Accession no.X07315

A cDNA library prepared from human placenta (1) was screened for sequences coding for the placental protein 15 (PP15). This protein is composed of two subunits each with a molecular weight of 15 000 and shows a very poor antigenicity (2,3). This was demonstrated by a significant inhibitory activity on lymphocyte transformation in the mixed leucocyte culture test in vitro.

We used partial amino acid sequence information from PP15 to design oligonucleotide probes for screening one million independent recombinants. Two recombinants with full length cDNA inserts were identified coding for a protein of 127 amino acids and a molecular weight of 14 478. The nucleotide sequence (894 bp) and the deduced amino acid sequence are shown. A putative ribosome binding site is marked by an open circle and the poly(A)-addition site by a closed circle. Peptide sequences determined from cyanogen bromide fragments are underlined. The amino-terminal residue of PP15 is blocked. The amino acid composition described by Bohn is in good agreement with the composition deduced from the cDNA sequence (2).
