Potter (1) investigated mass spectrometrically the equilibrium  $\text{CaCl}_2(\text{g}) + \text{ZrCl}_4(\text{g}) \rightleftharpoons \text{ZrCl}_3(\text{g}) + \text{CaCl}_2(\text{g})$  in the temperature range 1163-1557°K. Ion intensities were measured 2.5 eV above threshold and they were used in the calculation of equilibrium constants. Using the reported equilibrium constants, the heats of reaction at 298°K are evaluated by the third law and second law methods as -3.69 and -16.67 kcal/mol, respectively. The third law drift is 9.31 ± 1.25 eu. Using the third law  $\Delta H_f^\circ(298) = -3.69$  kcal/mol,  $\Delta H_f^\circ(298)(\text{ZrCl}_4, \text{g}) = -207.77$  kcal/mol (2),  $\Delta H_f^\circ(298)(\text{CaCl}_2, \text{g}) = -28.8$  kcal/mol (3) and  $\Delta H_f^\circ(298)(\text{ZrCl}_3, \text{g}) = -115.0$  kcal/mol (4). We obtain  $\Delta H_f^\circ(298)(\text{ZrCl}_3, \text{g}) = -125.3$  kcal/mol, which is adopted in the tabulation. Farber et al. (5) also studied mass spectrometrically the reaction  $\text{Zr}(\text{Cl}) + 3\text{ZrCl}_4(\text{g}) \rightleftharpoons 4\text{ZrCl}_3(\text{g})$  in the temperature range from 1579°K to 1729°K. They reported a second law heat of reaction as  $\Delta H_f^\circ(298) = 59.2 \pm 1.6$  kcal/mol. Since the attainment of equilibrium was questionable in their studies, the heat of reaction obtained from the third law method is generally more reliable. Using their reported ion intensities of run 3 (temperature range from 1667°K to 1696°K, five points), we have calculated the equilibrium constants  $K_1 = (I_{\text{ZrCl}_3})^2 / (I_{\text{ZrCl}_2} I_{\text{ZrCl}_4})$  for reaction (1)  $\text{ZrCl}_3(\text{g}) + \text{ZrCl}_2(\text{g}) \rightleftharpoons 2\text{ZrCl}_4(\text{g})$ ; and  $K_2 = (I_{\text{ZrCl}_3})^2 / (I_{\text{ZrCl}_4} I_{\text{ZrCl}_2})$  for reaction (2)  $\text{ZrCl}_4(\text{g}) + \text{ZrCl}_2(\text{g}) \rightleftharpoons 2\text{ZrCl}_3(\text{g})$ . Third law analyses of the equilibrium constants give  $\Delta H_f^\circ(298) = -11.0$  kcal/mol for reaction (1) and its drift 4.1 ± 1.7 eu; and  $\Delta H_f^\circ(298) = 1.4$  kcal/mol for reaction (2) and its drift 11.1 ± 1.2 eu. Using the third law heats of reaction, and  $\Delta H_f^\circ(298)(\text{ZrCl}_2, \text{g}) = 49.1$  kcal/mol (6) and  $\Delta H_f^\circ(298)(\text{ZrCl}_4, \text{g}) = -207.77$  kcal/mol (2), we obtain  $\Delta H_f^\circ(298)(\text{ZrCl}_3, \text{g}) = -124.9$  kcal/mol and  $\Delta H_f^\circ(298)(\text{ZrCl}_2, \text{g}) = -43.4$  kcal/mol which are in good agreement with the values adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be a pyramid similar to the group VA trichlorides. The bond distance is assumed to be the same as that of  $\text{ZrCl}_4(\text{g})$ . The three principal moments of inertia are  $I_A = I_B = 45.9145 \times 10^{-39}$  and  $I_C = 72.6247 \times 10^{-39}$  g cm<sup>2</sup>. The electronic levels are estimated as three times higher than those of  $\text{TiCl}_3(\text{g})$ , based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (7). The quantum weights are assumed to be the same as those of  $\text{TiCl}_3(\text{g})$ .

Vibrational frequencies are calculated from the estimated force constants by the valence force method (8). The force constants are estimated from those of  $\text{PbCl}_3$ ,  $\text{AsCl}_3$  and  $\text{SbCl}_3$  listed by Herzberg (9).

Bond Distance: Mg-Cl = [2.18] Å, Mg-Cl'(ring) = [2.3] Å  
 Bond Angles: Cl'-Mg-Cl'(in ring) = [90°], Cl-Mg-Cl' = [135°]  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 1.3313 x 10<sup>-111</sup> g<sup>3</sup> cm<sup>6</sup>

Heat of Formation  
 References relative to the monomer-dimer ratio in magnesium chloride vapor are given in the discussion for monomeric ideal gas. The selected best value for the heat of dimerization at 900°K is -39.2 kcal/mol. Combined with heat of formation data for the monomer and the heat capacity of the dimer, this yields ΔH<sub>f,298.15</sub><sup>o</sup> = -228.10 kcal/mol.

Heat Capacity and Entropy  
 A planar structure with D<sub>2h</sub> symmetry was assumed, with the outer Mg-Cl distance the same as in MgCl<sub>2</sub> and the ring Mg-Cl distance slightly larger. The ring was taken to be square, and the Cl-Mg-Cl' angle 135°. This structure gives individual moments of inertia of I<sub>A</sub> = 31.12 x 10<sup>-39</sup> g cm<sup>2</sup>, I<sub>B</sub> = 191.86 x 10<sup>-39</sup> g cm<sup>2</sup> and I<sub>C</sub> = I<sub>A</sub> + I<sub>B</sub>.

A reasonable set of frequencies was estimated by comparison with MgCl<sub>2</sub> monomer and other dimer molecules. The single observed frequency is from A. Buchler and W. Klemperer, J. Chem. Phys. 29, 121 (1958), who erroneously ascribed it to the bending mode of the monomer. The estimated values were adjusted until the entropy of dimerization at 900°K was -29.9 gibbs/mol, as selected in the discussion for ideal monomeric gas. The calculated thermodynamic properties of monomer and dimer give total vapor pressures in good agreement with experiment and yield a boiling point for magnesium chloride of 1624°K at one atmosphere pressure.

(CRYSTAL)

MOLYBDENUM TETRACHLORIDE (MoCl<sub>4</sub>)

GFW = 237.752

Molybdenum Tetrachloride (MoCl<sub>4</sub>)  
(Crystal) GFW = 237.752

ΔHf° = Unknown

ΔHf°<sub>298.15</sub> = -114 ± 2 kcal/mol

S°<sub>298.15</sub> = (53.5 ± 3) gibbs/mol

Δlim° = [4 ± 2] kcal/mol

Tm = 590°K

Heat of Formation

The adopted ΔHf°<sub>298</sub> = -114 kcal/mol was determined by Shchukarev et al. (1) by solution calorimetry. The authors measured the heat of solution of MoCl<sub>4</sub> in the aqueous solvent FeCl<sub>3</sub> + HCl and obtained the heat of formation from a comparison with the heat of solution of MoCl<sub>5</sub> measured in the same solvent.

The decomposition pressures of 2MoCl<sub>3</sub>(c) + Cl<sub>2</sub>(g) (80 - 150°C) were measured manometrically by Saeki and Matsuzaki (2). From the reported data we evaluate the enthalpy change for the above reaction by third law analysis. Based on ΔHf°<sub>298</sub>(MoCl<sub>5</sub>, c) = -126 kcal/mol and the third law ΔHf°<sub>298</sub> = 24,132 kcal/mol, we obtain ΔHf°<sub>298</sub>(MoCl<sub>4</sub>, c) = -113.94 kcal/mol, which is in very good agreement with the value reported by Shchukarev et al. (1).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of WCl<sub>4</sub>(c). The estimated S°<sub>298</sub> = 53.5 eu is based on the assumption that the entropy differences between MoCl<sub>4</sub>(c) and MoCl<sub>5</sub>(c) is about the same as that between WCl<sub>4</sub>(c) and WCl<sub>5</sub>(c). The entropy obtained from the second law analysis of the data of Saeki and Matsuzaki (2) agrees with the adopted one within the error of the vapor pressure data.

Melting Data

See liquid table.

MOLYBDENUM TETRACHLORIDE (MoCl<sub>4</sub>) (LIQUID)

GFW = 237.752

Molybdenum Tetrachloride (MoCl<sub>4</sub>) (Liquid)

GFW = 237.752

$\Delta H_f^{\circ} = [58.682] \text{ gibbs/mol}$

$\Delta H_m^{\circ} = [4 \pm 2] \text{ kcal/mol}$

$\Delta H_v^{\circ} = [14.7] \text{ kcal/mol}$

$S_{298.15}^{\circ} = [58.682] \text{ gibbs/mol}$

$T_m = 530^{\circ}\text{K}$

$T_b = [680]^{\circ}\text{K}$

$\Delta H_f^{\circ} = [-110.621 \pm 2] \text{ kcal/mol}$

$\Delta H_m^{\circ} = [4 \pm 2] \text{ kcal/mol}$

$\Delta H_v^{\circ} = [14.7] \text{ kcal/mol}$

Heat of Formation

The heat of formation is obtained from  $\Delta H_f^{\circ}(c)$  by adding  $\Delta H_m^{\circ}$  and the difference between  $H_{530}^{\circ} - H_{298}^{\circ}$  for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

$T_m$  is taken from V. Gutmann, "Halogen Chemistry," Vol. 3, Academic Press, New York, 1967.  $\Delta H_m^{\circ}$  is estimated such that the derived  $\Delta G_f^{\circ}$  for  $\text{MoCl}_4(l)$  yields a reasonable boiling point which is expected to be between 600 and 700°K from comparisons with related compounds.

Vaporization Data

$T_b$  is the temperature at which the Gibbs energy change ( $\Delta G_r^{\circ}$ ) of the following process  $\text{MoCl}_4(l) = \text{MoCl}_4(g)$  approaches zero. The difference between  $\Delta H_f^{\circ}$  for  $\text{MoCl}_4(l)$  and  $\text{MoCl}_4(g)$  at  $T_b$  is the heat of vaporization.

o = [12]

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [5.2829 x 10<sup>-112</sup>] g<sup>3</sup> cm<sup>6</sup>

Heat of Formation  
S. A. Shchukarev, G. I. Movikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin and A. K. Baev, Zh. Neorg. Khim. 5, 1850-4 (1960), derived the value ΔHf°<sub>298</sub>(MoCl<sub>4</sub>, g) = -89 kcal/mol from the decomposition pressures of 2MoCl<sub>3</sub>(c) + MoCl<sub>5</sub>(g) + MoCl<sub>4</sub>(g), 480-600°C, measured by a transpiration method. However, this ΔHf°<sub>298</sub> value is adjusted to be -92 ± 3 kcal/mol, in order to obtain a reasonable boiling point (see the MoCl<sub>4</sub>(l) table).

Heat Capacity and Entropy  
Vibrational frequencies and quantum weights are estimated by comparison with those of WCl<sub>4</sub>(g). The molecular configuration is assumed to be tetrahedral similar to those of WCl<sub>4</sub>(g), SiCl<sub>4</sub>(g), TiCl<sub>4</sub>(g) and PCl<sub>4</sub>(g). The bond distance is estimated to be the same as that of MoCl<sub>5</sub>(g). The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 80.89 x 10<sup>-39</sup> g cm<sup>2</sup>. The low lying electronic levels are estimated to be 0, 10000, and 30000, all triplets, by comparison with those of WCl<sub>4</sub>(g).

ΔHf° = Unknown

ΔHf°<sub>298.15</sub> = -160.4 ± 2 kcal/mol

ΔHm° = 10.846 ± 3 kcal/mol

S°<sub>298.15</sub> = [41.3 ± 4] gibbs/mol

Tm = 484°K

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov<sup>1</sup> measured calorimetrically the heats of reaction (1) and (2) at 298°K as -151.5 ± 0.5 and -13.6 ± 0.11 kcal/mol, respectively. The reactions are given as follows:

(1) WOCl<sub>4</sub>(c) + 6 NaOH(16.3 H<sub>2</sub>O) → Na<sub>2</sub>WO<sub>4</sub>(190,000 H<sub>2</sub>O) + 4 NaCl(50,000 H<sub>2</sub>O) + 3 H<sub>2</sub>O(l)

(2) H<sub>2</sub>WO<sub>4</sub>(c) + 2 NaOH(16.3 H<sub>2</sub>O) → Na<sub>2</sub>WO<sub>4</sub>(20,000 H<sub>2</sub>O) + 2 H<sub>2</sub>O(l)

Based on these data and the heats of dilution for NaOH(aq)<sup>2</sup>, and Na<sub>2</sub>WO<sub>4</sub>(aq)<sup>3</sup>, we obtain ΔHf°<sub>298</sub> = -118.0 ± 1.6 kcal/mol for WOCl<sub>4</sub>(c) + 40H<sub>2</sub>O(l) → H<sub>2</sub>WO<sub>4</sub>(c) + 4Cl<sup>-</sup>(∞H<sub>2</sub>O) + H<sub>2</sub>O(l). This leads to ΔHf°<sub>298</sub>(WOCl<sub>4</sub>,c) = -160.4 ± 2 kcal/mol, using ΔHf°<sub>298</sub>(H<sub>2</sub>WO<sub>4</sub>,c) = -270.5 ± 0.4 kcal/mol<sup>4</sup>.

Heat Capacity and Entropy.

Cp<sub>300</sub> = 35.0 gibbs/mol is estimated using Kopp's rule. Since the melting point of WOCl<sub>4</sub>(c) is approximately 500°K, which is relatively low for oxygen to reach its maximum contribution, we estimate Cp<sub>500</sub> = 40.0 gibbs/mol based on the values for WO<sub>2</sub>(c), WO<sub>3</sub>(c) and WCl<sub>6</sub>(c).

The entropy, S°<sub>298</sub> = 41.3 eu, is calculated from ΔS°<sub>457</sub> = 44.5 eu for WOCl<sub>4</sub>(c) → WOCl<sub>4</sub>(g) obtained from the second law analysis of the vapor pressure equation given by S. A. Shchukarev and A. V. Suvorov<sup>4</sup>. See WOCl<sub>4</sub>(g) table (Mar. 31, 1967) for details.

It is surprising that this entropy is smaller than the corresponding value for WOP<sub>4</sub>(c). See WOP<sub>4</sub>(c) table (Mar. 31, 1967) for details.

Melting Data.

Tm is calculated as the temperature at which the Gibbs energies of formation of crystal and liquid are equal. The difference between the heats of formation of crystal and liquid at the melting point is ΔHm°. This ΔHm° is derived from 2nd law analyses of the vapor pressure equation determined by Shchukarev and Suvorov<sup>4</sup>. See WOCl<sub>4</sub>(l,g) tables (Mar. 31, 1967) for details.

ΔH<sup>o</sup><sub>298,15</sub> = (60.6 ± 4) gttbbn/mol  
 ΔH<sup>o</sup> = 10.846 ± 3 kcal/mol  
 ΔH<sup>o</sup> = 10.5 kcal/mol

T<sub>m</sub> = 484°K  
 T<sub>b</sub> = 495°K

Heat of Formation.

The heat of formation, ΔH<sup>o</sup><sub>298</sub>(WOCl<sub>4</sub>,l) = -150.711 kcal/mol, is calculated from that of the gas by subtracting the heat of vaporization ΔH<sup>o</sup><sub>vap</sub> = 13.643 kcal/mol. The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev\* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH<sup>o</sup><sub>298</sub> = 10.32 kcal/mol (ΔH<sup>o</sup><sub>298</sub> = 13.643 kcal/mol) and the boiling point T<sub>b</sub> = 493°K. \*Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956); 3, 2630(1958); and 5, 1850 (1960), have been revised and they are not used here.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1956.

The entropy, S<sup>o</sup><sub>298</sub> = 60.6 eu, is calculated from ΔS<sup>o</sup><sub>298</sub> = 20.9 eu for WOCl<sub>4</sub>(l) → WOCl<sub>4</sub>(g) obtained from the second law analysis of the vapor pressure equation given by Shchukarev and Suvorov, loc. cit.

Melting Data.

See WOCl<sub>4</sub>(c) table (Mar. 31, 1967) for details.

Vaporization Data.

T<sub>b</sub> is calculated as the temperature at which the Gibbs energies of formation of liquid and gas are equal. The difference between the heats of formation of liquid and gas at the boiling point is ΔH<sup>o</sup>.

TUNGSTEN OXYTETRACHLORIDE (WOCl<sub>4</sub>)

Point Group [C<sub>2v</sub>]

ΔH<sub>f</sub><sup>0</sup> = -135.6 ± 5 kcal/mol

S<sub>298.15</sub><sup>0</sup> = [90.1] gibbs/mol

ΔH<sub>f</sub><sup>0</sup> = -137.0 ± 5 kcal/mol

Ground State Quantum Weight = 1

Bond Distance: W-Cl = [2.26] Å W-O = [1.81] Å

Bond Angle: Cl-W-O\* = Cl-W-Cl\* = [120°]

Cl\*-W-Cl\*\* = Cl\*\*-W-O\* = [90°]

Cl\*\*-W-Cl\*\*\* = [180°] σ = [2]

\*Equatorial \*\*Axial

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [5.873 x 10<sup>-112</sup>] g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

The heat of formation, ΔH<sub>f</sub><sup>0</sup>(WOCl<sub>4</sub>, g) = -137.0 kcal/mol, is calculated from ΔH<sub>f</sub><sup>0</sup>(g) = 23.4 kcal/mol for WOCl<sub>4</sub>(c) → WOCl<sub>4</sub>(g). The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH<sub>f</sub><sup>0</sup> = 21.9 kcal/mol (ΔH<sub>f</sub><sup>0</sup>(g) = 23.4 kcal/mol).

\*Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956), 3, 2630 (1956), 5, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOP<sub>4</sub>(g), reported by P. L. Ogggin, H. L. Roberts and L. A. Woodward<sup>1</sup>. The bond distance W-O and W-Cl are estimated to be the same as those in WO<sub>3</sub>(g) and WCl<sub>6</sub>(g), respectively. The three principal moments of inertia are I<sub>A</sub> = 8.260 x 10<sup>-36</sup>, I<sub>B</sub> = 1.052 x 10<sup>-37</sup> and I<sub>C</sub> = 6.757 x 10<sup>-36</sup> g cm<sup>2</sup>.

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOP<sub>4</sub>(g), WOCl<sub>4</sub>(c), WO<sub>3</sub>Cl<sub>2</sub>(g)<sup>2</sup>, CrO<sub>2</sub>Cl<sub>2</sub>(g)<sup>3</sup>, WO<sub>3</sub>(g)<sup>4</sup>, and WCl<sub>6</sub>(g)<sup>5</sup>. The frequencies are not listed in point group order.

June 30, 1962

Cl<sub>4</sub>Pb

(Ideal Gas)

Lead Tetrachloride (PbCl<sub>4</sub>)

Mol. Wt. = 349.04

ΔH<sub>f</sub><sup>0</sup> 298.15 = [-75] kcal. mole<sup>-1</sup>

ΔG<sub>f</sub><sup>0</sup> 298.15 = 91.9 cal. deg.<sup>-1</sup> mole<sup>-1</sup>

Point Group T<sub>d</sub>

Vibrational Levels and Multiplicities

ω<sub>i</sub>, cm.<sup>-1</sup>

326 (1)

63 (2)

341 (3)

99 (3)

Pb-Cl distance = 2.43 Å Cl-Pb-Cl angle = 109° 28'

I<sub>A</sub>B<sub>2</sub>C = 7.9660 X 10<sup>-112</sup> g.<sup>3</sup> cm.<sup>6</sup> σ<sup>-</sup> = 12

Heat of Formation, ΔH<sub>f</sub><sup>0</sup> 298.15 was estimated from the value of ΔH<sub>f</sub><sup>0</sup> 298.15 for PbCl<sub>2</sub>(s), using the relation between ΔH<sub>f</sub><sup>0</sup> 298.15 for dihalides and that for tetrahalides of titanium and zirconium as a reference.

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagarajan, Bull. Soc. Chim. Belg., 71, 119 (1962).

Cl<sub>4</sub>Pb

Silicon Tetrachloride (SiCl<sub>4</sub>)  
(Ideal Gas)

SILICON TETRACHLORIDE (SiCl<sub>4</sub>)  
Point Group T<sub>d</sub>  
S<sub>298,15</sub> = 79.07 gibbs/mol  
Ground State Quantum Weight = 1

(IDEAL GAS)  
GFW = 169.898

ΔH<sub>f,0</sub><sup>0</sup> = -156.58±0.6 kcal/mol  
ΔH<sub>f,298,15</sub><sup>0</sup> = -157.1±0.6 kcal/mol

Bond Distance: Si-Cl = 2.017±0.0034 Å  
 Bond Angle: Cl-Si-Cl = 109° 28'  
 Product of the Moments of Inertia:  $I_A I_B I_C = 2.60708 \times 10^{-112} \text{ g}^3 \text{ cm}^6$        $\sigma = 12$

**Heat of Formation**

The adopted value is calculated from ΔH<sub>f,298</sub><sup>0</sup> = 7.09 kcal/mol (see below) and ΔH<sub>f,298</sub><sup>0</sup> = -154.18 kcal/mol for the liquid. The latter is derived from the calorimetric study of Schäfer (1) using ΔH<sub>f,298</sub><sup>0</sup> (AgCl, c) = -30.37 kcal/mol (2). Both SiCl<sub>4</sub>(l) and Si(c) were reacted with AgHF(aq) to obtain the overall reaction. Other calorimetric studies (3-7) of SiCl<sub>4</sub>(l) yield values which differ by up to 7 kcal/mol, but each study appears to involve a final state which is not well known or not well defined. Results are summarized below for the overall experimental reactions. Data of Beezer (3) are combined with those of Good (8) for (H<sub>2</sub>)<sub>2</sub>SiF<sub>6</sub>. 4HF, 17.4H<sub>2</sub>O] by neglecting the unknown heat of dilution between the two calorimetric solutions. Data of Wolfe (9) involve a questionable conversion of Na<sub>2</sub>SiO<sub>3</sub> (calorimetric sol) = Na<sub>2</sub>SiO<sub>3</sub>(c). The aqueous hydrolysis reactions (5,7) yield SiO<sub>2</sub>(colloidal soln) which appears to be an ill-defined state judging by the variation in the observed heats. ΔH<sub>f</sub><sup>0</sup> for this colloidal solution is taken as -214.4 kcal/mol (2).

| Source              | Reaction   | ΔH <sub>f,298</sub> <sup>0</sup> Kcal/mol | ΔH <sub>f,298</sub> <sup>0</sup> (SiCl <sub>4</sub> , l) Kcal/mol |
|---------------------|--|---|---|
| 1. Schäfer (1964)   | SiCl <sub>4</sub> (l)+AgCl(c) = Si(c)+4AgCl(c)   | 42.740.4                                  | -164.18   |

| 7. Roth (1928)      | SiCl <sub>4</sub> (l)+2H <sub>2</sub> O(l) = WHCl(aq)+SiO <sub>2</sub> (colloidal soln)  | -70.1                                     | -166.9  |

The bond distance r<sub>g</sub> is from the precise electron diffraction study of Morino (9). Earlier data gave values of 2.00 to 2.02 Å. Vibrational frequencies are from the Raman and infrared spectra of the vapor reported by Morino (10). Infrared data of Smith (11) confirm that ν<sub>3</sub> is about 12 cm<sup>-1</sup> larger in the vapor than in the liquid. The moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 6.8863 × 10<sup>-38</sup> g cm<sup>2</sup>.

**Vaporization Data**

Vapor pressure data ranging from 70° below T<sub>m</sub> (supercooled liquid) to 10° above T<sub>m</sub> are in reasonable agreement as summarized below. The analysis is based on fugacities calculated from vapor pressures by the approximation of Pitzer (12) using T<sub>c</sub> = 506°K (20), P<sub>c</sub> = 37.1 atm (21) and ω = 0.26. At 298.15°K the calculated f/P is 0.982 compared with 0.984 observed by Wood (22). The analysis also presumes a linear variation of the liquid phase Cp based on 39.3 gibbs/mol at 210°K and 34.2 at 300°K. The latter value is from data of Vold (14) since earlier data (77-79°K) of Latimer (15) appear to have a large positive bias below T<sub>m</sub>. The Cp at 210°K assumes Latimer's value to have about 1 percent bias by analogy with his data for CCl<sub>4</sub>(l).

$\Delta Hf_0^\circ = -195.7 \pm 1.0$  kcal/mol  
 $\Delta Hf_{298.15}^\circ = -194.807 \pm 1.0$  kcal/mol  
 $\Delta Hm^\circ = 2.382$  kcal/mol

$S_{298.15}^\circ = 49.93 \pm 0.1$  gibbs/mol  
 $T_m = 249.05^\circ K$

Heat of Formation

The heat of formation,  $\Delta Hf_{298}^\circ$  of TiCl<sub>4</sub>(c) is calculated from the corresponding quantity for TiCl<sub>4</sub>(l) and the values of  $H_{249.05} - H_{298.15}$  for both crystal and liquid.

Heat Capacity and Entropy

The heat capacity of TiCl<sub>4</sub>(c) has been reported by Latimer (1) and by Furukawa (2). The data from the latter investigation are adopted. These data lead to a value of 44.5 eu for  $S_{249.05}^\circ$ . This compares with Latimer's value (1) of 43.8 eu for the same quantity. The heat capacity of the solid is extrapolated to a value of 18R at 600°K, based on the known heat capacities of TiBr<sub>4</sub>(c) and TiI<sub>4</sub>(c). The hypothetical entropy at 298°K is based on the integration of the extrapolated curve and the value at the melting point.

Melting Data

The triple point is reported to be 249.05°K, with a measured heat of fusion of 2.382 kcal/mol, by Furukawa (2). Latimer (1) reported values of 249.0°K and 2.233 kcal/mol for these quantities. The former data are adopted.

Heat of Formation

The heat of formation, ΔHf°<sub>298,15</sub> of TiCl<sub>4</sub>(l) is calculated from that of TiCl<sub>4</sub>(g) and the value of ΔHv°<sub>298,15</sub>. The value of ΔHv°<sub>298</sub> is determined from second and third law analyses of fugacity as follows.

| Source                        | Method       | Range   | No. Pts. | 2nd Law   | 3rd Law | Drift, eu | ΔHf° <sub>298</sub> |

\* two points rejected due to failure of a statistical test

\*\* three points rejected due to failure of a statistical test

\*\*\* selected points from extensive data

Third law analyses of the several vapor pressure sets result in drifts which are proportional to the mean temperatures. Conversion of these data to fugacity eliminates this temperature dependence and the drifts are then scattered randomly about a constant value. This constant value is made to be essentially zero by methods described on the TiCl<sub>4</sub>(g) table. The conversion to fugacity was made using Pitzer's method for normal fluids (5). The calculation was carried out using the value of 45.7 atm for the critical pressure, P<sub>c</sub>, reported by Minzer (6) and estimated values of 643 ± 15°K for the critical temperature, T<sub>c</sub>, and 0.23 ± 0.03 for the acentric constant, ω. Schafer et al. (7) reported a calorimetric determination of ΔHv°<sub>298</sub>. Their value of 9.9 ± 0.2 kcal/mol was used to check the reliability of their equipment, assuming that the vapor pressure data (3) gave a more accurate determination of ΔHv°<sub>298</sub>. The adopted value of ΔHv°<sub>298</sub> is 9.82 ± 0.02 kcal/mol.

Heat Capacity and Entropy

The entropy and heat capacity of TiCl<sub>4</sub>(l) has been measured by Furukawa (8). His reported values are adopted.

Melting Data

See TiCl<sub>4</sub>(c) table for details.

Vaporization Data

The boiling temperature, T<sub>b</sub>, is taken as the temperature at which K<sub>p</sub> = 1 for the reaction TiCl<sub>4</sub>(l) = TiCl<sub>4</sub>(g). The vapor pressure data are discussed above.

Heat of Formation

The heat of formation, ΔH<sub>f298</sub><sup>o</sup>, of TiCl<sub>4</sub>(g) and TiCl<sub>4</sub>(l) has been measured by several investigators. The results of these measurements are as follows.

| Investigators                    | Method       | Reaction  | TiCl <sub>4</sub> (l) | TiCl <sub>4</sub> (g) |
|----------------------------------|--------------|---|-----------------------|-----------------------|
| Johnson et al. (1959) (1)        | Calorimetric | Ti(c)+2Cl <sub>2</sub> (g) = TiCl <sub>4</sub> (g)                              | -192.2                | -182.440.7            |
| Farber and Darnell (1955) (2)    | Equilibrium  | TiO <sub>2</sub> (c)+4HCl(g) = TiCl <sub>4</sub> (g)+2H <sub>2</sub> O(g)       | -192.7                | -182.940.5            |
| Skinner and Ruehrwein (1955) (3) | Calorimetric | Ti(c)+Cl <sub>2</sub> (g) = [TiCl <sub>4</sub> (x-2)Cl <sub>2</sub> ] soln      | -190.3±3.0            | -180.5                |
| Gross et al. (1957) (4)          | Calorimetric | Ti(c)+KCl <sub>2</sub> (s) = [TiCl <sub>4</sub> (x-2)Cl <sub>2</sub> ] soln     | -191.5±0.3            | -181.7                |
| Krievie et al. (1956) (5)        | Calorimetric | Ti(c)+KCl <sub>2</sub> (s) = [TiCl <sub>4</sub> (x-2)Cl <sub>2</sub> ] soln     | -190.0±0.4            | -180.2                |
| Thomsen (1982) (6)               | Calorimetric | TiCl <sub>4</sub> (l)+2H <sub>2</sub> O(l) = 4HCl(0.002 m)+TiO <sub>2</sub> (c) | -194.5                | -184.7                |

The chosen value of ΔH<sub>f298</sub><sup>o</sup> is that reported by Johnson et al. (1). This investigation has the advantage of being independent of the heat of vaporization of chlorins and any heats of solution in deriving the value of the heat of formation.

Heat Capacity and Entropy

The adopted value for the interatomic distance is that reported by Kimura et al. (7). The tetrahedral structure was established by the Raman work of Bhagavantam (8). The vibrational frequencies determined from the infrared and Raman spectra of TiCl<sub>4</sub> by Hawkins and Carpenter (9) are adjusted downward 8 cm<sup>-1</sup> for ν<sub>2</sub> and ν<sub>4</sub> so that the heats of vaporization determined by both second and third law methods are in agreement. See TiCl<sub>4</sub>(l) table for details. The principal moments of inertia are: I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 74.943 × 10<sup>-39</sup> g cm<sup>2</sup>.

ΔHf<sup>o</sup> = Unknown

ΔHf<sup>o</sup><sub>298,15</sub> = -105.9 ± 15 kcal/mol

S<sup>o</sup><sub>298,15</sub> = [47.4] gibbs/mol

Td = [771]°K

Heat of Formation.

The heat of formation, ΔHf<sup>o</sup><sub>298</sub>(WCl<sub>4</sub>, c) = -105.9 kcal/mol, is calculated from ΔHf<sup>o</sup><sub>298</sub> = 58.9 kcal/mol for 3WCl<sub>4</sub>(c) = WCl<sub>2</sub>(c) + 2WCl<sub>5</sub>(g). The value of ΔHf<sup>o</sup><sub>298</sub> is calculated by the third law method from decomposition pressure data in the temperature range from 354°C to 436°C reported by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔHf<sup>o</sup><sub>298</sub> = 73.6 ± 7.9 kcal/mol and the third law drift is -24 ± 12 eu, which would correspond to a total entropy discrepancy of -8 ± 4 eu per mole of WCl<sub>4</sub>. This entropy discrepancy is probably within the combined uncertainty of the data and the estimated entropies for the three species. S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2, 78 (1959), have shown that decomposition pressures are essentially independent of the composition in the solid phase until WCl<sub>4</sub>(c) is almost completely decomposed to WCl<sub>2</sub>(c). This is consistent with the assumption of solid phase activities of unity which we have used in the equilibrium analysis.

Heat Capacity and Entropy.

CP<sub>298</sub> = 6.2 gibbs/g-atom and CP<sub>700</sub> = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 700°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy of WCl<sub>4</sub>(c), S<sup>o</sup><sub>298</sub> = 47.4 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prehite-Hall, Inc., New York, 1952.

Temperature of Decomposition.

Td is calculated as the temperature at which the Gibbs energy change of the reaction 3WCl<sub>4</sub>(c) = WCl<sub>2</sub>(c) + 2WCl<sub>5</sub>(g) approaches zero. We have also derived an approximate value of decomposition temperature, Td = 744°K, by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The difference between the two decomposition temperatures is related to the second law entropy and the adopted entropy.

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl = [109.47]°

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [5.154 × 10<sup>-112</sup>] g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

The heat of formation, ΔHf°<sub>298</sub> (WCl<sub>4</sub>(g)) = -80.3 kcal/mol, is calculated from ΔHf° = 37.7 kcal/mol for WCl<sub>6</sub>(g) → WCl<sub>4</sub>(g) + Cl<sub>2</sub>(g). The value of ΔHf°<sub>298</sub> is calculated by the third law method from the equation for log Kp given by S. A. Shekhtarev and A. V. Suvorov, *Vesnik Leningrad. Univ.*, 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961).

Heat Capacity and Entropy

The molecular configuration is assumed to be tetrahedral similar to those of SiCl<sub>4</sub>, TiCl<sub>4</sub>, VCl<sub>4</sub>, GeCl<sub>4</sub>, ZrCl<sub>4</sub>, SnCl<sub>4</sub>, PbCl<sub>4</sub>. The bond distance is estimated to be the same as that in WCl<sub>6</sub>(g). The three principal moments of inertia are: I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 80.18 × 10<sup>-39</sup> g cm<sup>2</sup>.

All vibrational frequencies are estimated from those of SiCl<sub>4</sub>, TiCl<sub>4</sub>, VCl<sub>4</sub>, GeCl<sub>4</sub>, SnCl<sub>4</sub> and PbCl<sub>4</sub> given by Kazuo Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley & Sons, Inc., New York, 1962.

If it is considered that the metal atoms are effectively ionized, then the W<sup>4+</sup> will have 2 d electrons in a field of chloride ions. The electronic splitting would be roughly the inverse of that in NiCl<sub>2</sub>(g), as given by D. W. DeKock and D. M. Gruen, *J. Chem. Phys.*, 44, 4387 (1966), where Ni has a d<sup>8</sup> configuration. By analogy with the splitting in NiCl<sub>2</sub>, the low lying electronic levels are estimated to be 10000 cm<sup>-1</sup> and 30000 cm<sup>-1</sup>, both triplets.

ΔH<sub>f</sub><sup>o</sup> = -234.42 ± 0.26 kcal/mol  
 ΔH<sub>f</sub><sup>o</sup><sub>298.15</sub> = -234.17 ± 0.26 kcal/mol  
 ΔH<sub>m</sub> = 12 ± 3 kcal/mol  
 ΔH<sub>s</sub><sup>o</sup><sub>298.15</sub> = 26.4 ± 0.3 kcal/mol

Heat of Formation  
 Gal'chenko et al. (1) determined the heat of formation of ZrCl<sub>4</sub>(c) by the direct chlorination of the highly pure Zr metal in a bomb calorimeter. Complete chlorination of the metal was accomplished as indicated by the absence of unreacted metal and of lower chlorides. Their value, ΔH<sub>f</sub><sup>o</sup>(ZrCl<sub>4</sub>, c) = -234.17 ± 0.26 kcal/mol, is adopted in the tabulation.  
 Gross et al. (2) measured calorimetrically ΔH<sub>f</sub><sup>o</sup><sub>298</sub> = -225.69 kcal/mol for Zr(c) + 2Cl<sub>2</sub>(g) + ZrCl<sub>4</sub>(c). Corrections for the difference in heat content between liquid and gaseous chlorine at 25°C and 1 atm led to the value of standard heat of formation, ΔH<sub>f</sub><sup>o</sup>(ZrCl<sub>4</sub>, c) = -234.7 ± 0.4 kcal/mol, which is in good agreement with the value adopted. Siemonsen and Siemonsen (3) also measured the heat of formation by direct chlorination of the metal in an enamelled bomb calorimeter. However, they did not report their detailed experimental procedure, neither the purity of their sample, nor the corrections. The value was given as ΔH<sub>f</sub><sub>298</sub> = -231.9 ± 0.5 kcal/mol.

Heat Capacity and Entropy  
 Todd (4) measured the low temperature heat capacities from 52.5 to 295.7°K, and made an extrapolation to 0°K which yielded an entropy of 8.12 eu at 51°K. We have adopted the measured heat capacities, but have made our own extrapolation to 0°K, based on the ratio of the measured heat capacities of ZrF<sub>4</sub> (5), TiF<sub>4</sub> (6), and TiCl<sub>4</sub> (7) from 6° to 50°K. This extrapolation gives S<sub>50</sub><sup>o</sup> = 6.758 ± 0.7 eu which is used in the table. Coughlin and King (8) measured high temperature enthalpy data from 335.9° to 566.8°K by drop calorimetry. Their data are smoothly joined with Todd's low temperature heat capacities and adopted in the table.

Melting Data  
 The melting point, 710°K, has been observed by Rahlfs and Fischer (9), Palko et al. (10), Denisova et al. (11, 12). Palko et al. derived the heat of melting as 9 ± 2.5 kcal/mol from their vapor pressure data. Denisova et al. (11, 12) determined thermographically the heat of melting as 14 ± 3 kcal/mol and also determined the heat of vaporization at 710°K as 10.4 kcal/mol which combined with the heat of sublimation at 710°K (23.6 kcal/mol) gives the heat of melting as 13.4 kcal/mol. A weighted average 12 ± 3 kcal/mol is adopted for the heat of melting.

Heat of Sublimation  
 Several investigators have measured the vapor pressure of ZrCl<sub>4</sub>(c) by the static method. Second and third law analyses for the vapor pressure data are summarized below:

| Source                 | No. of Points | Temperature Range (°K) | ΔH <sub>s</sub> <sup>o</sup> <sub>298</sub> (kcal/mol) | Drift (eu) |

\* 4 points rejected due to failure of a statistical test.  
 \*\* 1 point rejected due to failure of a statistical test.  
 The third law value, ΔH<sub>s</sub><sup>o</sup><sub>298</sub> = 26.4 kcal/mol, is adopted in the tabulation.  
 The sublimation temperature is obtained from the Gibbs free energy crossover between solid and gas. Rahlfs and Fischer (9) reported the sublimation temperature as 604°K.  
 Since the sublimation temperature is lower than the melting point, the liquid phase is thermodynamically unstable at normal conditions.

Bond Distance: Zr-Cl = 2.32 ± 0.02 Å  
 Bond Angle: Cl-Zr-Cl = 109°28'  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 6.03177 × 10<sup>-112</sup> g cm<sup>6</sup>  
 σ = 12

Heat of Formation

The heat of formation of gaseous ZrCl<sub>4</sub>, ΔH<sub>f</sub><sup>298</sup> = -207.77 ± 0.2 kcal/mol, is calculated from the heat of formation of the crystal and the formation derived from vapor pressure data. (See JANAF ZrCl<sub>4</sub>(c) table dated Dec. 31, 1969). Hildenbrand et al. (1) determined the equilibrium constants by the transpiration method for the reaction:  
 ZrO<sub>2</sub>(c) + 4HCl(g) → ZrCl<sub>4</sub>(g) + 2H<sub>2</sub>O(g)  
 Second and third law analyses for their data are given below:

| Series | No. of Points | Temp. Range (°K) | ΔH <sub>f</sub> <sup>298</sup> (kcal/mol) | Drift (eu) | ΔH <sub>f</sub> <sup>298</sup> (g)* (kcal/mol) |
|--------|---------------|------------------|---|------------|--|
| I      | 10            | 1171-1375        | 28.853                                    | 29.321     | -205.8   |
| II     | 9             | 1169-1374        | 31.397                                    | 30.007     | -205.0   |

\*Derived from third law ΔH<sub>f</sub><sup>298</sup> and ΔH<sub>f</sub><sup>298</sup>(ZrO<sub>2</sub>, c) = -282.3 kcal/mol, ΔH<sub>f</sub><sup>298</sup>(HCl, g) = -22.063 kcal/mol and ΔH<sub>f</sub><sup>298</sup>(H<sub>2</sub>O, g) = -57.798 kcal/mol.

The derived heat of formation is in fair agreement with the value adopted.

Heat Capacity and Entropy

Spiridonov et al. (2) measured the bond distance Zr-Cl = 2.32 ± 0.02 Å in the vapor phase by electron diffraction. The molecule was also found to be a regular tetrahedron. The same bond distance was also reported by Lister and Sutton (3) and Kimura et al. (4). The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 84.4942 × 10<sup>-39</sup> g cm<sup>2</sup>. Williams (5) observed one fundamental vibrational frequency (ν<sub>3</sub> = 421 cm<sup>-1</sup>) in the infrared spectrum of ZrCl<sub>4</sub> vapor, and made reasonable estimates (ν<sub>1</sub> = 368, ν<sub>2</sub> = 102 and ν<sub>4</sub> = 112 cm<sup>-1</sup>) for the three remaining unobserved fundamentals, based on observed overtone and combination bands. Godnev et al. (6) calculated the four fundamental vibrational frequencies (382, 108, 423 and 114 cm<sup>-1</sup>) from data for related group IV halides through the use of a 5-parameter potential function. Büchler et al. (7) also found in the infrared spectrum the vibrational frequency, ν<sub>3</sub> = 423 cm<sup>-1</sup>. Delvaulle and Francois (8) observed the symmetric stretching vibration ν<sub>1</sub> at 383 cm<sup>-1</sup> from the Raman spectrum of ZrCl<sub>4</sub> in CCl<sub>4</sub> and POC<sub>2</sub>, both of which form complexes with ZrCl<sub>4</sub>. Bobovich (9) reported the symmetric stretching vibration ν<sub>1</sub> at 315 cm<sup>-1</sup> from a partially polarized band in his Raman spectrometric studies. Pontrelli (10) observed in the Raman spectrum all four fundamental vibrational frequencies (376, 99, 418 and 110 cm<sup>-1</sup>) which are adopted in the tabulation.

$\Delta H_f^\circ =$  unknown  
 $\Delta H_{298,15}^\circ = -126 \pm 2$  kcal/mol  
 $\Delta H_m^\circ = [4.5 \pm 1.5]$  kcal/mol

**Heat of Formation**  
 The heat of formation is obtained from S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zh. Neorg. Khim. 5, 1650 (1960). The authors derived the  $\Delta H_f^\circ$  (MoCl<sub>5</sub>, c) = -126 kcal/mol by measuring the heat of solution of MoCl<sub>5</sub> in NaOH(aq), which was compared with the heats of solution of MoO<sub>3</sub> and NaCl measured in the same solvent.

**Heat Capacity and Entropy**  
 The heat capacity is estimated by comparison with that of MoCl<sub>5</sub>(c).  $S_{298}^\circ$  is estimated as 57 eu from the vapor pressure data for MoCl<sub>5</sub>(c) → MoCl<sub>5</sub>(g) measured by S. A. Shchukarev, I. V. Vasil'kova and B. N. Sharupin, J. Gen. Chem. USSR (English Transl.) 26, 2335 (1956).

**Melting Data**

Heat of Formation

The heat of formation is obtained from ΔHf<sub>298</sub><sup>o</sup>(c) by adding ΔHm<sup>o</sup> and the difference between H<sub>lm</sub><sup>o</sup> - H<sub>298</sub><sup>o</sup> for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and estimated as 42 gibbs/mol or 7 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from S. A. Shechukarev, G. I. Novikov, A. V. Suvorov and V. K. Mokesimov, Russ. J. Inorg. Chem. (English Transl.) 4, 935 (1959). ΔHm<sup>o</sup> is estimated by comparison with that of WCl<sub>5</sub>(c).

Vaporization Data

Tb is the temperature at which the difference between the Gibbs energy of formation for MoCl<sub>5</sub>(l) and MoCl<sub>5</sub>(g) approaches zero. The difference between ΔHf<sub>537</sub><sup>o</sup>(MoCl<sub>5</sub>, l) and ΔHf<sub>537</sub><sup>o</sup>(MoCl<sub>5</sub>, g) is ΔHv<sup>o</sup>.

Bond Distance: Mo-Cl = 2.27 ± 0.02 Å  
 Bond Angles: Cl-Mo-Cl = 120° Cl-Mo-Cl = 90° Cl-Mo-Cl = 180°  
 • Equatorial • Axial  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 1.02576 × 10<sup>-111</sup> g<sup>3</sup> cm<sup>6</sup>

Heat of Formation  
 The adopted ΔH<sub>f</sub>° = -107.0 kcal/mol is obtained from the vapor pressure data for MoCl<sub>5</sub>(c) = MoCl<sub>5</sub>(g) measured by Shchukarev et al. (1) and Saeiki and Matsuzaki (2).  
 Source Method Reaction Temperature Range, K  
 Shchukarev Transpiration MoCl<sub>5</sub>(c) = MoCl<sub>5</sub>(g) 343 - 435  
 Saeiki Manometric MoCl<sub>5</sub>(c) = MoCl<sub>5</sub>(g) 298 - 474  
 • Calculation based on third law ΔH<sub>f</sub>°<sub>298</sub>.

Heat Capacity and Entropy  
 The vibrational frequencies are estimated by comparison with those of NbCl<sub>5</sub> obtained from infrared and Raman spectra by Carlson (3). Structure, bond distance and bond angle are taken from Evans et al. (4). The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = 105.182 × 10<sup>-39</sup> and I<sub>C</sub> = 91.0024 × 10<sup>-39</sup> g cm<sup>2</sup>. The electronic levels are estimated to be 0, 7000 and 14000 cm<sup>-1</sup>, all doublets, by comparison with those of WCl<sub>5</sub>(g).

Bond angles: Cl<sub>2</sub>(equatorial)-P-Cl(equatorial) = 120° Cl<sub>2</sub>(axial)-P-Cl(equatorial) = 180° Cl<sub>2</sub>(axial)-P-Cl(equatorial) = 90°  
 Bond distance: P-Cl(equatorial) = 2.04 Å P-Cl(axial) = 2.19 Å  
 Product of moment of inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 6.3873 X 10<sup>-11</sup> g.<sup>3</sup> cm.<sup>6</sup>  
 $\sigma = 6$

Heat of Formation.

$\Delta H_f^\circ$  298.15 was calculated from the  $\Delta H_f^\circ$  298.15 for the reaction: PCl<sub>3</sub>(g) + Cl<sub>2</sub>(g) → PCl<sub>5</sub>(g). Third law calculations using experimental equilibrium constants, and free energy functions from JANAF Tables gave a  $\Delta H_f^\circ$  298.15 = -20.884 kcal. mole<sup>-1</sup>. This  $\Delta H_f^\circ$  is the average of (1)  $\Delta H_f^\circ$  298.15 = -20.768 + 0.26 kcal. mole<sup>-1</sup> and (2)  $\Delta H_f^\circ$  298.15 = -21.001 + 0.24 kcal. mole<sup>-1</sup>. The first,  $\Delta H_f^\circ$ (1), was obtained from eleven experimental equilibrium constants measured by C. Holland, Z. Electrochem. 18, 234 (1912) as corrected by W. Nernst, Z. Electrochem. 22, 37 (1916). The second,  $\Delta H_f^\circ$ (2), was obtained from thirteen experimental equilibrium constants measured by W. Fischer and O. Jüßermann, Z. anorg. u. allgem. Chem. 235, 337 (1938).

For the same reaction, PCl<sub>3</sub>(g) + Cl<sub>2</sub>(g) = PCl<sub>5</sub>(g), a third law calculation by D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941) gave a  $\Delta H_f^\circ = -21.320 \pm 0.107$  kcal. mole<sup>-1</sup>. With a new assignment of fundamental frequencies J. K. Wilmarsh and H. J. Bernstein, J. Chem. Phys. 27, 661 (1957) reported a  $\Delta S^\circ = -20.525 \pm 0.16$  kcal. mole<sup>-1</sup>.

The  $\Delta H_f^\circ$  298.15 values corresponding to these heats of reaction are:

| $\Delta H_f^\circ$ 298.15      | Source  |
|--------------------------------|---|
| -82.9 kcal. mole <sup>-1</sup> | D. P. Stevenson and D. M. Yost (loc. cit.).               |
| -82.1 kcal. mole <sup>-1</sup> | J. K. Wilmarsh and H. J. Bernstein (loc. cit.).           |
| -81.9 kcal. mole <sup>-1</sup> | Calculated using free energy functions from JANAF Tables. |

Heat Capacity and Entropy.

The fundamental vibrational frequencies were assigned by Wilmarsh and Bernstein (loc. cit.) from their infrared and Raman spectral data, except the frequency, 176 cm.<sup>-1</sup>, which they calculated. Electron diffraction data of M. Rouault, Ann. Phys. 14, 78 (1940) and Sargent and Schomaker, (quoted in) J. Chem. Phys. 9, 403 (1941), show the free PCl<sub>5</sub> molecule to be a trigonal bipyramid of D<sub>3h</sub> symmetry. The bond lengths were calculated from force constants and Badger's rule by Wilmarsh and Bernstein (loc. cit.). Their values are in good agreement with the electron diffraction bond lengths of M. Rouault, (loc. cit.). The calculated moments of inertia are I<sub>A</sub> = I<sub>B</sub> = 93.2177 X 10<sup>-39</sup> g. cm<sup>2</sup> and I<sub>C</sub> = 73.5053 X 10<sup>-39</sup> g. cm<sup>2</sup>.

TUNGSTEN PENTACHLORIDE (WCl<sub>5</sub>)

(CRYSTAL)

GFW = 361.115

ΔH<sub>f</sub><sup>o</sup> = Unknown

ΔH<sub>f</sub><sup>o</sup><sub>298.15</sub> = -122.6 ± 10 kcal/mol

ΔH<sub>m</sub><sup>o</sup> = 4.917 ± 1 kcal/mol

ΔH<sub>f</sub><sup>o</sup><sub>298.15</sub> = 24.0 kcal/mol

S<sup>o</sup><sub>298.15</sub> = [52.0] gibbs/mol

T<sub>m</sub> = 526°K

Heat of Formation.

The heat of formation, ΔH<sub>f</sub><sup>o</sup><sub>298</sub> (WCl<sub>5</sub>, c) = -122.6 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔH<sub>s</sub><sup>o</sup><sub>298</sub> = 24.0 kcal/mol. The latter is calculated by the third law method from partial pressures of WCl<sub>5</sub>(g) derived from the total pressure data\* of S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4 Ser. Fiz. i Khim., No. 1, 120 (1959). Dimer pressures, calculated from the same authors' dimer-monomer dissociation data, are subtracted from the total pressures in order to obtain the monomer pressures. Analyses of the monomer pressures over both crystal and liquid give similar results and the average values for ΔH<sub>s</sub><sup>o</sup><sub>298</sub> are 20.6 (second law) and 24.0 kcal/mol (third law) with a drift of about 7 eu.

\*Earlier data reported by Shchukarev et al., Zhur. Neorg. Khim. 1, 357 (1956); 2, 2630 (1956), have been revised and are not used here.

Heat Capacity and Entropy.

CP<sub>298</sub> = 6.2 gibbs/g-atom and Cp<sub>526</sub> = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 526°, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, S<sub>298</sub><sup>o</sup> = 52 eu, is estimated by comparison with those of WCl<sub>2</sub> (c), WCl<sub>4</sub> (c) and WCl<sub>6</sub> (c).

Melting Data.

The melting point was determined from vapor pressure data by Shchukarev et al., loc. cit. The heat of melting is the difference at the melting point between the second law heats of vaporization and sublimation derived from total vapor pressure data of Shchukarev et al., loc. cit.

Heat of Sublimation.

See the heat of formation of WCl<sub>5</sub>(g) for details.

TUNGSTEN PENTACHLORIDE (WCl<sub>5</sub>)  
(LIQUID)

S<sup>o</sup><sub>298.15</sub> = [59.393] gibbs/mol  
 ΔH<sup>o</sup><sub>298.15</sub> = -118.4 kcal/mol  
 T<sub>m</sub> = 526°K  
 ΔH<sub>m</sub><sup>o</sup> = 4.917 ± 1 kcal/mol  
 T<sub>b</sub> = 561.4°K  
 ΔH<sub>v</sub><sup>o</sup> = 16.266 kcal/mol

Heat of Formation.  
 The heat of formation, ΔH<sup>o</sup><sub>f,298</sub> (WCl<sub>5</sub>(l)) = -118.4 kcal/mol, is calculated from that of WCl<sub>5</sub>(c) by adding the heat of melting and the difference between H<sup>o</sup><sub>526</sub> - H<sup>o</sup><sub>298</sub> for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom.

The entropy of WCl<sub>5</sub>(l), S<sub>298.15</sub><sup>o</sup> = 59.393 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See WCl<sub>5</sub>(c) table for details.

Vaporization Data.

The boiling point 561.4°K is calculated as the temperature at which the Gibbs energy of formation for both WCl<sub>5</sub>(l) and WCl<sub>5</sub>(g) are equal. The difference in the heats of formation of WCl<sub>5</sub>(l) and WCl<sub>5</sub>(g) at the boiling point is the heat of vaporization. S. A. Shchukarev, G. I. Novikov and N. V. Andreeva<sup>1</sup> revised their previous data<sup>2</sup> and derived the boiling point as 561.2°K from their vapor pressure measurements.

 $\sigma = [6]$

Heat of Formation

The heat of formation,  $\Delta H^{\circ}_{298} (\text{WCl}_5, \text{g}) = -98.6 \text{ kcal/mol}$ , is calculated from  $\Delta H^{\circ}_{298} = 19.4 \text{ kcal/mol}$  for  $\text{WCl}_5(\text{g}) \rightarrow \text{WCl}_4(\text{g}) + 1/2 \text{ Cl}_2(\text{g})$ . The value of  $\Delta H^{\circ}_{298}$  is calculated by the third law method from the equation for  $\log K_p$  given by S. A. Shchukarev and A. V. Suvorov, *Vestnik Leningrad. Univ.* 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). The second law  $\Delta H^{\circ}_{298}$  is 24.6 kcal/mol and the third law drift is -8.5 eu.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of MoCl<sub>5</sub> determined by electron diffraction by R. V. G. Ewens and M. W. Lister, *Trans. Faraday Soc.* 34, 1358 (1938). The bond distance is estimated to be the same as that in WCl<sub>6</sub>(g). The three principal moments of inertia are  $I_A = I_B = 105.23 \times 10^{-39}$  and  $I_C = 90.20 \times 10^{-39} \text{ g cm}^2$ .

All vibrational frequencies are estimated from those of SbCl<sub>5</sub>, PCl<sub>5</sub>, NbCl<sub>5</sub> and TaCl<sub>5</sub> obtained from infrared and Raman spectra by G. L. Carlson, *Spectrochim. Acta* 19, 1291 (1963).

If it is considered that the metal atoms are effectively ionized, then the  $W^{5+}$  will have a single d electron in a field of chloride ions. The electronic splitting would be roughly the inverse of that in CuCl<sub>2</sub>(g) as given by C. W. DeKock and D. M. Gruen, *J. Chem. Phys.* 44, 4397 (1966), where Cu has a d<sup>9</sup> configuration. By analogy with the splitting in CuCl<sub>2</sub>, the low lying electronic levels are estimated to be 7000 cm<sup>-1</sup> and 14000 cm<sup>-1</sup>, both doublets.

Heat of Formation.

The vaporization of  $\text{FeCl}_3(\text{c})$  is complex. It involves three possible chemical reactions, i.e. (1)  $2\text{FeCl}_3(\text{c}) = \text{Fe}_2\text{Cl}_6(\text{g})$ ; (2)  $\text{FeCl}_3(\text{c}) = \text{FeCl}_2(\text{c}) + \text{Cl}_2(\text{g})$ . Although these equilibria have been studied previously by many investigators, a review of their reported data reveals inconsistencies and errors. At room temperature the main vapor species present above  $\text{FeCl}_3(\text{c})$  is  $\text{Fe}_2\text{Cl}_6(\text{g})$ , a dimer of  $\text{FeCl}_3(\text{g})$ . As temperature increases, the dimer gradually decomposes into monomers ( $\text{FeCl}_3(\text{g})$ ). Simultaneously, part of  $\text{FeCl}_3(\text{c})$  also decomposes into  $\text{FeCl}_2(\text{c})$  and  $\text{Cl}_2(\text{g})$ . Therefore in order to obtain the partial pressure of  $\text{Fe}_2\text{Cl}_6(\text{g})$ , the partial pressures of other vapor species, e.g.  $\text{Cl}_2(\text{g})$  and  $\text{FeCl}_3(\text{g})$ , must be known and deducted from the observed total pressures. However, only few investigators made such corrections. The total pressures above  $\text{FeCl}_3(\text{c})$ , at 500-600°K., have been determined by Meier<sup>1</sup> and Johnston et al.<sup>2</sup>, respectively. The partial pressures of  $\text{Fe}_2\text{Cl}_6(\text{g})$  were evaluated by the subtraction of the calculated equilibrium pressures of  $\text{Cl}_2(\text{g})$ , obtained from reaction (3), from the reported total pressures. The partial pressures of  $\text{FeCl}_3(\text{g})$  were found to be insignificant at these temperatures. Using the partial pressures obtained for  $\text{Fe}_2\text{Cl}_6(\text{g})$ , the enthalpy change ( $\Delta H_f^\circ$ , 298.15) of reaction (1) was derived by both the second and third law methods. Then the value of  $\Delta H_f^\circ$ , 298.15 ( $\text{Fe}_2\text{Cl}_6/\text{g}$ ) was calculated. The results are given in the table.

