Under Inlet Engineering Work Unit 32935

ABSTRACT: This physical model study of absorbing and reflecting jetties at coastal inlets was conducted to provide data sets that would aid in the calibration and verification of numerical wave models. The study was performed in the Coastal Inlet Research Program's (CIRP) idealized inlet experimental basin at the U.S. Army Engineer Research and Development Center (ERDC), Coastal and Hydraulics Laboratory (CHL), Vicksburg, MS. Safe navigation, sediment transport into navigation channels, and shoreline erosion are all concerns at coastal inlets and are related to the transformation of waves as they change direction and height due to complex bathymetry and coastal inlet structures. The idealized inlet physical model, created for inlet studies, provided a facility in which to make wave measurements of height and direction and the associated wave-generated currents in enough detail to document the wave height and current variation in a region with complex interactions. Measurements of wave information included use of wave rods for wave height and acoustic Doppler velocity sensors for wave direction and current. Qualitative dye photographs and videos were also obtained.

Wave height and velocity measurements were collected both upcoast of the jetty and between parallel jetties for a number of waves representative of tidal inlets. The composition of the jetty was designed to portray the extremes of an inlet jetty – a jetty that fully reflects the incident wave toward the upcoast shoreline adjacent to the jetty, and an almost fully absorbing jetty, which reflects very little energy. These two extreme conditions created two different circulation patterns associated with each jetty condition. The nearly fully absorbing jetty setup permitted the wave-generated longshore current to approach the jetty and essentially be deflected seaward ninety degrees, along the jetty. The waves fully reflecting from the jetty created a clockwise circulation cell at the intersection of the jetty and the shoreline. This cell was large enough to deflect the offshore movement of littoral currents a significant distance upcoast rather than approaching the base of the jetty before deflecting seaward as for the absorbing jetty setup.

feet	0.3048	meters
inches	2.54	centimeters
gallons	3.785	liters

Preface

The research investigation described herein was conducted as part of the Coastal Inlets Research Program (CIRP) under Work Unit 32935, “Inlet Laboratory Investigations.” Overall program management for CIRP is directed by Headquarters, U.S. Army Corps of Engineers (HQUSACE). Program Monitors for the CIRP at HQUSACE are Messrs. Barry W. Holliday and Charles B. Chesnutt. Technical Director for CIRP was Dr. Sandra Knight, U.S. Army Engineer Research and Development Center (ERDC), Coastal and Hydraulics Laboratory (CHL), Vicksburg, MS. The Program Manager was Dr. Nicholas C. Kraus, CHL. Mr. William C. Seabergh, CHL, is Principal Investigator of the Inlet Laboratory Investigations Work Unit.

The mission of the CIRP is to conduct applied research to improve USACE capability to manage Federally maintained inlets, which exist on all coasts of the United States (including the Atlantic, Gulf, Pacific, and the Great Lakes regions). Objectives are to (a) make management of channels—design, maintenance, and operation—more effective to reduce the cost of dredging, and (b) preserve the adjacent beaches in a systems approach that treats the inlet and beach together. To achieve these objectives, CIRP includes work units on short-wave and circulation modeling, channels and adjacent shorelines, inlet scour, laboratory investigations, field investigations, and technology transfer.

CHL personnel under the general direction of Mr. Thomas W. Richardson, Director, CHL, and Dr. Rose M. Kress, Chief, Navigation Division, conducted this study. Mr. Dennis G. Markle, former Chief, Harbors, Entrances and Structures Branch, CHL, provided direct guidance. Mr. John E. Evans and Mr. William G. Henderson, Civil Engineering Technicians, conducted the experiments under the direction of Mr. Seabergh, all of the Harbors, Entrances and Structures Branch. Messrs. Tim E. Nisley and David A. Daily of the ERDC Information Technology Laboratory provided instrumentation support. Mr. Seabergh, Dr. Lihwa Lin, Coastal Engineering Branch, and Dr. Zeki Demirbilek, Harbors, Entrances, and Structures Branch, prepared this report. Ms. J. Holley Messing, Coastal Engineering Branch, completed word processing and formatting. Ms. Julie D. Rosati and Mr. Ernest R. Smith, Coastal Processes Branch, provided helpful review comments.

At the time of publication of this report, COL James R. Rowan, EN, was Commander and Executive Director of ERDC. Dr. James R. Houston was Director.

1 Introduction

Waves approaching a tidal inlet refract, diffract, shoal, and interact with tidal currents as they travel from deeper water toward the vicinity of the inlet. The transforming waves eventually break along the shore, creating wave-driven currents at the inlet. These currents are of concern to operation and maintenance of the channel. Wave processes adjacent to and inside the inlet, especially near the navigation channel, move sediment around causing channel erosion and accretion and loss of depth to navigation. In particular, waves, where they encounter a jetty, breakwater, or other discontinuity, can create complex circulation patterns. Controlled measurements of wave and currents on a sloping beach near jetties are lacking, yet this combined wave transformation is driving processes at coastal inlets that determine navigational reliability, channel performance, and morphology change.

Objectives

In this report, wave-generated currents and wave heights were examined through physical-model measurements made in an idealized physical model inlet. The primary objective of the study was to provide laboratory data to develop and validate numerical models for representing hydrodynamic processes (waves and currents) at an inlet. A second objective of these experiments was to improve understanding of the water circulation patterns developing near the beach-jetty intersection region.

Background

Jetties are built at inlets to reduce wave height for improved navigability and minimizing sedimentation in the navigation channel. These structures provide protection from the waves, align tidal currents, and reduce sedimentation of the navigation channel. On the seaside of the jetties, wave breaking generates a current that typically flows along the shore until it is diverted seaward by irregular bathymetry or a coastal structure such as a jetty. A longshore current may carry sediment towards the navigation channel and possibly create a strong crosscurrent that reduces channel reliability. Longshore current and tide-generated current entering Grays Harbor, WA, are illustrated in Figure 1. If waves are high, the surf zone width increases, and the waves and wave-induced currents may strongly alter the inlet environment and activities therein.

Figure 1. Wave-generated longshore currents entering Grays Harbor, WA, during flood tide

In the past, physical models have been used to study inlets and develop solutions to problems associated with their use, such as channel alignment, high waves detrimental to navigation, and channel shoaling (e.g., Seabergh and Lane 1977; Seabergh 1983, 1988; Bottin et al. 1995 and many other physical model U.S. Army Engineer Research and Development Center (ERDC) reports). Today (2005), numerical models are being applied to study a variety of issues at inlets. However, data are needed to calibrate and verify numerical wave and circulation models developed for inlets.

Advanced numerical models have been developed for modeling flow, wave, and morphodynamics of coastal inlets. These process-based models can be applied to hindcast the morphological development of a coastal inlet and adjacent shoreface beaches. The U.S. Army Corps of Engineers' (USACE) Inlet Modeling System (IMS) (Zundel et al. 2002) is a state-of-the-art toolbox that presently consists of several two-dimensional (2D) horizontal hydrodynamic flow models, wave models, and sediment transport models specifically developed for coastal inlets. Details of the IMS and other aspects of the Coastal Inlets Research Program (CIRP) are available at <http://cirp.wes.army.mil/cirp/cirp.html>. The physical modeling experiments described in this report have been conducted primarily in support of the CIRP's model testing, validation, and enhancement.

Recent progress in coastal modeling has made sophisticated hydrodynamic and morphodynamic process-based models increasingly valuable tools for coastal engineers and managers. In particular, 2D horizontal (2DH) models have been widely applied in engineering studies for modeling spatial changes in bathymetry and wave climate, although this class of models rely on depth-averaged estimates that ignore vertical variation in the flow and wave characteristics that are

important to inlet processes. Cialone and Kraus (2001), Cialone et al. (2003), and Cialone (2003) present applications of the IMS at structured inlets. Grunnet et al. (2004) discuss these issues and describe a systematic approach to be used in the validation of the 2D and three-dimensional (3D) numerical models for shoreface nourishment. They also critique the lack of proper data used in some previous studies conducted for measuring nearshore data aimed at validation of nearshore zone hydrodynamic evolution in time and space.

The CIRP experiments were performed in two phases. Initial experiments, conducted as the first phase of the study, have been described in Seabergh et al. (2002). Phase I experiments focused on wave height and direction measurements of waves behind a breakwater, a dogleg jetty, and propagation of waves into the inlet bay through an idealized inlet. Data from this study have been used in the evaluation and validation of two steady-state spectral wave models (Lin and Demirbilek 2005).

In this Phase II study, experiments were conducted to obtain high-resolution measurements of waves and currents around jetties and within an idealized inlet. In the field, jetty structure composition may vary from porous rock rubble to strongly reflecting vertical sheet piles. The extreme structural conditions of a nearly fully wave absorbing jetty and a fully reflective jetty were examined in this study to provide information to numerical modelers. Waves breaking along the shore create a longshore current that is deflected seaward by a jetty. The circulation created by such currents interacts with the wave field that is propagating from the sea and may be reflected off the jetty. Wave and current measurements were made in the direct vicinity of these. Measurement stations were placed on a grid consisting of cross-shore and alongshore transects on the incident-wave side of the jetties that extended in the cross-shore direction. Measurements within the inlet were obtained on three transects, one at the channel centerline and the other two positioned near the side boundaries of inlet parallel to the channel centerline. Gauge layout and experimental arrangement are depicted in Chapter 3.

