### Abstract

The range of motion and output force of the often used electrostatic comb-drive with folded flexure straight guidance, as shown in Figure 1, is limited by sideways instability due to poor sideways stiffness of the folded flexure at relatively large deflections [1]. For example at displacements larger than 20 times the leaf-springs thickness ( $t$ ), the stiffness in  $x$ -direction has decreased by several orders of magnitude, causing sideways snap-in leading to limited travel and poor output force. The individual leaf-springs of the folded flexures would have to be  $20\mu\text{m}$  thick and  $5\text{mm}$  long for a output force of at least  $100\mu\text{N}$  over a range of  $\pm 100\mu\text{m}$ . The stress due to deformation is generally not a limiting factor. We have designed,

Figure 1. The Folded flexure on the left, and the exact constraint folded flexure using a 1:2 lever and using an extra leaf-spring on the right.

modeled, fabricated and tested several Watt's and 'Exact constrained folded flexures'. The combined device area of comb-drive and suspension has been minimized given a range of motion of 200 $\mu\text{m}$ , and an output force (electrostatic force minus elastic deformation force of the guidance) of at least 100 $\mu\text{N}$  over the full range of motion using a voltage limitation of 80V. The best performing mechanism, the 'Exact constraint folded flexure', shows that, compared to the folded flexure, the total device area has been reduced by a factor of 2.8 and the output force has been increased by a factor of 1.4 as shown in Table 1.

Table 1. Comparison of several modeled elastic guidance mechanisms

	Folded flexure	Exact constraint folded flexure	Double Watt's
Range of motion	100 $\mu\text{m}$	100 $\mu\text{m}$	100 $\mu\text{m}$
Min. output force over range	100 $\mu\text{N}$	140 $\mu\text{N}$	300 $\mu\text{N}$
Area of 2 mechanisms	4.5 $\text{mm}^2$	1.2 $\text{mm}^2$	7.2 $\text{mm}^2$
Area of actuator	0.85 $\text{mm}^2$	0.63 $\text{mm}^2$	0.67 $\text{mm}^2$
Performance: $F_{max} \cdot x_{max} / A_{total}$	3.2 $\text{mN}\cdot\text{m}/\text{m}^2$	12 $\text{mN}\cdot\text{m}/\text{m}^2$	7.0 $\text{mN}\cdot\text{m}/\text{m}^2$

## 1 Cause of low Support Stiffness

The main cause of the decreased  $x$ -stiffness of a folded flexure is that at a given  $y$ -displacement of the shuttle, a load in the  $x$ -direction on the shuttle will influence the  $y$ -position of the intermediate body. This geometric coupling to the flexure's bending compliance leads to reduced  $x$ -stiffness. This problem is solved by constraining the intermediate body to half the displacement of the shuttle [2] by a 1:2 lever (Figure 1). The mechanism design has been modeled with an elastic multibody software program [3]. A clear improvement is shown in Figure 2. Further improvements are reinforcing the leaf-springs over 5/7<sup>th</sup> of their lengths [2], and constraining the 1:2 lever in the  $x$ -direction by adding an extra leaf-spring in the  $x$ -direction. For comparison the performance is calculated by multiplying the maximum output force (just before pull-in, and at maximum stroke) by the maximum stroke, divided by the occupied area of the total mechanism and comb-drive as shown in Table 1. Figure 3a shows the performance of an 'Exact constrained folded flexure' as a function of several design variations.

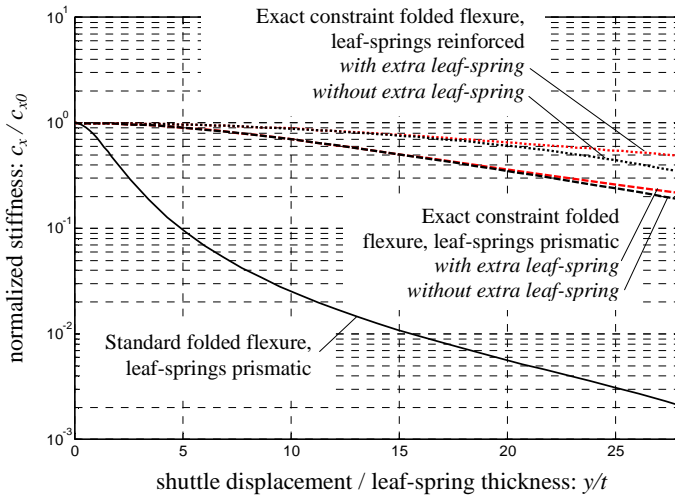

Figure 2. Axial stiffness reduction at deflection of several modeled design variations of the ‘Exact constraint folded flexure’ and a standard folded flexure as a reference, where the shuttle is constraint in the y-direction.

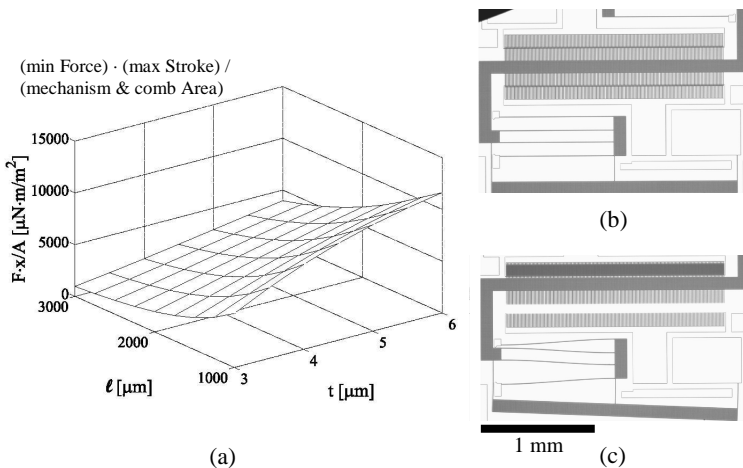

Figure 3. (a) Performance of the ‘Exact constraint folded flexure’ for varying thickness ( $t$ ) and length ( $l$ ) of the flexures. The leaf-springs are prismatic and no extra flexure is incorporated. (b) Microscope pictures of the undeflected and (c) 100 $\mu$ m deflected ‘Exact constraint folded flexure’.

## 2 Measurement and Fabrication

The devices are fabricated in a SOI wafer, by DRIE and vapor HF release etching. Figures 3b, 3c and 4 show microscope pictures of the fabricated devices in neutral and at 100 $\mu$ m deflected position. For both mechanisms the first Eigenfrequencies, calculated and measured, are shown in Table 2. The difference between the measured and calculated values is mainly caused by leaf-spring thickness variation due to etching. It is currently subject of improvement. Voltage–displacement measurements showed that in accordance to the models the long strokes did not lead to pull-in.

Figure 4. Microscope pictures of the undeflected and 100 $\mu$ m deflected Watt's mechanism.

Table 2. Measured and simulated first Eigenfrequencies

	Measured [Hz]	Calculated [Hz]	Error
Exact constraint folded flexure	401	462	15%
Watt's mechanism	551	498	-10%

## Conclusion

When using a long range of motion, the 'Exact constraint folded flexure', outperforms the folded flexure; given a range of motion of 200 $\mu$ m the total device area has been reduced by a factor of 2.8 and the output force has been increased by a factor of 1.4.