Wilson and Gregory<sup>3</sup> have investigated the vaporization and thermal decomposition equilibria of  $\text{FeCl}_3(\text{c})$  by gas saturation flow and diaphragm gage techniques. Using the partial pressures for  $\text{Fe}_2\text{Cl}_6(\text{g})$ , calculated from an equation, the values of  $\Delta H_f^\circ$ , 298.15 and  $\Delta H_f^\circ$ , 298.15 were also evaluated and listed in the table. Based on the total pressures measured by Stirrermann<sup>4</sup> and Sano<sup>5</sup>, the equations for the pressures of  $\text{Fe}_2\text{Cl}_6(\text{g})$  and  $\text{Cl}_2(\text{g})$  in equilibrium with  $\text{FeCl}_3(\text{c})$  and  $\text{FeCl}_2(\text{c})$  as a function of temperature were reported by Wilson and Gregory. The corresponding values of  $\Delta H_f^\circ$ , 298.15 and  $\Delta H_f^\circ$ , 298.15 were hence calculated. A brief summary and discussion of results of some other previous investigators were also given in the same report.

| Investigator                    | Temperature, °K. |                  | $\Delta H_f^\circ$ , 298.15* kcal. mole $^{-1}$ |
|---------------------------------|------------------|------------------|---|
|                                 | Second Law Value | Third Law Value  |   |
| Meier <sup>1</sup>              | 483.6-591.5      | 32.18 $\pm$ 0.40 | 34.67   |
| Johnston, et al. <sup>2</sup>   | 505.2-562.2      | 34.61 $\pm$ 0.49 | 34.50   |
| Wilson and Gregory <sup>3</sup> | 463.4-577.2      | 34.46            | 34.45   |
| Stirrermann <sup>4</sup>        | 526.2-574.2      | 35.04            | 34.49   |
| Sano <sup>5</sup>               | 513.2-569.2      | 30.67            | 34.76   |

\*Based on the third law values for  $\Delta H_f^\circ$ , 298.15.

4 E. Stirrermann, Neues Jahrb. Mineral., **52a**, 334 (1925).

5 K. Sano, J. Chem. Soc. Japan, **59**, 1073 (1936).

The value of  $\Delta H_f^\circ$ , 298.15 for  $\text{Fe}_2\text{Cl}_6(\text{g})$  is selected as  $-156.4 \pm 2.0$  kcal. mole $^{-1}$ .

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from E. Z. Zsornin, N. O. Rembid and P. A. Akhikhin, Zh. Strukt. Khim., **4**, 910 (1963). The vibrational frequencies were estimated by comparison with those for  $\text{Al}_2\text{Cl}_6(\text{g})$  such that the values of  $\Delta H_f^\circ$  derived from the equilibrium data by the second and third law methods are in reasonable agreement. The three principal moments of inertia are  $I_A = 2.79395 \times 10^{-37}$ ,  $I_B = 1.16349 \times 10^{-37}$  and  $I_C = 2.26385 \times 10^{-37}$  g. cm. $^2$ .

June 30, 1965

GFW = 308.658

(CRYSTAL)

MOLYBDENUM HEXACHLORIDE (MoCl<sub>6</sub>)

Molybdenum Hexachloride (MoCl<sub>6</sub>)

(Crystal) GFW = 308.658

ΔHf<sub>0</sub><sup>o</sup> = unknown

ΔHf<sub>298.15</sub><sup>o</sup> = [-125 ± 10] kcal/mol

S<sub>298.15</sub><sup>o</sup> = [61.0 ± 4.0] gibbs/mol

Ts = [527]°K

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. 10, 576-8 (1965), assumed that the equilibrium MoCl<sub>6</sub>(c) = MoCl<sub>5</sub>(g) + 1/2 Cl<sub>2</sub>(g) exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, ΔH<sub>T</sub><sup>o</sup> = 4 kcal/mol and ΔS<sub>T</sub><sup>o</sup> = 8 eu, of the equilibrium MoCl<sub>6</sub>(c) = MoCl<sub>5</sub>(c) + 1/2 Cl<sub>2</sub>(g), from which they obtained the ΔHf<sub>298</sub><sup>o</sup>(MoCl<sub>6</sub>, c) = -125 kcal/mol.

Heat Capacity and Entropy

The adopted heat capacity is the same as that of WCl<sub>6</sub>(g, c), since the heat capacities of W and Mo are almost the same. The entropy is estimated from that of MoCl<sub>5</sub>(c) by the addition of 4 eu due to one extra chlorine atom in the molecule.

Vaporization Data

The sublimation point is calculated from the free energy crossover between crystal and gas. However, it should be noted that MoCl<sub>6</sub>(c) is unstable with respect to MoCl<sub>5</sub>(c) at all temperatures and thus sublimation could occur only under an atmosphere of Cl<sub>2</sub>.

Bond Distance: Mo-Cl = [2.26] Å

Bond Angle: Cl-Mo-Cl = [90°]

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [1.7395 × 10<sup>-111</sup>] g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. **10**, 576-82 (1965), assumed that the equilibrium MoCl<sub>6</sub>(g) = MoCl<sub>5</sub>(g) + 1/2 Cl<sub>2</sub>(g) exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, ΔH<sub>f</sub>° = 2.5 kcal/mol and ΔS<sub>f</sub>° = 10 eu of the equilibrium MoCl<sub>6</sub>(g) = MoCl<sub>5</sub>(g) + 1/2 Cl<sub>2</sub>(g), from which they obtained the ΔH<sub>f</sub>°(MoCl<sub>6</sub>, g) = -105 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of MoF<sub>6</sub> and WF<sub>6</sub>, given by K. Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley and Sons, Inc., New York - London, 1963, and WCl<sub>6</sub> given by J. C. Evans and G. Y. S. Lo, J. Mol. Spectrosc. **25**, 147 (1968). Structure, bond distance and bond angle are estimated to be the same as those of WCl<sub>6</sub>. The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 120.2664 × 10<sup>-39</sup> g cm<sup>2</sup>.

$\Delta H^\circ_0$  = Unknown  
 $\Delta H^\circ_{298,15} = -141.9 \pm 6$  kcal/mol  
 $\Delta H^\circ (\alpha_1 \rightarrow \alpha_2) = [1.0]$  kcal/mol  
 $\Delta H^\circ (\alpha_2 \rightarrow \beta) = 3.77$  kcal/mol  
 $\Delta H^\circ_{298,15} = 23.9$  kcal/mol

$S^\circ_{298,15} = [57.0]$  gibbs/mol  
 $Tt (\alpha_1 \rightarrow \alpha_2) = 450 \pm 10^\circ K$   
 $Tt (\alpha_2 \rightarrow \beta) = 503 \pm 3^\circ K$

Heat of Formation.

S. A. Shchukarev, I. V. Vasilkova and G. I. Novikov, Zh. Neorg. Khim., 3, 2642 (1968), have measured calorimetrically the heat of solution of WCl<sub>6</sub>(c) and also of H<sub>2</sub>WO<sub>4</sub>(c) in a 10% solution of NaOH as -188.0 ± 0.3 and -13.6 ± 0.11 kcal/mol, respectively. Based on these data and a heat of dilution value for Na<sub>2</sub>WO<sub>4</sub> which is essentially zero, we obtain  $\Delta H^\circ_{298} = -174.4 \pm 0.3$  kcal/mol for WCl<sub>6</sub>(c) + 6NaOH(16.3H<sub>2</sub>O) → H<sub>2</sub>WO<sub>4</sub>(c) + 2H<sub>2</sub>O(l). This reaction gives  $\Delta H^\circ_{298}(WCl_6, c) = -141.9 \pm 6$  kcal/mol, using a revised  $\Delta H^\circ_{298}(H_2WO_4, c) = -270.5$  kcal/mol, and other auxiliary data from JANAP Tables and from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBSUS-NBS2, Natl. Bur. Std., Washington, D.C., April, 1965. The authors have suggested a possible uncertainty of the order of 5 kcal/mol due to the slowness of the dissolution of WCl<sub>6</sub>(c).

Heat Capacity and Entropy.

J. R. Welty<sup>1</sup> has measured the enthalpy changes for WCl<sub>6</sub>( $\alpha_1, c$ ) in the temperature range from 406° to 502.4°K by drop calorimetry. Few points were measured in the region of the  $\alpha_1 \rightarrow \alpha_2$  transition and no attempt was made to investigate the phase present at the conclusion of the drop. Thus, these data appear to be inadequate to define the heat capacities of the  $\alpha_1$  and  $\alpha_2$  phases. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy,  $S^\circ_{298} = 57.0$  eu, is calculated from that of the gas using  $\Delta S^\circ_{298} = 43.155$  eu from the vaporization and sublimation data given in the WCl<sub>6</sub>(g) table (December 31, 1966).

Transition Data.

Transition temperatures and heats of transition have been reported by the following investigators, and their results are summarized as follows:

| Investigator                   | Method                   | $\alpha_1 \rightarrow \alpha_2$ transition |                             | $\alpha_2 \rightarrow \beta$ transition |                             |

| Dobrotin <sup>5</sup>          | Vapor pressure           | -  | -                           | 504                                     | 3.4                         |
|                                | Approximate calorimetric | -  | -                           | 483 ± 10                                | 5.5                         |

The adopted  $\Delta H^\circ_{450} (\alpha_1 \rightarrow \alpha_2)$  and  $\Delta H^\circ_{503} (\alpha_2 \rightarrow \beta)$  are calculated as 1.0 and 3.77 kcal/mol, respectively, based on the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to  $\alpha_1$  phase as the final state, although no experimental evidence for this is given.

Melting Data.

See WCl<sub>6</sub> ( $\beta, c$ ) table (December 31, 1966).

Heat of Sublimation.

See WCl<sub>6</sub>(g) table (December 31, 1966) for detailed information about sublimation data.

The heat of formation,  $\Delta H_f^\circ$  ( $WCl_6, \beta, c$ ) = -136.921 kcal/mol, is calculated from that of  $WCl_6(g, c)$  by adding the heat of  $\alpha_2 \rightarrow \beta$  transition and the difference between  $H_{503}^\circ - H_{298.15}^\circ$  for  $WCl_6(g, c)$  and  $WCl_6(\beta, c)$ .

The entropy of  $WCl_6(\beta, c)$ ,  $S_{298.15}^\circ$  = 67.066 eu, is calculated in a manner analogous to that of the heat of formation.

Heat Capacity and Entropy.

J. R. Welty<sup>1</sup> has measured the enthalpy changes for  $WCl_6(\beta, c)$  in the temperature range from 508° to 553°K by drop calorimetry. Because of the short temperature range, poor distribution of points, and lack of identification of the phase present at the conclusion of each drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are consistent with the enthalpy data within their probable uncertainty.

The entropy of  $WCl_6(\beta, c)$ ,  $S_{298.15}^\circ$  = 67.066 eu, is calculated in a manner analogous to that of the heat of formation.

Transition Data.

See  $WCl_6(g, c)$  table (Dec. 31, 1966).

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized as follows:

| Investigator                   | Method                   | Melting Point (°K) | $\Delta H_m^\circ$ (kcal/mol) |
|--------------------------------|--------------------------|--------------------|-------------------------------|
| Ketelaar <sup>2</sup> et al.   | Vapor pressure           | 557                | 2.3                           |
| Stevenson <sup>3</sup>         | Cooling curve            | 555                | -                             |
| Welty <sup>1</sup>             | Vapor pressure           | 555                | 1.5                           |
| Shchukarev <sup>4</sup> et al. | Drop calorimetric        | 556                | 1.6                           |
| Dobrotin <sup>5</sup> et al.   | Vapor pressure           | 564                | 2.0                           |
|                                | Approximate calorimetric | 545 ± 12           | 4.2                           |

The adopted heat of melting,  $\Delta H_{555}^\circ$  = 1.6 kcal/mol, is calculated from the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to  $\alpha_1$  phase as the final state, although no experimental evidence for this is available.

Heat of Sublimation.

$\Delta H_{298.15}^\circ$  is calculated as the difference between  $\Delta H_{298.15}^\circ$  for  $WCl_6(\beta, c)$  and  $WCl_6(g)$ .

TUNGSTEN HEXACHLORIDE (WCl<sub>6</sub>) (LIQUID) OFW = 396.568

S<sub>298.15</sub><sup>o</sup> = [68.085] gibbs/mol  
 ΔH<sub>298.15</sub><sup>o</sup> = -136.091 kcal/mol  
 ΔH<sub>m</sub><sup>o</sup> = 1.60 kcal/mol  
 ΔH<sub>v</sub><sup>o</sup> = 14.319 kcal/mol

T<sub>m</sub> = 555 ± 2°K  
 T<sub>b</sub> = 613.6°K

Heat of Formation.

The heat of formation, ΔH<sub>298.15</sub><sup>o</sup>(WCl<sub>6</sub>(l)) = -136.091 kcal/mol, is calculated from that of WCl<sub>6</sub>(β,c) by adding the heat of melting and the difference between H<sub>655</sub><sup>o</sup> = H<sub>298.15</sub><sup>o</sup> for WCl<sub>6</sub>(β,c) and WCl<sub>6</sub>(l).

Heat Capacity and Entropy.

J. R. Wely, Ph.D. Thesis, Oregon State University (1962), has measured the enthalpy changes for WCl<sub>6</sub>(l) in the temperature range from 560° to 603°K by drop calorimetry. Since the temperature range was very short and no attempt was made to investigate the phase present at the conclusion of the drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy of WCl<sub>6</sub>(l), S<sub>298.15</sub><sup>o</sup> = 68.085 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See WCl<sub>6</sub>(β,c) table dated Dec. 31, 1966.

Vaporization Data.

The boiling point, 613.6°K, is calculated as the temperature at which the Gibbs energies of formation for both WCl<sub>6</sub>(l) and WCl<sub>6</sub>(g) are equal. The difference in the heats of formation of WCl<sub>6</sub>(l) and WCl<sub>6</sub>(g) at the boiling point is the heat of vaporization.

J. A. A. Ketelaar, G. M. Oosterhout and P. B. Braun, Rec. Trav. Chim. 62, 597 (1943), have determined the boiling point and the heat of vaporization as 603.7°K and 15.24 kcal/mol, respectively, from vapor pressure measurements. S. A. Shchukarev and A. V. Suvorov revised their previous data<sup>2,3</sup> and gave the boiling point and the heat of vaporization as 616.2°K and 14.7 kcal/mol, respectively, from their vapor pressure measurements.

See WCl<sub>6</sub>(g) table, dated Dec. 31, 1966, for detailed information about vaporization data.

Heats of Formation

The heat of formation of WCl<sub>6</sub>(g),  $\Delta H_f^{\circ} = -118.0 \text{ kcal/mol}$ , is calculated from that of the crystal plus the adopted heat of sublimation,  $\Delta H_{sub}^{\circ} = 23.9 \text{ kcal/mol}$  for WCl<sub>6</sub>(s,c) → WCl<sub>6</sub>(g). The latter was obtained from third law analysis of the vapor pressure data 1,2,3,4, using all JANAF functions (Dec. 31, 1966).

|                                   |               | 298 - 423       | 4             | 16.1 ± 4.1                          | 21.02   | 10.8 ± 12.8 | -120.88   |

A. A. Vernon<sup>4</sup> has also determined the equilibrium constants in the temperature range from 1350° to 1600°K for the decomposition of WCl<sub>6</sub>(g) to W(c) and Cl<sub>2</sub>(g) by reaction of the sample with a hot tungsten filament in a vacuum bulb. Using the reported equilibrium constants, the heat of formation of WCl<sub>6</sub>(g) at 298°K is calculated by the second and third law method as -131.8 ± 2.9 kcal/mol and -135.2 kcal/mol, respectively. The third law drift is 2.4 ± 1.9 au. Unfortunately, the reported equilibrium constants may be seriously in error, since atomic chlorine is the main species at the pressure and temperature studied.

\* Enthalpy changes are converted to  $\Delta H_{298}^{\circ}$  for WCl<sub>6</sub>(α, c) → WCl<sub>6</sub>(g).

\*\* Vapor pressure equations for the crystal (α,β) and the liquid to gas are given.

\*\*\* The third law  $\Delta H_{298}^{\circ}$  is used in calculation.

Heat Capacity and Entropy

R. O. Evans and K. W. Lister, Trans. Faraday Soc. 34, 1358 (1938), have determined the octahedral structure for WCl<sub>6</sub>(g) by electron diffraction and found the bond length to be 2.26 Å.

The vibrational frequency of  $\nu_3$ , 375 cm<sup>-1</sup>, was observed in the infrared spectra by J. C. Evans, The Dow Chemical Company, private communication, Dec. 1, 1966. The values of  $\nu_1$ ,  $\nu_2$  and  $\nu_5$  (360, 340 and 180 cm<sup>-1</sup>, respectively) are estimated, based on those of the aqueous ion PCl<sub>6</sub><sup>2-</sup> reported by L. A. Woodward and J. A. Creighton, Spectrochim. Acta 17, 594 (1961). The values of  $\nu_4$  and  $\nu_6$  (140 and 120 cm<sup>-1</sup>, respectively) are estimated by comparison with those of WF<sub>6</sub>(g).

The three principal moments of inertia are  $I_A = I_B = I_C = 120.2684 \times 10^{-39} \text{ g cm}^2$ .

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [8.638] x 10<sup>-110</sup> g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

The heat of formation, ΔHf°<sub>298</sub>(W<sub>2</sub>Cl<sub>10</sub>(g)) = -207.6 kcal/mol, is calculated from ΔHf°<sub>298</sub> = 10.4 kcal/mol for W<sub>2</sub>Cl<sub>10</sub>(g) = 2 WCl<sub>5</sub>(g), using all JANAF functions (Dec. 31, 1966). The value of ΔHf°<sub>298</sub> is obtained from third law analysis of the partial pressures of WCl<sub>5</sub>(g) and W<sub>2</sub>Cl<sub>10</sub>(g) derived from PIT data determined by S. A. Shchukarev, G. I. Novikov and N. V. Andreev, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔHf°<sub>298</sub> is 10.4 ± 0.3 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is estimated by analogy with that of Mo<sub>2</sub>Cl<sub>10</sub> reported by D. Z. Sands and P. Zaikin, Acta Cryst. 12, 723 (1959). Chlorine atoms are placed octahedrally around two tungsten atoms and these two octahedra share one common edge with six chlorine and two tungsten atoms in a plane. The bond length is estimated to be the same as that in WCl<sub>6</sub>(g). The three principal moments of inertia are I<sub>A</sub> = 210.5 x 10<sup>-30</sup>, I<sub>B</sub> = 576.8 x 10<sup>-39</sup> and I<sub>C</sub> = 566.8 x 10<sup>-39</sup> g cm<sup>2</sup>.

All vibrational frequencies are estimated, based on those of WCl<sub>5</sub>(AlCl<sub>3</sub>)<sub>2</sub> and Cs<sub>2</sub>Cl<sub>2</sub>, such that S°<sub>298</sub>(W<sub>2</sub>Cl<sub>10</sub>(g)) = 216.65 eu. This entropy is derived from ΔS°<sub>298</sub> = 19.92 ± 0.5 eu for W<sub>2</sub>Cl<sub>10</sub>(g) = 2WCl<sub>5</sub>(g), obtained by second law analysis of the data of Shchukarev et al., loc. cit. The frequencies are not in point group order.

COBALT (Co)

(CRYSTAL)

GFW = 58.9332

Co

ΔHf° = 0 kcal/mol

ΔHf°<sub>298.15</sub> = 0 kcal/mol

ΔHt° = 0.108 kcal/mol

ΔHm° = 3.87 ± 0.06 kcal/mol

ΔHs°<sub>298.15</sub> = 101.5 ± 0.5 kcal/mol

S°<sub>298.15</sub> = 7.18 ± 0.1 gibbs/mol

Tt = [700°] K

Tm = 1768°K

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity of Co(c) is adopted from Hultgren et al. (1). Their selected values are based on the data from nineteen investigations. The entropy values are based on S°<sub>1</sub> = 0.0011 eu. The heat capacity has a maximum value of 13.14 gibbs/mol at the Curie point (1394°K).

Transition Data

The exact nature of the α(hcp)-β(fcc) transition is yet to be clearly elucidated. Three investigations (2,3,4) indicate that it is not a simple time- and temperature-dependent phenomenon. Crystalline cobalt exists as pure β-phase above 700°K whereas mixtures of alpha and beta cobalt commonly coexist in varying proportions below this temperature. The values of Tt° and ΔHt° are those selected by Hultgren et al. (1).

Melting Data

The temperature and heat of melting are those selected by Hultgren et al. (1).

Heat of Sublimation

The heat of sublimation is calculated from the data of Edwards et al. (5). See Co(g) table for details.

S<sub>298.15</sub> = 9.79 gibbs/mol  
 ΔHf<sub>298.15</sub> = 4.303 ± 0.1 kcal/mol

ΔHm° = 3.87 ± 0.06 kcal/mol  
 ΔHv° = 89.219 kcal/mol

T<sub>b</sub> = 3170.29°K

Heat of Formation  
 The heat of formation (ΔHf<sub>298</sub>) of Co(l) is obtained from that of the crystal by adding ΔHm° and the differences between H<sub>1768</sub>-H<sub>298</sub> for crystal and liquid.

Heat Capacity and Entropy  
 The heat capacity of Co(l) selected by Hultgren et al. (1) is used at temperatures above 1768°K. The heat capacities at temperatures below the melting point are estimated by assuming a glass transition at 1100°K and heat capacities similar to those of the crystal below 1100°K.

Melting Data  
 See Co(c) table for details.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K so that the free energy functions calculated by integration of the crystal liquid data and by statistical methods from the gas phase are equal at the boiling point.

Heat of Formation

The heat of formation is the heat of sublimation at 298°K. The adopted value is that reported by Edwards et al. (1). Their value is used because their vapor pressure measurements for Fe (1) and Cu (2) have proved to be very reliable. The results obtained by Vintakin and Tomash (3) are rejected because their vapor pressure data for Fe (4) resulted in a value for the heat of sublimation which was higher than the accepted value (see JANAF Fe(7) Table for details). The remaining vapor pressure data are rejected either because the drift was too large or because there were not enough points. Second and third law analyses of the available vapor pressure data gave the following results, with reaction A corresponding to Co(c) = Co(g) and reaction B corresponding to Co(l) = Co(g).

| Source         | Reaction | Method      | No. Pts. | Range, T,°K | ΔHr° <sub>298.15</sub> | ΔHf° <sub>298</sub> |

\*\*Calculation based on third law ΔHr°<sub>298</sub>.

Heat Capacity and Entropy

The electronic levels are taken from Moore (10). Levels above 25,000 cm<sup>-1</sup> are averaged. Unobserved levels below 20,000 cm<sup>-1</sup> are estimated.

Heat of Formation

The heat of formation,  $\Delta H_f^{\circ}$ , is calculated from the equation  $\text{Co}(g) = e^- + \text{Co}^+(g)$  with the JANAF auxiliary value for  $\text{Co}(g)$ ; using an ionization potential of  $63438 \text{ cm}^{-1}$  (191.377 kcal/mol) obtained from C. E. Moore, "Atomic Energy Levels," Vol. II, U. S. Natl. Bur. Std. Circ. 467, 1949. The value of  $H_0^{\circ} - H_{298}^{\circ}$  is  $-1.504$  kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, loc. cit. Levels above  $30,000 \text{ cm}^{-1}$  are averaged.

| T, °K | $C_p^{\circ}$ | $S^{\circ}$ | $-(C^{\circ} - H^{\circ}_{298})/T$ | $H^{\circ} - H^{\circ}_{298}$ | $\Delta H_f^{\circ}$ | $\Delta G_f^{\circ}$ | Log Kp   |

June 30, 1970

ΔHf° = -160.2 ± 1.0 kcal/mol

ΔHf°<sub>298.15</sub> = -160.5 ± 1.0 kcal/mol

ΔHm° = 14.058 ± 3.0 kcal/mol

ΔHs° = 75.3 ± 3.0 kcal/mol

S°<sub>298.15</sub> = 19.60 ± 0.10 gibbs/mol

Tm = 1400°K

Heat of Formation

Heus and Egan (1) measured the electromotive force of a solid state galvanic cell which involved the reactions  
 $Al(c) + 3/2 CoF_2(c) + AlF_3(c) + 3/2 Co(c)$   
 $Mg(c) + CoF_2(c) + MgF_2(c) + Co(c)$   
 E<sub>973</sub> = 1.611 volts  
 E<sub>973</sub> = 2.231 volts

Combining these results with auxiliary thermodynamic data (2) for the reactants and products, we derive ΔHf°(CoF<sub>2</sub>, c) = -160.2 and -159.5 kcal/mol.

Several equilibrium studies (3, 4, 5) involving CoF<sub>2</sub>(c) have been reported in the literature. Second and third law analyses of these equilibrium data are summarized below, auxiliary data for CoO(c) and CoCl<sub>2</sub>(c) are from (6).

| Reference | Chemical Reaction   | Temp. Range<br>°K | Points | ΔHf° <sub>298</sub> -kcal/mol | 2nd law<br>gibbs/mol | 3rd law<br>gibbs/mol | Drift<br>kcal/mol |
|-----------|---|-------------------|--------|-------------------------------|----------------------|----------------------|-------------------|
| (3)       | CoF <sub>2</sub> (c) + 2HCl(g) ⇌ CoCl <sub>2</sub> (c) + 2HF(g) | 588-805           | 3      | 4.1                           | 1.75±0.4             | -1.74±0.1            | -162.6±2.0        |
| (4)       | CoF <sub>2</sub> (c) + H <sub>2</sub> (g) ⇌ Co(c) + 2HF(g)      | 673-873           | 3      | 35.2                          | 31.5±1.0             | -4.2±3.5             | -161.8±2.0        |
| (5)       | CoF <sub>2</sub> (c) + H <sub>2</sub> O(g) ⇌ CoO(c) + 2HF(g)    | 773-1023          | 5      | 30.2                          | 31.1±0.2             | 0.3±0.3              | -160.4±2.1.0      |

\*Third law values except for the first reaction.

We note that Heus and Egan (1), in the same paper, measured ΔHf°<sub>298</sub>(AlF<sub>3</sub>, c) = -360.2 kcal in excellent agreement with the JANAF value (2). Domange (5) also measured similar equilibria for MgF<sub>2</sub> and CaF<sub>2</sub>, which were very consistent with the JANAF heats of formation (2). Jellinek and Rudat (4) reported similar equilibria for PbF<sub>2</sub>(c), which show excellent consistency with the JANAF heat of formation (2). Thus, it is apparent that these three sets are probably quite reliable, and we adopt ΔHf°<sub>298.15</sub>(CoF<sub>2</sub>, c) = -160.5 ± 1 kcal/mol.

Heat Capacity and Entropy

Catalano and Stout (7) measured low temperature heat capacities in the temperature range 10° to 300°K. Heat capacity data above 300°K are calculated from the high temperature (468-1400°K) enthalpy data of Binford et al. (8). Both sets of data were smoothed by computer and joined at 298.15°K.

The value of S°<sub>298.15</sub> is obtained from the low temperature heat capacity data of Catalano and Stout (7) and is based on S°<sub>10</sub> = 0.013 gibbs/mol.

Melting Data

Tm = 1400°K is from the high temperature enthalpy studies of Binford et al. (8). ΔHm is calculated from their enthalpy data. Premelting of the sample is assumed to be responsible for the rapid rise in the enthalpy near the melting point. This enthalpy is included in ΔHm.

Heat of Sublimation

Kana'an et al. (9) made sublimation studies of CoF<sub>2</sub> using Knudsen and Langmuir techniques over the temperature range 972°-1241°K. Second and third law analyses of these sublimation pressures are summarized below.

| Method   | Temp. Range<br>°K | No. of Points | ΔHs° <sub>298</sub> -kcal/mol | Drift<br>gibbs/mol |
|----------|-------------------|---------------|-------------------------------|--------------------|
| Knudsen  | 1058-1242         | 17            | 75.0                          | 0.1±0.2            |
| Langmuir | 972-1032          | 6             | 72.8                          | 75.5±0.2           |

The selected value is ΔHs°<sub>298</sub> = 75.3 ± 3.0 kcal/mol.

COBALT DIFLUORIDE (CoF<sub>2</sub>) (LIQUID) GFW = 96.9300

S<sub>298.15</sub> = 20.61 ± 2.5 gibbs/mol  
 ΔH<sub>f,298.15</sub> = -152.412 ± 4.0 kcal/mol  
 ΔH<sub>m</sub><sup>\*</sup> = 14.058 ± 3.0 kcal/mol  
 T<sub>m</sub> = 1400°K  
 T<sub>b</sub> = [2012]°K  
 ΔH<sub>v</sub><sup>\*</sup> = [48.0] kcal/mol

**Heat of Formation**  
 ΔH<sub>f</sub><sup>\*</sup>(l) is calculated from ΔH<sub>f</sub><sup>\*</sup>(c) by adding the heat of melting and the difference in (H<sub>1400</sub>-H<sub>298</sub>) between the crystal and liquid.

**Heat Capacity and Entropy**  
 The heat capacity of liquid CoF<sub>2</sub> is estimated by comparison with those for FeCl<sub>2</sub>(l), MgF<sub>2</sub>(l), and PbF<sub>2</sub>(l) and is assumed constant in the temperature range 298°-3000°K. Binford et al. (1) reported C<sub>p</sub> = 30.3 gibbs/mol for liquid CoF<sub>2</sub> at 1444°K. This value is based on only two enthalpy points near the melting point and appears high in comparison with heat capacities for other liquid metal dihalides. Therefore, the value is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

**Melting Data**  
 See the CoF<sub>2</sub>(c) table for details.

**Vaporization Data**  
 T<sub>b</sub> is the temperature at which the Gibbs energy change for the process CoF<sub>2</sub>(l) + CoF<sub>2</sub>(g) approaches zero. The difference between the heat of formation of the gas and liquid at T<sub>b</sub> is ΔH<sub>v</sub><sup>\*</sup>.

Bond Distance: Co-F = [1.72] Å

Bond Angle: F-Co-F = [165°]

Product of Moments of Inertia:  $I_{A^1B^1C} = 6.5424 \times 10^{-116}$  g<sup>3</sup> cm<sup>6</sup>  $\sigma = 2$

Heat of Formation

The heat of formation of gaseous CoF<sub>2</sub>,  $\Delta H_f^\circ = -88.1 \pm 7.0$  kcal/mol, is calculated from the heat of formation of the crystal,  $\Delta H_f^\circ = -163.4 \pm 4.0$  kcal/mol, and the heat of sublimation,  $\Delta H_{sub}^\circ = 75.3 \pm 3.0$  kcal/mol. The sublimation value is determined from a third law analysis of the vapor pressure data for CoF<sub>2</sub> reported by Kana'an et al. (1). See CoF<sub>2</sub>(c) table for details.

Heat Capacity and Entropy

Büchler et al. (2) investigated the deflection of a molecular beam of CoF<sub>2</sub>(g) by an electric field and found that within the sensitivity of the apparatus the molecule was nonpolar and consequently possessed a linear structure. Hastie et al. (3) recently investigated the infrared absorption spectra of several transition metal difluorides through the use of matrix isolation techniques. Isotopic shift measurements for matrix isolated NiF<sub>2</sub>, ZnF<sub>2</sub>, and CuF<sub>2</sub> in neon and argon indicated that these species were slightly bent. Based upon these results, the authors estimated the F-Co-F angle as 165°. This value is adopted here. The bond length was estimated by Bravay et al. (4). Individual moments of inertia are  $I_A = 0.1925 \times 10^{-39}$ ,  $I_B = 18.341 \times 10^{-39}$ , and  $I_C = 18.533 \times 10^{-39}$  g cm<sup>2</sup>.

Hastie et al. (3) isolated CoF<sub>2</sub> in neon and argon matrices and observed the  $\nu_3$  fundamental at 762 cm<sup>-1</sup>. They also calculated  $\nu_1 = 600$  cm<sup>-1</sup> by a valence force field method and estimated  $\nu_2$  as 151 cm<sup>-1</sup> by applying the variation in the frequencies for the chlorides of Co, Ni, Cu, and Zn to the fluorides. The electronic levels and quantum weights are estimated by comparison with the electronic energy levels for Co<sup>2+</sup>(g) ion (5) and those for CoCl<sub>2</sub>(g) observed by Hougan et al. (6).

$$T_m = 301.55 \pm 0.01^\circ \text{K}$$

## Heat of Formation

Zero by definition.

## Heat Capacity and Entropy

Lien (1), Filby (2), and Horgan (3), have been measured by Dauphinee (1), McCollum (2), Martin (3), and Lien (4). The adopted values are derived based on the Cp data reported by Filby (2) and Lien (4). Lien measured the heat capacities in the temperature range 0.1874 to 1.20°K in the adiabatic demagnetization cryostat and at higher temperatures, 1.2 to 4.09°K, in the liquid-helium temperature cryostat. The Cs sample was obtained from a commercial source of 99.8 per cent purity. Filby determined the Cp values in the temperature ranges 0.4-1.5°K, 3-26°K and 20-320°K, using commercial samples of 99.9 per cent purity. These two sets of measurements are joined smoothly at 4°K. S<sub>298.15</sub> is derived from the adopted heat capacities, based on S<sub>0,20</sub> = 0.0002 eu.

Dauphinee (1) determined the heat capacities of Cs(c) employing a sample badly contaminated with oxygen. In the temperature range of approximately 100 to 200°K, an anomaly of Cp curve somewhat similar to those found for sodium and potassium was reported. This anomaly was not observed by Filby who used the higher purity cesium sample. The Cp values reported by Dauphinee are lower than the adopted ones by about 0.5 to 1.5 per cent in the temperatures 55 to 220°K; above 270°K his reported heat capacities are unreasonably high. Therefore the data are not adopted for evaluation. McCollum (2) calculated the Debye 8 values from the measured low temperature heat capacities and plotted them, since no numerical data were reported these were not used. The low temperature Cp values determined by Martin (3) and Horgan (3) are in good agreement with the adopted ones.

## Melting Data

See Cs(4) table for details.

## Heat of Sublimation

ΔH<sub>s</sub><sup>°</sup><sub>298.15</sub> is calculated as the difference between ΔH<sub>f</sub><sup>°</sup><sub>298.15</sub> for Cs(g) and Cs(c).

GFW = 132.905

(LIQUID)

GFW = 132.905

$S_{298.15}^{\circ} = 22.005$  gibbs/mol

$\Delta H_f^{\circ} = 0.499$  kcal/mol

$T_m = 301.55 \pm 0.01^{\circ}K$

$\Delta H_m^{\circ} = 0.499 \pm 0.001$  kcal/mol

$T_b = 961.6^{\circ}K$

$\Delta H_v^{\circ} = 16.198$  kcal/mol

Heat of Formation

The heat of formation is obtained from  $\Delta H_f^{\circ}(c)$  by adding  $\Delta H_m^{\circ}$  and the difference between  $H_f^{\circ}(s)$  and  $H_f^{\circ}(c)$  for Cs(c) and Cs(l).

Heat Capacity and Entropy

The enthalpies of Cs(l) have been measured by Tepper et al. (1), Achener (2), and Lemmon et al. (3), using drop calorimetry. Lemmon et al. used a cesium sample of 99.99% pure and encapsulated in Pb-12% alloy. They found that Cs(l) does not behave as a normal liquid from about 100-300°C. The thermal conductivity measurements of Cs(l) show a change of slope at about 200°C and its electrical resistivity also shows scatter in this region. The heat capacities,  $301.55-1435.7^{\circ}K$ , derived from the reported enthalpies (corrected for vapor condensation), are consistent with the low temperature heat capacity data on Cs(c) at 298°K and are adopted.

Tepper et al. measured the enthalpies in the temperature range 351.1-1238°K. The reported enthalpy values are considerably higher, over 20 per cent, at the lower end of the measured temperature range than the adopted ones. However, the agreement becomes better at the higher temperature end. Achener determined the enthalpies of Cs(l) at the temperatures 340.1-1175.7°K. Using the reported enthalpies, the average heat capacity is derived to be 9.75 gibbs/mol, which is unreasonably high by comparison with those for the other alkali metals. The above two sets of data are not used for evaluation. The enthalpies of Cs(l), 773-1423°K, were also measured by Shapiro (4) and quoted by (3). The derived constant heat capacity, 7.60 gibbs/mol, is in reasonable agreement with the adopted ones.

Heat capacities of Cs(l), 301.55-373.2°K, were reported by Filby (5), 301.55-320°K, Dauphinee (6), 310-320°K, and Rengado (7), 301.7-373.2°K. The values obtained are consistent with the adopted ones.

$S_{298.15}^{\circ}$  is derived in a manner analogous to that of the heat of formation.

Melting Data

The melting point and heat of melting have been determined by many investigators. The results reported are presented in the table below. The adopted  $T_m$  and  $\Delta H_m^{\circ}$  are obtained from (5). The two determinations of fraction melted against temperature are in very good agreement with one another and lead to a linear plot of reciprocal fraction melted against temperature thus indicating that the major impurity is solid insoluble. This is confirmed by a graph of excess heat capacity against the reciprocal of  $(T_0 - T)^{-1}$ , where  $T_0$  is the melting point, which indicates an impurity (mainly oxygen) concentration of 0.06 atomic per cent.

Vaporization Data

$T_b$  is the temperature at which the Gibbs energy change ( $\Delta G_r^{\circ}$ ) for the reaction  $Cs(l) = Cs(g)$  approaches zero. The difference between  $\Delta H_f^{\circ}(Cs, g)$  and  $\Delta H_f^{\circ}(Cs, l)$  at  $T_b$  is  $\Delta H_v^{\circ}$ . Due to the presence of dimer ( $Cs_2$ ) in the vapor (see Cs(g) and  $Cs_2(g)$  tables for details), the real boiling point of Cs(l) is calculated to be 941.3°K at which the vapor mixture contains 0.835 mol of monomer/mol of Cs(l) vaporized, or 9.0 per cent of dimer. The corresponding heat of vaporization is evaluated as 15.26 kcal/mol of vapor mixture.

## Heat of Formation

The total pressures of Cs(g) and Cs<sub>2</sub>(g) over Cs(c) and Cs(l) in the temperature range 238.6 to 1268.3°K have been measured, using the boiling point method, by Bonilla (4), Tepper (3) and Achener (2); using the static method, by Kröner (10), Scott (7) and Stone (1); and the positive ion method by Taylor (8). Fichtbauer (8) and Hacksbill (9) have determined the vapor pressures of Cs(l) by a spectroscopic method and P-V-T relationships, respectively. Based on the reported total pressures, the partial pressures of Cs(g) and Cs<sub>2</sub>(g) are evaluated by use of dimer-monomer ratios calculated from JANAF free energy functions and ΔHf°<sub>298.15</sub> = 11.24 kcal/mol for the reaction Cs<sub>2</sub>(g) = 2Cs(g). The value of ΔHf°<sub>298.15</sub> is adopted such that the derived monomer partial pressures give consistent second and third law heats of vaporization. The results are presented in the table below.

Stone et al. (1) measured the vapor pressures of Cs(l) at temperatures 920-1662°K and pressures 0.811-33.53 atm in both the saturation and superheat regions, using a static method and a refractory metal apparatus with a diaphragm as a null-point detector. These vapor pressures reported at temperatures 920-1267.3°K and total pressure below 10 atm are used for evaluation and are reasonably represented by a mixture of monomer and dimer ideal gases. The value of ΔHf°<sub>298.15</sub> is adopted as 18.32 ± 0.5 kcal/mol which is derived based on the vapor pressures reported by Stone et al. The results obtained are in reasonable agreement with the values derived from the other vapor pressure sets.

\*Calculation based on the third law ΔHf°<sub>298</sub> and ΔHf°<sub>298</sub> = 0 and 0.499 kcal/mol for Cs(c) and Cs(l), respectively.

## Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights (n ≤ 10) are obtained from Moore (11). The electronic levels above 25000 cm<sup>-1</sup> are average values calculated from those given by Moore. The missing electronic levels, where quantum number n = 7, 8, 9 and 10, and the corresponding quantum weights are estimated according to the method recommended by Gurvich (12). The calculated values at 6000°K, e.g. Cp = 19.668 gibbs/mol and S° = 61.980 eu, are not significantly different from the corresponding values, Cp = 19.650 gibbs/mol and S° = 61.871 eu, obtained from using all the electronic levels reported by Moore for calculation without cutting or adding any levels.

June 30, 1968

CESIUM UNIPOSITIVE ION (Cs<sup>+</sup>)  
 Ground State Configuration <sup>1</sup>S<sub>0</sub>  
 $S^{\circ}_{298.15} = 40.565 \pm 0.0005$  gibbs/mol  
 $\Delta H^{\circ}_0 = 108.5 \pm 1$  kcal/mol  
 $\Delta H^{\circ}_{298.15} = 108.1 \pm 1$  kcal/mol

Electronic Levels and Quantum Weights  
 $\frac{\epsilon_i, \text{cm}^{-1}}{0} \frac{g_i}{1}$

Heat of Formation  
 The ionization potential of Cs(g) was reported as 3.893 eV or 89,776 kcal/mol by C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, 1958. Based on this data we derived  $\Delta H^{\circ}_{298.15} = 108.1 \pm 1$  kcal/mol for Cs<sup>+</sup>(g).

Heat Capacity and Entropy  
 The ground state configuration, electronic levels and quantum weights were reported by Moore, loc. cit. However, the lowest electronic level above ground state is given as 107392.33 cm<sup>-1</sup> which is so high that the evaluated thermodynamic properties of Cs<sup>+</sup>(g) will not be affected if we disregard all of these higher levels for calculation. Therefore we do not use them. The H<sup>-</sup>H<sub>298</sub> value at 0 K is -1.481 kcal/mol.

CESIUM FLUORIDE (CsF)

(CRYSTAL)

GFW = 151.9034

$\Delta H^{\circ}_F = \text{Unknown}$

$\Delta H^{\circ}_{298.15} = -132.57 \pm 0.5 \text{ kcal/mol}$

$\Delta H_m^{\circ} = 5.19 \text{ kcal/mol}$

$\Delta H^{\circ}_{298.15} (\text{to monomer}) = 47.37 \text{ kcal/mol}$

$S^{\circ}_{298.15} = [21.1 \pm 2] \text{ gibbs/mol}$

$T_m = 976^{\circ}\text{K}$

Heat of Formation

The enthalpy of solution ( $\Delta H_{\text{soln}}$ ) of CsF(c) in water at 298.15°K has been carefully determined with an adiabatic calorimeter by Somsen (1). Based on the reported value,  $\Delta H_{\text{soln}}^{\circ}_{298} = -8.62 \pm 0.04 \text{ kcal/mol}$  and  $\Delta H^{\circ}_{298} = -61.69$  (2) and  $-79.5 \text{ kcal/mol}$  (3) for Cs<sup>+</sup>(aq, H<sub>2</sub>O) and F<sup>-</sup>(aq, H<sub>2</sub>O), respectively, the heat of formation for CsF(c) is calculated to be  $-132.57 \text{ kcal/mol}$  which is adopted. The value,  $\Delta H_{\text{soln}}^{\circ}_{298} = -8.81 \pm 0.2 \text{ kcal/mol}$  for CsF(c), was reported by Parker (4), which is in agreement with the value measured by Somsen (1).

Heat Capacity and Entropy

The heat capacities of CsF(c) are estimated according to the method of Kristov (5), based on  $H^{\circ}_{576} - H^{\circ}_{298} = 9.4 \text{ kcal/mol}$  reported by Dwoipkin (6). The entropy ( $S^{\circ}_{298}$ ) is estimated such that the calculated and observed vapor pressures are in good agreement (see CsF(g) and Cs<sub>2</sub>F<sub>2</sub>(g) tables for details).

Melting Data

$T_m$  and  $\Delta H_m^{\circ}$  are obtained from Bredig (7) and Dwoipkin (8). Bukhalova (9) reported  $T_m = 958^{\circ}\text{K}$ , which is not adopted.

Heat of Sublimation

$\Delta H^{\circ}_{298}$  is calculated as the difference between  $\Delta H^{\circ}_{298}$  for CsF(g) and CsF(c).

## CESIUM FLUORIDE (CsF)

(LIQUID)

GFW = 151.9034

 $S_{298.15}^{\circ} = [21.534]$  gibbs/mol $\Delta H_{298.15}^{\circ} = -129.983$  kcal/mol $\Delta H_m^{\circ} = 5.19$  kcal/mol $T_m = 976^{\circ}\text{K}$  $\Delta H_v^{\circ} = 27.6$  kcal/mol of liquid $T_b = 1504^{\circ}\text{K}$ 

## Heat of Formation

 $\Delta H_{298}^{\circ}(l)$  is obtained from  $\Delta H_{298}^{\circ}(c)$  by adding  $\Delta H_m^{\circ}$  and the difference between  $H_{976}^{\circ}$  and  $H_{298}^{\circ}$  for crystal and liquid.

## Heat Capacity and Entropy

Dierkin (1) measured the heat capacity of CsF(l) at the melting point to be 17.7 gibbs/mol which is adopted and assumed to be constant in the temperature range 298 - 3000 K. The entropy is obtained in a manner analogous to that of the heat of formation.

## Melting Data

See CsF(c) for details.

## Vaporization Data

Tb is the temperature at which the calculated vapor pressures of CsF(g) and Cs<sub>2</sub>F<sub>2</sub>(g) equal one atmosphere. The vapor composition at Tm is calculated as CsF 80.3 per cent and Cs<sub>2</sub>F<sub>2</sub> 19.7 per cent. The heat required to vaporize one mole of liquid to the above vapor mixture at Tm is  $\Delta H_v^{\circ}$ .

Tb has been observed as 1524 and 1526°K by Wartenberg (1) and Ruff (2), respectively, which are in fair agreement with the calculated one, 1504°K.

The vapor pressures of CsF(c) and CsF(l) were measured by the manometric method (A) by Wartenberg (1), Ruff (2) and Cantor (3); the torsion-fiber effusion method (B) by Pugh (4); and the Knudsen effusion method (C) by Scheer (5). Based on the reported total pressures, the corresponding partial pressures of CsF(g) and CsF<sub>2</sub>(g) were evaluated using the adjusted heats of vaporization and Gibbs free energy functions such that the calculated and observed total pressures are in reasonable agreement, and the derived enthalpy changes by the second and third law methods are consistent. The results obtained are presented in the table below. The value of  $\Delta H^{\circ}_{298}$  (CsF, g) is adopted as  $-82.5 \pm 0.5$  kcal/mol.

The dissociation energy ( $D_0$ ) of CsF(g) has been reported using the spectroscopic convergence limit as 5.65eV(130.3 kcal/mol) and 5.56eV(126.8 kcal/mol) by Herzberg (6) and Gaydon (7), respectively. Based on the above two  $D_0$  values, and  $\Delta H^{\circ}_f = 18.68$  and 18.36 for Cs(g) and F(g), we obtain the corresponding value for  $\Delta H^{\circ}_{298}$  (CsF, g) as  $-93.86$  and  $-90.39$  kcal/mol, which are not adopted.

\*1 represents the reaction CsF(c) = CsF(g); 2, the reaction CsF(l) = CsF(g).  
 \*\*Calculation based on the third law  $\Delta H^{\circ}_{298}$  and  $\Delta H^{\circ}_f = -132.57$  and  $-129.983$  kcal/mol for CsF(c) and CsF(l), respectively.

Heat Capacity and Entropy  
 The ground state configuration was reported by Herzberg (6). The molecular constants are obtained from Honig (7), who observed the microwave spectra of CsF(g) at temperatures of about 700°K. Based on the  $J = 1 + 2$  transition, the molecular constants are derived. The vibrational frequency ( $\omega_e$ ) has been reported, from different kinds of spectra, in the range 270 - 385 cm<sup>-1</sup> by many investigators, e.g. radiofrequency, infrared, ultraviolet, microwave, etc. The value of  $\omega_e$  adopted was reported by Balok (8), who also reviewed the  $\omega_e$  values obtained by the earlier investigators.

Cesium Monoxide (CsO)

(Ideal Gas) GFW = 148.9044

Ground State Configuration [2<sup>2</sup>π]  
 $S_{298,15}^\circ = (61 \pm 1)$  gibbs/mol  
 $\Delta H_f^\circ = (15.5 \pm 10)$  kcal/mol  
 $\Delta H_{298,15}^\circ = (15.0 \pm 10)$  kcal/mol

Electronic Levels and Quantum Weights

$$\frac{E_i}{\text{cm}^{-1}} - \frac{E_0}{\text{cm}^{-1}} \quad [H]$$

$$\omega_e X_e = [1.0] \text{ cm}^{-1} \quad \sigma = 1$$

$$\sigma_0 = [0.001] \text{ cm}^{-1} \quad r_e = [2.40] \text{ \AA}$$

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of estimation are described as follows. Brewer and Margrave (1) suggested that the  $\Delta H_f$  value for MO(g) from the gaseous ions can be taken as the mean of the corresponding  $\Delta H_f$  values for the alkali fluoride and chlorides with a maximum uncertainty of 10 kcal/mol. Adopting  $\Delta H_f^\circ = -131.1$  and  $-109.6$  kcal/mol for the reaction  $\text{Cs}^+(g) + \text{F}^-(g) = \text{CsF}(g)$  and  $\text{Cs}^+(g) + \text{Cl}^-(g) = \text{CsCl}(g)$ , respectively, we obtain  $\Delta H_{298}^\circ = -120.4$  kcal/mol for  $\text{Cs}^+(g) + \text{O}^-(g) = \text{CsO}(g)$  which leads to  $\Delta H_{298}^\circ(\text{CsO}, g) = 12.0$  kcal/mol. The  $\Delta H_{298}^\circ$  values of the above species used for calculation are taken from the respective JANAF Thermochemical Tables.

Based on the assumption that  $D(\text{Cs-O}) = 1/2[D(\text{Cs}_2) + D(\text{O}_2)]$ , we derive  $D_{298}(\text{Cs-O}) = 65.2$  kcal/mol and  $\Delta H_{298}^\circ = 12.7$  kcal/mol for  $\text{CsO}(g)$ .

Adopting the Cs-O bond energy as half of the atomization energy of  $\text{Cs}_2\text{O}$ , we calculate  $D(\text{Cs-O}) = 60 \pm 10$  kcal/mol and  $\Delta H_{298}^\circ(\text{CsO}, g) = 17 \pm 10$  kcal/mol.

The heat of formation for  $\text{CsO}(g)$  is tentatively selected as  $15 \pm 10$  kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of the isoelectronic molecule OH(g).  $\omega_e$  is estimated from those of LiO(g), GaF(g), and CsCl(g). The bond distance is taken from that in CsOH(g) reported by Lide and Kuczkowski (2).  $\omega_e X_e$  is estimated by comparison with those of the other alkali oxides. The values of  $B_e$  and  $B_0$  are calculated from  $r_e$ ,  $\omega_e$  and  $\omega_e X_e$  by the method suggested by Herzberg (3). The moment of inertia is  $1.413 \times 10^{-36}$  g cm<sup>2</sup>.

r<sub>e</sub> = [4.48] Å

## Heat of Formation

The vapor pressures of Cs(g) and Cs<sub>2</sub>(g) over Cs(l) have been measured by many investigators (see Cs(g) table for details). For internal consistency, the vapor pressures determined at temperatures 900-1684°K and pressures 1.1-7.5 atm by Stone (1) are employed for evaluation. The P-T data on cesium reported by Tepper (2) are employed for comparison. Using the reported pressures, the JANAF free energy functions and ΔHf°<sub>298</sub> = 11.24 kcal/mol for the reaction Cs<sub>2</sub>(g) = 2Cs(g), the equilibrium constants for this reaction are evaluated. From the derived equilibrium constants, the enthalpy change of the reaction Cs<sub>2</sub>(g) = 2Cs(g) is calculated and ΔHf°<sub>298</sub> is adopted as 26.40 ± 1.0 kcal/mol. The results are presented in the table below. The value of ΔHf°<sub>298</sub>(Cs<sub>2</sub>, g) is adopted as 26.40 ± 1.0 kcal/mol.

The D<sub>0</sub>(Cs-Cs) was reported as 0.48 eV or 10.39 kcal/mol by Gaydon (3) and Herzberg (4), yielding ΔHf°<sub>298</sub> = 26.93 ± 0.92 kcal/mol for Cs<sub>2</sub>(g) which is in agreement with the adopted value, within the experimental uncertainty.

| Expt. No.      | No. of Points | Temperature, °K | Pressure, atm | ΔHf° <sub>298</sub> , kcal/mol | ΔHf° <sub>298</sub> , kcal/mol |
|----------------|---------------|-----------------|---------------|--------------------------------|--------------------------------|

## Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights, ω<sub>e</sub> and ω<sub>e</sub>x<sub>e</sub> are obtained from Herzberg (3). The second electronic level is reported as 8600-11000 cm<sup>-1</sup> and the value 9000 cm<sup>-1</sup> is chosen for calculation. The last two electronic states are estimated by comparison with those for K<sub>2</sub>(g) given by (3). The bond distance r<sub>e</sub> is calculated from ω based on the method suggested by Guggenheimer (1). The values of B<sub>e</sub> and ω<sub>e</sub> are calculated (3). The moment of inertia is 2.2145 × 10<sup>-37</sup> g cm<sup>2</sup>.

## Heat of Formation

Evidence from the velocity distribution in molecular beams (1) has shown that alkali halide vapors contain significant amounts of polymeric species. Using the same method Eisenstadt (2) determined the molecular composition of CsF vapor in the temperature range 838 - 919°K. Based on the reported equilibrium constants for the reaction (CsF)<sub>2</sub>(g) = 2CsF(g), we evaluate the enthalpy change (ΔH<sub>f</sub>°<sub>298</sub>) by the second and third law methods to be 40.53 ± 1.75 and 42.34 ± 0.26 kcal/mol, respectively. Employing ΔH<sub>f</sub>°<sub>298</sub> = 42.34 and ΔH<sub>f</sub>°<sub>298</sub>(CsF, g) = -85.2 kcal/mol, we obtained ΔH<sub>f</sub>°<sub>298</sub> = -212.74 kcal/mol for Cs<sub>2</sub>F<sub>2</sub>(g), which is adopted.

## Heat Capacity and Entropy

The Cs<sub>2</sub>F<sub>2</sub> molecule is assumed to have a rhombic configuration of symmetry D<sub>2h</sub> as Cs<sub>2</sub>Cl<sub>2</sub>(3). The Cs-F bond distance is taken as the same as that in CsF(g). The bond angles and vibrational frequencies are estimated by comparison with those of other dimeric alkali halides (3, 4). The three principal moments of inertia are: I<sub>A</sub> = 1.590 × 10<sup>-38</sup>, I<sub>B</sub> = 1.325 × 10<sup>-37</sup> and I<sub>C</sub> = 1.484 × 10<sup>-37</sup> g cm<sup>2</sup>.

Heat of Formation

The appearance potentials of CsOH and Cs<sub>2</sub>O ions were investigated by Emel'yanov et al. (1), using the electron-impact method with a mass spectrometer fitted with a heated ion source and a Pt effusion chamber. The heat of atomization of Cs<sub>2</sub>O was derived as 117 ± 9 kcal/mol. Based on this value we calculate the heat of formation (ΔHf<sub>298</sub><sup>0</sup>) of Cs<sub>2</sub>O to be -22 ± 10 kcal/mol, employing ΔHf<sub>0</sub><sup>0</sup> = 16.68 and 56.99 kcal/mol for Cs(g) and O(g), respectively. Brewer and Mastick (2) calculated theoretically the stability of gaseous alkali oxides according to ionic models and gave the heats of formation from gaseous atoms for Cs<sub>2</sub>O(g) as -24 kcal/mol. The ΔHf<sub>298</sub><sup>0</sup> value is evaluated to be 71.2 kcal/mol which is not adopted.

Heat Capacity and Entropy

The molecular structure of Cs<sub>2</sub>O(g) has been determined to be nonlinear by Büchler et al. (3), using electric-deflection method. The Cs-O bond distance is assumed to be the same as that in CsOH(g) reported by Lide and Kuczkowski (4). The bond angle is estimated by comparison with that in the H<sub>2</sub>O molecule. Three vibrational frequencies are estimated from those for H<sub>2</sub>O(g). The three principal moments of inertia are: I<sub>A</sub> = 5.350 × 10<sup>-39</sup>, I<sub>B</sub> = 1.600 × 10<sup>-37</sup>, and I<sub>C</sub> = 1.6535 × 10<sup>-37</sup> g cm<sup>2</sup>.