Previous work on data collection in the beach-jetty region has been limited due to its energetic wave environment. Seabergh (1988) discussed flow patterns at inlets based on physical, analytical, and numerical models. Even in physical model studies, data collection was limited to using dye to measure the current field, as the inertia of mechanical current meters precluded accurate measurements. With the advent of acoustic-Doppler type current meters in the laboratory (Kraus et al. 1994), collection of accurate measurements has been greatly enhanced (Seabergh and Smith 2001). This also is true for field measurements. Osborne (2003) and Sherwood et al. (2001) obtained data sets in the high-energy environment adjacent to Grays Harbor, WA. Sherwood et al. (2001) describe measuring currents on the ebb shoal and adjacent regions at Grays Harbor. Helicopters have been used by Pollock (1995) to insert instruments into the energetic hydrodynamic environment near jetties at Siuslaw River, OR, and by Osborne et al. (2002) at the north jetty at Grays Harbor, WA.

Motivation

The experiments in this study were designed to provide an extreme range of reflection coefficients for numerical modeling of waves and currents near inlet structures. Not only is this a severe test of numerical modeling capability, but it is also important in the representation of actual field conditions, where there are a variety of structures that may be modeled. Reflectivity depends primarily on the structure type and to some degree on water elevation and depth near jetty structure, and currents in the vicinity of the jetty.

Examples of the many jetty structures that need proper representation in numerical models are shown in Figure 2. In general, structures with high reflectivity include those with vertical sheet-metal or wood piles such as those seen in Figure 2a-2c. Lower reflectivity structures can be characterized by gentle side slopes and higher transmissibility such as large rubble-mound or preformed concrete unit structures (Figures 2d and 2e).

A “pier” type structure, composed of vertical wood pilings at White Lake Harbor, MI, is shown in Figure 2a. Interesting to note from Figure 2a is the high degree of wave reflection occurring for this structure. Figure 2b shows complex configuration of rubble mound plus stone filled vertical sheet pile at the lakeside end at Charlievoix Harbor, MI. Another multi-component jetty at Big Bay Harbor, MI, with filled cellular construction at the lake end of rubble mound is shown in Figure 2c. These vertical sheet pile jetty elements are highly reflective. A more typical rubble mound jetty at San Marino Inlet, Guatemala, is shown in Figure 2d. At many locations in the United States, there are a variety of rubble-mound jetties with stone size in proportion to the wave climate. Some rubble-mound jetties may be more transmissive to wave energy at higher elevations in the structure, due to relatively large stone that have large voids. At lower levels of the structure, smaller core stone makes them impermeable to wave penetration. Figure 2e is a rubble-mound jetty that is being rehabbed at the seaward end with concrete Core-Loc armor at Manasquan Inlet, NJ. A jetty at Puerto Quetzal, Guatemala, with a solid concrete core that serves as a pier, flanked by armor units is shown in Figure 2f. All these examples indicate the large range of jetty types the modeler may encounter.

Scope

Following this introduction are descriptions of the laboratory facility and equipment used. Experiment basin bathymetry and scaling relationships are discussed in Chapter 2. The inlet structures studied, gauge layouts for various setups, and experimental wave conditions are discussed in Chapter 3. Examples of data collected, including velocity, wave height, wave direction, and dye current patterns are discussed in Chapter 4. Chapter 5 summarizes the report and presents conclusions. A CD containing the data collected is included with this report.

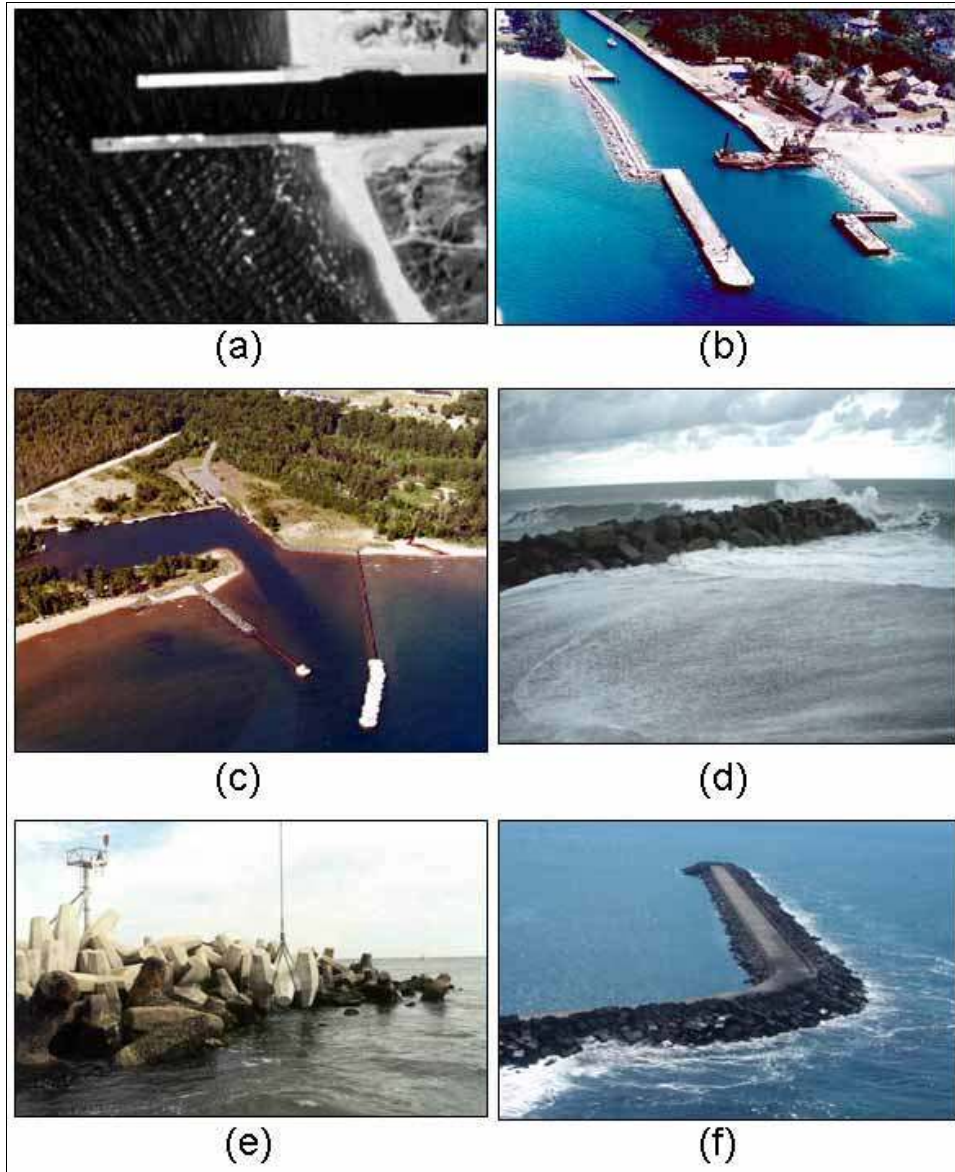

Figure 2. Jetty examples of varying wave reflectivity discussed in text

2 Laboratory Facility and Equipment

As part of the CIRP, a physical model facility was created to address research and field problems of tidal inlets (Seabergh 1999). The model and appurtenances necessary to the study and procedures and analysis of data are discussed in this chapter.

Idealized Inlet Facility

An idealized inlet was designed within a 46 m (150 ft) wide by 99 m (325 ft) long concrete basin with 0.6-m (2 ft) high walls. The approach was to design an inlet with simplified bathymetry and relatively steep beach slopes so additional features (such as an ebb shoal) could easily be added. Plans included using fine sand as both a tracer and as a fully mobile bed that could be placed over the concrete bottom in a thick veneer. A 1:50 undistorted scale was specified to determine reasonable inlet dimensions to model; however, other scales can easily be assumed to accommodate studies of specific processes with the simplified bathymetry.

The idealized inlet facility (Figure 3) is connected to a large sump (not shown), with volume of 1.98×10^6 L (523,000 gal) for water exchange. A tide may be produced in the facility's "ocean" to drive tidal currents into and out of the inlet bay. A constant inflow is introduced from the sump into the basin's ocean, and a rolling gate either reduces or increases flow area over an exit pipe into the sump that causes ocean rise or fall, respectively. The two cylinders in Figure 3 are storage tanks, each tank holding 182,000 L (48,000 gal) water. The tanks can be activated to simulate a much larger bay area by storing flood tide water and releasing it back to the bay to flow to the ocean during ebb flow. Pumps and control valves associated with this procedure are located adjacent to the storage tanks.

The piping system shown in Figure 3 can establish a steady-state flow for simulating ebbing or flooding currents. Water is either collected (flood flow) or distributed (ebb flow) through a system of manifolds in the bay that may be adjusted for one, two, or three bay channels or a uniform flow across the bay. Water is either released (flood flow) or taken from (ebb flow) the ocean headbay to complete the circulation energized by the pumps located in the upper right side of Figure 3.

