Machine and deep learning for sport-specific movement recognition: a systematic review of model development and performance --Manuscript Draft--

Full Title:	Machine and deep learning for sport-specific movement recognition: a systematic review of model development and performance
Manuscript Number:	RJSP-2018-0332R2
Article Type:	Original Manuscript
Keywords:	Sport movement classification; inertial sensors; computer vision; Machine learning; performance analysis.
Abstract:	<p>Objective assessment of an athlete's performance is of importance in elite sports to facilitate detailed analysis. The implementation of automated detection and recognition of sport-specific movements overcomes the limitations associated with manual performance analysis methods. The object of this study was to systematically review the literature on machine and deep learning for sport-specific movement recognition using inertial measurement unit (IMU) and, or computer vision data inputs. A search of multiple databases was undertaken. Included studies must have investigated a sport-specific movement and analysed via machine or deep learning methods for model development. A total of 52 studies met the inclusion and exclusion criteria. Data pre-processing, processing, model development and evaluation methods varied across the studies. Model development for movement recognition were predominantly undertaken using supervised classification approaches. A kernel form of the Support Vector Machine algorithm was used in 53% of IMU and 50% of vision-based studies. Twelve studies used a deep learning method as a form of Convolutional Neural Network algorithm and one study also adopted a Long Short Term Memory architecture in their model. The adaptation of experimental set-up, data pre-processing, and model development methods are best considered in relation to the characteristics of the targeted sports movement(s).</p>
Order of Authors:	Emily Elizabeth Cust Alice J Sweeting Kevin Ball Sam Robertson
Response to Reviewers:	<p>The authorship team have read and responded to the comments of reviewer #3. The red coloured text in the revised manuscript highlights the new alterations and additions.</p> <p>Reviewer #1: The authors replied to my previous comments in a satisfactory way, then, I would approve the publication of this systematic review. Author's response: The authorship team thank Reviewer #1 for their previous constructive comments.</p> <p>Reviewer #3: I think two important datasets are missing here. oThe Volleyball dataset proposed by [1]. This dataset is for group activity recognition in sport footage. I think most of the team sport datasets contains multiple people, so group activity recognition is an important task in the team sport analysis. oNCAA Basketball dataset, this is a multi-person action video dataset in team sport context. [5] Author's response: We thank the reviewer for alerting us to these two papers. Given that they meet the requirements for inclusion, both these articles have now been included in the review. Tables 4, 7, 8 have been amended to include the relevant information. Also, these articles have been cited in the discussion section on lines 543 - 545. The Prisma flow diagram (Figure 1) has been updated and the study result numbers throughout this review have also been updated to reflect the additional articles.</p> <p>Reviewer #3:</p>

One resource is missed here, MIT SLOAN SPORTS ANALYTICS Conference [2] is a one important source for recent works on sport analytics.

Author's response:

The papers mentioned by the reviewer did not meet the whole inclusion and exclusion criteria for this review paper.

Reviewer #3:

Table 2 shows the inclusion and exclusion criteria for the search. In the Exclusion criteria, it has been mentioned that works with this condition are excluded:

"Solely investigated player field positional tracking methods using data such as X, Y coordinates or displacement without any form of sport-specific skill detection and classification associated to it" and "Used ball trajectory and audio cue data as the major determinant for event detection".

I don't understand why these works are excluded. I think that trajectories (Players X,Y coordinates) are a valuable source for activity recognition.[3][4]

Author's response:

The papers mentioned by the reviewer did not meet the whole inclusion and exclusion criteria for this review paper.

Reviewer #3:

Missing reference: [6]

Author's response:

This article has now been included in the review. Tables 4, 7, 8 have been amended to include the relevant information. Also, this article has been cited in the discussion section on lines 543 -545. The Prisma flow diagram (Figure 1) has been updated and the study result numbers throughout this review have also been updated to reflect the additional article.

43 Objective assessment of an athlete’s performance is of importance in elite sports to facilitate
44 detailed analysis. The implementation of automated detection and recognition of sport-specific
45 movements overcomes the limitations associated with manual performance analysis methods. The
46 object of this study was to systematically review the literature on machine and deep learning for
47 sport-specific movement recognition using inertial measurement unit (IMU) and, or computer
48 vision data inputs. A search of multiple databases was undertaken. Included studies must have
49 investigated a sport-specific movement and analysed via machine or deep learning methods for
50 model development. A total of 52 studies met the inclusion and exclusion criteria. Data pre-
51 processing, processing, model development and evaluation methods varied across the studies.
52 Model development for movement recognition were predominantly undertaken using supervised
53 classification approaches. A kernel form of the Support Vector Machine algorithm was used in
54 53% of IMU and 50% of vision-based studies. Twelve studies used a deep learning method as a
55 form of Convolutional Neural Network algorithm and one study also adopted a Long Short Term
56 Memory architecture in their model. The adaptation of experimental set-up, data pre-processing,
57 and model development methods are best considered in relation to the characteristics of the
58 targeted sports movement(s).

62 Sport movement classification; inertial sensors; computer vision; machine learning; performance
63 analysis.

65 1. Introduction

66

67 Performance analysis in sport science has experienced considerable recent changes, due largely to
68 access to improved technology and increased applications from computer science. Manual
69 notational analysis or coding in sports, even when performed by trained analysts, has limitations.
70 Such methods are typically time intensive, subjective in nature, and prone to human error and bias.
71 Automating sport movement recognition and its application towards coding has the potential to
72 enhance both the efficiency and accuracy of sport performance analysis. The potential automation
73 of recognising human movements, commonly referred to as human activity recognition (HAR), can
74 be achieved through machine or deep learning model approaches. Common data inputs are
75 obtained from inertial measurement units (IMUs) or vision. Detection refers to the identification of
76 a targeted instance, i.e., tennis strokes within a continuous data input signal (Bulling, Blanke, &
77 Schiele, 2014). Recognition or classification of movements involves further interpretations and
78 labelled predictions of the identified instance (Bulling et al., 2014; Bux, Angelov, & Habib, 2017),
79 i.e., differentiating tennis strokes as a forehand or backhand. In machine and deep learning, a
80 model represents the statistical operations involved in the development of an automated prediction
81 task (LeCun, Yoshua, & Geoffrey, 2015; Shalev-Shwartz & Ben-David, 2014).

82 Human activities detected by inertial sensing devices and computer vision are represented
83 as wave signal features corresponding to specific actions, which can be logged and extracted.
84 Human movement activities are considered hierarchically structured and can be broken down to
85 basic movements. Therefore, the context of signal use, intra-class variability, and inter-class
86 similarity between activities require consideration during experimental set-up and model
87 development. Wearable IMUs contain a combination of accelerometer, gyroscope, and
88 magnetometer sensors measuring along one to three axes. These sensors quantify acceleration,
89 angular velocity, and the direction and orientation of travel respectively (Gastin, McLean, Breed, &
90 Spittle, 2014). These sensors can capture repeated movement patterns during sport training and
91 competitions (Camomilla, Bergamini, Fantozzi, & Vannozzi, 2018; Chambers, Gabbett, Cole, &
92 Beard, 2015; J. F. Wagner, 2018). Advantages include being wireless, lightweight and self-
93 contained in operation. Inertial measurement units have been utilised in quantifying physical output

94 and tackling impacts in Australian Rules football (Gastin et al., 2014; Gastin, McLean, Spittle, &
95 Breed, 2013) and rugby (Gabbett, Jenkins, & Abernethy, 2012, 2011; Howe, Aughey, Hopkins,
96 Stewart, & Cavanagh, 2017; Hulin, Gabbett, Johnston, & Jenkins, 2017). Other applications
97 include swimming analysis (Mooney, Corley, Godfrey, Quinlan, & ÓLaighin, 2015), golf swing
98 kinematics (Lai, Hetchl, Wei, Ball, & McLaughlin, 2011), over-ground running speeds (Wixted,
99 Billing, & James, 2010), full motions in alpine skiing (Yu et al., 2016); and the detection and
100 evaluation of cricket bowling (McNamara, Gabbett, Blanch, & Kelly, 2017; McNamara, Gabbett,
101 Chapman, Naughton, & Farhart, 2015; Wixted, Portus, Spratford, & James, 2011).

102 Computer vision has applications for performance analysis including player tracking,
103 semantic analysis, and movement analysis (Stein et al., 2018; Thomas, Gade, Moeslund, Carr, &
104 Hilton, 2017). Automated movement recognition approaches require several pre-processing steps
105 including athlete detection and tracking, temporal cropping and targeted action recognition, which
106 are dependent upon the sport and footage type (Barris & Button, 2008; Saba & Altameem, 2013;
107 Thomas et al., 2017). Several challenges including occlusion, viewpoint variations, and
108 environmental conditions may impact results, depending on the camera set-up (Poppe, 2010; Zhang
109 et al., 2017). Developing models to automate sports-vision coding may improve resource efficiency
110 and reduce feedback times. For example, coaches and athletes involved in time-intensive notational
111 tasks, including post-swim race analysis, may benefit from rapid objective feedback before the next
112 race in the event program (Liao, Liao, & Liu, 2003; Victor, He, Morgan, & Miniutti, 2017). For
113 detecting and recognising movements, body worn sensor signals do not suffer from the same
114 environmental constraints and stationary set-up of video cameras. Furthermore, multiple sensors
115 located on different body segments have been argued to provide more specific signal
116 representations of targeted movements (J. B. Yang, Nguyen, San, Li, & Shonali, 2015). But it is
117 not clear if this is solely conclusive, and the use of body worn sensors in some sport competitions
118 may be impractical or not possible.

119 Machine learning algorithms learn from data input for automated model building and
120 perform tasks without being explicitly programmed. The algorithm goal is to output a response
121 function $\overline{f_{\sigma}(\bar{x})}$ that will predict a ground truth variable \bar{y} from an input vector of variables \bar{x} . Models
122 are run for classification techniques to predict a target class (Kotsiantis, Zaharakis, & Pintelas,
123 2007), or regression to predict discrete or continuous values. Models are aimed at finding an

124 optimal set of parameters $\bar{\varphi}$ to describe the response function, and then make predictions on unseen
125 unlabelled data input. Within these, model training approaches can generally run as supervised
126 learning, unsupervised learning or semi-supervised learning (Mohammed, Khan, & Bashier, 2016;
127 Sze, Chen, Yang, & Emer, 2017).

128 Processing raw data is limited for conventional machine learning algorithms, as they are
129 unable to effectively be trained on abstract and high-dimensional data that is inconsistent, contains
130 missing values or noisy artefacts (Bux et al., 2017; Kautz, 2017). Consequently, several pre-
131 processing stages are required to create a suitable data form for input into the classifier algorithm
132 (Figo, Diniz, Ferreira, & Cardoso, 2010). Filtering (Figo et al., 2010; Wundersitz, Gastin,
133 Robertson, Davey, & Netto, 2015), window capture durations (Mitchell, Monaghan, & O'Connor,
134 2013; Preece, Goulermas, Kenney, & Howard, 2009; Wundersitz, Josman, et al., 2015), and signal
135 frequency cut-offs (Wundersitz, Gastin, Richter, Robertson, & Netto, 2015; Wundersitz, Gastin,
136 Robertson, et al., 2015) are common techniques applied prior to data prior to dynamic human
137 movement recognition. Well-established filters for processing motion signal data include the
138 Kalman filter (Kautz, 2017; Titterton & Weston, 2009; D. Wagner, Kalischewski, Velten, &
139 Kummert, 2017) and a Fourier transform filter (Preece, Goulermas, Kenney, Howard, et al., 2009)
140 such as a fast Fourier transform (Kapela, Świetlicka, Rybarczyk, Kolanowski, & O'Connor, 2015;
141 Preece, Goulermas, Kenney, & Howard, 2009). Near real-time processing benefits from reducing
142 memory requirements, computational demands, and essential bandwidth during whole model
143 implementation. Signal feature extraction and selection favours faster processing by reducing the
144 signals to the critical features that can discriminate the targeted activities (Bulling et al., 2014).
145 Feature extraction involves identifying the key features that help maximise classifier success, and
146 removing features that have minimal impact in the model (Mannini & Sabatini, 2010). Thus,
147 feature selection involves constructing data representations in subspaces with reduced dimensions.
148 These identified variables are represented in a compact feature variable (Mannini & Sabatini,
149 2010). Common methods include principal component analysis (PCA) (Gløersen, Myklebust,
150 Hallén, & Federolf, 2018; Young & Reinkensmeyer, 2014), vector coding techniques (Hafer &
151 Boyer, 2017) and empirical cumulative distribution functions (ECDF) (Plötz, Hammerla, &
152 Olivier, 2011). An ECDF approach has been shown to be advantageous over PCA as it derives
153 representations of raw input independent of the absolute data ranges, whereas PCA is known to

154 have reduced performance when the input data is not properly normalised (Plötz et al., 2011). For
155 further detailed information on the acquisition, filtering and analysis of IMU data for sports
156 application and vision-based human activity recognition, see (Kautz, 2017) and (Bux et al., 2017),
157 respectively.

158 Deep learning is a division of machine learning, characterised by deeper neural network
159 model architectures and are inspired by the biological neural networks of the human brain (Bengio,
160 2013; LeCun et al., 2015; Sze et al., 2017). The deeper hierarchical models create a profound
161 architecture of multiple hidden layers based on representative learning with several processing and
162 abstraction layers (Bux et al., 2017; J. B. Yang et al., 2015). These computational models allow
163 data input features to be automatically extracted from raw data and transformed to handle
164 unstructured data, including vision (LeCun et al., 2015; Ravi, Wong, Lo, & Yang, 2016). This
165 direct input avoids several processing steps required in machine learning during training and
166 testing, therefore reducing overall computational times. A current key element within deep learning
167 is backpropagation (Hecht-Nielsen, 1989; LeCun, Bottou, Orr, & Müller, 1998). Backpropagation
168 is a fast and computationally efficient algorithm, using gradient descent, that allows training deep
169 neural networks to be tractable (Sze et al., 2017). Human activity recognition has mainly been
170 performed using conventional machine learning classifiers. Recently, deep learning techniques
171 have enhanced the bench mark and applications for IMUs (Kautz et al., 2017; Ravi et al., 2016;
172 Ronao & Cho, 2016; J. B. Yang et al., 2015; Zebin, Scully, & Ozanyan, 2016; Zeng et al., 2014)
173 and vision (Ji, Yang, Yu, & Xu, 2013; Karpathy et al., 2014a; Krizhevsky, Sutskever, & Hinton,
174 2012; Nibali, He, Morgan, & Greenwood, 2017) in human movement recognition producing more
175 superior model performance accuracy.

176 The objective of this study was to systematically review the literature investigating sport-
177 specific automated movement detection and recognition. The review focusses on the various
178 technologies, analysis techniques and performance outcome measures utilised. There are several
179 reviews within this field that are sensor-based including wearable IMUs for lower limb
180 biomechanics and exercises (Fong & Chan, 2010; M. O'Reilly, Caulfield, Ward, Johnston, &
181 Doherty, 2018), swimming analysis (Magalhaes, Vannozzi, Gatta, & Fantozzi, 2015; Mooney et
182 al., 2015), quantifying sporting movements (Chambers et al., 2015) and physical activity
183 monitoring (C. C. Yang & Hsu, 2010). A recent systematic review has provided an evaluation on

184 the in-field use of inertial-based sensors for various performance evaluation applications
185 (Camomilla et al., 2018). Vision-based methods for human activity recognition (Aggarwal & Xia,
186 2014; Bux et al., 2017; Ke et al., 2013; Zhang et al., 2017), semantic human activity recognition
187 (Ziaeefard & Bergevin, 2015) and motion analysis in sport (Barris & Button, 2008) have also been
188 reviewed. However, to date, there is no systematic review across sport-specific movement
189 detection and recognition via machine or deep learning. Specifically, incorporating IMUs and
190 vision-based data input, focussing on in-field applications as opposed to laboratory-based protocols
191 and detailing the analysis and machine learning methods used.

192 Considering the growth in research and potential field applications, such a review is
193 required to understand the research area. This review aims to characterise the evolving techniques
194 and inform researchers of possible improvements in sports analysis applications. Specifically: 1)
195 What is the current scope for IMUs and computer vision in sport movement detection and
196 recognition? 2) Which methodologies, inclusive of signal processing and model learning
197 techniques, have been used to achieve sport movement recognition? 3) Which evaluation methods
198 have been used in assessing the performance of these developed models?

199

200 **2. Methods**

201

202 **2.1 Search strategy**

203 The preferred PRISMA recommendations (Moher, Liberati, Tetzlaff, Altman, & Group, 2009) for
204 systematic reviews were used. A literature search was undertaken by the first author on the
205 following databases; IEEE Xplore, PubMed, ScienceDirect, Scopus, Academic Search Premier,
206 and Computer and Applied Science Complete. The searched terms were categorised in order to
207 define the specific participants, methodology and evaluated outcome measure in-line with the
208 review aims. Searches used a combination of key words with AND/OR phrases which are detailed
209 in Table 1. Searches were filtered for studies from January 2000 to May 2018 as no relevant studies
210 were identified prior to this. Further studies were manually identified from the bibliographies of
211 database-searched studies identified from the abstract screen phase, known as snowballing. Table 2
212 provides the inclusion and exclusion criteria of this review.