Dec. 31, 1965

$$\Delta H_f^0 298.15 = 9.683 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^0 298.15 = 2.224 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = 3.17 \pm 0.15 \text{ kcal. mole}^{-1}$$

$$T_m^0 = 1356.6^\circ \text{K.}$$

$$\Delta H_v^0 = 72.743 \text{ kcal. mole}^{-1}$$

$$T_b^0 = 2848^\circ \text{K.}$$

**Heat of Formation.**

The heat of formation was calculated from that of the crystal by adding  $\Delta H_m^0$  and the difference between  $H_{1356.6}^0 - H_{298}^0$  for (c) and (1).

**Heat Capacity and Entropy.**

The heat capacity was calculated from the enthalpy data of F. Kusl, A. Weithen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1916). The entropy was obtained in a manner analogous to the heat of formation.

**Melting Data.**

See crystal table for details.

**Vaporization Data.**

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation.

The heat of sublimation has been determined by second and third law analysis of the vapor pressure data of a large number of investigators. The results are summarized below:

| Ref. | Range°K.  | Method    | Points | ΔH <sub>subl.</sub> 298.15 kcal. mole <sup>-1</sup> | 3rd law      | Drift       |
|------|-----------|-----------|--------|---|--------------|-------------|
| 1.   | 1242-1340 | Knudsen   | 6      | 80.6 ± 0.2  | 81.39 ± 0.04 | 0.3 ± 0.2   |
| 2.   | 1357-1523 | Knudsen   | 16*    | 79.8 ± 0.3  | 80.25 ± 0.03 | -1.9 ± 0.5  |
| 3.   | 1605-1879 | Transport | 21*    | 79.7 ± 0.6  | 80.55 ± 0.25 | 0.5 ± 0.4   |
| 4.   | 1192-1360 | Knudsen   | 13     | 80.6 ± 4.0  | 81.16 ± 1.2  | 0.4 ± 3.1   |
| 5.   | 1143-1292 | Langmuir  | 5      | 81.3 ± 1.0  | 80.61 ± 0.2  | -0.6 ± 0.8  |
| 6.   | 1145-1707 | Knudsen   | 8      | 83.2 ± 1.3  | 81.05 ± 0.4  | -1.4 ± 0.8  |
| 7.   | 1356-1336 | Knudsen   | 15     | 91.1 ± 2.3  | 92.36 ± 1.7  | 2.7 ± 2.0   |

The three Langmuir values are grouped closely together at about 80.3 kcal. mole<sup>-1</sup>. The Knudsen values all lie a little higher averaging 81.4 kcal. mole<sup>-1</sup>, the single transport determination is at 80.55 kcal. mole<sup>-1</sup>. If the evaporation coefficient is not unity in the Langmuir experiments then one would observe lower pressures and higher heats of sublimation, thus it appears that the coefficient must be unity and that all techniques are measuring valid heats of sublimation. A value of 81 ± 0.5 kcal. mole<sup>-1</sup> was chosen weighted toward the more precise Knudsen work of Hersh.

The electronic ground state configuration and higher electronic levels were taken from C. E. Moore "Atomic Energy Levels", Natl. Bur. Stde. Circular 467, Washington 1952.

Heat Capacity and Entropy.

The electronic ground state configuration and higher electronic levels were taken from C. E. Moore "Atomic Energy Levels", Natl. Bur. Stde. Circular 467, Washington 1952.

Heat of Formation.

The heat of formation was obtained from the dissociation limit of Cu(g) which was given as 62317.2 cm.<sup>-1</sup> (or 178.187 kcal. mole<sup>-1</sup>) by C. E. Moore "Atomic Energy Levels", Nat. Bur. Stds. Circ. 467, Washington 1952. This value applies to 0°K. the enthalpy of Cu, Cu<sup>+</sup> and e<sup>-</sup> between 298°K. and zero are all 1.481 kcal. mole<sup>-1</sup>, thus at 298°K. the dissociation energy is 178.668 kcal. mole<sup>-1</sup>. The heat of formation was then obtained from the reaction Cu(g) → Cu<sup>+</sup> + e<sup>-</sup> as ΔH<sub>f</sub><sup>o</sup> = 260.668 ± 0.5 kcal. mole<sup>-1</sup>, the uncertainty is that due to Cu(g).

Heat Capacity and Entropy.

The ground state configuration and higher electronic levels were taken from C. E. Moore, loc. cit. Levels above 100,000 cm.<sup>-1</sup> were not included since they do not affect the thermodynamic function, levels above 30,000 cm.<sup>-1</sup> were averaged.

COPPER MONOFLUORIDE (CuF) (CRYSTAL)

OPW = 82.5384

ΔH<sub>f0</sub><sup>o</sup> = Unknown

ΔH<sub>f298.15</sub><sup>o</sup> = [-46 ± 10] kcal/mol

ΔH<sub>m</sub><sup>o</sup> = Unknown

ΔH<sub>s298.15</sub><sup>o</sup> = [58] kcal/mol

S<sub>298.15</sub><sup>o</sup> = [15.5 ± 0.5] gibbs/mol

T<sub>m</sub> = Unknown

Heat of Formation.

The heat of formation (ΔH<sub>f298.15</sub><sup>o</sup>) for CuF(c) is not available from literature at the present time. The lattice energy (U<sub>o</sub>) for CuF(c) has been calculated to be 209, 213 and 232 kcal/mol, based on the assumption of ionic bonding in CuF(c), by Pauling, Zachariasen and Ebert and Kottinek, respectively (see T. C. Waddington, Trans. Faraday Soc. 55, 1531 (1959) for details). The corresponding enthalpy change for the reaction CuF(c) = Cu<sup>+</sup>(g) + F<sup>-</sup>(g) was evaluated as 210.18, 214.18 and 233.18 kcal/mol. Using ΔH<sub>f</sub><sup>o</sup> = 260.67 kcal/mol for Cu<sup>+</sup>(g) and -62.2 kcal/mol for F<sup>-</sup>(g), the values of ΔH<sub>f298.15</sub><sup>o</sup> (CuF, c) were calculated to be -11.7, -15.7 and -34.7 kcal/mol. However, based on ΔH<sub>f298.15</sub><sup>o</sup>(CuF, g) = 12 ± 9 kcal/mol which was measured, the value of ΔH<sub>f298.15</sub><sup>o</sup> would be 23.7, 27.7 and 46.7 kcal/mol which seem to be too small. By comparison with those for KF(c) and HgF(c), the value of ΔH<sub>f298.15</sub><sup>o</sup> was estimated as 58 kcal/mol. From this ΔH<sub>f298.15</sub><sup>o</sup> value and ΔH<sub>s298.15</sub><sup>o</sup> (CuF, g), the heat of formation for CuF(c) was derived.

Heat Capacity and Entropy.

The heat capacities, 298.15-1000°K, and S<sub>298.15</sub><sup>o</sup> were estimated by comparison with those for CuCl(c), NaCl(c) and NaF(c). The Cp values above 1000°K were obtained by graphical extrapolation.

Heat of Sublimation.

The value of ΔH<sub>s298.15</sub><sup>o</sup> was estimated by comparison with those for KF(c) and HgF(c).

Heat Capacity and Entropy.

The values of ground state configuration,  $\omega_e$ ,  $\omega_e^x$ ,  $B_e$ ,  $C_e$ , and  $r_e$  were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950, and corrected to the average isotopic species.

June 30, 1966

| Ground State Configuration       | $1\Sigma^+$ | $\Delta H_f^\circ$                     | $\Delta H_f^\circ$ |
|----------------------------------|-------------|--|--------------------|
| $S_{298.15} = 54.11$ gibbs/mol   |             | $\Delta H_f^\circ = 12 \pm 9$ kcal/mol |                    |
| $S_{298.15} = 12 \pm 9$ kcal/mol |             | $\Delta H_f^\circ = 12 \pm 9$ kcal/mol |                    |

Electronic Levels and Quantum Weights

$$\frac{\xi_1, \text{cm}^{-1}}{0} \frac{\xi_1}{1}$$

$$\omega_e^x = 3.941 \text{ cm}^{-1}$$

$$\alpha_e = 0.004586 \text{ cm}^{-1}$$

$$r_e = 1.743 \text{ \AA}$$

Heat of Formation.

Based on spectroscopic data, the dissociation energy ( $D_0$ ) of CuF (g) was selected as  $3.0 \pm 1.0$  eV by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953. Using  $\Delta H_f^\circ(298.15) = 18.36$  and  $80.71$  kcal/mol for F(g) and Cu(g), respectively, the value of  $\Delta H_f^\circ(298.15)$  for CuF (g) was calculated to be  $30 \pm 23$  kcal/mol.

Values of the dissociation energy for CuF(g) have been derived by R. A. Kent, J. D. McDonald, and J. L. Margrave, J. Phys. Chem. 70, 874 (1966), as  $3.63 \pm 0.2$  to  $4.1 \pm 0.5$  eV, based on mass spectrometric studies of CuF<sub>2</sub> sublimation from a Knudsen cell, the appearance potential of CuF<sup>+</sup> ion from CuF<sub>2</sub> in both reducing and nonreducing systems, and a theoretical calculation assuming an ionic model like that used by E. S. Rittner, J. Chem. Phys. 19, 1030 (1951). Until further data are available, a value  $D(\text{CuF}) = 3.8 \pm 0.5$  eV was recommended. Using this dissociation energy for CuF (g), the heat of formation (298.15°K) for CuF(g) was evaluated to be  $12 \pm 9$  kcal/mol which is adopted here.

Heat Capacity and Entropy.

(CRYSTAL)

COPPER DIFLUORIDE (CuF<sub>2</sub>)

ΔHf° = Unknown

ΔHf°<sub>298.15</sub> = -131.2 ± 0.8 kcal/mol

ΔHm° = [9.4] kcal/mol

ΔHf°<sub>298.15</sub> = 62.5 ± 0.6 kcal/mol

S°<sub>298.15</sub> = [16.4] gibbs/mol

Tm = 1043°K

Heat of Formation.

The chemical equilibrium for the reaction (1) CuF<sub>2</sub>(c) + H<sub>2</sub>(g) = Cu(c) + 2HF(g) has been studied by K. Jellinek and A. Rudet, Z. anorg. allgem. Chem. 175, 281 (1928). The equilibrium gas phase composition was found to be HF 4.3% and H<sub>2</sub> 95.7% at 423°K. From this data the enthalpy change (ΔH°<sub>298.15</sub>) of the reaction was evaluated. The equilibrium for the reaction (2) CuF<sub>2</sub>(c) + H<sub>2</sub>O(g) = CuO(c) + 2HF(g) was investigated by L. Domange, Compt. rend. 200, 259 (1935). Based on the equilibrium data reported, the ΔHf°<sub>298.15</sub> value for the reaction was derived. The results obtained are presented as follows.

| Reaction | Temperature, °K | Second Law Value | Third Law Value | Drift        | ΔHf° <sub>298.15</sub> kcal/mol |
|----------|-----------------|------------------|-----------------|--------------|---------------------------------|
| (1)      | 423             | 22.38            | 22.38           | —            | -152.0                          |
| (2)      | 473.15-723.15   | 23.06 ± 1.33     | 22.15           | -1.67 ± 1.96 | -131.2                          |

Using the third law values for ΔHf°<sub>298.15</sub>, the corresponding ΔHf°<sub>298.15</sub> (CuF<sub>2</sub>, c) values were calculated. The adopted heat of formation for CuF<sub>2</sub>(c) is -131.2 ± 0.8 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, S°<sub>298.15-1000°K</sub>, and S°<sub>298.15</sub> were estimated by comparison with those for CuCl<sub>2</sub>(c), CaF<sub>2</sub>(c) and CaCl<sub>2</sub>(c), respectively. The Cp values above 1000°K were obtained by graphical extrapolation.

Melting Data.

This was reported by H. M. Haendler, L. H. Towle, E. F. Bennett and M. L. Patterson, Jr., J. Am. Chem. Soc. 76, 2178 (1954). Tm for CuF<sub>2</sub>(c) in HF(g) or H<sub>2</sub>(g) was found to be 950 ± 5°C or 785 ± 10°C, respectively, by H. von Wartenberg, Z. anorg. allgem. Chem. 241, 381 (1939). Heat of melting was estimated by comparison with those for other related compounds.

Heat of Sublimation.

See CuF<sub>2</sub>(g) table for details.

$\Delta H_f^{\circ}{}_{298.15} = [20.584] \text{ gibbs/mol}$   
 $\Delta H_f^{\circ}{}_{298.15} = [-124.30] \text{ kcal/mol}$   
 $\Delta H_m^{\circ} = [9.4] \text{ kcal/mol}$   
 $\Delta H_v^{\circ} = [43.98] \text{ kcal/mol}$

$S^{\circ}_{298.15} = [20.584] \text{ gibbs/mol}$   
 $T_m = 1043^{\circ}\text{K}$   
 $T_b = [1722]^{\circ}\text{K}$

Heat of Formation.  
 The heat of formation ( $\Delta H_f^{\circ}{}_{298.15}$ ) was obtained from  $\Delta H_f^{\circ}{}_{298.15}$  (CuF<sub>2</sub>, c) by adding  $\Delta H_m^{\circ}$  and the difference between  $H^{\circ}_{1043}$  and  $H^{\circ}_{298.15}$  for crystal and liquid.

Heat Capacity and Entropy.  
 The heat capacity was estimated based on an assumption that the average heat capacity for CuF<sub>2</sub>(l) is 7.5 gibbs/atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.  
 See CuF<sub>2</sub>(c) table for details.

Vaporization Data.  
 T<sub>b</sub> is the temperature at which the free energy change for the reaction CuF<sub>2</sub>(l) = CuF<sub>2</sub>(g) becomes zero. The difference between  $\Delta H_f^{\circ}$  for liquid and gas at T<sub>b</sub> is  $\Delta H_v^{\circ}$ .

Heat of Formation.

The vapor pressures of CuF<sub>2</sub>(c), at temperatures from 897 to 1026°K, have been determined by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Based on these data, the heat of sublimation (ΔH<sub>sub</sub><sup>298.15</sup>) of CuF<sub>2</sub>(c) was derived to be 62.45 ± 0.5 and 62.50 kcal/mol by the second and third law method, respectively. From the values of ΔH<sub>sub</sub><sup>298.15</sup> and ΔH<sub>f</sub><sup>298.15</sup> for CuF<sub>2</sub>(c), the heat of formation (ΔH<sub>f</sub><sup>298.15</sup>) for CuF<sub>2</sub>(g) was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by L. Brewer, O. R. Somayajulu and E. Bracklet, Chem. Rev. 63, 111 (1963). The ground state electronic configuration, 2Σ<sub>g</sub><sup>+</sup>, was obtained from A. Büchler, J. L. Stauffer and M. Klemperer, Internat. J. Phys. Chem. 10, 874 (1966). Arthur D. Little, Inc., Cambridge, Mass. The other electronic levels and quantum weights were assumed from those for CuCl<sub>2</sub>(g) reported by J. T. Hougen, G. E. Leroy and T. C. James, J. Chem. Phys. 33, 1670 (1961). The vibrational frequency, ν<sub>2</sub>, was determined by P. H. Kasai, E. B. Whipple and M. Weltner, Jr., J. Chem. Phys. 44, 2581 (1966). The other two frequencies, ν<sub>1</sub> and ν<sub>3</sub>, were calculated by Valence Force Treatment described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is I = 1.66649 × 10<sup>-38</sup> g cm<sup>2</sup>.

June 30, 1966

ΔHf°<sub>0</sub> = Unknown  
 ΔHf°<sub>298.15</sub> = -107.64 ± 2.0 kcal/mol

S°<sub>298.15</sub> = [25.9] gibbs/mol  
 T<sub>0</sub> = 433°K

Heat of Formation.

The enthalpy change (ΔHf°<sub>433</sub>) for the reaction Cu(OH)<sub>2</sub>(c) = CuO(c) + H<sub>2</sub>O(g) has been determined by L. V. My, Bull. soc. chim. France, No. 3, 545 (1964). Based on the reported value, ΔHf°<sub>433</sub> = 12 kcal/mol, the heat of formation (ΔHf°<sub>298.15</sub>) for Cu(OH)<sub>2</sub>(c) was derived as -107.64 kcal/mol, using ΔHf°<sub>298.15</sub> = -37.250 and -57.798 kcal/mol for CuO(c) and H<sub>2</sub>O(g), respectively, which was adopted here.

The free energy change (ΔGf°<sub>298.15</sub>) of the reaction Cu(OH)<sub>2</sub>(c) = Cu<sup>++</sup>(aq) + 2 OH<sup>-</sup>(aq) was evaluated to be 26.36 and 26.26 kcal/mol, based on the solubility product for Cu(OH)<sub>2</sub>(c) reported by (1) E. S. Ornelina, Zh. prikl. Khim. 37, 1358 (1964) and (2) N. P. Zhuk, Zh. Fiz. Khim. 28, 1523 (1954), respectively. Using values of S°<sub>298.15</sub> and ΔHf°<sub>298.15</sub> for Cu<sup>++</sup>(aq) and OH<sup>-</sup>(aq) from "Selective Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1, 1965, by D. D. Wagman and co-workers, the corresponding enthalpy change ΔHf°<sub>298.15</sub> and heat of formation (ΔHf°<sub>298.15</sub>) for Cu(OH)<sub>2</sub>(c) were derived. The results obtained are presented as follows.

| Chemical Reaction  | ΔHf° <sub>298.15</sub><br>kcal/mol | ΔHf° <sub>298.15</sub><br>kcal/mol | Reference |
|--|------------------------------------|------------------------------------|-----------|
| Cu(OH) <sub>2</sub> (c) = Cu <sup>++</sup> (aq) + 2 OH <sup>-</sup> (aq) | 10.06                              | -104.61                            | (1)       |
| Cu(OH) <sub>2</sub> (c) = Cu <sup>++</sup> (aq) + 2 OH <sup>-</sup> (aq) | 9.97                               | -104.52                            | (2)       |
| CuO(c) + H <sub>2</sub> O(l) = Cu(OH) <sub>2</sub> (c)                   | -1.9                               | -107.5                             | (3)       |
| CuO(c) + H <sub>2</sub> O(l) = Cu(OH) <sub>2</sub> (c)                   | 0.3                                | -105.3                             | (4)       |

The heats of solution of CuO(c) and Cu(OH)<sub>2</sub>(c) in HNO<sub>3</sub>(aq.) have been determined by (3) de Forcrand, Compt. rend. 157, 441 (1913) to be -16.38 and -14.46 kcal/mol, respectively. From these data the enthalpy change for the reaction CuO(c) + H<sub>2</sub>O(l) = Cu(OH)<sub>2</sub>(c) was derived as -1.9 kcal/mol. For the same reaction, the enthalpy change was reported to be 0.3 kcal/mol by (4) P. Sabatier, Compt. rend. 125, 301 (1897). Based on ΔHf°<sub>298.15</sub> = -37.25 and -68.315 kcal/mol for CuO(c) and H<sub>2</sub>O(l), respectively, the heat of formation for Cu(OH)<sub>2</sub>(c) was evaluated. The results obtained are presented in the above table.

Heat Capacity and Entropy.

The heat capacities, 298.15-700°K, were estimated by comparison with those for CuO(c), CaO(c) and Cs(OH)<sub>2</sub>(c). The Cp values above 700°K were obtained by graphical extrapolation. S°<sub>298.15</sub> was estimated such that the derived ΔGf° (Cu(OH)<sub>2</sub>, c) = ΔGf° (CuO, c) + ΔGf° (H<sub>2</sub>O, g) at 433°K.

Decomposition Temperature.

T<sub>d</sub> is the temperature at which the Gibbs energy change for the reaction Cu(OH)<sub>2</sub>(c) = CuO(c) + H<sub>2</sub>O(g) equals zero.

CuO

(CRYSTAL) OFM = 79.5394

ΔH°<sub>f,0</sub> = -36.71 kcal/mol  
ΔH°<sub>f,298,15</sub> = -37.25 ± 0.5 kcal/mol

S°<sub>298,15</sub> = 10.18 ± 0.1 gibbs/mol  
Td = 1395°K

Heat of Formation.

The more consistent data relative to the heat of formation are reviewed below. The selected value of -37.25 kcal/mol was derived from ΔH°<sub>f,298</sub> = -40.7 kcal/mol for Cu<sub>2</sub>O(c) and ΔH°<sub>f,298</sub> = 33.80 kcal/mol for 2CuO(c) = Cu<sub>2</sub>O(c) + 0.5 O<sub>2</sub>. Four different sets of oxygen dissociation pressure measurements yield heats of reaction in close agreement with each other and with the aqueous calorimetry of Thomsen. Thomsen's data may be reduced to the heat of reduction of CuO(c) with H<sub>2</sub> by combining heats of reaction for CuO + H<sub>2</sub>SO<sub>4</sub>, Fe + H<sub>2</sub>SO<sub>4</sub>, and Fe + CuSO<sub>4</sub>(aq). Direct calorimetric measurement of the heat of reduction by von Wartenberg and Werth yields ΔH°<sub>f,298</sub> = -38.04 ± 0.2 when corrected for incomplete condensation of water. Direct measurement is difficult and this value may correspond to incomplete reduction. The value of -33.02 reported by Wöhler and Jochum, Z. physik. Chem. 167A, 169 (1933), is unreasonable. Equilibrium constants derived from Balessant and Chiche yield -37.6 kcal/mol by third law analysis, but a serious entropy error is present. This is no doubt due to uncertainties in the activity of Cu in Cu-Au alloys. Other data have been reviewed by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931).

Heat Capacity and Entropy.

Low temperature values are based on data (15-297°K) from J. Hu and H. L. Johnston, J. Am. Chem. Soc. 75, 2471 (1953). Earlier data from R. W. Millar (71-302°K), J. Am. Chem. Soc. 51, 215 (1929), are in satisfactory agreement, while those of K. Clausius and P. Harteck (30-200°K), Z. physik. Chem. 134, 243 (1928), are higher by several percent. A small anomaly in the heat capacity is observed in the region 210-230°K. Magnetic measurements of M. O'Keefe and F. S. Stone, Phys. Chem. Solids 23, 261 (1962), and neutron diffraction studies of B. N. Brockhouse, Phys. Rev. 94, 781 (1954), suggest that this is a Néel point associated with antiferromagnetism. The entropy was obtained from the heat capacities based on S°<sub>15</sub> = 0.016 eu.

High temperature values are based on specific heats (373-1273°K) obtained from a dynamic method by D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. im. A. A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 5800 b (1963). Enthalpy data (523-1253°K) of Wöhler and Jochum, loc. cit., lead to a value for S°<sub>1200</sub> lower by about 0.25 eu, but this is inconsistent with the equilibrium data for 2CuO = Cu<sub>2</sub>O + 0.5 O<sub>2</sub>.

Temperature of Decomposition.

T<sub>d</sub> is calculated as the temperature at which ΔF equals zero for 2CuO(c) = Cu<sub>2</sub>O(c) + 0.5 O<sub>2</sub>(g).

## Heat of Formation

The heat of formation is calculated from that of the crystal,  $\Delta H_{298}^\circ = 85.1 \text{ kcal/mol}$ , which was obtained by 3rd law analysis of the sublimation pressure at 1773°K reported by Mack et al. (1). They employed a transpiration method and analyzed for copper (in minute amounts) by its catalytic effect on the oxidation rate of sodium sulfite. The resulting pressure is only 100 times the predicted pressure of Cu(g) over CuO(c). These pressures were reported but not used in the range 873-1173°K, since these yield a much larger value for the heat of vaporization and imply a high dissociation energy.

Some estimates of  $D_0^\circ$  CuO obtained by different methods are given below. These estimates along with a correlation of  $D_0^\circ$  values for MnO, FeO, NiO and ZnO favor  $D_0^\circ = 82 \pm 10$ , close to the value adopted.

| Method  | kcal/mol               |             |
|---|------------------------|-------------|
|   | $\Delta H_{298}^\circ$ | $D_0^\circ$ |

## Heat Capacity and Entropy

The visible spectrum of CuO has been extensively investigated, but only very recently has significant progress been made in its analysis. Antic-Jovanovic et al. (2) were able to obtain a vibrational analysis of the major band system by use of  $O^{18}$  isotope studies. Shirk and Bass (3) recently reported absorption and fluorescence spectra in inert-gas matrices which allows assignment of the ground state and the first two excited states. They have strong evidence for the lower state of the blue system being the ground state and also for the second system, which corresponds to the red-orange system, originating in the upper state of the blue system. Thus, it is probable that the B state is  $\Sigma$  and the X and A states are both  $\Sigma$  with very similar molecular constants, which serves to confuse the analysis of the spectra. It also appears likely that the 4187Å band analysed by Lagerqvist and Uhler (4) is a  $\Sigma$ - $\Sigma$  transition terminating in the ground state; thus we adopt their rotational constants for the X and C states. The vibrational frequencies and anharmonicities for the A and B states were from Antic-Jovanovic (2), as well as the vibrational interval for the ground state. The anharmonicity for the ground state was chosen so as to provide a reasonable Birge-Sponer extrapolation of the dissociation energy. The values of the  $q_e$  were estimated from the Morse potential function relations. The rotational constants were assumed to be nearly constant. The values of the splitting in the electronic levels in the X and A states are from Antic-Jovanovic (2), and are roughly confirmed by Shirk and Bass (3).

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states.

Copper Sulfate (CuSO<sub>4</sub>)

(Crystal) GFW = 159.6016

CuO<sub>4</sub>S

(CRYSTAL) GFW = 159.6016

$\Delta H_f^{\circ} = -181.66 \pm 0.2$  kcal/mol  
 $\Delta H_f^{\circ}{}_{298.15} = -184.03 \pm 0.2$  kcal/mol

$S^{\circ}_{298.15} = 26.11 \pm 0.1$  gibbs/mol  
 $T_D = 1078^{\circ}K$

Heat of Formation.

The heat of solution ( $\Delta H_{298.15}$ ) of CuO(c) in sulfuric acid to form CuSO<sub>4</sub>(c) has been measured by L. H. Adams and E. G. King, U. S. Bur. Mines RI 6617, 1965. From the reported value,  $\Delta H_f^{\circ} = -5.61 \pm 0.09$  kcal/mol for the reaction CuO(c) + H<sub>2</sub>SO<sub>4</sub>(7.068 H<sub>2</sub>O) = CuSO<sub>4</sub>(c) + H<sub>2</sub>O(l), the heat of formation ( $\Delta H_f^{\circ}{}_{298.15}$  for CuSO<sub>4</sub>(c) was evaluated as -184.03 kcal/mol, using  $\Delta H_f^{\circ}{}_{298.15} = -37.25$ , -209.49 and -68.315 kcal/mol for CuO(c), H<sub>2</sub>SO<sub>4</sub>(7.068 H<sub>2</sub>O) and H<sub>2</sub>O(l), respectively. See Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) table for the sources of the last two  $\Delta H_f^{\circ}{}_{298.15}$  values.

The equilibrium pressures for the following chemical reactions: (A) 2CuSO<sub>4</sub>(c) = CuO·CuSO<sub>4</sub>(c) + SO<sub>3</sub>(g), (B) 3Cu(c) + CuSO<sub>4</sub>(c) = 2Cu<sub>2</sub>O(c) + SO<sub>2</sub>(g), and (C) 4CuSO<sub>4</sub>(c) + Cu<sub>2</sub>O(c) = 3CuO·CuSO<sub>4</sub>(c) + SO<sub>2</sub>(g), were determined by several investigators. For reaction (A), the partial pressures of SO<sub>3</sub>(g) at different temperatures were calculated from the measured total pressures exerted by SO<sub>3</sub>(g), SO<sub>2</sub>(g) and O<sub>2</sub>(g) produced by the reaction SO<sub>3</sub>(g) = SO<sub>2</sub>(g) + 1/2 O<sub>2</sub>(g). From these vapor pressure data, the corresponding enthalpy changes ( $\Delta H_{298.15}$ ) for the three reactions were evaluated by the second and third law methods. The results obtained are presented in the following table. The value of  $\Delta H_f^{\circ}{}_{298.15}$  (CuSO<sub>4</sub>, c) adopted was -184.03 ± 0.2 kcal/mol.

| Investigator               | Reaction | Temperature, °K | Second Law Value | Third Law Value | Drift      | $\Delta H_f^{\circ}{}_{298.15}$ kcal/mol |

Heat Capacity and Entropy.

The low temperature heat capacities, 52.67-296.29°K, were obtained from W. W. Weller, U. S. Bur. Mines RI 6689, 1965. The high temperature heat capacities were measured by H. Schottky, Z. phys. Chem. 54, 415 (1908), 282°K; R. Ewald, Ann. Physik, 44, 1213 (1914), 275-373°K; A. N. Krestovnikov and E. J. Peigine, J. Gen. Chem. USSR, 6, 1481 (1935), 288-873°K; and D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. Im. A. A. Baikov, Akad. Nauk SSSR, No. 12 79-84 (1963), 373-1273°K. The heat capacities below 51°K were obtained from J. W. Stout, J. Chem. Phys. 2, 285 (1941). In that paper, the Cp values, 15-58°K, were plotted as function of temperature and the Cp curve shows a maximum at 34.8°K. In an attempt to evaluate the entropy due to the anomalous portion of the curve, a "normal" heat capacity curve was drawn. The entropy above the normal Cp curve is reported to be 0.46 eu, rather than a magnetic entropy of Rln2 = 1.377 eu. Apparently the magnetic entropy increases gradually above 40°K so that it is not feasible to separate the heat capacity due to magnetic effects from that of the crystal lattice.

The Cp values above 298.15°K were extrapolated smoothly by comparison with those for MnSO<sub>4</sub>(c) (see FeSO<sub>4</sub>(c) table for details). The adopted Cp values are close to the average of the reported Cp values.

The value of  $S^{\circ}_{298.15}$  was derived using the low temperature Cp data reported by W. W. Weller, loc. cit., based on  $S^{\circ}_{51} = 2.851$  eu evaluated from Cp data determined by J. W. Stout, loc. cit.

Decomposition Temperature.

$T_D$  is the temperature at which the total pressure of the gaseous decomposition products equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for CuSO<sub>4</sub>(c), determined by T. R. Ingraham, loc. cit.

| T, °K | Cp <sup>o</sup> | S <sup>o</sup> - (G <sup>o</sup> - H <sup>o</sup> <sub>298</sub> )/T | H <sup>o</sup> - H <sup>o</sup> <sub>298</sub> | $\Delta H_f^{\circ}$ kcal/mol | $\Delta G_f^{\circ}$ | Log Kp   |

Heat of Formation.

The heat of formation was calculated from that of Cu(g) using ΔHf°<sub>298</sub> = 46.0 kcal/mol for Cu<sub>2</sub>(g) → 2 Cu(g) obtained by third law analysis of the mass spectrometric data of Ackerman et al. Earlier studies of mass spectra and of the electronic band spectra yield values in reasonable agreement as shown below. The selected ΔHf° corresponds to D<sub>0</sub> = 1.97 eV compared with the linear Birge-Sponer extrapolation of 2.1 eV.

Heat Capacity and Entropy.

Molecular constants, except for ω<sub>e</sub>x<sub>e</sub>, were taken from the rotational analysis of bands of the B-X system given by D. N. Travis and R. F. Barrow, *Proc. Chem. Soc. (London)*, **44** (1962). The value for ω<sub>e</sub>x<sub>e</sub> was obtained from the earlier study of Klemen and Lindqvist, *loc. cit.*, who showed by means of the vibrational isotope effect that the emitter was Cu<sub>2</sub>. The spectroscopic characters of the ground and excited states are uncertain, but Travis and Barrow indicate that the transition is probably 1Σ<sup>+</sup>u - 1Σ<sup>+</sup>g for the B-X system. Vibrational and rotational constants were adjusted for 30.91% <sup>65</sup>Cu.

Summarized below are the more consistent results for the heat of formation. The selected value of -40.7 kcal/mol is based on data from Thomsen and Kimura. More recent equilibrium data yield essentially the same average for ΔHf° but the separate values scatter by about ±0.7 kcal/mol and significant entropy errors are apparent. Thomsen obtained values of -40.80, -40.87 and -41.51 from aqueous calorimetry using three different paths. He favored the first path which may be recalculated by combination of the heats of reaction of Cu<sub>2</sub>O + H<sub>2</sub>SO<sub>4</sub> and Fe + CuSO<sub>4</sub>(aq) to yield the heat of reduction of Cu<sub>2</sub>O with H<sub>2</sub>. Direct measurements of the heat of reduction reported by L. Wöhler and N. Jochum, Z. Physik. Chem. 167A, 169 (1933), appear to be unreliable since they lead to -43.0 for the heat of formation. The cell data of Ishakawa and Kimura show very little drift and are in excellent agreement with Thomsen.

**Heat Capacity and Entropy.**  
 Low temperature values are based on data from L. V. Oregon (2.8-21°K), J. Phys. Chem. 66, 1645 (1962) and from J. Hu and H. L. Johnston (15-300°K), J. Am. Chem. Soc. 73, 4550 (1951). Earlier data by R. W. Miller (76-291°K), J. Am. Chem. Soc. 51, 215 (1929) are in satisfactory agreement. The entropy was obtained from the heat capacities based on S°<sub>298</sub> = 0.0015 eu.  
 High temperature values were obtained from specific heats (373-1273°K) determined with a dynamic method by D. M. Chizhikov and A. S. Knirik, Tr. Inst. Met. in A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 79 (1963). Enthalpy data (543-1223°K) from Wöhler and Jochum, loc. cit., yield for S°<sub>1000</sub> a value about 0.4 eu higher, but this is inconsistent with extensive equilibrium data for 2CuO(c) = Cu<sub>2</sub>O(c) + 0.5 O<sub>2</sub> (see CuO(c)).

**Melting Data.**  
 For details see Cu<sub>2</sub>O(l).

June 30, 1966

Cu<sub>2</sub>O

$$\Delta H_{298}^{f, \text{liq}} = 22.901 \text{ gibbs/mol}$$

$$\Delta H_{298}^{f, \text{cr}} = -32.029 \text{ kcal/mol}$$

$$T_m = 1509^\circ \text{K}$$

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding  $\Delta H_m^\circ$  and the difference between  $(H_{1509}^\circ - H_{298}^\circ)$  for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated on the basis of 8 gibbs per g atom, giving a value of 24 gibbs/mol which is essentially the same as that of the crystal at the melting point. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

$T_m$  is the value recommended by S. J. Schneider, NBS Monograph 88, U. S. Govt. Printing Office, Washington, D.C., October, 1963, based on pressure-temperature-composition studies of H. S. Roberts and P. H. Smyth, J. Am. Chem. Soc. 43, 1061 (1921). The heat of melting was selected as 13.58 kcal/mol, corresponding to  $\Delta S_m^\circ = 3 \text{ eu per g atom}$ . A value of 13.4 kcal/mol has been derived from the Cu<sub>2</sub>O-CuCl phase diagram by K. K. Kelley, USNM Bulletin 393, U. S. Govt. Printing Office, Washington, 1936. Another value may be obtained from oxygen dissociation pressures for the system Cu<sub>2</sub>O(l)-CuO(c) determined by Roberts and Smyth, loc. cit. Equilibrium constants may be obtained for the reaction  $2\text{CuO}(c) = \text{Cu}_2\text{O}(l) + 0.5 \text{ O}_2$  by assuming the activity of Cu<sub>2</sub>O in the melt to be equal to its mole fraction. Based on the mole fractions given by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931), the equilibrium data yield  $\Delta H_m^\circ = 15.8 \pm 0.8 \text{ kcal/mol}$  by second law analysis of all points or  $12.9 \pm 1.6$  by omission of 4 points at high pressure and low mole fraction. These results appear to be consistent with the selected value within the approximations involved.

ΔH<sub>f</sub><sup>0</sup> = UNKNOWN  
ΔH<sub>f</sub><sup>298.15</sup> = -221.7 ± 0.5 kcal/mol

S<sub>298.15</sub> = [37.5 ± 2] e.u./mol  
T<sub>M</sub> = 1135.4°K

Heat of Formation

The equilibrium pressures for the following reactions: (A) CuO·CuSO<sub>4</sub>(c) = 2CuO(c) + SO<sub>2</sub>(g) and SO<sub>2</sub>(g) = SO<sub>2</sub>(g) + 0.5 O<sub>2</sub>(g), and (B) CuO·CuSO<sub>4</sub>(c) + Cu<sub>2</sub>O(c) = 4CuO(c) + SO<sub>2</sub>(g), were determined by (1) S. Reinders and P. Schmalzer, *J. Electrochem. Soc.*, **126**, 25 (1979), and (2) E. B. Ingraham, *Trans. Am. Soc. Appl. Phys.*, **55** (1955). Using the reported vapor pressures, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

| Reference | Reaction | Temperature, °K | Second Law Value | Third Law Value | ΔH <sub>f</sub> <sup>298.15</sup> , kcal/mol |
|-----------|----------|-----------------|------------------|-----------------|--|
| (1)       | A        | 1015 - 1025     | 63.03 ± 2.53     | 52.43           | -0.7 ± 2.4                                   |
| (2)       | B        | 827 - 1027      | 41.72 ± 3.42     | 42.45           | 0.5 ± 3.4                                    |
| (2)       | A**      | 825 - 1155      | 50.52 ± 0.16     | 52.57           | 1.6 ± 0.2                                    |

\* Based on the third law value for ΔH<sub>f</sub><sup>298.15</sup>.

\*\* Partial pressures were calculated from JANAF values for the SO<sub>2</sub> - SO<sub>2</sub> equilibrium. The value of ΔH<sub>f</sub><sup>298.15</sup> (CuO·CuSO<sub>4</sub>, c) adopted is -221.7 ± 0.5 kcal/mol.

Heat Capacity and Entropy

The heat capacities were calculated as the sum of those for CuO(c) and CuSO<sub>4</sub>(c). The value of S<sub>298.15</sub> was estimated by comparison with those for CuO(c) and CuSO<sub>4</sub>(c), and adjusted so that, using the derived free energy functions, the second and third law values for ΔH<sub>f</sub><sup>298.15</sup> agree reasonably.

Decomposition Temperature

T<sub>D</sub> is the temperature at which the total pressure of the gaseous decomposition products of reaction (A) equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for CuO·CuSO<sub>4</sub>(c), determined by E. B. Ingraham, loc. cit.

Heat of Formation.

The dissociation energy ( $D_0$ ) of fluorine has been discussed by numerous investigators for many years. Until about fifteen years ago, high values of  $D_0(F_2)$ , about 63 kcal. mole<sup>-1</sup>, were widely accepted. These values were obtained from extrapolations of the spectroscopic data for the halogens, e.g.  $D_0 = 63.3$  kcal. mole<sup>-1</sup> was reported by H. V. Hartenberg, O. Sprenger and J. Taylor, *Z. Physik. Chem., Bodenstein-Festband*, 61 (1931). However, meanwhile many indirect determinations as well as estimation have been carried out, which yield appreciably lower values. In 1950 the available data were examined critically by M. O. Evans, E. Warhurst and E. Whittle, *J. Chem. Soc.* 1524 (1950) and shown to support a value,  $D_0(F_2) = 37 \pm 8$  kcal. mole<sup>-1</sup>. The indirect determinations include (1) the thermal conductivity measurements by E. U. Franck and E. Wicke, *Z. Elektrochem.* 55, 643 (1951); (2) the explosion method by H. Fritz, *Dissert., Göttingen, 1952*; (3) estimation by use of the relations between  $D_0$  and the vibrational frequencies by A. Bucken and E. Wicke, *Naturwiss.*, 37, 233 (1950); and (4) spectroscopic data on the dissociation energy of diatomic fluorides. Recently more direct methods have been used to determine  $D_0(F_2)$ . They gave similar values. The  $D_0$  values reported by the previous investigators have been reviewed by L. Haar and C. W. Beckett, National Bureau of Standards Report 1435 (1952), and E. Wicke and H. Fritz, *Z. Elektrochem.* 57, 9 (1953).

The low bond dissociation energy of  $F_2(g)$  has been attributed to the repulsion between the unshared electrons on the bound fluorine atoms by K. S. Pitzer, *J. Am. Chem. Soc.* 70, 2140 (1948), or to the absence in fluorine of strengthening of the bond by hybridization of the p- or d- orbitals as may take place in the higher halogens by R. S. Mulliken, *J. Am. Chem. Soc.* 77, 884 (1955). M. O. Brown, *Trans. Faraday Soc.* 55, 9 (1959) suggests that the observed low  $D_0$  value results from the large energy required to promote the p atoms to the valence state from which the bond may be formed.

The equilibrium pressures for the reaction  $F_2(g) \rightarrow 2F(g)$  have been measured by several investigators. Using the reported equilibrium constants, the dissociation energy,  $D_{298.15}$ , was evaluated by both the second and third law methods. The results obtained are presented as follows.

| Temperature, °K. | $D_{298.15}$ , kcal. mole <sup>-1</sup> |               |               | Reference |
|------------------|---|---------------|---------------|-----------|
|                  | 2nd Law Value                           | 3rd Law Value | 3rd Law Value |           |
| 759 - 1115       | 36.91 ± 0.41                            | 37.76         | 1             |           |
| 810 - 960        | 36.7 ± 18.2                             | 38.1          | 2             |           |
| 723 - 820        | 41.8 ± 0.2                              | 38.0          | 4             |           |

2. F. M. Olliles and J. L. Margrave, *J. Chem. Phys.* 21, 381 (1953).
3. H. Wase, *J. Phys. Chem.* 59, 389 (1954).
4. M. Farber, et al. "Study of Rocket Engine Exhaust Products", Thirteenth Quarterly Report, June 1 - Oct. 31, 1964, Westmont Corporation, Pasadena, California.

By use of  $H_2-F_2$  mixture explosion method,  $D_0(F_2)$  was reported as  $37 \pm 2$  kcal. mole<sup>-1</sup> by E. Wicke and H. Fritz, loc. cit. K. L. Wray and D. P. Hornig, *J. Chem. Phys.* 24, 1271 (1956), using shock wave method, obtained  $D_0 = 31.0 \pm 4.3$  kcal. mole<sup>-1</sup>. The continuous absorption electronic spectrum of  $F_2(g)$  and the Raman displacement for the  $0 \rightarrow 1$  vibrational transition have been used by A. L. O. Rees, *J. Chem. Phys.* 26, 1567 (1957) to compute the potential energy curve for the repulsive  ${}^1\Sigma_u$  state dissociating to two normal  $F(g)$ . This curve is consistent with the value,  $D_0 = 37.1 \pm 0.85$  kcal. mole<sup>-1</sup>. The absorption spectrum of  $F_2(g)$  has been observed in the vacuum UV region by R. F. Iczkowski and J. L. Margrave, *J. Chem. Phys.* 30, 403 (1959). From a progression of bands at 8744, the value,  $D_0 = 37.5 \pm 2$  kcal. mole<sup>-1</sup> is deduced.

The  $D_0$  dissociation energy is selected as  $37.72 \pm 0.60$  kcal. mole<sup>-1</sup>, yielding  $\Delta H_f^0 298.15(F, g) = 18.66 \pm 0.40$  kcal. mole<sup>-1</sup>.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weights were taken from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Fluorine Uninegative Ion (F<sup>-</sup>)  
(Ideal Gas) Mol. wt. = 18.99895

FLUORINE UNINEGATIVE ION (F<sup>-</sup>) (IDEAL GAS) MOL. WT. = 18.99895

Ground State Configuration <sup>1</sup>S<sub>0</sub>  
 $\Delta H_f^\circ = 34.768 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$   
 $\Delta H_f^\circ = -61.1 \pm .5 \text{ kcal/mole}$   
 $\Delta H_f^\circ = -62.2 \pm .5 \text{ kcal/mole}$

Electronic Levels and Quantum Weight

$$\frac{C_1}{0.00} \frac{g_1}{1}$$

Heat of Formation.

The heat of formation was calculated from the equation:  $F(g) + e^- \rightarrow F^-(g)$  with the JANAF auxiliary value for  $F(g)$  using the measured electron affinity = 3.448 e.v. (79.511 kcal/mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. 39, 1540 (1963). Other calculated values for the electron affinity are: 3.37 reported by E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 3.08 e.v. E. Clementi, A. D. McLean, D. L. Raimondi, and M. Yoshimine, 133, A1274 (1964); 3.50 e.v. B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Neon. The electronic levels above  $1 \times 10^5 \text{ cm}^{-1}$  were omitted because their contribution is negligible below 6000°K. The  $h^\circ$ - $h^\circ$  value at 0°K. is -1.481 kcal/mole.

Sept. 30, 1965

(IDEAL GAS)

IRON MONOFLUORIDE (FeF)

MOL. WT. = 74.8454

Round State Configuration  $[\Sigma]$   
 $S_{298.15}^{\circ} = [57.4] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$   
 $\Delta H_f^{\circ} 0 = [11.4 \pm 5.0] \text{ kcal. mole}^{-1}$   
 $\Delta H_f^{\circ} 298.15 = [11.4 \pm 5.0] \text{ kcal. mole}$

## Electronic Levels and Quantum Weight

$\frac{E_1}{\epsilon, \text{ cm.}^{-1}}$        $\frac{g_1}{[6]}$

$\omega_e x_e = [2.7] \text{ cm.}^{-1}$

$\alpha_e = [0.0017] \text{ cm.}^{-1}$

$r_e = [1.8] \text{ \AA}$

## Heat of Formation.

The dissociation energy ( $D_0$ ) of FeF(g) was estimated as  $4.64 \pm 0.22 \text{ e.v.}$  or  $107 \pm 5 \text{ kcal. mole}^{-1}$  by J. L. Margrave, "Optical Spectra and Molecular Parameters of Light Element Molecules", Progress Report No. 8, Jan. 1 to Mar. 31, 1965, William Marsh Rice University, Houston, Texas. From the value of  $D^{\circ}$  (Fe-F) the heat of formation ( $\Delta H_f^{\circ} 298.15$ ) for FeF(g) was derived to be  $11.4 \pm 5.0 \text{ kcal. mole}^{-1}$ .

## Heat Capacity and Entropy.

The ground state configuration and bond distance ( $r_e$ ) were estimated by comparison with those for FeCl(g). The value of  $B_e$  was calculated using the relationship  $B_e = \frac{2.79889 \times 10^{-39}}{I}$  where  $I$  = moment of inertia of FeF(g), and  $\omega_e$  was estimated by comparison with those for AlF(g), AlCl(g) and FeCl(g). The value of  $\omega_e$  was derived from the bond distance, reduced mass and number of valence electrons according to the method given by K. M. Ouggenheimer, Proc. Phys. Soc. (London) 59, 456 (1946), and the  $\omega_e x_e$  was estimated from those for AlF(g), AlCl(g) and FeCl(g). The moment of inertia is  $7.6259 \times 10^{-39} \text{ g. cm.}^2$ .

HYDROGEN FLUORIDE (HF) (IDEAL GAS)

GFW = 20.00637

$\Delta H_f^\circ = -65.13 \pm 0.2$  kcal/mol

$\Delta H_{298.15}^\circ = -65.14 \pm 0.2$  kcal/mol

Ground State Configuration  $1s^2$

$S_{298.15} = 41.508$  gibbs/mol

Electronic Levels and Quantum Weights

| $\epsilon_i$ , cm <sup>-1</sup>           | $g_i$                   |
|---|-------------------------|
| 0   | 1                       |
| $\omega_e X_e = 4138.39$ cm <sup>-1</sup> | $\sigma = 1$            |
| $\omega_e = 20.9557$ cm <sup>-1</sup>     | $\alpha_e = 0.798^{-1}$ |
|   | $r_e = 0.9168$ Å        |

Heat of Formation

The selected value is obtained from a least squares, simultaneous solution (1) for the heats of formation of HF(g), HF(50 H<sub>2</sub>O) and five closely related fluorides. Other results, based on 23 selected observations relating the 7 variables, are as follows in kcal/mol: HF(50 H<sub>2</sub>O), -76.78 ± 0.1; NaF(c), -137.52 ± 0.2; BF<sub>3</sub>(g), -271.42 ± 0.4; Cl<sub>4</sub>(g), -221.04 ± 0.3; NF<sub>3</sub>(g), -31.43 ± 0.3; and C<sub>2</sub>F<sub>4</sub> (polymer), -198.2 ± 0.7. The ± values are approximate estimates of the overall uncertainty including systematic error. Further details of the simultaneous solution are given in (1).

The values given above require the use of certain auxiliary data; e.g., the value for NaF(c) presumes  $\Delta H_{\text{cool}}^\circ = 0.23 \pm 0.01$  and  $\Delta H_f^\circ[\text{Na}^\circ(\infty \text{H}_2\text{O})] = -57.47 \pm 0.04$  kcal/mol. Use of these auxiliary data leads to  $\Delta H_{298.15}^\circ = -79.82$  kcal/mol for HF( $\infty \text{H}_2\text{O}$ ) and  $F^\circ(\infty \text{H}_2\text{O})$ ; however, values for HF(n H<sub>2</sub>O) should be obtained from that of HF(50 H<sub>2</sub>O) by use of  $(n - 1000)$  taken from the tables of Parker (2). This procedure should be reliable except in dilute solutions ( $n > 1000$ ) where the equilibria  $\text{HF} + \text{H}^+ + \text{F}^- + \text{HF}_2^-$  yield an overall  $\Delta H$  of about 3 kcal/mol. Parker (2) used thermodynamic data for these equilibria in order to calculate  $\Delta H_L$  for the dilute solutions, but recent data (3-5) suggest that minor changes in the calculations may be desirable. For this reason the simultaneous solution includes  $\Delta H_L(50) = 3184 \pm 300$  cal/mol (2) as an "observation" rather than as a fixed value. The result of the simultaneous solution is smaller by only 150 cal/mol, suggesting that  $\Delta H_L(50)$  does not contain a major inconsistency.

Heat Capacity and Entropy

The ground state configuration is that deduced from UV spectra by Johns and Barrow (6). The excited state near 85000 cm<sup>-1</sup> is omitted since its contribution to the thermodynamic functions is negligible. High-resolution studies of the vibration-rotation spectrum were reported by Mann et al. (7) and subsequently confirmed by others (8, 9). The analysis of Webb and Rao (2) is adopted for this table.

Bond Distance: H-O = [0.96] Å O-F = [1.41] Å  
 Bond Angle: H-O-F = [104]°  
 Product of the Moments of Inertia:  $I_A I_B I_C = [1.2926 \times 10^{-11}] \text{ g.}^3 \text{ cm.}^6$   
 $\sigma^- = 1$

Heat of Formation.

The value of  $\Delta H_f^{\circ} 298.15$  for HFO(g) was calculated based on an estimated value for the heat of atomization 1.e.  $\Delta H_f^{\circ} = 161.6 \text{ kcal. mole}^{-1}$  for the reaction  $\text{HFO(g)} = \text{H(g)} + \text{F(g)} + \text{O(g)}$ . The  $\Delta H_f^{\circ}$  value was assumed to be the sum of the F-O and H-O bond energies which were obtained from the corresponding bond energies in  $\text{F}_2\text{O(g)}$  and  $\text{H}_2\text{O(g)}$  molecules.

Heat Capacity and Entropy.

The H-O and F-O bond distances were assumed to be the same as those in the  $\text{H}_2\text{O(g)}$  and  $\text{F}_2\text{O(g)}$  molecules. The vibrational frequencies and H-O-F bond angle were estimated by the corresponding values for  $\text{H}_2\text{O(g)}$ ,  $\text{F}_2\text{O(g)}$  and  $\text{Cl}_2\text{O(g)}$ . The three principal moments of inertia are  $I_A = 0.1332 \times 10^{-39}$ ,  $I_B = 3.0366 \times 10^{-39}$  and  $I_C = 3.1689 \times 10^{-39} \text{ g. cm.}^2$

Moments of Inertia: I<sub>A</sub> = 0.9784 X 10<sup>-39</sup> g. cm.<sup>2</sup>    C = 3  
 I<sub>B</sub> = 5.8578 X 10<sup>-39</sup> g. cm.<sup>2</sup>    I<sub>C</sub> = 5.8578 X 10<sup>-39</sup> g. cm.<sup>2</sup>

Heat of Formation, ΔH<sub>f</sub>° 298.15 was estimated in C. B. Henderson and R. S. Scheffe, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were found in Henderson and Scheffe, op. cit. Moments of Inertia were calculated using the constants found in C. Newman, J. K. O'Loane, S. R. Polo, and M. K. Wilson, J. Chem. Phys. 25, 855 (1956).

FH<sub>3</sub>Si

Ground State Configuration  $2z$

$\Delta H_f^\circ 298.15 = 0.7 \pm 12.0$  kcal mole $^{-1}$

$S_{298.15}^\circ = 59.338$  cal deg $^{-1}$  mole $^{-1}$

Electronic Levels and Multiplicities

$$\frac{E_i, \text{cm}^{-1}}{0} \quad \frac{g_i}{2}$$

$\sigma = 1$

$\omega_e x_e = 4.05$  cm $^{-1}$

$r_e = [1.89] \text{ \AA}$

$\alpha_e = [0.0026]$  cm $^{-1}$

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives  $32 \pm 12$  kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg (loc. cit.). Bond length estimated by comparison of the mercurous halides with thallium and cesium halides.

INTERIM TABLE

MOL. WT. = 145.9028

(IDEAL GAS)

IODINE MONOFLUORIDE (IF)

Ground State Configuration [1Σ<sup>+</sup>]  
 $\Delta H_f^\circ = 56.451 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$   
 $\Delta H_f^\circ = 238.15 = -22.648 \pm 0.9 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$\frac{E_j}{\text{e.v. cm.}^{-1}} \quad \frac{g_j}{1}$

$\omega_e X_e = 4 \text{ cm.}^{-1}$   
 $\omega_e = 1.906 \text{ \AA}$   
 $\alpha'_e = 0.00763 \text{ cm.}^{-1}$   
 $\sigma = 1$

Heat of Formation.

R. A. Durie and A. O. Gaydon, J. Phys. Chem. 56, 316 (1952), have obtained the dissociation limit (from the spectra) of IF as 23570 cm.<sup>-1</sup>. The first excited states of F and I are 404 and 7598 cm.<sup>-1</sup> above the ground state respectively. There are two sets of dissociation products possible: I(<sup>2</sup>P<sub>1/2</sub>) + F(<sup>2</sup>P<sub>3/2</sub>) or I(<sup>2</sup>P<sub>3/2</sub>) + F(<sup>2</sup>P<sub>1/2</sub>). When corrected to the normal atoms, the observed limit gives D<sub>0</sub>(IF(g)) 2.87 ± 0.04 e.v. or 66.18 ± 0.9 kcal. mole<sup>-1</sup> and 1.98 ± 0.04 e.v. or 45.66 ± 0.9 kcal. mole<sup>-1</sup> for dissociation energy respectively. Durie and Gaydon, loc. cit., favored the lower value. However L. Slutsky and S. H. Bauer, J. Am. Chem. Soc. 76, 270 (1954) have pointed out a numerical error in their calculations, which removes the chief support for the lower value and presented additional evidence favoring the higher value. More weight was given to the higher value which gives ΔH<sub>f</sub>° 298.15 = -22.648 ± 0.9 kcal. mole<sup>-1</sup> for the reaction 1/2 I<sub>2</sub>(g) + 1/2 F<sub>2</sub>(g) = IF(g).

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. Standards 55, 147 (1955) except  $\nu_e = 1.906 \text{ \AA}$  was obtained from L. O. Cole and O. W. Elverum Jr., J. Chem. Phys. 20, 1543 (1952) and ground state configuration was estimated by comparison with that for IBr and ICl from O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

POTASSIUM FLUORIDE (KF)

GFW = 58.1004

Potassium Fluoride (KF)  
(Crystal)

GFW = 58.1004

$\Delta H_f^\circ = -135.5 \pm 0.1$  kcal/mol  
 $\Delta H_f^{298.15} = -135.9 \pm 0.1$  kcal/mol

$\Delta H_m^\circ = 6.50$  kcal/mol

$\Delta H_f^{298.15} = 57.8$  kcal/mol (to monomer)

$S_{298.15}^\circ = 15.905 \pm 0.05$  gibbs/mol

$T_m = 1131^\circ K$

Heat of Formation

The heat of solution of KF(c) in water has been measured by several investigators. Their results have been converted to  $\Delta H_{sol}^\circ$  by Fankar (5) and listed in the table below. Using  $\Delta H_{sol}^\circ = -4.24$ ,  $\Delta H_f^{298}(K^+, \infty H_2O) = -60.32$  (6), and  $\Delta H_f^{298}(F^-, \infty H_2O) = -79.82$  kcal/mol (7), we obtain  $\Delta H_f^{298} = -135.9 \pm 0.1$  kcal/mol which is adopted.

| Investigator                | Temperature, °K | Concentration, molality | $\Delta H_{sol}^\circ$ , kcal/mol |

Heat Capacity and Entropy

The low temperature heat capacities, 16-323°K, were measured by Westrum and Pitzer (g). The high temperature enthalpies, 298-530°K and 291-1187°K, were determined by Westrum and Pitzer (g), and Lyashenko (g), respectively. However, the high temperature Cp values derived from both sets appear to be inconsistent with the low temperature Cp values. The heat capacities derived from the enthalpy data of Westrum and Pitzer are too high (3% at 530°K less at lower temperatures) to be joined smoothly with their low temperature Cp's. The adopted enthalpy at 530°K is about 1.4% lower than the reported value. The heat capacity derived from the enthalpy data of Lyashenko is 2.5% lower than the adopted one at 900°K. The differences are smaller at lower temperatures. At 900°K, the adopted enthalpy is 1.3% higher than the reported value. The adopted heat capacities in the temperature range, 323-2000°K, are estimated by graphical comparison with other alkali fluorides and chlorides, and joined smoothly with the low temperature data at 298°K.