Figure 3. Idealized inlet model research facility

The ocean-side parallel contours (Figure 4) were specified by applying an equilibrium profile equation from Dean (1977).

$$d = Ax^{0.67} \quad (1)$$

where

d = still-water depth

x = distance offshore from the shoreline

and A is determined by sediment characteristics. A value of $A = 0.24 \text{ ft}^{1/3}$ was specified to represent a relatively steep beach. The contoured beach slope extends to the 0.183 m (0.6 ft) mean low water (mlw) depth (or 9.1 m (30 ft) scaled by 1:50).

The inlet throat region converges to a depth of 0.152 m (or if scaled to 1:50, to a depth of 7.6 m (25 ft)) relative to a mlw datum. The minimum width is 2.67 m (8.76 ft) across the inlet between mlw contours (or if scaled by 1:50, it represents a width of 133.4 m (438 ft)). The inlet with a parallel jetty configuration is shown in Figure 5.

Based on Froude's model law (Hughes 1993) and the linear scale of 1:50, the model-prototype relations in Table 1 were derived. Dimensions are in terms of length (ℓ) and time (t). Figure 4 shows the model inlet during testing. As mentioned previously, other scales may be assumed for the bathymetric contours, so different scaling relationships would apply than those listed in Table 1.

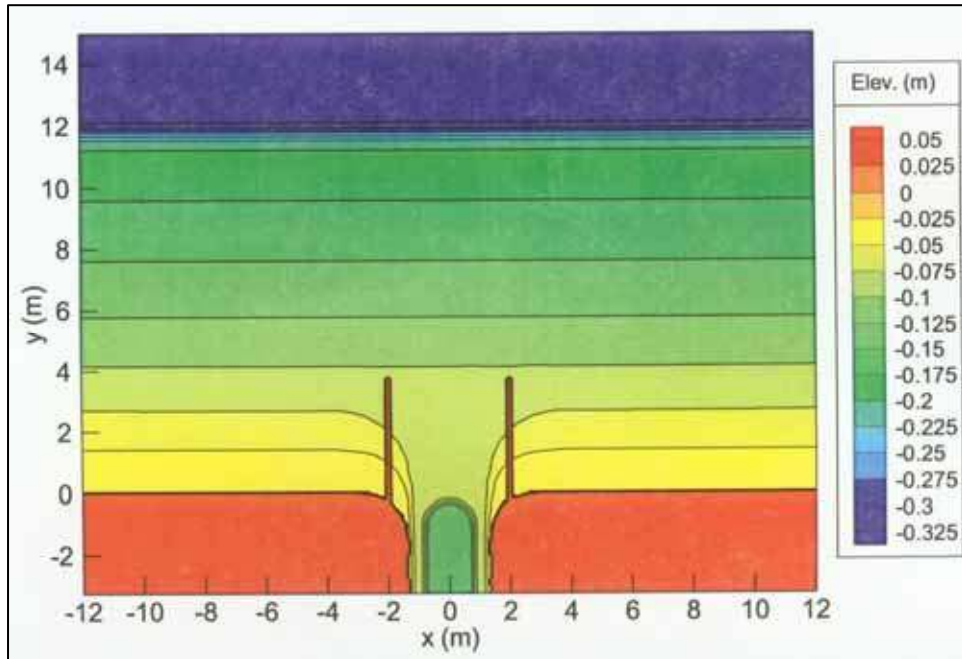

Figure 4. Contours in model units in idealized inlet

Figure 5. Idealized inlet entrance channel with oblique wave approaching inlet (spacing 0.62 m between "+" marking on research facility basin floor)

Table 1 Model-Prototype Scale Relations at 1:50 Undistorted Scale		
Characteristic	Dimension	Model-Prototype Scale Relation
Length	ℓ	$\ell_r = 1:50$
Area	ℓ^2	$Ar = \ell_r^2 = 1:2,500$
Volume	ℓ^3	$Vr = \ell_r^3 = 1:125,000$
Time	t	$Tr = \sqrt{\ell_r} = 1:7.07$
Velocity	ℓ/t	$Ur = \ell_r/t_r = 1:7.07$

A movable, 24-m-long (80-ft-long) unidirectional-wave generator (Figure 3) was located on the ocean side of the facility to produce either irregular or monochromatic waves. Unscaled wave periods can be varied from 0.5 to about 3 sec and wave heights to 0.1 m (at the generator location and for this model configuration). Wave angle can be varied for specific tests by moving the generator on its castors.

Instrumentation and Calibration

Wave height and period data were collected on electrical capacitance wave gauges (Figure 6) that were calibrated daily with a computer-controlled procedure. The calibration procedure incorporated a least square fit of measurements at 11 steps that were determined by moving the wave rod incrementally through still water. This averaging technique, using 21 voltage samples per gauge, minimizes the errors of slack in the gear drives and hysteresis in the sensors. Typical wave height calibration errors are less than 1 percent of full scale for the capacitance wave gauges. Wave signal generation and data acquisition were controlled by a personal computer.

Velocity data were collected with SonTek 2D Acoustic Doppler Velocimeters (ADV) with a side-looking probe (Figure 7) that was oriented to collect x-y horizontal velocity information in a horizontal plane. Samples were collected at 20 Hz, though the instrument makes 250 pings/sec and averages for each output sample. Accuracy is 0.5 percent of the measured velocity, with resolution of 0.1 mm/sec and threshold of 0.1 cm/sec. The probe samples a 0.25 cu cm

Figure 6. Capacitance wave gauge

Figure 7. Acoustic Doppler Velocimeter

(0.015 cu in.) volume located 5 cm (2 in.) from the sensor heads. The velocity data also were analyzed for wave direction.

The sensor placement locations are discussed in Chapter 3. A gauge rack was designed to hold the velocity sensors in a co-linear manner, with a 0.61 m (2.0 ft) separation between gauges. The rack could be moved to other locations for various test runs as described in Chapter 3.

Data Sampling and Wave Generation

Following daily calibration of the wave gauges and incident wave conditions, the experiments began and either current or wave data were collected. The wave generator was operated for 600 sec with a 10-sec ramp-up and ramp-down time. The wave gauge-sampling rate was 20 Hz, and 12,000 water elevation data points were collected at each gauge. Velocity data samples (a 20-Hz sampling rate) for each sensor were usually of slightly shorter duration, as data collection was not initiated until a short time after waves began.

All wave tests were monochromatic, and no flood or ebb currents were generated in the model. This was done to establish a more consistent circulation pattern that would be easier to interpret and compare to the numerical model results.

Data Analysis

Wave data included with this report were analyzed by simple averaging of the middle one-third of the 20-Hz water-level measurements. These data are tabulated in Appendix B. The raw data are included as an ASCII text file in units of meters on a compact disk (CD) included with this report. Each record has 12,000 data points with time interval $\Delta t = 0.05$ sec.

The velocity data are collected in a special format that must be interpreted by a program specific to the Sontek current meter. Such a program has been written by Mr. Tony Wahl (U.S. Bureau of Reclamation). This program may be downloaded from the web at:

http://www.usbr.gov/pmts/hydraulics_lab/twahl/winadv/index.html. The raw data files are included on the CD, and the analyzed resultant data are included in Excel spreadsheet format. Plots of the data are contained within the spreadsheet. The current meters have an internal coordinate convention with respect to flow direction. Five of the six meters had the same x-y convention (Probes 1 thru 5, Figure 8) with the sixth (Probe 0) having the positive x-axis opposite to that of the others. Outside the jetties, the raw velocity data had a (x',y') coordinate system (Figure 8) and inside the jetties a (x'',y'') coordinate system (Figure 8). The current measurements were all adjusted to a common (x,y) convention used by many modelers, with positive x-axis shoreward and positive y-axis along the coast as shown in Figure 8. Final velocity components also followed this system (Figure 8). If the user would like to start with the raw data, the user's resultant data should be compared with the final data set included on the CD to ensure the correct coordinate directions are achieved. Also, there is a text file in the CD explaining the directional convention of each velocity probe and its orientation relative to the coordinate system.

Figure 8. Coordinate system convention for data. Upper left (x,y) coordinate system for gauge locations and final velocity data. Lower (x,y) coordinate system for raw velocity data upcoast of jetties

Wave direction was calculated as follows. Based on a standard stochastic method, the wave propagation direction was determined from velocity component measurements in the two orthogonal directions (Cartwright 1963; Long 1980). For instance, if u and v represent time series of wave orbital velocity components measured in the easting and westing directions, respectively, the wave direction θ associated with a frequency, f , can be computed as:

$$\theta(f) = \frac{1}{2} \tan^{-1} \left\{ \frac{2R_{uv}(f)}{R_{uu}(f) - R_{vv}(f)} \right\} \quad (2)$$

where $R_{uu}(f)$ and $R_{vv}(f)$ are spectra of u and v signals, respectively, and $R_{uv}(f)$ is the co-spectrum of u and v signals. The direction for waves was measured counter-clockwise from the positive x-axis and is given as the direction the wave is propagating towards.

3 Experiment Gauge Setup, Layout, and Conditions

This chapter provides information on the experiment setup, locations of data collected, and data collection procedure and analysis. Selected example plots of data are also shown.

