# LENGTH-WEIGHT RELATIONSHIPS, AGE COMPOSITION, GROWTH, AND CONDITION FACTORS OF CARP IN LAKE CARL BLACKWELL 

Paul E. Mauck and Robert C. Summerfolt<br>Oklahoma Cooperative Fishery Unit¹, Oklahoma State University, Stillwater, Oklahoma

#### Abstract

This report presents length-weight relationships, age composition, and condition factors for carp in Lake Carl Blackwell, Oklahoma. The study is based upon examinations of a total of 619 carp collected, chiefly by electrofishing, in 12 monthly samples from December, 1967 through November, 1968.

Carp (Cyprinus carpio Linnaeus) are ubiquitous in the lower mainstream of most major U.S. rivers and occur in all large mainstream impoundments in Oklahoma (1-4). Carp generally comprise a sizeable percentage of the standing crop of fishes in Oklahoma reservoirs. Additional knowledge of the biology of carp is needed to assess their role in the function of these ecosystems. The objective of this report is to describe aspects of growth and condition of carp in Lake Carl Blackwell.

## LAKE CARL BLACKWELL

Lake Carl Blackwell is a turbid, shallow reservoir located in north-central Oklahoma, approximately 9 miles west of Stillwater on State Highway 51C. The dam is situated in Section 3, Township 19 N, Range 1 W in Payne County. The majority of the lake lies within Payne County but a small finger extends northward into Noble County. The reservoir was formed in 1937 by damming Stillwater Creek, thus providing a water supply and a recreational area for the City of Stillwater. The reservoir first reached spillway level in 1945. The maximum surface area at spillway level is 1,486 hectares, the volume 79.9 million $\mathrm{m}^{3}(5)$.

Due to below average rainfall from 1961 through 1967, the water level of the lake receded approximately 4 meters below the spillway level at which time the surface area was 856 hectares and the volume was 33.9 million $\mathrm{m}^{3}$. Growth of young-of-theyear channel catfish showed a progressive decline between 1962 and 1968, when rain-
fall was below average (6). In the seven dry years, succession of terrestrial vegetation advanced down former beaches behind the receding water level. In the spring of 1968, the lake level rose about 1.6 meters which caused flooding of the terrestrial vegetation on the perimeter of the lake.

The main body of water in Lake Carl Blackwell lies in an east-west direction, with the deepest section being in the old stream channel near the dam and the shallowest section occurring in the west end of the lake. The north shore of the lake has gradual sloping contours forming many shallow mud flats, while the south shore has numerous rocky outcroppings and fewer mud flats. The basin of the lake is quite level except in the former channel of Stillwater Creek and its tributaries.
The low, unprotected landscape of the watershed surrounding the lake and the relatively shallow water depth permit the winds to promote vertical circulation. The intensity of the circulation varies with density differences in the water column and variations in direction and intensity of the wind. The water mass stratifies for short intervals in June, July and August, when high ambient temperature and diminished winds allow this. The wind-driven circulation, which is so prevalent, causes high turbidity, uniform vertical temperatures, and uniform dissolved oxygen levels (5).
The majority of fish in this study were collected by electrofishing in the shallow, wind-protected arms that lie to the north or south of the main east-west axis of the lake.

[^0]The water of these areas usually ranged in depth from 1 to 2 meters.

## METHODS

## Age and growth

Age and back-calculation of growth were made from scales of 262 carp collected by all methods and during all months of the study. The total length in millimeters and the weight in grams were recorded for each fish.
A plastic impression of at least three scales per fish was made with a roller press. The age determinations of the scales were made on a scale projector using a 72 mm microtessar lens which gave a total magnification of 17 X .

Fish collections
A total of 619 carp were collected in 12 monthly samples from December 1967 through November 1968. Electrofishing accounted for $89 \%$, rotenone cove samples $6 \%$, and gill netting $4 \%$ of the total collection. The remaining $1 \%$ were collected by trap nets, wire traps and barrel traps.

## RESULTS

## Length-weight relationships

Length-weight relationships were calculated for all carp collected. The relationship was first determined separately for
male and female carp, but when an analysis of covariance indicated no apparent differ ences in the length-weight regression coefficients and adjusted means for either sex. the data for both sexes were pooled.
The length-weight relationships were derived by using the formula: $W=\mathrm{cL}^{n}$, where $W=$ weight in grams; $L=$ length in milli meters; and c and n are constants. Following the conversion of lengths and weights to logarithmic form, the linear relationship was found to be: $\log W=-10.5355+2.8638$ $\log \mathrm{L}$, where $\mathrm{W}=.00002658 \mathrm{~L}^{2.8838}$. The slope of the regression line (2.8638) was less than 3.0, indicating that carp in Lake Carl Blackwell tend to become less robust with growth. Carlander (7) also reported that the regression slopes were usually less than 3.0 for carp populations sampled in Iowa, Oklahoma, and Utah.