$S_{298}^\circ$  is derived based on the adopted low temperature heat capacities.

Heating Data

See the KF(4) table.

Heat of Sublimation

The value of  $\Delta H_{sub}^{298}$  is obtained as the difference between  $\Delta H_f^{298}$  for KF(c) and KF(g).

$$S_{298.15}^{\circ} = 16.167 \text{ gibbs/mol}$$

$$T_m = 1131^{\circ}\text{K}$$

$$T_b = 1790^{\circ}\text{K}$$

## Heat of Formation

The  $\Delta H_f^{\circ}(t)$  is obtained from  $\Delta H_f^{\circ}(c)$  by adding  $\Delta H_m^{\circ}$  and the difference between  $H_{1131}^{\circ}$  and  $H_{298}^{\circ}$  for crystal and liquid.

## Heat Capacity and Entropy

The heat capacity is estimated by comparison with those of the alkali fluorides and chlorides, and is assumed to be constant in the temperature range, 298-3000°K. The Cp value, 16 gibbs/mol, derived from the enthalpy data of Lyashenko (12) appears low and is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

## Melting Data

Tm has been reported as 1119 (1, 2), 1129 (3, 4), 1131 (5, 6), and 1153°K (7). The value 1131°K is adopted. Kelley (8) evaluated the following freezing-point data of binary systems: KF-AlF<sub>3</sub> (9), KF-K<sub>2</sub>SO<sub>4</sub> (10), KF-KCl (11), KF-K<sub>2</sub>CO<sub>3</sub> (13), and KF-K<sub>2</sub>PO<sub>4</sub> (14), and derived the values of  $\Delta H_m^{\circ}$  (in kcal/mol) as 5.5, 5.55, 6.51, 7.1, and 7.1 respectively. The best value is recommended as 6.50 kcal/mol. Other reported  $\Delta H_m^{\circ}$  values are 6.70 (2) and 6.75 ± 0.1 kcal/mol (12). The value of heat of melting is tentatively adopted as 6.50 kcal/mol.

## Vaporization Data

The boiling point (Tb) is calculated to be the temperature at which the partial pressures of KF(g) and K<sub>2</sub>F<sub>2</sub>(g) equal one atmosphere. The composition of the gaseous mixture in equilibrium with KF(l) at Tb is calculated as K<sub>2</sub>F<sub>2</sub> 21.1% and KF 78.9%. The heat required to vaporize one mole of liquid at Tb is evaluated to be 33.9 kcal. The experimental values for the boiling point are 1778°K (1) and 1771°K (15).

Heat of Formation

The heats of solution and reaction of LiF(c) in water and hydrochloric acid have been measured by many investigators. The reported ΔHsoln values are listed in the table below. Using ΔHf298(Li<sup>+</sup>, aq H<sub>2</sub>O) = -66.56 kcal/mol (8), and ΔHf298(F<sup>-</sup>, aq H<sub>2</sub>O) = -79.82 kcal/mol (9), we calculate the corresponding ΔHf298 values for LiF(c). Based on the heat of solution of LiOH(c) in excess HF solution measured by Sinko (7), the value, ΔHf298(LiF,c) = -146.65 ± 0.5 kcal/mol is derived. The value of ΔHf298 for LiF(c) is adopted as -147.45 ± 0.2 kcal/mol

| Investigator                | Solvent          | Temperature, °K | ΔHr, kcal/mol              | ΔHf298, kcal/mol* |
|-----------------------------|------------------|-----------------|----------------------------|-------------------|

| 5. Cox and Harrop (1964)    | H <sub>2</sub> O | 298.2           | 50400 H <sub>2</sub> O     | -147.44           |

\*The heat of dilution data of Parker (5) are used to convert ΔHr to ΔHf.

Heat Capacity and Entropy

Clausius, Goldman, and Perlick (10) measured the low temperature heat capacities in the temperature range 19 to 272°K and Clausius and Eichenauer (11) from 10 to 111°K. Below 20°K a number of investigators have reported values of Cp and the average value of 729 ± 6 is used here. The high temperature enthalpies from 298°K to the melting point 1121.3°K were measured by Douglas and Dever (12), and Voskresenskaya et al. (13). All these data are taken and smoothed by computer up to 400°K. Above 400°K the Cp values are obtained graphically by drawing a smooth line through the data points.

S<sub>298</sub> is derived from the adopted low temperature heat capacities, based on S<sub>270</sub> = 0.064 eu.

Melting Data

See the LiF(l) table for details.

Heat of Sublimation

The difference between ΔHf298 for LiF(g) and LiF(c) is ΔHs298.

$\Delta H_f^{298.15} = -143.081 \text{ kcal/mol}$

$\Delta H_m = 6.474 \pm 0.005 \text{ kcal/mol}$

$\Delta H_v^*(\text{to mixture}) = 35.08 \text{ kcal/mol}$

$S_{298.16}^{\circ} = 10.269 \text{ gibbs/mol}$

$T_m = 1121.3 \pm 1.0^{\circ}\text{K}$

$T_b = 1990^{\circ}\text{K}$

Heat of Formation

The  $\Delta H_f^{298}(l)$  is obtained from  $\Delta H_f^{298}(c)$  by adding  $\Delta H_m^{\circ}$  and the difference between  $H_{1121.3}^{\circ} - H_{298}^{\circ}$  for crystal and liquid.

Heat Capacity and Entropy

T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. 76, 4826 (1954), and N. K. Voskresenskaya, V. A. Sokolov, E. I. Banashek, and N. E. Shmidt, Akad. Nauk SSSR, Invest. Sekt. Fiz. - Khim. Anal. 27, 233 (1956), have measured the enthalpies of LiF liquid to 1200 and 1400°K, respectively. Using the reported enthalpy data, a constant heat capacity is derived for each set. The adopted Cp for LiF(l) is the mean of the two derived heat capacities, and is extended arbitrarily to the temperatures above T<sub>b</sub> and below T<sub>m</sub>. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been determined by many investigators. See the table below for details. The adopted value, 1121.3 ± 1.0°K, is that reported by Douglas and Dever, loc. cit. The heat of melting is the mean of the  $\Delta H_m^{\circ}$  values reported by Douglas and Dever, loc. cit., and Voskresenskaya et al., loc. cit.

Vaporization Data

T<sub>b</sub> is the temperature at which the partial pressures of LiF(g), Li<sub>2</sub>F<sub>2</sub>(g), and Li<sub>3</sub>F<sub>3</sub>(g), in equilibrium with LiF(l), equal one atmosphere. The vapor composition at the boiling point is evaluated as LiF 69%, Li<sub>2</sub>F<sub>2</sub> 26.6%, and Li<sub>3</sub>F<sub>3</sub> 4.4%. The heat required to vaporize one mole of liquid to form 0.739 mole of vapor mixture of the above composition at T<sub>b</sub> is calculated to be 35.08 kcal.

The value of T<sub>b</sub> for LiF(l) has been reported to be 1943 and 1949°K by O. Ruff, G. Schmidt, and S. Muggdan, Z. Anorg. Allgem. Chem. 123, 83 (1922), and H. von Wartenberg and H. Schulz, loc. cit., respectively, which were obtained by extrapolation of their vapor pressure data, measured by the boiling point method.

Heat of Formation

The molecular species produced on vaporization of lithium fluoride have been studied by many investigators during the last ten years. The occurrence of dimer and trimer molecules in addition to the monomer has been established by use of mass spectroscopic (3, 7, 8), torsion effusion (3, 6), molecular beam (9, 10), and transpiration (11) methods. To evaluate ΔH<sub>f</sub><sup>0</sup>(LiF, g), we have used a trial and error variation of ΔH<sub>f</sub><sup>0</sup> and ΔH<sub>v</sub><sup>0</sup> for the monomer, dimer and trimer in order to obtain reasonable agreement with the observed total pressures, 997-1939 K. (3, 7, 8, 9, 10). Using, as guidelines, these total pressures and the equilibrium data for dimer and trimer (see these tables), we adopt ΔH<sub>f</sub><sup>0</sup>(g) = 66.0, 69.57 and 79.73 and ΔH<sub>v</sub><sup>0</sup>(g) = 61.63, 60.83 and 66.62 kcal/mol for LiF, Li<sub>2</sub>F<sub>2</sub> and Li<sub>3</sub>F<sub>3</sub>, respectively. The adopted value ΔH<sub>f</sub><sup>0</sup> = 63.1 kcal/mol is in agreement with the reported values: 64.8 ± 2 (12), 63.6 ± 1 (6) and 63.0 ± 1.5 kcal/mol (8) at 1000 K.

A second and third law analysis of the total pressure data is given below. Monomer pressures for this analysis are obtained by deducing dimer and trimer pressures calculated from JANAF free energy functions and the adopted values of ΔH<sub>f</sub><sup>0</sup>(g) and ΔH<sub>v</sub><sup>0</sup>(g).

The vapor pressure data reported by Eisenstadt et al. (3, 10) are too low and so not consistent with the others and are not used for evaluation. The transpiration data of Sense and Stone (11) and Knudsen-effusion data of Evseev et al. (13) are not considered for analysis because of the complications involved in converting the reported apparent pressures to the real total pressures of the gaseous mixtures containing monomer, dimer and trimer.

Herzberg (14) and Gaydon (15) reported the dissociation energies (D<sub>0</sub>) of LiF(g) to be 5.6 and 5.95 ± 0.3 eV, respectively. Using these D<sub>0</sub> values, we derive ΔH<sub>f</sub><sup>0</sup>(LiF, g) as -95.9 and -80.9 ± 6.9 kcal/mol. By use of flame-photometric method, Page and Sugden (16) and Bulewicz et al. (17) gave D<sub>0</sub> = 141 and 136 ± 8 kcal/mol, yielding ΔH<sub>f</sub><sup>0</sup>(LiF, g) = -84.7 and -79.7 ± 8 kcal/mol.

† Data points are calculated from the given vapor pressure equation.  
\* Process I: LiF(g) = LiF(g); ΔH<sub>f</sub><sup>0</sup>(LiF, g) values are calculated based on the third law ΔH<sub>f</sub><sup>0</sup>(g).  
† Process II: LiF(g) = LiF(g); ΔH<sub>f</sub><sup>0</sup>(LiF, g) values are calculated based on the third law ΔH<sub>f</sub><sup>0</sup>(g).

The infrared spectrum of LiF(g) and microwave spectrum of Li<sub>2</sub>F<sub>2</sub> have been observed by Vidale (19), and Wharten and Klemperer (21), respectively. The reported vibrational and rotational constants for Li<sub>2</sub>F<sub>2</sub>(g) and Li<sub>3</sub>F<sub>3</sub>(g), are adopted and corrected to the average isotopic species. Veazey and Gordy (18) measured the rotational transitions of Li<sub>2</sub>F with a high resolution molecular-beam absorption spectrometer. By use of the electric resonance method of molecular beam spectroscopy, Braunstein and Trischka (22) observed the transitions between v = 0 and v = 1 vibrational states. The infrared spectrum of LiF(g) have also been measured by Vasilievskii and Baikov (20).

Table with 6 columns: Investigator, Temperature, Method, Process, Points, Drift. Rows include Wartenberg (1921), Ruff (1922), Pugh (1958)\*, Porter (1958), Cantor (1958)\*, Hildenbrand (1964)\*.

Heat Capacity and Entropy

The infrared spectrum of LiF(g) and microwave spectrum of Li<sub>2</sub>F<sub>2</sub> have been observed by Vidale (19), and Wharten and Klemperer (21), respectively. The reported vibrational and rotational constants for Li<sub>2</sub>F<sub>2</sub>(g) and Li<sub>3</sub>F<sub>3</sub>(g), are adopted and corrected to the average isotopic species. Veazey and Gordy (18) measured the rotational transitions of Li<sub>2</sub>F with a high resolution molecular-beam absorption spectrometer. By use of the electric resonance method of molecular beam spectroscopy, Braunstein and Trischka (22) observed the transitions between v = 0 and v = 1 vibrational states. The infrared spectrum of LiF(g) have also been measured by Vasilievskii and Baikov (20).

 Product of the Moments of Inertia:  $I_A I_B I_C = [4.21684 \times 10^{-116}] \text{ g.}^3 \text{ cm.}^6$   
 $\sigma = 1$

Heat of Formation.

The heat of formation ( $\Delta H^{\circ}_{f,298,15}$ ) for LiFO(g) was calculated from  $\Delta H^{\circ}_{f,298,15} = 139 \text{ kcal. mole}^{-1}$  for the reaction  $\text{LiFO(g)} = \text{Li(g)} + \text{F(g)} + \text{O(g)}$  where the value of  $\Delta H^{\circ}_{f,298,15}$  was estimated to be the sum of the P-O and Li-O bond energies. The values of the P-O and Li-O bond energies were obtained from those in  $\text{P}_2\text{O(g)}$  and  $\text{Li}_2\text{O(g)}$  molecules, respectively.

Heat Capacity and Entropy.

The P-O and Li-O bond distances were assumed to be the same as those in  $\text{P}_2\text{O(g)}$  and  $\text{Li}_2\text{O(g)}$  molecules, respectively. The P-O-Li bond angle and vibrational frequencies were estimated by comparison with the corresponding values for the same oxide molecules. The three principal moments of inertia are:  $I_A = 5.1543 \times 10^{-35}$ ,  $I_B = 1.2729 \times 10^{-35}$  and  $I_C = 6.4272 \times 10^{-35} \text{ g. cm.}^2$

The equilibrium constants for the decomposition of MgF(g) into Mg(g), MgF<sub>2</sub>(c) and MgF<sub>2</sub>(g) were determined by T. C. Ehlert, Ph.D. Thesis, University of Wisconsin, 1963. Using this data, the heats of decomposition are evaluated by both the third and second law methods. The results are presented in the table below. The equilibrium constants for the reaction  $AlF_3(g) + 2Mg(g) \rightarrow AlF(g) + 2MgF(g)$  were also reported by T. C. Ehlert, loc. cit. The heat of reaction is calculated by the third and second law methods, respectively. The dissociation energy ( $D_0^\circ$ ) of MgF(g) was reported to be  $3.2 \pm 0.7$  and  $4.2$  eV by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, and G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., 1950, respectively. The corresponding values of  $\Delta H_f^{298.15}$  for MgF(g) are derived. The results are also listed in the table. The value of  $\Delta H_f^{298.15}$  for MgF(g) adopted is the average of the first two  $\Delta H_f^{298.15}$  values.

A. G. Gaydon

Chemical Reaction  
 $2MgF(g) = Mg(g) + MgF_2(g)$   
 $2MgF(g) = Mg(g) + MgF_2(c)$   
 $AlF_3(g) + 2Mg(g) = AlF(g) + 2MgF(g)$   
 $MgF(g) = Mg(g) + F(g)$

Third Law Value  
Second Law Value  
 $-34.76 \pm 0.74$   
 $-70 \pm 19$   
 $-126.66 \pm 0.80$   
 $-92 \pm 21$   
 $18.66 \pm 0.40$   
 $2.7 \pm 3.2$   
 $D_0^\circ = 4.2$  eV  
 $D_0^\circ = 3.2 \pm 0.7$  eV

Based on  $\Delta H_f^{298.15}$  value by the third law method.  
All the molecular constants are taken from G. Herzberg, loc. cit., except  $\alpha_e$  which is estimated.

NITROGEN MONOFLUORIDE (NF)

(IDEAL GAS)

MOL. WT. = 33.0051

FN

Ground State Configuration ( $\frac{1}{2}^{\pm}$ )  
 $S_{298.15}^{\circ} = 51.427$  cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 $\Delta H_f^{\circ} = 59.5 \pm 8$  kcal. mole  
 $\Delta H_f^{\circ} = 59.5 \pm 8$  kcal. mole

Electronic Levels and Quantum Weight

$$\frac{E_i, \text{ cm.}^{-1}}{0} \frac{g_i}{5}$$

$$\psi_0^{\circ} \chi_0 = [12.175] \quad \sigma = 1$$

$$B_0 = [-.923] \text{ cm.}^{-1} \quad r_0 = [1.51 \text{ \AA}]$$

Heat of Formation.

The heat of formation was obtained by taking an average of two estimates of the dissociation energy of NF. The first estimate of 5.15 e.v. (72.4 kcal./mole) was obtained from W. C. Fricke, T. R. Pasmore and D. M. Rossler Discussion Faraday Soc. 53, 201 - 11 (1953). The second estimate of 70.4 kcal./mole was obtained by taking one-half the dissociation energy of NF<sub>2</sub> (g) calculated from JANAF values. The  $\Delta H_f^{\circ}$  298.15 for NF (g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal./mole.

Heat Capacity and Entropy.

The  $\chi_0^{\circ}$  value was obtained from infrared studies of D. E. Milligan and M. E. Jacox, J. Chem. Phys. 40, 2461 (1964). The  $r_0$  value was estimated from Duggeheimer's relation for single bonded molecules. [K. M. Duggeheimer, Proc. Phys. Soc. (London), 58, 456 (1946)] The anharmonicity constant  $x_0$  was estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The  $\chi_0^{\circ}$  value was then calculated using the Morse potential function;  $B_0$  was determined from the bond length. The ground state configuration was assumed to be the same as that in NFR. The principal moment of inertia is 3.05247 x 10<sup>-39</sup> g. cm.<sup>2</sup>

Heat of Formation

For the reaction 2N(O)(g) + F<sub>2</sub>(g) → 2ONF(g), H. S. Johnston and H. J. Bertin, J. Am. Chem. Soc. 81, 6402 (1959), report ΔH<sub>f</sub><sup>o</sup> 298.15 = -74.8 ± 0.8 kcal., determined calorimetrically. This yields -15.7 ± 0.4 kcal. mole<sup>-1</sup> for ΔH<sub>f</sub><sup>o</sup> 298.15.

Heat Capacity and Entropy

C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 135 (1952), report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum.

Point Group C<sub>2v</sub>  
 $\Delta H_f^0 = -24.8 \pm 5 \text{ kcal. mole}^{-1}$   
 $\Delta H_f^{298.15} = -26.0 \pm 5 \text{ kcal. mole}^{-1}$   
 Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

 N-O = 1.21 Å  
 Bond Angle: O-N-O = 129.5°  
 Product of the Moments of Inertia:  $I_A I_B I_C = 6.401698 \times 10^{-115} \text{ g.}^3 \text{ cm.}^6$   
 $\sigma = 2$

Heat of Formation.

The heat of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine (NO<sub>2</sub>(g) + 1/2 F<sub>2</sub>(g) = NO<sub>2</sub>F(g)) has been measured calorimetrically as -33.9 kcal. mole<sup>-1</sup> by J. D. Breazeale and R. O. MacJaren, "Thermochemistry of Oxygen-Fluorine Bonding" (Final Tech. Summary Report, Contract No. Nonr 3433(00), ARPA Order No. 184-62) United Technology Corporation, Sunnyvale, Calif., Mar. 1963. The heat of formation,  $\Delta H_f^{298} = -26.0 \text{ kcal. mole}^{-1}$ , for NO<sub>2</sub>F(g) was then derived. The values of  $\Delta H_f^{298} = -20 \pm 5$  and  $-19 \pm 2 \text{ kcal. mole}^{-1}$  were issued in their second and third quarterly tech. reports, and have been quoted in the literature by E. Tschukow-Roux, J. Phys. Chem. 65, 1636 (1962).

G. Heberington and P. L. Robinson, Special Publication No. 10, The Chem. Soc., London, 1957 quoted  $\Delta H_f^{298} = 26 \text{ kcal. mole}^{-1}$  (presumably it has a minus sign) for NO<sub>2</sub>F(g) which was derived from the heat of solution measured by Nichols and Robinson, a private communication to Hetherington and Robinson.

Heat Capacity and Entropy.

D. F. Smith and D. M. Magnuson, Phys. Rev. 67, 226(1952), have measured the moments of inertia from microwave spectrum of NO<sub>2</sub>F(g). In order to calculate the bond distances, given as N-F = 1.35 Å and N-O = 1.23 Å, the bond angle O-N-O was assumed to be 125°. The selected bond distances and angle were obtained from L. Clayton, G. Williams and T. Wætherly, J. Chem. Phys. 30, 1328 (1959). Clayton et al. assumed the bond angle O-N-O in NO<sub>2</sub>F(g) should be the same as that in NO<sub>2</sub>(g), and then calculated the bond distances N-F and N-O from Smith and Magnuson's data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by R. Dodd, J. Rolfe and L. Woodward, Trans. Faraday Soc. 52, 145 (1956).

The three principal moments of inertia are  $I_A = 6.3658 \times 10^{-39}$ ,  $I_B = 7.3383 \times 10^{-39}$  and  $I_C = 13.7041 \times 10^{-39} \text{ g. cm.}^2$

Bond Distances: O-N = 1.29 ± 0.05 Å N-O = 1.39 ± 0.05 Å O-F = 1.42 ± 0.05 Å

Bond Angle: O-N-O = 125° ± 5° F-O-N = 105° ± 5°

Angle between NO<sub>2</sub>F plane and O<sub>2</sub>NO' plane = 90°.

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 3.68637 X 10<sup>-114</sup> g.<sup>3</sup> cm.<sup>6</sup>

Heat of Formation.

The value, 2.5 ± 0.5 kcal. mole<sup>-1</sup>, for the heat of formation of FNO<sub>3</sub>(g) reported by A. Palm and M. Kilpatrick, *J. Chem. Phys.* **23**, 1562 (1955). Bond distances and angles were taken from L. Pauling and L. O. Brockway, *J. Am. Chem. Soc.* **59**, 13 (1937). The three principal moments of inertia are: 8.6598 X 10<sup>-39</sup>, 1.8572 X 10<sup>-38</sup>, and 2.3618 X 10<sup>-38</sup> g. cm.<sup>2</sup>. The possible existence of restricted internal rotation in the molecule was not considered. Thus the values of C<sub>p</sub> and S<sup>o</sup> calculated may be low.

Heat Capacity and Entropy.

Vibrational frequencies were estimated by comparison with those of HNO<sub>3</sub>(g) reported by A. Palm and M. Kilpatrick, *J. Chem. Phys.* **23**, 1562 (1955). Bond distances and angles were taken from L. Pauling and L. O. Brockway, *J. Am. Chem. Soc.* **59**, 13 (1937). The three principal moments of inertia are: 8.6598 X 10<sup>-39</sup>, 1.8572 X 10<sup>-38</sup>, and 2.3618 X 10<sup>-38</sup> g. cm.<sup>2</sup>. The possible existence of restricted internal rotation in the molecule was not considered. Thus the values of C<sub>p</sub> and S<sup>o</sup> calculated may be low.

FNO<sub>3</sub>

Sodium Fluoride (NaF)

(Crystal) GFW = 41.9882

GFW = 41.9882

$\Delta H_f^\circ = -136.95 \pm 0.2$  kcal/mol

$\Delta H_f^\circ_{298.15} = -137.52 \pm 0.2$  kcal/mol

$\Delta H_m^\circ = 7.97$  kcal/mol

$\Delta H_s^\circ_{298.15} = 88.1$  kcal/mol

$S^\circ_{298.15} = 12.24 \pm 0.02$  gibbs/mol

$T_m = 1269 \pm 2^\circ K$

Heat of Formation

The heats of solution and reaction of NaF(c) have been determined by many investigators. Incorporating their reported data with auxiliary  $\Delta H_f^\circ$  values (1, 2), we calculate the corresponding values of  $\Delta H_f^\circ$  (NaF, c). The results are presented in the table below. The adopted  $\Delta H_f^\circ$  (NaF, c) is  $-137.52 \pm 0.2$  kcal/mol.

| Investigator                   | Reaction* | Temperature, °K | Concentration NaF, mH <sub>2</sub> O | No. of determination | $\Delta H_f^\circ_{298}$ kcal/mol | $\Delta H_f^\circ_{998}$ kcal/mol |

\*A represents NaF(c); B, NaOH(200 H<sub>2</sub>O) + HF(200 H<sub>2</sub>O); C, NaF(401 H<sub>2</sub>O) + H<sub>2</sub>O(lat+0.1 H<sub>2</sub>O); D, NaCl(c) + 1/2 F<sub>2</sub>(g); E, NaCl(c) + HF(5.716 H<sub>2</sub>O) = NaF(c) + HCl(12.731 H<sub>2</sub>O); F, 4Na(c) + CF<sub>4</sub>(g) = 4NaF(c) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05 - 15°K and 54.01 - 295.86°K, were measured by Harrison et al. (10) and King (11), respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298°K which were derived from the enthalpy measurements, 406.1 - 1282.2°K, determined by O'Brien and Kelley (12). The Cp values above 1282.2°K are obtained by linear extrapolation. S<sub>998</sub> is calculated using the adopted low temperature heat capacities and S<sub>298</sub> = 0.555 eu.

Frank (13) commented that the temperature measurements of O'Brien and Kelley (12) seemed to be about 20°K high at 1000° with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Dittmars (14) have questioned this correction, since new enthalpy data for AlF<sub>3</sub> yielded Cp values in better agreement with the original Cp values of O'Brien and Kelley than with the corrected values of Frank. The  $\alpha + \beta$  transition of AlF<sub>3</sub>(c) was found in the range 723 - 8°K, while O'Brien and Kelley selected 727°K based on a point at 728.1°K in the  $\beta$  region and a point at 724.9°K in the pretransition region. Frank's correction yields an error of 9° at 727°K, yet the true error appears to be negligible (<2°) for AlF<sub>3</sub>(c). Based on the above reasoning and the comparison of the Cp curve of NaF(c) with those of NaCl(c), LiCl(c), and LiF(c) in the temperature range 300 - 1300°K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 61 - 190 and 198 - 273°K were also measured by Koref (15) and high temperature enthalpies at temperatures 288 - 1073 and 290 - 1287°K were reported by Krestovnikov and Karetnikov (16), and Lyashenko (17), respectively. They are not used for evaluation.

Melting Data

See the NaF(l) table for details.

Heat of Sublimation

$\Delta H_s^\circ$  is the difference between  $\Delta H_f^\circ$  for NaF(g) and NaF(c).

GFW = 41.9882

(LIQUID)

SODIUM FLUORIDE (NaF)

Sodium Fluoride (NaF)  
(Liquid)

S<sub>298.15</sub> = 17.559 gibbs/mol

ΔH<sub>f,298.15</sub><sup>o</sup> = -130.545 kcal/mol

T<sub>m</sub> = 1269 ± 2°K

ΔH<sub>m</sub><sup>o</sup> = 7.97 kcal/mol

ΔH<sub>f</sub><sup>o</sup>(to mixture) = 42.1 kcal/mol of NaF(ℓ)

T<sub>b</sub> = 2060°K

Heat of Formation

ΔH<sub>f,298</sub><sup>o</sup>(ℓ) is obtained from ΔH<sub>f,298</sub><sup>o</sup>(c) by adding ΔH<sub>m</sub><sup>o</sup> and the difference between H<sub>1269</sub><sup>o</sup> and H<sub>298</sub><sup>o</sup> for crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(ℓ) are derived from the enthalpy data, 1287.6 - 1746.5°K, determined by O'Brien and Kelley (1). A glass transition temperature is assumed at 900°K, i.e. the heat capacities below 900°K are taken from those for NaF(c). The Cp values above 1746.5°K are obtained by extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The value of T<sub>m</sub> has been reported as (°K): 1313 (2), 1285 (1), 1270 (3, 4, 5), 1269 (6), 1268 (7, 8, 9), 1267 (10, 11, 12), 1265 (13), 1263 (14), and 1253 (15). We select T<sub>m</sub> = 1269°K. The value 1285°K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved (17). The heat of melting is calculated as the difference between the adopted enthalpies for NaF(c) and NaF(ℓ) at 1269°K. Kelley (18) derived ΔH<sub>m,1265</sub> to be 5.87 - 8.43 kcal/mol, based on 13 sets of molten salts equilibrium data involving NaF. The value ΔH<sub>m,1285</sub> = 8.03 kcal/mol reported by O'Brien and Kelley is not used.

Vaporization Data

T<sub>b</sub> is the temperature at which the partial pressures of NaF(g) and Na<sub>2</sub>F<sub>2</sub>(g) in equilibrium with NaF(ℓ) equal one atmosphere. The vapor composition at T<sub>b</sub> is evaluated as NaF 84.81 and Na<sub>2</sub>F<sub>2</sub> 15.2%. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at T<sub>b</sub> is calculated to be 42.1 kcal/mol. Ruff et al. (16) measured the vapor pressure of NaF(ℓ) in the temperature range of 1899 - 1974°K and reported T<sub>b</sub> = 1978°K.

Electronic Levels and Quantum Weights

Table with columns for level index i, energy E\_i in cm^-1, and quantum weight g\_i

E\_0 = 536.10 ± 0.35 cm^-1

E\_1 = 0.4369 cm^-1

E\_2 = 0.00456 cm^-1

Heat of Formation

The total pressures of NaF(g) and NaF\_2(g), in equilibrium with NaF(c), at temperatures 1020 - 1974 K, have been determined by many investigators, using manometric (1, 2, 5), torsion-effusion (6, 8), Knudsen-effusion (3, 7), transpiration (4), and molecular-beam velocity-selector (9, 10) methods. In order to evaluate ΔH°(NaF, g), we have used a trial and error variation of ΔH° and ΔH°\* for the monomer and dimer such that the ΔH°\_298 values derived by the second and third law methods are in reasonable agreement.

Incorporating ΔH°\_298 = 68.1 and 72.7, and ΔH°\_298 = 61.12 and 58.75 kcal/mol for NaF and NaF\_2, respectively, with JANAF functions for NaF(c), NaF(g), and NaF\_2(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding heats of vaporization are evaluated by the second and third law methods. Using the third law ΔH°\_298 and ΔH°\_298 = -137.52 and -130.545 kcal/mol for NaF(c) and NaF(g), we obtain values of ΔH°\_298 for NaF(g). The results are presented in the table below. The ΔH°\_298 (NaF, g) value adopted is -69.42 kcal/mol.

The vapor pressure data reported by Miller and Kusch (3) and Eisenstadt et al. (10) are not consistent with the other sets and are not used for evaluation. Gaydon (11) and Herzberg (12) reported D° = 114.2 ± 6.9 (4.95 ± 0.3 eV) and ± 122.2 kcal/mol (5.3 eV), respectively. Using JANAF ΔH°\_298 values for Na(g) and F(g), we obtain ΔH°\_298 (NaF, g) = -70.5 ± 5.8 and -78.5 kcal/mol. Employing flame-photometric method, Bulewicz et al. (13) and Page and Sugden (14) derived D° = 121 ± 7 and 119 ± 120 kcal/mol for NaF(g), which lead to ΔH°\_298 (NaF, g) = -77.3 ± 7 and -75 to -76 kcal/mol.

Table with columns: Investigator, Temperature (K), Process, No. of Points, ΔH°\_298 (kcal/mol), Second Law, Third Law, and Drift (eu). Rows include Wartenberg-Schulz (1921), Ruff et al. (1922), Niwa (1938), Sense et al. (1957), Cantor-Blankenship (1958), Pugh-Barrow (1958), Porter-Schoonmaker (1958), Entner-Neckel (1967), and data points calculated from a given total pressure equation.

Heat Capacity and Entropy

Veazey and Gordy (15) have measured the rotational transitions of NaF in the millimeter- and sub-millimeter-wave region with a high-resolution molecular-beam absorption spectrometer. The derived values of ω\_e, ω\_e', B\_e, B\_e' and r\_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew (16) measured the transition between the J = 0 and J = 1 rotational levels of NaF\_2 in the three lowest vibrational states. Radio-frequency transitions for NaF\_2 have been observed by Hollowell et al. (19). Infrared spectra of NaF have been analyzed by Shelton and Pitzer (17), Ritchie and Lew (18), and Baikov and Vasilievskii (20). The molecular constants derived by the above authors are similar to the values adopted, except the value ω\_e = 550 cm^-1 (17) which is different from the value 536.1 cm^-1 reported by Veazey and Gordy (15).

w<sub>e</sub> = 1066 cm<sup>-1</sup>  
 B<sub>e</sub> = [1.148] cm<sup>-1</sup>  
 w<sub>e</sub>x<sub>e</sub> = [15] cm<sup>-1</sup>  
 α<sub>e</sub> = [0.020] cm<sup>-1</sup>  
 σ = 1  
 r<sub>e</sub> = [1.30] Å

Heat of Formation.

Several values have been proposed for the heat of formation of F0(g). V. H. Dibeler, R. M. Reese and J. L. Franklin, J. Chem. Phys. 27, 1296 (1957), obtained D<sub>0</sub>(F0, g) = 24 kcal from electron impact studies. However, theoretical estimates give D<sub>0</sub> values in the range 45 - 56 kcal. W. C. Price, T. R. Passmore and D. M. Roessler, Discussions Faraday Soc. 25, 207 (1963), estimated 52 kcal for D<sub>0</sub>(F0, g).

From a consideration of the central bond energies in FNP and HNH with that in HOOH, using all JANAP values of 101, 109 and 50 kcal, we predict the bond dissociation energy in F0-OF to be 46 ± 4 kcal, which yields D<sub>0</sub>(F0, g) = 51 ± 2 kcal. The average F-O bond dissociation energy in F<sub>2</sub>O(g) is 49.8 ± 0.5 kcal. Also, since there is one less antibonding electron in F0 than in F<sub>2</sub>, we should expect the F-O bond to be greater than that in F<sub>2</sub> (38 kcal). Thus a median value of D<sub>0</sub>(F0, g) = 51.4 ± 10 kcal is adopted here which leads to ΔH<sub>f</sub><sup>o</sup>(F0) = 26 kcal/mol.

Heat Capacity and Entropy.

The fundamental frequency is obtained by adding 2w<sub>e</sub>x<sub>e</sub> to the value reported by A. Arkell, R. R. Reinhard and L. P. Larson, J. Am. Chem. Soc. 87, 1016 (1965), from matrix isolation studies. The bond length was taken equal to that in the isoelectronic molecule O<sub>2</sub>(g). The value of w<sub>e</sub>x<sub>e</sub> was obtained from the Morse potential function and the assumed dissociation energy. The rotational constant α<sub>e</sub> was also estimated from the above parameters and the Morse potential curve. The 2Π ground state is that predicted by molecular orbital theory and the first excited state would also be 2Π. By analogy with the isoelectronic O<sub>2</sub>(g) states, the first excited level was estimated at 29000 cm<sup>-1</sup>.

Bond Distances: Ti-O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O-Ti-F = [180°]  $\sigma = 1$

Rotational Constant:  $B_0 = [0.1705] \text{ cm.}^{-1}$

Heat of Formation

$\Delta H_f^{\circ}$  was estimated as -103 kcal. mole<sup>-1</sup> by J. S. Oordon, AstroSystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963.  $\Delta H_f^{\circ}$  298.15 was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by J. S. Oordon, loc. cit. Principal moment was  $16.419 \times 10^{-39} \text{ g. cm.}^2$

FOTI

Monofluorine Dioxide (F<sub>2</sub>)  
(Ideal Gas)       $G^{\circ}F = 50.9972$

Bond Distance: O-O = 1.22 Å      O-P = 1.58 Å

Bond Angle: O-O-P = 109.5°

Product of the Moments of Inertia:  $I_A I_B I_C = 7.7504 \times 10^{-116}$  g<sup>3</sup>cm<sup>6</sup>

Heat of Formation.

The heat of formation for F<sub>2</sub>(g) is unavailable in the literature. Based on a kinetic study of the thermal decomposition of F<sub>2</sub>O<sub>2</sub>(g) reported by K. J. Schumacher and P. Friach, Z. physik. Chem. **B24**, 332 (1934), the enthalpy change for the reaction F<sub>2</sub>O<sub>2</sub>(g) = F(g) + O<sub>2</sub>F(g) was estimated to be +17.3 kcal/mol by J. B. Levy and B. K. Kaaley, J. Phys. Chem. **59**, 408 (1965), assuming that the activation energy for the reverse reaction is negligible. From this data the value of  $\Delta H_f^{\circ} 298.15$ (F<sub>2</sub>, g) was calculated as +3.2 kcal/mol, using  $\Delta H_f^{\circ} 298.15$  = +4.73 kcal/mol for F<sub>2</sub>O<sub>2</sub>(g) determined calorimetrically by A. D. Kirshenbaum, A. V. Grosse and J. G. Aston, J. Am. Chem. Soc. **81**, 6396 (1959).

Based on the assumption that the enthalpy change for the reaction F<sub>2</sub>O<sub>2</sub>(g) = F(g) + O<sub>2</sub>F(g) is 16.5 kcal/mol, which is half of the enthalpy change for the reaction F<sub>2</sub>O<sub>2</sub>(g) = 2F(g) + O<sub>2</sub>(g), the heat of formation ( $\Delta H_f^{\circ} 298.15$ ) for F<sub>2</sub>(g) was derived as +2.4 kcal/mol.

The value of  $\Delta H_f^{\circ} 298.15$ (F<sub>2</sub>, g) adopted is  $3 \pm 5$  kcal/mol.

Heat Capacity and Entropy.

The vibrational frequencies for F<sub>2</sub>O<sub>2</sub>(g) were assumed to be the same as those obtained from matrix isolation by P. N. Noble and G. C. Pimentel, J. Chem. Phys. **44**, 3641 (1966). These authors have observed two more frequencies for isotopically substituted F<sub>2</sub>O<sub>2</sub> and combined them with those observed by R. D. Spratley, J. J. Turner and G. C. Pimentel, J. Chem. Phys. **44**, 2063 (1966), and performed a normal coordinate analysis. The results confirm the fact that the bond distances and angles in F<sub>2</sub>O<sub>2</sub> are essentially the same as those reported for F<sub>2</sub>O<sub>2</sub>(g) by R. H. Jackson, J. Chem. Soc., 4585 (1962). The same molecular structure for F<sub>2</sub>O<sub>2</sub> was also deduced from electron spin resonance and electron paramagnetic resonance data reported by R. W. Fessenden and R. H. Schuler, J. Chem. Phys. **44**, 434 (1966) and P. H. Kasal and A. D. Kirshenbaum, J. Am. Chem. Soc. **87**, 3069 (1965), respectively. Hence this molecular structure was adopted. Two vibrational frequencies,  $\nu_1$  and  $\nu_3$ , for F<sub>2</sub>O<sub>2</sub> molecule were also observed by A. Arkell, J. Am. Chem. Soc. **57**, 4057 (1935).

The three principal moments of inertia are:  $I_A = 1.1103 \times 10^{-39}$ ,  $I_B = 7.9182 \times 10^{-39}$  and  $I_C = 8.9285 \times 10^{-39}$  g cm<sup>2</sup>.

Dec. 31, 1960; Sept. 30, 1962

Phosphorus Monofluoride (PF) (Ideal Gas)

Mol. Wt. = 49.975

ΔH<sub>f</sub><sup>0</sup> 298.16 = -14 ± 3 kcal. mole<sup>-1</sup>

S<sup>0</sup> 298.15 = 53.7 cal. deg.<sup>-1</sup> mole<sup>-1</sup>

Ground State Configuration  $\sum$

Electronic Level and Multiplicity

$$\frac{\epsilon_1}{\epsilon_2} = \frac{0}{3}$$

ω<sub>e</sub> = 846.75 cm.<sup>-1</sup> ω<sub>e</sub>x<sub>e</sub> = 4.489 cm.<sup>-1</sup> B<sub>e</sub> = 0.5665 cm.<sup>-1</sup>

d<sub>e</sub> = 0.00456 cm.<sup>-1</sup> r<sub>e</sub> = 1.590 Å σ = 1

Heat of Formation. ΔH<sub>f</sub><sup>0</sup> 298.15 was derived from a D<sub>0</sub> calculated with spectroscopic constants reported by A. E. Douglas and M. Prackowiak, Can. J. Phys. 40, 832 (1962). The D<sub>0</sub> value was calculated using the dissociation and spectroscopic relations given by O. Herzberg in "Spectra of Diatomic Molecules", D. van Nostrand Co., N. Y., 2nd Ed. (1950) pages 93 and 100. If the PF molecule dissociates to the ground state atoms, F(3s<sup>2</sup>2p<sup>2</sup>) + F(2s<sup>2</sup>2p<sup>2</sup>), the corresponding ΔH<sub>f</sub><sup>0</sup> 298.15 is -14 ± 3 kcal. mole<sup>-1</sup>. If the dissociation is to an excited F(2p<sup>1</sup>/2) atom was assumed to obtain the selected ΔH<sub>f</sub><sup>0</sup> 298.15 = -14 ± 3 kcal. mole<sup>-1</sup>.

The heat of formation was estimated to be -17 kcal. mole<sup>-1</sup> by J. S. Gordon, "Thermodynamic Data for Combustion Products", January, 1960, Thiokol Chemical Corp. This estimate when changed from white(X) to red(V) phosphorus reference state (-13 kcal. mole<sup>-1</sup>) agrees within uncertainty limits with the derived ΔH<sub>f</sub><sup>0</sup> 298.15 values.

Heat Capacity and Entropy. The molecular constants were reported by Douglas and Prackowiak (loc. cit.). They photographed and analyzed the electronic spectra of PF in the emission spectrum of a discharge through a mixture of PF<sub>3</sub> and He.

PHOSPHORUS SULFIDE FLUORIDE (PSF) (Ideal Gas)

Mol. Wt. = 82.041

ΔH<sub>f</sub><sup>0</sup> 298.15 = [57 ± 15] kcal. mole<sup>-1</sup>

S<sub>298.15</sub><sup>0</sup> = [66.35 ± 3] cal. deg.<sup>-1</sup> mole<sup>-1</sup>

Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

ω cm.<sup>-1</sup>  
[940] (1)  
[740] (1)  
[400] (1)

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [7.999 X 10<sup>-11</sup>]<sup>3</sup>

σ = 1

Heat of Formation. The ΔH<sub>f</sub><sup>0</sup> 298.15 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. This estimated ΔH<sub>f</sub><sup>0</sup> 298.15 was corrected for the change in the reference state of phosphorus from white α to red V.

Heat Capacity and Entropy. The vibrational frequencies were estimated by comparison with the corresponding frequencies of PF<sub>3</sub>(g), PS(g), and P<sub>2</sub>(g). The vibrational levels of P<sub>2</sub>(g) in turn were estimated by J. S. Gordon, Thokol Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products," January, 1960. The entropy was estimated by C. B. Henderson and R. S. Scheffee (loc. cit.). The product of the moment of inertia was derived from the estimated entropy.

Lead Monofluoride (PbF) (Ideal Gas) Mol. Wt. = 226.21

Lead Monofluoride (PbF) (Ideal Gas)

Mol. Wt. = 226.21  
 $\Delta H_f^\circ 298.15 = -8.0 \pm 8.2$  kcal. mole<sup>-1</sup>  
 $S_{298.15}^\circ = 59.627$  cal. deg<sup>-1</sup> mole<sup>-1</sup>  
 Ground State Configuration  $^2\Pi$

Electronic Levels and Multiplicities

| $\epsilon$ , cm <sup>-1</sup> | $E_1$ |
|-------------------------------|-------|
| 0                             | 2     |
| 8266                          | 2     |

$\omega_e = 507.2$  cm<sup>-1</sup>     $\omega_e x_e = 2.30$  cm<sup>-1</sup>     $\sigma = 1$   
 $B_e = [0.2397]$  cm<sup>-1</sup>     $\alpha_e = [0.0017]$  cm<sup>-1</sup>

Heat of Formation.  $\Delta H_f^\circ 298.15$  was calculated from the dissociation energy of PbF(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration,  $\epsilon$ ,  $\omega_e$ , and  $\omega_e x_e$  were given by G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950.  $B_e$  and  $\alpha_e$  were estimated by J. S. Gordon, AstroSystems, Inc., private communication, May, 1962.

## Silicon Monofluoride (SiF)

(Ideal Gas) GFW = 47.0844

Ground State Configuration  $2^1\Pi$  $\Delta H_f^\circ = -5.0 \pm 3$  kcal/mol $S_{298.15}^\circ = 53.937 \pm 0.01$  gibbs/mol $\Delta H_f^\circ = -4.6 \pm 3$  kcal/mol

## Electronic Levels and Quantum Weights

| State           | $\epsilon_i$ , cm <sup>-1</sup> | $g_i$ |
|-----------------|---------------------------------|-------|

 $\omega_e x_e = 4.74 \pm 0.03$  cm<sup>-1</sup>  $\sigma = 1$  $B_e = 0.58138$  cm<sup>-1</sup>  $r_e = 1.6008$  Å

## Heat of Formation

Ehler and Margrave (1) have studied mass-spectrometrically the reaction  $Si(g) + SiF_2(g) \rightarrow 2SiF(g)$  by monitoring the intensities of the  $Si^+$ ,  $SiF^+$  and  $SiF_2^+$  ions in an equilibrium system containing  $CaF_2$  and Si. The ionization cross-sections are assumed to cancel so that equilibrium constants can be obtained directly from the ion intensities. We have analysed the above data using present JANAF functions and obtain  $\Delta H_f^\circ = 23.5 \pm 3$  kcal by the third law technique with a drift of  $-0.8 \pm 1.1$  eu, the second law value is  $23.9 \pm 7$  kcal. We adopt the third law value which with JANAF auxiliary data gives  $\Delta H_f^\circ(SiF, g) = -4.6 \pm 3$  kcal/mol.

Johns and Barrow (2) have selected  $D_0^0(SiF, g) = 125 \pm 10$  kcal/mol, from Birge-Sponer extrapolations of several states, this gives  $\Delta H_f^\circ = 0.1 \pm 10$  kcal/mol in good agreement with the adopted value.

## Heat Capacity and Entropy

The molecular constants of the various electronic levels have been documented by Johns and Barrow (2), Verma (3), Barrow et al. (4), and Appelblad et al. (5). The approximation involving the use of the ground state constants for all electronic levels is used since it introduces negligible error in this molecule.

 $\alpha_e = [ 0.0016 ]$  cm<sup>-1</sup>  
 $\sigma = 1$   
 $r_e = [ 1.95 ]$  Å

Heat of Formation

The heat of formation,  $\Delta H_{298}^{\circ}$ , of TiF(g) is calculated from the dissociation energy,  $D_0^{\circ}$ . The dissociation energy is estimated as 148 ± 6 kcal/mol using the corresponding quantity for TiF<sub>2</sub>(g) and the relation  $D(\text{HF})/D(\text{MF}_2) = 0.46 \pm 0.02$  which Zmbov and Hargrave (1) found held for other mono- and di-fluorides.

Heat Capacity and Entropy

The vibrational frequency,  $\omega_e$ , and anharmonic vibrational term,  $\omega_e x_e$ , are estimated from those of the alkali and mercury monohalides. The interatomic distance,  $r_e$ , is estimated from those of TiCl(g), TiF<sub>2</sub>(g) and TiF<sub>3</sub>(g).  $B_e$  is calculated from  $r_e$ . The ground state term and electronic levels are estimated from the ground state multiplet of Ti<sup>3+</sup> (2).

w<sub>e</sub>x<sub>e</sub> = [2.9] cm<sup>-1</sup>      σ = 1  
 w<sub>e</sub> = [728.5] cm<sup>-1</sup>      w<sub>e</sub>x<sub>e</sub> = [0.0015] cm<sup>-1</sup>      r<sub>e</sub> = [1.83] Å  
 B<sub>e</sub> = [0.2923] cm<sup>-1</sup>

Heat of Formation

The heat of formation, ΔH<sub>f°298</sub>(WF<sub>2</sub>g) = 92.3 kcal/mol, is calculated from the bond dissociation energy D<sub>0</sub><sup>0</sup><sub>298</sub>(WF) = 130 ± 15 kcal/mol. This value of D<sub>0</sub><sup>0</sup><sub>298</sub> is estimated to be slightly higher than the average bond dissociation energy of WF<sub>2</sub>(g) by analogy with the WCl<sub>x</sub> system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WF<sub>6</sub>(g). This distance is then used with Ougsenheimer's relation to calculate the fundamental vibrational frequency, w<sub>e</sub> (K. M. Ougsenheimer, Proc. Phys. Soc. 58, 456 (1946)). The anharmonicity correction x<sub>e</sub> is estimated roughly by assuming x<sub>e</sub> = w<sub>e</sub>/4(D<sub>0</sub> + 0.5 w<sub>e</sub>) = 0.0042. The rotational constant B<sub>e</sub> is calculated from the estimated bond distance. The value of w<sub>e</sub> is calculated from the Morse potential function. The moment of inertia is 9.575 × 10<sup>-39</sup> g cm<sup>2</sup>.

The ground state configuration, low lying electronic levels and their quantum weights are estimated based on the tentative molecular orbital diagram for W<sub>2</sub> given by N. Weltner, Jr., and D. McLeod, Jr., J. Chem. Phys. 42, 882 (1965). Using this scheme, we obtain the ground state configuration as n<sub>g</sub><sup>2</sup>d<sub>g</sub><sup>4</sup>, which yields a <sup>2</sup>Δ ground state. The first excited state is assumed to have n<sub>g</sub><sup>2</sup>d<sub>g</sub><sup>4</sup> which yields a <sup>2</sup>Σ state. Higher levels are considered to be formed by transition to n\* antibonding orbitals, and by analogy with W<sub>2</sub> these are assumed to lie in the 15000 cm<sup>-1</sup> region. The degeneracy of these levels is estimated roughly from the large number of possible configurations.

FW

Ground State Configuration [  $4f^2$  ]

$\Delta H_f^0 = [20.0 \pm 5]$  kcal/mol

$\Delta H_f^0 = [20.0 \pm 5]$  kcal/mol

$\Delta H_f^0 = [20.0 \pm 5]$  kcal/mol

$S_{298.15}^0 = [58 \pm 2]$  gibbs/mol

$S_{298.15}^0 = [58 \pm 2]$  gibbs/mol

$S_{298.15}^0 = [58 \pm 2]$  gibbs/mol

$\omega_e X_e = [4.0] \text{cm}^{-1}$

$\omega_e = [0.29699] \text{cm}^{-1}$

$r_e = [1.90] \text{A}$

Heat of Formation

Based on [D(ZrF)/D(ZrF<sub>2</sub>)] = 0.46, as indicated by recent work on the fluorides of Groups II and IV elements (1, 2, 3, 4, 5), and D<sub>0</sub>(ZrF<sub>2</sub>) = 318.1 kcal/mol, the D<sub>0</sub>(ZrF) is calculated as 146.3 kcal/mol. Using  $\Delta H_f^0(\text{Zr}, g) = 147.99$ ,  $\Delta H_f^0(\text{F}, g) = 18.36$ , and D<sub>0</sub>(ZrF, g) = 146.3 kcal/mol, we derive  $\Delta H_f^0(\text{ZrF}, g) = 20.0$  or  $\Delta H_f^0(\text{ZrF}, g) = 19.8 \pm 5$  kcal/mol which is adopted. The  $\Delta H_f^0$  for ZrF(g) was evaluated as approximately 16 ± 5 kcal/mol by Hurd and Hildenbrand (8), employing different D(ZrF<sub>2</sub>) value. Their value is in agreement with the adopted one, within the assigned uncertainty.

Heat Capacity and Entropy

The ground state configuration is taken from the ground state multiplet of Zr\* (6). The electronic levels are estimated as three times higher than those of TlF(g) and the quantum weights are assumed to be the same.  $\omega_e$  is taken to be approximately the same as the Zr-F stretching frequency  $\nu_1$  for ZrF<sub>4</sub>(g).  $B_e$  is calculated from the formula  $B_e = (2.798076 \times 10^{-39} / I_e)$  where  $I_e = \mu r_e^2$ ,  $\mu$  = reduced mass of ZrF(g),  $r_e = 1.90$  A which is estimated from those of ZrF<sub>4</sub>, CF<sub>4</sub>, Cl<sub>2</sub> and other related gaseous molecules.  $a_e$  is derived from  $B_e$ ,  $\omega_e$ , and  $\omega_e X_e$  (estimated), according to the method suggested by Herzberg (7). The moment of inertia is  $9.473 \times 10^{-39}$  c.m.

ΔH<sub>f</sub><sup>0</sup> = -168.6 ± 10 kcal. mole<sup>-1</sup>  
 ΔH<sub>f</sub><sup>0</sup> 298.15 = -168.7 ± 10 kcal. mole<sup>-1</sup>  
 ΔH<sub>m</sub><sup>0</sup> = [12.4] kcal. mole<sup>-1</sup>  
 ΔH<sub>f</sub><sup>0</sup> 298.15 = 75.6 ± 2.0 kcal. mole<sup>-1</sup>

S<sub>298.15</sub><sup>0</sup> = 20.79 ± 0.04 cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 T<sub>m</sub> = [1373]°K.

Heat of Formation.

The equilibrium pressures for the reaction FeF<sub>2</sub>(c) + H<sub>2</sub>(g) = Fe(c) + 2HF(g) have been measured by K. Jelinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928) at 773, 873 and 973°K. The enthalpy change (ΔH<sub>f</sub><sup>0</sup> 298.15) of the reaction was evaluated by the second and third law methods to be 27.19 and 39.08 kcal. mole<sup>-1</sup>, respectively. Based on the third law value of ΔH<sub>f</sub><sup>0</sup> 298.15, the ΔH<sub>f</sub><sup>0</sup> 298.15 (FeF<sub>2</sub>, c) was calculated to be -168.7 ± 10 kcal. mole<sup>-1</sup>. The drift in the third law values of ΔH<sub>f</sub><sup>0</sup> 298.15 was evaluated to be 13.3 ± 1.8 e.u.

Heat Capacity and Entropy.

The low temperature (11.33 - 307.50°K.) heat capacities were determined by E. Catalano and J. W. Stout, J. Chem. Phys. 23, 1803 (1955). The heat capacities above 307°K. were estimated by comparison with those of FeCl<sub>2</sub>(c), MgCl<sub>2</sub>(c) and MgF<sub>2</sub>(c). The value of S<sub>298.15</sub><sup>0</sup> was obtained from E. Catalano and J. W. Stout, loc. cit., in which a sharp maximum C<sub>p</sub> of 17.8 cal. deg.<sup>-1</sup> mole<sup>-1</sup> at 78.35°K. was reported. The S<sub>298.15</sub><sup>0</sup> value was based on S<sub>15</sub><sup>0</sup> = 0.039 e.u.

Melting Data.

T<sub>m</sub> was estimated as 1100°C based on the data reported by W. Biltz and E. Rehlf, Z. anorg. allgem. Chem. 155, 363 (1927). The value of ΔH<sub>m</sub><sup>0</sup> was calculated using ΔS<sub>m</sub><sup>0</sup> = 9 e.u. which was assumed to be the same as the corresponding value for MgF<sub>2</sub>(c).

Heat of Sublimation.

The value of ΔH<sub>g</sub><sup>0</sup> 298.15 was obtained from J. L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William Marsh Rice University, Houston, Texas. See FeF<sub>2</sub>(g) table for details.

$\Delta H_f^{\circ} 298.15 = [-161.229] \text{ kcal. mole}^{-1}$

$\Delta H_m^{\circ} = [12.4] \text{ kcal. mole}^{-1}$

$\Delta H_v^{\circ} = [53.64] \text{ kcal. mole}^{-1}$

$S_{298.15}^{\circ} = [21.951] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_m = [1373]^{\circ}\text{K.}$

$T_b = [2110]^{\circ}\text{K.}$

Heat of Formation.

The value of  $\Delta H_f^{\circ} 298.15$  (FeF<sub>2</sub>, l) was obtained from  $\Delta H_f^{\circ} 298.15$  (FeF<sub>2</sub>, c) by adding  $\Delta H_m^{\circ}$  and the difference between  $H_m^{\circ} - H_l^{\circ} 298.15$  for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeF<sub>2</sub>(l) was estimated by comparison with those for FeCl<sub>2</sub>(c), MgCl<sub>2</sub>(c), MgF<sub>2</sub>(c), CaCl<sub>2</sub>(c) and CaF<sub>2</sub>(c). The  $C_p$ (FeF<sub>2</sub>, l) value was assumed to be constant in the temperature range, 298.15 - 3000°K. The entropy ( $S_{298.15}^{\circ}$ ) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See the FeF<sub>2</sub>(c) table for details.