Jetty Description

The initial jetty setup was designed to be of a nonreflecting nature. This was achieved by lining the up-shore face of an impermeable rock jetty with a fibrous material used for wave absorption at the boundaries of physical models. Wire mesh held the absorber in place. A photograph of the jetty is shown in Figure 9. The second jetty setup was designed for a totally reflecting type. A plywood face (Figure 10) was placed at the edge of the fibrous material so that the same location was maintained for the edge of the jetty as the nonreflecting type.

Figure 9. Wave-absorbing jetty perpendicular to shore in physical model

Figure 10. Plywood reflecting jetty face

Data Sampling Locations

The main objective of these experiments was to collect velocity and current data for numerical model calibration in the region upcoast (or upwave) of an inlet jetty system, as comprehensive data sets have not been available for model calibration in this part of an inlet system. As the experiments progressed, the addition of wave and current data in the region between the jetties was added. Even though tidal currents were not being reproduced for these experiments, circulation currents normally are generated by wave activity in the channel area between the jetties. Wave heights also were measured in this region. Photographs of wave gauges during data collection and ADV meters are shown in Figures 11 and 12. When wave and current measurements were collected in the region between the jetties, a six-position gauge rack was used to hold the gauges. Figure 13 shows the rack with six current meters.

Schematic diagrams of gauge location for the wave gauges and current meters for the region upcoast of the jetty are shown in Figures 14 and 15. Figure 16 shows wave gauge locations inside the jetty region. The complete set of data locations is shown in Appendix A. The location of gauges defined by x , y , z coordinates (see Figure A1 for orientation of axis) are listed in tables in Appendix A. Wave gauges were organized by “transect” numbers. Each transect had eight gauges, with Channel 1 gauge always being the incident wave gauge near the wave generator (see Figure 14). Channels 2 through 8 progressed shoreward along the transect. Current meters were identified by probe number and organized in “range” numbers (Figure 15).

Figure 11. Wave gauges near jetty

Figure 12. Current meters seaward of jetty

Figure 13. Rack holding six current meters in entrance channel

Spur Jetty Experiment

The last experiment setup was designed for a three-spur jetty structure (Figure 17). Current and wave height measurements were collected at many of the same locations discussed for earlier experiments. The structure in this case was composed entirely of rock and had an impermeable core. A detailed gauge location for this experiment is described in Appendix A.

Experiment Conditions

Waves

The experiments were conducted with only waves being reproduced in the model basin. All currents measured were derived from the waves. Some current measurements were purely oscillatory under the wave motion, whereas in a region of breaking waves a net current is measured. The incident waves at the seaward channel boundary were always monochromatic for these experiments and initial wave crest was 20 deg with respect to the shore (Figure 15) or 20 deg counter-clockwise from the x -axis. Table 2 presents wave heights and periods reproduced in the present study.

As noted in Table 2, only the first three experiment conditions were run for data in the channel. The in-channel data should be similar for both the absorbing and reflective conditions as the change was only for the outside part of the jetty. Inside the channel, both jetties were rock with an impermeable core.

Figure 17. Spur jetty

Table 2 Experiment Conditions (Wave Direction, 20 deg, Type-Monochromatic)		
Jetty Type	Incident Wave Height, m (Prototype Scale, 1:50, m)	Wave Period, sec (Prototype Scale, 1:7.07, sec)
Absorbing	0.02 (1.0)	1.56 (11)
Absorbing	0.04 (2.0)	1.56 (11)
Absorbing	0.07 (3.4)	1.13 (8)
Absorbing	0.02 (1.0)	1.13 (8)
Absorbing	0.033 (1.65)	1.56 (11)
Reflecting	0.02 (1.0)	1.56 (11)
Reflecting	0.04 (2.0)	1.56 (11)
Reflecting	0.02 (1.0)	1.13 (8)
Reflecting	0.07 (3.4)	1.13 (8)
Reflecting	0.015 (0.75)	1.13 (8)
Spur	0.02 (1.0)	1.56 (11)
Spur	0.04 (2.0)	1.56 (11)
Spur	0.07 (3.4)	1.13 (8)

Note: Only the first three experiment conditions were run for the in-channel data (see Figure 16).

Water level

The experiments were conducted with a constant water level. The water surface elevation was at 0.33 m (1.52 m prototype) above the low water datum.

Additional Information

The contoured region of the experimental facility is molded to templates with concrete mortar. The surface has a smooth troweled finish and has been painted. An estimated Manning's n for this surface is 0.015.

The absorbing jetty (Figure 9) was composed of fibrous rubberized hair filter material. Keulegan (1972) examined this material in a laboratory study. From his data it may be estimated that the coefficient of reflection for the jetty ranges from 0.10 to 0.25. The reflective jetty was constructed of smooth, $\frac{3}{4}$ -in. marine plywood. The spur jetty was constructed of rock with a typical diameter in the range of 1- to 2.5-in.

Other data collected included dye visualization, documented with still and video photography. These data are discussed in Chapter 4.

4 Discussion of Results

This chapter provides a discussion of the data and how to interpret the data. Also discussed are the differences noted in response between the wave-absorbing jetty, the fully reflecting jetty and a spur jetty.

Steady-State Data Segments

The raw wave height and velocity data included with this report are the entire time series, from initiation of wave generation to its conclusion. Therefore, transient conditions also are captured. This section is provided to guide the user in choosing appropriate windows of the data, if desired. If the forcing conditions are near steady-state in an experiment, a more or less steady-state condition is reached after a period of time. The user may be interested in the initial transient event, but most likely will analyze or model the near steady-state portion of the data. Examination of wave height measurements shows that for the smaller wave heights (0.02 m height, 1.56 sec period), about 100 sec is required to reach steady-state. The total time of data recording is 600 sec. The steady-state time also is dependent on location of the measurement, and can be less (farther away from the jetty) where wave-current interaction is less. Larger waves (e.g., 0.04 m height, 1.56 sec period) may require up to 200 sec for relatively steady-state conditions. Figure 18 shows wave height measurements at the wave generator (channel 1) and along the jetty at Transect 1, channel 6 (see Figure 14) for the 0.04-m, 1.56-sec wave (absorbing jetty). Gauge locations are shown in Figure 14.

Current measurements have about the same steady-state setup time as for wave measurements. Figure 19 shows an example of current data for a location near the absorbing jetty (see Figure 15 for location). Current speeds represent the wave orbital velocity, and the net current for the x and y components can be seen to be greater than zero. Current is near-steady-state from 200 to 500 sec. Figure 20 shows a 10-sec segment of the record seen in Figure 19.

Results

This section provides examples and examination of the data collected. Sample contour plots of currents and wave heights are shown. Illustrative plots of current direction and wave direction are also presented.

Figure 18. Wave height measurements (in meters) showing (a) waves at generator and (b) waves along Transect 1, channel 6

Figure 19. Current speed at Range 26, probe 0

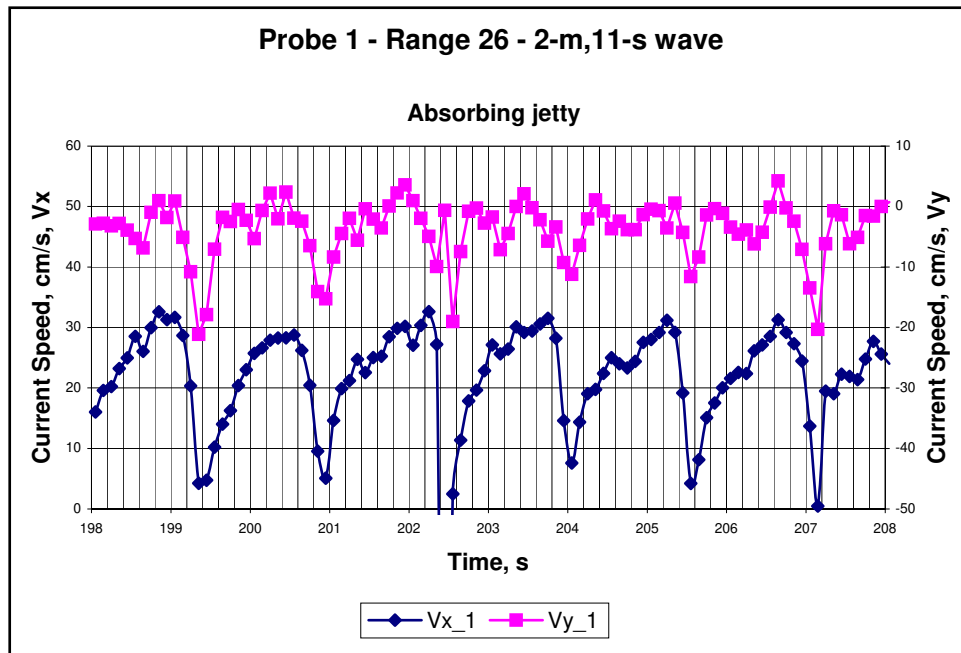

Figure 20. Current speed at Range 26, probe 0, for time 198 to 208 sec of Figure 17

Wave height

Wave height contours for the 2-m, 11-sec offshore wave (prototype units, 0.04-m, 1.56-sec in model units) with the absorbing jetty are shown in Figure 21. On the seaward side of the absorbing jetty (lower jetty in Figure 21), the contours generally move seaward, indicating reduction in wave height shoreward. Wave height contours in the channel indicate the 20-deg wave approach, with the greater wave heights located toward the top of the figure inside the channel and penetrating farther bayward.