## Coefficient of condition

Coefficients of condition (ponderal index or condition factor) expressing the relative plumpness or degree of well-being of the carp were computed using the formula: $K(T L)=\frac{W-1 D^{5}}{L^{3}}$, where $W=$ weight in grams, and $L \stackrel{1}{=}$ total length in millimeters. Seasonal changes in cocfficients of condition of 210 males and 279 females were calculated, separately and combined, for all months, except February when no males were collected (Table 1). Males and fe-

[^1]males were combined since there was no sig. nificant difference in their length-weight regression coefficients.
The average K values, with $95 \%$ confidence intervals, for males ranged between $1.10 \pm 0.15$ in November to $1.26 \pm 0.06$ in June. The average K for all months combined for males was 1.20 as compared to 1.21 for females. The ponderal index values for males fluctuated from December through August, but declined in the fall months. The average $K$ values for females ranged between $1.09 \pm .11$ in May to $1.27 \pm 0.29$ in September. Spawning occurred in April and May, but K values did not increase conspicuously in pre-spawning fish. The low $K$ value
for females in May might have been the result of a large percentage of spawned fish in the May samples.

The average K values of all (619) carp sampled (even though the sex was not known) were calculated using 20 mm size classes (Table 2). The K values generally increased to the 200 mm size class and then declined with an increase in length. However, the correlation coefficient, $\mathrm{r}=.39$, between the $K$ values and average length for size groups 200 through 616 mm (when K values decline with size) was not significant at the $5 \%$ level. A decrease in ponderal index values with increase in length was also noted by Frey (8) in Wisconsin lakes;

Shields (9) in Fort Randall Reservoir, South Dakota, Sigler (10) in Utah, and Hancock (11) in Canton Reservoir, Oklahoma. No decrease occurred in condition factors with age of comparable size carp in Grand Lake, Oklahoma (12) or in most U.S. localities (7).

The overall average K value was found to be 1.22 , similar to the K value of 1.23 calculated from lengths and weights of 351 carp sampled by Jenkins (12) in Grand Lake, Oklahoma. However, the K values of carp in Lake Carl Blackwell (Table 2) were below average compared with $K$ values reported for carp from other U. S. lakes or reservoirs as tabulated by Carlander (7).
Body-scale relationship
The body-scale relationship was determined from 262 carp ranging in length from 70 mm to 616 mm . Both linear and curvilincar regressions were computed to determine the best model describing this relationship. The mean total length and mean scalc radius was calculated for successive 20 mm length intervals of all fish begiming with 70 mm (Table 3).
The linear regression for Lake Carl Blackwell carp was found to be $\mathrm{L}=-8.484+$ 2.478 X , where $\mathrm{L}=$ total length in millimeters and $X=$ scale radius in millimeters times 17. The correlation cocfficient of the
body length-scale radius relationship was .97. The calculated $F$ value used to test linearity was 3552.6 (with 1 and 261 degrees of freedom) where $F$.oms is 7.88 (13). The reduction in variance due to curvilinearity was tested using an analysis of variance. The calculated $F$ value was 2.05 (with 1 and 260 degrees of freedom) where $F$.s is 2.71 . Therefore, the linear model was used for back-calculations in this study.

## Age and growth

Total length at time of annulus formation was back-calculated from the scales of 215 carp from Lake Carl Blackwell collected January through November 1968 (Table 4). The maximum scale radius was obtained by measuring the distance from the focus to the anterior-lateral margin. The following formula was used in back-calculating size at each scale annulus: $L+a \frac{s_{i}}{\mathbf{S}}(\mathrm{~L}-\mathrm{a})$, where $\mathrm{L}=$ total length at capture; $\mathbf{L}_{\mathbf{i}}=$ estimated length of fish at time of formation of annulus $i ; S=$ scale radius; $S_{i}=$ scale radius to each annulus; and $a=$ hypothetical length of the fish before the appearance of its scales, estimated from the intercept value of the lincar body-scale regression, according to the Lee method as cited by Chugunova (14). A mean calculated total length for each age group and year class (for males, females, and both sexes combined) was

omputed as well as an unweighted mean .tal length for all age groups for these fish. iccause differcnces between the mean annal growth increments for males and fe. Hales were small, a combined average rowth for both sexes (Table 4) was used III the following discussion.

Ricker (15) noted that few investigators have calculated the variance associated with kugth of the fish being studied. The corresponding variances of these calculated kengths were also computed (Table 5).

Often lengths of the fish in a year-class vary less when back-calculated from older as opposed to younger fish. This reduction in variability apparently results from selective mortality. Reduction in variation of lengths back-calculated from older sear-class fish was obsen ed for carp (Table 5).