Vaporization Data.

$T_b$  is calculated as the temperature at which the free energy change of the reaction FeF<sub>2</sub>(l) = FeF<sub>2</sub>(g) approaches zero. The difference between  $\Delta H_f^{\circ}$  for FeF<sub>2</sub>(l) and FeF<sub>2</sub>(g) at  $T_b$  is  $\Delta H_v^{\circ}$ .

Point Group [D<sub>2h</sub>h]  
 $\Delta H_f^{\circ} 0 = -92.9 \pm 3.4$  kcal. mole<sup>-1</sup>  
 $\Delta H_f^{\circ} 298.15 = -93.1 \pm 3.4$  kcal. mole<sup>-1</sup>

Bond Distances Fe-F = [1.8] Å  
 Bond Angle F-Fe-F = [180]°  
 Rotational Constant: B<sub>0</sub> = 0.13692 cm.<sup>-1</sup>  
 $\sigma = 2$

Heat of Formation.

The rate of sublimation of FeF<sub>2</sub>(c) was measured between 965 and 1149°K. by the Knudsen technique employing the high temperature magnetic mass spectrometer by John L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William March Rice University, Houston, Texas. The only vapor species of importance is FeF<sub>2</sub>(g). From the vapor pressure data the third law heat of sublimation ( $\Delta H_f^{\circ} 298.15$ ) was reported as  $75.6 \pm 2.0$  kcal. mole<sup>-1</sup>. The sum of the values of  $\Delta H_f^{\circ} 298.15$  and  $\Delta H_f^{\circ} 298.15$  for FeF<sub>2</sub>(c) is the  $\Delta H_f^{\circ} 298.15$  (FeF<sub>2</sub>(g)).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The Fe-F bond distance was estimated from that in FeF<sub>2</sub>(c) reported by W. H. Burr, Acta Cryst. 11, 468 (1958). The vibrational frequencies,  $\lambda_j$  and  $\lambda_{j'}$ , were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The values of  $\lambda_j$ ,  $\lambda_{j'}$ , electronic levels and quantum weights were estimated by comparison with those for FeCl<sub>2</sub>(g). See FeCl<sub>2</sub>(g) table for details. The moment of inertia is  $2.04404 \times 10^{-39}$  g. cm.<sup>2</sup>

| T, °K. | C <sub>v</sub> | S°     | $-(F^{\circ} - H_{298}^{\circ})/T$ | H° - H <sub>298}^{\circ}</sub> | $\Delta H_f^{\circ}$ | $\Delta F_f^{\circ}$ | Log K <sub>p</sub> |

F<sub>2</sub>HK

MOL. WT. = 78.108

(CRYSTAL)

POTASSIUM BIFLUORIDE (KHF<sub>2</sub>)

ΔH<sub>f</sub><sup>o</sup> 0 = -220.74 ± 0.35 kcal. mole<sup>-1</sup>  
 ΔH<sub>f</sub><sup>o</sup> 298.15 = -221.90 ± 0.35 kcal. mole<sup>-1</sup>  
 ΔH<sub>t</sub><sup>o</sup> = 2.671 ± 0.01 kcal. mole<sup>-1</sup>  
 ΔH<sub>m</sub><sup>o</sup> = 1.582 ± 0.003 kcal. mole<sup>-1</sup>

S° 298.15 = 25.0 ± 0.1 cal. deg. mole<sup>-1</sup>  
 T<sub>t</sub> = 469.8°K.  
 T<sub>m</sub> = 511.8°K.

Heat of Formation.

The heat of formation was obtained from the enthalpy of decomposition measurements of M. L. Davis and E. F. Westrum, J. Phys. Chem. 65, 338 (1961) who gave ΔH<sub>d</sub> 500 = 18.82 ± 0.05 kcal. mole<sup>-1</sup> and the heats of formation of HF(g) and KF(c) from the JANAF Tables, in conjunction with enthalpies at 500°K. from E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949). A third law analysis of the decomposition vapor pressure by Westrum and Pitzer, loc. cit. did not agree with enthalpy of decomposition measurements, giving ΔH<sub>d</sub> 298 = 21.274 ± 0.2 kcal. mole<sup>-1</sup> as compared to Davis and Westrum's value at 298°K. of 21.505 ± 0.05 kcal. mole<sup>-1</sup>. As the liquid vapor pressure data, which were not used, have a large trend in the third law heat of vaporization with temperature it was suspected that the pressure measurements were in error. This is borne out somewhat by a small trend in the values over the solid in the range 480-500°K.

Heat Capacity and Entropy.

Westrum and Pitzer, loc. cit., have measured the heat capacity from 16°K. to the melting point. Their data has been used to calculate the entropy at 298° using a T<sup>3</sup> law extrapolation below 16°K., giving S<sub>16</sub> = 0.103 e.u.

Melting and Transition Data.

The temperatures of melting and transition and the heats of melting and transition were taken from Davis and Westrum, loc. cit.

$\Delta H_f^o$  298.15 = 32.3 cal. deg. mole<sup>-1</sup>  
 $\Delta H_m^o$  = -218.24 ± 0.35 kcal. mole<sup>-1</sup>  
 $\Delta H_m^o$  = 1.582 ± 0.003 kcal. mole<sup>-1</sup>

T<sub>m</sub> = 511.8°K.  
 T<sub>decomp.</sub> = [751]°K.

Heat of Formation.

This was calculated from the heat of formation of the crystal, the heat of melting and K<sub>511.8</sub><sup>H</sup> 298.15 for crystal and liquid.

Heat Capacity and Entropy.

The entropy was determined from that of the crystal in a manner analogous to the heat of formation. The heat capacity just above the melting point was measured by E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949) and was assumed constant above the melting point. A glass type transition was assumed at 341°K. below which the heat capacity is that of the solid.

Melting.

See table for crystal.

Decomposition.

The temperature of decomposition was estimated from the free energy cross-over and is the point where the HF(g) reaches 1 atm. It should be noted that the vapor pressures over the liquid of Westrum and Pitzer, loc. cit. are apparently in error, being high by roughly 10%. A 3rd law analysis at each vapor pressure point gave an almost constant heat of reaction in the solid region but in the liquid region the value changed abruptly with temperature. The only factors which were variable were the pressure and the liquid heat capacity, a trial change of 20% in the heat capacity produced an almost negligible change in the heat of reaction. Thus the vapor pressures over the liquid appear to be in error and the decomposition point of 702°K. obtained by extrapolating to 1 atmosphere is also in error.

December 31, 1960.

Difluorosilane (SiH<sub>2</sub>F<sub>2</sub>) (Ideal Gas)

Mol. wt. = 68.106  
 ΔH<sub>f</sub><sup>o</sup> 298.15 = [-1.94 ± 15] kcal. mole<sup>-1</sup>  
 S<sub>298.15</sub><sup>o</sup> = [62.576] cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 Point Group C<sub>2v</sub>  
 Ground State Multiplicity = 1

**Vibrational Frequencies and Degeneracies**

Moments of Inertia: I<sub>A</sub> = 3.40 X 10<sup>-39</sup> g. cm.<sup>2</sup>    I<sub>C</sub> = 13.16 X 10<sup>-39</sup> g. cm.<sup>2</sup>  
 I<sub>B</sub> = 10.76 X 10<sup>-39</sup> g. cm.<sup>2</sup>

Heat of Formation. ΔH<sub>f</sub><sup>o</sup> 298.15 was estimated in C. B. Henderson and R. S. Scheffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were taken from G. Janz and Y. Mikawa, Bull. Chem. Soc. Japan 34, 1485 (1961). Moments of inertia were found in Henderson and Scheffer, op. cit.

F<sub>2</sub>H<sub>2</sub>Si

MERCURY DIFLUORIDE (HgF<sub>2</sub>)

(Crystal)

Mol. Wt. = 238.61

 $\Delta H_f^{\circ} 298.15 = [-101.0 \pm 10.0] \text{ kcal. mole}^{-1}$  $S_{298.15}^{\circ} = [27.800 \pm 2.0] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$  $T_m = 918^{\circ}\text{K}$  $\Delta H_m = [5.5 \pm 1.0] \text{ kcal. mole}^{-1}$ 

Heat of Formation. Estimated by comparison of the mercurous and mercuric halides.

Heat Capacity and Entropy. The heat capacity was assumed to be a linear function of temperature and was estimated to be 7.0 cal. deg.<sup>-1</sup> per atom at the melting point. The entropy was estimated by comparison with the other mercuric and mercurous halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1950).Melting.  $T_m$  was given by O. Ruff and G. Bahlau, Ber. 51, 1752 (1918). The heat of melting was from L. Brewer, paper 7, National Nuclear Energy Series 1-133 "Thermodynamics" McGraw-Hill (1950).

F<sub>2</sub>Hg

MERCURY DIFLUORIDE (HgF<sub>2</sub>) (Liquid)

Mol. Wt. = 238.61  
 ΔH<sub>f</sub><sup>o</sup> 298.15 = [-96.772 ± 10.0] kcal. mole<sup>-1</sup>  
 S<sub>298.15</sub><sup>o</sup> = [32.083 ± 2.0] cal. deg<sup>-1</sup> mole<sup>-1</sup>  
 T<sub>m</sub> = 918°K  
 ΔH<sub>m</sub> = [5.5 ± 1.0] kcal. mole<sup>-1</sup>  
 T<sub>b</sub> = 920°K  
 ΔH<sub>v</sub> = [22.0 ± 4.0] kcal. mole<sup>-1</sup>

Heat of Formation. Calculated from ΔH<sub>f</sub><sup>o</sup> (crystal).

Heat Capacity and Entropy. C<sub>p</sub> was estimated by analogy with mercuric iodide and bromide. A glass type transition was assumed at 613°K below which the heat capacity was that of HgF<sub>2</sub>(crystal). The entropy was calculated from S°(crystal) and the estimated ΔH<sub>m</sub> and heat capacities of crystal and liquid.

Fusion and Vaporization. T<sub>m</sub> was given by O. Ruff and G. Bahlson, Ber. SI, 1752 (1918). T<sub>b</sub>, ΔH<sub>m</sub>, and ΔH<sub>v</sub> were all taken from L. Brewer, paper 7, National Nuclear Energy Series 4-199 "Thermodynamics" McGraw-Hill (1950).

Heat of Formation  
 Estimated by comparison with the other gaseous mercuric halides and with the crystalline mercurous mercuric fluorides.

Heat Capacity and Entropy

Vibrational constants were estimated by analogy with the other mercuric halides and the mercurous halides. The bond length was estimated by assuming the mercurous bond to be 0.965 of the mercuric bond by analogy with the mercury chlorides.

MERCURY MONOFLUORIDE, DIMERIC (Hg<sub>2</sub>F<sub>2</sub>) (crystal)

Mol. Wt. = 439.22  
 $\Delta H_f^{298.15} = [-116.0 \pm 3.0]$  kcal. mole<sup>-1</sup>  
 $S_f^{298.15} = [38.4 \pm 2.0]$  cal. deg<sup>-1</sup> mole<sup>-1</sup>  
 $T_{sub} = [91.8]^\circ K$  (decomp.)

Heat of Formation. A value of  $\Delta H_f^{298.15}$  was obtained from the cell measurements of G. G. Koerber and T. de Vries, J. Amer. Chem. Soc. 71, 5000 (1949). This was combined with  $\Delta S_f^\circ$  from the estimated entropy.

Heat Capacity and Entropy. The heat capacity was estimated by comparison with mercurous chloride. The entropy was estimated by comparison with the other mercurous and mercuric halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Sublimation. Sublimation with decomposition to Hg(l) and HgF<sub>2</sub>(g) was assumed at 94.9°K from the free energy change of the reaction.

Potassium Difluoride Uninegative Ion (KF<sub>2</sub><sup>-</sup>)  
(Ideal Gas) GFW = 77.09935

POTASSIUM DIFLUORIDE UNINEGATIVE ION (KF<sub>2</sub><sup>-</sup>) (IDEAL GAS)

GFW = 77.09935

Point Group [D<sub>2h</sub>]  
S<sub>298.15</sub> = {63 ± 2} gibbs/mol  
Ground State Quantum Weight = {1}

F<sub>2</sub>K

ΔHf<sub>0</sub><sup>o</sup> = -165 ± 10 kcal/mol  
ΔHf<sub>298.15</sub><sup>o</sup> = -166 ± 10 kcal/mol

Bond Distance: K-F = {2.17} Å  
Bond Angle: F-K-F = {180}°

σ = 2

Rotational Constant: B<sub>0</sub> = {0.094} cm<sup>-1</sup>

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of calculation are described as follows. In a manner analogous to LiF<sub>2</sub>(g), the first reaction considered is KF(g) + F<sup>-</sup>(g) = KF<sub>2</sub><sup>-</sup>(g) and the ΔH<sub>f,298</sub><sup>o</sup>(KF<sub>2</sub><sup>-</sup>, g) is evaluated to be between 0 and 1/2(-50) = -25 kcal/mol (see LiF<sub>2</sub><sup>-</sup>(g) table for details), yielding from JANAF Tables.

The second reaction employed for estimation is K<sub>2</sub>F<sub>2</sub>(g) = KF<sub>2</sub><sup>-</sup>(g) + K<sup>+</sup>(g). The enthalpy change of this reaction is calculated as ΔH<sub>r,298</sub><sup>o</sup> = 1/2(50.0) + 138.8 = 166.8 kcal/mol where the KF<sub>2</sub><sup>-</sup> ion is considered to be converted from KF<sub>2</sub>(g) by breaking one of the two dimer association bonds (ΔH<sub>r,298</sub><sup>o</sup> = 50.0 kcal/mol) and one K<sup>+</sup>-F<sup>-</sup> ionic bond (ΔH<sub>r,298</sub><sup>o</sup> = 138.8 kcal/mol). Using ΔH<sub>f,298</sub><sup>o</sup> = -206.2 and 122.9 kcal/mol for K<sub>2</sub>F<sub>2</sub>(g) and K<sup>+</sup>(g), we obtain the heat of formation for KF<sub>2</sub><sup>-</sup>(g) as -165 kcal/mol.

Based on an assumption that the electron affinity of KF<sub>2</sub><sup>-</sup>(g) is similar to that of F (see LiF<sub>2</sub><sup>-</sup>(g) table for details), i.e. ΔHr<sub>0</sub><sup>o</sup> = 81.5 kcal/mol (1) for the reaction KF<sub>2</sub><sup>-</sup>(g) = KF<sub>2</sub>(g) + e<sup>-</sup>(g), we derive ΔHf<sub>298</sub><sup>o</sup>(KF<sub>2</sub><sup>-</sup>, g) = -167.7 kcal/mol. The ΔH<sub>f,298</sub><sup>o</sup> for KF<sub>2</sub>(g) is calculated as -84.2 kcal/mol from the value ΔH<sub>r,298</sub><sup>o</sup> = 143.3 kcal/mol for the reaction K<sub>2</sub>F<sub>2</sub>(g) = KF<sub>2</sub>(g) + K(g) where the ΔH<sub>r,298</sub><sup>o</sup> value is calculated as the sum of two enthalpy changes, i.e. half of the heat of dimer dissociation into two monomers or 1/2(50.0) = 25.0 kcal/mol, and the heat of dissociation of KF(g) or 118.3 kcal/mol. The value of ΔH<sub>f</sub><sup>o</sup> for KF<sub>2</sub><sup>-</sup>(g) is tentatively adopted as -166 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion given by Walsh (2) that molecules with not more than 16 valency electrons are linear in their ground states. The K-F bond distance is taken to be the same as that of KF(g) reported by Veazey and Gordy (3). The vibrational frequencies are estimated from the vibrational frequency of KF(g) using the method suggested by Herzberg (4). The moment of inertia is 2.971 × 10<sup>-38</sup> g cm<sup>2</sup>. The enthalpy at 0°K is -3.293 kcal/mol.

Bond Distance: K-F = 2.2 Å  
Bond Angles: F-K-F = [90°] K-F-K = [90°]  
Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [2.240 × 10<sup>-113</sup>] g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

The equilibrium constants (K<sub>c</sub>) for the reaction K<sub>2</sub>F<sub>2</sub>(g) = 2KF(g), in the temperature range 974-1052°K, were determined by Eisenstadt, Rothberg, and Kusch (2). Although the reported absolute values of the vapor pressures of KF(g) are not adopted for evaluation, the reported K<sub>c</sub> values are used to calculate the enthalpy change (ΔH<sub>f,298</sub>) for the above reaction. The second law and third law values of ΔH<sub>f,298</sub> are derived as 51.0 ± 1.6 and 50.0 kcal/mol, respectively. Based on the third law ΔH<sub>f,298</sub> and ΔH<sub>f,298</sub>(KF, g) = -76.1 kcal/mol, we obtain ΔH<sub>f,298</sub> = -206.2 kcal/mol for K<sub>2</sub>F<sub>2</sub>(g) which is tentatively adopted.

Heat Capacity and Enthalpy

The molecular structure and K-F bond distance were determined by Akishin and Rambidi (2), using electron diffraction with sector microphotometry. The bond angles are estimated by comparison with other alkali halide dimers. The vibrational frequencies are taken from Berkowitz (3) which were calculated based on an ionic model. The three principal moments of inertia are: I<sub>A</sub> = 3.1423 × 10<sup>-38</sup>, I<sub>B</sub> = 1.5267 × 10<sup>-38</sup>, and I<sub>C</sub> = 4.6690 × 10<sup>-38</sup> g cm<sup>2</sup>.

Rotational Constant:  $B_0 = [0.180] \text{ cm}^{-2}$

Heat of Formation

Due to lack of thermal data, the heat of formation for  $LiF_2^-(g)$  is arbitrarily selected from the following three estimated values. For the reaction (1)  $LiF(g) + F^-(g) = LiF_2^-(g)$ , we expect the enthalpy change would be between 0 to -31 kcal/mol. Comparison with the other molecules like  $CO_2$ ,  $BO_2$ ,  $B_2O_2$ , etc. having 16 valence electrons leads us to assume that the isoelectronic molecule  $LiF_2^-$  should also be quite stable. This indicates that reaction (1) is favorable or  $\Delta H_f^{298}$  is negative. However, the Li-F bond strength is expected to be weaker than half of the two ionic bonds between  $Li^+$  and  $F^-$  in  $Li_2F_2$  molecule (see  $Li_2F_2(g)$  table for the molecular structure). In other words, the  $\Delta H_f^{298}$  value of reaction (1) is less negative than half of the heat of dimerization (-62.4 kcal/mol). Incorporating  $\Delta H_f^{298} = 0$  and -31 kcal/mol, respectively, for reaction (1), with  $\Delta H_f^{298} = -81.45$  and -62.2 kcal/mol for  $LiF(g)$  and  $F^-(g)$ , we derived the corresponding values for  $\Delta H_f^{298}(LiF_2^-(g))$  as -144 and -175 kcal/mol, which are the upper and lower limits.

The electron affinities of Li and F atoms are reported as 0.7 and 3.448 eV, respectively, by Beckett and Cassidy (1). From this data we estimate that the electron affinity of  $LiF_2^-(g)$  should be closer to that of F atom than to that of Li. Assuming  $\Delta H_f^{298}$  = electron affinity of F atom = 83.5 kcal/mol for the reaction  $LiF_2^-(g) = LiF(g) + F^-(g)$ , we obtain the heat of formation for  $LiF_2^-(g)$  as -177.3 kcal/mol. The  $\Delta H_f^{298}(LiF_2^-(g))$  used for calculation is derived from an estimated  $\Delta H_f^{298} = 169.9$  kcal/mol for the decomposition of LiF dimer or  $Li_2F_2(g) = LiF_2^-(g) + Li(g)$  as the sum of two enthalpy changes, namely, half of the heat of dissociation of the dimer and the heat of dissociation of the monomer.

The third estimated value for the heat of formation of  $LiF_2^-(g)$  is calculated as follows. Based on the two heats of reaction, i.e.  $\Delta H_f^{298} = 62.4$  kcal/mol for  $Li_2F_2(g) = LiF(g)$ , and  $\Delta H_f^{298} = 183.5$  kcal/mol for  $LiF(g) = Li^+(g) + F^-(g)$ , we assume the enthalpy change of the reaction  $Li_2F_2(g) = LiF_2^-(g) + Li^+(g) + Li^+(g) + Li^+(g) + Li^+(g)$ . In other words, we consider the  $LiF_2^-(g)$  molecule is formed by breaking half of the dimer dissociation bonds and one monomer dissociation bond to produce two ions. Using  $\Delta H_f^{298} = -225.33$  and  $164.24$  kcal/mol for  $Li_2F_2(g)$  and  $Li^+(g)$ , we evaluate  $\Delta H_f^{298}(LiF_2^-(g)) = -174.9$  kcal/mol.

From the above three estimated values, we tentatively choose  $\Delta H_f^{298}(LiF_2^-(g))$  as -170  $\pm$  15 kcal/mol.

Heat Capacity and Entropy

According to A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953), molecules with not more than 16 valence electrons are linear in their ground states. Since  $LiF_2^-(g)$  has 16 valence electrons, we assume its molecular structure is linear. The Li-F bond distance is estimated by comparison with that of  $LiF(g)$  reported by Wharton et al. (2). The vibrational frequencies are estimated from those of the isoelectronic gaseous molecules,  $CO_2$  and  $BeF_2$ . The moment of inertia is  $1.555 \times 10^{-38} \text{ g cm}^2$ . The enthalpy at 0°K is -2.653 kcal/mol.

Heat of Formation

The heat of formation (ΔH<sub>f</sub><sup>298</sup>) is calculated based on the adopted value ΔH<sub>f</sub><sup>0</sup> = 61.4 kcal/mol for the reaction Li<sub>2</sub>F<sub>2</sub>(g) = 2LiF(g) which is consistent with the literature values listed in the table below. Due to lack of knowledge of the fragmentation patterns, the relative ionization cross sections of the ionic species formed in the mass spectrometer and the molecular constants of the LiF polymers, the evaluation of equilibrium constants used to calculate ΔH<sub>f</sub><sup>0</sup> involves considerable uncertainty. In order to solve this problem more research work seems necessary.

Investigator

1. Berkowitz et al. (1962) mass spectrometry with a double-oven apparatus
  2. Buchler and Stauffer (1966) mass spectrometry with a two-piece Ni Knudsen cell
  3. Eisenstadt et al. (1958) molecular-beam velocity-selector
  4. Hildenbrand et al. (1964) torsion effusion
  5. Akishin et al. (1959) mass spectrometry with a double effusion chamber
  6. Porter and Schoonmaker (1958) mass spectrometry with a Mo Knudsen cell
- \* derived from reported vapor pressures of LiF(g) and Li<sub>2</sub>F<sub>2</sub>(g) at 1073°K.

Experimental Method

1. mass spectrometry with a double-oven apparatus
2. mass spectrometry with a two-piece Ni Knudsen cell
3. molecular-beam velocity-selector
4. torsion effusion
5. mass spectrometry with a double effusion chamber
6. mass spectrometry with a Mo Knudsen cell

Heat Capacity and Entropy

The molecular structure of Li<sub>2</sub>F<sub>2</sub>(g) was determined as D<sub>2h</sub> by Buchler et al. (12), using electric deflection and mass spectrometric detection. Akishin and Rambidi (7) studied the structure of Li<sub>2</sub>F<sub>2</sub>(g) by electron deflection with sector microphotometry and assigned the bond distances of Li-F and F-F which are adopted. Evidence for a matrix stabilized linear structure of Li<sub>2</sub>F<sub>2</sub> has been obtained by extending the spectral measurements for matrix isolated lithium fluoride into the far infrared region by Redington (8) and Abramovitz et al. (9).

Klemperer and Norris (10) observed two infrared-active vibrational frequencies, 640 and 460 cm<sup>-1</sup>, and assigned them as ν<sub>5</sub>(B<sub>2u</sub>) and ν<sub>6</sub>(B<sub>2u</sub>). The infrared absorption spectra of lithium fluoride monomer and dimer isolated in solid inert gas matrices were investigated by Linevsky (11), Snelson and Pitzer (13), and Schlick and Schnepf (14). Redington (8) obtained infrared spectra of LiF species suspended in solid Ne, O<sub>2</sub>, CO, and CH<sub>4</sub> at liquid-helium temperature. The observed solvent shifts for LiF and Li<sub>2</sub>F<sub>2</sub> spectra exhibit several regularities. The vibrational frequencies used for calculation are those reported by Snelson (15) who re-examined the spectrum of LiF species over the range 200 - 4000 cm<sup>-1</sup>, using sample purity of 99.3%. The saturated vapor was isolated at 90°C and the superheated unsaturated vapor at 1200°C. A variety of deposition rates and matrix dilutions was tried. Based on the frequencies assigned to the isotopic species, the vibrational frequencies of the natural isotopic Li<sub>2</sub>F<sub>2</sub>(g) are calculated. It appears that the vibrational frequencies calculated on the basis of the potential function for an ionic model by Berkowitz (16) are too low.

The three principal moments of inertia are: I<sub>A</sub> = 2.3970 × 10<sup>-39</sup>, I<sub>B</sub> = 1.1244 × 10<sup>-38</sup> and I<sub>C</sub> = 1.3641 × 10<sup>-38</sup> g<sup>2</sup>cm<sup>2</sup>.

MAGNESIUM DIFLUORIDE (MgF<sub>2</sub>)

(CRYSTAL)

F<sub>2</sub>Mg

MOL. WT. = 62.3088

$$\Delta H_f^o = -267.8 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^o 298.15 = -268.7 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^o = 13.90 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^o 298.15 = 95.5 \pm 1.5 \text{ kcal. mole}^{-1}$$

$$S_{298.15} = 13.68 \pm 0.07 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1536^\circ \text{K.}$$

## Heat of Formation.

The value of  $\Delta H_f^o 298.15$  for MgF<sub>2</sub>(c) was obtained from E. Rudzitis and W. N. Hubbard, Argonne National Laboratory, Argonne, Illinois, private communication, dated June 18, 1964. This value was determined by fluorine bomb calorimetry which is considered as comparatively the best method available at the present time. The heats of reaction involving MgF<sub>2</sub>(c) were measured by many early investigators. However, the  $\Delta H_f^o 298.15$ (MgF<sub>2</sub>, c) values derived are in reasonable agreement. The results are presented as follows.

| Investigator         | Chemical Reaction   | $\Delta H_f^o 298.15$ , kcal. mole <sup>-1</sup> | $\Delta H_f^o 298.15$ , kcal. mole <sup>-1</sup> |
|----------------------|---|--|--|

(1) L. Domange, Ann. chim. phys., 7(11)225 (1937). The  $\Delta H_f^o$  value was calculated by the third law method.

(2) H. V. Wartenberg, Z. anorg. allgem. Chem. 249, 100 (1942).

(3) D. R. Torgeson and T. G. Saha, J. Am. Chem. Soc. 70, 2156 (1948).

(4) P. Gross, C. Hayman and D. L. Levi, Trans. Faraday Soc. 50, 477 (1954).

## Heat Capacity and Entropy.

The low temperature heat capacities, 54.22-296.5°K., were measured by S. Todd, J. Am. Chem. Soc. 71, 4115 (1949). The high temperature heat capacities, 298-1536°K., were obtained from the heat content measurements determined by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). These two sets of data were joined smoothly at 298°K. S<sub>298.15</sub> was obtained from Cp data reported by S. S. Todd, loc. cit., using S<sub>21</sub> (extrap.) = 0.537 cal. deg.<sup>-1</sup> mole<sup>-1</sup>.

## Melting Data.

T<sub>m</sub> and  $\Delta H_m^o$  were taken from B. F. Naylor, loc. cit.

## Heat of Sublimation.

The vapor pressure of MgF<sub>2</sub>(c) has been measured by seven investigators. Using the reported data, the respective  $\Delta H_m^o 298.15$  for MgF<sub>2</sub>(c) were calculated (see MgF<sub>2</sub>(g) table for detail). The adopted value was selected to be 95.5 ± 1.5 kcal. mole<sup>-1</sup>.

$\Delta H_f^o$  298.15 = 15.290 cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 $\Delta H_m^o$  = 13.90 kcal. mole<sup>-1</sup>  
 $\Delta H_v^o$  = [63.48] kcal. mole<sup>-1</sup>  
 $T_m$  = 1536°K.  
 $T_b$  = [2499]°K.

Heat of Formation.  
 $\Delta H_f^o$  298.15(l) was obtained from  $\Delta H_f^o$  298.15(c) by adding  $\Delta H_m^o$  and the difference between  $H_m^o$  -  $H_m^o$  298.15 for crystal and liquid.

Heat Capacity and Entropy.  
 Heat capacity (1691-1800°K.) was reported by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). The same value was used for other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.  
 $T_m$  and  $\Delta H_m^o$  were obtained from B. F. Naylor, loc. cit.

Vaporization Data.  
 $T_b$  was obtained from equilibrium calculation between the species MgF<sub>2</sub>(l), MgF<sub>2</sub>(g), and (MgF<sub>2</sub>)<sub>2</sub>(g), i.e., the temperature at which the sum of the partial pressures of MgF<sub>2</sub>(g) and (MgF<sub>2</sub>)<sub>2</sub>(g) equals one atmosphere. From the difference between the heats of formation of MgF<sub>2</sub>(l) and MgF<sub>2</sub>(g) at the boiling point, the heat of vaporization was calculated. At the boiling point the amount of dimeric species is negligible in comparison with that of the monomeric species.

## Heat of Formation.

The vapor pressure of MgF<sub>2</sub>(g) over MgF<sub>2</sub>(c) and MgF<sub>2</sub>(l) has been measured by many investigators using different methods. Based on the reported vapor pressure data, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

| Investigator                        | Temperature, °K. | Method* | ΔH <sub>f</sub> <sup>o</sup> 298.15 <sup>o</sup> , kcal. mole <sup>-1</sup> |                 | Drift        |

2 K. O. Guenther, Oiletech. Ber. **31**, 9 (1959).

3 R. R. Hammer, Ph.D. Thesis, University of California, 1961. Also see R. R. Hammer and J. A. Peek, J. Am. Ceram. Soc. **47**, 284 (1964).

4 J. Berkowitz and J. R. Marquart, J. Chem. Phys. **37**, 1853 (1962). The value, 91.38 kcal. mole<sup>-1</sup>, was converted from the reported value 88 kcal. mole<sup>-1</sup> at 1330°K.

5 M. A. Greenbaum, R. G. Ho, R. Wong and M. Farber, J. Phys. Chem. **68**, 985 (1964), whose reported ΔH<sub>f</sub><sup>o</sup> 298.15 value was derived using different values of free energy functions for MgF<sub>2</sub>(c) and MgF<sub>2</sub>(g) from those used here.

6 The value was derived from data obtained from D. L. Hildenbrand, et al., J. Am. Chem. Soc. **79**, 5786 (1957), Experimental Paper, October 1957. The last ΔH<sub>f</sub><sup>o</sup> value was given by D. L. Hildenbrand, private communication, March 19, 1961. The rest were reported by D. L. Hildenbrand, loc. cit., p. 2289, Fifth Quarterly Technical Report, Sept. 15, 1963. These values were summarized by D. L. Hildenbrand, et al., J. Chem. Phys. **40**, 2882 (1964).

7 J. W. Green, G. D. Blue, T. C. Ehler and J. L. Margrave, J. Chem. Phys. **41**, 2245 (1964).

When vapor pressure data were determined above melting point, 1536°K., the heat of sublimation was derived from the heat of vaporization obtained incorporating heat of melting. All data were carefully examined and some inconsistent vapor pressure points were discarded. The heat value of ΔH<sub>f</sub><sup>o</sup> 298.15 for MgF<sub>2</sub>(c) was selected as 95.5 ± 1.5 kcal. mole<sup>-1</sup>. The heat of formation for MgF<sub>2</sub>(g) was calculated from the heats of formation and sublimation for MgF<sub>2</sub>(c).

## Heat Capacity and Entropy.

The molecular structure of MgF<sub>2</sub>(g) has been reported to be linear by A. Büchler, J. L. Steuffer and W. Klemperer, Interim Technical Report No. 7, June 30, 1964, A. D. Little, Inc., and bent by M. J. Linevsky, First Quarterly Report, Nov. 1, 1963 - Jan. 31, 1964, General Electric Company. An intensive investigation of the matrix spectrum of MgF<sub>2</sub>(g) has been made recently by D. E. Mann and O. V. Calder, National Bureau of Standards Report 8919, July 1, 1965. The final results were presented by D. E. Mann at the ICRP Working Group on Thermochemistry meeting on Mar. 17, 1966. The vibrational frequencies, bent structure and bond angle were confirmed by use of isotopic substitution, and were adopted here. The Mg-F bond distance was reported by P. A. Akishin, V. P. Spiridonov, O. A. Sobolev and V. A. Naumov, Zh. Fiz. Khim. **31**, 461 (1957). The three principal moments of inertia are: I<sub>A</sub> = 5.1680 × 10<sup>-40</sup>, I<sub>B</sub> = 1.8442 × 10<sup>-38</sup> and I<sub>C</sub> = 1.8959 × 10<sup>-38</sup> g. cm<sup>2</sup>.

NITROGEN DIFLUORIDE (NF<sub>2</sub>)

Point Group = C<sub>2v</sub>
S<sub>298.15</sub> = 59.72 cal. mole<sup>-1</sup> deg.<sup>-1</sup>
Ground State Quantum Weight = 2

(IDEAL GAS)

MOL. WT. = 52.008
ΔH<sub>f</sub><sup>o</sup> = 10.7 ± 2.0 kcal. mole<sup>-1</sup>
ΔH<sub>f</sub><sup>o</sup> 298.15 = 10.1 ± 2.0 kcal. mole<sup>-1</sup>

Vibrational Frequencies and Degeneracies

Table with 2 columns: ν, cm.<sup>-1</sup> and degeneracy values (1074, 573, 931).

Bond Distance: N-F = 1.37 Å

Bond Angle: F-N-F = 104.2°

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 7.6097 X 10<sup>-116</sup> gm.<sup>3</sup> cm.<sup>6</sup>

Heat of Formation.

C. B. Colburn and P. A. Johnson, J. Chem. Phys. 35, 1869 (1960), report the study of the dissociation reaction N<sub>2</sub>F<sub>4</sub>(g) = 2NF<sub>2</sub>(l) by two independent methods: (a) measurement of the pressure variation with temperature at constant volume and (b) a spectrophotometric method based on the temperature dependence of the ultraviolet absorption of the NF<sub>2</sub> radical. The authors give a more detailed account of their data in J. Am. Chem. Soc. 83, 3043 (1961). The contents of these articles indicate that 2NF<sub>2</sub>(l) should read 2NF<sub>2</sub>(g) in the above reaction. The first method gave a value of 19.85 kcal. mole<sup>-1</sup> for the heat of dissociation in the temperature range 373 to 423°K. which corresponds to 19.87 kcal. mole<sup>-1</sup> at 298°K. From their ΔH and ΔS data, ΔP was calculated and used in a third law evaluation of the heat of dissociation. The ΔH<sub>298</sub> so calculated showed an increasing trend with increasing temperature; the average value was 22.87 kcal. mole<sup>-1</sup> which is not in agreement with their value of 19.87 kcal. mole<sup>-1</sup>. The spectrophotometric value of 21.7 kcal. mole<sup>-1</sup> at 298°K. was obtained from the integrated Van't Hoff equation.

L. H. Piette, F. A. Johnson, K. A. Boonen and C. B. Colburn, J. Chem. Phys. 35, 1481 (1961), studied the temperature dependence of the EPR spectrum of the NF<sub>2</sub> radical. They obtained a second law value of 19.3 kcal. mole<sup>-1</sup> for the heat of dissociation. This value, however, depends upon the degree of dissociation of N<sub>2</sub>F<sub>4</sub> which they calculated from the (dP/dT) measurements of Colburn and Johnson. Any error in the (dP/dT) measurements would manifest itself in like manner here.

H. E. Doornbos and B. R. Loy, J. Chem. Phys. 39, 2393 (1963), investigated the ESR spectrum of the N<sub>2</sub>F<sub>4</sub><sup>-</sup> NF<sub>2</sub> equilibrium from which they calculated a second law value of 19.8 kcal. mole<sup>-1</sup> for the heat of dissociation. They report that at 25°C. and 13 atm. N<sub>2</sub>F<sub>4</sub> is 0.022% dissociated in the vapor phase. A third law calculation using this datum and the relationship K<sub>p</sub> = (4α<sup>2</sup>/Δ - α<sup>2</sup>)P<sub>0</sub>, where α is the degree of dissociation of N<sub>2</sub>F<sub>4</sub> and P<sub>0</sub> is the total pressure, gave a heat of dissociation of 21.79 kcal. mole<sup>-1</sup> at 298°K.; this is not in agreement with their second law value.

J. T. Herron and V. H. Dibeler, J. Research Natl. Bur. Standards 65A, 405 (1961), report thermal dissociation data for N<sub>2</sub>F<sub>4</sub>. From their data they calculate a second law value of 21.5 kcal. mole<sup>-1</sup> for the heat of dissociation of N<sub>2</sub>F<sub>4</sub>. A second and third law evaluation of their data was performed in the Dow Thermal Laboratory. It was found that if the k factor, relating their measured ion abundances to partial pressures, was taken as 4.72 X 10<sup>-9</sup>, a third law value was obtained that showed slight scatter but no temperature dependence. Excluding those points that showed scatter, the third law heat of dissociation at 298°K. was 22.27 kcal. mole<sup>-1</sup>. A second law plot gave a heat value of 22.23 kcal. mole<sup>-1</sup> at an average temperature of 400°K. or 22.25 kcal. mole<sup>-1</sup> at 298°K. Those points that deviated from the chosen straight line in the second law plot showed corresponding deviations in the third law calculation. Those points lying on the second law slope gave a constant third law value.

The heat of dissociation for N<sub>2</sub>F<sub>4</sub>(g) = 2NF<sub>2</sub>(g) was taken to be 22.26 kcal. mole<sup>-1</sup>. Utilizing the heat of formation of N<sub>2</sub>F<sub>4</sub>(g) (see N<sub>2</sub>F<sub>4</sub> table), the heat of formation of the difluoramine radical becomes 10.1 ± 2.0 kcal. mole<sup>-1</sup>. All values for the heat of dissociation fall within the limits of error assigned to the heat of formation of NF<sub>2</sub>.

Heat Capacity and Entropy.

See table on tetrafluorohydrazine (N<sub>2</sub>F<sub>4</sub>) (ideal gas) for writeup.

Nitrogen Difluoride (NF<sub>2</sub>)

Mol. Wt. = 52.008

Table with columns: T, °K.; C<sub>p</sub>; S° - (F° - H<sub>298</sub>°)/T; H° - H<sub>298</sub>°; ΔH<sub>f</sub><sup>o</sup>; ΔF<sub>f</sub><sup>o</sup>; Log K<sub>p</sub>. Rows range from 100 to 6000 K.

 $\sigma = 2$

Heat of Formation.

The heat of formation was derived from the heat of reaction N<sub>2</sub>F<sub>2</sub>(g) + 8/5 NH<sub>3</sub>(g) = 2NH<sub>4</sub>F(c) + 4/3 N<sub>2</sub>(g) which was measured calorimetrically by G. T. Armstrong and S. Marantz<sup>1</sup>. There are two isomers, the trans and the active form of difluorodiazine. The heats of formation were determined to be 19.4 and 16.4 kcal. mole<sup>-1</sup> for the trans and the active isomers respectively. The active form of N<sub>2</sub>F<sub>2</sub> has been interpreted here as the cis isomer which will be discussed later. The heat of isomerization has also been reported as 3.0 kcal. mole<sup>-1</sup> by Armstrong and Marantz. The value,  $\Delta H_f^{\circ} 298$  (cis N<sub>2</sub>F<sub>2</sub>, g) = 16.4 kcal. mole<sup>-1</sup>, is adopted in the tabulation.

A. V. Pankratov et al.<sup>2</sup> have measured the enthalpy of reaction N<sub>2</sub>F<sub>2</sub>(g) + 3KI = 2KF + N<sub>2</sub> + KI<sub>3</sub> in acidic solution (pH = 3), and reported  $\Delta H_f^{\circ} 298$  (active N<sub>2</sub>F<sub>2</sub>, g) = 25.3 ± 2.0 kcal. mole<sup>-1</sup>.

The "heat of isomerization" has been reported as 27.5 ± 5.0 kcal. mole<sup>-1</sup> by C. B. Colburn et al.<sup>9</sup> The derivation of this value is unknown. The authors observed three values of the equilibrium constant for the isomerization reaction. Third law analysis of their data gives  $\Delta H_f^{\circ} 298 = 2.52 \pm 0.05$  kcal. mole<sup>-1</sup> for the reaction cis N<sub>2</sub>F<sub>2</sub>(g) → trans N<sub>2</sub>F<sub>2</sub>(g) which is in good agreement with Armstrong and Sidway's data.

Heat Capacity and Entropy.

Although the infrared spectrum<sup>7,8</sup> of the active form of N<sub>2</sub>F<sub>2</sub>(g) has been interpreted as favoring the 1,1-difluorodiazine over the cis-configuration<sup>3,4</sup>, n.m.r.<sup>5</sup> and microwave studies definitely indicate the latter. The vibrational frequencies<sup>7</sup> previously assigned to the 1,1-difluorodiazine have been adopted here for the cis isomer. The selected bond distances and angle were taken from the isotopic nitrogen microwave studies<sup>6</sup>. The principal moments of inertia were: I<sub>A</sub> = 4.2438 X 10<sup>-39</sup>, I<sub>B</sub> = 10.5129 X 10<sup>-39</sup> and I<sub>C</sub> = 14.7567 X 10<sup>-39</sup> g. cm.<sup>2</sup>

See the trans N<sub>2</sub>F<sub>2</sub>(g) table for the comparison of the different physical properties between trans and cis isomers.

Heat of Formation.

G. T. Armstrong and S. Marantz, J. Chem. Phys. 39, 169 (1963) have measured calorimetrically the enthalpy of reaction N<sub>2</sub>F<sub>2</sub>(g) + 8/3 NH<sub>3</sub>(g) = 2NH<sub>4</sub>F(c) + 4/3 N<sub>2</sub>(g), and reported  $\Delta H_f^{298}$  (trans N<sub>2</sub>F<sub>2</sub>, g) = 19.4 ± 1.2 kcal. mole<sup>-1</sup> which is adopted in this tabulation.

Heat Capacity and Entropy.

The bond distances and bond angle were obtained from S. H. Bauer, J. Am. Chem. Soc. 69, 3104 (1947), by electron diffraction. The fundamental vibrational frequencies were obtained from R. H. Sanborn, J. Chem. Phys. 33, 1855 (1960) by infrared spectroscopy. The three principal moments of inertia are I<sub>A</sub> = 0.919 × 10<sup>-39</sup>, I<sub>B</sub> = 21.2433 × 10<sup>-39</sup> and I<sub>C</sub> = 22.1623 × 10<sup>-39</sup> g. cm.<sup>2</sup>

As pointed out by R. Ettinger, F. A. Johnson and C. B. Colburn, J. Chem. Phys. 34, 2187 (1961), the trans N<sub>2</sub>F<sub>2</sub> is the less active isomer which is different from the active isomer by its (1) vapor pressure (2) boiling point (3) heat of vaporization (4) critical temperature (5) melting point (6) mass spectral cracking pattern (7) NMR spectrum (8) infrared spectrum (9) heat of isomerization (10) reactivity with mercury and glass.

Heat of Formation

The heat of formation for NaF<sub>2</sub><sup>-</sup>(g) is estimated from three calculated values. The methods of calculation are described as follows. The first reaction we take into consideration is NaF(g) + F<sup>-</sup>(g) = NaF<sub>2</sub><sup>-</sup>(g). In a manner analogous to LiF<sub>2</sub><sup>-</sup>(g) molecule (see LiF<sub>2</sub><sup>-</sup> table for details), we assume NaF<sub>2</sub><sup>-</sup>(g) is stable and  $\Delta H_f^\circ$  for the reaction NaF(g) + F<sup>-</sup>(g) = NaF<sub>2</sub><sup>-</sup>(g) is somewhere between 0 to 1/2(-84) = -42 kcal/mol where the value -84 kcal/mol is the heat of dimerization. Based on  $\Delta H_f^\circ$  0 and -28 kcal/mol, respectively, with JANAF  $\Delta H_f^\circ$  values for the species involved, we obtain  $\Delta H_f^\circ$ (NaF<sub>2</sub><sup>-</sup>, g) = -132 and -164 kcal/mol as the upper and lower limits.

The heat of formation, calculated based on the reaction NaF<sub>2</sub><sup>-</sup>(g) = NaF<sub>2</sub>(g) + e<sup>-</sup>(g), is -165.8 kcal/mol, using  $\Delta H_f^\circ$  298 and  $\Delta H_f^\circ$  298 (NaF<sub>2</sub>, g) estimated as 83.6 and -82.3 kcal/mol, respectively. The  $\Delta H_f^\circ$  298 value is obtained from an assumption that the enthalpy change for removing an electron from NaF<sub>2</sub><sup>-</sup>(g) is comparable to that from F<sup>-</sup>(g). Due to the fact that the Na atom has smaller electronegativity (0.9) than that of the F atom (4.0), we expect that there is less possibility that the electron will associate with Na atom in the NaF<sub>2</sub><sup>-</sup> molecule. Therefore we adopt the electron affinity of F(g) reported by H. O. Pritchard, Chem. Rev. 53, 529 (1963), or  $\Delta H_f^\circ$  298 = 83.6 kcal/mol for the reaction F<sup>-</sup>(g) = F(g) + e<sup>-</sup>(g) as the  $\Delta H_f^\circ$  298 for NaF<sub>2</sub><sup>-</sup>(g) = NaF<sub>2</sub>(g) + e<sup>-</sup>(g). The value of  $\Delta H_f^\circ$  298 for NaF<sub>2</sub>(g) is calculated using the enthalpy change for the reaction NaF<sub>2</sub>(g) = NaF(g) + Na(g) as 145.8 kcal/mol which is derived from the sum of two enthalpy changes, namely, half of the  $\Delta H_f^\circ$  298 value for the dimer dissociation reaction Na<sub>2</sub>F<sub>2</sub>(g) = 2NaF(g), and the  $\Delta H_f^\circ$  298 for the monomer dissociation reaction NaF(g) = Na(g) + F(g).

Employing  $\Delta H_f^\circ$  298 = 63.5 kcal/mol for NaF<sub>2</sub>(g) and 153.0 kcal/mol for NaF(g) = Na<sup>+</sup>(g) + F<sup>-</sup>(g), we estimate  $\Delta H_f^\circ$  298 = 1/2(63.5) + 153.0 = 184.7 kcal/mol for the reaction NaF<sub>2</sub>(g) = Na<sup>+</sup>(g) + Na<sup>-</sup>(g), which leads to  $\Delta H_f^\circ$  298 = 163.4 kcal/mol for NaF<sub>2</sub><sup>-</sup>(g). For all calculations the  $\Delta H_f^\circ$  298 values of the chemical species involved are taken from JANAF Thermochemical Tables.

The value of  $\Delta H_f^\circ$  298 for NaF<sub>2</sub><sup>-</sup>(g) is tentatively adopted as -160 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion by A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953) that molecules with not more than 16 valence electrons are linear in their ground state. The Na-F bond distance is estimated by comparison with that of NaF(g) reported by S. E. Veazey and W. Gordy, Phys. Rev. 138, A1303 (1965). The vibrational frequencies are estimated from those for the isoelectronic molecule SiO<sub>2</sub>(g). The moment of inertia is 2.350 × 10<sup>-38</sup> gm<sup>2</sup>. The enthalpy at 0°K is -3.117 kcal/mol.

Bond Distance: Na-F = 2.02 Å  
 Bond Angle: Na-F-Na = [95°]  
 $\sigma = [4]$   
 Product of the Moments of Inertia:  $I_{A}I_{B}I_{C} = [5.613 \times 10^{-114}] \text{ g}^3 \text{ cm}^6$

Heat of Formation

Although the absolute values of the vapor pressure measurements are not used for evaluation, the ratios of the numbers of dimeric and monomeric NaF molecules that effuse from the oven at the temperatures 1115 - 1191°K determined by Eisenstadt, Rothberg, and Kusch (1) by use of the electron-beam velocity-selector method are used. Based on the reported equilibrium data we evaluate the enthalpy change of the reaction (A) Na<sub>2</sub>F<sub>2</sub>(g) = 2NaF(g) by the second and third law methods. The results are presented in the table below.

Porter and Schoonmaker (2) analyzed the vapor effusing from a Knudsen cell at 1121°K mass spectrometrically and derived the partial pressures of NaF(g) and Na<sub>2</sub>F<sub>2</sub>(g) at that temperature. Using these reported partial pressures we calculate, by the third law method, the value  $\Delta H_{298}^\circ = 64.1 \text{ kcal/mol}$  for reaction (A).

Sidorov et al. (3) studied the NaF - ZrF<sub>4</sub> system by the mass spectrometric method and derived the partial pressures of NaF(g) and Na<sub>2</sub>F<sub>2</sub>(g) as a function of composition and temperature. Employing the data points reported at 1074 and 1167°K we obtain the third law value  $\Delta H_{298}^\circ = 62.0 \pm 1.6 \text{ kcal/mol}$  for the same reaction.

The  $\Delta H_f^\circ$  (Na<sub>2</sub>F<sub>2</sub>, g) is calculated based on the adopted third law value  $\Delta H_{298}^\circ = 63.5 \text{ kcal/mol}$  for the reaction Na<sub>2</sub>F<sub>2</sub>(g) = 2NaF(g), using  $\Delta H_f^\circ$  (NaF, g) = -69.5 kcal/mol. Brewer and Brackett (3) reported  $\Delta H_{1000}^\circ = 56.9 \text{ kcal/mol}$  for the above reaction. According to our tables the  $\Delta H_{1000}^\circ$  value is 62.5 kcal/mol.

Heat Capacity and Entropy

The Na<sub>2</sub>F<sub>2</sub> molecule is assumed to have a rhombic structure with D<sub>2h</sub> (h) symmetry (4, 5). The Na-F bond distance is reported by Akishin and Rambidi (5), who studied the molecular structure of alkali halide vapors by electron diffraction with sector microphotometry. The bond angle is estimated by comparison with those of the other alkali halides. Berkowitz (4, 6) has calculated the vibration frequencies of Na<sub>2</sub>F<sub>2</sub> based on an ionic model. By comparison of the calculated frequencies of Li<sub>2</sub>F<sub>2</sub> (g) with those of the observed ones (see Li<sub>2</sub>F<sub>2</sub>(g) table for details) we reestimate the vibrational frequencies for Na<sub>2</sub>F<sub>2</sub>(g) to be higher than the ones reported by Berkowitz (6). Bauer et al. (7) used a pseudo-electrostatic model, similar to the one suggested by O'Konski and Higuchi (8), to calculate the entropies of dimerization for a number of gaseous alkali halides and estimated the six vibrational frequencies as 477, 318, 291, 477, 291, and 291 cm<sup>-1</sup>. Bauer et al. calculated  $\Delta H_{1146}^\circ = -32.5 \text{ eu}$  for the reaction  $2\text{NaF}(g) = \text{Na}_2\text{F}_2(g)$ , in reasonable agreement with the value -33.5 eu which is derived using JANAF S<sub>1146</sub> values for NaF(g) and Na<sub>2</sub>F<sub>2</sub>(g).

The three principal moments of inertia are:  $I_A = 1.399 \times 10^{-38}$ ,  $I_B = 1.422 \times 10^{-38}$ , and  $I_C = 2.821 \times 10^{-38} \text{ g cm}^2$ .

**Heat of Formation**  
 King and Armstrong (1) have established the heat of formation with a series of reactions in a flame calorimeter. They burned F<sub>2</sub>O in hydrogen to give HF aqueous, in addition they burned F<sub>2</sub> in hydrogen and O<sub>2</sub> in hydrogen so that the heat of formation, 5.86 kcal/mol, is directly obtainable. This value is in good agreement with the recalculated values (1) from Wartenberg and Klinkott (2), 5.7 ± 2 kcal/mol, and Ruff and Menzel (3), 4.7 ± 2 kcal/mol but differs from that of Bisbee et al. (4), -4.06 ± 2.2 kcal/mol. There were several factors in the experiments of Bisbee that might cause a too negative heat of formation and we choose to adopt the definitive value of 5.86 kcal/mol reported by King and Armstrong.

**Heat Capacity and Entropy**

The structural parameters are those reported by Pierce et al. (5) for the average ground state molecule from the microwave spectrum. Earlier measurements of Hilton et al. (6) disagree but according to Pierce et al. (7) the line assignments used by Hilton are incorrect. The vibrational frequencies were reported by Jones et al. (8), several other investigators report similar values (9, 10, 11). Neβgen et al. (12) have obtained the anharmonic constants for the three vibrations. Individual moments of inertia are I<sub>A</sub> = 1.4396 × 10<sup>-39</sup>, I<sub>B</sub> = 7.7255 × 10<sup>-39</sup> and I<sub>C</sub> = 9.1651 × 10<sup>-39</sup> g cm<sup>2</sup>.

Bond Distances: O-S = 1.412 Å S-F = 1.585 Å  
 Bond Angle: O-S-F = 106° 49' F-S-F = 92° 49'  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 1.65545 × 10<sup>-114</sup> g.<sup>3</sup> cm.<sup>6</sup>

Heat of Formation.

From the enthalpy change,  $\Delta H_f^\circ = 131.03 \text{ kcal. mole}^{-1}$ , for the reaction  $\text{SO}_2\text{F}_2(\text{g}) = \text{SO}_2(\text{g}) + \text{O}(\text{g})$ , the value of  $\Delta H_f^\circ$  for  $\text{SO}_2(\text{g})$  was calculated to be -133.5 kcal. mole<sup>-1</sup>, using  $\Delta H_f^\circ = -205.0$  and 59.56 kcal. mole<sup>-1</sup> for  $\text{SO}_2(\text{g})$  and  $\text{O}(\text{g})$ , respectively. The value of  $\Delta H_f^\circ$  for  $\text{SO}_2(\text{g})$  was assumed to be the same as that for the reaction  $\text{SO}_2(\text{g}) = \text{SO}(\text{g}) + \text{O}(\text{g})$  which was calculated based on  $\Delta H_f^\circ = -70.95$ , 0.52 and 59.56 kcal. mole<sup>-1</sup> for  $\text{SO}_2(\text{g})$ ,  $\text{SO}(\text{g})$  and  $\text{O}(\text{g})$ , respectively. Using  $\Delta H_f^\circ = 127.86 \text{ kcal. mole}^{-1}$  for the reaction  $\text{SO}_2\text{F}_2(\text{g}) = \text{SO}_2(\text{g}) + \text{F}_2(\text{g})$ , the value of  $\Delta H_f^\circ$  for  $\text{SO}_2\text{F}_2(\text{g})$  was evaluated as -136.7 kcal. mole<sup>-1</sup> where the  $\Delta H_f^\circ$  for  $\text{SO}_2(\text{g})$  was assumed to be the same as the S-O bond energy in  $\text{SO}_2(\text{g})$ . The value of  $\Delta H_f^\circ$  for  $\text{SO}_2\text{F}_2(\text{g})$  adopted is -135 ± 10 kcal. mole<sup>-1</sup>.

Heat Capacity and Entropy.

The bond distances and angles were obtained from R. C. Ferguson, J. Am. Chem. Soc. 76, 850 (1954). The vibrational frequencies were taken from R. J. Gillespie and E. A. Robinson, Can. J. Chem. 39, 2171 (1961). The assignment of these vibrational frequencies was based on the previous measurements of the infrared and Raman spectra reported by J. K. O'Loane and M. K. Wilson, J. Chem. Phys. 23, 1313 (1955), P. Bender and J. M. Wood, J. Chem. Phys. 23, 1316 (1955) and D. M. Yost, Proc. Indian Acad. Sci. B, 333 (1939). The fundamental assignment reported by J. K. O'Loane and M. K. Wilson, loc. cit., was 1333, 808, 530, (410), 748 and 390 cm<sup>-1</sup>. The three principal moments of inertia are: I<sub>A</sub> = 1.0034 × 10<sup>-38</sup>, I<sub>B</sub> = 9.7421 × 10<sup>-39</sup> and I<sub>C</sub> = 1.6935 × 10<sup>-38</sup> g. cm.<sup>2</sup>.