Results of the 2-m, 11-sec wave for the reflective jetty are shown in Figure 22. An increase in wave height can be seen in the region of the jetty due to reflection from the jetty. The largest wave results (3.5-m, 8-sec wave, prototype units, 0.07-m, 1.13-sec in model units) are presented in Figure 23.

Currents due to waves

Figure 24 shows wave-generated currents in the region upcoast of the absorbing jetty (bottom jetty in Figure 22). The wave condition with the absorbing jetty was the 2-m, 11-sec wave (prototype units, 0.02-m, 1.56-sec in model units) and was the same as that used for Figure 21. The maximum current along the jetty is 1.6 m/sec, greater than the longshore current along the beach. Current direction may also be noted in Figure 24. Typically, all vectors have a component toward the jetty (except those closest to jetty), indicating no significant circulation cells in the region of the jetty.

Figure 21. Contours of wave height for 2-m, 11-sec wave, absorbing jetty setup

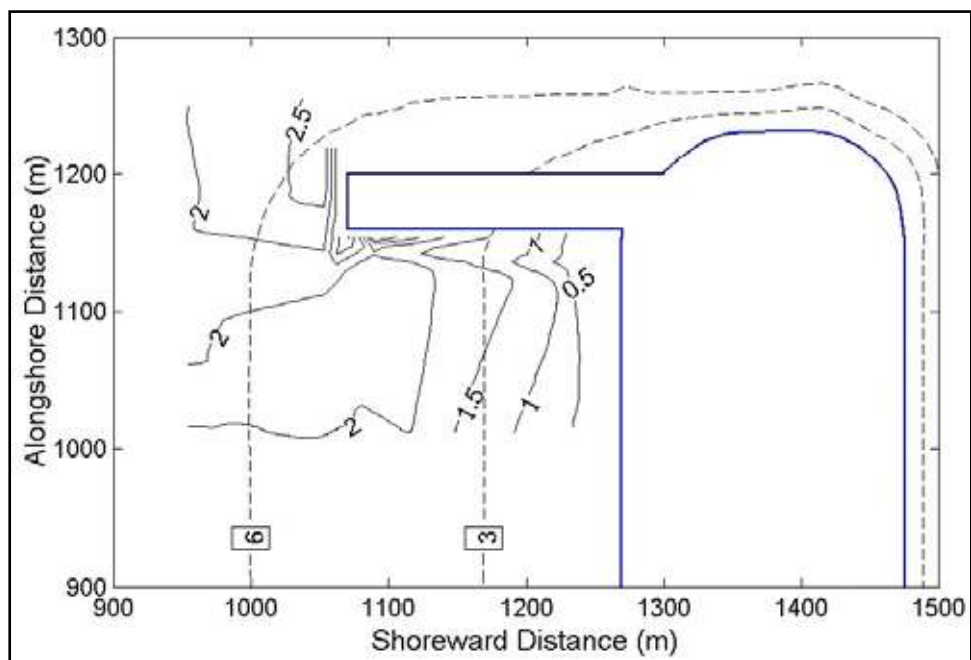

Figure 22. Contours of wave height for 2-m, 11-sec wave, reflecting jetty setup

Figure 23. Contours of wave height for 3-m, 8-sec wave, absorbing jetty setup

Wave direction

Wave direction for three conditions is shown in Figure 25. Figure 25a shows wave direction approaching the jetty is unchanged as the wave enters the absorbing jetty. Figure 25b indicates the effect of the reflective jetty by the vectors being parallel to the jetty. It should be noted that wave direction in this region was affected by the current that was moving alongshore then seaward as the current approached the jetty.

Circulation Near Reflective and Wave-Absorbing Jetties

The above examination of the sample data indicated there are distinct differences in waves and circulation between the reflective and absorbing jetties. This section examines dye photographs that illustrate differences in the circulation pattern. Figures 26 and 27 show the differences in the circulation pattern upcoast of the absorbing and reflecting jetties respectively. For the absorbing jetty

Figure 24. Wave-generated current for 2-m, 11-sec wave, absorbing jetty setup

(Figure 26), the dye patch is inserted in model as shown in the first photograph (1), and the sequential movement is followed in frames (2) to (7). The dye usually moves towards the jetty and is deflected seaward. The breaker location is roughly along a line that passes through the middle of the jetty. For the reflecting jetty (Figure 27), the dye patch begins to move seaward in (2), and further seaward in the following photograph frames (3) to (5). The waves for the reflecting jetty experiment have created a clockwise circulation along the shoreward half of the jetty that deflects the incoming longshore current seaward further up-drift than for the absorbing jetty.

The circulation difference between the two jetty types also can be seen in plots of velocities. Figures 28-30 show current patterns and magnitudes for a small wave (1-m, 11-sec), a moderate wave (2-m, 11-sec), and a larger wave (3.5-m, 8-sec). These figures compare the absorbing-jetty current velocity with the reflecting-jetty velocity. Note the velocity scale on each figure. The reflected wave energy drives a shoreward circulation along the vertical plywood-faced jetty.

Figure 27. Sequence of photographs (1-5) of dye patch approaching reflecting jetty (2-m, 11-sec wave)

