- ▶ Cumbersome control definition

Remaining challenges

- ▶ Non-skeleton input and output (e.g. soft body of caterpillar)
- ▶ Unreliable user input (user imprecision)
- ▶ Easy definition of control modality (interface for non-technical users)

Goal – Control by Body Motion

Method Overview

Method Overview – Learning and Synthesis

1. Input

Example mesh animation

Key poses

2. Motion Mapping

Example motions

3. Character Control

Input motion

Character motion

Motion Mapping – Correspondence Definition

Goal: Easy and flexible control definition

Our approach

- ▶ Performance based
- ▶ Few pose examples
- ▶ Guided

The non-technical users is unaware of

- ▶ the expressiveness of his motion
- ▶ the allowed similarity of two control motions

Interactive Correspondence Definition

Confidence score

Input pose

Phase 3: press controller to choose correspondence frame 1 of 8

1-2. bend left & right

3. lift head

4. jump

5-8. crawl

Control by Body Motion

Motion Mapping

Mapping from input to target character

Implemented as linear map $Mx = y$

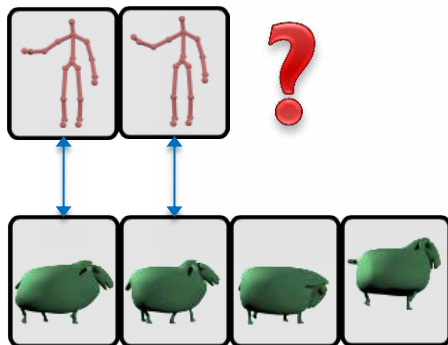

$$M \begin{pmatrix} \begin{matrix} \text{Input pose} \\ t \end{matrix} \\ \begin{matrix} \text{Input pose} \\ t-1 \end{matrix} \end{pmatrix} = \begin{pmatrix} \text{Character pose} \\ t \end{pmatrix}$$

Bayesian Regression

Properties:

- ▶ Explicit noise model (here Gaussian)
- ▶ Predicts **most probable** character pose

- ▶ Estimates **variance** of prediction:
 - ▶ Low variance \Rightarrow Well represented
 - ▶ High variance \Rightarrow Underrepresented

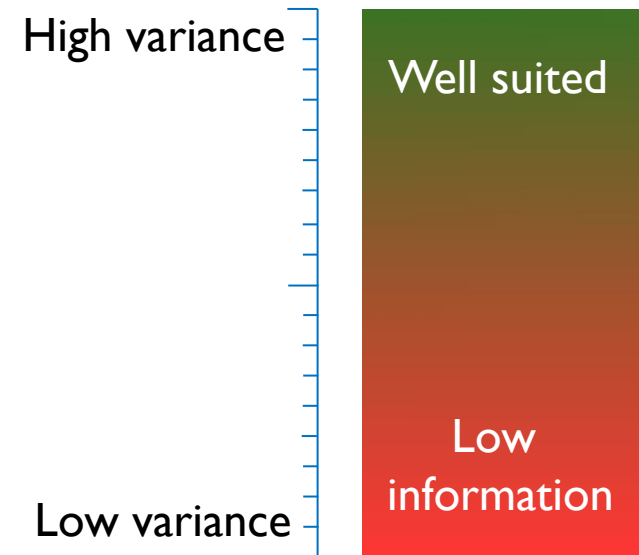

Outcomes:

- ▶ Mapping Φ^{pose}

$$M \left(\begin{array}{c} \text{dots} \\ \text{dots} \\ \text{dots} \\ \text{dots} \end{array} \right) = \left(\begin{array}{c} \text{dots} \\ \text{dots} \\ \text{dots} \\ \text{dots} \end{array} \right)$$

- ▶ Confidence bar

Processing of Example Motion – Range of Motion

Problem: Undesired character deformation

Solution: Exploit example motion

Example animation
(artist created)

“Range of motion”

The Latent Volume

Goal: Prevent undesired character deformations

Approach: Approximate the character's range of motion by a high-dimensional box

Method:

- ▶ Represent mesh in vector form
- ▶ Find orientation by principal component analysis
- ▶ Set bounds such that the example motion is included