213

214 *****Table 1 near here: Key word search term strings per database *****

215

216 *****Table 2 near here: Inclusion and exclusion criteria*****

217

218 **2.2 Data extraction**

219 The first author extracted and collated the relevant information from the full manuscripts identified
220 for final review. A total of 18 parameters were extracted from the 52 research studies, including the
221 title, author, year of publication, sport, participant details, sport movement target(s), device
222 specifications, device sample frequency, pre-processing methods, processing methods, feature
223 selected, feature extraction, machine learning model used, model evaluation, model performance
224 accuracy, validation method, samples collected, and computational information. A customised
225 Microsoft Excel™ spreadsheet was developed to categorise the relevant extracted information from
226 each study. Participant characteristics of number of participants, gender, and competition level,
227 then if applicable a further descriptor specific to a sport, for example, ‘medium-paced cricket
228 bowler’. Athlete and participant experience level was categorised as written in the corresponding
229 study to avoid misrepresentations. The age of participants was not considered an important
230 characteristic required for model development. The individual ability in which the movement is
231 performed accounts for the discriminative signal features associated with the movements. For the
232 purposes of this review, a sport-specific movement was defined from a team or individual sport,
233 and training activities associated with a particular sport. For example, weight-lifting as strength
234 training, recognised under the Global Association of International Sports Federations. The targeted
235 sports and specific movements were defined for either detection or recognition. Model
236 development techniques used included pre-processing methods to transform data to a more suitable
237 form for analysis, processing stages to segment data for identified target activities, feature
238 extraction and selections techniques, and the learning algorithm(s). Model evaluation measures
239 extracted were the model performance assessment techniques used, ground-truth validation
240 comparison, number of data samples collected, and the model performance outcomes results
241 reported. If studies ran multiple experiments using several algorithms, only the superior algorithm
242 and relevant results were reported as the best method. This was done so in the interest of concise
243 reporting to highlight favourable method approaches (Sprager & Juric, 2015). Any further relevant

244 results or information identified from the studies was included as a special remark (Sprager &
245 Juric, 2015). Hardware and specification information extracted included the IMU or video
246 equipment used, number of units, attachment of sensors (IMUs), sample frequency, and sensor data
247 types used in analysis (IMUs). Studies identified and full data extracted were reviewed by a second
248 author.

250 **3. Results**

251
252 An outline of the search results and study exclusions has been provided in Fig 1. Of the initial
253 database search which identified 4885 results, a final 52 studies met criteria for inclusion in this
254 review. Of these, 29 used IMUs and 22 were vision-based. One study (Ó Conaire et al., 2010) used
255 both sensors and vision for model development separately then together via data fusion. Tables 3 -
256 8 provide a description of the characteristics of the reviewed studies, detailed in the following
257 sections.

259 ***** Fig 1 near here: PRISMA flow diagram *****

261 **3.1 Experimental design**

262 A variety of sports and their associated sport-specific movements were investigated, implementing
263 various experimental designs as presented in Tables 5 and 7. Across the studies, sports reported
264 were tennis (n = 10), cricket (n = 3), weightlifting or strength training (n = 6), swimming (n = 4),
265 skateboarding (n = 2), ski jumping (n = 2), snowboarding (n = 1), golf (n = 4), volleyball (n = 2),
266 rugby (n = 2), ice hockey (n = 2), gymnastics (n = 2), karate (n = 1), basketball (n = 3), Gaelic
267 football (n = 1), hurling (n = 1), boxing (n = 2), running (n = 2), diving (n = 1), squash (n = 1),
268 badminton (n = 1), cross-country skiing (n = 2) and soccer (n = 4). The Sports 1-M dataset
269 (Karpathy et al., 2014b) was also reported, which consists of 1,133,158 video URLs annotated
270 automatically with 487 sport labels using the YouTube Topic API. A dominant approach was the
271 classification of main characterising actions for each sport. For example, serve, forehand, backhand
272 strokes in tennis (Connaghan et al., 2011; Kos & Kramberger, 2017; Ó Conaire et al., 2010; Shah,
273 Chokalingam, Paluri, & Pradeep, 2007; Srivastava et al., 2015), and the four competition strokes in

274 swimming (Jensen, Blank, Kugler, & Eskofier, 2016; Jensen, Prade, & Eskofier, 2013; Liao et al.,
275 2003; Victor et al., 2017). Several studies further classified sub-categories of actions. For example,
276 three further classes of the two main classified snowboarding trick types Grinds and Airs (Groh,
277 Fleckenstein, & Eskofier, 2016), and further classifying the main tennis stroke types as either flat,
278 topspin or slice (Srivastava et al., 2015). Semantic descriptors were reported for classification
279 models that predicted athlete training background, experience and fatigue level. These included
280 running (Buckley et al., 2017; Kobsar, Osis, Hettinga, & Ferber, 2014), rating of gymnastic
281 routines (Reily, Zhang, & Hoff, 2017), soccer pass classification based on its quality (Horton,
282 Gudmundsson, Chawla, & Estephan, 2014), cricket bowling legality (Qaisar et al., 2013; Salman,
283 Qaisar, & Qamar, 2017), ski jump error analysis (Brock & Ohgi, 2017; Brock, Ohgi, & Lee, 2017)
284 and strength training technique deviations (M. A. O'Reilly, Whelan, Ward, Delahunt, & Caulfield,
285 2017a; M. O'Reilly et al., 2015; M. O'Reilly, Whelan, Ward, Delahunt, & Caulfield, 2017). One
286 approach (Yao & Fei-Fei, 2010), encoded the mutual context of human pose and sporting
287 equipment using semantics, to facilitate the detection and classification of movements including a
288 cricket bat and batsman coupled movements.

289 Total participant numbers for IMU-based studies ranged from one (Qaisar et al., 2013) to
290 30 (Kautz et al., 2017). Reported data individual instance sample sizes for sensor studies ranged
291 from 150 (Salman et al., 2017) to 416, 737 (Rassem, El-Beltagy, & Saleh, 2017). Vision-based
292 studies that explicitly reported total participant details ranged from five (Ó Conaire et al., 2010) to
293 40 (Victor et al., 2017). Vision dataset sample sizes varied across studies, from 50 individual action
294 clips (Liao et al., 2003) to 15, 000 (Victor et al., 2017). One study (Karpathy et al., 2014a) used the
295 publicly available Sports-1M, as previously described. Vision-based studies also reported datasets
296 in total time, 10.3 hours (Bertasius, Park, Yu, & Shi, 2017), 3 hours (Montoliu, Martín-Félez,
297 Torres-Sospedra, & Martínez-Usó, 2015), 1, 500 minutes (Shah et al., 2007), and 50 hours (Kapela
298 et al., 2015), and by frame numbers, 6, 035 frames (Zhu, Xu, Gao, & Huang, 2006) and 10, 115
299 frames (Reily et al., 2017).

300

301 **3.2 Inertial measurement unit specifications**

302 A range of commercially available and custom-built IMUs were used in the IMU-based studies (n=
303 30), as presented in Table 3. Of these, 23% reported using a custom-built sensor. Of the IMU-based

304 studies, the number of sensors mounted or attached to each participant or sporting equipment piece
305 ranged from one to nine. The majority of studies (n= 22) provided adequate details of sensor
306 specifications including sensor type, axes, measurement range, and sample rate used. At least one
307 characteristic of sensor measurement range or sample rate used in data collection was missing from
308 eight studies. All studies used triaxial sensors and collected accelerometer data. For analysis and
309 model development, individual sensor data consisted of only accelerometer data (n = 8), both
310 accelerometer and gyroscope data (n = 15), and accelerometer, gyroscope and magnetometer data
311 (n = 7). The individual sensor measurement ranges reported for accelerometer were ± 1.5 g to ± 16
312 g, gyroscope ± 500 °/s to ± 2000 °/s, magnetometer ± 1200 μ T or 1.2 to 4 Ga. Individual sensor
313 sample rates ranged from 10 Hz to 1000 Hz for accelerometers, 10 Hz to 500 Hz for gyroscopes
314 and 50 Hz to 500 Hz for magnetometers.

315

316 *** Table 3 near here***

317

318 3.3 Vision capture specification

319 Several experimental set-ups and specifications were reported in the total 23 vision-based studies
320 (Table 4). Modality was predominately red, green, blue (RGB) cameras. Depth cameras were
321 utilised (Kasiri-Bidhendi, Fookes, Morgan, Martin, & Sridharan, 2015; Kasiri, Fookes, Sridharan,
322 & Morgan, 2017; Reily et al., 2017), which add depth perception for 3-dimensional image
323 mapping. Seven studies clearly reported the use of a single camera set-up (Couceiro, Dias, Mendes,
324 & Araújo, 2013; Díaz-Pereira, Gómez-Conde, Escalona, & Olivieri, 2014; Hachaj, Ogiela, &
325 Koptyra, 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Nibali et al., 2017; Reily et al.,
326 2017). One study reported 16 stationary positioned cameras at a ‘bird’s eye view’ (Montoliu et al.,
327 2015), and Ó Conaire et al. (2010) reported the use of one overhead and 8 stationary cameras
328 around a tennis court baseline, although data from two cameras were only used in final analysis due
329 to occlusion issues. Sample frequency and, or pixel resolution were reported in seven of the studies
330 (Couceiro et al., 2013; Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017;
331 Montoliu et al., 2015; Victor et al., 2017; Zhu et al., 2006), with sample frequencies ranging from
332 30 Hz to 210 Hz.

333

334 *** Table 4 near here***

335

336 3.4 Inertial measurement unit recognition model development methods

337 Key stages of model development from data pre-processing to recognition techniques for IMU-
338 based studies are presented in Table 5. Data pre-processing filters were reported as either a low-
339 pass filter (n = 7) (Adelsberger & Tröster, 2013; Buckley et al., 2017; Kelly, Coughlan, Green, &
340 Caulfield, 2012; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2015, 2017; Rindal, Seeberg,
341 Tjønnås, Haugnes, & Sandbakk, 2018), high-pass filter (n = 2) (Kautz et al., 2017; Schuldhaus et
342 al., 2015), or calibration with a filter (Salman et al., 2017). Processing methods were reported in
343 67% of the IMU-based studies (Adelsberger & Tröster, 2013; Anand, Sharma, Srivastava,
344 Kaligounder, & Prakash, 2017; Brock et al., 2017; Buckley et al., 2017; Buthe, Blanke, Capkevics,
345 & Tröster, 2016; Groh et al., 2016; Groh, Fleckenstein, Kautz, & Eskofier, 2017; Groh, Kautz, &
346 Schuldhaus, 2015; Jensen et al., 2016, 2015; Jiao, Wu, Bie, Umek, & Kos, 2018; Kautz et al.,
347 2017; Kobsar et al., 2014; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2017; Ó Conaire et al.,
348 2010; Pernek, Kurillo, Stiglic, & Bajcsy, 2015; Qaisar et al., 2013; Salman et al., 2017; Schuldhaus
349 et al., 2015). Methods included, calibration of data (Groh et al., 2016, 2017; Jensen et al., 2015;
350 Qaisar et al., 2013), a one-second window centred around identified activity peaks in the signal
351 (Adelsberger & Tröster, 2013; Schuldhaus et al., 2015), temporal alignment (Pernek et al., 2015),
352 normalisation (Ó Conaire et al., 2010), outlier adjustment (Kobsar et al., 2014) or removal (Salman
353 et al., 2017), and sliding windows ranging from one to 3.5 seconds across the data (Jensen et al.,
354 2016). The three studies that investigated trick classification in skateboarding (Groh et al., 2017,
355 2015) and snowboarding (Groh et al., 2016) corrected data for different rider board stance styles,
356 termed Regular or Goofy, by inverting signal axes.

357 Movement detection methods were specifically reported in 16 studies (Adelsberger &
358 Tröster, 2013; Anand et al., 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015, Jensen et
359 al., 2013, 2015; Kautz et al., 2017; Kelly et al., 2012; Kos & Kramberger, 2017; Ó Conaire et al.,
360 2010; Rindal et al., 2018; Salman et al., 2017; Schuldhaus et al., 2015; Whiteside, Cant, Connolly,
361 & Reid, 2017). Detection methods included thresholding (n = 5), windowing segmenting (n = 4),
362 and a combination of threshold and windowing techniques (n = 5).

363 Signal feature extraction techniques were reported in 80% of the studies, with the number
364 of feature parameters in a vector ranging from a vector of normalised X, Y, Z accelerometer signals
365 (Ó Conaire et al., 2010) to 240 features (M. A. O'Reilly et al., 2017a). Further feature selection to
366 reduce the dimensionality of the feature vector was used in 11 studies. Both feature extraction and
367 selection methods varied considerably across the literature (Table 5).

368 Algorithms trialled for movement recognition were diverse across the literature (Table 5).
369 Supervised classification using a kernel form of Support Vector Machine (SVM) was most
370 prevalent (n = 16) (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Brock et al., 2017; Buckley
371 et al., 2017; Buthe et al., 2016; Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Kautz et al.,
372 2017; Kelly et al., 2012; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et al., 2017;
373 Schuldhaus et al., 2015; Whiteside et al., 2017). The next highest tested were Naïve Bayesian (NB)
374 (n = 8) (Buckley et al., 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015; Kautz et al.,
375 2017; Salman et al., 2017; Schuldhaus et al., 2015) and k-Nearest Neighbour (kNN) (n = 8)
376 (Buckley et al., 2017; Groh et al., 2016, 2017, 2015; Kautz et al., 2017; Ó Conaire et al., 2010;
377 Salman et al., 2017; Whiteside et al., 2017), followed by Random Forests (RF) (n = 7) (Buckley et
378 al., 2017; Groh et al., 2017; Kautz et al., 2017; M. A. O'Reilly et al., 2017a; M. O'Reilly et al.,
379 2017; Salman et al., 2017; Whiteside et al., 2017). Supervised learning algorithms were the most
380 common (n = 29). One study used an unsupervised discriminative analysis approach for detection
381 and classification of tennis strokes (Kos & Kramberger, 2017). Five IMU-based study investigated
382 a deep learning approach including using Convolutional Neural Networks (CNN) (Anand et al.,
383 2017; Brock et al., 2017; Jiao et al., 2018; Kautz et al., 2017; Rassem et al., 2017) and Long Short
384 Term Memory (LSTM) (Hochreiter & Schmidhuber, 1997) architectures (Rassem et al., 2017;
385 Sharma, Srivastava, Anand, Prakash, & Kaligounder, 2017). In order to assess the effectiveness of
386 the various classifiers from each study, model performance measures quantify and visualise the
387 predictive performance as reported in the following section.

388

389 ***** Table 5 near here*****

390

391 **3.5 Inertial measurement unit recognition model evaluation**

392 Reported performance evaluations of developed models across the IMU-based studies are shown in
393 Table 6. Classification accuracy, as a percentage score for the number of correct predictions by
394 total number of predictions made, was the main model evaluation measure (n = 24). Classification
395 accuracies across studies ranged between 52% (Brock & Ohgi, 2017) to 100% (Buckley et al.,
396 2017). Generally, the reported highest accuracy for a specific movement was $\geq 90\%$ (n = 17)
397 (Adelsberger & Tröster, 2013; Anand et al., 2017; Buckley et al., 2017; Connaghan et al., 2011;
398 Groh et al., 2015; Jensen et al., 2013; Jiao et al., 2018; Kobsar et al., 2014; Kos & Kramberger,
399 2017; M. A. O'Reilly et al., 2017a; Ó Conaire et al., 2010; Pernek et al., 2015; Qaisar et al., 2013;
400 Rindal et al., 2018; Schuldhaus et al., 2015; Srivastava et al., 2015; Whiteside et al., 2017) and \geq
401 80% to 90% (n = 7) (Brock & Ohgi, 2017; Brock et al., 2017; Groh et al., 2017; Jensen et al., 2016;
402 M. O'Reilly et al., 2015, 2017; Salman et al., 2017). As an estimate of the generalised performance
403 of a trained model on $\overline{n-x}$ samples, a form of leave-one-out cross validation (LOO-CV) was used in
404 47% of studies (Buthe et al., 2016; Groh et al., 2016, 2017, 2015, Jensen et al., 2016, 2013; Kobsar
405 et al., 2014; M. O'Reilly et al., 2015, 2017; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et
406 al., 2017; Schuldhaus et al., 2015). Precision, specificity and sensitivity (also referred to as recall)
407 evaluations were derived for detection (n = 6) and classification models (n = 10). Visualisation of
408 prediction results in the form of a confusion matrix featured in six studies (Buthe et al., 2016; Groh
409 et al., 2017; Kautz et al., 2017; Pernek et al., 2015; Rindal et al., 2018; Whiteside et al., 2017).