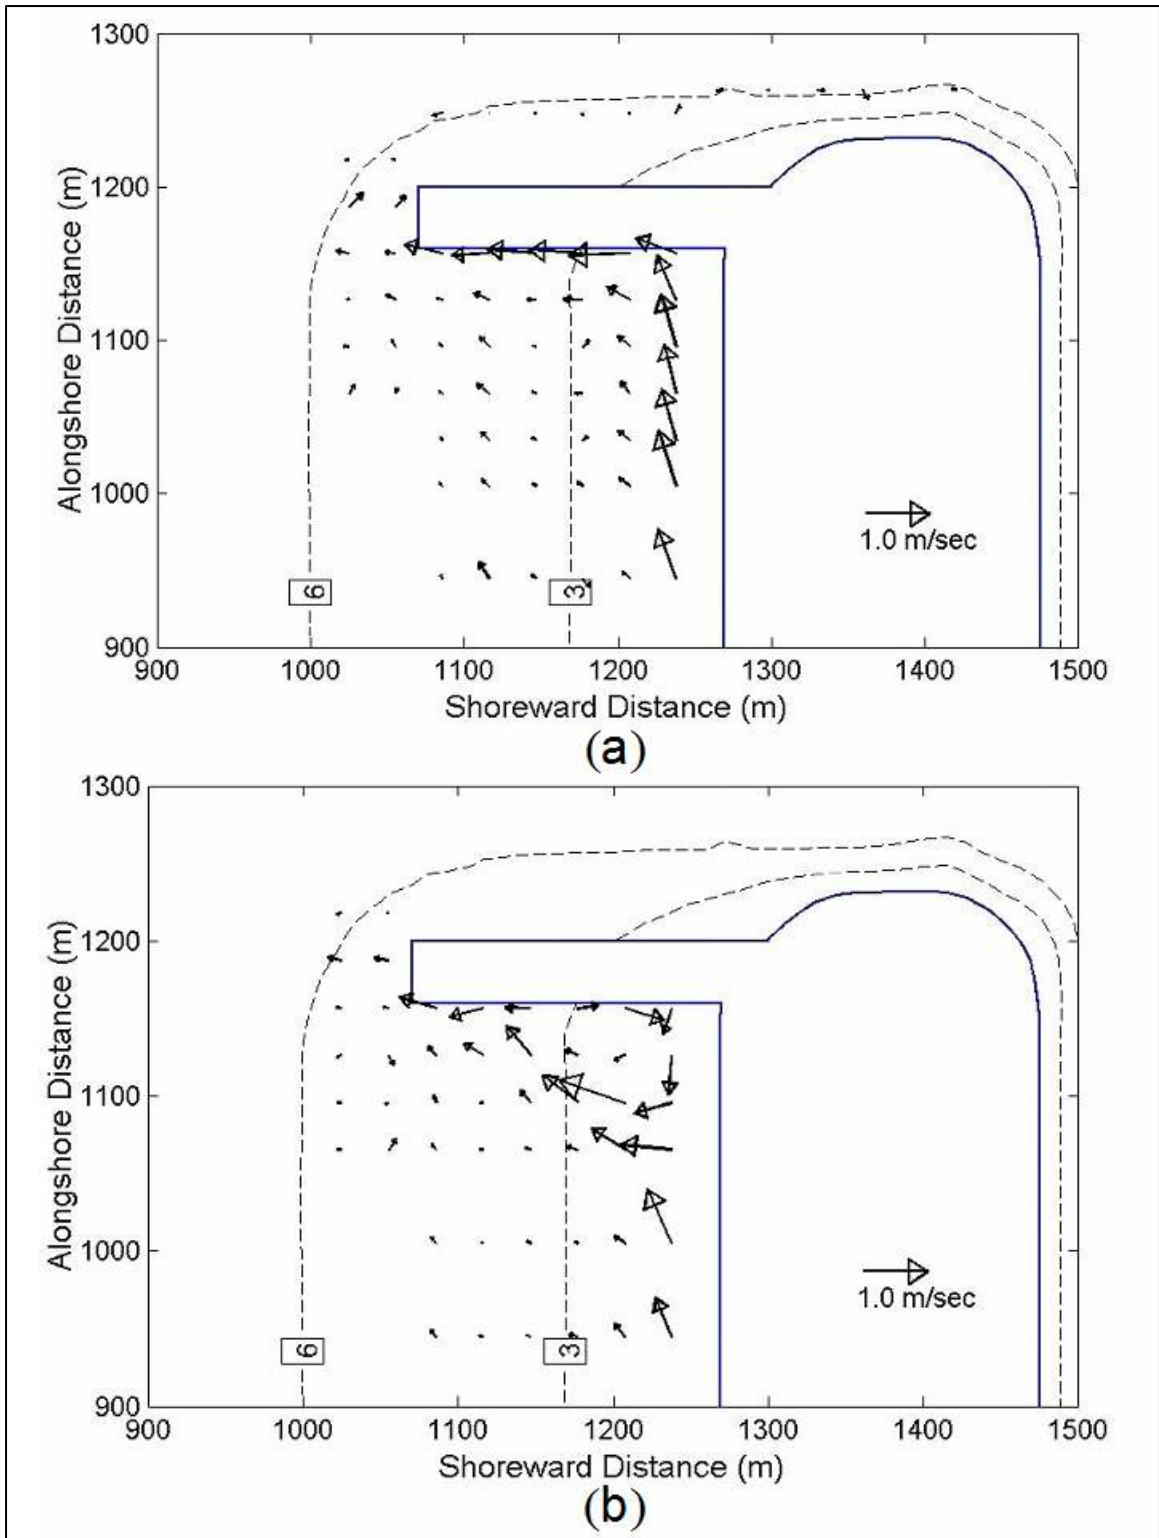

Figure 28. Comparison of (a) absorbing jetty and (b) reflecting jetty for 1-m, 11-sec wave

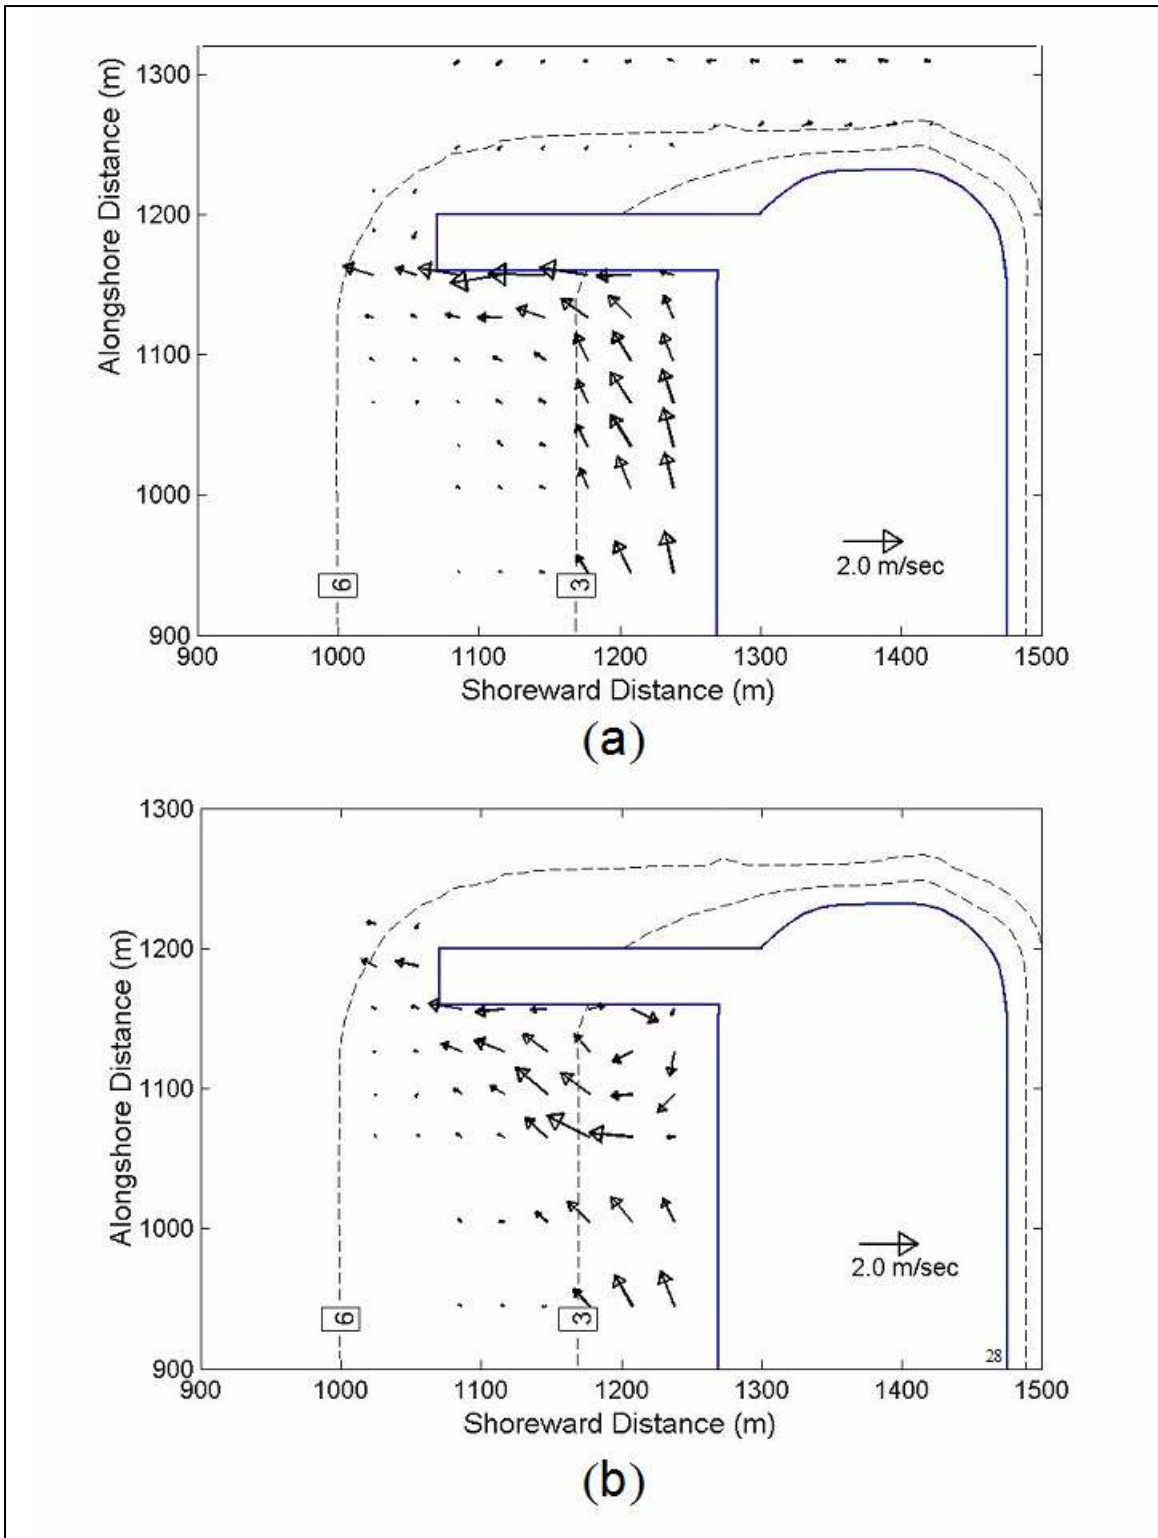

Figure 29. Comparison of (a) absorbing jetty and (b) reflecting jetty for 2-m, 11-sec wave