Length increased at cach successive anmulus (Table 4) inclicating indefinite grow th, albeit at a progressively slower ratc. The calculated ammual growth inctement in the first summer was faster tham all other

annual increments (Table 4). Faster growth in the first year of life was also obscrved in other Oklahoma waters: Linton (4) in the Arkansas River; Buck and Cross (2) in Canton Lake; Houscr (16) in Lake Lawtonka. Carlander ( 7 ) also notes this phenomenon in other areas in the country. English (17), however, stated that carp in Clear Lake, lowa grew most rapidly in the sccond summer. The average length of voung-of-theycar carp (lable 4) in the 1065 vear class was greater than that of carp in other years. The 1965 vear class mantained this comparative adiantage as 2-and 3 vear olds compared with growth rates of fish of the same age from other year classes.
Jearld (6) reported a decrease in backcalculated length at age 1 year for channel catfish in Lake Carl Blackwell from 1961. $1 W_{6}{ }^{2}$. This reversed leces phenomenon was apparently caused by receeding water levels. fohnson (18) stated that extremely low
water levels retarded the growth of crappic in Greenwood Lake, Indiana. The prolonged drought in the Lake Carl Blackwell watershed had little noticeable retarding effects on the growth of age I carp from 1961-1967 (Table 4). However, total lengths of young-of-the-vear in September and October 1968 ranged from 144 to 156 mm which was 34 to 48 mm greater than the mean lengths of carp during the first year of life in the years from 1961 to 1967 . Either spawning or survival of carp was apparently reduced in 1966 as judged by a conspicuous scarcity of that age group (Table 4). Yearling carp ware more numerous in the summer of 1969 than 1968, suggesting that a strong ycar-class resulted from the 1.6 meter increase in avcrage water level in 1968.
The size of carp from Lake Carl Blackwell is generally smaller than that of carp of the same age from other bodics of water (Table 6). This is especially truc of the first 2-year

-All values nere given in inches and converted to millimeters from Conversion Tables, Lagler (1956) ex-
cept values bisted for Lake Carl Blachwell, Oklahoma and Clear Lake, lowa.
classes. The calculated total length for Lake Carl Blackwell carp at ammulus 1 was 108 mom and 191 at amulus 2 . The growth rate of carp in this study is much less than reported by Thompson (19) and Jenkins (12) for Grand Lake, Oklahoma. We believe that the poor growth of carp is related to a low density of benthic invertebrates ( 283 organisnis/ $\mathbf{M}^{2}$ and only 2.0 grams wet wt./ $\mathbf{M}^{2}$ in this reservoir (5) compared with other reservoirs in this region (20). It is presumed that the sparse benthos in Lake Carl Blackwell results from low transparcncy and the unstable substratc caused by strong, windinduced, vertical currents.

## SUMMARY

A total of 619 carp were collected during the sampling period from December, 1967 through November, 1968. The majority of the fish were collected by electrofishing which was cffective in capturing carp along the shoreline of the lake when the water temperature was above 8 C . Electrofishing was not cffective during winter months because carp moved into decper waters during this time.
An analysis of covariance indicated no apparent differences in the length-weight regression coefficients and adjusted means for cither sex. The lincar relationship was found to be: $\log W=-10.5355+2.8638$ $\log \mathrm{L}$, where $W=.00002658 \mathrm{~L}^{2 . \text {.snass. }}$. The slope of the regression line was less than 3.0 indicating that carp in Lake Carl Blackwell usually became less robust with increased body length.
The cocfficients of condition were calculated according to sex, month and size. No apparent difference in condition existed betwecn males and females. Monthly variations in condition of carp showed no definite scasonal trends. The average $\mathbf{K}$ values for all months combined for males was 1.20 is compared to 1.21 for females. The conlition factor increased in small carp until he 200 mm size class and then declined ith an increase in length. The average $K$ alue for 619 fish was calculated to be 1.22 .
The body-scale relationship was deteruned from 262 carp ranging in length from 0 mm to 616 mm . The linear regression
was found to be: $L=-8.484+2.478 \mathrm{X}$, with a correlation cocfficient (r) of 97.

The total length at time of annulus formation was back-calculated from the scales of 215 carp collected during January through November, 1968. A mean calculated total length for cach group and ycar class (for males, females, and combined sexes) was computed as well as an unweighted mean total length for all age groups.

No apparent differcnce in growth was obscried between males and females. The calculated growth rates show that carp grew most rapidly during their first summer of growth. A gradual reduction in mean ambual growth increment occurred with an increase in agc. Age groups III, IV and V comprised $62.8 \%$ of the total number of fish in the sample. Young-of-the-ycar and yearling fish (age group. 1) werc poorly sampled with the clectrofishing gear.

An Oklahoma average growth rate was not available for comparison, but carp in Lake Carl Blackwell grew slower than in other Oklahoma impoundments for which data werc available.

## ACKNOWLEDGEMENTS

The authors arc grateful to Dr. B. E. Brown for computer program, and to $R$. Tafancli, P. L. Zwciacker and P. R. Turner for help in collecting fish. Financial support from the 3 cooperating agencics and from Grant No. 14-17-0007.769 of the Bureau of Commercial Fishcries (PL 88-309) is gratcfully acknowledged.