410

411 ***** Table 6 near here*****

412

413 **3.6 Vision recognition model development methods**

414 Numerous processing and recognition methods featured across the vision-based studies to
415 transform and isolated relevant input data (Table 7). Pre-processing stages were reported in 14 of
416 studies, and another varied 13 studies also provided details of processing techniques. Signal feature
417 extraction and feature selection methods used were reported in 78% of studies.

418 Both machine (n = 16) and deep learning (n = 7) algorithms were used to recognise
419 movements from vision data. Of these, a kernel form of the SVM algorithm was most common in
420 the studies (n = 10) (Couceiro et al., 2013; Horton et al., 2014; Kasiri-Bidhendi et al., 2015; Kasiri

421 et al., 2017; Li et al., 2018; Montoliu et al., 2015; M. A. O'Reilly, Whelan, Ward, Delahunt, &
422 Caulfield, 2017b; Ó Conaire et al., 2010; Reily et al., 2017; Shah et al., 2007; Zhu et al., 2006).
423 Other algorithms included kNN (n = 3) (Díaz-Pereira et al., 2014; Montoliu et al., 2015; Ó Conaire
424 et al., 2010), decision tree (DT) (n = 2) (Kapela et al., 2015; Liao et al., 2003), RF (n = 2) (Kasiri-
425 Bidhendi et al., 2015; Kasiri et al., 2017), and Multilayer Perceptron (MLP) (n = 2) (Kapela et al.,
426 2015; Montoliu et al., 2015). Deep learning was investigated in seven studies (Bertasius et al.,
427 2017; Ibrahim, Muralidharan, Deng, Vahdat, & Mori, 2016; Karpathy et al., 2014a; Nibali et al.,
428 2017; Ramanathan et al., 2015; Tora, Chen, & Little, 2017; Victor et al., 2017) of which used
429 CNNs or LSTM RNNs as the core model structure.

431 *** Table 7 near here***

433 3.7 Vision recognition model evaluation

434 Performance evaluation methods and results for vision-based studies are reported in Table 8. As
435 with IMU-based studies, classification accuracy was the common method for model evaluations,
436 featured in 61%. Classification accuracies were reported between 60.9% (Karpathy et al., 2014a)
437 and 100% (Hachaj et al., 2015; Nibali et al., 2017). In grouping the reported highest accuracies for
438 a specific movement that were $\geq 90\%$ (n = 9) (Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015;
439 Kasiri et al., 2017; Li et al., 2018; Montoliu et al., 2015; Nibali et al., 2017; Ó Conaire et al., 2010;
440 Reily et al., 2017; Shah et al., 2007), and $\geq 80\%$ to 90% (n = 2) (Horton et al., 2014; Yao & Fei-
441 Fei, 2010). A confusion matrix as a visualisation of model prediction results was used in nine
442 studies (Couceiro et al., 2013; Hachaj et al., 2015; Ibrahim et al., 2016; Karpathy et al., 2014a;
443 Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Lu, Okuma, & Little, 2009; Shah et al., 2007; Tora
444 et al., 2017). Two studies assessed and reported their model computational average speed (Lu et al.,
445 2009) and time (Reily et al., 2017).

447 *** Table 8 near here***

449 4 Discussion

450

451 The aim of this systematic review was to evaluate the use of machine and deep learning for sport-
452 specific movement recognition from IMUs and, or computer vision data inputs. Overall, the search
453 yielded 52 studies, categorised as 29 which used IMUs, 22 vision-based and one study using both
454 IMUs and vision. Automation or semi-automated sport movement recognition models working in
455 near-real time is of particular interest to avoid the error, cost and time associated with manual
456 methods. Evident in the literature, models are trending towards the potential to provide optimised
457 objective assessments of athletic movement for technical and tactical evaluations. The majority of
458 studies achieved favourable movement recognition results for the main characterising actions of a
459 sport, with several studies exploring further applications such as an automated skill quality
460 evaluation or judgement scoring, for example automated ski jump error evaluation (Brock et al.,
461 2017).

462 Experimental set-up of IMU placement and numbers assigned per participant varied
463 between sporting actions. The sensor attachment locations set by researchers appeared dependent
464 upon the specific sporting conditions and movements, presumably to gain optimal signal data.
465 Proper fixation and alignment of the sensor axes with limb anatomical axes is important in
466 reducing signal error (Fong & Chan, 2010). The attachment site hence requires a biomechanical
467 basis for accuracy of the movement being targeted to obtain reliable data. Single or multiple sensor
468 use per person also impacts model development trade-off between accuracy, analysis complexity,
469 and computational speed or demands. In tennis studies, specificity whilst using a single sensor was
470 demonstrated by mounting the IMU on the wrist or forearm of the racquet arm (Connaghan et al.,
471 2011; Kos & Kramberger, 2017; Srivastava et al., 2015; Whiteside et al., 2017). A single sensor
472 may also be mounted in a low-profile manner on sporting equipment (Groh et al., 2016, 2017,
473 2015; Jensen et al., 2015). Unobtrusive use of a single IMU to capture generalised movements
474 across the whole body was demonstrated, with an IMU mounted on the posterior head in
475 swimming (Jensen et al., 2016, 2013), lower back during running (Kobsar et al., 2014), and
476 between the shoulder blades in rugby union (Kelly et al., 2012).

477 The majority of vision-based studies opted for a single camera set-up of RGB modality.
478 Data output from a single camera as opposed to multiple minimises the volume of data to process,
479 therefore reducing computational effort. However, detailed features may go uncaptured,

480 particularly in team sport competition which consists of multiple individuals participating in the
481 capture space at one time. In contrast, a multiple camera set-up reduces limitations including
482 occlusion and viewpoint variations. However, this may also increase the complexity of the
483 processing and model computational stages. Therefore, a trade-off between computational demands
484 and movement recording accuracy often needs to be made. As stated earlier, the placement of
485 cameras needs to suit the biomechanical nature of the targeted movement and the environment
486 situated in. Common camera capture systems used in sports science research such as Vicon Nexus
487 (Oxford, UK) and OptiTrack (Oregon, USA) were not present in this review. As this review
488 targeted studies investigating during on-field or in-situation sporting contexts, efficiency in data
489 collection is key for routine applications in training and competition. A simple portable RGB
490 camera is easy to set-up in a dynamic and changing environment, such as different soccer pitches,
491 rather than a multiple capture system such as Vicon that requires calibrated precision and are
492 substantially more expensive.

493 Data acquisition and type from an IMU during analysis appears to influence model trade-
494 off between accuracy and computational effort of performance. The use of accelerometer,
495 gyroscope or magnetometer data may depend upon the movement properties analysed. Within
496 tennis studies, gyroscope signals were the most efficient at discriminating between stroke types
497 (Buthe et al., 2016; Kos & Kramberger, 2017) and detecting an athlete's fast feet court actions
498 (Buthe et al., 2016). In contrast, accelerometer signals produced higher classification accuracies in
499 classifying tennis stroke skills levels (Connaghan et al., 2011). The authors expected lower
500 gyroscope classification accuracies as temporal orientation measures between skill levels of tennis
501 strokes will differ (Connaghan et al., 2011). Conversely, data fusion from all three individual
502 sensors resulted in a more superior model for classifying advanced, intermediate and novices tennis
503 player strokes (Connaghan et al., 2011). Fusion of accelerometer and vision data also resulted in a
504 higher classification accuracy for tennis stroke recognition (Ó Conaire et al., 2010).

505 Supervised learning approaches were dominant across IMU and vision-based studies. This
506 is a method which involves a labelled ground truth training dataset typically manually annotated by
507 sport analysts. Labelled data instances were recorded as up to 15, 000 for vision-based (Victor et
508 al., 2017) and 416, 737 for sensor-based (Rassem et al., 2017) studies. Generation of a training data
509 set for supervised learning can be a tedious and labour-intensive task. It is further complicated if

510 multiple sensors or cameras are incorporated for several targeted movements. A semi-supervised or
511 unsupervised learning approach may be advantageous as data labelling is minimal or not required,
512 potentially reducing human errors in annotation. An unsupervised approach could suit specific
513 problems to explain key data features, via clustering (Mohammed et al., 2016; Sze et al., 2017).
514 Results computed by an unsupervised model (Kos, Ženko, Vlaj, & Kramberger, 2016) for tennis
515 serve, forehand and backhand stroke classification compared favourably well against a proposed
516 supervised approach (Connaghan et al., 2011).

517 Recognition of sport-specific movements was primarily achieved using conventional
518 machine learning approaches, however nine studies implemented deep learning algorithms. It is
519 expected that future model developments will progressively feature deep learning approaches due
520 to development of better hardware, and the advantages of more efficient model learning on large
521 data inputs (Sze et al., 2017). Convolutional Neural networks (CNN) (LeCun, Bottou, Bengio, &
522 Haffner, 1998) were the core structure of five of the seven deep learning study models. Briefly,
523 convolution applies several filters, known as kernels, to automatically extract features from raw
524 data inputs. This process works under four key ideas to achieve optimised results: local connection,
525 shared weights, pooling and applying several layers (LeCun et al., 2015; J. B. Yang et al., 2015).
526 Machine learning classifiers modelled with generic hand-crafted features, were compared against a
527 CNN for classifying nine beach volleyball actions using IMUs (Kautz et al., 2017). Unsatisfactory
528 results were obtained from the machine learning model, and the CNN markedly achieved higher
529 classification accuracies (Kautz et al., 2017). The CNN model produced the shortest overall
530 computation times, requiring less computational effort on the same hardware (Kautz et al., 2017).
531 Vision-based CNN models have also shown favourable results when compared to a machine
532 learning study baseline (Karpathy et al., 2014a; Nibali et al., 2017; Victor et al., 2017).
533 Specifically, consistency between a swim stroke detection model for continuous videos in
534 swimming which was then applied to tennis strokes with no domain-specific settings introduced
535 (Victor et al., 2017). The authors of this training approach (Victor et al., 2017) anticipate that this
536 could be applied to train separate models for other sports movement detection as the CNN model
537 demonstrated the ability to learn to process continuous videos into a 1-D signal with the signal
538 peaks corresponding to arbitrary events. General human activity recognition using CNN have
539 shown to be a superior approach over conventional machine learning algorithms using both IMUs

540 (Ravi et al., 2016; J. B. Yang et al., 2015; Zebin et al., 2016; Zeng et al., 2014; Zheng, Liu, Chen,
541 Ge, & Zhao, 2014) and computer vision (Ji et al., 2013; Krizhevsky et al., 2012; LeCun et al.,
542 2015). As machine learning algorithms extract heuristic features requiring domain knowledge, this
543 creates shallower features which can make it harder to infer high-level and context aware activities
544 (J. B. Yang et al., 2015). Given the previously described advantages of deep learning algorithms
545 which apply to CNN, and the recent results of deep learning, future model developments may
546 benefit from exploring these methods in comparison to current bench mark models.

547 Model performance outcome metrics quantify and visualise the error rate between the
548 predicted outcome and true measure. Comparatively, a kernel form of an SVM was the most
549 common classifier implemented and produced the strongest machine learning approach model
550 prediction accuracies across both IMU (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Buthe
551 et al., 2016; Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Pernek et al., 2015; Salman et al.,
552 2017; Schuldhaus et al., 2015; Whiteside et al., 2017) and vision-based study designs (Horton et
553 al., 2014; Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Li et al., 2018; Reily et al., 2017; Shah et
554 al., 2007; Zhu et al., 2006). Classification accuracy was the most common reported measure
555 followed by confusion matrices, as ways to clearly present prediction results and derive further
556 measures of performance. Further measures included sensitivity (also called recall), specificity and
557 precision, whereby results closer to 1.0 indicate superior model performance, compared to 0.0 or
558 poor model performance. The F1-score (also called a F-measure or F-score) conveys the balances
559 between the precision and sensitivity of a model. An in-depth analysis performance metrics
560 specific to human activity recognition is located elsewhere (Minnen, Westeyn, Starner, Ward, &
561 Lukowicz, 2006; Ward, Lukowicz, & Gellersen, 2011). Use of specific evaluation methods
562 depends upon the data type. Conventional performance measures of error rate are generally
563 unsuitable for models developed from skewed training data (Provost & Fawcett, 2001). Using
564 conventional performance measures in this context will only take the default decision threshold on
565 a model trained, if there is an uneven class distribution this may lead to imprecision (Provost &
566 Fawcett, 2001; Seiffert, Khoshgoftaar, Van Hulse, & Napolitano, 2008). Alternative evaluators
567 including Receiver Operating Characteristics (ROC) curves and its single numeric measure, Area
568 Under ROC Curve (AUC), report model performances across all decision thresholds (Seiffert et al.,
569 2008). Making evaluations between study methodology have inherent complications due to each

570 formulating their own experimental parameter settings, feature vectors and training algorithms for
571 movement recognition. The No-Free-Lunch theorems are important deductions in the formation of
572 models for supervised machine learning (David H. Wolpert, 1996), and search and optimisation
573 algorithms (D H Wolpert & Macready, 1997). The theorems broadly reference that there is no ‘one
574 model’ that will perform optimally across all recognition problems. Therefore, experiments with
575 multiple model development methods for a particular problem is recommended. The use of prior
576 knowledge about the task should be implemented to adapt the model input and model parameters in
577 order to improve overall model success (Shalev-Shwartz & Ben-David, 2014).

578 Acquisition of athlete specific information, including statistics on number, type and
579 intensity of actions, may be of use in the monitoring of athlete load. Other potential applications
580 include personalised movement technique analysis (M. O’Reilly et al., 2017), automated
581 performance evaluation scoring (Reily et al., 2017) and team ball sports pass quality rating (Horton
582 et al., 2014). However, one challenge lies in delivering consistent, individualised models across
583 team field sports that are dynamic in nature. For example, classification of soccer shots and passes
584 showed a decline in model performance accuracy from a closed environment to a dynamic match
585 setting (Schuldhaus et al., 2015). A method to overcome accuracy limitations in dynamic team field
586 sports associated with solely using IMUs or vision may be to implement data fusion (Ó Conaire et
587 al., 2010). Furthermore, vision and deep learning approaches have demonstrated the ability to track
588 and classify team sport collective court activities and individual player specific movements in
589 volleyball (Ibrahim et al., 2016), basketball (Ramanathan et al., 2015) and ice hockey (Tora et al.,
590 2017). Accounting for methods from experimental set-up to model evaluation, previous reported
591 models should be considered and adapted based on the current problem. Furthermore, the balance
592 between model computational efficiency, results accuracy and complexity trade-offs calculations
593 are an important factor.

594 In the present study, meta-analysis was considered however variability across developed
595 model parameter reporting and evaluation methods did not allow for this to be undertaken. As this
596 field expands and further methodological approaches are investigated, it would be practical to
597 review analysis approaches both within and between sports. This review was delimited to machine
598 and deep learning approaches to sport movement detection and recognition. However, statistical or
599 parametric approaches not considered here such as discriminative functional analysis may also

600 show efficacy for sport-specific movement recognition. However, as the field of machine learning
601 is a rapidly developing area shown to produce superior results, a review encompassing all possible
602 other methods may have complicated the reporting. Since sport-specific movements and their
603 environments alter the data acquisition and analysis, the sports and movements reported in the
604 present study provide an overview of the current field implementations.

605

606 **5 Conclusions**

607
608 This systematic review reported on the literature using machine and deep learning methods to
609 automate sport-specific movement recognition. In addressing the research questions, both IMUs
610 and computer vision have demonstrated capacity in improving the information gained from sport
611 movement and skill recognition for performance analysis. A range of methods for model
612 development were used across the reviewed studies producing varying results. Conventional
613 machine learning algorithms such as Support Vector Machines and Neural Networks were most
614 commonly implemented. Yet in those studies which applied deep learning algorithms such as
615 Convolutional Neural Networks, these methods outperformed the machine learning algorithms in
616 comparison. Typically, the models were evaluated using a leave-one-out cross validation method
617 and reported model performances as a classification accuracy score. Intuitively, the adaptation of
618 experimental set-up, data processing, and recognition methods used are best considered in relation
619 to the characteristics of the sport and targeted movement(s). Consulting current models within or
620 similar to the targeted sport and movement is of benefit to address bench mark model performances
621 and identify areas for improvement. The application within the sporting domain of machine
622 learning and automated sport analysis coding for consistent uniform usage appears currently a
623 challenging prospect, considering the dynamic nature, equipment restrictions and varying
624 environments arising in different sports.

625 Future work may look to adopt, adapt and expand on current models associated with a
626 specific sports movement to work towards flexible models for mainstream analysis
627 implementation. Investigation of deep learning methods in comparison to conventional machine
628 learning algorithms would be of particular interest to evaluate if the trend of superior performances
629 is beneficial for sport-specific movement recognition. Analysis as to whether IMUs and vision

630 alone or together yield enhanced results in relation to a specific sport and its implementation
631 efficiency would also be of value. In consideration of the reported study information, this review
632 can assist future researchers in broadening investigative approaches for sports performance analysis
633 as a potential to enhancing upon current methods.