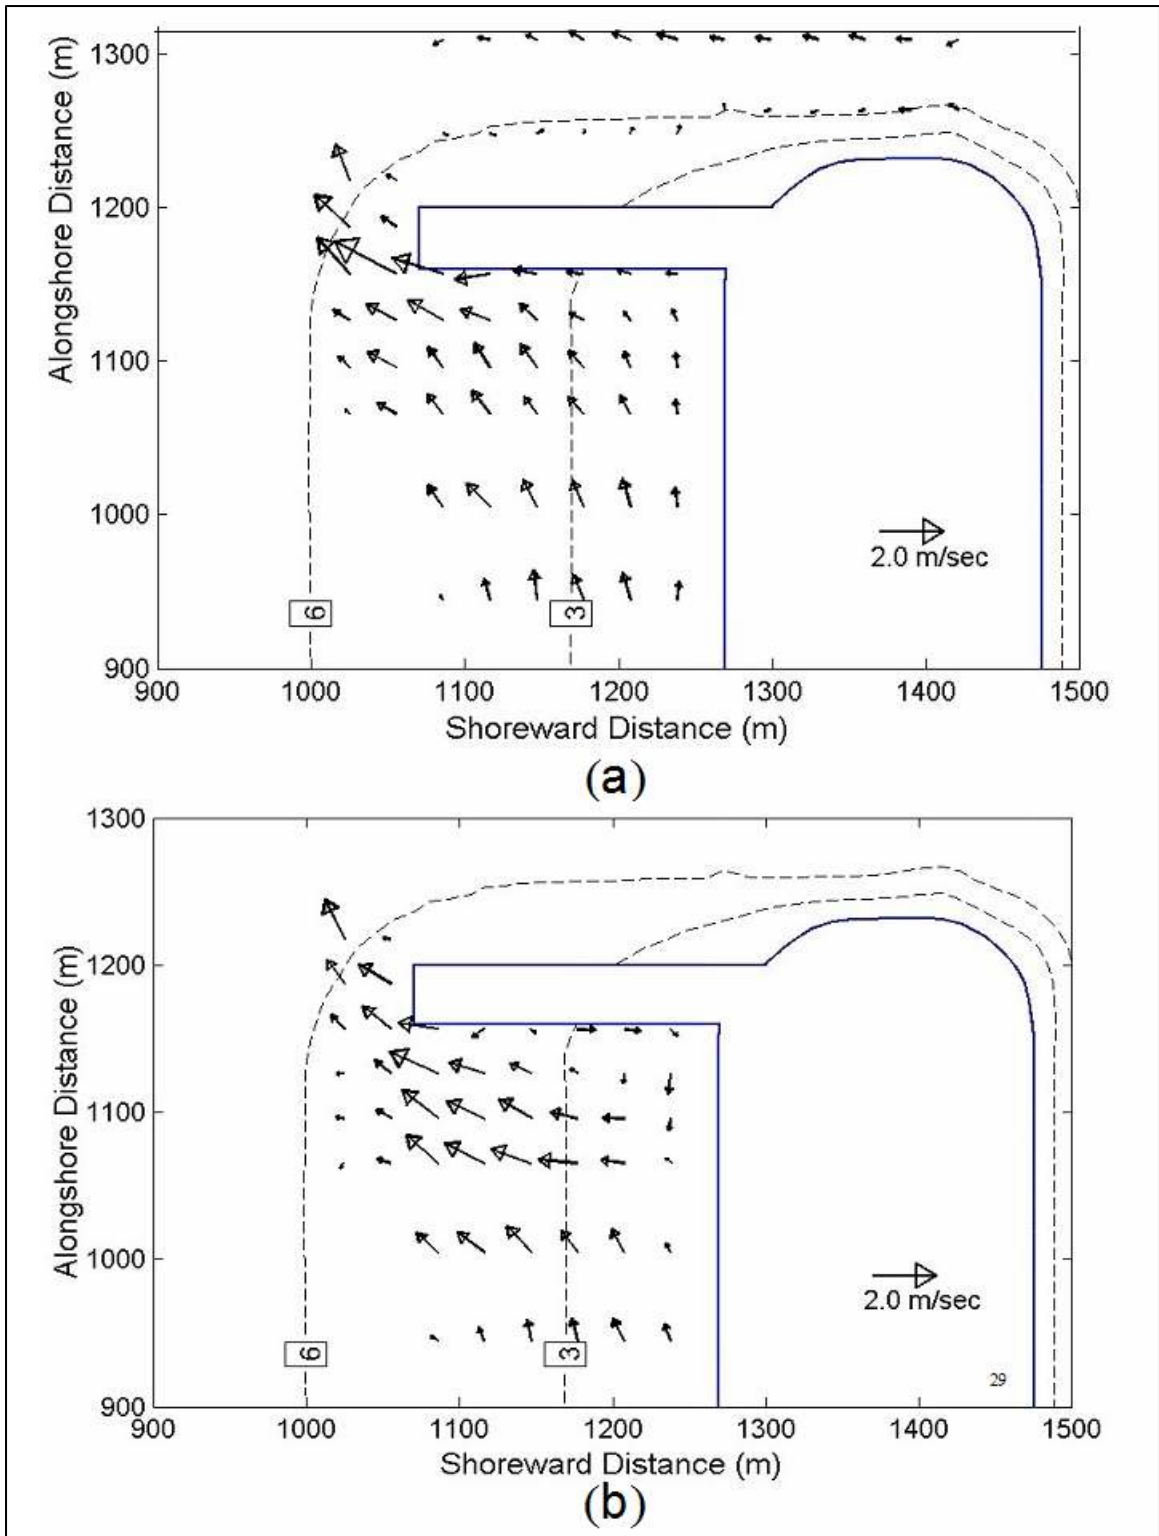

Figure 30. Comparison of (a) absorbing jetty and (b) reflecting jetty for 3.4-m, 8-sec wave

Spur Jetty Velocity Examples

The spatially dense spur jetty velocity data indicated small circulation cells between the spur segments. Plots of velocity data for the 2.0-m, 11-sec wave and the 3.4-m, 8-sec wave are shown in Figure 31. Of interest with respect to current patterns, the three-spur configuration does not produce a deflected current. The current pattern is similar to the wave-absorbing jetty, i.e., it is deflected seaward, parallel to the basic jetty alignment though there are small circulation cells formed between spurs.

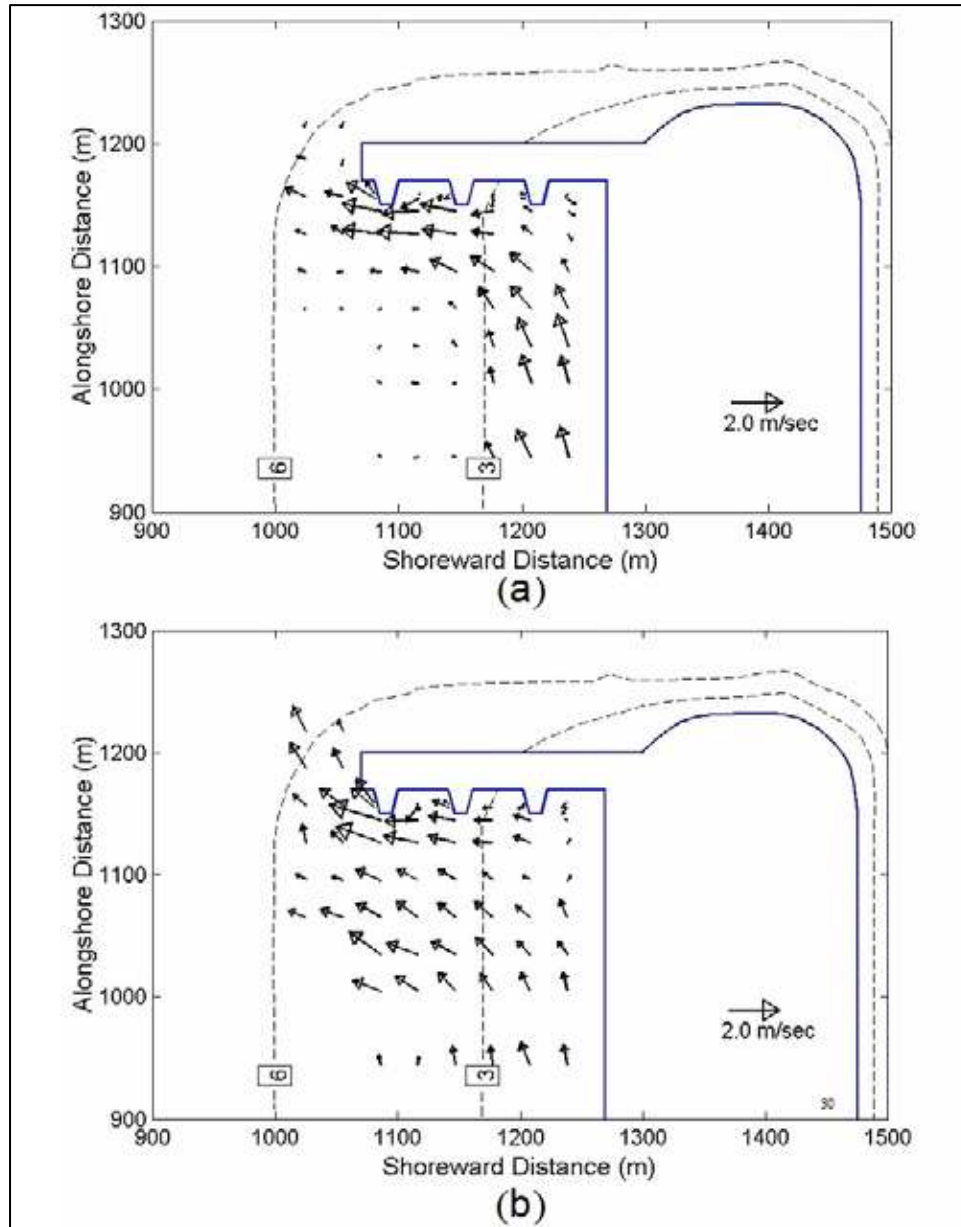

Figure 31. Spur jetty velocities for (a) 2.0-m, 11-sec wave and (b) 3.4-m, 8-sec wave

Data on CD

The CD with this report contains data on measured waves, current velocity, and bathymetry. The data are tied to a coordinate system established for a numerical model grid that is included on the CD. Figure 32 shows this bathymetry. The x-axis is aligned along shore-normal, and the y-axis is alongshore. The files on CD are ASCII format time series of water elevation collected at 20 Hz for 600 sec and tables of analyzed mean wave height and wave direction. The velocity measurements are provided in raw data files. These may be analyzed as discussed in Chapter 2. The measurements also are provided in a spreadsheet format and in summary tables. These velocities have been reduced and are in x and y component form. These measurements have not been filtered for spikes or time periods when the signal to noise level is below a certain threshold. The occurrences of spikes are rare. The coordinates of x and y velocity components of the raw velocity data are relative to the meter's coordinate system as noted in Figure 8 and discussed in Chapter 2. Current velocity data in spreadsheets and tables have been converted to the common coordinate system.