Application of the Latent Volume

Real motion

Our method

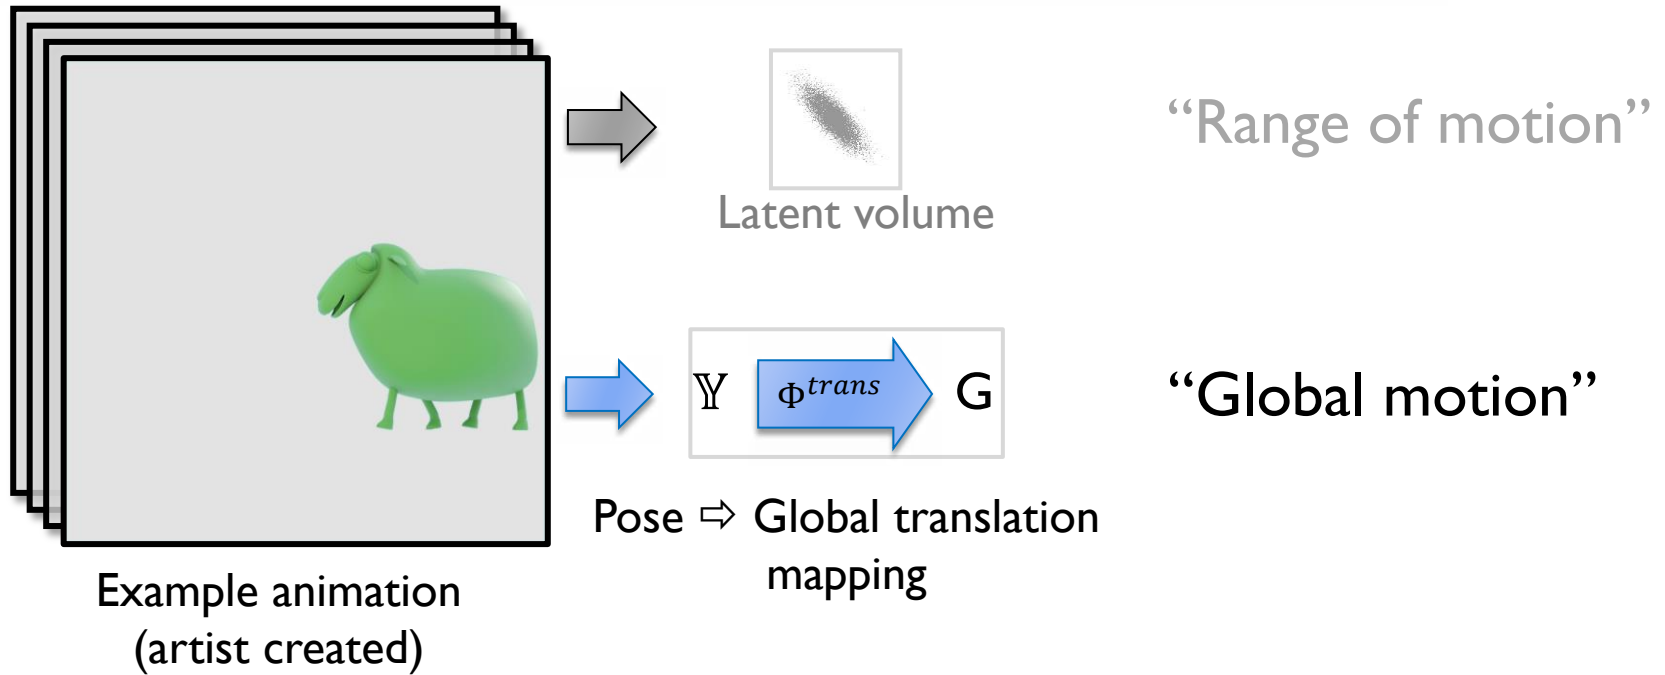

Source motion

No latent volume

Processing of Example Motion – Global Motion

Shape Representation of Target Character

Problem: Direct mesh representation leads to deformations

Solution: Variant of *deformation gradient* representation [Sumner et al. 2004]

Vertices

Face rotation & shear

Character representation

- ▶ Models rotational motions more faithfully
- ▶ Reconstruction required to solve sparse linear system (real-time, 30 fps)

Results – Full-body Input on Horse

Source poses

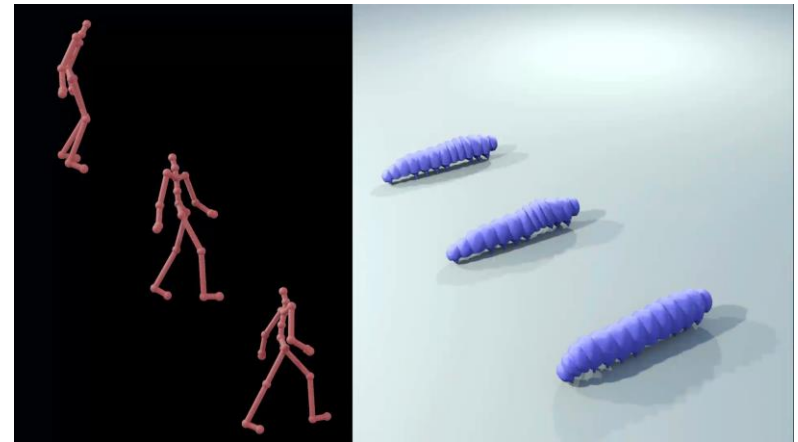

Target poses

Why a Linear Map?

Linear map

- ▶ Real time
- ▶ Superposition (additivity)
 $f(\mathbf{x} + \mathbf{y}) = f(\mathbf{x}) + f(\mathbf{y})$
- ▶ Transfer of intensity (homogeneity)
 $f(\alpha\mathbf{x}) = \alpha f(\mathbf{x})$

Results – Full-body Input on Sheep

Results - Facial Expression Input

Source motion

Synthesized output

Results - Hand Motion

Discussion

Human coordination is limited

- ▶ Controllable degrees of freedom
- ▶ Observable degrees of freedom

Granularity of control

- ▶ The mapping is learned from only 4-8 correspondences

Summary – Algorithmic Contributions

Challenge

- ▶ Non-skeletal characters
- ▶ Unreliable user input
- ▶ Easy definition of the control

Solution

- ▶ Character representation in shape space
- ▶ Bayesian regression
- ▶ Latent volume
- ▶ Guided correspondence through confidence measure
- ▶ Sparse correspondences

Summary – Achievements

- ▶ Robust real-time character control that is independent of a skeleton
- ▶ Interface is accessible to non-technical users
- ▶ Ongoing cooperation with animation artists indicates the applicability to character animation