Table 5 Inertial measurement unit study description and model characteristics.

Reference	Sport: target movement(s)	Participants Number: gender, level	Dataset sample No.	Data pre-processing			Feature extraction	Feature selection	Recogniti on algorithm
				Filter	Processing	Detection			
(Adelsberger & Tröster, 2013)	Weight-lifting: thruster (squat press)	16: four females and 12 males, beginner to expert		Low-pass filter	1 s window	Heuristically found threshold value to derive start and end indices of each thruster episode	Accelerometer magnitude modelled on sum of six Gaussian functions with four parameters each: scale α_i , amplitude offset β_i , standard deviation σ_i , and mean value μ_i	1.5 s window around detected signal peaks. Nelder Mead simplex direct search MATLAB	SVM
(Anand, Sharma, Srivastava, Kaligounder, & Prakash, 2017)	Tennis: forehand topspin, forehand slice, backhand topspin, backhand slice, serve Badminton: serve, clear, drop, smash Squash: forehand, backhand, serve	31 tennis players, 34 badminton players, 5 squash players	Total training set: ~8500. Total testing set: ~7100			Detection shot: 3 cues to identify shot regions across the three sports: 1) threshold, 2) jerk based detection, 3) shot shape-based detection. Once shot swing detected a fixed number or sample before and after impact point assigned as shot region	Seven shot windows developed for each stage of a shot. Three feature set types generated from all shot windows resulting in ~2000 features including: 1) statistical features, 2) pairwise correlation coefficients between elements of the window set, 3) shape-based features	Pearson correlation coefficient minimum redundancy maximum relevance (MRMR) technique	LR, bi-directional LSTM
(Brock & Ohgi, 2017)	Ski Jumping: error jump, non-error jump	Four: male, junior athletes					Set 1: discrete feature values based on one-dimensional data points built from the raw and processed data of every sensor Set 2: different time-series features based on the estimated positions and orientations of every sensor		SVM, DTW

Table 5 continued.

Reference	Sport: target movement(s)	Participants Number: gender, level	Dataset sample No.	Data pre-processing			Feature extraction	Feature selection	Recogniti on algorithm
				Filter	Processing	Detection			
(Brock, Ohgi, & Lee, 2017)	Ski jumping: nine motion style errors in flight and landing (5 errors during aerial phase/ 4 error during landing phase)	Three: ski jump athletes	85 measured jump motions		1) removal of internal noise 2) sensor alignment to bone direction of mounted segment using standardised calibration measurement 3) neutralisation 4) segmentation of motion streams into jump phases 5) all sensor streams down-sampled by factor of 2 along temporal domain		CNN model - transformed every pre-processed data segment into a multi-channel motion image of size [R, C, D] with D = 3		CNN, SVM
(Buckley et al., 2017)	Running: classification of running form as a non-fatigued or fatigued state	21: 11 females, 10 males, recreationally active	584 extracted stride repetitions labelled as 292 non-fatigued and 292 fatigued	Low-pass Butterworth filter with a frequency cut-off of 5 Hz od order n = 5	Additional signals computed: Euler, pitch, roll, yaw and Quaternion W, X, Y, Z using algorithms on board the Shimmer IMUs. Stride segmentation by an adaptive algorithm		16 time-domain and frequency-domain features computed to describe the 16 IMU signals over each stride repetition.	Wilcoxon Rank Sum Test, the top 20 signal features extracted	RF, SVM, kNN, NB
(Buthe, Blanke, Capkevics, & Tröster, 2016)	Tennis: forehand topspin, forehand slice, backhand topspin, backhand slice, smash, shot steps, side steps	Four: male athletes, three intermediate and 1 advanced	Shots n = 200 Steps n = 640		Shots: discretize data using kMeans algorithm Steps: deadreckoning technique				Shots: LCS Steps: SVM

- 1 **Machine and deep learning for sport-specific movement recognition: a systematic review of**
- 2 **model development and performance**
- 3
- 4 **Running title:**
- 5 Machine and deep learning for sport movement recognition review
- 6

7 **Abstract**

8

9 Objective assessment of an athlete’s performance is of importance in elite sports to facilitate detailed
10 analysis. The implementation of automated detection and recognition of sport-specific movements
11 overcomes the limitations associated with manual performance analysis methods. The object of this
12 study was to systematically review the literature on machine and deep learning for sport-specific
13 movement recognition using inertial measurement unit (IMU) and, or computer vision data inputs.
14 A search of multiple databases was undertaken. Included studies must have investigated a sport-
15 specific movement and analysed via machine or deep learning methods for model development. A
16 total of 52 studies met the inclusion and exclusion criteria. Data pre-processing, processing, model
17 development and evaluation methods varied across the studies. Model development for movement
18 recognition were predominantly undertaken using supervised classification approaches. A kernel
19 form of the Support Vector Machine algorithm was used in 53% of IMU and 50% of vision-based
20 studies. Twelve studies used a deep learning method as a form of Convolutional Neural Network
21 algorithm and one study also adopted a Long Short Term Memory architecture in their model. The
22 adaptation of experimental set-up, data pre-processing, and model development methods are best
23 considered in relation to the characteristics of the targeted sports movement(s).

24

25

26 **Key Words:**

27 Sport movement classification; inertial sensors; computer vision; machine learning; performance
28 analysis.

29 **1. Introduction**

30

31 Performance analysis in sport science has experienced considerable recent changes, due largely to
32 access to improved technology and increased applications from computer science. Manual notational
33 analysis or coding in sports, even when performed by trained analysts, has limitations. Such methods
34 are typically time intensive, subjective in nature, and prone to human error and bias. Automating
35 sport movement recognition and its application towards coding has the potential to enhance both the
36 efficiency and accuracy of sport performance analysis. The potential automation of recognising
37 human movements, commonly referred to as human activity recognition (HAR), can be achieved
38 through machine or deep learning model approaches. Common data inputs are obtained from inertial
39 measurement units (IMUs) or vision. Detection refers to the identification of a targeted instance, i.e.,
40 tennis strokes within a continuous data input signal (Bulling, Blanke, & Schiele, 2014). Recognition
41 or classification of movements involves further interpretations and labelled predictions of the
42 identified instance (Bulling et al., 2014; Bux, Angelov, & Habib, 2017), i.e., differentiating tennis
43 strokes as a forehand or backhand. In machine and deep learning, a model represents the statistical
44 operations involved in the development of an automated prediction task (LeCun, Yoshua, &
45 Geoffrey, 2015; Shalev-Shwartz & Ben-David, 2014).

46 Human activities detected by inertial sensing devices and computer vision are represented
47 as wave signal features corresponding to specific actions, which can be logged and extracted. Human
48 movement activities are considered hierarchically structured and can be broken down to basic
49 movements. Therefore, the context of signal use, intra-class variability, and inter-class similarity
50 between activities require consideration during experimental set-up and model development.
51 Wearable IMUs contain a combination of accelerometer, gyroscope, and magnetometer sensors
52 measuring along one to three axes. These sensors quantify acceleration, angular velocity, and the
53 direction and orientation of travel respectively (Gastin, McLean, Breed, & Spittle, 2014). These
54 sensors can capture repeated movement patterns during sport training and competitions (Camomilla,
55 Bergamini, Fantozzi, & Vannozzi, 2018; Chambers, Gabbett, Cole, & Beard, 2015; J. F. Wagner,
56 2018). Advantages include being wireless, lightweight and self-contained in operation. Inertial
57 measurement units have been utilised in quantifying physical output and tackling impacts in
58 Australian Rules football (Gastin et al., 2014; Gastin, McLean, Spittle, & Breed, 2013) and rugby

59 (Gabbett, Jenkins, & Abernethy, 2012, 2011; Howe, Aughey, Hopkins, Stewart, & Cavanagh, 2017;
60 Hulin, Gabbett, Johnston, & Jenkins, 2017). Other applications include swimming analysis (Mooney,
61 Corley, Godfrey, Quinlan, & ÓLaighin, 2015), golf swing kinematics (Lai, Hetchl, Wei, Ball, &
62 McLaughlin, 2011), over-ground running speeds (Wixted, Billing, & James, 2010), full motions in
63 alpine skiing (Yu et al., 2016); and the detection and evaluation of cricket bowling (McNamara,
64 Gabbett, Blanch, & Kelly, 2017; McNamara, Gabbett, Chapman, Naughton, & Farhart, 2015;
65 Wixted, Portus, Spratford, & James, 2011).

66 Computer vision has applications for performance analysis including player tracking,
67 semantic analysis, and movement analysis (Stein et al., 2018; Thomas, Gade, Moeslund, Carr, &
68 Hilton, 2017). Automated movement recognition approaches require several pre-processing steps
69 including athlete detection and tracking, temporal cropping and targeted action recognition, which
70 are dependent upon the sport and footage type (Barris & Button, 2008; Saba & Altameem, 2013;
71 Thomas et al., 2017). Several challenges including occlusion, viewpoint variations, and
72 environmental conditions may impact results, depending on the camera set-up (Poppe, 2010; Zhang
73 et al., 2017). Developing models to automate sports-vision coding may improve resource efficiency
74 and reduce feedback times. For example, coaches and athletes involved in time-intensive notational
75 tasks, including post-swim race analysis, may benefit from rapid objective feedback before the next
76 race in the event program (Liao, Liao, & Liu, 2003; Victor, He, Morgan, & Miniutti, 2017). For
77 detecting and recognising movements, body worn sensor signals do not suffer from the same
78 environmental constraints and stationary set-up of video cameras. Furthermore, multiple sensors
79 located on different body segments have been argued to provide more specific signal representations
80 of targeted movements (J. B. Yang, Nguyen, San, Li, & Shonali, 2015). But it is not clear if this is
81 solely conclusive, and the use of body worn sensors in some sport competitions may be impractical
82 or not possible.

83 Machine learning algorithms learn from data input for automated model building and
84 perform tasks without being explicitly programmed. The algorithm goal is to output a response
85 function $h\sigma(\bar{x})$ that will predict a ground truth variable y from an input vector of variables \bar{x} . Models
86 are run for classification techniques to predict a target class (Kotsiantis, Zaharakis, & Pintelas, 2007),
87 or regression to predict discrete or continuous values. Models are aimed at finding an optimal set of
88 parameters σ to describe the response function, and then make predictions on unseen unlabelled data

89 input. Within these, model training approaches can generally run as supervised learning,
90 unsupervised learning or semi-supervised learning (Mohammed, Khan, & Bashier, 2016; Sze, Chen,
91 Yang, & Emer, 2017).

92 Processing raw data is limited for conventional machine learning algorithms, as they are
93 unable to effectively be trained on abstract and high-dimensional data that is inconsistent, contains
94 missing values or noisy artefacts (Bux et al., 2017; Kautz, 2017). Consequently, several pre-
95 processing stages are required to create a suitable data form for input into the classifier algorithm
96 (Figo, Diniz, Ferreira, & Cardoso, 2010). Filtering (Figo et al., 2010; Wundersitz, Gastin, Robertson,
97 Davey, & Netto, 2015), window capture durations (Mitchell, Monaghan, & O'Connor, 2013; Preece,
98 Goulermas, Kenney, & Howard, 2009; Wundersitz, Josman, et al., 2015), and signal frequency cut-
99 offs (Wundersitz, Gastin, Richter, Robertson, & Netto, 2015; Wundersitz, Gastin, Robertson, et al.,
100 2015) are common techniques applied prior to data prior to dynamic human movement recognition.
101 Well-established filters for processing motion signal data include the Kalman filter (Kautz, 2017;
102 Titterton & Weston, 2009; D. Wagner, Kalischewski, Velten, & Kummert, 2017) and a Fourier
103 transform filter (Preece, Goulermas, Kenney, Howard, et al., 2009) such as a fast Fourier transform
104 (Kapela, Świetlicka, Rybarczyk, Kolanowski, & O'Connor, 2015; Preece, Goulermas, Kenney, &
105 Howard, 2009). Near real-time processing benefits from reducing memory requirements,
106 computational demands, and essential bandwidth during whole model implementation. Signal
107 feature extraction and selection favours faster processing by reducing the signals to the critical
108 features that can discriminate the targeted activities (Bulling et al., 2014). Feature extraction involves
109 identifying the key features that help maximise classifier success, and removing features that have
110 minimal impact in the model (Mannini & Sabatini, 2010). Thus, feature selection involves
111 constructing data representations in subspaces with reduced dimensions. These identified variables
112 are represented in a compact feature variable (Mannini & Sabatini, 2010). Common methods include
113 principal component analysis (PCA) (Gløersen, Myklebust, Hallén, & Federolf, 2018; Young &
114 Reinkensmeyer, 2014), vector coding techniques (Hafer & Boyer, 2017) and empirical cumulative
115 distribution functions (ECDF) (Plötz, Hammerla, & Olivier, 2011). An ECDF approach has been
116 shown to be advantageous over PCA as it derives representations of raw input independent of the
117 absolute data ranges, whereas PCA is known to have reduced performance when the input data is not
118 properly normalised (Plötz et al., 2011). For further detailed information on the acquisition, filtering

119 and analysis of IMU data for sports application and vision-based human activity recognition, see
120 (Kautz, 2017) and (Bux et al., 2017), respectively.

121 Deep learning is a division of machine learning, characterised by deeper neural network
122 model architectures and are inspired by the biological neural networks of the human brain (Bengio,
123 2013; LeCun et al., 2015; Sze et al., 2017). The deeper hierarchical models create a profound
124 architecture of multiple hidden layers based on representative learning with several processing and
125 abstraction layers (Bux et al., 2017; J. B. Yang et al., 2015). These computational models allow data
126 input features to be automatically extracted from raw data and transformed to handle unstructured
127 data, including vision (LeCun et al., 2015; Ravi, Wong, Lo, & Yang, 2016). This direct input avoids
128 several processing steps required in machine learning during training and testing, therefore reducing
129 overall computational times. A current key element within deep learning is backpropagation (Hecht-
130 Nielsen, 1989; LeCun, Bottou, Orr, & Müller, 1998). Backpropagation is a fast and computationally
131 efficient algorithm, using gradient descent, that allows training deep neural networks to be tractable
132 (Sze et al., 2017). Human activity recognition has mainly been performed using conventional
133 machine learning classifiers. Recently, deep learning techniques have enhanced the bench mark and
134 applications for IMUs (Kautz et al., 2017; Ravi et al., 2016; Ronao & Cho, 2016; J. B. Yang et al.,
135 2015; Zebin, Scully, & Ozanyan, 2016; Zeng et al., 2014) and vision (Ji, Yang, Yu, & Xu, 2013;
136 Karpathy et al., 2014a; Krizhevsky, Sutskever, & Hinton, 2012; Nibali, He, Morgan, & Greenwood,
137 2017) in human movement recognition producing more superior model performance accuracy.

138 The objective of this study was to systematically review the literature investigating sport-
139 specific automated movement detection and recognition. The review focusses on the various
140 technologies, analysis techniques and performance outcome measures utilised. There are several
141 reviews within this field that are sensor-based including wearable IMUs for lower limb biomechanics
142 and exercises (Fong & Chan, 2010; M. O'Reilly, Caulfield, Ward, Johnston, & Doherty, 2018),
143 swimming analysis (Magalhaes, Vannozzi, Gatta, & Fantozzi, 2015; Mooney et al., 2015),
144 quantifying sporting movements (Chambers et al., 2015) and physical activity monitoring (C. C.
145 Yang & Hsu, 2010). A recent systematic review has provided an evaluation on the in-field use of
146 inertial-based sensors for various performance evaluation applications (Camomilla et al., 2018).
147 Vision-based methods for human activity recognition (Aggarwal & Xia, 2014; Bux et al., 2017; Ke
148 et al., 2013; Zhang et al., 2017), semantic human activity recognition (Ziaeefard & Bergevin, 2015)

149 and motion analysis in sport (Barris & Button, 2008) have also been reviewed. However, to date,
150 there is no systematic review across sport-specific movement detection and recognition via machine
151 or deep learning. Specifically, incorporating IMUs and vision-based data input, focussing on in-field
152 applications as opposed to laboratory-based protocols and detailing the analysis and machine
153 learning methods used.

154 Considering the growth in research and potential field applications, such a review is required
155 to understand the research area. This review aims to characterise the evolving techniques and inform
156 researchers of possible improvements in sports analysis applications. Specifically: 1) What is the
157 current scope for IMUs and computer vision in sport movement detection and recognition? 2) Which
158 methodologies, inclusive of signal processing and model learning techniques, have been used to
159 achieve sport movement recognition? 3) Which evaluation methods have been used in assessing the
160 performance of these developed models?