The heat capacities of thionyl fluoride (SO<sub>2</sub>F<sub>2</sub>) have been measured, from 12° to 230°K., by E. L. Pace and B. F. Turnbull, J. Chem. Phys. 43, 1953 (1965), for a sample of 99.976 mole % purity. Incorporating them with the measured  $\Delta H_f^\circ = 1.506 \text{ kcal. mole}^{-1}$  at T<sub>0</sub> = 143.25°K., and  $\Delta H_f^\circ = 5.091 \text{ kcal. mole}^{-1}$  at T<sub>0</sub> = 228.84°K., which was derived from the measured vapor pressure of SO<sub>2</sub>F<sub>2</sub>(l), the entropy of SO<sub>2</sub>F<sub>2</sub>(g) at 228.84°K. was evaluated as 63.56 e.u. This value is in excellent agreement with the corresponding value, 63.522 e.u., calculated using the adopted molecular constants. This indicates the fact that the molecular constants used for the calculation of the tabulated thermodynamic functions are adequate. Hence the new vibrational frequencies suggested by Pace and Turnbull, loc. cit., were not used.

Bond Distance: Si-O = [1.60] Å      Si-F = [1.54] Å       $\sigma = 2$   
 Bond Angle: P-Si-O = [120]°      P-Si-F = [120]°  
 Product of the Moments of Inertia:  $I_A I_B I_C = 2.56608 \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

$\Delta H_f^{298.15}$  was estimated by comparison with those for SiF<sub>4</sub>(g) and SiO<sub>2</sub>(g).

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for COF<sub>2</sub>(g) and TiOF<sub>2</sub>(g). The vibrational frequencies for COF<sub>2</sub>(g) were obtained from R. J. Lovell, C. V. Stephenson, and E. A. Jones, J. Chem. Phys. 22, 1953 (1954), and J. S. Gordon, private communication, May 12, 1961, respectively. The bond distances of Si-O and Si-F were assumed to be the same as those for SiO(g) and SiF<sub>4</sub>(g), respectively. Point group, ground state multiplicity, and bond angles were estimated.

Bond Distances: Ti-O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O-Ti-F = [120°]

Product of Moments of Inertia:  $I_A I_B I_C = [4.34 \times 10^{-41}] \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

$\Delta H_f^o$  was estimated as -220 kcal. mole<sup>-1</sup> by J. S. Gordon, AstroSystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963.  $\Delta H_f^o = -221$  was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. The principal moments of inertia are:  $I_A = 14.3274 \times 10^{-39} \text{ g. cm.}^2$ ,  $I_B = 11.6632 \times 10^{-39} \text{ g. cm.}^2$ , and  $I_C = 25.9807 \times 10^{-39} \text{ g. cm.}^2$

Bond Distance: S-O =  $1.405 \pm 0.003 \text{ \AA}$  S-F =  $1.530 \pm 0.003 \text{ \AA}$   
 Bond Angle: O-S-O =  $123^\circ 58' \pm 12'$  F-S-F =  $98^\circ 7' \pm 10'$   
 Product of the Moments of Inertia:  $I_A I_B I_C = 4.4673 \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of formation was reported by R. M. Reese, V. H. Dabeler and J. L. Franklin, J. Chem. Phys. 29, 880 (1958). The value was calculated from the appearance potential of the SO<sub>2</sub><sup>+</sup> ion obtained from electron impact studies of SO<sub>2</sub> and SO<sub>2</sub>P<sub>2</sub>.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from O. R. Hunt, and M. K. Wilson, Spectrochim. Acta, 16, 570 (1960). The bond distances and bond angles were reported by D. R. Lide, Jr., D. E. Mann, and R. M. Fristrom, J. Chem. Phys., 26, 734 (1957). The entropy of sulfonyl fluoride gas has been calculated from the calorimetric data and the third law of thermodynamics to be 62.66 cal. deg.<sup>-1</sup> mole<sup>-1</sup> at 21.78°K. by P. J. Bockhoff, R. V. Petrellis, and E. L. Pace, J. Chem. Phys. 32, 799 (1960). The discrepancy between entropy value calculated from calorimetric data and that calculated from molecular and spectroscopic data (1 atm., 21.78°K) is attributed to randomness in the solid at 0°K by P. J. Bockhoff and E. L. Pace, J. Chem. Phys. 34, 3502 (1962). The vibrational frequencies reported by W. D. Perkins and M. Kent Wilson, J. Chem. Phys. 20, 1791 (1952) were 1269 (1), 848 (1), 544 (1), [500] (1), [386] (1), 1502 (1), 553 (1), 885 (1), and 339 (1) cm.<sup>-1</sup>. The three principal moments of inertia are:  $1.6567 \times 10^{-36}$ ,  $1.6567 \times 10^{-36}$ , and  $1.6549 \times 10^{-36} \text{ g. cm.}^2$ .

Phosphorus Difluoride (PF<sub>2</sub>)  
(Ideal Gas) Mol. Wt. = 68.975

June 30, 1962

Phosphorus Difluoride (PF<sub>2</sub>) (Ideal Gas)

Mol. Wt. = 68.975

ΔH<sub>f</sub> 298.15 = [-105 ± 15] kcal. mole<sup>-1</sup>

S<sub>298.15</sub> = [62.2 ± 3] cal. deg<sup>-1</sup> mole<sup>-1</sup>

Ground State Multiplicity = 2

Point Group C<sub>2v</sub>

Vibrational Levels and Multiplicities

$\frac{U}{J}, \text{ cm.}^{-1}$

I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [1.9059 × 10<sup>-115</sup>] g.<sup>3</sup> cm.<sup>6</sup> σ = 2

Heat of Formation. ΔH<sub>f</sub> 298.15 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. For their estimation they assumed certain bond energies for the dissociation of PF<sub>3</sub>(g). Bond one was assumed 20% greater than bond two and three which were assumed to be equal. ΔH<sub>f</sub> 298.18 was corrected for the change in phosphorus reference state (white α → red V).

Heat Capacity and Entropy. Molecular constants and vibrational levels were estimated by J. S. Gordon, Thiokol Chemical Corp., Reaction Motors Division, Denver, N. J., "Thermodynamic Data for Combustion Products," January, 1960.

Lead Difluoride (PbF<sub>2</sub>)

Mar. 31, 1962; Dec. 31, 1963; Dec. 31, 1965; June 30, 1969

$\Delta H^{\circ}_0$  = Unknown  
 $\Delta H^{\circ}_{298.15}$  = -161.8 ± 1.0 kcal/mol  
 $\Delta H^{\circ}_2$  = [0.61] kcal/mol  
 $\Delta H^{\circ}_1$  = 0.65 kcal/mol  
 $\Delta H_m$  = 2.98 kcal/mol  
 $\Delta H^{\circ}_{298.15}$  = 89.5 kcal/mol

The heats of formation at 298.15°K derived from the enthalpy changes of different chemical reactions are listed below. The adopted one is the average of the last three  $\Delta H^{\circ}_{298.15}$  values, which is also in reasonable agreement with the  $\Delta H^{\circ}_{298.15}$  values evaluated from (1) and (5).

| Reference | Chemical Reaction   | $\Delta H^{\circ}_{298.15}$ Kcal/mol | $\Delta H^{\circ}_{298.15}$ Kcal/mol |
|-----------|---|--------------------------------------|--------------------------------------|
| 1         | PbF <sub>2</sub> (c) + H <sub>2</sub> (g) = Pb(l) + 2 HF(g)                 | 32.0 ± 0.56*                         | -161.3 ± 0.6                         |

\* This is the third law value. The second law value is 32.4 ± 0.9 kcal/mol. The entropy drift is -0.5 ± 1.2 eu.  
 \*\* This is the third law value. The second law value is 39.6 ± 0.7 kcal/mol. The entropy drift is -10.9 ± 0.8 eu.

**Heat Capacity and Entropy**  
 Banashek, Patsukova, and Rasonskaya (10) measured the high temperature enthalpies (H°-H°<sub>298.15</sub>) for PbF<sub>2</sub>(c) in the temperature range 670-1165°K. Based on their enthalpy measurements the heat capacity of PbF<sub>2</sub>(c) at temperatures 725-1099°K is derived as 24.3 ± 0.2 gibbs/mol by the least square method. The heat capacities below 725°K are estimated using their reported enthalpies at 670-725°K, which are based on a mixture of β and γ, as a guide.

The S°<sub>298.15</sub> is estimated to be 25 eu by the method suggested by Kubaschewski and Evans (11), and adjusted to 27 eu so that the second and third law  $\Delta H^{\circ}_{298.15}$  values derived from the equilibrium data reported by Jellinek and Rudat (1) are in good agreement.

**Transition Data**  
 The transition temperatures are obtained from Banashek, Patsukova, and Rasonskaya (10). The β + γ transition at 613°K was reported as either slow or irreversible and the γ + β transition at 725°K was reversible. The polymorphism of PbF<sub>2</sub>(c) has been studied by many other investigators. However, the relations between the temperature and the character of polymorphic transformation are not consistent (10).

The enthalpy difference at 725°K for PbF<sub>2</sub>(γ) and PbF<sub>2</sub>(β) is  $\Delta H^{\circ}_1$ . The value of  $\Delta H^{\circ}_2$  is estimated such that the generated functions yield reasonable agreement among the derived  $\Delta H^{\circ}_{298}$  values (see the above table).

**Melting Data**  
 See PbF<sub>2</sub>(l) table.

**Heat of Sublimation**  
 The difference between  $\Delta H^{\circ}_{298.15}$  for PbF<sub>2</sub>(g) and PbF<sub>2</sub>(c) is  $\Delta H^{\circ}_{298.15}$ .

GFW = 245.1868

(LIQUID)

LEAD DIFLUORIDE (PbF<sub>2</sub>)

Lead Difluoride (PbF<sub>2</sub>)  
(Liquid) GFW = 245.1868

S<sup>o</sup><sub>298.15</sub> = (28.647) gibbs/mol

Tm = 1099°K

ΔH<sup>o</sup><sub>f,298.15</sub> = -158.722 kcal/mol

ΔH<sup>o</sup><sub>m</sub> = 2.98 kcal/mol

**Heat of Formation**  
ΔH<sup>o</sup><sub>f,298.15</sub>(l) is obtained from ΔH<sup>o</sup><sub>f,298.15</sub>(c) by adding ΔH<sup>o</sup><sub>m</sub> and the difference between H<sup>o</sup><sub>lm</sub> - H<sup>o</sup><sub>298.15</sub> for crystal and liquid.

**Heat Capacity and Entropy**  
The enthalpies (H<sup>o</sup> - H<sup>o</sup><sub>298.15</sub>) of PbF<sub>2</sub>(l) in the temperature range 1104-1165°K were determined by Banashek, Patsukova, and Rassonskaya (1). Based on their reported results the heat capacity of PbF<sub>2</sub>(l) is evaluated to be 24 ± 2 gibbs/mol by the least square method. This Cp value is adopted and extended to 298 and 2500°K, respectively.  
The entropy (S<sup>o</sup><sub>298.15</sub>) is calculated in a manner analogous to that of the heat of formation.

**Melting Data**

Tm is taken from Banashek, Patsukova, and Rassonskaya (1). The enthalpy difference at Tm for PbF<sub>2</sub>(l) and PbF<sub>2</sub>(γ) is ΔH<sup>o</sup><sub>m</sub>.  
Other values of Tm (°K) reported are 1091 (2, 11), 1097 (3, 4, 5) and 1128 (6). Using the freezing point data of binary systems PbF<sub>2</sub>-PbBr<sub>2</sub> (5), PbF<sub>2</sub>-PbCl<sub>2</sub> (5, 7), PbF<sub>2</sub>-PbI<sub>2</sub> (5, 8), PbF<sub>2</sub>-PbO (9), and PbF<sub>2</sub>-NaF (10), Kelley (3) evaluated the corresponding values of ΔH<sup>o</sup><sub>m</sub> (kcal/mol) as 1.70, 1.70, 1.96, 3.87, and 2.47. Other reported values of ΔH<sup>o</sup><sub>m</sub> are 3.00 (1) and 4.16 (2) kcal/mol.

**Vaporization Data**

From mass spectroscopic study on the vapor species in PbF<sub>2</sub>, Zmbov, Hastie, and Margrave (4) have shown that molten PbF<sub>2</sub> vaporizes partly as molecular PbF<sub>2</sub>. There is considerable disproportionation, and at 715°K the vapor composition is approximately 66% PbF<sub>2</sub>, 25% PbF, 21% PbF, and 74% Pb (4, 12). T<sub>b</sub> has been reported as 1565°K (11) where the vapor is expected to be a mixture of the above species.

Bond Distance: Pb-F = 2.13 ± 0.02 Å  
 Bond Angle: F-Pb-F = [95°]  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [4.5690 × 10<sup>-114</sup>] g<sup>3</sup> cm<sup>6</sup> σ = 2

Heat of Formation

Vapor pressure data for PbF<sub>2</sub> have previously been interpreted on the assumption that PbF<sub>2</sub> was the only species present in the gas phase (1, 2). Zmbov, Hastie, and Margrave (3) have studied the vapor species over PbF<sub>2</sub>(c, l) mass spectrometrically and shown that PbF<sub>2</sub> vaporizes only partly as molecular PbF<sub>2</sub> and there is considerable disproportionation. The vapor composition at 988°K is approximately 66% PbF<sub>2</sub>, 25% PbF, and 7% Pb (3, 4). From extrapolation of the ion intensity data from 1043 to 988°K to the temperature region in which Nemmyanov and Iofa (2) measured the saturated vapor pressures of PbF<sub>2</sub>(c), 792-988°K, by Knudsen effusion method, the partial pressure of PbF<sub>2</sub>(c), at 988°K was calculated to be 0.0435 ± 0.005 torr. Based on this calculated vapor pressure, the heat of sublimation ( $\Delta H_{988}^\circ$ ) of PbF<sub>2</sub>(c) is derived as 58.50 kcal/mol by the third law method, yielding  $\Delta H_f^\circ$ (PbF<sub>2</sub>, g) = -103.3 ± 1 kcal/mol.

Due to lack of data on vapor compositions over PbF<sub>2</sub>(c, l) at various temperatures, the total pressure measurements reported by Wartenberg and Bose (1), using boiling point method, and those of Nemmyanov and Iofa (2) are not used for evaluation.

Heat Capacity and Entropy

The bond distance was determined by Akishin, Spiridonov and Khodchenkov (5). The bond angle is assumed to be the same as that in PbX<sub>2</sub>(g) where X = Cl, Br or I (6). The vibrational frequencies are calculated by valence force method (10) using force constants estimated by comparison with those for PbF (7), CaF (7), CaF<sub>2</sub> (8), HgF (7), and HgF<sub>2</sub> (9). The value of ν<sub>2</sub> is in fair agreement with the value, 145 cm<sup>-1</sup>, estimated by (4). The three principal moments of inertia are: I<sub>A</sub> = 1.5559 × 10<sup>-38</sup>, I<sub>B</sub> = 1.1040 × 10<sup>-38</sup>, and I<sub>C</sub> = 2.6599 × 10<sup>-38</sup> g cm<sup>2</sup>.

GFW = 66.0828

(IDEAL GAS)

SILICON DIFLUORIDE (SiF<sub>2</sub>)

Silicon Difluoride (SiF<sub>2</sub>)

(Ideal Gas) GFW = 66.0828

Point Group (C<sub>2v</sub>)

ΔHf° = -140.3 ± 3 kcal/mol

S<sub>298.15</sub> = 61.30 ± 0.05 gibbs/mol

Electronic Levels and Quantum Weights

Vibrational Levels and Degeneracies

Bond Distance: Si-F = 1.5913 Å

Bond Angle: F-Si-F = 100°59'

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 3.20372 × 10<sup>-115</sup> g<sup>3</sup> cm<sup>6</sup>

σ = 2

Heat of Formation

J. L. Margrave, A. S. Kanaan, and D. C. Pease, J. Phys. Chem. **66**, 1200 (1962), have reported some approximate equilibrium constants for the reaction Si(c) + SiF<sub>4</sub>(g) + 2SiF<sub>2</sub>(g). These were calculated from yields of polymerized products and a knowledge of the total system pressure given in U. S. Patent No. 2,840,588 (1958). The data were subjected to third law analysis using the present JANAF functions and yielded ΔH<sub>f,298</sub>° = 92 ± 10 kcal/mol, which gives ΔH<sub>f,298</sub>°(SiF<sub>2</sub>, g) = -147 ± 5 kcal/mol.

T. C. Ehler and J. L. Margrave, J. Chem. Phys. **41**, 1066 (1964), have reported equilibrium constants for three reactions determined mass spectrometrically.

A. CaF<sub>2</sub>(c) + Si(g) + Ca(g) + SiF<sub>2</sub>(g)

B. CaF<sub>2</sub>(g) + Si(g) + Ca(g) + SiF<sub>2</sub>(g)

C. 2CaF(g) + Si(g) + 2Ca(g) + SiF<sub>2</sub>(g)

A 2nd and 3rd law analysis of the data is shown below.

We adopt ΔH<sub>f,298.15</sub>°(SiF<sub>2</sub>, g) = -140.5 ± 3 kcal/mol.

Heat Capacity and Entropy

The microwave, ultraviolet and infrared spectra have all been extensively studied (1, 2, 3, 4, 5, 6, 7). We have adopted the vibrational frequencies and molecular structure from V. M. Khanna et al. (1). The electronic levels are from V. M. Khanna et al. (2), with an estimated triplet level by analogy with CF<sub>2</sub>.

The individual moments of inertia are I<sub>A</sub> = 2.7482 × 10<sup>-39</sup> g cm<sup>2</sup>, I<sub>B</sub> = 9.5100 × 10<sup>-39</sup> g cm<sup>2</sup>, and I<sub>C</sub> = 12.2582 × 10<sup>-39</sup> g cm<sup>2</sup>.

Bond Distance: Ti-F = (1.95) Å  
Bond Angle: F-Ti-F = (180°)  
Rotational Constant: B<sub>0</sub> = (0.1167) cm<sup>-1</sup>

Heat of Formation  
Zimov and Margrave (1) have reported ion intensities and the corresponding equilibrium constants for the reaction  
Ca(g) + TiF<sub>3</sub>(g) = CaF(g) + TiF<sub>2</sub>(g). Second and third law analyses of their data give a second law ΔH<sub>f,298</sub>° of 7.0 kcal/mol, a  
third law ΔH<sub>f,298</sub>° of 11.76 kcal/mol and a third law drift of 3.1 ± 3.8 au. The heat of formation, ΔH<sub>f,298</sub>° of TiF<sub>2</sub>(g) is  
calculated from the third law ΔH<sub>f,298</sub>° above, and the JANAF heat of formation of TiF<sub>3</sub>(g), CaF(g) and Ca(g).

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiCl<sub>2</sub>, TiCl<sub>4</sub>, and TiF<sub>4</sub>. The vibrational frequencies are estimated from a valence force field model.  
The electronic levels are assumed to be the same as TiCl<sub>2</sub>(g). The levels of TiCl<sub>2</sub>(g) are estimated by assuming they correspond to the inverted states of NiCl<sub>2</sub>(g) (2). The linear configuration is assumed because experimental evidence (3) indicates that other transition metal difluorides, viz. those of Mn, Co, Ni, Cu, and Zn, are linear.

$\Delta H_m^\circ = [9 \pm 2]$  kcal/mol

$\Delta H_s^\circ_{298.15} = [96.6]$  kcal/mol

$S^\circ_{298.15} = [18 \pm 2]$  gibbs/mol

$T_m = [1175 \pm 150]^\circ K$

Heat of Formation

More recent thermal data related to the heat of formation of ZrF<sub>2</sub>(c) is unavailable. The adopted  $\Delta H_f^\circ_{298}(ZrF_2, c)$  value is taken from (1) which was estimated by Brewer (2).

Heat Capacity and Entropy

The heat capacities in the temperature range 298-2000°K are estimated by comparison with those of ZrF<sub>4</sub>(c) and Zr(c). The  $S^\circ_{298}$  is calculated as 17.2 and 17.0 eu based on the assumptions that  $S(ZrF_2) = 1/2[S(ZrF_4) + S(Zr)]$  and  $S(ZrF_2) = S(ZrF_2) - S(Zn) + S(Zr)$ . Using the additive entropy constants  $S^\circ_{298} = 12.1$  and 4.7 eu for Zr and F suggested by Kubaschewski and Evans (3), we obtain  $S^\circ_{298}(ZrF_2, c) = 12.1 + 2(4.7) = 21.5$  eu. Based on  $S^\circ_{298} = 11.5$  and 3.9 eu for Zr<sup>4+</sup> and F<sup>-</sup> recommended by Kelley (4), the value  $S^\circ_{298}(ZrF_2, c)$  is derived as 19.3 eu. The entropy at 298°K for ZrF<sub>2</sub>(c) is tentatively adopted as  $18 \pm 2$  eu.

Melting Data

Both  $T_m$  and  $\Delta H_m^\circ$  are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of ZrF<sub>4</sub>(c) which was obtained from experimental measurements (5). Therefore these estimated values are tentatively adopted.

Heat of Sublimation

The difference between  $\Delta H_f^\circ_{298}$  for ZrF<sub>2</sub>(g) and ZrF<sub>2</sub>(c) is  $\Delta H_s^\circ_{298}$ .

Dec. 31, 1960; June 30, 1961; June 30, 1969

S<sup>a</sup><sub>298.15</sub> = [24.103] gibbs/mol  
 Th = [1175 ± 150]°K  
 Tb = [2529]°K

**Heat of Formation**  
 The ΔH<sup>c</sup><sub>298</sub>(l) is obtained from ΔH<sup>c</sup><sub>298</sub>(c) by adding ΔH<sup>m</sup> and the difference between H<sup>c</sup><sub>1175</sub> - H<sup>c</sup><sub>298</sub> for crystal and liquid.

**Heat Capacity and Entropy**  
 The heat capacity is estimated from those of ZrF<sub>4</sub>(l), CaF<sub>2</sub>(l), Zr(l), and Ca(l), and is assumed to be constant in the temperature range 800-1000°K. A glass transition temperature is assumed at 800°K. The Cp values below 800°K are adopted from the ZrF<sub>2</sub>(c) table.  
 The entropy is obtained in a manner analogous to that of the heat of formation.

**Melting Data**  
 Both Th and ΔH<sup>m</sup> are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of ZrF<sub>4</sub>(c) which was obtained from experimental measurements (1). Therefore these estimated values are tentatively adopted.

**Vaporization Data**  
 Tb is the temperature at which the Gibbs energy change of the process ZrF<sub>2</sub>(l) = ZrF<sub>2</sub>(g) approaches zero. The difference between ΔH<sup>v</sup> for ZrF<sub>2</sub>(l) and ZrF<sub>2</sub>(g) at Tb is ΔH<sup>v</sup>.

Bond Angle: F-Zr-F = (125°)

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = (1.3968 × 10<sup>-114</sup>) g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF<sub>4</sub>, ZrF<sub>3</sub>, ZrF<sub>2</sub>, Ca, and CaF<sub>2</sub> mass-spectrometrically. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K, and the equilibrium constants for the reaction 2 Ca(g) + ZrF<sub>4</sub>(g) = 2 CaF(g) + ZrF<sub>2</sub>(g) were calculated. Using the reported equilibrium constants, the enthalpy changes (ΔH<sub>f,298</sub>°) of this reaction are evaluated by the second and third law methods to be 15.4 and 50.9 kcal/mol, respectively. The drift in third law values is 10.4 ± 17.6 eu. Based on the third law ΔH<sub>f,298</sub>° value and ΔH<sub>f,298</sub>° = 42.85 ± 0.3, -65.0 ± 2, and -400.0 ± 0.5 kcal/mol for Ca(g), CaF(g), and ZrF<sub>4</sub>(g), respectively, we obtain ΔH<sub>f,298</sub>°(ZrF<sub>2</sub>, g) = -133.4 ± 5 kcal/mol, which is adopted.

Using Gibbs energy functions derived from different molecular constants for the reactants and products, Murad and Hildenbrand (1) derived a third law ΔH<sub>f,298</sub>° = 42.6 ± 5 and ΔH<sub>f,298</sub>°(ZrF<sub>2</sub>, g) = -141 ± 5 kcal/mol, which are in fair agreement with the adopted values.

Heat Capacity and Entropy

According to the correlations of Charkin and Dyatkina (2), the ZrF<sub>2</sub>(g) molecule has an angular configuration. The F-Zr-F angle is estimated as 125°, which is similar to the value reported by Hastie, Hauge, and Margrave (3) for TiF<sub>2</sub>(g). The F-Zr bond distance is estimated from that of ZrF<sub>4</sub>(g). The vibrational frequencies are calculated based on the method suggested by Herzberg (3). The value ν<sub>1</sub> is calculated from the vibrational frequency (ν) of ZrF(g) by use of the relation ν<sub>1</sub> = ν<sub>2</sub>√(Zr/F) where Zr and F are gram atomic weights of zirconium and fluorine. ν<sub>3</sub> is derived from ν<sub>1</sub> using the formula ν<sub>3</sub> = ν<sub>1} N<sub>ZrF</sub> where N<sub>ZrF</sub> is calculated as 0.44 ν<sub>3</sub> where the value 0.44 is estimated by comparison with the ratios of ν<sub>2</sub>/ν<sub>3</sub> for other related compounds. Ground state quantum weight is taken to be the same as that of TiF<sub>2</sub>(g). The three principal moments of inertia are: I<sub>A</sub> = 1.830 × 10<sup>-38</sup>, I<sub>B</sub> = 3.502 × 10<sup>-39</sup> and I<sub>C</sub> = 2.180 × 10<sup>-38</sup> g cm<sup>2</sup>. The electronic levels and quantum weights are estimated to be the same as those of TiF<sub>2</sub>(g).</sub>

ΔH<sub>f</sub><sup>o</sup> = UnknownΔH<sub>f</sub><sup>o</sup> 298.15 = -249 ± 3 kcal. mole<sup>-1</sup>ΔH<sub>f</sub><sup>o</sup> 298.15 = [52.8] kcal. mole<sup>-1</sup>S<sup>o</sup> 298.15 = [23.5 ± 2] cal. deg.<sup>-1</sup> mole<sup>-1</sup>T<sub>g</sub> = [1200]°K.Heat of Formation.

The equilibrium pressures for the reaction  $2\text{FeF}_3(\text{c}) + \text{H}_2(\text{g}) = 2\text{FeF}_2(\text{c}) + 2\text{HF}(\text{g})$  have been measured at temperatures 623, 723 and 823°K. by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. **175**, 281 (1928). Using the reported data, the enthalpy change of the reaction was evaluated as 37.9 and 31.3 kcal. mole<sup>-1</sup> by the third and second law methods, respectively. The corresponding ΔH<sub>f</sub><sup>o</sup> 298.15 (FeF<sub>3</sub>, c) values are calculated to be -252.4 and -249.2 kcal. mole<sup>-1</sup>. The equilibrium constants for the reaction  $2\text{FeF}_3(\text{c}) + 3\text{H}_2\text{O}(\text{g}) = \text{Fe}_2\text{O}_3(\text{c}) + 6\text{HF}(\text{g})$  were determined by L. Donange, Ann. Chim., **7**, 225 (1937). Based on the third law value of ΔH<sub>f</sub><sup>o</sup> 298.15° 62.0 kcal. mole<sup>-1</sup>, the ΔH<sub>f</sub><sup>o</sup> 298.15 (FeF<sub>3</sub>, c) was calculated as -237.4 kcal. mole<sup>-1</sup>. The value of ΔH<sub>f</sub><sup>o</sup> 298.15 for FeF<sub>3</sub>(c) is selected to be -249 ± 3 kcal. mole<sup>-1</sup>.

Heat Capacity and Entropy.

The heat capacities of FeF<sub>3</sub>(c) at temperatures 100-450°K. were determined by H. Bizette, R. Mainard and J. Picard, Comp. rend. 5508 (1965). The results were presented graphically by plotting C<sub>p</sub> vs. T. The C<sub>p</sub> curve shows a peak at 367°K. An antiferromagnetic transition at about 394°K. was reported by E. O. Mollan, H. R. Child, W. C. Koshler and M. K. Wilkinson, Phys. Rev. **112**, 1132 (1958). The heat capacities above 450°K. and 298.15 were estimated by comparison with those for FeCl<sub>3</sub>(c) AlCl<sub>3</sub>(c) and AlF<sub>3</sub>(c).

Sublimation Data.

The phenomenon that FeF<sub>3</sub>(c) sublimates without fusion at temperatures near 1000°K. has been observed and reported by Poulenc, Ann. Chim. phys. (7), **2**, 1 (1894). Based on this data the value of T<sub>m</sub> was estimated. The value of heat of sublimation (ΔH<sub>f</sub><sup>o</sup> 298.15°) was calculated using an estimated entropy of sublimation, ΔS<sub>f</sub><sup>o</sup> = 40 e.u. In order to have ΔF<sub>f</sub><sup>o</sup> = 0 for the reaction FeF<sub>3</sub>(c) = FeF<sub>3</sub>(g) at 1200°K.

 [250] (1)      [220] (2)

Bond Distance: Fe-F = [1.9] cm.<sup>-1</sup>  
 Bond Angle: F-Fe-F = [120]°  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [9.96723 X 10<sup>-11</sup>] g.<sup>3</sup> cm.<sup>6</sup>  
 $\sigma = [6]$

Heat of Formation.

The value of  $\Delta H^{\circ}_{f, 298.15} (\text{FeF}_3, g)$  was calculated from  $\Delta H^{\circ}_{f, 298.15}$  and  $\Delta H^{\circ}_{f, 298.15}$  for FeF<sub>3</sub>(c). The value  $\Delta H^{\circ}_{f, 298.15} = 65.5 \text{ kcal. mole}^{-1}$  was derived from  $\Delta H^{\circ}_{f, 1200}$  (see FeF<sub>3</sub>(c) table for details).

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by comparison with those for AlF<sub>3</sub>(g). The vibrational frequencies were estimated by comparison with those for AlF<sub>3</sub>(g), TlF<sub>3</sub>(g) and ZrF<sub>3</sub>(g). The three principal moments of inertia are: I<sub>A</sub> = I<sub>B</sub> = 1.7081 X 10<sup>-39</sup> and I<sub>C</sub> = 3.4182 X 10<sup>-38</sup> g. cm.<sup>2</sup>.

Trifluorosilane (SiHF<sub>3</sub>)

Bond Angles: F-Li-F = [120°] Li-F-Li = [120°]

Product of the Moments of Inertia:  $I_A I_B I_C = [1.2122 \times 10^{-41}]$  g<sup>3</sup>cm<sup>6</sup>

Heat of Formation

The heat of formation ( $\Delta H_f^\circ$ ) is derived based on the adopted value  $\Delta H_f^\circ = 79.73$  kcal/mol for the reaction  $3LiF(c) = Li_3F_3(g)$ , using  $\Delta H_f^\circ(LiF, c) = -147.45$  kcal/mol. The  $\Delta H_f^\circ$  value is calculated to be 73.9 kcal/mol at 1000°K, which is consistent with the values  $\Delta H_f^\circ = 73.9 \pm 3$  and  $74.9 \pm 1$  kcal/mol reported by Büchler and Strauffer (1) and Akishin et al. (2), respectively. Using the adopted  $\Delta H_f^\circ$  values for monomer, dimer, and trimer, we also evaluate the value  $\Delta H_f^\circ = 53.8$  kcal/mol for the reaction  $Li_3F_3(g) = Li_2F_2(g) + LiF(g)$  which is in agreement with the value  $50 < \Delta H_f^\circ < 65$  kcal/mol reported by Porter and Schoonmaker (3). Rothberg et al. (4) have determined the partial pressures of LiF monomer, dimer, and trimer in the temperature range 980 - 1070°K, using the molecular-beam velocity-selector method (5). However, the total pressures derived from these data are too low in comparison with the other reported vapor pressures. Thus their data are not adopted for evaluation.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of the BeO trimer. The Li-F bond distance is taken from that of the Li<sub>2</sub>F<sub>2</sub> molecule determined by Akishin and Rambidi (6). Four vibrational frequencies,  $\nu_2$  and three  $\nu_1$ , are reported by Snelson (7) from analysis of the infrared spectra of LiF using the matrix isolation technique. The reported frequencies are corrected to the average isotopic species. The other four frequencies,  $\nu_2$  and three  $\nu_1$ , are estimated by comparison with those for the isoelectronic molecule Be<sub>3</sub>O<sub>3</sub>. The three principal moments of inertia are  $I_A = I_B = 1.823 \times 10^{-38}$  and  $I_C = 3.646 \times 10^{-38}$  g<sup>2</sup>cm<sup>2</sup>.

(IDEAL GAS)

NITROGEN TRIFLUORIDE (NF<sub>3</sub>)

Point Group C<sub>3v</sub>

Ground State Quantum Weight = 1

ΔHf° = -30.06 ± 0.3 kcal/mol

ΔHf<sub>298.15</sub>° = -31.43 ± 0.3 kcal/mol

ΔHf° = -30.06 ± 0.3 kcal/mol

ΔHf<sub>298.15</sub>° = -31.43 ± 0.3 kcal/mol

Ground State Quantum Weight = 1

ΔHf° = -30.06 ± 0.3 kcal/mol

ΔHf<sub>298.15</sub>° = -31.43 ± 0.3 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm<sup>-1</sup>

1032 (1)

842 (1)

906 (2)

492 (2)

Bond Distance: N-F = 1.371 Å

Bond Angle: F-N-F = 102°9'

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 8.855 × 10<sup>-115</sup> g<sup>3</sup> cm<sup>6</sup>

σ = 3

Heat of Formation

Walker (1) reported ΔHr<sub>298</sub>° = -1308.8 ± 1.3 kcal/mol.

Sinke (2) reported ΔHr<sub>298</sub>° = -1308.8 ± 1.3 kcal/mol.

Walker (3) reported ΔHr<sub>298</sub>° = -228.26 ± 0.25 kcal/mol.

D. NF<sub>3</sub>(g) + 1.5 H<sub>2</sub>(g) → 3HF(50 H<sub>2</sub>O) + 0.5 N<sub>2</sub>(g)

Sinke (4) reported ΔHr<sub>298</sub>° = 31.44 ± 0.3 kcal/mol for a final state of HF(123 H<sub>2</sub>O); the corrected value is -139.40 ± 0.22 kcal/mol.

C. 2 NF<sub>3</sub>(g) + S(C, rh) → SF<sub>6</sub>(g) + N<sub>2</sub>(g)

Walker (3) reported ΔHr<sub>298</sub>° = -228.26 ± 0.25 kcal/mol.

D. NF<sub>3</sub>(g) + 0.5 N<sub>2</sub>(g) + 1.5 F<sub>2</sub>(g)

Sinke (4) reported ΔHr<sub>298</sub>° = 31.44 ± 0.3 kcal/mol for a final state of HF(123 H<sub>2</sub>O); the corrected value is -139.40 ± 0.22 kcal/mol.

E. NF<sub>3</sub>(g) + B(C, β) + BF<sub>3</sub>(g) + 0.5 N<sub>2</sub>(g)

Ludwig and Cooper (5) reported ΔHr<sub>298</sub>° = -239.46 ± 1.2 kcal/mol, 5 percent of the boron remained unreacted and was detected by analysis.

Further details of the simultaneous adjustment are given by Syverud (6).

The vibrational frequencies are from the infrared studies of Schatz and Levin (7) and are in good agreement with those of Pace and Pierce (8), and Wilson and Polo (9). The adopted values are also in agreement with the Raman studies of Kotov and Tatevskii (10). The bond length and angle were from the microwave studies of Sheridan and Gordy (11), whose values are in substantial agreement with the electron diffraction results of Schomaker and Liu (12).

The individual moments of inertia are I<sub>A</sub> = I<sub>B</sub> = 7.854 × 10<sup>-39</sup> g cm<sup>2</sup> and I<sub>C</sub> = 14.354 × 10<sup>-39</sup> g cm<sup>2</sup>.

Pierce and Pace (13) have obtained the entropy of the gas at 144.15°K from solid heat capacity measurements and the heats of melting and vaporization. Their reported value of 54.50 eu is in good agreement with our calculated value of 54.56 eu.

June 30, 1970

Heat of Formation  
Bougon et al. (1) determined equilibrium constants for the reaction NOF(g) + F<sub>2</sub>(g) ⇌ NOF<sub>3</sub>(g) as a function of temperature and total pressure. Second and third law analyses of these equilibrium data are given below:

| Set | I | II | No. of Points | Temp. Range, °K | ΔH <sub>f</sub> ° <sub>298</sub> , kcal/mol | Drift |
|-----|---|----|---------------|-----------------|---|-------|
|     | 7 | 1  | 7             | 533-643         | -17.1                                       | -18.7 |
|     |   |    | 1             | 533.2           | -17.1                                       | -18.2 |

Set I contains their equilibrium data as a function of temperature, while Set II is their adopted equilibrium constant, K<sub>p</sub>(553.2°K) = 0.015 ± 0.005 atm.<sup>-1</sup>, corresponding to the lowest pressure (103 atm.) that was studied. Estimated corrections for nonideality are small and neglected. Adopting ΔH<sub>f</sub>°<sub>298</sub> = -18.7 ± 1.0 kcal/mol, we derive ΔH<sub>f</sub>°(NOF<sub>3</sub>, g) = -34.4 ± 1.4 kcal/mol with ΔH<sub>f</sub>°(NOF, g) = -15.7 ± 0.4 kcal/mol (2).

Armstrong and King (2) determined ΔH<sub>f</sub>°<sub>304</sub> = -253.7 ± 0.6 kcal/mol for the reaction NOF<sub>2</sub>(g) + 5/2 H<sub>2</sub>(g) + 122 H<sub>2</sub>O(l) + 1/2 N<sub>2</sub>(g) + [3HF·123 H<sub>2</sub>O(l)] in a constant pressure flame calorimeter. Combining this result with their earlier enthalpy data for reduction reactions involving F<sub>2</sub>(g) and O<sub>2</sub>(g) with H<sub>2</sub>(g), they obtained ΔH<sub>f</sub>°<sub>304</sub>(NOF<sub>3</sub>, g) = -44.7 ± 1.5 kcal/mol. Very recently, Dabier and Walker (3) investigated the photoionization of NOF<sub>3</sub> by mass spectrometry. From their ionization threshold data, they determined ΔH<sub>f</sub>°(NOF<sub>3</sub>, g) = -63.6 ± 1.2 kcal/mol.

The value for the heat of formation of gaseous NOF<sub>3</sub> is tentatively selected as -39.0 ± 5.0 kcal/mol.

Heat Capacity and Entropy  
Several recent infrared (5, 6, and 7) and Raman (8) studies of NOF<sub>3</sub> have been reported in the literature. The fundamental vibrational frequencies observed in the infrared spectrum of the molecule by the various investigators are in good agreement, although the assignment of the ν<sub>3</sub> and ν<sub>5</sub> bending modes has varied. Fox et al. (6) assigned ν<sub>3</sub> = 558 cm<sup>-1</sup> and ν<sub>5</sub> = 528 cm<sup>-1</sup>, while Curtis et al. (7) reversed the assignments. Very recently, Abramowitz and Levin (8) investigated the Raman spectrum of polycrystalline film of NOF<sub>3</sub> at 78°K and assigned ν<sub>3</sub> = 535 cm<sup>-1</sup> and ν<sub>5</sub> = 522 cm<sup>-1</sup>, consistent with the infrared work of Fox et al. (6). The fundamental vibrational frequencies and assignments given by Fox et al. (6) are adopted here.

Fox et al. (6) also investigated the nuclear magnetic resonance spectrum of NOF<sub>3</sub> which indicated that the molecule contained three equivalent fluorine atoms. This result, along with the general appearance of the infrared spectrum, clearly establishes that the molecule has C<sub>3v</sub> symmetry. The N-O bond distance and bond angles are estimated quantities from the work of Curtis et al. (7). These estimated data have been used in calculating the N-F bond distance from the rotational constants given by Curtis et al. (7). Individual moments of inertia calculated from the structural data given above are: I<sub>A</sub> = I<sub>B</sub> = 14.86 × 10<sup>-39</sup> g cm<sup>2</sup>, and I<sub>C</sub> = 18.44 × 10<sup>-39</sup> g cm<sup>2</sup>.

Heat of Formation

Ebel and Bretcher (1) measured the enthalpy change for the following reaction:

They reported a heat of reaction of -70.6 ± 1 kcal/mol. Combining this result with the heat of formation of PF<sub>3</sub>, ΔH<sub>f</sub>°<sub>298</sub> = -224.9 ± 0.9 kcal/mol (2), we derive, ΔH<sub>f</sub>°<sub>298</sub>(POF<sub>3</sub>, g) = -295.6 ± 1.9 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Sellig and Claassen (3) and are in good agreement with the Raman and infrared studies of Gutavsky and Liehr (4). Several microwave studies (5, 6, 7) of POF<sub>3</sub> have been reported. As pointed out by Williams et al. (2), the rotational constant calculated from their microwave studies leads to a moment of inertia, I<sub>B</sub>, which is in disagreement with the moment of inertia calculated from the molecular constants obtained from electron-diffraction studies by Brockway and Beach (8). Since insufficient microwave data were available for an independent determination, Williams et al. (2) sought to find parameters which were consistent with both measurements. Their molecular constants are adopted for this tabulation. Individual moments of inertia are I<sub>A</sub> = I<sub>B</sub> = 18.244 × 10<sup>-39</sup> g cm<sup>2</sup> and I<sub>C</sub> = 17.731 × 10<sup>-39</sup> g cm<sup>2</sup>.

 S<sup>o</sup><sub>298.15</sub> = 65.23 ± 0.03 gibbs/mol  
 ΔH<sub>f</sub><sup>o</sup><sub>298.15</sub> = -224.9 ± 0.9 kcal/mol  
 Ground State Quantum Weight = 1

**Vibrational Frequencies and Degeneracies**

| ω <sub>c</sub> , cm <sup>-1</sup> | ω <sub>c</sub> , cm <sup>-1</sup> |
|-----------------------------------|-----------------------------------|
| 892 (1)                           | 860 (2)                           |
| 487 (1)                           | 344 (2)                           |

Bond Distance: P-F = 1.5700 ± 0.0012 Å F...·F = 2.3643 ± 0.0028 Å  
 Bond Angles: F-P-F = 97.8 ± 0.2°  
 Product of Moments of Inertia: 2.0621 × 10<sup>-114</sup> g<sup>3</sup> cm<sup>6</sup>  
 σ = 3

**Heat of Formation**

24.5 kcal/mol, for the reaction  
 PF<sub>3</sub>(g) + 3KCl·157 H<sub>2</sub>O + PCl<sub>3</sub>(l) + 3KF·112 H<sub>2</sub>O.  
 Combining this result with the following heat of formation data,  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PCl<sub>3</sub>, l) = -72.2 kcal/mol (2)  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(KCl·157 H<sub>2</sub>O) = -100.0 kcal/mol (3)  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(KF·112 H<sub>2</sub>O) = -138.5 kcal/mol (3)  
 we derive, ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PF<sub>3</sub>, g) = -212.2 kcal/mol. (3)

Duus and Mykytyk (4) reported a heat of reaction of -2.361 kcal/mol (corrected to 25°C) for the following reaction  
 PCl<sub>3</sub>(g) + 3/2 CaF<sub>2</sub>(s) + PF<sub>3</sub>(g) + 3/2 CaCl<sub>2</sub>(s).  
 Combining this result with the following heat of formation data,  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PCl<sub>3</sub>, g) = -64.4 kcal/mol (2)  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(CaF<sub>2</sub>, s) = 293.0 ± 1.5 kcal/mol (5)  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(CaCl<sub>2</sub>, s) = -190.0 kcal/mol (3)  
 we derive, ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PF<sub>3</sub>, g) = -221.9 kcal/mol.  
 Recently, Rudzitis et al. (6) measured the heat of combustion of PF<sub>3</sub> in fluorine in a two-chambered bomb calorimeter at 25°C. They reported a heat of combustion of -182.0 ± 0.2 kcal/mol for the reaction  
 PF<sub>3</sub>(g) + F<sub>2</sub>(g) + PF<sub>5</sub>(g).

Combining this result with the heat of formation of PF<sub>5</sub>, ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PF<sub>5</sub>, g) = -376.9 ± 0.7 kcal/mol (7), we derive,  
 ΔH<sub>f</sub><sup>o</sup><sub>298</sub>(PF<sub>3</sub>, g) = -224.9 ± 0.9 kcal/mol. This result is adopted for this tabulation.

**Heat Capacity and Entropy**

The vibrational frequencies are those reported by Wilson and Palo (8). Several different values for the P-F bond length and F-P-F bond angle have been reported in the literature. This problem was recently discussed by Morino et al. (9), who also reported new data obtained from electron-diffraction studies. Their results are adopted for this tabulation. Individual moments of inertia calculated according to their structure are: I<sub>A</sub> = I<sub>B</sub> = 10.814 × 10<sup>-39</sup> g cm<sup>2</sup> and I<sub>C</sub> = 17.634 × 10<sup>-39</sup> g cm<sup>2</sup>.

Heat of Formation

The heat of formation of PSF<sub>3</sub> is calculated from the heat of formation of POF<sub>3</sub> and estimated P-O and P-S bond strengths. Mortimer (1) calculated several P-O and P-S bond dissociation energies from heat of reaction data reported in the literature. Some of these data are given below.

| Reaction   | D(P=O) | D(P=S) |
|--|--------|--------|
| ΔH oxidation PF <sub>3</sub> to POF <sub>3</sub>         | 130.3  |        |
| ΔH oxidation P(OEt) <sub>3</sub> to PS(OEt) <sub>3</sub> | 81.6   |        |
| ΔH oxidation PPr <sub>3</sub> to PSPr <sub>3</sub>       | 82.6   |        |

Mole and McCoubrey (2) reported the following heat of reaction:

Combining this result with heat of vaporization data for PCl<sub>3</sub> (3) and PSCl<sub>3</sub> (4), along with the heat of sublimation of S (5), we derive, D(P=S) = 71 kcal/mol. Averaging this result with the two values given above, we obtain D(P=S) = 78.4 kcal/mol.

We assume that this result represents the enthalpy change for reaction

Combining this result with similar data for POF<sub>3</sub>, namely D(P=O) = 130.3 kcal/mol and ΔH<sub>f</sub>°(POF<sub>3</sub>, g) = -235.6 ± 1.9 kcal/mol (6), we derive, ΔH<sub>f</sub>°(PSF<sub>3</sub>, g) = -237 ± 15 kcal/mol, from the relationship

$\Delta H_f^\circ(\text{PSF}_3, g) = \Delta H_f^\circ(\text{POF}_3, g) + \Delta H_f^\circ(\text{S}, g) - D(\text{P=O}) + D(\text{P=S})$ .

Heat Capacity and Entropy

Several recent infrared and Raman studies (7, 8, 9, 10) of PSF<sub>3</sub> have been reported. These data are in good agreement, except for the ν<sub>1</sub> fundamental. Dewaille and Francois (11) assigned this fundamental to the 469 cm<sup>-1</sup> band observed in their spectra. The recent work indicates that this fundamental should be assigned to the 901 cm<sup>-1</sup> band. Average values of the vibrational frequencies reported by (8, 9, 10) are adopted for this tabulation. The molecular structure of this molecule was determined by Williams et al. (12) and Hawkins and Cohen (13) from microwave studies. The individual moments of inertia calculated from the constants given by Williams et al. (12) are I<sub>A</sub> = I<sub>B</sub> = 3.1527 × 10<sup>-38</sup> g cm<sup>2</sup> and I<sub>C</sub> = 1.7410 × 10<sup>-38</sup> g cm<sup>2</sup>.

| 290 (2)                       | 2          |

Bond Distance: Si-F = (1.56) Å  
 Bond Angle: F-Si-F = (109.47)°  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 2.5135 x 10<sup>-114</sup> g<sup>3</sup> cm<sup>6</sup>

$\sigma = 3$

Heat of Formation

The heat of formation is estimated from the assumption of a 0.5 kcal heat for the reaction:

$\Delta H^{\circ}_{298}(\text{SiF}_3, g) = -263$  kcal/mol is derived from  $\Delta H^{\circ}_{298}(\text{SiF}_4, g) = -385.98$  kcal/mol and  $\Delta H^{\circ}_{298}(\text{SiF}_2, g) = -140.5$  kcal/mol. The above value is confirmed by the observations of Layne (1), whose total pressure data above the silicon-fluoride system agree with those calculated from these tables.

Heat Capacity and Entropy

The bond length is estimated between those of SiF<sub>4</sub> and SiF<sub>2</sub>. The vibrational frequencies are from Milligan et al. (2), and the angle is taken to be tetrahedral, since they also reported an angle of approximately 71° between the Si-F bonds and the threefold axis. The spectra of the radical were obtained in inert gas matrices and all the fundamentals were observed. The individual moments of inertia are I<sub>A</sub> = I<sub>C</sub> = 11.081 x 10<sup>-39</sup> g cm<sup>2</sup>, I<sub>B</sub> = 20.472 x 10<sup>-39</sup> g cm<sup>2</sup>.

ΔHf°<sub>0</sub> = unknown.  
 ΔHf°<sub>298.15</sub> = -343.1 ± 10.0 kcal/mol  
 ΔH° = 52.97 kcal/mol

S°<sub>298.15</sub> = [21.0 ± 3.0]  
 T<sub>9</sub> = 1309.7 °K

Heat of Formation

Blocher and Hall (1) have reported vapor pressure data for the process 1/2Hg<sub>2</sub>F<sub>2</sub> + TiF<sub>3</sub>(c) = TiF<sub>4</sub>(g) + Hg(l). Second and third law analyses of their data give a second law ΔHr°<sub>298</sub> of 23.7 kcal/mol, a third law ΔHr°<sub>298</sub> of 29.864, and a third law drift of 11.9 ± 1.0 eu. The third law value is combined with the JANAF values for the heat of formation of Hg<sub>2</sub>F<sub>2</sub>(c) and TiF<sub>4</sub>(g) to give a ΔHf°<sub>298</sub> of -343.1 ± 10.0 kcal/mol. The large uncertainty on ΔHf°<sub>298</sub> is assigned because Blocher and Hall were not able to identify TiF<sub>3</sub>(c) as the reaction product in the above process. They reported that the X-ray pattern of the products contained lines corresponding to Hg<sub>2</sub>F<sub>2</sub>(c) plus others that did not correspond to TiF<sub>3</sub>(c).

Heat Capacity and Entropy

The heat capacity of TiF<sub>3</sub>(c) is estimated from the heat capacities of ZrF<sub>4</sub> and TiF<sub>4</sub>. The entropy, S°<sub>298</sub>, is estimated from CrF<sub>3</sub> and from ionic entropy contributions. Both methods give values which are within ±0.8eu of the chosen value of 21 ± 3eu.

Heat of Sublimation

The heat of sublimation is calculated from the vapor pressure data of Zmbov and Margrave (2). See TiF<sub>3</sub>(g) table for details. The sublimation temperature is taken as the point at which ΔGr = 0 for the reaction TiF<sub>3</sub>(c) = TiF<sub>3</sub>(g).

Bond Distance: Ti-F = [1.9] Å  
Bond Angle: F-Ti-F = [100°]  
Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [7.45 × 10<sup>-114</sup> g<sup>3</sup> cm<sup>6</sup>]

Heat of Formation

The heat of formation of TiF<sub>3</sub>(g) is calculated from that of TiF<sub>3</sub>(c) and the heat of sublimation determined from the mass spectrometric vapor pressure data of Zmbov and Margrave (1). Their data give nine points over the temperature range 759 - 865°K. Second and third law analyses of their data give a second law ΔHf°<sub>298</sub> of 81.2 ± 0.4 kcal/mol and a third law ΔHf°<sub>298</sub> of 59.0 kcal/mol with an entropy drift of -2.7 ± 0.5 units. The third law value is used to calculate ΔHf°<sub>298</sub>.

Heat Capacity and Entropy

The internuclear distance is estimated from those of TiF<sub>4</sub>(g) and TiCl<sub>3</sub>(g), and TiCl<sub>3</sub>(g). The pyramidal bond angle is estimated assuming TiF<sub>3</sub>(g) similar to the group V trihalides. The principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = 1.68 × 10<sup>-38</sup> g cm<sup>2</sup> and I<sub>C</sub> = 2.66 × 10<sup>-38</sup> g cm<sup>2</sup>. The vibrational frequencies are estimated from those of PF<sub>3</sub> and AsF<sub>3</sub>. The electronic levels are estimated from the levels of Ti<sup>3+</sup> (2).

ΔHf° = Unknown  
 ΔHf°<sub>298,15</sub> = [-335 ± 20] kcal/mol  
 ΔHs°<sub>298,15</sub> = [70.1] kcal/mol

S°<sub>298,15</sub> = [21 ± 2] gibbs/mol

Heat of Formation

The heat of formation at 298°K for ZrF<sub>3</sub>(c) was reported as -350 kcal/mol (1) which was estimated by Brewer (2). Based on this ΔHf°<sub>298</sub> value, the crystal lattice energy (U) of ZrF<sub>3</sub>(c) is calculated to be 1371 kcal/mol by the Born-Haber cycle method (3). For the evaluation of U from the relation: ΔHf°(ZrF<sub>3</sub>, c) = Σ I<sub>1</sub> + L - 3(E - D/2) - U, the following values (kcal/mol) are used: Σ I<sub>1</sub> (the sum of the successive three ionization potentials of Zr metal) = 1055 (4), L (the enthalpy of sublimation of Zr metal) = 148.3 (5), E (the electron affinity of fluorine) = 79.5 (6), and D (the enthalpy of dissociation of fluorine) = 37.7 (7). The derived value of U(ZrF<sub>3</sub>, c) is of the same order of magnitude of the value, U(TiF<sub>3</sub>, c) = 1176 kcal/mol, calculated by Cavell and Clark (3) using the same method.

From ΔHf°<sub>298</sub>(ZrF<sub>3</sub>, c) = -350 kcal/mol, the derived ΔGf°(ZrF<sub>3</sub>, c) values indicate that ZrF<sub>3</sub>(c) is thermodynamically more stable than the system ZrF<sub>4</sub>(c) + Zr(c). For example, in the temperature range 298-1200°K, the Gibbs energy changes for the reaction 3 ZrF<sub>3</sub>(c) + Zr(c) = 4 ZrF<sub>2</sub>(c) are about -29 ± 1 kcal/mol. However, this product ZrF<sub>3</sub>(c) has never been prepared successfully from this reaction in many laboratories (8). In order to make the ΔGf°(ZrF<sub>3</sub>, c) values consistent with the experimental observations, the heat of formation of ZrF<sub>3</sub>(c) is arbitrarily adjusted to be 15 kcal/mol less negative, or ΔHf°<sub>298</sub>(ZrF<sub>3</sub>, c) = -335 kcal/mol with uncertainty as high as ±20 kcal/mol. This value is tentatively adopted.

The Gibbs energy changes for the reaction 3 ZrF<sub>2</sub>(g) + Zr(c) = 4 ZrF<sub>3</sub>(c) are evaluated to be very favorable at temperatures below 900°K, e.g. ΔGr° = -93.9 and -6.7 kcal/mol at 298 and 900°K, respectively. But according to Larsen and Leddy (9), this reaction does not occur in the temperature range 473-973°K, and pressure range 5-15 atm. One possible explanation is that these heterogeneous reactants may require very high activation energy to initiate the reaction. In other words, this reaction is unfavorable at these temperatures probably due to kinetic rather than thermodynamic reasons.

Heat Capacity and Entropy

The heat capacities of ZrF<sub>3</sub>(c) are not available in the literature. They are estimated from the Cp values of ZrF<sub>4</sub>(c) by deduction of one F atom Cp contributions which are calculated as 1/4(Cp<sub>ZrF<sub>4</sub></sub>(c) - Cp<sub>Zr(c)</sub>). The S°<sub>298,15</sub> is taken to be 1/2(S°<sub>298</sub>(ZrF<sub>4</sub>, c) + S°<sub>298</sub>(ZrF<sub>2</sub>, c)) of which the value S°<sub>298</sub>(ZrF<sub>2</sub>, c) is estimated (see ZrF<sub>2</sub>(c) table for details).

Heat of Sublimation

The difference between ΔHf°<sub>298</sub> for ZrF<sub>2</sub>(g) and ZrF<sub>3</sub>(c) is ΔHs°<sub>298</sub>. Actually, ZrF<sub>3</sub>(c) is thermodynamically unstable, e.g. the Gibbs energy changes for the reaction 4 ZrF<sub>3</sub>(c) = 3 ZrF<sub>4</sub>(c) + Zr(c) are about -30 kcal/mol in the temperature range 298-1400°K. In other words, ZrF<sub>3</sub>(c) decomposes into ZrF<sub>4</sub>(c) + Zr(c) before sublimation occurs.