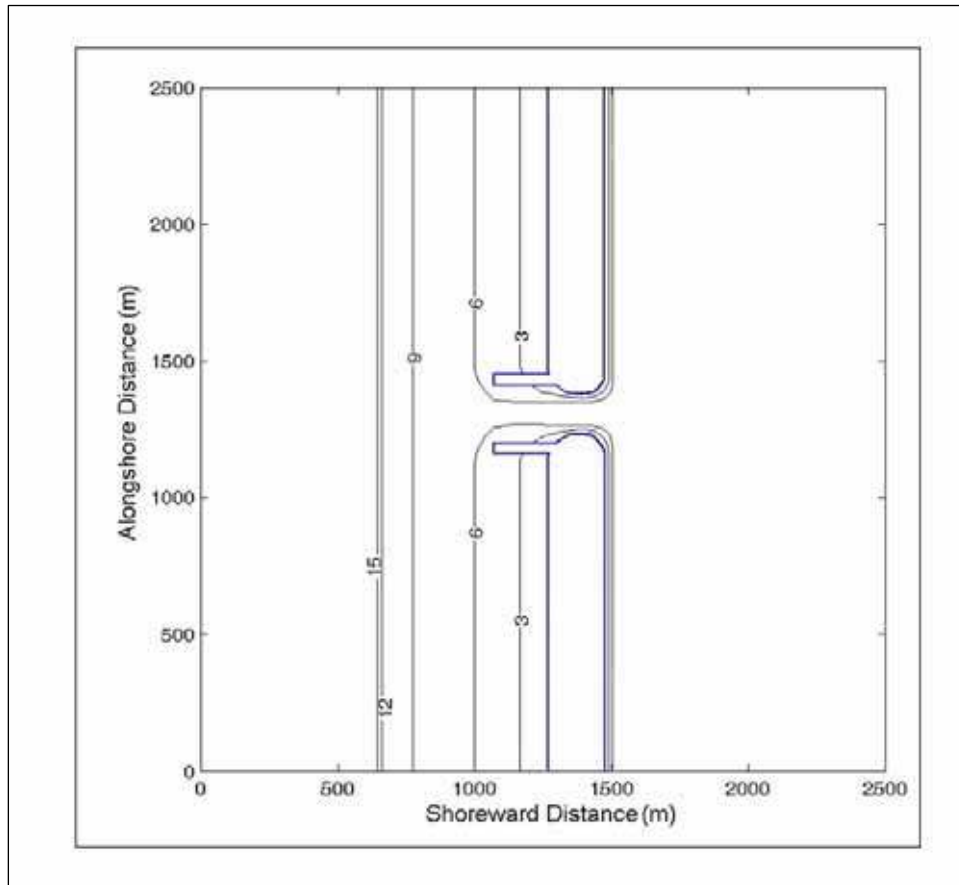

Figure 32. Contours of bathymetry in prototype meters relative to water level

The file structure of the data CD has been constructed in the following manner:

- a.* Raw data.
 - (1) Wave heights
 - (2) Current velocities
- b.* Analyzed data.
 - (1) Wave heights
 - (2) Wave direction (from velocity data)
 - (3) Current velocities
- c.* Gauge location coordinates.
- d.* Summary tables of wave height and interpolated wave direction at the location of wave height measurement.
- e.* Summary tables of velocity, wave direction, and interpolated wave height at the location of velocity measurement.

Items *c*, *d*, and *e* in the above list are presented in Appendices A through C, respectively. A help text file is included on the CD.

5 Conclusions

Water-level fluctuation, wave-height variation, wave direction, and velocity data were collected at numerous locations for situations typical of jetties at coastal inlets. The primary region of measurements was upcoast of a jettied inlet. In this region, the longshore current is deflected seaward by the jetty system. The main objective in this study was to supply laboratory data sets for numerical modeling that contain wave height and current information near an inlet where waves are breaking, which generate currents that interact with waves and jetties and cause circulation and sedimentation. The data obtained in this study may be used in the development of numerical models that simulate field conditions.

The measurements were made at an idealized inlet with smooth contours. Wave height and velocity measurements were made both upcoast of a jetty protecting the inlet and between two parallel jetties on both sides of an inlet. Measurements were performed for a number of wave conditions representative of tidal inlets. Three inlet/jetty configurations were examined:

- a.* An inlet protected by absorbing jetty perpendicular to the beach. The absorbing jetty was composed of a material that minimized reflection of wave energy.
- b.* An inlet that had a jetty with reflective face along the beach side. The jetty in this case was fully reflective of incident wave energy.
- c.* A spur jetty with three short spurs, equally spaced along the jetty length.

Differences in the response of the wave-generated currents for the reflected versus the wave absorbing jetties were observed. The composition of the jetty was designed to portray the extremes of an inlet jetty – a jetty that fully reflects the incident waves toward the upcoast shoreline adjacent to the jetty, and an almost fully absorbing jetty, which reflects very little energy. These two extreme jetty structures created different circulation patterns. The nearly fully absorbing jetty configuration permitted the wave-generated longshore current to approach the jetty and essentially be deflected seaward 90 deg along the jetty. The waves fully reflecting from the jetty created a clockwise circulation cell, starting at the mid-section of jetty and reaching the shoreline. This cell was large enough to deflect the offshore movement of the longshore current a distance of approximately one wavelength upcoast. This was significantly different from the circulation for the absorbing jetty, where flow approached the base of the jetty before deflecting seaward. The spur jetty setup had small circulation cells between spurs. However, the cells did not deflect the longshore current, as the main body of the current deflected seaward parallel to the jetty.

Appendix A

Gauge Layouts and Locations

The orientation of the x-y coordinate system is shown in Figure A1. The origin is actually located beyond the figure's upper left corner. The gauge locations are shown in Figures A2 to A9. The x-y-z coordinates for each gauge follow in Tables A1 to A5. The physical model was operated at the +1.5 m (+5.0 ft) mhw water level (prototype (1:50 scale)). The figure below shows the origin with the positive x-axis running vertically down from the point located in the upper left corner, and the y-axis running horizontally, parallel to the shore.

Appendix B

Wave Height Data Tables

Tables of the analyzed wave height and interpolated wave direction are included in this appendix (Tables B1-B15). These data also are included in the accompanying CD, where the time series data also are provided. The interpolated value of the wave direction is the value of wave direction from the surrounding velocity gauge locations because velocity and wave height gauges were not usually collocated. At some locations an interpolated wave direction value is not provided when there is no velocity gauge nearby, or if there was a problem with the velocity data. The channel 1 gauge is located near the wave generator in an area of constant depth and the wave direction represents the incident wave direction (20 deg). Tables of the analyzed velocities and direction are included in Appendix C. These data are also included in the accompanying CD, where the time series data may also be found.

Appendix C

Velocity Data Tables

Tables of the analyzed velocity and wave height and direction are included in this appendix (Tables C1-C14). These data also are included in the accompanying CD, where the time series data also may be found. Additionally, the tables include an interpolated value of the wave height at the velocity gauge location, as velocity and wave height gauges are not usually collocated.

Table C1

OMB No. 0704-0188

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. **PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.**

14. ABSTRACT <p>This physical model study of absorbing and reflecting jetties at coastal inlets was conducted to provide data sets that would aid in the calibration and verification of numerical wave models. The study was performed in the Coastal Inlet Research Program's (CIRP) idealized inlet experimental basin at the U.S. Army Engineer Research and Development Center (ERDC), Coastal and Hydraulics Laboratory (CHL), Vicksburg, MS. Safe navigation, sediment transport into navigation channels, and shoreline erosion are all concerns at coastal inlets and are related to the transformation of waves as they change direction and height due to complex bathymetry and coastal inlet structures. The idealized inlet physical model, created for inlet studies, provided a facility in which to make wave measurements of height and direction and the associated wave-generated currents in enough detail to document the wave height and current variation in a region with complex interactions. Measurements of wave information included use of wave rods for wave height and acoustic Doppler velocity sensors for wave direction and current. Qualitative dye photographs and videos were also obtained.</p> <p>Wave height and velocity measurements were collected both upcoast of the jetty and between parallel jetties for a number of waves representative of tidal inlets. The composition of the jetty was designed to portray the extremes of an inlet jetty – a jetty that fully reflects the incident wave toward the upcoast shoreline adjacent to the jetty, and an almost fully absorbing jetty, which reflects</p> <p style="text-align: right;">(Continued)</p>

very little energy. These two extreme conditions created two different circulation patterns associated with each jetty condition. The nearly fully absorbing jetty setup permitted the wave-generated longshore current to approach the jetty and essentially be deflected seaward ninety degrees, along the jetty. The waves fully reflecting from the jetty created a clockwise circulation cell at the intersection of the jetty and the shoreline. This cell was large enough to deflect the offshore movement of littoral currents a significant distance upcoast rather than approaching the base of the jetty before deflecting seaward as for the absorbing jetty setup.