161

162 **2. Methods**

163

164 **2.1 Search strategy**

165 The preferred PRISMA recommendations (Moher, Liberati, Tetzlaff, Altman, & Group, 2009) for
166 systematic reviews were used. A literature search was undertaken by the first author on the following
167 databases; IEEE Xplore, PubMed, ScienceDirect, Scopus, Academic Search Premier, and Computer
168 and Applied Science Complete. The searched terms were categorised in order to define the specific
169 participants, methodology and evaluated outcome measure in-line with the review aims. Searches
170 used a combination of key words with AND/OR phrases which are detailed in Table 1. Searches
171 were filtered for studies from January 2000 to May 2018 as no relevant studies were identified prior
172 to this. Further studies were manually identified from the bibliographies of database-searched studies
173 identified from the abstract screen phase, known as snowballing. Table 2 provides the inclusion and
174 exclusion criteria of this review.

175

176 *****Table 1 near here: Key word search term strings per database *****

177

178 *****Table 2 near here: Inclusion and exclusion criteria*****

179

180 **2.2 Data extraction**

181 The first author extracted and collated the relevant information from the full manuscripts identified
182 for final review. A total of 18 parameters were extracted from the 52 research studies, including the
183 title, author, year of publication, sport, participant details, sport movement target(s), device
184 specifications, device sample frequency, pre-processing methods, processing methods, feature
185 selected, feature extraction, machine learning model used, model evaluation, model performance
186 accuracy, validation method, samples collected, and computational information. A customised
187 Microsoft Excel™ spreadsheet was developed to categorise the relevant extracted information from
188 each study. Participant characteristics of number of participants, gender, and competition level, then
189 if applicable a further descriptor specific to a sport, for example, ‘medium-paced cricket bowler’.
190 Athlete and participant experience level was categorised as written in the corresponding study to
191 avoid misrepresentations. The age of participants was not considered an important characteristic
192 required for model development. The individual ability in which the movement is performed
193 accounts for the discriminative signal features associated with the movements. For the purposes of
194 this review, a sport-specific movement was defined from a team or individual sport, and training
195 activities associated with a particular sport. For example, weight-lifting as strength training,
196 recognised under the Global Association of International Sports Federations. The targeted sports and
197 specific movements were defined for either detection or recognition. Model development techniques
198 used included pre-processing methods to transform data to a more suitable form for analysis,
199 processing stages to segment data for identified target activities, feature extraction and selections
200 techniques, and the learning algorithm(s). Model evaluation measures extracted were the model
201 performance assessment techniques used, ground-truth validation comparison, number of data
202 samples collected, and the model performance outcomes results reported. If studies ran multiple
203 experiments using several algorithms, only the superior algorithm and relevant results were reported
204 as the best method. This was done so in the interest of concise reporting to highlight favourable
205 method approaches (Sprager & Juric, 2015). Any further relevant results or information identified
206 from the studies was included as a special remark (Sprager & Juric, 2015). Hardware and
207 specification information extracted included the IMU or video equipment used, number of units,

208 attachment of sensors (IMUs), sample frequency, and sensor data types used in analysis (IMUs).
209 Studies identified and full data extracted were reviewed by a second author.

210

211 **3. Results**

212

213 An outline of the search results and study exclusions has been provided in Fig 1. Of the initial
214 database search which identified 4885 results, a **final 52 studies** met criteria for inclusion in this
215 review. Of these, 29 used IMUs **and 22 were vision-based**. One study (Ó Conaire et al., 2010) used
216 both sensors and vision for model development separately then together via data fusion. Tables 3 - 8
217 provide a description of the characteristics of the reviewed studies, detailed in the following sections.

218

219 ***** Fig 1 near here: PRISMA flow diagram *****

220

221 **3.1 Experimental design**

222 A variety of sports and their associated sport-specific movements were investigated, implementing
223 various experimental designs as presented in Tables 5 and 7. Across the studies, sports reported were
224 tennis (n = 10), cricket (n = 3), weightlifting or strength training (n = 6), swimming (n = 4),
225 skateboarding (n = 2), ski jumping (n = 2), snowboarding (n = 1), golf (n = 4), **volleyball (n = 2)**,
226 rugby (n = 2), **ice hockey (n = 2)**, gymnastics (n = 2), karate (n = 1), **basketball (n = 3)**, Gaelic football
227 (n = 1), hurling (n = 1), boxing (n = 2), running (n = 2), diving (n = 1), squash (n = 1), badminton (n
228 = 1), cross-country skiing (n = 2) and soccer (n = 4). The Sports 1-M dataset (Karpathy et al., 2014b)
229 was also reported, which consists of 1,133,158 video URLs annotated automatically with 487 sport
230 labels using the YouTube Topic API. A dominant approach was the classification of main
231 characterising actions for each sport. For example, serve, forehand, backhand strokes in tennis
232 (Connaghan et al., 2011; Kos & Kramberger, 2017; Ó Conaire et al., 2010; Shah, Chokalingam,
233 Paluri, & Pradeep, 2007; Srivastava et al., 2015), and the four competition strokes in swimming
234 (Jensen, Blank, Kugler, & Eskofier, 2016; Jensen, Prade, & Eskofier, 2013; Liao et al., 2003; Victor
235 et al., 2017). Several studies further classified sub-categories of actions. For example, three further
236 classes of the two main classified snowboarding trick types Grinds and Airs (Groh, Fleckenstein, &
237 Eskofier, 2016), and further classifying the main tennis stroke types as either flat, topspin or slice

238 (Srivastava et al., 2015). Semantic descriptors were reported for classification models that predicted
239 athlete training background, experience and fatigue level. These included running (Buckley et al.,
240 2017; Kobsar, Osis, Hettinga, & Ferber, 2014), rating of gymnastic routines (Reily, Zhang, & Hoff,
241 2017), soccer pass classification based on its quality (Horton, Gudmundsson, Chawla, & Estephan,
242 2014), cricket bowling legality (Qaisar et al., 2013; Salman, Qaisar, & Qamar, 2017), ski jump error
243 analysis (Brock & Ohgi, 2017; Brock, Ohgi, & Lee, 2017) and strength training technique deviations
244 (M. A. O'Reilly, Whelan, Ward, Delahunt, & Caulfield, 2017a; M. O'Reilly et al., 2015; M.
245 O'Reilly, Whelan, Ward, Delahunt, & Caulfield, 2017). One approach (Yao & Fei-Fei, 2010),
246 encoded the mutual context of human pose and sporting equipment using semantics, to facilitate the
247 detection and classification of movements including a cricket bat and batsman coupled movements.

248 Total participant numbers for IMU-based studies ranged from one (Qaisar et al., 2013) to 30
249 (Kautz et al., 2017). Reported data individual instance sample sizes for sensor studies ranged from
250 150 (Salman et al., 2017) to 416, 737 (Rassem, El-Beltagy, & Saleh, 2017). Vision-based studies
251 that explicitly reported total participant details ranged from five (Ó Conaire et al., 2010) to 40 (Victor
252 et al., 2017). Vision dataset sample sizes varied across studies, from 50 individual action clips (Liao
253 et al., 2003) to 15, 000 (Victor et al., 2017). One study (Karpathy et al., 2014a) used the publicly
254 available Sports-1M, as previously described. Vision-based studies also reported datasets in total
255 time, 10.3 hours (Bertasiu, Park, Yu, & Shi, 2017), 3 hours (Montoliu, Martín-Félez, Torres-
256 Sospedra, & Martínez-Usó, 2015), 1, 500 minutes (Shah et al., 2007), and 50 hours (Kapela et al.,
257 2015), and by frame numbers, 6, 035 frames (Zhu, Xu, Gao, & Huang, 2006) and 10, 115 frames
258 (Reily et al., 2017).

259

260 **3.2 Inertial measurement unit specifications**

261 A range of commercially available and custom-built IMUs were used in the IMU-based studies (n=
262 30), as presented in Table 3. Of these, 23% reported using a custom-built sensor. Of the IMU-based
263 studies, the number of sensors mounted or attached to each participant or sporting equipment piece
264 ranged from one to nine. The majority of studies (n= 22) provided adequate details of sensor
265 specifications including sensor type, axes, measurement range, and sample rate used. At least one
266 characteristic of sensor measurement range or sample rate used in data collection was missing from
267 eight studies. All studies used triaxial sensors and collected accelerometer data. For analysis and

268 model development, individual sensor data consisted of only accelerometer data (n = 8), both
269 accelerometer and gyroscope data (n = 15), and accelerometer, gyroscope and magnetometer data (n
270 = 7). The individual sensor measurement ranges reported for accelerometer were ± 1.5 g to ± 16 g,
271 gyroscope ± 500 °/s to ± 2000 °/s, magnetometer ± 1200 μ T or 1.2 to 4 Ga. Individual sensor sample
272 rates ranged from 10 Hz to 1000 Hz for accelerometers, 10 Hz to 500 Hz for gyroscopes and 50 Hz
273 to 500 Hz for magnetometers.

274

275 ***** Table 3 near here*****

276

277 **3.3 Vision capture specification**

278 Several experimental set-ups and specifications were reported in the total **23 vision-based studies**
279 (Table 4). Modality was predominately red, green, blue (RGB) cameras. Depth cameras were utilised
280 (Kasiri-Bidhendi, Fookes, Morgan, Martin, & Sridharan, 2015; Kasiri, Fookes, Sridharan, &
281 Morgan, 2017; Reily et al., 2017), which add depth perception for 3-dimensional image mapping.
282 Seven studies clearly reported the use of a single camera set-up (Couceiro, Dias, Mendes, & Araújo,
283 2013; Díaz-Pereira, Gómez-Conde, Escalona, & Olivieri, 2014; Hachaj, Ogiela, & Koptyra, 2015;
284 Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Nibali et al., 2017; Reily et al., 2017). One study
285 reported 16 stationary positioned cameras at a ‘bird’s eye view’ (Montoliu et al., 2015), and Ó
286 Conaire et al. (2010) reported the use of one overhead and 8 stationary cameras around a tennis court
287 baseline, although data from two cameras were only used in final analysis due to occlusion issues.
288 Sample frequency and, or pixel resolution were reported in seven of the studies (Couceiro et al.,
289 2013; Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Montoliu et al., 2015;
290 Victor et al., 2017; Zhu et al., 2006), with sample frequencies ranging from 30 Hz to 210 Hz.

291

292 ***** Table 4 near here*****

293

294 **3.4 Inertial measurement unit recognition model development methods**

295 Key stages of model development from data pre-processing to recognition techniques for IMU-based
296 studies are presented in Table 5. Data pre-processing filters were reported as either a low-pass filter
297 (n = 7) (Adelsberger & Tröster, 2013; Buckley et al., 2017; Kelly, Coughlan, Green, & Caulfield,

298 2012; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2015, 2017; Rindal, Seeberg, Tjønnås,
299 Haugnes, & Sandbakk, 2018), high-pass filter ($n = 2$) (Kautz et al., 2017; Schuldhaus et al., 2015),
300 or calibration with a filter (Salman et al., 2017). Processing methods were reported in 67% of the
301 IMU-based studies (Adelsberger & Tröster, 2013; Anand, Sharma, Srivastava, Kaligounder, &
302 Prakash, 2017; Brock et al., 2017; Buckley et al., 2017; Buthe, Blanke, Capkevics, & Tröster, 2016;
303 Groh et al., 2016; Groh, Fleckenstein, Kautz, & Eskofier, 2017; Groh, Kautz, & Schuldhaus, 2015;
304 Jensen et al., 2016, 2015; Jiao, Wu, Bie, Umek, & Kos, 2018; Kautz et al., 2017; Kobsar et al., 2014;
305 M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2017; Ó Conaire et al., 2010; Pernek, Kurillo, Stiglic,
306 & Bajcsy, 2015; Qaisar et al., 2013; Salman et al., 2017; Schuldhaus et al., 2015). Methods included,
307 calibration of data (Groh et al., 2016, 2017; Jensen et al., 2015; Qaisar et al., 2013), a one-second
308 window centred around identified activity peaks in the signal (Adelsberger & Tröster, 2013;
309 Schuldhaus et al., 2015), temporal alignment (Pernek et al., 2015), normalisation (Ó Conaire et al.,
310 2010), outlier adjustment (Kobsar et al., 2014) or removal (Salman et al., 2017), and sliding windows
311 ranging from one to 3.5 seconds across the data (Jensen et al., 2016). The three studies that
312 investigated trick classification in skateboarding (Groh et al., 2017, 2015) and snowboarding (Groh
313 et al., 2016) corrected data for different rider board stance styles, termed Regular or Goofy, by
314 inverting signal axes.

315 Movement detection methods were specifically reported in 16 studies (Adelsberger &
316 Tröster, 2013; Anand et al., 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015, Jensen et
317 al., 2013, 2015; Kautz et al., 2017; Kelly et al., 2012; Kos & Kramberger, 2017; Ó Conaire et al.,
318 2010; Rindal et al., 2018; Salman et al., 2017; Schuldhaus et al., 2015; Whiteside, Cant, Connolly,
319 & Reid, 2017). Detection methods included thresholding ($n = 5$), windowing segmenting ($n = 4$), and
320 a combination of threshold and windowing techniques ($n = 5$).

321 Signal feature extraction techniques were reported in 80% of the studies, with the number of
322 feature parameters in a vector ranging from a vector of normalised X, Y, Z accelerometer signals (Ó
323 Conaire et al., 2010) to 240 features (M. A. O'Reilly et al., 2017a). Further feature selection to reduce
324 the dimensionality of the feature vector was used in 11 studies. Both feature extraction and selection
325 methods varied considerably across the literature (Table 5).

326 Algorithms trialled for movement recognition were diverse across the literature (Table 5).
327 Supervised classification using a kernel form of Support Vector Machine (SVM) was most prevalent

328 (n = 16) (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Brock et al., 2017; Buckley et al., 2017;
329 Buthe et al., 2016; Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Kautz et al., 2017; Kelly et al.,
330 2012; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et al., 2017; Schuldhaus et al., 2015;
331 Whiteside et al., 2017). The next highest tested were Naïve Bayesian (NB) (n = 8) (Buckley et al.,
332 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015; Kautz et al., 2017; Salman et al., 2017;
333 Schuldhaus et al., 2015) and k-Nearest Neighbour (kNN) (n = 8) (Buckley et al., 2017; Groh et al.,
334 2016, 2017, 2015; Kautz et al., 2017; Ó Conaire et al., 2010; Salman et al., 2017; Whiteside et al.,
335 2017), followed by Random Forests (RF) (n = 7) (Buckley et al., 2017; Groh et al., 2017; Kautz et
336 al., 2017; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2017; Salman et al., 2017; Whiteside et
337 al., 2017). Supervised learning algorithms were the most common (n = 29). One study used an
338 unsupervised discriminative analysis approach for detection and classification of tennis strokes (Kos
339 & Kramberger, 2017). Five IMU-based study investigated a deep learning approach including using
340 Convolutional Neural Networks (CNN) (Anand et al., 2017; Brock et al., 2017; Jiao et al., 2018;
341 Kautz et al., 2017; Rassem et al., 2017) and Long Short Term Memory (LSTM) (Hochreiter &
342 Schmidhuber, 1997) architectures (Rassem et al., 2017; Sharma, Srivastava, Anand, Prakash, &
343 Kaligounder, 2017). In order to assess the effectiveness of the various classifiers from each study,
344 model performance measures quantify and visualise the predictive performance as reported in the
345 following section.

346

347 ***** Table 5 near here*****

348

349 **3.5 Inertial measurement unit recognition model evaluation**

350 Reported performance evaluations of developed models across the IMU-based studies are shown in
351 Table 6. Classification accuracy, as a percentage score for the number of correct predictions by total
352 number of predictions made, was the main model evaluation measure (n = 24). Classification
353 accuracies across studies ranged between 52% (Brock & Ohgi, 2017) to 100% (Buckley et al., 2017).
354 Generally, the reported highest accuracy for a specific movement was $\geq 90\%$ (n = 17) (Adelsberger
355 & Tröster, 2013; Anand et al., 2017; Buckley et al., 2017; Connaghan et al., 2011; Groh et al., 2015;
356 Jensen et al., 2013; Jiao et al., 2018; Kobsar et al., 2014; Kos & Kramberger, 2017; M. A. O'Reilly
357 et al., 2017a; Ó Conaire et al., 2010; Pernek et al., 2015; Qaisar et al., 2013; Rindal et al., 2018;

358 Schuldhaus et al., 2015; Srivastava et al., 2015; Whiteside et al., 2017) and $\geq 80\%$ to 90% ($n = 7$)
359 (Brock & Ohgi, 2017; Brock et al., 2017; Groh et al., 2017; Jensen et al., 2016; M. O'Reilly et al.,
360 2015, 2017; Salman et al., 2017). As an estimate of the generalised performance of a trained model
361 on $n - x$ samples, a form of leave-one-out cross validation (LOO-CV) was used in 47% of studies
362 (Buthe et al., 2016; Groh et al., 2016, 2017, 2015, Jensen et al., 2016, 2013; Kobsar et al., 2014; M.
363 O'Reilly et al., 2015, 2017; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et al., 2017;
364 Schuldhaus et al., 2015). Precision, specificity and sensitivity (also referred to as recall) evaluations
365 were derived for detection ($n = 6$) and classification models ($n = 10$). Visualisation of prediction
366 results in the form of a confusion matrix featured in six studies (Buthe et al., 2016; Groh et al., 2017;
367 Kautz et al., 2017; Pernek et al., 2015; Rindal et al., 2018; Whiteside et al., 2017).