Bond Distance: Zr-F = (1.93) Å  
 Bond Angle: F-Zr-F = (105°)  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = (9.8857 × 10<sup>-114</sup>) g<sup>3</sup> cm<sup>6</sup>  
 σ = {3}

**Heat of Formation**  
 Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF<sub>4</sub>, ZrF<sub>3</sub>, ZrF<sub>2</sub>, Ca and CaF. These species were generated at high temperatures in a graphite Knudsen cell containing powdered calcium fluoride and elemental zirconium. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K and the equilibrium constants were calculated for the following isomolecular reaction: Ca(g) + ZrF<sub>4</sub>(g) = CaF(g) + ZrF<sub>3</sub>(g). Based on the reported equilibrium constants, the enthalpy change of this reaction is evaluated by the second and third law methods as -8.0 ± 25 and 28.0 ± 2 kcal/mol, respectively. The third law entropy drift is 20 ± 15 eu. Using the third law value and ΔH<sub>f,298</sub><sup>0</sup> = 42.85 ± 0.3, -400.0 ± 0.5, and -85.0 ± 2 kcal/mol for Ca(g), ZrF<sub>4</sub>(g), and CaF(g) we obtain ΔH<sub>f,298</sub><sup>0</sup>(ZrF<sub>3</sub>, g) = -264.2 ± 5 kcal/mol, which is adopted. Employing slightly different Gibbs energy functions and ΔH<sub>f,298</sub><sup>0</sup> values for the products and reactants, Murad and Hildenbrand (1) evaluated the third law enthalpy change of the above reaction as 29.4 ± 5 and ΔH<sub>f,298</sub><sup>0</sup>(ZrF<sub>3</sub>, g) = -262 ± 5 kcal/mol, which are in reasonable agreement with the values adopted here.

**Heat Capacity and Entropy**  
 The molecular structure is assumed to be the same as that of TiF<sub>3</sub>(g). The Zr-F bond distance is estimated by comparison with those for ZrF<sub>4</sub>(g) and ZrF<sub>2</sub>(g). The F-Zr-F bond angle is taken to be slightly larger than the F-Ti-F bond angle in the TiF<sub>3</sub>(g) molecule. The vibrational frequencies are calculated by the valence force method (2) using force constants transferred from those for the ZrF<sub>2</sub>(g) molecule. The three principal moments of inertia are: I<sub>A</sub> = I<sub>B</sub> = 1.8280 × 10<sup>-38</sup>, and I<sub>C</sub> = 2.9593 × 10<sup>-38</sup> g cm<sup>2</sup>. The electronic levels are estimated to be three times higher than those of TiF<sub>3</sub>(g), based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (3). The quantum weights are assumed to be the same as those of TiF<sub>3</sub>(g).

Bond Distance: Mg-F = 1.771 Å  
 Bond Angle: F-Mg-F = 135°  
 Product of the Moments of Inertia:  $I_{A, B, C} = [5.5711 \times 10^{-113}] g^2 \text{ cm.}^6$

Heat of Formation.  
 The enthalpy change,  $\Delta H_f^o = 30$  kcal. mole<sup>-1</sup>, for the reaction  $MgF_2(c) + MgF_2(g) = (MgF_2)_2(g)$  was determined by J. Berkowitz and J. R. Marquart, J. Chem. Phys. 3, 1853 (1962). Hence the heat of formation for  $(MgF_2)_2(g)$  was calculated.

Heat Capacity and Entropy.  
 The molecular structure was assumed to be planar. The two Mg atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two F atoms. The two remaining F atoms are situated outside the square on a straight line joining the two Mg atoms. The bond distance between Mg and F atom was estimated to be the same as that in the  $MgF_2(g)$  molecule. Vibrational frequencies were estimated by comparison with those for  $MgF(g)$  and  $(MgF)_2$ . The vibrational frequencies for  $(MgF)_2$  were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The three principal moments are  $9.8896 \times 10^{-39}$ ,  $7.02705 \times 10^{-38}$ , and  $8.01631 \times 10^{-38}$  g. cm.<sup>2</sup>

GFW = 187.933

Bond Distance: Mo-O = (1.64) Å Mo-F = (1.82) Å

Bond Angle: O-Mo-F = (90°) F-Mo-F = (90°)

Product of Moments of Inertia:  $\bar{I}_A \bar{I}_B \bar{I}_C = [3.1468 \times 10^{-113}] \text{ g}^3 \text{ cm}^6$

Heat of Formation

Zmbov et al. (1) investigated the stabilities of some molybdenum and tungsten oxyfluorides by means of mass spectrometry. These studies led to heats of formation for MoO<sub>2</sub>F<sub>2</sub>(g), WO<sub>2</sub>F<sub>2</sub>(g), and MoF<sub>4</sub>(g) which were used by the authors to develop a correlation among the heats of formation of the oxides, oxyfluorides, and fluorides of Mo and W.  $\Delta H_f^\circ$  varies almost linearly with the number of oxygen atoms (1) for the series WF<sub>6</sub>, WOF<sub>4</sub>, and MoF<sub>4</sub>. Assuming a similar variation for MoF<sub>6</sub>, MoOF<sub>4</sub>, and MoO<sub>2</sub>F<sub>2</sub>, we estimate  $\Delta H_f^\circ(\text{MoOF}_4, g) = -320 \text{ kcal/mol}$ .

Heat of formation data (2) for MoF<sub>6</sub>(g), MoOF<sub>4</sub>(g), and MoO<sub>3</sub>(g) have been used to derive the following average bond dissociation energies (2):

$$\bar{D}(\text{Mo-F}) = 107 \text{ kcal/mol}$$

$$\bar{D}(\text{Mo-O}) = 135 \text{ kcal/mol}$$

$$\bar{D}(\text{Mo-O}) = -271 \text{ kcal/mol}$$

From these data we derive  $\Delta H_f^\circ(\text{MoOF}_4, g) = -271 \text{ kcal/mol}$ .

Heat Capacity and Entropy

Blanchard (3) suggested that MoOF<sub>4</sub>(g) possessed C<sub>4v</sub> symmetry by reason of the similarity of its infrared spectra with that of XeOF<sub>4</sub>(g). X-ray diffraction studies of crystalline MoOF<sub>4</sub> by Edwards et al. (4, 5) support this view. The structure of the molecule is assumed to be square-pyramidal. The bond lengths are from the crystallographic studies of MoOF<sub>4</sub> by Edwards et al. (4, 5). Individual moments of inertia are  $I_A = I_B = 27.437 \times 10^{-39} \text{ g cm}^2$ ,  $I_C = 41.801 \times 10^{-39} \text{ g cm}^2$ . Blanchard (3) reported the following vibrational frequencies and assignments:

$$\nu_1 = 1045, \nu_2 = 720, \nu_3 = 680, \text{ and } \nu_6 = 530 \text{ cm}^{-1}$$

Similar frequencies have been reported by Edwards et al. (4) from their study of the infrared spectra of gaseous MoOF<sub>4</sub>. The rest of the frequencies and assignments are estimated by comparison with data for XeOF<sub>4</sub> (6).

Bond Distances: N-N = [1.47 Å] N-F = [1.37 Å]  
Bond Angles: F-N-F = [108°] N-N-F = [104°] Dihedral Angle = [66°]  
Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [1.1817 X 10<sup>-113</sup>] gm.<sup>3</sup> cm.<sup>6</sup>

Heat of Formation  
O. T. Armstrong, S. Marantz, and C. F. Coyle, National Bureau of Standards Report No. 5561, October, 1959,  
studied the reaction  
N<sub>2</sub>F<sub>4</sub>(g) + 16/3 NH<sub>3</sub>(g) = 4NH<sub>4</sub>F(s) + 5/3 N<sub>2</sub>(g).

From this reaction, they calculate the heat of formation of N<sub>2</sub>F<sub>4</sub> to be -2.0 ± 2.5 kcal. mole<sup>-1</sup>. The recalculated heat of formation of NH<sub>4</sub>F(s) (see NF<sub>4</sub> table) differs from the value quoted in Circular 500 by 0.06 kcal. mole<sup>-1</sup>. This correction would make the heat of formation of tetrafluorohydrazine more negative by 0.24 kcal. mole<sup>-1</sup>. In view of the large uncertainty in the heat of formation, however, this correction was not applied.

Heat Capacity and Entropy.

The fundamental frequencies were taken from the vapor phase infrared work of J. R. Durig and R. C. Lord, reported by D. R. Lide, Jr. and D. E. Mann, J. Chem. Phys. 31, 1129 (1959). Lide and Mann calculated the bond angles for assumed values of the NN and NF distances.

The principal moments of inertia are: I<sub>A</sub> = 1.5051 X 10<sup>-38</sup> gm. cm.<sup>2</sup>, I<sub>B</sub> = 2.6315 X 10<sup>-39</sup> gm. cm.<sup>2</sup>, I<sub>C</sub> = 2.9836 X 10<sup>-38</sup> gm. cm.<sup>2</sup>.

continued from the table nitrogen difluoride (NF<sub>2</sub>) (ideal gas).

Heat Capacity and Entropy.

M. D. Harmony, R. J. Myers, L. J. Schoen, D. R. Lide, Jr., and D. E. Mann, J. Chem. Phys. 35, 1129 (1961), investigated the infrared spectrum of NF<sub>2</sub>. They were able to assign the band center at 1074 cm.<sup>-1</sup> to the symmetric stretching mode ω<sub>1</sub>. The absorption in the 950-940 cm.<sup>-1</sup> region was assigned to ω<sub>3</sub>.

M. D. Harmony and R. J. Myers, J. Chem. Phys. 37, 656 (1962), performed matrix isolation experiments on NF<sub>2</sub>. They arrived at the assignments ω<sub>1</sub> = 1070 cm.<sup>-1</sup>, ω<sub>2</sub> = 573 cm.<sup>-1</sup>, and ω<sub>3</sub> = 931 cm.<sup>-1</sup>. The stretching frequencies for similar molecules in an N<sub>2</sub> matrix are about 5 cm.<sup>-1</sup> below the gas phase values. A comparison of the gas phase and matrix values of ω<sub>1</sub> show excellent agreement.

F. A. Johnson and C. B. Colburn, Inorg. Chem. 1, 431 (1962), report infrared studies on NF<sub>2</sub> but they draw no definite conclusions.

The gas phase value for ω<sub>1</sub> and the matrix values for ω<sub>2</sub> and ω<sub>3</sub> were taken to represent the fundamental vibrational frequencies of NF<sub>2</sub>.

Harmony, Myers, Schoen, Lide, and Mann estimated the N-F distance as 1.37 Å and used this with their data to calculate an F-N-F angle of 104.2°. Using these data the moments of inertia are: I<sub>A</sub> = 7.3728 X 10<sup>-49</sup> gm. cm.<sup>2</sup>, I<sub>B</sub> = 1.2035 X 10<sup>-39</sup> gm. cm.<sup>2</sup>, I<sub>C</sub> = 6.5763 X 10<sup>-39</sup> gm. cm.<sup>2</sup>.

ΔH<sub>f,0</sub><sup>o</sup> = Unknown

ΔH<sub>f,298.15</sub><sup>o</sup> = [-355.37 ± 6] kcal/mol

ΔH<sub>m</sub><sup>o</sup> = 1.219 ± 2 kcal/mol

S<sub>298.15</sub><sup>o</sup> = [42.0 ± 4] gibbs/mol

T<sub>m</sub> = 379°K

Heat of Formation.

The heat of formation, ΔH<sub>f,298</sub><sup>o</sup>(WOF<sub>4</sub>, c) = -355.37 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔH<sub>g,298</sub><sup>o</sup> = 16.97 kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and O. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔH<sub>f,298</sub><sup>o</sup> is 17.01 kcal/mol.

Heat Capacity and Entropy.

The heat capacities are estimated from those of WOCl<sub>4</sub>(c), WO<sub>3</sub>(c), WO<sub>2</sub>(c), WO<sub>2</sub>(c), WOCl<sub>2</sub>(c) and WF<sub>6</sub>(c,l). The entropy, S<sub>298</sub><sup>o</sup> = 42.0 au, is calculated from ΔS<sub>3,48</sub><sup>o</sup> = 37.0 eu for WOF<sub>4</sub>(c) → WOF<sub>4</sub>(g), obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

It is surprising that this entropy is larger than the corresponding value for WOCl<sub>4</sub>(c) (JANAF WOCl<sub>4</sub>(c) table dated Mar. 31, 1967). In both cases the entropies of the condensed phases are derived from the gas phase values using second law analysis of sublimation and vaporization data. The resulting entropy of melting for WOF<sub>4</sub>, 3.2 eu, is much smaller than the value 22.4 eu for WOCl<sub>4</sub>. This extreme difference may be a reflection of the uncertainty inherent in derivation of ΔS<sub>m</sub><sup>o</sup> as the difference between the values for sublimation and vaporization. If the values of ΔS<sub>m</sub><sup>o</sup> are correct, they suggest the possibility of an undiscovered solid state transition for WOF<sub>4</sub> similar to that observed for WF<sub>6</sub>.

Melting Data.

T<sub>m</sub> is calculated as the temperature at which the Gibbs energy of reaction WOF<sub>4</sub>(c) → WOF<sub>4</sub>(l) approaches zero. The difference between the heats of formation for crystal and liquid at the melting point is ΔH<sub>m</sub><sup>o</sup>.

O. Ruff, F. Elander, and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the melting point as 393°K. Cady and Hargreaves, loc. cit., derived the melting point as 379°K, and the heat of fusion as 2.26 kcal/mol from vapor pressure equations for crystal and liquid. This second law value of ΔH<sub>m</sub><sup>o</sup>, when corrected for ΔC<sub>p</sub> of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

$S^o_{298,15} = [42.8 \pm 4]$  gibbs/mol  
 $T_m = 379^\circ\text{K}$   
 $T_b = 460^\circ\text{K}$

$\Delta H^o_{298,15} = [-354.955]$  kcal/mol  
 $\Delta H_m^o = 1.219 \pm 2$  kcal/mol  
 $\Delta H_v^o = 13.4$  kcal/mol

Heat of Formation.

The heat of formation,  $\Delta H^o_{298}(WOF_4(l)) = -354.955$  kcal/mol, is calculated from that of the gas less the heat of vaporization,  $\Delta H_v^o_{298} = 16.555$  kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by O. H. Cady and O. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law  $\Delta H^o_{298}$  is 16.60 kcal/mol.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959.

The entropy,  $S^o_{298} = 42.8$  eu, is calculated from  $\Delta S^o_{415} = 31.2$  eu for  $WOF_4(l) \rightarrow WOF_4(g)$ , obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

Melting Data.

See WOF<sub>4</sub>(c) table (Mar. 31, 1967).

Vaporization Data.

$T_b$  is calculated as the temperature at which the Gibbs energy of reaction  $WOF_4(l) \rightarrow WOF_4(g)$  approaches zero. The difference between the heats of formation for liquid and gas at the boiling point is  $\Delta H_v^o$ .

O. Ruff, P. Eisner and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the boiling point as 459°K. Cady and Hargreaves, loc. cit., derived the boiling point as 459°K, and the heat of vaporization as 14.23 kcal/mol from the vapor pressure equation for the liquid. This second law value of  $\Delta H_v^o$ , when corrected for  $\Delta C_p$  of vaporization, is in good agreement with the value adopted in the tabulation.

Vibrational Frequencies and Degeneracies

Bond Distance: W-F = [1.85] Å W-O = [1.81] Å  
Bond Angle: F-W-O = F-W-F = [120°]  
F-W-F = F-W-O = [90°]  
F-W-F = [180°]  
σ = [2]

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = [3.868] × 10<sup>-113</sup> g<sup>3</sup> cm<sup>6</sup>  
\*Equatorial \*\*Axial  
P\*-W-P\* = P\*-W-O\* = [190°]

Heat of Formation.

The heat of formation, ΔH<sub>f298</sub><sup>0</sup>(WOF<sub>4</sub>, g) = -338.4 kcal/mol, is the value determined mass spectrometrically by K. F. Zmbov and J. L. Margrave, Rice Univ., private communication, Mar. 1967, from equilibrium studies of 2WOF<sub>3</sub>(g) + WO<sub>3</sub>(g) = 2 WO<sub>2</sub>F<sub>2</sub>(g) + WOF<sub>4</sub>(g).

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOF<sub>4</sub>(g), reported by P. L. Doolan, H. L. Roberts and L. A. Woodward.<sup>1</sup> The bond distances W-O and W-F are estimated to be the same as those in WO<sub>3</sub>(g) and WF<sub>6</sub>(g), respectively. The three principal moments of inertia are I<sub>A</sub> = 3.509 × 10<sup>-38</sup>, I<sub>B</sub> = 3.698 × 10<sup>-38</sup> and I<sub>C</sub> = 2.981 × 10<sup>-38</sup> g cm<sup>2</sup>.

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOF<sub>4</sub>(g), MoOCl<sub>4</sub>(g), WO<sub>2</sub>Cl<sub>2</sub>(g), CrO<sub>2</sub>Cl<sub>2</sub>(g), W<sub>2</sub>O<sub>3</sub>(g) and WF<sub>6</sub>(g). These frequencies are not in point group order.

June 30, 1962

Lead Tetrafluoride (PbF<sub>4</sub>) (Ideal Gas)

Mol. Wt. = 283.21  
 ΔH<sub>f</sub>° 298.15 = [-186] kcal. mole<sup>-1</sup>  
 S° 298.15 = 79.7 cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 Point group T<sub>d</sub>

Vibrational Levels and Multiplicities

| ΔJ, cm. <sup>-1</sup> | g       |
|-----------------------|---------|
| 564 (1)               | 570 (3) |
| 158 (2)               | 180 (3) |

Pb-F distance = 2.08 Å F-Pb-F angle = 109° 28'  
 I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 4.8233 X 10<sup>-113</sup> g.<sup>3</sup> cm.<sup>6</sup> σ = 12

Heat of Formation. ΔH<sub>f</sub>° 298.15 was estimated by comparison with the value of ΔH<sub>f</sub>° 298.15 for PbF<sub>2</sub>(s).

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagarsjan, Bull. Soc. Chim. Belg., 71, 119 (1962).

GF<sub>W</sub> = 108.058

(IDEAL GAS)

SULFUR TETRAFLUORIDE (SF<sub>4</sub>)

Sulfur Tetrafluoride (SF<sub>4</sub>)

(Ideal Gas) GF<sub>W</sub> = 108.058

Point Group C<sub>2v</sub>

S<sub>298.15</sub> = 71.83 ± 0.10 gibbs/mol

Ground State Quantum Weight = 1

ΔH<sub>f</sub><sup>0</sup> = -185.1 ± 6 kcal/mol  
ΔH<sub>f</sub><sup>0</sup> = -186.6 ± 6 kcal/mol

Bond Distance: (S-F) eq. = 1.545 ± 0.003 Å

(S-F) ax. = 1.646 ± 0.003 Å

Bond Angle: (F-S-F) eq. = 101.93° ± 30°

(F-S-F) ax. = 186.56° ± 30°

Product of Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 6.721 × 10<sup>-114</sup> g<sup>3</sup> cm<sup>6</sup>

Heat of Formation

Vaughn and Muetterties (1) reported calorimetric data for the hydrogenation of SF<sub>4</sub>. Their experiments produced HF in amounts ranging from 5.8 to 7.5g. Roughly 1.3g should have been present as saturated, real vapor in the bomb volume of 360 ml at the final temperature of the experiment. Although the authors made allowance for this mixture of HF(g) and HF(real vapor), their values appear to be quite unrealistic. More reliable corrections are readily obtained from the recent report by Vanderzee (2) of PVT and calorimetric data for HF liquid and real vapor.

We choose to reduce the data to a standard state of HF(l), starting from the authors' values of the calorimeter heat capacity and the observed temperature rise. Calculated values for the heat evolved are corrected by a) an increase of ~120 cal for conversion of real vapor to liquid, b) a decrease of 113 to 175 cal for oxidation of H<sub>2</sub>(g) to S(c) in the last three experiments, and c) an increase of 22 to 78 cal for adjustment of the reaction to 25°C from the final temperature of the experiment. At 298.15 K we obtain

SF<sub>4</sub>(g) + 2H<sub>2</sub>(g) + 4HF(l) + S(c), ΔH<sup>0</sup> = -102.9 ± 4 kcal/mol,

where the uncertainty is increased by 1.5 kcal/mol for other possible corrections which are neglected due to insufficient information.

The adopted ΔH<sup>0</sup> = -186.6 ± 6 kcal/mol, is derived from ΔH<sup>0</sup> using ΔH<sup>0</sup> = -72.38 ± [0.5] kcal/mol (2, 3) for HF(l). Smith (3) details a value of ΔH<sup>0</sup> = -176 kcal/mol for SF<sub>4</sub> as determined by Nicholls (5) from hydrolysis studies. We do not have details of the hydrolysis studies, but the result presumably should be adjusted for changes in ΔH<sup>0</sup> of aqueous HF.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Levin and Benney (6) and are in good agreement with the frequencies reported by Dodd et al. (2) except for the 353 and 171 cm<sup>-1</sup> bands. The structural data are from the microwave studies of Tollies and Gwinn (8) and are in good agreement within experimental error with electron-diffraction data reported by Kimura and Bauer (9) and Dising and Sutton (10). Individual moments of inertia calculated from the rotational constants reported by Tollies and Gwinn (8) are I<sub>A</sub> = 1.2552 × 10<sup>-36</sup> g cm<sup>2</sup>, I<sub>B</sub> = 2.0540 × 10<sup>-36</sup> g cm<sup>2</sup>, and I<sub>C</sub> = 2.6069 × 10<sup>-36</sup> g cm<sup>2</sup>.

Bond Distance: Si-F = 1.54 ± 0.02 Å

Bond Angle: F-Si-F = 109° 28'

Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 7.93269 × 10<sup>-114</sup> g.<sup>3</sup> cm.<sup>6</sup>

## Heat of Formation.

The heat of formation of SiF<sub>4</sub>(g) was measured by direct combination of the elements in a bomb calorimeter by S. S. Wise, J. L. Margrave, H. M. Feder and W. N. Hubbard, *J. Phys. Chem.* **67**, 815 (1963).  $\Delta H_f^0 298.15$  was found to be  $-385.98 \pm 0.19$  kcal. mole<sup>-1</sup>. Heats of the reaction between SiF<sub>4</sub>(g) and Ne(c), 1% HF solution, 0.4% HF solution, a solution of HF saturated with Ne<sub>2</sub>SiF<sub>6</sub>, and water have been measured by A. P. Vorob'ev, V. P. Kolesov, and S. M. Skuratov, *Zh. Neorg. Khim.* **5**, 1402 (1960). The value of  $\Delta H_f^0 298.15$  for SiF<sub>4</sub>(g) was reported to be  $-372.4 \pm 0.4$  kcal. mole<sup>-1</sup> which was not used.

## Heat Capacity and Entropy.

The vibrational frequencies used were reported by E. A. Jones, J. S. Kirby-Smith, P. J. H. Woltz, and A. H. Melsen, *J. Chem. Phys.* **19**, 242 (1951). The values of vibrational frequencies were given as 800(1), 285(2), 1000(3), and 431(3) cm.<sup>-1</sup> for SiF<sub>4</sub>(g) by D. M. Yost, B. M. Leasette, and S. T. Cross, *J. Chem. Phys.* **4**, 325 (1936). The molecular data were obtained from L. Pauling and L. O. Brockway, *J. Am. Chem. Soc.* **57**, 2684 (1935). The three principal moments of inertia are: I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 1.99437 × 10<sup>-38</sup> g. cm.<sup>2</sup>

TITANIUM TETRAFLUORIDE (TiF<sub>4</sub>) (CRYSTAL)

GFW = 123.8936

ΔHf° = -393.67 ± 0.9 kcal/mol  
 ΔHf°<sub>298.15</sub> = -394.2 ± 0.9 kcal/mol  
 ΔHs°<sub>298.15</sub> = 21.37 ± 0.1 kcal/mol

S°<sub>298.15</sub> = 32.02 gibbs/mol  
 Ts = 558.6°K

Heat of Formation

The heat of formation (ΔHf°<sub>298.15</sub>) of TiF<sub>4</sub>(c) was measured using a fluorine bomb calorimeter by Greenberg et al. (1). Gross et al. (2) reported a value of -393.4 kcal/mol for ΔHf°<sub>298</sub>. The latter measurements were not corrected for impurities in the titanium sample, thus the value reported by Greenberg et al. is adopted.

Heat Capacity and Entropy

The heat capacity of TiF<sub>4</sub>(c) has been measured over the temperature range 6° to 304°K by Euler and Westrum (3). They obtained the value of S°<sub>298</sub> based on S°<sub>10</sub> = 0.11 eu. Heat capacities above 300°K are estimated from those of ZrF<sub>4</sub>(c) (4).

Heat of Sublimation

The sublimation point is calculated as the temperature at which ΔG° = 0 for TiF<sub>4</sub>(c) = TiF<sub>4</sub>(g). The heat of sublimation is obtained from the data of Hall et al. (5).

Heat of Formation

The heat of formation of TiF<sub>4</sub>(g) is calculated from that of the crystal and the heat of sublimation, ΔH<sub>298</sub><sup>o</sup>, obtained from vapor pressure measurements. E. H. Hall, J. M. Blocher, Jr., and I. E. Campbell, J. Electrochem. Soc. 105, 275 (1958), have reported extensive vapor pressure data for the reaction TiF<sub>4</sub>(c) = TiF<sub>4</sub>(g). Second and third law analyses of their data yielded the following results.

| Method           | No. Pts. | Range, °K | ΔH <sub>298</sub> <sup>o</sup> , kcal/mol | Drift, eu  | ΔH <sub>298</sub> <sup>o</sup> * |

\*\*\*Eight points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The interatomic distance is obtained from a correlation of the measured values for TiCl<sub>4</sub>(g), TiBr<sub>4</sub>(g), TiCl<sub>6</sub><sup>-2</sup>, and TiF<sub>6</sub><sup>-2</sup>. The principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = I<sub>C</sub> = 2.724 × 10<sup>-38</sup> g cm<sup>2</sup>.

The vibrational frequencies are estimated by a valence force field treatment of estimated force constants. The force constants are estimated from a correlation with the constants of CF<sub>4</sub>, SiF<sub>4</sub>, CO<sub>2</sub>, SiCl<sub>4</sub>, CBr<sub>4</sub>, SiBr<sub>4</sub>, TiCl<sub>4</sub>, and TiBr<sub>4</sub>. The resulting frequencies are adjusted so that calculations of ΔH<sub>298</sub><sup>o</sup> by both second and third law methods are in agreement.

ΔH<sub>m</sub><sup>\*</sup> = 15.35 ± 0.10 kcal/mol

ΔH<sub>s</sub><sup>\*</sup> = 51.64 kcal/mol

ΔH<sub>s</sub><sup>298.15</sup> = 56.80 kcal/mol

Heat of Formation

The heat of formation of zirconium tetrafluoride was measured by direct combination of the elements in a bomb calorimeter by Greenberg, Settle, Feder, and Hubbard (1). The reported value ΔH<sub>f</sub><sup>298</sup>(ZrF<sub>4</sub>, c) = -456.80 ± 0.25 kcal/mol is adopted.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range 5 to 307°K were determined by adiabatic calorimetry by Westrum (2). Using these low temperature Cp data the value of S<sub>298</sub> is derived as 25.024 ± 0.05 eu, based on S<sub>10</sub> = 0.0074 eu. McDonald, Sinke, and Stull (3) measured the high temperature enthalpies of ZrF<sub>4</sub>(c) at temperatures 283.9 - 1225.8°K in a copper block drop calorimeter. Smith, Miller, and Taylor (4) used a Bunsen ice calorimeter for the heat-content measurements in the temperature range 273 - 1150°K. These two sets of enthalpy data are not in good agreement. It is possible that the discrepancies are due to the difference in crystal structure of the samples used (see "Transition Data" for more information). In order to join smoothly with the low temperature heat capacities at 298°K, the high temperature heat capacities derived from the enthalpy data of McDonald, Sinke, and Stull (3) are adopted. The Cp values above 1200°K are obtained by smooth extrapolation.

Transition Data

Zirconium tetrafluoride has three crystal structures (α, β and γ) and one amorphous form (δ). From a differential thermal analysis of (NH<sub>4</sub>)<sub>3</sub>ZrF<sub>7</sub> sample, Chretien and Gaudreau (5) found that ZrF<sub>4</sub>(c) has an α and β form with a transition temperature above 678°K. They also determined the densities of α(tetragonal) and β(monoclinic) as 4.25 ± 0.05 and 4.61 ± 0.03 gm/cc, and a transition temperature as T<sub>m</sub>(α + β) = 723°K (7). It was observed that the α phase is unstable at all temperatures above 298°K. In reference (5), Gaudreau mentioned the methods of preparation of the four varieties of ZrF<sub>4</sub> and indicated that α-, γ-, and amorphous ZrF<sub>4</sub> transform irreversibly to β-ZrF<sub>4</sub> at 773 - 773°K.

The ZrF<sub>4</sub> sample employed by McDonald, Sinke, and Stull (3) for enthalpy measurement was prepared by dissolving hafnium-free zirconium metal in 4M aqueous HF, and the resulting solution was evaporated to dryness. The crystalline product was heated slowly to 773°K in a platinum boat in a slow current of anhydrous HF. X-ray diffraction showed only crystalline ZrF<sub>4</sub>. Wet analysis indicated 54.61 Zr (theory 54.55) and 44.91 F (theory 45.45). Due to the above facts we are uncertain whether the sample prepared is a mixture of α and β forms or a pure ZrF<sub>4</sub>(β). Smith, Miller, and Taylor (4) obtained their ZrF<sub>4</sub> sample from the Oak Ridge National Laboratories, Oak Ridge, Tenn. Since the method of preparation of the compound is unavailable from the report, we do not know what kind of sample they used for measurement.

Because of the above complicated situation, we emphasize that this ZrF<sub>4</sub>(c) table is not strictly a α, β-combined phase table. However, the differences in the calculated functions are probably not significant.

Melting Data

T<sub>m</sub> and ΔH<sub>m</sub><sup>\*</sup> are taken from McDonald, Sinke, and Stull (3). The values were obtained under conditions greater than one atmosphere.

Sublimation Data

The sublimation temperature (T<sub>s</sub>) is calculated as the temperature at which the Gibbs energy change of the process ZrF<sub>4</sub>(c) = ZrF<sub>4</sub>(g) approaches zero. The difference between ΔH<sub>f</sub><sup>298</sup>(ZrF<sub>4</sub>(g)) and ZrF<sub>4</sub>(c) at 1179 and 298°K is ΔH<sub>s</sub><sup>\*</sup> and ΔH<sub>s</sub><sup>298</sup>, respectively.

Since the sublimation temperature is lower than the melting point, the ZrF<sub>4</sub> sublimates before it melts.

Bond Distances: Zr-F = 1.94 ± 0.02 Å  
 Bond Angle: F-Zr-F = 109.47°  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 3.17347 × 10<sup>-113</sup> g<sup>3</sup> cm<sup>6</sup>  
 σ = 12

Heat of Formation

The vapor pressures of ZrF<sub>4</sub>(g) in the temperature range 617-1150°K were determined by many investigators using various methods. Based on the reported vapor pressure data, the corresponding heats of sublimation are evaluated by the second and third law methods. Using the third law ΔH<sub>298</sub> and ΔH<sub>f,298</sub>(ZrF<sub>4</sub>, c) = -456.8 kcal/mol, the heats of formation at 298°K for ZrF<sub>4</sub>(g) are evaluated. The results are presented in the table below. The values of ΔH<sub>f,298</sub>(ZrF<sub>4</sub>, g) listed in the last column of this table are in excellent agreement which indicate that the estimated missing vibrational frequencies ν<sub>1</sub> and ν<sub>2</sub> are reasonable. The heat of formation at 298°K for ZrF<sub>4</sub>(g) is adopted as -400.0 kcal/mol.

| Investigator                 | Method            | Temperature, °K | ΔH <sub>f,298</sub> , kcal/mol |           | Drift    |

Heat Capacity and Entropy

The molecular structure of ZrF<sub>4</sub>(g) has been studied by electron diffraction by Spiridonov (11). The configuration was found to be a regular tetrahedron with interatomic distance Zr-F = 1.94 ± 0.02 Å and F-Zr-F bond angle = 109.47° which are adopted. Employing the estimated interaction coefficients and interatomic distance Zr-F = 1.85 Å, Godnev, Aleksandrovaika, and Rigina (12) calculated three vibrational frequencies for ZrF<sub>4</sub>(g) as ν<sub>1</sub> = 600 - 725, ν<sub>2</sub> = 150 - 200, and ν<sub>4</sub> = 180 ± 230 cm<sup>-1</sup>. Büchler, Berkowitz, and Dugre (13) observed the infrared spectra of some group IV halides and assigned ν<sub>3</sub> = 686 and ν<sub>4</sub> = 190 ± 20 cm<sup>-1</sup> for ZrF<sub>4</sub>(g). The frequency ν<sub>3</sub> has also been reported as 670 cm<sup>-1</sup> (14). The values of ν<sub>3</sub> and ν<sub>4</sub> adopted here are those reported by Büchler, Berkowitz, and Dugre (13). The adopted ν<sub>1</sub> is obtained by correlating the corresponding frequencies of the tetrafluorides of C, Pb, Si, Ti and Ge with their respective interatomic distances. ν<sub>2</sub> is calculated from ν<sub>1</sub>, ν<sub>3</sub> and ν<sub>4</sub> using the relationship (15) ν<sub>2</sub> = √(2/3) √(ν<sub>1</sub>ν<sub>3</sub>ν<sub>4</sub>) where F and Zr are gram atomic weights of fluorine and zirconium, respectively. The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 3.166 × 10<sup>-38</sup> g cm<sup>2</sup>.

Bond Distance: I-F(equatorial) = (1.86) Å I-F(axial) = (1.75) Å  
 Bond Angle: F-I-F = (90°)  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = (4.10383 × 10<sup>-113</sup>) g<sup>3</sup> cm<sup>6</sup>

Heat of Formation  
 The adopted value is derived from calorimetric data of Settle et al. (1) for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF<sub>5</sub> and IF<sub>3</sub>, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave ΔHf° = -210.8 ± 0.3 kcal/mol for IF<sub>5</sub>(g) at 298.15 K. The result is essentially independent of the heptafluoride. Comparison values of -208.9 ± (±1.7) kcal/mol may be obtained from calorimetric data of Woolf (2) for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data (3). In particular, we estimate lower limits of ±0.8 kcal/mol for ΔHf° of HIO<sub>3</sub>(1250 H<sub>2</sub>O) and KIO<sub>3</sub>(1250 H<sub>2</sub>O) by comparison with recent data (4).

ΔHf° for the ideal gas is derived from that of the liquid by use of ΔHv° = 9.96 kcal/mol at 298.15 K. ΔHv° was derived by Osborne et al. (5) from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy  
 There is no published structural determination for gaseous IF<sub>5</sub>, but spectral data are consistent with C<sub>4v</sub> symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I-F distances are equal. We adopt the structure used by Begun et al. (7) in correlation of infrared and Raman spectra of BrF<sub>5</sub>, IF<sub>5</sub>, ClF<sub>5</sub>, and XeOF<sub>4</sub> by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF<sub>5</sub>. The iodine is presumed to be in the base of the pyramid. Simplified Hückel-molecular-orbital calculations (8) predict that C<sub>4v</sub> is the most stable symmetry, that the axial bond is shorter, and that the equatorial fluorines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun et al. (7) note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are I<sub>A</sub> = I<sub>B</sub> = 30.86 × 10<sup>-39</sup> and I<sub>C</sub> = 43.65 × 10<sup>-39</sup> g cm<sup>2</sup>.

Vibrational frequencies are based on the assignments of Begun et al. (7) as modified by the vapor-phase Raman spectra observed by Selig (6). Location of the band center of ν<sub>3</sub> (~200 cm<sup>-1</sup>) is difficult, so we substitute the liquid value of 190 cm<sup>-1</sup>. The Raman-active fundamental ν<sub>3</sub> is not observed for IF<sub>5</sub>, or any of the similar molecules, so its value is taken from the calculations (7).

Osborne et al. (5) used calorimetric data at low temperatures to derive S° = 57.96 ± 0.06 gibbs/mol for the liquid at 330 K. Combining this with ΔSv° based on their vapor pressure equation, the authors obtained S° = 83.06 ± 0.70 gibbs/mol for the ideal gas at 330 K. The corresponding value from this table (82.50) is lower by 0.56 gibbs/mol. Part of this difference arises from uncertainties in ν<sub>3</sub>, ν<sub>9</sub>, and the product of the moments of inertia. We estimate this uncertainty at about 0.5 gibbs/mol. Another source of minor uncertainty is the neglect of anharmonicity in the calculations.

Heat of Formation

Gross, Hayman, and Stuart (1) measured the heat of combustion of α-white phosphorus in fluorine at 25°C. They reported a heat of formation of -381.4 ± 0.6 kcal/mol (based on α-white phosphorus standard state) calculated from their combustion studies. Similar combustion studies were performed by O'Hare and Hubbard (2). They reported a heat of formation of -380.8 ± 0.3 kcal/mol (α-white phosphorus standard state), which is in excellent agreement with the work of Gross et al. (1). An average value of -381.1 ± 0.5 kcal/mol is adopted for this tabulation. Converting to the P(red, V) standard state with a ΔH trans = 4.2 ± 0.2 kcal/mol (3), we derive, ΔH<sub>f298</sub><sup>0</sup>(PF<sub>5</sub>, g) = -376.9 ± 0.7 kcal/mol.

Heat Capacity and Entropy

The molecular structure and bond lengths given above for PF<sub>5</sub> were recently determined by Hansen and Bartell (4) from electron-diffraction studies. These results indicate that PF<sub>5</sub> has a trigonal bipyramidal structure with nonequivalent axial and equatorial bonds. Wyatt et al. (5) determined rotational constants for PF<sub>5</sub> from a study of the infrared vibration-rotation band contour of the ν<sub>4</sub> (575 cm<sup>-1</sup>) fundamental. Their analysis led to the following P-F bond lengths which are in excellent agreement with the electron-diffraction results: r<sub>ax</sub> = 1.534 ± 0.024 Å and r<sub>eq</sub> = 1.581 ± 0.025 Å. Individual moments of inertia, calculated from the rotational constants given by Wyatt et al. (5) and adopted for this table, are I<sub>A</sub> = 2.230 × 10<sup>-38</sup> g cm<sup>2</sup> and I<sub>B</sub> = I<sub>C</sub> = 2.690 × 10<sup>-38</sup> g cm<sup>2</sup>. The electron diffraction data lead to a product of moments of inertia of 1.604 × 10<sup>-113</sup> g<sup>3</sup> cm<sup>6</sup>.

Several recent infrared and Raman studies (6, 7, and 8) have been reported for PF<sub>5</sub>. These data are in good agreement except for the ν<sub>7</sub> fundamental. Griffiths et al. (6) originally assigned this fundamental to the 126 cm<sup>-1</sup> band observed in their infrared spectra. Hoskins (7) later attributed this band to one of the pure rotational lines of hydrogen fluoride, which he felt was present in the sample as an impurity. Further work by Griffiths (10) on the pressure dependence of the infrared spectra of PF<sub>5</sub> indicated that the missing fundamental should be assigned to the weak band at 301 cm<sup>-1</sup>. Beaters and Holmes (11) recently showed that this band is not a fundamental of PF<sub>5</sub> but a difference band (ν<sub>3</sub>-ν<sub>2</sub>). Very recently, Levin (8) investigated the Raman spectra of solid phosphorus pentafluoride and assigned the ν<sub>7</sub> fundamental to the 179 cm<sup>-1</sup> band. Also, Beattie et al. (12) investigated the Raman spectra of PF<sub>5</sub> in the gas phase at 25°C and 125°C and assigned the ν<sub>7</sub> fundamental to 175 cm<sup>-1</sup> band which is in excellent agreement with Levin's assignment (8). The fundamental vibrational frequencies of Holmes and Lord (7) are adopted along with Levin's assignment (8) of the ν<sub>7</sub> fundamental (179 cm<sup>-1</sup>).

Heat of Formation

The adopted heat of formation,  $\Delta H_f^\circ(\text{MoF}_6, \ell)$  = -379,080 ± 0.3 kcal/mol, is calculated from the heat of formation of the gas,  $\Delta H_f^\circ(\text{MoF}_6, g)$  = -372.4 ± 0.2 kcal/mol (1), and the heat of vaporization,  $\Delta H_v^\circ$  = 6.680 ± 0.03 kcal/mol at 298.15°K. The value for the heat of vaporization is obtained from a third law analysis of the vapor pressure data reported by Osborne et al. (2). Myers and Brady (3) determined calorimetrically  $\Delta H_f^\circ$  = -154.7 kcal/mol for the hydrolysis reaction:

Heats of formation of  $\text{Na}_2\text{CO}_3$  and NaF in the final solution were determined from the following two auxiliary heat of reaction measurements:

Combining these results with the following heat of formation data:

$\Delta H_f^\circ(\text{MoO}_3, c)$  = -178.1 ± 0.1 kcal/mol (4)  
 $\Delta H_f^\circ(\text{NaF}, c)$  = -137.52 ± 0.2 kcal/mol (5)  
 $\Delta H_f^\circ(\text{NaOH} \cdot 500 \text{H}_2\text{O})$  = -112.12 kcal/mol (6)

we derive  $\Delta H_f^\circ(\text{Na}_2\text{CO}_3, \text{in soln.})$  = -351.6 kcal/mol and  $\Delta H_f^\circ(\text{NaF}, \text{in soln.})$  = -137.4 kcal/mol. These data, when combined with the results for the hydrolysis of  $\text{MoF}_6$ , lead to  $\Delta H_f^\circ(\text{MoF}_6, \ell)$  = -379.6 kcal/mol. This result is not in agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity measurements for liquid  $\text{MoF}_6$  by Osborne et al. (2) are adopted. Outside the observed range Cp was extrapolated linearly with temperature.  $S^\circ_{298.15}$  is evaluated from the thermal data of Osborne et al. (2) and the third law of thermodynamics. They reported heat capacity data in the range 5°-350°K with  $S^\circ_K$  = 0.024 gibbs/mol.

Melting Data

Melting point and heat of melting data for  $\text{MoF}_6$  have been reported by several investigators. These results are summarized below.

| Investigator            | Method         | Melting Point °K | $\Delta H_m^\circ$ kcal/mol |
|-------------------------|----------------|------------------|-----------------------------|
| Osborne et al. (2)      | Calorimetric   | 290.76 ± 0.02    | 1.034 ± 0.001               |
| Brady et al. (2)        | Calorimetric   | 290.7            | 1.059 ± 0.010               |
| Cady and Hargreaves (8) | Vapor Pressure | 290.55           | 1.00 ± 0.03*                |
| Ruff and Ascher (9)     | Vapor Pressure | 290.65           | 1.31 ± 0.2*                 |

\* This value is the difference between the 2nd law heat of sublimation corrected for Cp of the process and the adopted heat of vaporization calculated at 290.76°K with  $(H_{290.76}^\circ - H_{298.15}^\circ)$  for the vapor and liquid. The value  $\Delta H_m^\circ_{290.76}$  = 1.034 ± 0.001 kcal/mol from Osborne et al. (2) is adopted.

Vaporization Data

Second and third law analyses of various sets of vapor pressure data (2, 8, 9) are summarized below. Corrections for nonideality of the vapor have been calculated from the second virial coefficient equation reported by Osborne et al. (2).

| Investigator            | Temp. Range °K  | No. of Points | Boiling Point °K | $\Delta H_v^\circ$ kcal/mol |
|-------------------------|-----------------|---------------|------------------|-----------------------------|
| Osborne et al. (2)      | 291.15 - 320.15 | 21            | 307.04           | 6.680                       |
| Cady and Hargreaves (8) | 290.55 - 307.15 | Equation      | 307.15           | 6.74                        |
| Ruff and Ascher (9)     | 290.65 - 294.85 | 4             | 308.15           | 5.99                        |

\* with  $\Delta C_p$  = -11.77 gibbs/mol

The value  $\Delta H_v^\circ_{298}$  = 6.680 ± 0.03 ( $\Delta H_v^\circ_{307.04} = 6.512 \pm 0.04$ ) kcal/mol, determined from the vapor pressure data of Osborne et al. (2), is adopted in the tabulation. The temperature at which  $\Delta G_v^\circ = 0$  is 308.0°K and the corresponding  $\Delta H_v^\circ = 6.562$  kcal/mol.

 σ = 24

Heat of Formation

Settle et al. (1) measured the heat of formation of gaseous MoF<sub>6</sub> by direct combination of its elements in a nickel bomb calorimeter. Their result was ΔHf°<sub>298</sub>(MoF<sub>6</sub>, g) = -372.4 ± 0.2 kcal/mol. This value is adopted in the tabulation.

Heat Capacity and Entropy

Tanner and Duncan (2) investigated the Raman spectra of liquid MoF<sub>6</sub>, and their results indicated that the structure of the molecule was a regular octahedron with O<sub>h</sub> symmetry rather than an unsymmetrical structure as reported by Braune and Pinnow (3) from electron diffraction studies. The Mo-F bond length, is from the electron diffraction studies of Nazarian (4). Individual moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 4.268 × 10<sup>-38</sup> g cm<sup>2</sup>.

Several infrared (5, 6, 7, 8) and Raman (5, 7) studies of MoF<sub>6</sub> have been reported. The vibrational frequencies reported for MoF<sub>6</sub> from these studies are in good agreement except for the infrared and Raman inactive ν<sub>6</sub> vibration. Burke et al. (5) and Hellberg et al. (8) derived ν<sub>6</sub> = 234 cm<sup>-1</sup>, while Claassen et al. (7) assigned ν<sub>6</sub> = 130 cm<sup>-1</sup> and Gaunt (6) assigned ν<sub>6</sub> = 240 cm<sup>-1</sup>. Weinstein and Goodman (9) recently analyzed the infrared and Raman data for MoF<sub>6</sub> and assigned ν<sub>6</sub> = 122 cm<sup>-1</sup>.

Osborne et al. (10) calculated S° = 62.06 ± 0.06 gibbs/mol for liquid MoF<sub>6</sub> at 298.15°K from their low temperature thermal data. Combining this with ΔS<sub>v</sub>, they obtained S° = 83.75 ± 0.10 gibbs/mol for the ideal gas at 298.15°K. Accepting the assignments of Weinstein and Goodman (9), we calculate S<sub>298.15</sub> = 83.76 gibbs/mol, which is in excellent agreement with the thermal results. The other assignments given above for ν<sub>6</sub> all lead to ideal gas entropies that are lower than the thermal results. Therefore, the assignments given by Weinstein and Goodman (9) are adopted here.

Bond Length = 1.564 Å  
 Bond Angle: F-S-F = 90°  
 Product of the Moments of Inertia:  $I_A I_B I_C = 29,400 \times 10^{-117}$  g.<sup>3</sup> cm.<sup>6</sup>

$\sigma = 24$

Heat of Formation.

P. A. O. Hsre, J. L. Settle, and W. N. Hubbard, Preprint of Paper XIV on Fluorine Bomb Calorimetry, July, 1965, measured the enthalpy of combustion of rhombic sulfur in fluorine. Their result yields  $\Delta H_f^{298} = -291.79 \pm 0.24$  kcal. mole<sup>-1</sup>. P. Gross, C. Hayman, and L. L. Levi, XVIII Intern. Congr. Pure and Appl. Chem., Abstr., J, 30 (1959), reported  $-289.5$  kcal. mole<sup>-1</sup> also based on direct combination of the elements. O'Hare, Settle, and Hubbard mentioned a private communication from Dr. Gross indicating  $-289.5$  kcal. mole<sup>-1</sup> may be in error due to oxygen in the fluorine used and preliminary results of a redetermination are in better agreement with  $-291.79$  kcal. mole<sup>-1</sup>. D. M. Yost and W. H. Clausen, J. Am. Chem. Soc. 55, 887 (1933) determined  $-262$  kcal. mole<sup>-1</sup>, again by direct reaction of the elements, which now appears too low. The work of O'Hare et al., loc. cit., is adopted.

Heat Capacity and Entropy.

V. C. Ewing and L. E. Sutton, Trans. Faraday Soc. 59, 124 (1963) measured the bond length adopted here by the electron diffraction technique. Earlier less accurate work by the same method by H. Brune and S. Knoke, Z. Physik. Chem. B21, 297 (1933) and L. O. Brockway and L. Pauling, Proc. Nat. Acad. Sci. USA 19, 68 (1933) is in agreement within experimental error. T. E. Morsy, Ber. Bunsenges Physik. Chem. 68, 277 (1964) reviewed the literature on Raman and infrared spectra. Frequencies given here differ slightly from his selection because more weight was given to the Raman frequencies of C. W. Oullikoon, J. R. Nielsen, and A. T. Stair, Jr., J. Mol. Spectroscopy 1, 151 (1957). Calculated functions by Moray loc. cit. are in reasonable agreement with the present work.

A. Eucken and E. Schröder, Z. Physik. Chem. 41B, 307 (1938) measured low temperature thermal data from which K. K. Kelley and E. O. King, U. S. Bur. Mines Bull. 592 (1961) calculated  $s_{298}^0 = 70.3 \pm 0.7$  cal. mole<sup>-1</sup> deg.<sup>-1</sup> which agrees within experimental error with the spectroscopic result.

The three principal moments of inertia are  $I_A = I_B = I_C = 3.0863 \times 10^{-38}$  g. cm.<sup>2</sup>

(LIQUID)

OPW = 297.8404

$S_{298}^{298,15} = 59.564 \pm 0.2$  gibbs/mol  
 $T_m = 275.2^\circ\text{K}$   
 $T_b = 290.3^\circ\text{K}$   
 $\Delta H_f^{298,15} = -417.87 \pm 0.5$  kcal/mol  
 $\Delta H_m^\circ = 0.980$  kcal/mol  
 $\Delta H_v^\circ = 6.465 \pm 0.08$  kcal/mol

Heat of Formation.

The adopted heat of formation, -417.87 kcal/mol, is calculated from the chosen  $\Delta H_f^{298,15} = 6.465 \pm 0.08$  kcal/mol with  $\Delta H_f^{298}(\text{WF}_6, \text{g}) = -411.5 \pm 0.4$  kcal/mol using all JANAF functions. The value of  $\Delta H_f^{298,15}$  is obtained by corrected 2nd law analysis of vapor pressure data<sup>6,7,8</sup> which are given in the vaporization section of this table.

O. E. Myers and A. P. Brady<sup>1</sup> measured calorimetrically  $\Delta H_f^{298} = -150.1$  kcal/mol for the reaction  $\text{WF}_6(\text{l}) + 6 \text{ NaOH}(500\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(4900\text{H}_2\text{O}) + 6\text{H}_2\text{O}(\text{l}) + 6\text{NaF}(500\text{H}_2\text{O})$ . V. I. Spitsyn and N. N. Patsukova<sup>2</sup> measured calorimetrically  $\Delta H_f^{298} = -13.8$  kcal/mol for the reaction  $\text{WO}_3(\text{c}) + 2 \text{ NaOH}(80\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(4200\text{H}_2\text{O}) + \text{H}_2\text{O}(\text{l})$ . Based on these data and auxiliary data for  $\text{NaOH}(\text{aq})^{3,9}$ ,  $\text{NaF}(\text{aq})^{3,10}$  and  $\text{Na}_2\text{WO}_4(\text{aq})^4$ , we obtain  $\Delta H_f^{298} = -138.2$  kcal/mol for  $\text{WF}_6(\text{l}) + 6 \text{ NaOH}(\text{aq}) \rightarrow \text{WO}_3(\text{c}) + 3 \text{ H}_2\text{O}(\text{l}) + 6 \text{ NaF}(\text{aq})$ . This leads to  $\Delta H_f^{298}(\text{WF}_6, \text{l}) = -418.9 \pm 1$  kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy.

The heat capacity, 40.5 gibbs/mol, is obtained from a graph of the Cp versus temperature curve determined calorimetrically by E. F. Westrum, Jr.<sup>5</sup>  
 The entropy,  $S_{298}^{298}$  = 59.564 eu, is calculated from the chosen  $\Delta H_f^{298,15} = 6.465$  kcal/mol with  $S_{298}^{298}(\text{WF}_6, \text{g}) = 61.504$  eu using all JANAF functions.

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized below. Ruff and Acharova value, 2.40 kcal/mol, is too high because they did not know of the existence of a solid-solid transition<sup>5</sup> at 264.7°K with  $\Delta H_m^\circ = 2.087$  kcal/mol. Westrum's data are adopted in the tabulation.

| Investigator <sup>5</sup>      | Method         | Melting Point (°K) | $\Delta H_m^\circ$ (kcal/mol) |
|--------------------------------|----------------|--------------------|-------------------------------|
| Westrum <sup>5</sup>           | Calorimetric   | 275.2              | 0.980                         |
| Ruff and Acharova <sup>7</sup> | Vapor pressure | 275.4              | 2.400*                        |
| Barber & Gady <sup>8</sup>     | Warming curve  | 275.1              | 0.500                         |
| Cady & Hargreaves <sup>6</sup> | Vapor pressure | 275.2              | 0.420*                        |

\*This value is the difference between the 2nd law heats of sublimation and vaporization without correction for  $\Delta Cp^\circ$  for both processes.

Vaporization Data.

Second law analyses of the data<sup>6,7,8</sup>, neglecting corrections for nonideality of the vapor, are summarized below. The value of  $\Delta H_v^{298} = 6.37$  kcal/mol ( $\Delta H_v^{298,15} = 6.465$  kcal/mol) is selected in the tabulation.

| Investigator <sup>7</sup>        | Temp. Range (°K) | No. of Points | Boiling Point (°K) | $\Delta H_v^{298}$ (kcal/mol) | $\Delta S_v^{298}$ (eu) |
|----------------------------------|------------------|---------------|--------------------|-------------------------------|-------------------------|
| Ruff and Acharova <sup>7</sup>   | 275 - 287.5      | 5             | 290.7 ± 0.2        | 6.30 ± 0.12                   | 21.70                   |
| Barber and Gady <sup>8</sup>     | 285 - 324.5      | 16            | 290.2 ± 0.05       | 6.37 ± 0.01                   | 21.94                   |
| Cady and Hargreaves <sup>6</sup> | 275 - 290        | Equation      | 290.3 ± 0.05       | 8.12                          | 21.09                   |

\*From second law analysis using  $\Delta Cp = -12.4$  gibbs/mol

Bond Distance: W-F = 1.83 Å  
 Bond Angle: F-W-F = 90°  
 Product of the Moments of Inertia: I<sub>A</sub>I<sub>B</sub>I<sub>C</sub> = 7.54576 x 10<sup>-113</sup> g<sup>3</sup> cm<sup>6</sup> σ = 24

Heat of Formation

P. A. O'Hare and W. N. Hubbard, J. Phys. Chem. **70**, 3553 (1966), determined the heat of formation, ΔH<sub>f298</sub>(WF<sub>6</sub>) = -411.5 ± 0.4 kcal/mol, by combustion of tungsten in fluorine in a bomb calorimeter. This value is adopted in the tabulation.

Heat Capacity and Entropy

The molecular configuration and vibrational frequencies were obtained from the infrared and Raman spectroscopic studies by J. Gaunt<sup>1</sup>, T. O. Burke, D. P. Smith and A. H. Nielsen<sup>2</sup>; K. N. Tanner and A. B. P. Duncan<sup>3</sup>.

The bond distance was reported by H. H. Claassen<sup>4</sup>, based on the preliminary result of V. Schomaker, M. Kimura and B. Weinstein<sup>5</sup> who determined the bond distance by electron diffraction. J. Gaunt<sup>6</sup> derived W-F = 1.89 Å from correlation with other hexafluorides and a valence force constant calculation. The three principal moments of inertia are I<sub>A</sub> = I<sub>B</sub> = I<sub>C</sub> = 4.22572 x 10<sup>-38</sup> g cm<sup>2</sup>.

Bond Distance: I-F(equatorial) = 1.86 Å I-F(axial) = 1.76 Å  
 Bond Angle: F(eq)-I-F(eq) = 90° F(ax)-I-F(ax) = 72°  
 Product of the Moments of Inertia:  $I_{AB} I_C = 1.1965 \times 10^{-112} \text{ g}^2 \text{ cm}^2$

Heat of Formation

Settle et al. (1) derived  $\Delta H_f^\circ = -229.7 \pm 0.6$  kcal/mol for IF<sub>7</sub>(g) at 298.15 K from treatment of their calorimetric data on combustion of iodine in fluorine. The combustion products, consisting of mixtures of IF<sub>5</sub> and IF<sub>3</sub>, were expanded, treated to remove excess fluorine, and then hydrolyzed. The solutions were analyzed for iodate and the sum of iodate plus periodate. Since the recovery of iodine was not complete (about 70 to 98%), it was necessary to try various assumptions about the form of the unrecovered iodine. Consistent results were obtained only by assigning the unrecovered iodine to IF<sub>3</sub>, the less volatile product. This treatment indicated that IF<sub>7</sub> was formed in yields ranging from about 1 to 70%.