368

369 *** Table 6 near here***

370

371 3.6 Vision recognition model development methods

372 Numerous processing and recognition methods featured across the vision-based studies to transform
373 and isolated relevant input data (Table 7). Pre-processing stages were reported in 14 of studies, and
374 another varied 13 studies also provided details of processing techniques. Signal feature extraction
375 and feature selection methods used were reported in 78% of studies.

376 Both machine ($n = 16$) and deep learning ($n = 7$) algorithms were used to recognise
377 movements from vision data. Of these, a kernel form of the SVM algorithm was most common in
378 the studies ($n = 10$) (Couceiro et al., 2013; Horton et al., 2014; Kasiri-Bidhendi et al., 2015; Kasiri
379 et al., 2017; Li et al., 2018; Montoliu et al., 2015; M. A. O'Reilly, Whelan, Ward, Delahunt, &
380 Caulfield, 2017b; Ó Conaire et al., 2010; Reily et al., 2017; Shah et al., 2007; Zhu et al., 2006). Other
381 algorithms included kNN ($n = 3$) (Díaz-Pereira et al., 2014; Montoliu et al., 2015; Ó Conaire et al.,
382 2010), decision tree (DT) ($n = 2$) (Kapela et al., 2015; Liao et al., 2003), RF ($n = 2$) (Kasiri-Bidhendi
383 et al., 2015; Kasiri et al., 2017), and Multilayer Perceptron (MLP) ($n = 2$) (Kapela et al., 2015;
384 Montoliu et al., 2015). Deep learning was investigated in seven studies (Bertasius et al., 2017;
385 Ibrahim, Muralidharan, Deng, Vahdat, & Mori, 2016; Karpathy et al., 2014a; Nibali et al., 2017;

386 Ramanathan et al., 2015; Tora, Chen, & Little, 2017; Victor et al., 2017) of which used CNNs or
387 LSTM RNNs as the core model structure.

388

389 ***** Table 7 near here*****

390

391 **3.7 Vision recognition model evaluation**

392 Performance evaluation methods and results for vision-based studies are reported in Table 8. As with
393 IMU-based studies, classification accuracy was the common method for model evaluations, **featured**
394 **in 61%**. Classification accuracies were reported between 60.9% (Karpathy et al., 2014a) and 100%
395 (Hachaj et al., 2015; Nibali et al., 2017). In grouping the reported highest accuracies for a specific
396 movement that were $\geq 90\%$ ($n = 9$) (Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al.,
397 2017; Li et al., 2018; Montoliu et al., 2015; Nibali et al., 2017; Ó Conaire et al., 2010; Reily et al.,
398 2017; Shah et al., 2007), and $\geq 80\%$ to 90% ($n = 2$) (Horton et al., 2014; Yao & Fei-Fei, 2010). A
399 confusion matrix as a visualisation of model prediction results was used in **nine studies** (Couceiro et
400 al., 2013; Hachaj et al., 2015; Ibrahim et al., 2016; Karpathy et al., 2014a; Kasiri-Bidhendi et al.,
401 2015; Kasiri et al., 2017; Lu, Okuma, & Little, 2009; Shah et al., 2007; Tora et al., 2017). Two
402 studies assessed and reported their model computational average speed (Lu et al., 2009) and time
403 (Reily et al., 2017).

404

405 ***** Table 8 near here*****

406

407 **4 Discussion**

408

409 The aim of this systematic review was to evaluate the use of machine and deep learning for sport-
410 specific movement recognition from IMUs and, or computer vision data inputs. Overall, the search
411 yielded **52 studies**, categorised as 29 which used IMUs, **22 vision-based** and one study using both
412 IMUs and vision. Automation or semi-automated sport movement recognition models working in
413 near-real time is of particular interest to avoid the error, cost and time associated with manual
414 methods. Evident in the literature, models are trending towards the potential to provide optimised

415 objective assessments of athletic movement for technical and tactical evaluations. The majority of
416 studies achieved favourable movement recognition results for the main characterising actions of a
417 sport, with several studies exploring further applications such as an automated skill quality evaluation
418 or judgement scoring, for example automated ski jump error evaluation (Brock et al., 2017).

419 Experimental set-up of IMU placement and numbers assigned per participant varied between
420 sporting actions. The sensor attachment locations set by researchers appeared dependent upon the
421 specific sporting conditions and movements, presumably to gain optimal signal data. Proper fixation
422 and alignment of the sensor axes with limb anatomical axes is important in reducing signal error
423 (Fong & Chan, 2010). The attachment site hence requires a biomechanical basis for accuracy of the
424 movement being targeted to obtain reliable data. Single or multiple sensor use per person also
425 impacts model development trade-off between accuracy, analysis complexity, and computational
426 speed or demands. In tennis studies, specificity whilst using a single sensor was demonstrated by
427 mounting the IMU on the wrist or forearm of the racquet arm (Connaghan et al., 2011; Kos &
428 Kramberger, 2017; Srivastava et al., 2015; Whiteside et al., 2017). A single sensor may also be
429 mounted in a low-profile manner on sporting equipment (Groh et al., 2016, 2017, 2015; Jensen et
430 al., 2015). Unobtrusive use of a single IMU to capture generalised movements across the whole body
431 was demonstrated, with an IMU mounted on the posterior head in swimming (Jensen et al., 2016,
432 2013), lower back during running (Kobsar et al., 2014), and between the shoulder blades in rugby
433 union (Kelly et al., 2012).

434 The majority of vision-based studies opted for a single camera set-up of RGB modality. Data
435 output from a single camera as opposed to multiple minimises the volume of data to process,
436 therefore reducing computational effort. However, detailed features may go uncaptured, particularly
437 in team sport competition which consists of multiple individuals participating in the capture space at
438 one time. In contrast, a multiple camera set-up reduces limitations including occlusion and viewpoint
439 variations. However, this may also increase the complexity of the processing and model
440 computational stages. Therefore, a trade-off between computational demands and movement
441 recording accuracy often needs to be made. As stated earlier, the placement of cameras needs to suit
442 the biomechanical nature of the targeted movement and the environment situated in. Common
443 camera capture systems used in sports science research such as Vicon Nexus (Oxford, UK) and
444 OptiTrack (Oregon, USA) were not present in this review. As this review targeted studies

445 investigating during on-field or in-situation sporting contexts, efficiency in data collection is key for
446 routine applications in training and competition. A simple portable RGB camera is easy to set-up in
447 a dynamic and changing environment, such as different soccer pitches, rather than a multiple capture
448 system such as Vicon that requires calibrated precision and are substantially more expensive.

449 Data acquisition and type from an IMU during analysis appears to influence model trade-off
450 between accuracy and computational effort of performance. The use of accelerometer, gyroscope or
451 magnetometer data may depend upon the movement properties analysed. Within tennis studies,
452 gyroscope signals were the most efficient at discriminating between stroke types (Buthe et al., 2016;
453 Kos & Kramberger, 2017) and detecting an athlete's fast feet court actions (Buthe et al., 2016). In
454 contrast, accelerometer signals produced higher classification accuracies in classifying tennis stroke
455 skills levels (Connaghan et al., 2011). The authors expected lower gyroscope classification
456 accuracies as temporal orientation measures between skill levels of tennis strokes will differ
457 (Connaghan et al., 2011). Conversely, data fusion from all three individual sensors resulted in a more
458 superior model for classifying advanced, intermediate and novices tennis player strokes (Connaghan
459 et al., 2011). Fusion of accelerometer and vision data also resulted in a higher classification accuracy
460 for tennis stroke recognition (Ó Conaire et al., 2010).

461 Supervised learning approaches were dominant across IMU and vision-based studies. This
462 is a method which involves a labelled ground truth training dataset typically manually annotated by
463 sport analysts. Labelled data instances were recorded as up to 15, 000 for vision-based (Victor et al.,
464 2017) and 416, 737 for sensor-based (Rassem et al., 2017) studies. Generation of a training data set
465 for supervised learning can be a tedious and labour-intensive task. It is further complicated if multiple
466 sensors or cameras are incorporated for several targeted movements. A semi-supervised or
467 unsupervised learning approach may be advantageous as data labelling is minimal or not required,
468 potentially reducing human errors in annotation. An unsupervised approach could suit specific
469 problems to explain key data features, via clustering (Mohammed et al., 2016; Sze et al., 2017).
470 Results computed by an unsupervised model (Kos, Ženko, Vlaj, & Kramberger, 2016) for tennis
471 serve, forehand and backhand stroke classification compared favourably well against a proposed
472 supervised approach (Connaghan et al., 2011).

473 Recognition of sport-specific movements was primarily achieved using conventional
474 machine learning approaches, however nine studies implemented deep learning algorithms. It is

475 expected that future model developments will progressively feature deep learning approaches due to
476 development of better hardware, and the advantages of more efficient model learning on large data
477 inputs (Sze et al., 2017). Convolutional Neural networks (CNN) (LeCun, Bottou, Bengio, & Haffner,
478 1998) were the core structure of five of the seven deep learning study models. Briefly, convolution
479 applies several filters, known as kernels, to automatically extract features from raw data inputs. This
480 process works under four key ideas to achieve optimised results: local connection, shared weights,
481 pooling and applying several layers (LeCun et al., 2015; J. B. Yang et al., 2015). Machine learning
482 classifiers modelled with generic hand-crafted features, were compared against a CNN for
483 classifying nine beach volleyball actions using IMUs (Kautz et al., 2017). Unsatisfactory results were
484 obtained from the machine learning model, and the CNN markedly achieved higher classification
485 accuracies (Kautz et al., 2017). The CNN model produced the shortest overall computation times,
486 requiring less computational effort on the same hardware (Kautz et al., 2017). Vision-based CNN
487 models have also shown favourable results when compared to a machine learning study baseline
488 (Karpathy et al., 2014a; Nibali et al., 2017; Victor et al., 2017). Specifically, consistency between a
489 swim stroke detection model for continuous videos in swimming which was then applied to tennis
490 strokes with no domain-specific settings introduced (Victor et al., 2017). The authors of this training
491 approach (Victor et al., 2017) anticipate that this could be applied to train separate models for other
492 sports movement detection as the CNN model demonstrated the ability to learn to process continuous
493 videos into a 1-D signal with the signal peaks corresponding to arbitrary events. General human
494 activity recognition using CNN have shown to be a superior approach over conventional machine
495 learning algorithms using both IMUs (Ravi et al., 2016; J. B. Yang et al., 2015; Zebin et al., 2016;
496 Zeng et al., 2014; Zheng, Liu, Chen, Ge, & Zhao, 2014) and computer vision (Ji et al., 2013;
497 Krizhevsky et al., 2012; LeCun et al., 2015). As machine learning algorithms extract heuristic
498 features requiring domain knowledge, this creates shallower features which can make it harder to
499 infer high-level and context aware activities (J. B. Yang et al., 2015). Given the previously described
500 advantages of deep learning algorithms which apply to CNN, and the recent results of deep learning,
501 future model developments may benefit from exploring these methods in comparison to current
502 bench mark models.

503 Model performance outcome metrics quantify and visualise the error rate between the
504 predicted outcome and true measure. Comparatively, a kernel form of an SVM was the most common

505 classifier implemented and produced the strongest machine learning approach model prediction
506 accuracies across both IMU (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Buthe et al., 2016;
507 Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Pernek et al., 2015; Salman et al., 2017; Schuldhaus
508 et al., 2015; Whiteside et al., 2017) and vision-based study designs (Horton et al., 2014; Kasiri-
509 Bidhendi et al., 2015; Kasiri et al., 2017; Li et al., 2018; Reily et al., 2017; Shah et al., 2007; Zhu et
510 al., 2006). Classification accuracy was the most common reported measure followed by confusion
511 matrices, as ways to clearly present prediction results and derive further measures of performance.
512 Further measures included sensitivity (also called recall), specificity and precision, whereby results
513 closer to 1.0 indicate superior model performance, compared to 0.0 or poor model performance. The
514 F1-score (also called a F-measure or F-score) conveys the balances between the precision and
515 sensitivity of a model. An in-depth analysis performance metrics specific to human activity
516 recognition is located elsewhere (Minnen, Westeyn, Starner, Ward, & Lukowicz, 2006; Ward,
517 Lukowicz, & Gellersen, 2011). Use of specific evaluation methods depends upon the data type.
518 Conventional performance measures of error rate are generally unsuitable for models developed from
519 skewed training data (Provost & Fawcett, 2001). Using conventional performance measures in this
520 context will only take the default decision threshold on a model trained, if there is an uneven class
521 distribution this may lead to imprecision (Provost & Fawcett, 2001; Seiffert, Khoshgoftaar, Van
522 Hulse, & Napolitano, 2008). Alternative evaluators including Receiver Operating Characteristics
523 (ROC) curves and its single numeric measure, Area Under ROC Curve (AUC), report model
524 performances across all decision thresholds (Seiffert et al., 2008). Making evaluations between study
525 methodology have inherent complications due to each formulating their own experimental parameter
526 settings, feature vectors and training algorithms for movement recognition. The No-Free-Lunch
527 theorems are important deductions in the formation of models for supervised machine learning
528 (David H. Wolpert, 1996), and search and optimisation algorithms (D H Wolpert & Macready, 1997).
529 The theorems broadly reference that there is no ‘one model’ that will perform optimally across all
530 recognition problems. Therefore, experiments with multiple model development methods for a
531 particular problem is recommended. The use of prior knowledge about the task should be
532 implemented to adapt the model input and model parameters in order to improve overall model
533 success (Shalev-Shwartz & Ben-David, 2014).

534 Acquisition of athlete specific information, including statistics on number, type and intensity
535 of actions, may be of use in the monitoring of athlete load. Other potential applications include
536 personalised movement technique analysis (M. O'Reilly et al., 2017), automated performance
537 evaluation scoring (Reily et al., 2017) and team ball sports pass quality rating (Horton et al., 2014).
538 However, one challenge lies in delivering consistent, individualised models across team field sports
539 that are dynamic in nature. For example, classification of soccer shots and passes showed a decline
540 in model performance accuracy from a closed environment to a dynamic match setting (Schuldhaus
541 et al., 2015). A method to overcome accuracy limitations in dynamic team field sports associated
542 with solely using IMUs or vision may be to implement data fusion (Ó Conaire et al., 2010).
543 Furthermore, vision and deep learning approaches have demonstrated the ability to track and classify
544 team sport collective court activities and individual player specific movements in volleyball (Ibrahim
545 et al., 2016), basketball (Ramanathan et al., 2015) and ice hockey (Tora et al., 2017). Accounting for
546 methods from experimental set-up to model evaluation, previous reported models should be
547 considered and adapted based on the current problem. Furthermore, the balance between model
548 computational efficiency, results accuracy and complexity trade-offs calculations are an important
549 factor.

550 In the present study, meta-analysis was considered however variability across developed
551 model parameter reporting and evaluation methods did not allow for this to be undertaken. As this
552 field expands and further methodological approaches are investigated, it would be practical to review
553 analysis approaches both within and between sports. This review was delimited to machine and deep
554 learning approaches to sport movement detection and recognition. However, statistical or parametric
555 approaches not considered here such as discriminative functional analysis may also show efficacy
556 for sport-specific movement recognition. However, as the field of machine learning is a rapidly
557 developing area shown to produce superior results, a review encompassing all possible other methods
558 may have complicated the reporting. Since sport-specific movements and their environments alter
559 the data acquisition and analysis, the sports and movements reported in the present study provide an
560 overview of the current field implementations.

561

562 **5 Conclusions**

563

564 This systematic review reported on the literature using machine and deep learning methods to
565 automate sport-specific movement recognition. In addressing the research questions, both IMUs and
566 computer vision have demonstrated capacity in improving the information gained from sport
567 movement and skill recognition for performance analysis. A range of methods for model
568 development were used across the reviewed studies producing varying results. Conventional machine
569 learning algorithms such as Support Vector Machines and Neural Networks were most commonly
570 implemented. Yet in those studies which applied deep learning algorithms such as Convolutional
571 Neural Networks, these methods outperformed the machine learning algorithms in comparison.
572 Typically, the models were evaluated using a leave-one-out cross validation method and reported
573 model performances as a classification accuracy score. Intuitively, the adaptation of experimental
574 set-up, data processing, and recognition methods used are best considered in relation to the
575 characteristics of the sport and targeted movement(s). Consulting current models within or similar to
576 the targeted sport and movement is of benefit to address bench mark model performances and identify
577 areas for improvement. The application within the sporting domain of machine learning and
578 automated sport analysis coding for consistent uniform usage appears currently a challenging
579 prospect, considering the dynamic nature, equipment restrictions and varying environments arising
580 in different sports.

581 Future work may look to adopt, adapt and expand on current models associated with a specific sports
582 movement to work towards flexible models for mainstream analysis implementation. Investigation
583 of deep learning methods in comparison to conventional machine learning algorithms would be of
584 particular interest to evaluate if the trend of superior performances is beneficial for sport-specific
585 movement recognition. Analysis as to whether IMUs and vision alone or together yield enhanced
586 results in relation to a specific sport and its implementation efficiency would also be of value. In
587 consideration of the reported study information, this review can assist future researchers in
588 broadening investigative approaches for sports performance analysis as a potential to enhancing upon
589 current methods.

41 Objective assessment of an athlete’s performance is of importance in elite sports to facilitate detailed
42 analysis. The implementation of automated detection and recognition of sport-specific movements
43 overcomes the limitations associated with manual performance analysis methods. The object of this
44 study was to systematically review the literature on machine and deep learning for sport-specific
45 movement recognition using inertial measurement unit (IMU) and, or computer vision data inputs.
46 A search of multiple databases was undertaken. Included studies must have investigated a sport-
47 specific movement and analysed via machine or deep learning methods for model development. A
48 total of 52 studies met the inclusion and exclusion criteria. Data pre-processing, processing, model
49 development and evaluation methods varied across the studies. Model development for movement
50 recognition were predominantly undertaken using supervised classification approaches. A kernel
51 form of the Support Vector Machine algorithm was used in 53% of IMU and 50% of vision-based
52 studies. Twelve studies used a deep learning method as a form of Convolutional Neural Network
53 algorithm and one study also adopted a Long Short Term Memory architecture in their model. The
54 adaptation of experimental set-up, data pre-processing, and model development methods are best
55 considered in relation to the characteristics of the targeted sports movement(s).

58 Key Words:

59 Sport movement classification; inertial sensors; computer vision; machine learning; performance
60 analysis.

61 **1. Introduction**

62

63 Performance analysis in sport science has experienced considerable recent changes, due largely to
64 access to improved technology and increased applications from computer science. Manual notational
65 analysis or coding in sports, even when performed by trained analysts, has limitations. Such methods
66 are typically time intensive, subjective in nature, and prone to human error and bias. Automating
67 sport movement recognition and its application towards coding has the potential to enhance both the
68 efficiency and accuracy of sport performance analysis. The potential automation of recognising
69 human movements, commonly referred to as human activity recognition (HAR), can be achieved
70 through machine or deep learning model approaches. Common data inputs are obtained from inertial
71 measurement units (IMUs) or vision. Detection refers to the identification of a targeted instance, i.e.,
72 tennis strokes within a continuous data input signal (Bulling, Blanke, & Schiele, 2014). Recognition
73 or classification of movements involves further interpretations and labelled predictions of the
74 identified instance (Bulling et al., 2014; Bux, Angelov, & Habib, 2017), i.e., differentiating tennis
75 strokes as a forehand or backhand. In machine and deep learning, a model represents the statistical
76 operations involved in the development of an automated prediction task (LeCun, Yoshua, &
77 Geoffrey, 2015; Shalev-Shwartz & Ben-David, 2014).

78 Human activities detected by inertial sensing devices and computer vision are represented
79 as wave signal features corresponding to specific actions, which can be logged and extracted. Human
80 movement activities are considered hierarchically structured and can be broken down to basic
81 movements. Therefore, the context of signal use, intra-class variability, and inter-class similarity
82 between activities require consideration during experimental set-up and model development.
83 Wearable IMUs contain a combination of accelerometer, gyroscope, and magnetometer sensors
84 measuring along one to three axes. These sensors quantify acceleration, angular velocity, and the
85 direction and orientation of travel respectively (Gastin, McLean, Breed, & Spittle, 2014). These
86 sensors can capture repeated movement patterns during sport training and competitions (Camomilla,
87 Bergamini, Fantozzi, & Vannozzi, 2018; Chambers, Gabbett, Cole, & Beard, 2015; J. F. Wagner,
88 2018). Advantages include being wireless, lightweight and self-contained in operation. Inertial
89 measurement units have been utilised in quantifying physical output and tackling impacts in
90 Australian Rules football (Gastin et al., 2014; Gastin, McLean, Spittle, & Breed, 2013) and rugby

91 (Gabbett, Jenkins, & Abernethy, 2012, 2011; Howe, Aughey, Hopkins, Stewart, & Cavanagh, 2017;
92 Hulin, Gabbett, Johnston, & Jenkins, 2017). Other applications include swimming analysis (Mooney,
93 Corley, Godfrey, Quinlan, & ÓLaighin, 2015), golf swing kinematics (Lai, Hetchl, Wei, Ball, &
94 McLaughlin, 2011), over-ground running speeds (Wixted, Billing, & James, 2010), full motions in
95 alpine skiing (Yu et al., 2016); and the detection and evaluation of cricket bowling (McNamara,
96 Gabbett, Blanch, & Kelly, 2017; McNamara, Gabbett, Chapman, Naughton, & Farhart, 2015;
97 Wixted, Portus, Spratford, & James, 2011).

98 Computer vision has applications for performance analysis including player tracking,
99 semantic analysis, and movement analysis (Stein et al., 2018; Thomas, Gade, Moeslund, Carr, &
100 Hilton, 2017). Automated movement recognition approaches require several pre-processing steps
101 including athlete detection and tracking, temporal cropping and targeted action recognition, which
102 are dependent upon the sport and footage type (Barris & Button, 2008; Saba & Altameem, 2013;
103 Thomas et al., 2017). Several challenges including occlusion, viewpoint variations, and
104 environmental conditions may impact results, depending on the camera set-up (Poppe, 2010; Zhang
105 et al., 2017). Developing models to automate sports-vision coding may improve resource efficiency
106 and reduce feedback times. For example, coaches and athletes involved in time-intensive notational
107 tasks, including post-swim race analysis, may benefit from rapid objective feedback before the next
108 race in the event program (Liao, Liao, & Liu, 2003; Victor, He, Morgan, & Miniutti, 2017). For
109 detecting and recognising movements, body worn sensor signals do not suffer from the same
110 environmental constraints and stationary set-up of video cameras. Furthermore, multiple sensors
111 located on different body segments have been argued to provide more specific signal representations
112 of targeted movements (J. B. Yang, Nguyen, San, Li, & Shonali, 2015). But it is not clear if this is
113 solely conclusive, and the use of body worn sensors in some sport competitions may be impractical
114 or not possible.

115 Machine learning algorithms learn from data input for automated model building and
116 perform tasks without being explicitly programmed. The algorithm goal is to output a response
117 function $h\sigma(\bar{x})$ that will predict a ground truth variable y from an input vector of variables \bar{x} . Models
118 are run for classification techniques to predict a target class (Kotsiantis, Zaharakis, & Pintelas, 2007),
119 or regression to predict discrete or continuous values. Models are aimed at finding an optimal set of
120 parameters σ to describe the response function, and then make predictions on unseen unlabelled data

121 input. Within these, model training approaches can generally run as supervised learning,
122 unsupervised learning or semi-supervised learning (Mohammed, Khan, & Bashier, 2016; Sze, Chen,
123 Yang, & Emer, 2017).

124 Processing raw data is limited for conventional machine learning algorithms, as they are
125 unable to effectively be trained on abstract and high-dimensional data that is inconsistent, contains
126 missing values or noisy artefacts (Bux et al., 2017; Kautz, 2017). Consequently, several pre-
127 processing stages are required to create a suitable data form for input into the classifier algorithm
128 (Figo, Diniz, Ferreira, & Cardoso, 2010). Filtering (Figo et al., 2010; Wundersitz, Gastin, Robertson,
129 Davey, & Netto, 2015), window capture durations (Mitchell, Monaghan, & O'Connor, 2013; Preece,
130 Goulermas, Kenney, & Howard, 2009; Wundersitz, Josman, et al., 2015), and signal frequency cut-
131 offs (Wundersitz, Gastin, Richter, Robertson, & Netto, 2015; Wundersitz, Gastin, Robertson, et al.,
132 2015) are common techniques applied prior to data prior to dynamic human movement recognition.
133 Well-established filters for processing motion signal data include the Kalman filter (Kautz, 2017;
134 Titterton & Weston, 2009; D. Wagner, Kalischewski, Velten, & Kummert, 2017) and a Fourier
135 transform filter (Preece, Goulermas, Kenney, Howard, et al., 2009) such as a fast Fourier transform
136 (Kapela, Świetlicka, Rybarczyk, Kolanowski, & O'Connor, 2015; Preece, Goulermas, Kenney, &
137 Howard, 2009). Near real-time processing benefits from reducing memory requirements,
138 computational demands, and essential bandwidth during whole model implementation. Signal
139 feature extraction and selection favours faster processing by reducing the signals to the critical
140 features that can discriminate the targeted activities (Bulling et al., 2014). Feature extraction involves
141 identifying the key features that help maximise classifier success, and removing features that have
142 minimal impact in the model (Mannini & Sabatini, 2010). Thus, feature selection involves
143 constructing data representations in subspaces with reduced dimensions. These identified variables
144 are represented in a compact feature variable (Mannini & Sabatini, 2010). Common methods include
145 principal component analysis (PCA) (Gløersen, Myklebust, Hallén, & Federolf, 2018; Young &
146 Reinkensmeyer, 2014), vector coding techniques (Hafer & Boyer, 2017) and empirical cumulative
147 distribution functions (ECDF) (Plötz, Hammerla, & Olivier, 2011). An ECDF approach has been
148 shown to be advantageous over PCA as it derives representations of raw input independent of the
149 absolute data ranges, whereas PCA is known to have reduced performance when the input data is not
150 properly normalised (Plötz et al., 2011). For further detailed information on the acquisition, filtering

151 and analysis of IMU data for sports application and vision-based human activity recognition, see
152 (Kautz, 2017) and (Bux et al., 2017), respectively.

153 Deep learning is a division of machine learning, characterised by deeper neural network
154 model architectures and are inspired by the biological neural networks of the human brain (Bengio,
155 2013; LeCun et al., 2015; Sze et al., 2017). The deeper hierarchical models create a profound
156 architecture of multiple hidden layers based on representative learning with several processing and
157 abstraction layers (Bux et al., 2017; J. B. Yang et al., 2015). These computational models allow data
158 input features to be automatically extracted from raw data and transformed to handle unstructured
159 data, including vision (LeCun et al., 2015; Ravi, Wong, Lo, & Yang, 2016). This direct input avoids
160 several processing steps required in machine learning during training and testing, therefore reducing
161 overall computational times. A current key element within deep learning is backpropagation (Hecht-
162 Nielsen, 1989; LeCun, Bottou, Orr, & Müller, 1998). Backpropagation is a fast and computationally
163 efficient algorithm, using gradient descent, that allows training deep neural networks to be tractable
164 (Sze et al., 2017). Human activity recognition has mainly been performed using conventional
165 machine learning classifiers. Recently, deep learning techniques have enhanced the bench mark and
166 applications for IMUs (Kautz et al., 2017; Ravi et al., 2016; Ronao & Cho, 2016; J. B. Yang et al.,
167 2015; Zebin, Scully, & Ozanyan, 2016; Zeng et al., 2014) and vision (Ji, Yang, Yu, & Xu, 2013;
168 Karpathy et al., 2014a; Krizhevsky, Sutskever, & Hinton, 2012; Nibali, He, Morgan, & Greenwood,
169 2017) in human movement recognition producing more superior model performance accuracy.

170 The objective of this study was to systematically review the literature investigating sport-
171 specific automated movement detection and recognition. The review focusses on the various
172 technologies, analysis techniques and performance outcome measures utilised. There are several
173 reviews within this field that are sensor-based including wearable IMUs for lower limb biomechanics
174 and exercises (Fong & Chan, 2010; M. O'Reilly, Caulfield, Ward, Johnston, & Doherty, 2018),
175 swimming analysis (Magalhaes, Vannozzi, Gatta, & Fantozzi, 2015; Mooney et al., 2015),
176 quantifying sporting movements (Chambers et al., 2015) and physical activity monitoring (C. C.
177 Yang & Hsu, 2010). A recent systematic review has provided an evaluation on the in-field use of
178 inertial-based sensors for various performance evaluation applications (Camomilla et al., 2018).
179 Vision-based methods for human activity recognition (Aggarwal & Xia, 2014; Bux et al., 2017; Ke
180 et al., 2013; Zhang et al., 2017), semantic human activity recognition (Ziaefard & Bergevin, 2015)

181 and motion analysis in sport (Barris & Button, 2008) have also been reviewed. However, to date,
182 there is no systematic review across sport-specific movement detection and recognition via machine
183 or deep learning. Specifically, incorporating IMUs and vision-based data input, focussing on in-field
184 applications as opposed to laboratory-based protocols and detailing the analysis and machine
185 learning methods used.

186 Considering the growth in research and potential field applications, such a review is required
187 to understand the research area. This review aims to characterise the evolving techniques and inform
188 researchers of possible improvements in sports analysis applications. Specifically: 1) What is the
189 current scope for IMUs and computer vision in sport movement detection and recognition? 2) Which
190 methodologies, inclusive of signal processing and model learning techniques, have been used to
191 achieve sport movement recognition? 3) Which evaluation methods have been used in assessing the
192 performance of these developed models?

194 **2. Methods**

196 **2.1 Search strategy**

197 The preferred PRISMA recommendations (Moher, Liberati, Tetzlaff, Altman, & Group, 2009) for
198 systematic reviews were used. A literature search was undertaken by the first author on the following
199 databases; IEEE Xplore, PubMed, ScienceDirect, Scopus, Academic Search Premier, and Computer
200 and Applied Science Complete. The searched terms were categorised in order to define the specific
201 participants, methodology and evaluated outcome measure in-line with the review aims. Searches
202 used a combination of key words with AND/OR phrases which are detailed in Table 1. Searches
203 were filtered for studies from January 2000 to May 2018 as no relevant studies were identified prior
204 to this. Further studies were manually identified from the bibliographies of database-searched studies
205 identified from the abstract screen phase, known as snowballing. Table 2 provides the inclusion and
206 exclusion criteria of this review.

208 *****Table 1 near here: Key word search term strings per database*****

210 *****Table 2 near here: Inclusion and exclusion criteria*****

211

212 2.2 Data extraction

213 The first author extracted and collated the relevant information from the full manuscripts identified
214 for final review. A total of 18 parameters were extracted from the 52 research studies, including the
215 title, author, year of publication, sport, participant details, sport movement target(s), device
216 specifications, device sample frequency, pre-processing methods, processing methods, feature
217 selected, feature extraction, machine learning model used, model evaluation, model performance
218 accuracy, validation method, samples collected, and computational information. A customised
219 Microsoft Excel™ spreadsheet was developed to categorise the relevant extracted information from
220 each study. Participant characteristics of number of participants, gender, and competition level, then
221 if applicable a further descriptor specific to a sport, for example, ‘medium-paced cricket bowler’.
222 Athlete and participant experience level was categorised as written in the corresponding study to
223 avoid misrepresentations. The age of participants was not considered an important characteristic
224 required for model development. The individual ability in which the movement is performed
225 accounts for the discriminative signal features associated with the movements. For the purposes of
226 this review, a sport-specific movement was defined from a team or individual sport, and training
227 activities associated with a particular sport. For example, weight-lifting as strength training,
228 recognised under the Global Association of International Sports Federations. The targeted sports and
229 specific movements were defined for either detection or recognition. Model development techniques
230 used included pre-processing methods to transform data to a more suitable form for analysis,
231 processing stages to segment data for identified target activities, feature extraction and selections
232 techniques, and the learning algorithm(s). Model evaluation measures extracted were the model
233 performance assessment techniques used, ground-truth validation comparison, number of data
234 samples collected, and the model performance outcomes results reported. If studies ran multiple
235 experiments using several algorithms, only the superior algorithm and relevant results were reported
236 as the best method. This was done so in the interest of concise reporting to highlight favourable
237 method approaches (Sprager & Juric, 2015). Any further relevant results or information identified
238 from the studies was included as a special remark (Sprager & Juric, 2015). Hardware and
239 specification information extracted included the IMU or video equipment used, number of units,

240 attachment of sensors (IMUs), sample frequency, and sensor data types used in analysis (IMUs).

241 Studies identified and full data extracted were reviewed by a second author.

242

243 **3. Results**

244

245 An outline of the search results and study exclusions has been provided in Fig 1. Of the initial
246 database search which identified 4885 results, a **final 52 studies** met criteria for inclusion in this
247 review. Of these, 29 used IMUs **and 22 were vision-based**. One study (Ó Conaire et al., 2010) used
248 both sensors and vision for model development separately then together via data fusion. Tables 3 - 8
249 provide a description of the characteristics of the reviewed studies, detailed in the following sections.