$\Delta H_f^\circ$  for the reaction  $\text{IF}_7(\text{g}) \rightarrow \text{IF}_5(\text{g}) + \text{F}_2(\text{g})$  may be checked via equilibrium data (2). Using six points read from Fig. 2 of Bernstein and Katz, we obtain  $\Delta H_f^\circ(3\text{rd law}) = 29.36 \pm 0.2$  kcal/mol and  $\Delta H_f^\circ(2\text{nd law}) = 29.53 \pm 0.7$  kcal/mol, both at 298.15 K. The entropy test,  $\Delta S_r^\circ(2\text{nd law}) - \Delta S_r^\circ(\text{JANAF functions}) = 0.3 \pm 1.4$  gibbs/mol, indicates consistency with the JANAF functions. Combination of  $\Delta H_f^\circ(3\text{rd law})$  with  $\Delta H_f^\circ$  for IF<sub>5</sub>(g) yields  $\Delta H_f^\circ(\text{IF}_7, \text{g}) = -230.2 \pm 0.6$  kcal/mol. In deriving the uncertainty, we assume that  $\Delta H_f^\circ(3\text{rd law})$  is uncertain by  $\pm 0.5$  kcal/mol due to an estimated uncertainty of about 1.0 gibbs/mol in the JANAF value of  $\Delta S_r^\circ$  at 500 K.

Heat Capacity and Entropy

Recent evidence favors D<sub>5h</sub> symmetry and a pentagonal bipyramidal structure for the heptafluoride. Claassen et al. (3) review the earlier debate about structures of lower symmetry. They provide convincing evidence of D<sub>5h</sub> symmetry from the first observation of Raman spectra of the vapor state and re-examination of the infrared spectra. Their data—including five fundamentals in Raman (two polarized), five fundamentals in infrared, no coincidences between Raman and infrared, and one fundamental inactive—are consistent only with D<sub>5h</sub> symmetry. This is confirmed by Falconer et al. (4) who interpret their electric-deflection experiments as indicating a symmetry-forbidden dipole moment. Extended Hückel-molecular-orbital calculations (5) also predict D<sub>5h</sub> symmetry. The adopted structural parameters are from our approximate analysis of the electron-diffraction data of Thompson and Bartell (6). The authors gave a radial distribution curve and suggested only a gross (unrefined) structure because of the probable presence of a fluorocarbon impurity in their sample. Principal moments of inertia are  $I_A = I_B = 46.93 \times 10^{-39}$  and  $I_C = 54.57 \times 10^{-39} \text{ g cm}^2$ .

Observed vibrational fundamentals are from Claassen et al. (3). The inactive fundamental is estimated from the calculations of Khanna (7).

 $\Delta H_{f,298.15}^{\circ} = 99.5 \pm 0.4$  kcal. mole<sup>-1</sup>

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The heat capacity below 298°K. was obtained by smoothing graphically the data of G. Duycleerts, *Physica* 6, 401 (1939) and W. H. Keom and B. Kurrelmeyer, *Physica*, 6, 633 (1939) over the range 1° - 20°K; F. E. Simon and R. C. Swain, *Z. Physik. Chem.* 28B, 189 (1935) (30-220°K.), A. Eucken and H. Herth, *Z. Anorg. Chem.* 188, 152 (1930) (17-206°K.) and K. K. Kelley, *J. Chem. Phys.* 11, 16 (1943) (55-295°K.). This data on integration yielded  $S_{298.15} = 6.529$  starting with  $S_{1}^{\circ} = 0.0003$  cal. deg.<sup>-1</sup> mole<sup>-1</sup>. The heat capacity and enthalpy data above room temperature are extensive and the heat capacities and enthalpies chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York 1963, were adopted here. These values have a sharp peak in the heat capacity curve at the Curie point\* and through this region follow closely the work of P. R. Pallister, *J. Iron Steel Inst.* 167, 87 (1949). This data has recently been corroborated using a pulse heating technique by D. C. Wallace, P. H. Sides and G. C. Danielson, *J. App. Phys.* 31, 168 (1960). It should be noted that there is some disagreement between the heat capacities chosen and the enthalpies measured by P. D. Anderson and R. Hultgren, *Trans. Met. Soc. AIME*, 224, 842 (1962). The measured values lie consistently above the chosen enthalpies in the range 298-900°K. by from 30 to 60 calories, however the chosen values are considered to be the more reliable. The  $\delta$ -iron heat capacities adopted here have recently been substantiated confirmed by W. A. Dench and O. Kubaschewski, *J. Iron Steel Inst.* (London) 201, 140 (1963).

Transition Data.

The enthalpies of the  $\alpha$ - $\delta$  transition at 1184°K. and the  $\delta$ - $\gamma$  transition at 1665°K. were also taken from Hultgren et al. loc. cit.

Melting Data.

The temperature and heat of melting were those adopted by Hultgren et al. loc. cit.

Heat of Sublimation.

The value adopted is from a critical second and third law analysis of the data of 14 investigators over gamma-iron and liquid iron. See the  $P_e(g)$  table for details.

\*See W. P. Giauque, G. E. Brodale, R. A. Fisher and E. W. Hornung, *J. Chem. Phys.* 42, 1 (1965) for the definition of "permt".

AT. WT. = 55.85

(LIQUID)

IRON (Fe)

ΔH<sub>f</sub><sup>o</sup> 298.15 = 3.138 kcal. mole<sup>-1</sup>

ΔH<sub>m</sub><sup>o</sup> = 3.650 kcal. mole<sup>-1</sup>

ΔH<sub>v</sub><sup>o</sup> = 83.679 kcal. mole<sup>-1</sup>

S<sub>298.15</sub><sup>o</sup> = 8.195 cal. deg.<sup>-1</sup> mole<sup>-1</sup>

T<sub>m</sub> = 1809°K.

T<sub>b</sub> = 3145.4°K.

Heat of Formation.

The ΔH<sub>f</sub><sup>o</sup> 298.15 was obtained from that of the crystal by adding ΔH<sub>m</sub> and the difference between H<sub>1809</sub> - H<sub>298</sub> for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was that chosen by R. Hultgren, R. L. Orr, F. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York (1963).

Melting Data.

See Fe(c) for details.

Vaporization Data.

The boiling point was calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K. so that the free energy function calculated by integration of the crystal liquid data or by statistical methods from the gas phase were equal at the boiling point.

Heat of Formation.

The heat of formation is the heat of sublimation at 298°K. which was obtained by second and third law analysis of the following vapor pressure data.

| Method           | Points | ΔH <sub>v</sub> 298.15 2nd law<br>Kcal. mole <sup>-1</sup> | ΔH <sub>v</sub> 298.15 3rd law<br>Kcal. mole <sup>-1</sup> | Drift in 3rd law<br>cal. deg. <sup>-1</sup> mole <sup>-1</sup> |

The adopted value of 99.5 kcal. mole<sup>-1</sup> is based mainly on the work of Refs. 5, 8 and 14, which have the best drift analysis and agreement between second and third law.

Heat Capacities and Entropies.

The electronic levels were taken from C. E. Moore, Natl. Bur. Standards Circ. 467 (1949). Levels above 20,000 cm.<sup>-1</sup> were averaged.

Heat of Formation.

The heat of combustion of Fe(OH)<sub>2</sub>(c), according to the chemical reaction Fe(OH)<sub>2</sub>(c) + 1/4 O<sub>2</sub>(g) = 1/2 Fe<sub>2</sub>O<sub>3</sub>(c) + H<sub>2</sub>O(l), was determined to be -29.8 ± 0.65 kcal/mol by R. Fricke and S. Rühl, Z. anorg. allgem. chem. 251, 414 (1943). From this data the heat of formation ( $\Delta H^{\circ}_{298.15}$ ) was evaluated to be -137.2 ± 0.7 kcal/mol, which was adopted here.

The enthalpy changes for the following three reactions were determined by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886:

| Reaction   | $\Delta H^{\circ}_{298}$ , kcal/mol |
|--|-------------------------------------|
| 1. FeCl <sub>2</sub> (c) = FeCl <sub>2</sub> (400 H <sub>2</sub> O)  | -17.9                               |
| 2. FeCl <sub>2</sub> (200 H <sub>2</sub> O) + H <sub>2</sub> SO <sub>4</sub> (200 H <sub>2</sub> O) = FeSO <sub>4</sub> (200 H <sub>2</sub> O) + 2 HCl(100 H <sub>2</sub> O) | -3.6                                |
| 3. FeSO <sub>4</sub> (aq.) + 2KOH(aq.) = Fe(OH) <sub>2</sub> (c) + K <sub>2</sub> SO <sub>4</sub> (aq.)  | -6.34                               |

Using  $\Delta H^{\circ}_{298.15} = -81.7$  kcal/mol for FeCl<sub>2</sub>(c) and those for the other compounds in aqueous solution (assuming aq. = 200 H<sub>2</sub>O in Reaction 3) obtained from D.D. Wagman, M. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, National Bureau of Standards, 1965, the heat of formation (298.15°K) for Fe(OH)<sub>2</sub>(c) was derived as -135.8 kcal/mol which agrees reasonably with the adopted value.

Heat Capacity and Entropy.

The heat capacities, 298.15 - 700°K, and  $S^{\circ}_{298.15}$  were estimated by comparison with those for FeCl<sub>2</sub>(c), CaCl<sub>2</sub>(c) and Ca(OH)<sub>2</sub>(c). The Cp values above 700°K were obtained by graphical extrapolation of the Cp curve plotted using the above Cp values.

Heat of Sublimation.

The value of  $\Delta H^{\circ}_{298.15}$  was calculated as the difference between  $\Delta H^{\circ}_{298.15}$  for Fe(OH)<sub>2</sub>(g) and Fe(OH)<sub>2</sub>(c).

Point group [C<sub>2h</sub>]  
S<sub>288.15</sub> = [67.58] gibbs/mol  
ΔH<sub>f</sub><sup>0</sup> = [-77.2 ± 0.5] kcal/mol  
ΔH<sub>f</sub><sup>288.15</sup> = [-79.0 ± 0.5] kcal/mol

Heat of Formation

The equilibrium constants, at temperatures between 1300 and 1460°C, for the chemical reaction Fe(c) + 2H<sub>2</sub>O(g) = Fe(OH)<sub>2</sub>(g) + H<sub>2</sub>(g), were determined by G. R. Belton and F. D. Richardson, Trans. Faraday Soc. 55, 1562 (1962). Using these data, the enthalpy change (ΔH<sub>f</sub><sup>288.15</sup>) of the reaction is evaluated to be 35.53 ± 3.0 and 35.57 kcal/mol by the second and third law method, respectively. Based on the third law value for ΔH<sub>f</sub><sup>288.15</sup>, the heat of formation (ΔH<sub>f</sub><sup>288.15</sup>) for Fe(OH)<sub>2</sub>(g) is calculated to be -79 ± 0.5 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for B(OH)<sub>2</sub>(g). The Fe-O bond distance is taken from FeO(g). The O-H bond distance and Fe-O-H bond angle are estimated from those for H<sub>2</sub>O(g). The vibrational frequencies, and electronic levels and quantum weights are obtained by comparison with those for B(OH)<sub>2</sub>(g) and FeCl<sub>2</sub>(g), respectively. These values are adjusted to give reasonable second and third law agreements. The three principal moments of inertia are: I<sub>A</sub> = 2.658 × 10<sup>-40</sup>, I<sub>B</sub> = 1.664 × 10<sup>-39</sup> and I<sub>C</sub> = 1.890 × 10<sup>-38</sup> g cm<sup>2</sup>.

Tm = Unknown

Heat of Formation.

P. Schindler, W. Michaelis and W. Feltmeyer, *Helv. Chim. Acta*, **45**, 444 (1963), investigated the solubility of aged Fe(OH)<sub>3</sub> precipitates by determining the Fe<sup>+++</sup> and H<sup>+</sup> ion concentration of solution in contact with the solid phase. The ion concentration was measured by the EMF method at the constant ionic strength 3M NaClO<sub>4</sub> (solution). The precipitates were investigated by X-ray and electron microscope methods. The equilibrium constant was derived as log [Fe<sup>+++</sup>] [H<sup>+</sup>]<sup>-3</sup> = log K = 3.55 ± 0.1 for amorphous inactive hydroxide at 25°C. From these data the quantity log K<sub>a</sub> = -39.1 ± 0.2 was evaluated where K<sub>a</sub> is the solubility product of Fe(OH)<sub>3</sub>. The Gibbs energy change (ΔH°<sub>298.15</sub>) of the reaction Fe(OH)<sub>3</sub>(c) = Fe<sup>+++</sup>(aq) + 3OH<sup>-</sup>(aq) was calculated to be 53.34 ± 0.27 kcal/mol. Using S°<sub>298.15</sub> = 70.1 and -2.57 gibbs/mol for Fe<sup>+++</sup>(aq) and OH<sup>-</sup>(aq), respectively, and an estimated S°<sub>298.15</sub>(Fe(OH)<sub>3</sub>, c) = 25 gibbs/mol, the enthalpy change (ΔH°<sub>298.15</sub>) of the reaction is calculated to be 22.69 kcal/mol, according to the relationship ΔH = ΔF + TΔS. The entropy values for Fe<sup>+++</sup> and OH<sup>-</sup> ions were obtained from "Selected Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1 by D. D. Wagman and co-workers, 1965, respectively. Based on ΔH°<sub>298.15</sub>(Fe<sup>+++</sup>, aq) = -11.4 and ΔH°<sub>298.15</sub>(OH<sup>-</sup>, aq) = -54.97 kcal/mol, taken from the same source, the heat of formation (ΔH°<sub>298.15</sub>) for Fe(OH)<sub>3</sub>(c) was evaluated to be -199 ± 3 kcal/mol, which was adopted here.

The divergent values for solubility product (SP) of Fe(OH)<sub>3</sub> found in the literature may be due not only to the various forms of precipitate, but also to the tendency to form colloidal solutions. The SP values for Fe(OH)<sub>3</sub> were also reported by Evans and Pryor, *J. Chem. Soc.* S157 (1949); Kriukor and Awsejwitsch, *Z. Elektrochem.* **39**, 884 (1935); Ruff and Hirsch, *Z. Anorg. Chem.* **146**, 338 (1925); Britton, *J. Chem. Soc.* 2148 (1925); and Jellinek and Gordon, *Z. Phys. Chem.* **112**, 207 (1924).

The enthalpy changes (ΔH°<sub>298.15</sub>) for the reactions: (1) FeCl<sub>3</sub>(aq) + 3NaOH(aq) = Fe(OH)<sub>3</sub>(c) + 3NaCl(aq) and (2) FeCl<sub>3</sub>(c) = FeCl<sub>3</sub>(aq) were determined to be -24.50 and -31.68 kcal/mol, respectively, by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886. Assuming the aqueous solutions all contain 200 mol of H<sub>2</sub>O, the heat of formation (ΔH°<sub>298.15</sub>) for Fe(OH)<sub>3</sub> was calculated as -196.9 kcal/mol from Reactions (1) and (2). The ΔH°<sub>298.15</sub> values for NaOH(aq) and NaCl(aq) were obtained from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-RS-2, National Bureau of Standards, 1965, and JANAF ΔH°<sub>298.15</sub> values for NaOH(c) and NaCl(c).

Heat Capacity and Entropy.

The heat capacities, 298.15 - 1000°K, were estimated by comparison with those for Fe<sub>2</sub>O<sub>3</sub>(c), Fe<sub>2</sub>O<sub>3</sub>(c) and B(OH)<sub>3</sub>(c). The Cp values above 1000°K were obtained by graphical extrapolation. The S°<sub>298.15</sub>(Fe(OH)<sub>3</sub>, c) value was estimated by comparison with that for B(OH)<sub>3</sub>(c).

Sept. 30, 1966

$\Delta H^l_0$  = Unknown  
 $\Delta H^l_{298.15} = -25 \pm 4$  kcal/mol  
 $\Delta H^l = 0.2$  kcal/mol  
 $\Delta H^m = [10.7]$  kcal/mol  
 $\Delta H^l_{298.15}$  (to monomer) =  $[46]$  kcal/mol  
 $\Delta H^l_{298.15}$  (to dimer) =  $[52]$  kcal/mol

$\Delta S^l_{298.15} = [40 \pm 2]$  gibbs/mol  
 $T_c = 850^\circ K$   
 $T_m = 860 \pm 2^\circ K$

Heat of Formation.

The chemical equilibrium of the decomposition of FeI<sub>2</sub>(c), 771.15 - 858.15°K, has been studied by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 488 (1966). Using the reported partial pressures for I<sub>2</sub>(g), the enthalpy change ( $\Delta H^l_{298.15}$ ) for the reaction FeI<sub>2</sub>(c) = Fe(c) + I<sub>2</sub>(g) was evaluated by both the second and third law methods to be 39.79 ± 1.0 and 39.69 ± 0.3 kcal/mol, respectively. Based on the third law  $\Delta H^l_{298.15}$  value, the heat of formation ( $\Delta H^l_{298.15}$ ) for FeI<sub>2</sub>(c) was calculated as -25 kcal/mol which was adopted here.

The enthalpy change for the reaction FeI<sub>2</sub>(c) = Fe<sup>++</sup>(aq) + 2 I<sup>-</sup>(aq) was determined to be -19.48 ± 0.03 kcal/mol by P. Paolletti, A. Sabatini and A. Vacca, *Chim. Ind. (Milan)*, 48, 2417 (1966), using a solution calorimetric method. Adopting  $\Delta H^l_{298.15} = -21.3$  and  $-13.19$  kcal/mol for Fe<sup>++</sup>(aq) and I<sup>-</sup>(aq), respectively, the value of  $\Delta H^l_{298.15}$  (FeI<sub>2</sub>, c) was derived as -28.22 ± 1 kcal/mol. The value of  $\Delta H^l_{298.15}$  (I<sup>-</sup>, aq) was taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, National Bureau of Standards, 1965. The value of  $\Delta H^l_{298.15}$  (Fe<sup>++</sup>, aq) was derived from heats of solution and formation for FeCl<sub>2</sub>(c).

The heats of solution of Fe(c), I<sub>2</sub>(c) and FeI<sub>2</sub>(c) in aqueous Br<sub>2</sub>-KBr solution were measured by W. Heber and A. Moerner, Z. Elektrochem. 40, 287 (1936), using an ice calorimeter. From the results obtained the heat of formation for FeI<sub>2</sub>(c) was reported as -30.1 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 343.15 - 773.15°K, were measured by F. L. Oetting and N. W. Gregory, J. Phys. Chem. 65, 173 (1961). The Cp values at temperatures below 343.15 and above 773.15°K were estimated by graphical extrapolation. The low temperature heat capacities, 11-130°K, were determined by O. Milljutin and E. A. Parfenova, Phys. Trans. Ukrain. Acad. Sci., 81 (1940). These data appear to be inadequate for the derivation of the entropy at 298.15°K. The value of  $S^l_{298.15}$  adopted was calculated from the entropy change,  $\Delta S^l_{298.15} = 28.7$  eu, for the decomposition reaction FeI<sub>2</sub>(c) = Fe(c) + I<sub>2</sub>(g), obtained by the second law analysis of the equilibrium pressure data reported by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 486 (1966).

Transition Data.

A minor transition in the vicinity of 370°K (350-385°K) has been reported by F. L. Oetting and N. W. Gregory, loc. cit. Subsequent studies by T. J. Mydeven, Ph. D. Thesis, University of Washington, Seattle, Wash., 1964, have shown the magnitude of the transition to be sensitive to trace amounts of impurities, but the nature of the transition has not been clearly established. A magnetic transition at 10°K was reported by H. Bizette, C. Terrier and B. Tsal, *Compt. Rend.* 245, 507 (1957). The  $\Delta H^l_0$  value was evaluated from the heat capacity - temperature plot given by F. L. Oetting and N. W. Gregory, loc. cit.

Melting Data.

$T_m$  was reported by W. Fischer and R. Gewehr, Z. anorg. allgem. Chem. 222, 303 (1935).  $\Delta H^m$  was estimated by comparison with that for FeBr<sub>2</sub>(c).

Heat of Sublimation.

$\Delta H^l_{298.15}$  (to monomer) is calculated as the difference between  $\Delta H^l_{298.15}$  for FeI<sub>2</sub>(c) and FeI<sub>2</sub>(g).  $\Delta H^l_{298.15}$  (to dimer) was calculated as the difference between those for FeI<sub>4</sub>(g) and 2 FeI<sub>2</sub>(c).

ΔH<sub>f,298.15</sub><sup>o</sup> = [16.965] kcal/mol

ΔH<sub>m</sub><sup>o</sup> = [10.7] kcal/mol

ΔH<sub>v</sub><sup>o</sup> = [25.0] kcal/mol

S<sub>298.15</sub><sup>o</sup> = [46.720] gibbs/mol

T<sub>m</sub> = 860 ± 2° K

T<sub>b</sub> = [1366] °K

Heat of Formation.

The heat of formation (ΔH<sub>f,298.15</sub><sup>o</sup>) was obtained from ΔH<sub>f,298.15</sub><sup>o</sup> (c) by adding ΔH<sub>m</sub><sup>o</sup> and the difference between H<sub>m</sub><sup>o</sup> - H<sub>l</sub><sup>o</sup> for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K. The value of C<sub>p</sub> was calculated on an assumption that C<sub>p</sub> = 9.0 gibbs/g-atom for FeI<sub>2</sub>(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Vaporization Data.

T<sub>b</sub> is the temperature at which the vapor pressure of FeI<sub>2</sub>(g) and Fe<sub>2</sub>I<sub>4</sub>(g) over FeI<sub>2</sub>(l) equals one atmosphere. The value of ΔH<sub>v</sub><sup>o</sup> is derived from the vapor composition and the heats of vaporization of FeI<sub>2</sub>(l) to monomer and dimer at T<sub>b</sub>.

Heat of Formation.  
The chemical equilibria for the reactions: (A) FeI<sub>2</sub>(g) = FeI<sub>2</sub>(g), (B) FeI<sub>2</sub>(g) = FeI<sub>2</sub>(g), and (C) Fe(c)+2I(g)=FeI<sub>2</sub>(g), changes were studied by several investigators. Based on the equilibrium pressures reported, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented in the table below. Using the third law ΔH<sub>298.15</sub> values, the heats of formation for FeI<sub>2</sub>(g) were calculated. The adopted value for ΔH<sub>298.15</sub>(FeI<sub>2</sub>,g) is 21.0 ± 3 kcal/mol. The disagreement between the sets of second and third law ΔH<sub>298.15</sub> values listed in the table may be due to the presence of dimer, Fe<sub>2</sub>I<sub>4</sub>(g), which was not accounted for in deriving the partial pressure of FeI<sub>2</sub>(g). The data obtained from Schoonmaker et al. was adjusted for the presence of dimer.

Heat Capacity and Entropy.  
The molecular structure was assumed to be linear. The Fe-I bond distance was estimated by L. Brewer, G. R. Somayajulu and E. Brockert, Chem. Rev. 53, 111 (1963). The vibrational frequencies were estimated so that the derived gibbs energy functions yielded second and third law ΔH<sub>298.15</sub> values in reasonable agreement (see the above table). The electronic levels and quantum weights were estimated from those for FeCl<sub>2</sub>(g) reported by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The moment of inertia is 2.48844 x 10<sup>-37</sup> g cm<sup>2</sup>.

Heat of Formation.

The chemical equilibria in the Fe-C-O and Fe-H-O systems have been studied by many investigators. Using the reported equilibrium constants for the following two reactions (1) Fe<sub>0.9470</sub>(c) + CO(g) = 0.947Fe(c) + CO<sub>2</sub>(g) and (2) Fe<sub>0.9470</sub>(c) + H<sub>2</sub>(g) = 0.947Fe(c) + H<sub>2</sub>O(g), the corresponding enthalpy changes ( $\Delta H_f^0$ ) were evaluated by both the second and third law methods. Based on the third law values for  $\Delta H_f^0$ , the  $\Delta H_f^{298.15}$  (Wüstite, c) values were also calculated. The results obtained are presented as follows.

| Investigator                    | Reaction | Temperature, °K. | Second Law Value | Third Law Value | $\Delta H_f^{298.15}$ kcal. mole <sup>-1</sup> |

- 4 E. V. Britzke, A. F. Kaputinsky and T. I. Schachkins, Z. anorg. allgem. Chem. **219**, 287 (1954). The  $K_p$  value at 1123°K. for reaction (2) is rejected by a statistical criterion.
- 5 W. E. Jominy and D. W. Murphy, Ind. Eng. Chem. **23**, 364 (1931). The  $K_p$  values at 1530 and 1645°K. are rejected by a statistical criterion.
- 6 J. Chipman and S. Marshall, J. Am. Chem. Soc. **52**, 299 (1940).

Britzke et al. also determined the equilibrium pressures for the reaction (3) 1.894 Fe(c) + O<sub>2</sub>(g) = 2Fe<sub>0.9470</sub>(c). The corresponding  $\Delta H_f^{298.15}$  for Wüstite was evaluated based on the third law value for  $\Delta H_f^{298.15}$ . The adopted value of  $\Delta H_f^{298.15}$  (Wüstite, c) is the weighted average of the  $\Delta H_f^{298.15}$  listed in the above table.

Heat Capacity and Entropy.

The low temperature (54.37-298.16°K.) heat capacities ( $C_p$ ) were measured by S. S. Todd and K. R. Bonnicksen, J. Am. Chem. Soc. **73**, 3694 (1951). The high temperature (298-1650°K.) heat capacities were determined by J. P. Coughlin, E. O. King and K. R. Bonnicksen, J. Am. Chem. Soc. **73**, 3691 (1951). The two sets of  $C_p$  data were plotted and joined smoothly at 298°K. The  $C_p$  values above 1650°K. were obtained by graphical extrapolation. The low temperature (70.7-279.8°K.)<sup>a</sup> heat capacities reported by R. W. Miller, J. Am. Chem. Soc. **51**, 215 (1929).  $S_{298.15}^0$  was derived from the low temperature heat capacities, based on  $S_{52}^0 = 0.696$  cal. deg.<sup>-1</sup> mole<sup>-1</sup>. S. S. Todd and K. R. Bonnicksen, loc. cit. added 0.41 e.u., the amount calculated for completely random distribution of the vacant Fe spaces in the Wüstite lattice. However, the free energy functions derived from  $S_{52}^0 = 0.696$  e.u. give better agreement between second and third law values for  $\Delta H_f^0$  than those derived from  $S_{52}^0 = 1.11$  e.u. Therefore the value 0.41 e.u. was not added here.

Melting Data.

$T_m$  and  $\Delta H_m^0$  were taken from J. P. Coughlin, E. O. King and K. R. Bonnicksen, et al.  $T_m$  was reported as 1372°K. (1645°K.) by L. S. Darken and R. W. Murphy, J. Am. Chem. Soc. **68**, 798 (1946) and as 1369°K. (1642°K.) by J. Chipman and S. Marshall, loc. cit.

ΔH<sub>f</sub><sup>o</sup> = UnknownΔH<sub>f</sub><sup>o</sup> 298.15 = [-65.02] kcal. mole<sup>-1</sup>ΔH<sub>m</sub><sup>o</sup> = [5.75] kcal. mole<sup>-1</sup>ΔH<sub>g</sub><sup>o</sup> 298.15 = [121.62] kcal. mole<sup>-1</sup>S<sub>298.15</sub><sup>o</sup> = [14.52] cal. deg<sup>-1</sup> mole<sup>-1</sup>T<sub>m</sub> = [1650]°K.Heat of Formation.

The value of ΔH<sub>f</sub><sup>o</sup> 298.15 for FeO(c) was derived based on an assumption that at 1650°K., ΔH<sub>f</sub><sup>o</sup> (FeO, c) = ΔH<sub>f</sub><sup>o</sup> (FeO, l). From the value ΔH<sub>f</sub><sup>o</sup> 1650 (FeO, c) = -39.77 kcal. mole<sup>-1</sup>, ΔH<sub>f</sub><sup>o</sup> 1650 (FeO, c) was calculated to be -63.97 kcal. mole<sup>-1</sup>, yielding ΔH<sub>f</sub><sup>o</sup> 298.15 (FeO, c) = -65.02 kcal. mole<sup>-1</sup>.

Heat Capacity and Entropy.

The C<sub>p</sub> values were estimated assuming C<sub>p</sub> (FeO, c) = C<sub>p</sub> (Wüstite, c) + 0.053 C<sub>p</sub> (Fe, c). The C<sub>p</sub> values obtained were plotted. The adopted C<sub>p</sub> points were taken from the smoothed C<sub>p</sub> curve. S<sub>298.15</sub><sup>o</sup> for FeO(c) was calculated as S<sup>o</sup> (FeO, c) = S<sup>o</sup> (Wüstite, c) + 0.053 S<sup>o</sup> (Fe, c) + ΔS<sup>o</sup> (mixing) where ΔS<sup>o</sup> is the entropy of mixing (0.41 cal. deg<sup>-1</sup> mole<sup>-1</sup>).

Melting Data.

T<sub>m</sub> is assumed to be the same as that for Wüstite. The difference between ΔH<sub>f</sub><sup>o</sup> 1650 for FeO(l) and FeO(c) is ΔH<sub>m</sub><sup>o</sup>.

Heat of Sublimation.

ΔH<sub>g</sub><sup>o</sup> 298.15 is calculated as the difference between ΔH<sub>f</sub><sup>o</sup> 298.15 for FeO(g) and FeO(c).

Iron Oxide (FeO)

(Liquid) Mol. wt. = 71.8464

MOL. WT. = 71.8464

(LIQUID)

$$\Delta H_f^\circ 298.15 = 18.029 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^\circ 298.15 = [-59.642] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = [1650]^\circ \text{K.}$$

$$\Delta H_m^\circ = [3687]^\circ \text{K.}$$

$S_{298.15}^\circ = 18.029 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_m = [1650]^\circ \text{K.}$

$T_d = [3687]^\circ \text{K.}$

Heat of Formation.

The heat of formation ( $\Delta H_f^\circ 298.15^\circ$ ) was evaluated based on an assumption that the heat of melting of Wüstite,  $\Delta H_m^\circ 1650 = 7.49 \text{ kcal. mole}^{-1}$ , represents the enthalpy change of the reaction  $\text{Fe}_{0.947}\text{O}(c) = 0.947 \text{ FeO}(l) + \frac{0.053}{2} \text{ O}_2(g)$ . In other words, during melting the wüstite releases  $\text{O}_2(g)$  and converts to  $\text{FeO}(l)$ .

Heat Capacity and Entropy.

The enthalpy changes ( $H_f^\circ - H_c^\circ$ ) of liquid iron oxide were determined by J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. **73**, 3693 (1951). The  $C_p$  (FeO, l) was derived as  $16.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ . This value was adopted as the heat capacity for  $\text{FeO}(l)$  up to  $4000^\circ \text{K}$ . A glass transition temperature was assumed at  $1100^\circ \text{K}$ .  $S_{298.15}^\circ$  (FeO, l) was calculated based on an assumption that the entropy of melting of Wüstite represents also the entropy change of the reaction,  $\text{Fe}_{0.947}\text{O}(c) = 0.947 \text{ FeO}(l) + \frac{0.053}{2} \text{ O}_2(g)$ . From the entropy of melting,  $\Delta S_m^\circ 1650 = 4.559 \text{ e.u.}$ , the value  $S_{298.15}^\circ$  (FeO, l) =  $18.029 \text{ e.u.}$  was derived.

Melting Data.

The melting point ( $T_m$ ) for Wüstite ( $\text{Fe}_{0.947}\text{O}$ , c) has been reported by many investigators. However, the composition of the liquid state of Wüstite was not identified. An assumption was made that during melting the reaction  $\text{Fe}_{0.947}\text{O}(c) = 0.947 \text{ FeO}(l) + \frac{0.053}{2} \text{ O}_2(g)$  occurs. Hence the related thermodynamic properties were derived.

Decomposition Temperature.

$T_d$  is the temperature at which  $\Delta F_d^\circ$  equals zero.

| T, °K. | C <sub>p</sub> | S <sup>o</sup> | $-(F^\circ - H_{298}^\circ)/T$ | H <sup>o</sup> - H <sub>298</sub> <sup>o</sup> | $\Delta H_f^\circ$ | $\Delta F_d^\circ$ | Log K <sub>p</sub> |

Heat of Formation

The heat of formation for FeO(g) is not well established at the present time. The values of  $\Delta H_f^\circ$  (FeO, g) derived from the following reactions: (1) FeO(g) = Fe(g) + 1/2 O<sub>2</sub>(g), and (2) FeO(l) = FeO(g), are not in agreement. There are three D° (Fe-O) values reported for reaction (1). The enthalpy change for reaction (2) was evaluated based on the partial pressure data (P<sub>FeO</sub>/P<sub>O<sub>2</sub></sub>) = 0.2 at 1600°C, measured by Washburn<sup>4</sup>, using a mass spectrometric method, U. S. Atomic Energy Commission, UCRJ-10991, August 1963, and P<sub>O<sub>2</sub></sub> = 1.66 x 10<sup>-6</sup> atm reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 85, 796 (1963). The enthalpy value for reaction (3) was calculated based on the reported value,  $\Delta H_f^\circ = 96.096$  kcal/mol determined by Burtsev, Karasev and Samarin<sup>5</sup>. The results obtained are presented as follows. The value of  $\Delta H_f^\circ$  for FeO(g) adopted is 60 ± 5 kcal/mol.

 5. V. T. Burtsev, R. A. Karasev and A. M. Samarin, Fiz.-Khim. Otmory Proizv. Stal', Akad. Nauk SSSR, Inst. Met., Tr. 5-01 (Shestol' Konf., Moscow, 366 (1961); published in 1964).

Heat Capacity and Entropy

Since the ground state configuration is due to Fe<sup>++</sup> in a ligand field, it was assumed to be the same as that of FeCl<sub>2</sub>(g) reported by C. W. DeLoock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The electronic levels and quantum weights were estimated by comparison with those of FeCl<sub>2</sub>(g). The values of  $\omega_e$  and  $\omega_e x_e$  were taken from G. Herzberg, loc. cit. The bond distance was calculated according to the method suggested by K. M. Osgenheimer, Proc. Phys. Soc. (London) 55, 456 (1946), assuming FeO(g) as a polar molecule. The value of  $r_e$  was calculated by use of the relationship:  $r_e = (2.79076 \times 10^{-19}) / I$  where I is the moment of inertia of FeO(g). The value of  $\chi_e$  was derived from  $\omega_e$ ,  $\omega_e x_e$  and  $r_e$  by the method suggested by G. Herzberg, loc. cit. The principal moment of inertia is 6.689 x 10<sup>-39</sup> g cm<sup>2</sup>.

IRON SULFATE (FeSO<sub>4</sub>)

(CRYSTAL)

OPW = 151.9086

ΔHf° = -219.7 ± 2 kcal/mol

ΔHf°<sub>298.15</sub> = -222.0 ± 2 kcal/mol

S°<sub>298.15</sub> = 28.91 ± 0.3 gibbs/mol

Td = 944°K

Heat of Formation.

The enthalpy change for the reaction FeSO<sub>4</sub>(c) = FeSO<sub>4</sub>(110 H<sub>2</sub>O) was determined to be -14.9 kcal/mol by R. de Forcrand, Comp. rend. 156, 20 (1914). Using ΔHf°<sub>298.15</sub> = -235.85 kcal/mol for FeSO<sub>4</sub>(110 H<sub>2</sub>O), the heat of formation (298.15°K) was calculated as -221 kcal/mol. The value of ΔHf°<sub>298.15</sub> (FeSO<sub>4</sub>, c) was estimated based on ΔHf°<sub>298.15</sub> = 235.9 kcal/mol for FeSO<sub>4</sub>(200 H<sub>2</sub>O) which was derived from the enthalpy change for the reaction FeCl<sub>2</sub>(200 H<sub>2</sub>O) + H<sub>2</sub>SO<sub>4</sub>(200 H<sub>2</sub>O) = FeSO<sub>4</sub>(200 H<sub>2</sub>O) + 2HCl(100 H<sub>2</sub>O) measured by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886. See the Fe(OH)<sub>2</sub>(c) table for details.

The decomposition pressures of FeSO<sub>4</sub>(c) at different temperatures were investigated by J. D'Ans and E. Oreulich. Using their reported partial pressures for SO<sub>3</sub>(g) and SO<sub>2</sub>(g), the enthalpy change for the reaction 2 FeSO<sub>4</sub>(c) = Fe<sub>2</sub>O<sub>3</sub>(c) + SO<sub>3</sub>(g) + SO<sub>2</sub>(g) was evaluated by both the second and third law methods. The results obtained are presented in the following table.

| Investigator                        | Temperature, °K | Second Law Value | Third Law Value | ΔHf° <sub>298.15</sub><br>kcal/mol |
|-------------------------------------|-----------------|------------------|-----------------|------------------------------------|
| 1. J. D'Ans (1905)                  | 753.15 - 908.15 | 83.2 ± 4.6       | 82.7 ± 1.1      | -222.7                             |
| 2. E. Oreulich (1927)               | 897.15 - 971.15 | 84.8 ± 8.8       | 80.1 ± 1.4      | -221.5                             |
| 3. B. Neumann and O. Heintke (1937) | 833.15 - 862.15 | 72.4 ± 5.4       | 75.3 ± 0.5      | -219.1                             |

1. J. D'Ans, Dissertation, Darmstadt, 1905. Data quoted by B. Neumann and O. Heintke, loc. cit.
2. E. Oreulich, Z. anorg. Chem. 168, 197 (1927). Only the last seven high temperature points were adopted for evaluation.
3. B. Neumann and O. Heintke, Z. Elektrochem. 43, 246 (1937), based on the last 18 high temperature points adopted.

The decomposition pressures assumed for the same reaction have been determined by B. Neumann and O. Heintke. From their data the partial pressures for SO<sub>3</sub>(g) and SO<sub>2</sub>(g) were evaluated. Using the derived SO<sub>3</sub>(g) and SO<sub>2</sub>(g) partial pressures, the corresponding enthalpy changes for the reaction were calculated by both the second and third law methods. The results obtained are also listed in the same table.

The value of ΔHf°<sub>298.15</sub> for FeSO<sub>4</sub>(c) is selected as -222 ± 2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 53.0-294.9°K, were determined by O. E. Moore and K. K. Kelley, J. Am. Chem. Soc., 64, 2949 (1942). Based on S°<sub>298.15</sub> = 2.10 eu, the value of S°<sub>298.15</sub> (FeSO<sub>4</sub>, c) was reported to be 25.71 ± 0.2 eu. Using the free energy functions for FeSO<sub>4</sub>(c) based on this S°<sub>298.15</sub> value, to evaluate the vapor pressure data for Reaction (1), the second and third law values of ΔHf°<sub>298.15</sub> were derived as 72.35 ± 7.60 and 86.51 ± 1.26 kcal/mol, respectively. Since the report by Moore and Kelley, loc. cit., did not mention the magnetic contribution, an attempt was made to add 3.20 (- R ln 5) eu to S°<sub>298.15</sub> (FeSO<sub>4</sub>, c) and re-evaluate the decomposition pressure data. The results obtained were better than before (see the paragraph on "Heat of Formation" for details). Therefore the value, S°<sub>298.15</sub> = 25.71 + 3.2 = 28.91 eu for FeSO<sub>4</sub>(c), was adopted. The heat capacities above 294.9°K were estimated by comparison with those for MnSO<sub>4</sub>(c). The high temperature heat capacities, 870.3-1082.3°K, were determined by J. C. Southard and C. H. Shomate, J. Am. Chem. Soc. 64, 1770 (1942). The two sets of data were joined smoothly at 298.15°K by use of Shomata-function plot.

Temperature of Decomposition.

Td is the temperature at which the vapor pressure of the gaseous decomposition products equals one atmosphere, which was obtained by graphical interpolation of the decomposition pressure data on FeSO<sub>4</sub>(c), reported by E. Oreulich, loc. cit.

Heat of Formation

The chemical equilibrium of the interaction of Fe(c) and I(g) has been studied by a transpiration method by W. E. Zeugs and N. W. Gregory, J. Phys. Chem. **70**, 490 (1966). Using the reported equilibrium constants in the temperature range from 691 to 761°K, the enthalpy change ( $\Delta H_{298.15}$ ) of the reaction  $2Fe(c) + 4I(g) = Fe_2I_4(g)$  was evaluated by both the second and third law method to be -85.3 and -103.76 kcal/mol, respectively. The corresponding values of the heat of formation ( $\Delta H_f^{298.15}$ ) for Fe<sub>2</sub>I<sub>4</sub>(g) were calculated as +16.9 and -1.6 kcal/mol.

Mass spectrometric and Knudsen effusion techniques have been used to study the vaporization of FeI<sub>2</sub>(c) by R. C. Schoonmaker, A. H. Friedman and R. P. Porter, J. Chem. Phys. **31**, 1968 (1959). Using the reported vapor pressure, P = 1.21 x 10<sup>-6</sup> atm. at 714°K for Fe<sub>2</sub>I<sub>4</sub>(g), the enthalpy change ( $\Delta H_{298.15}$ ) for the reaction  $2FeI_2(c) = Fe_2I_4(g)$  was evaluated by the third law method as 52.8 kcal/mol, yielding  $\Delta H_f^{298.15} = 2.8$  kcal/mol for Fe<sub>2</sub>I<sub>4</sub>(g). The adopted value of  $\Delta H_f^{298.15}$  for Fe<sub>2</sub>I<sub>4</sub>(g) is 2.0 ± 5 kcal/mol.

Heat Capacity and Entropy

The molecular structure was assumed to be the same as that assumed for Fe<sub>2</sub>Br<sub>4</sub>(g). The Fe-I bond distance was estimated from that in FeI<sub>2</sub>(g) molecule. Four vibrational frequencies ( $\omega_j$ ), i.e. i = 2, 4, 5 and 6, were estimated by comparison with those for K<sub>2</sub>I<sub>2</sub>(g), calculated by J. Berkowitz, J. Chem. Phys. **32**, 1519 (1960). The other frequency values were estimated from those for FeI<sub>2</sub>(g). The electronic levels and quantum weights were estimated from those for FeI<sub>2</sub>(g). The three principal moments of inertia are: I<sub>A</sub> = 1.2442 x 10<sup>-5</sup>, I<sub>B</sub> = 7.7996 x 10<sup>-37</sup>, and I<sub>C</sub> = 9.0439 x 10<sup>-37</sup> g cm<sup>2</sup>.

 ΔH<sub>f</sub><sup>298.15</sup> = -197.3 ± 0.3 kcal. mole<sup>-1</sup>  
 ΔH<sub>f</sub><sup>298.15</sup> = 20.889 cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 T<sub>d</sub> = 1735°K.

Heat of Formation.

The chemical equilibria for the reaction 4Fe<sub>2</sub>O<sub>3</sub>(c) + O<sub>2</sub>(g) = 6Fe<sub>2</sub>O<sub>3</sub>(c) have been studied by several investigators. From the reported data the corresponding values of ΔH<sub>f</sub><sup>298.15</sup> and ΔH<sub>f</sub><sup>298.15</sup> (Fe<sub>2</sub>O<sub>3</sub>, c) were evaluated. The results obtained are given as follows.

| Investigator                         | Temperature, °K. | Second Law Value | Third Law Value | ΔH <sub>f</sub> <sup>298.15*</sup> |
|--------------------------------------|------------------|------------------|-----------------|------------------------------------|
| Tretyskov and Khomyakov <sup>1</sup> | 1373-1728        | -106.32 ± 0.19   | -111.05         | -197.11                            |
| Schmahl <sup>2</sup>                 | 1583-1683        | -123.95 ± 1.37   | -112.94         | -197.42                            |
| Smiltema <sup>3</sup>                | 1373-1673        | -117.68 ± 0.38   | -114.25         | -197.64                            |

\*Calculation based on the third law values for ΔH<sub>f</sub><sup>298.15</sup>.

- 1 Y.D. Tretyskov and K. O. Khomyakov, Russ. J. Inorg. Chem. **7**, 628 (1962).
- 2 N. G. Schmahl, Z. Elektrochem. **47**, 821 (1941).
- 3 J. Smilten, J. Am. Chem. Soc. **79**, 4877 (1957).
- 4 L. S. Derken and R. W. Gurry, J. Am. Chem. Soc. **68**, 796 (1946). ΔH<sub>f</sub><sup>298.15</sup> was calculated based on ΔH<sub>f</sub><sup>1725</sup> = -94.5 kcal. mole<sup>-1</sup>.

The value of ΔH<sub>f</sub><sup>298.15</sup> adopted for Fe<sub>2</sub>O<sub>3</sub>(c) is the weighted average of the ΔH<sub>f</sub><sup>298.15</sup> values listed in the above table.

Heat Capacity and Entropy.

The low temperature (5.58-345.42°K.) heat capacities were determined by F. Gronvold and E. F. Westrum, Jr., J. Am. Chem. Soc. **81**, 1780 (1959). The high temperature (289-1750°K.) C<sub>p</sub> values were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. **73**, 3691 (1951). The two sets of data were plotted and joined smoothly at 298°K. The C<sub>p</sub> values above 1750°K. were obtained by graphical extrapolation. The heat capacities of Fe<sub>2</sub>O<sub>3</sub>(c) have also been reported by G. G. Brown and C. C. Furnas, Trans. Am. Inst. Chem. Eng. **18**, 309 (1926), 0-650°K., and G. S. Parka and K. K. Kelley, J. Phys. Chem. **50**, 47 (1946), 69-289°K. S<sub>298.15</sub> for Fe<sub>2</sub>O<sub>3</sub>(c) was derived from the smoothed C<sub>p</sub> data, based on S<sub>5</sub> = 0.0003 e.u. J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for hematite and found two anomalies, presumably of magnetic nature, at about 950 and 1050°K., respectively. Both appear to involve maxima in the heat-capacity curves rather than isothermal heats of transformation. The complex magnetic properties at low temperatures were discussed by F. Gronvold and E. F. Westrum, Jr., loc. cit. No heat capacity anomaly was observed at the magnetic transition about 250°K. The Curie points of the antiferromagnetic α-Fe<sub>2</sub>O<sub>3</sub> were reported by A. Aharoni, E. H. Frei and M. Schieber, Phys. Rev. **127**, 439 (1962) and J. Lielemez and A. C. D. Chekelder, Phys. Rev. Letters, **13**, 866 (1965).

Temperature of Decomposition.

T<sub>d</sub> is the temperature at which ΔH<sub>f</sub><sup>0</sup> = 0 for the reaction 6Fe<sub>2</sub>O<sub>3</sub>(c) = 4Fe<sub>3</sub>O<sub>4</sub>(c) + O<sub>2</sub>(g). In other words, Fe<sub>2</sub>O<sub>3</sub>(c) decomposes into Fe<sub>3</sub>O<sub>4</sub>(c) and O<sub>2</sub>(g) at 1735°K.

ΔHf° = Unknown  
ΔHf°<sub>298.15</sub> = -617.35 ± 0.40 kcal/mol  
S°<sub>298.15</sub> = [ 73.5 ± 2 ] gibbs/mol  
Td = 1451°K

Heat of Formation.

The enthalpy change (ΔHf°<sub>298.15</sub>) for the chemical reaction Fe<sub>2</sub>O<sub>3</sub>(c) + 3H<sub>2</sub>SO<sub>4</sub>(14.855 H<sub>2</sub>O) = Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) + 3H<sub>2</sub>O(l) was measured to be 6.54 ± 0.16 kcal/mol by solution calorimetry by R. Barzany and L. H. Idami, U. S. Bur. Mines RI 6887, 1965. Using ΔHf°<sub>298.15</sub> = -211.176 kcal/mol for H<sub>2</sub>SO<sub>4</sub>(14.855 H<sub>2</sub>O) and -68.315 kcal/mol for H<sub>2</sub>O(l), obtained from "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, by D. D. Wagman and coworkers, National Bureau of Standards, 1965, and -197.3 kcal/mol for Fe<sub>2</sub>O<sub>3</sub>(c), the heat of formation (ΔHf°<sub>298.15</sub>) for Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) was evaluated as -617.35 ± 0.40 kcal/mol which was adopted here.

The equilibrium pressures for the decomposition of Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) have been determined by several investigators at different temperatures. The chemical reactions involved are: (1) Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) = Fe<sub>2</sub>O<sub>3</sub>(c) + 3SO<sub>2</sub>(g) and (2) SO<sub>3</sub>(g) = SO<sub>2</sub>(g) + 0.5 O<sub>2</sub>(g). However, the measured pressure of the chemical equilibrium is the total pressure of three partial pressures, namely, P<sub>SO<sub>2</sub></sub>, P<sub>SO<sub>3</sub></sub>, and P<sub>O<sub>2</sub></sub>. In order to calculate the enthalpy change of Reaction (1), the partial pressures of SO<sub>3</sub>(g) were evaluated from the total vapor pressure data at each temperature. Based on the derived values for P<sub>SO<sub>2</sub></sub>, the ΔHf°<sub>298.15</sub> value for Reaction (1) was calculated by both the second and third law methods. The results obtained are presented in the following table. The ΔHf°<sub>298.15</sub> (Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c)) values were derived, using the third law ΔHf°<sub>298.15</sub>. These determinations were not given any weight.

The decomposition pressures of Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>(c) have also been investigated by: M. Ordnzweig, Ph. D. dissertation, Darmstadt, Germany, 1913, 785-994°K; R. P. Blanka, Ph. D. dissertation, University of Melbourne, Australia, 1961, 845 - 978°K; and T. R. Ingraham, Internal Rept. EMT-63-17, Department of Mines and Technical Surveys, Ottawa, Canada, 1963, 856-995°K. These data together with some of the data mentioned previously were critically reviewed by H. H. Kellogg, Trans. AIME, 230, 1622 (1964).

Heat Capacity and Entropy.

The heat capacities were estimated by comparison with those for FeSO<sub>4</sub>(c), assuming their average specific heats, Gibbs/g, to be the same. The value of S°<sub>298.15</sub> was estimated so that the second and third law ΔHf°<sub>298.15</sub> values, derived from decomposition pressure data, are in reasonable agreement.

Temperature of Decomposition.

Td is the temperature at which the total pressure of the gaseous products equals one atmosphere, which was obtained by graphical extrapolation of the decomposition pressure data measured by Warner and Ingraham, loc. cit.

Magnetite (Fe<sub>3</sub>O<sub>4</sub>)

June 30, 1965

ΔH<sub>f</sub><sup>o</sup> = -266.4 ± 0.2 kcal. mole<sup>-1</sup>  
 ΔH<sub>f</sub><sup>o</sup> 298.15 = -267.9 ± 0.2 kcal. mole<sup>-1</sup>  
 ΔH<sub>m</sub><sup>o</sup> = 33.0 ± 2.0 kcal. mole<sup>-1</sup>

S<sub>298.15</sub> = 34.72 cal. deg.<sup>-1</sup> mole<sup>-1</sup>  
 T<sub>m</sub> = 1870 ± 2°K.

Heat of Formation.

The equilibrium constants for the following four reactions, i.e. (1) 3Fe(c) + 4H<sub>2</sub>O(g) = Fe<sub>3</sub>O<sub>4</sub>(c) + 4H<sub>2</sub>(g); (2) Fe<sub>3</sub>O<sub>4</sub>(c) + H<sub>2</sub>(g) = 3FeO(c) + CO(g); (3) Fe<sub>3</sub>O<sub>4</sub>(c) + CO(g) = 3FeO(c) + CO<sub>2</sub>(g); and (4) 2Fe<sub>3</sub>O<sub>4</sub>(c) = 6FeO(c) + O<sub>2</sub>(g), have been studied by several investigators. Using their reported equilibrium data, the corresponding enthalpy changes (ΔH<sub>f</sub><sup>o</sup> 298.15) were evaluated by both the second and third law methods. Based on the third law value for ΔH<sub>f</sub><sup>o</sup> 298.15, the respective ΔH<sub>f</sub><sup>o</sup> 298.15 values for Fe<sub>3</sub>O<sub>4</sub>(c) were also derived. The results obtained are presented as follows.

| Investigator                   | Reaction | Temperature, °K. | Second Law Value | Third Law Value | ΔH <sub>f</sub> <sup>o</sup> 298.15 kcal. mole <sup>-1</sup> |

1 R. Fricke, K. Walter and W. Lehrer, Z. Elektrochem. 47, 487 (1941). The two ΔH<sub>f</sub><sup>o</sup> 298.15 values listed are the average values of three separate results derived from three sets of experimental data.

2 E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

3 E. D. Eastman and R. M. Evans, J. Am. Chem. Soc. 45, 888 (1924).

4 P. H. Emmett and J. P. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

5 O. N. Salmon, J. Phys. Chem. 65, 550 (1961).

The enthalpy change of the reaction Fe<sub>0.917</sub>O(c) + 0.8215 Fe(c) + 0.6787 O<sub>2</sub>(g) = 0.5895 Fe<sub>3</sub>O<sub>4</sub>(c) has been determined by O. L. Humphrey, E. O. King and K. K. Kelley, U. S. Bur. Mines RI 4870 (1952). Based on ΔH<sub>f</sub><sup>o</sup> 298.15 = -93.46 kcal. mole<sup>-1</sup> (average of two separate values derived from two experimental determinations) and ΔH<sub>f</sub><sup>o</sup> 298.15 (Wülfite, c) = -63.64 kcal. mole<sup>-1</sup>, the value of ΔH<sub>f</sub><sup>o</sup> 298.15 (Fe<sub>3</sub>O<sub>4</sub>, c) was calculated as -266.5 kcal. mole<sup>-1</sup>. The enthalpy change, ΔH<sub>f</sub><sup>o</sup> 298.15 = 4.33 kcal. mole<sup>-1</sup>, for the reaction 3Fe(c) + 4CO<sub>2</sub>(g) = Fe<sub>3</sub>O<sub>4</sub>(c) + 4CO(g) was reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). The corresponding ΔH<sub>f</sub><sup>o</sup> 298.15 (Fe<sub>3</sub>O<sub>4</sub>, c) was evaluated as -266.22 kcal. mole<sup>-1</sup>. The adopted value of ΔH<sub>f</sub><sup>o</sup> 298.15 for Fe<sub>3</sub>O<sub>4</sub>(c) is selected as -267.9 ± 0.2 kcal. mole<sup>-1</sup>.

Heat Capacity and Entropy.

The low temperature (60.5-299.7°K.) heat capacities were reported by R. W. Millar, J. Am. Chem. Soc. 51, 215 (1929). The high temperature (298-1800°K.) heat capacities were obtained from J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3691 (1951). These two sets of data were plotted and joined smoothly at 298°K. The C<sub>p</sub> values above 1800°K. were obtained by graphical extrapolation. Heat capacities (90-298°K.) for Fe<sub>3</sub>O<sub>4</sub>(c) were also reported by O. S. Parks and K. K. Kelley, J. Phys. Chem. 50, 47 (1926). S<sub>298.15</sub> (Fe<sub>3</sub>O<sub>4</sub>, c) was derived from the smoothed C<sub>p</sub> data mentioned previously, using S<sub>4.7</sub> = 0.969 e.u. J. P. Coughlin, E. O. King and K. R. Bonnickson, loc. cit. measured the heat-content for magnetite and found a magnetic anomaly around 880°K., corresponding to a maximum in heat capacity. A maximum heat capacity of 37.1 cal. deg.<sup>-1</sup> mole<sup>-1</sup> at 114.15°K. was also reported by R. W. Millar, loc. cit.

Melting Data.

T<sub>m</sub> and ΔH<sub>m</sub><sup>o</sup> were obtained from L. S. Darken and R. W. Gurry, loc. cit.

Fe<sub>3</sub>O<sub>4</sub>

HYDROGEN, MONATOMIC (H) (IDEAL GAS)

AT. WT. = 1.00797

Ground State Configuration  $1s^2_1/2$

## Heat of Formation.

The heat of formation was calculated from  $D^{\circ}(\text{H}_2) = 36113.0 \pm 0.3 \text{ cm.}^{-1}$ , reported by G. Herzberg and A. Morfilla, J. of Molecular Spectroscopy 5, 482 (1960). This value was measured more precisely than the value  $D^{\circ}(\text{H}_2) = 36116 \pm 6 \text{ cm.}^{-1}$  by H. Baulter, Z. Phys. Chem. B29, 315 (1935).

## Heat Capacity and Entropy.

Electronic levels taken from C. E. Moore, Natl. Bur. Standards (U. S.) Circ. 467 (1949).

(IDEAL GAS)

PROTON (H<sup>+</sup>)

GF<sub>W</sub> = 1.00742

ΔH<sub>f,0</sub><sup>o</sup> = 365.236 ± 0.01 kcal/mol

ΔH<sub>f,298.15</sub><sup>o</sup> = 367.186 ± 0.01 kcal/mol

S<sub>298.15</sub><sup>o</sup> = 26.012 gibbs/mol

Heat of Formation.

The heat of formation was calculated from the equation H(g) → H<sup>+</sup>(g) + e<sup>-</sup> with the JANAF auxiliary data for H(g), using an ionization potential = 13.598 eV (313.605 kcal/mol) for H(g) obtained from C. W. Beckett, National Bureau of Standards Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy.

Calculated by assuming the proton to be an ideal monatomic gas. The enthalpy between 298° and 0°K is 1.481 kcal/mol as for all unexcited monatomic gases.

Hydrogen Uninegative Ion (H<sup>-</sup>)  
(Ideal Gas) At. Wt. = 1.00852