250

251 ***** Fig 1 near here: PRISMA flow diagram *****

252

253 **3.1 Experimental design**

254 A variety of sports and their associated sport-specific movements were investigated, implementing
255 various experimental designs as presented in Tables 5 and 7. Across the studies, sports reported were
256 tennis (n = 10), cricket (n = 3), weightlifting or strength training (n = 6), swimming (n = 4),
257 skateboarding (n = 2), ski jumping (n = 2), snowboarding (n = 1), golf (n = 4), **volleyball (n = 2)**,
258 **rugby (n = 2)**, **ice hockey (n = 2)**, gymnastics (n = 2), karate (n = 1), **basketball (n = 3)**, Gaelic football
259 (n = 1), hurling (n = 1), boxing (n = 2), running (n = 2), diving (n = 1), squash (n = 1), badminton (n
260 = 1), cross-country skiing (n = 2) and soccer (n = 4). The Sports 1-M dataset (Karpathy et al., 2014b)
261 was also reported, which consists of 1,133,158 video URLs annotated automatically with 487 sport
262 labels using the YouTube Topic API. A dominant approach was the classification of main
263 characterising actions for each sport. For example, serve, forehand, backhand strokes in tennis
264 (Connaghan et al., 2011; Kos & Kramberger, 2017; Ó Conaire et al., 2010; Shah, Chokalingam,
265 Paluri, & Pradeep, 2007; Srivastava et al., 2015), and the four competition strokes in swimming
266 (Jensen, Blank, Kugler, & Eskofier, 2016; Jensen, Prade, & Eskofier, 2013; Liao et al., 2003; Victor
267 et al., 2017). Several studies further classified sub-categories of actions. For example, three further
268 classes of the two main classified snowboarding trick types Grinds and Airs (Groh, Fleckenstein, &
269 Eskofier, 2016), and further classifying the main tennis stroke types as either flat, topspin or slice

270 (Srivastava et al., 2015). Semantic descriptors were reported for classification models that predicted
271 athlete training background, experience and fatigue level. These included running (Buckley et al.,
272 2017; Kobsar, Osis, Hettinga, & Ferber, 2014), rating of gymnastic routines (Reily, Zhang, & Hoff,
273 2017), soccer pass classification based on its quality (Horton, Gudmundsson, Chawla, & Estephan,
274 2014), cricket bowling legality (Qaisar et al., 2013; Salman, Qaisar, & Qamar, 2017), ski jump error
275 analysis (Brock & Ohgi, 2017; Brock, Ohgi, & Lee, 2017) and strength training technique deviations
276 (M. A. O'Reilly, Whelan, Ward, Delahunt, & Caulfield, 2017a; M. O'Reilly et al., 2015; M.
277 O'Reilly, Whelan, Ward, Delahunt, & Caulfield, 2017). One approach (Yao & Fei-Fei, 2010),
278 encoded the mutual context of human pose and sporting equipment using semantics, to facilitate the
279 detection and classification of movements including a cricket bat and batsman coupled movements.

280 Total participant numbers for IMU-based studies ranged from one (Qaisar et al., 2013) to 30
281 (Kautz et al., 2017). Reported data individual instance sample sizes for sensor studies ranged from
282 150 (Salman et al., 2017) to 416, 737 (Rassem, El-Beltagy, & Saleh, 2017). Vision-based studies
283 that explicitly reported total participant details ranged from five (Ó Conaire et al., 2010) to 40 (Victor
284 et al., 2017). Vision dataset sample sizes varied across studies, from 50 individual action clips (Liao
285 et al., 2003) to 15, 000 (Victor et al., 2017). One study (Karpathy et al., 2014a) used the publicly
286 available Sports-1M, as previously described. Vision-based studies also reported datasets in total
287 time, 10.3 hours (Bertasius, Park, Yu, & Shi, 2017), 3 hours (Montoliu, Martín-Félez, Torres-
288 Sospedra, & Martínez-Usó, 2015), 1, 500 minutes (Shah et al., 2007), and 50 hours (Kapela et al.,
289 2015), and by frame numbers, 6, 035 frames (Zhu, Xu, Gao, & Huang, 2006) and 10, 115 frames
290 (Reily et al., 2017).

291

292 **3.2 Inertial measurement unit specifications**

293 A range of commercially available and custom-built IMUs were used in the IMU-based studies (n=
294 30), as presented in Table 3. Of these, 23% reported using a custom-built sensor. Of the IMU-based
295 studies, the number of sensors mounted or attached to each participant or sporting equipment piece
296 ranged from one to nine. The majority of studies (n= 22) provided adequate details of sensor
297 specifications including sensor type, axes, measurement range, and sample rate used. At least one
298 characteristic of sensor measurement range or sample rate used in data collection was missing from
299 eight studies. All studies used triaxial sensors and collected accelerometer data. For analysis and

300 model development, individual sensor data consisted of only accelerometer data (n = 8), both
301 accelerometer and gyroscope data (n = 15), and accelerometer, gyroscope and magnetometer data (n
302 = 7). The individual sensor measurement ranges reported for accelerometer were ± 1.5 g to ± 16 g,
303 gyroscope ± 500 °/s to ± 2000 °/s, magnetometer ± 1200 μ T or 1.2 to 4 Ga. Individual sensor sample
304 rates ranged from 10 Hz to 1000 Hz for accelerometers, 10 Hz to 500 Hz for gyroscopes and 50 Hz
305 to 500 Hz for magnetometers.

306

307 ***** Table 3 near here*****

308

309 **3.3 Vision capture specification**

310 Several experimental set-ups and specifications were reported in the total **23 vision-based studies**
311 (Table 4). Modality was predominately red, green, blue (RGB) cameras. Depth cameras were utilised
312 (Kasiri-Bidhendi, Fookes, Morgan, Martin, & Sridharan, 2015; Kasiri, Fookes, Sridharan, &
313 Morgan, 2017; Reily et al., 2017), which add depth perception for 3-dimensional image mapping.
314 Seven studies clearly reported the use of a single camera set-up (Couceiro, Dias, Mendes, & Araújo,
315 2013; Díaz-Pereira, Gómez-Conde, Escalona, & Olivieri, 2014; Hachaj, Ogiela, & Koptyra, 2015;
316 Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Nibali et al., 2017; Reily et al., 2017). One study
317 reported 16 stationary positioned cameras at a ‘bird’s eye view’ (Montoliu et al., 2015), and Ó
318 Conaire et al. (2010) reported the use of one overhead and 8 stationary cameras around a tennis court
319 baseline, although data from two cameras were only used in final analysis due to occlusion issues.
320 Sample frequency and, or pixel resolution were reported in seven of the studies (Couceiro et al.,
321 2013; Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al., 2017; Montoliu et al., 2015;
322 Victor et al., 2017; Zhu et al., 2006), with sample frequencies ranging from 30 Hz to 210 Hz.

323

330 2012; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2015, 2017; Rindal, Seeberg, Tjønnås,
331 Haugnes, & Sandbakk, 2018), high-pass filter ($n = 2$) (Kautz et al., 2017; Schuldhaus et al., 2015),
332 or calibration with a filter (Salman et al., 2017). Processing methods were reported in 67% of the
333 IMU-based studies (Adelsberger & Tröster, 2013; Anand, Sharma, Srivastava, Kaligounder, &
334 Prakash, 2017; Brock et al., 2017; Buckley et al., 2017; Buthe, Blanke, Capkevics, & Tröster, 2016;
335 Groh et al., 2016; Groh, Fleckenstein, Kautz, & Eskofier, 2017; Groh, Kautz, & Schuldhaus, 2015;
336 Jensen et al., 2016, 2015; Jiao, Wu, Bie, Umek, & Kos, 2018; Kautz et al., 2017; Kobsar et al., 2014;
337 M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2017; Ó Conaire et al., 2010; Pernek, Kurillo, Stiglic,
338 & Bajcsy, 2015; Qaisar et al., 2013; Salman et al., 2017; Schuldhaus et al., 2015). Methods included,
339 calibration of data (Groh et al., 2016, 2017; Jensen et al., 2015; Qaisar et al., 2013), a one-second
340 window centred around identified activity peaks in the signal (Adelsberger & Tröster, 2013;
341 Schuldhaus et al., 2015), temporal alignment (Pernek et al., 2015), normalisation (Ó Conaire et al.,
342 2010), outlier adjustment (Kobsar et al., 2014) or removal (Salman et al., 2017), and sliding windows
343 ranging from one to 3.5 seconds across the data (Jensen et al., 2016). The three studies that
344 investigated trick classification in skateboarding (Groh et al., 2017, 2015) and snowboarding (Groh
345 et al., 2016) corrected data for different rider board stance styles, termed Regular or Goofy, by
346 inverting signal axes.

347 Movement detection methods were specifically reported in 16 studies (Adelsberger &
348 Tröster, 2013; Anand et al., 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015, Jensen et
349 al., 2013, 2015; Kautz et al., 2017; Kelly et al., 2012; Kos & Kramberger, 2017; Ó Conaire et al.,
350 2010; Rindal et al., 2018; Salman et al., 2017; Schuldhaus et al., 2015; Whiteside, Cant, Connolly,
351 & Reid, 2017). Detection methods included thresholding ($n = 5$), windowing segmenting ($n = 4$), and
352 a combination of threshold and windowing techniques ($n = 5$).

353 Signal feature extraction techniques were reported in 80% of the studies, with the number of
354 feature parameters in a vector ranging from a vector of normalised X, Y, Z accelerometer signals (Ó
355 Conaire et al., 2010) to 240 features (M. A. O'Reilly et al., 2017a). Further feature selection to reduce
356 the dimensionality of the feature vector was used in 11 studies. Both feature extraction and selection
357 methods varied considerably across the literature (Table 5).

358 Algorithms trialled for movement recognition were diverse across the literature (Table 5).
359 Supervised classification using a kernel form of Support Vector Machine (SVM) was most prevalent

360 (n = 16) (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Brock et al., 2017; Buckley et al., 2017;
361 Buthe et al., 2016; Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Kautz et al., 2017; Kelly et al.,
362 2012; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et al., 2017; Schuldhaus et al., 2015;
363 Whiteside et al., 2017). The next highest tested were Naïve Bayesian (NB) (n = 8) (Buckley et al.,
364 2017; Connaghan et al., 2011; Groh et al., 2016, 2017, 2015; Kautz et al., 2017; Salman et al., 2017;
365 Schuldhaus et al., 2015) and k-Nearest Neighbour (kNN) (n = 8) (Buckley et al., 2017; Groh et al.,
366 2016, 2017, 2015; Kautz et al., 2017; Ó Conaire et al., 2010; Salman et al., 2017; Whiteside et al.,
367 2017), followed by Random Forests (RF) (n = 7) (Buckley et al., 2017; Groh et al., 2017; Kautz et
368 al., 2017; M. A. O'Reilly et al., 2017a; M. O'Reilly et al., 2017; Salman et al., 2017; Whiteside et
369 al., 2017). Supervised learning algorithms were the most common (n = 29). One study used an
370 unsupervised discriminative analysis approach for detection and classification of tennis strokes (Kos
371 & Kramberger, 2017). Five IMU-based study investigated a deep learning approach including using
372 Convolutional Neural Networks (CNN) (Anand et al., 2017; Brock et al., 2017; Jiao et al., 2018;
373 Kautz et al., 2017; Rassem et al., 2017) and Long Short Term Memory (LSTM) (Hochreiter &
374 Schmidhuber, 1997) architectures (Rassem et al., 2017; Sharma, Srivastava, Anand, Prakash, &
375 Kaligounder, 2017). In order to assess the effectiveness of the various classifiers from each study,
376 model performance measures quantify and visualise the predictive performance as reported in the
377 following section.

378

379 ***** Table 5 near here*****

380

381 **3.5 Inertial measurement unit recognition model evaluation**

382 Reported performance evaluations of developed models across the IMU-based studies are shown in
383 Table 6. Classification accuracy, as a percentage score for the number of correct predictions by total
384 number of predictions made, was the main model evaluation measure (n = 24). Classification
385 accuracies across studies ranged between 52% (Brock & Ohgi, 2017) to 100% (Buckley et al., 2017).
386 Generally, the reported highest accuracy for a specific movement was $\geq 90\%$ (n = 17) (Adelsberger
387 & Tröster, 2013; Anand et al., 2017; Buckley et al., 2017; Connaghan et al., 2011; Groh et al., 2015;
388 Jensen et al., 2013; Jiao et al., 2018; Kobsar et al., 2014; Kos & Kramberger, 2017; M. A. O'Reilly
389 et al., 2017a; Ó Conaire et al., 2010; Pernek et al., 2015; Qaisar et al., 2013; Rindal et al., 2018;

390 Schuldhaus et al., 2015; Srivastava et al., 2015; Whiteside et al., 2017) and $\geq 80\%$ to 90% ($n = 7$)
391 (Brock & Ohgi, 2017; Brock et al., 2017; Groh et al., 2017; Jensen et al., 2016; M. O'Reilly et al.,
392 2015, 2017; Salman et al., 2017). As an estimate of the generalised performance of a trained model
393 on $n - x$ samples, a form of leave-one-out cross validation (LOO-CV) was used in 47% of studies
394 (Buthe et al., 2016; Groh et al., 2016, 2017, 2015, Jensen et al., 2016, 2013; Kobsar et al., 2014; M.
395 O'Reilly et al., 2015, 2017; Ó Conaire et al., 2010; Pernek et al., 2015; Salman et al., 2017;
396 Schuldhaus et al., 2015). Precision, specificity and sensitivity (also referred to as recall) evaluations
397 were derived for detection ($n = 6$) and classification models ($n = 10$). Visualisation of prediction
398 results in the form of a confusion matrix featured in six studies (Buthe et al., 2016; Groh et al., 2017;
399 Kautz et al., 2017; Pernek et al., 2015; Rindal et al., 2018; Whiteside et al., 2017).

400

401 *** Table 6 near here***

402

403 3.6 Vision recognition model development methods

404 Numerous processing and recognition methods featured across the vision-based studies to transform
405 and isolated relevant input data (Table 7). Pre-processing stages were reported in 14 of studies, and
406 another varied 13 studies also provided details of processing techniques. Signal feature extraction
407 and feature selection methods used were reported in 78% of studies.

408 Both machine ($n = 16$) and deep learning ($n = 7$) algorithms were used to recognise
409 movements from vision data. Of these, a kernel form of the SVM algorithm was most common in
410 the studies ($n = 10$) (Couceiro et al., 2013; Horton et al., 2014; Kasiri-Bidhendi et al., 2015; Kasiri
411 et al., 2017; Li et al., 2018; Montoliu et al., 2015; M. A. O'Reilly, Whelan, Ward, Delahunt, &
412 Caulfield, 2017b; Ó Conaire et al., 2010; Reily et al., 2017; Shah et al., 2007; Zhu et al., 2006). Other
413 algorithms included kNN ($n = 3$) (Díaz-Pereira et al., 2014; Montoliu et al., 2015; Ó Conaire et al.,
414 2010), decision tree (DT) ($n = 2$) (Kapela et al., 2015; Liao et al., 2003), RF ($n = 2$) (Kasiri-Bidhendi
415 et al., 2015; Kasiri et al., 2017), and Multilayer Perceptron (MLP) ($n = 2$) (Kapela et al., 2015;
416 Montoliu et al., 2015). Deep learning was investigated in seven studies (Bertasius et al., 2017;
417 Ibrahim, Muralidharan, Deng, Vahdat, & Mori, 2016; Karpathy et al., 2014a; Nibali et al., 2017;

418 Ramanathan et al., 2015; Tora, Chen, & Little, 2017; Victor et al., 2017) of which used CNNs or
419 LSTM RNNs as the core model structure.

420

421 *** Table 7 near here***

422

423 3.7 Vision recognition model evaluation

424 Performance evaluation methods and results for vision-based studies are reported in Table 8. As with
425 IMU-based studies, classification accuracy was the common method for model evaluations, featured
426 in 61%. Classification accuracies were reported between 60.9% (Karpathy et al., 2014a) and 100%
427 (Hachaj et al., 2015; Nibali et al., 2017). In grouping the reported highest accuracies for a specific
428 movement that were $\geq 90\%$ ($n = 9$) (Hachaj et al., 2015; Kasiri-Bidhendi et al., 2015; Kasiri et al.,
429 2017; Li et al., 2018; Montoliu et al., 2015; Nibali et al., 2017; Ó Conaire et al., 2010; Reily et al.,
430 2017; Shah et al., 2007), and $\geq 80\%$ to 90% ($n = 2$) (Horton et al., 2014; Yao & Fei-Fei, 2010). A
431 confusion matrix as a visualisation of model prediction results was used in nine studies (Couceiro et
432 al., 2013; Hachaj et al., 2015; Ibrahim et al., 2016; Karpathy et al., 2014a; Kasiri-Bidhendi et al.,
433 2015; Kasiri et al., 2017; Lu, Okuma, & Little, 2009; Shah et al., 2007; Tora et al., 2017). Two
434 studies assessed and reported their model computational average speed (Lu et al., 2009) and time
435 (Reily et al., 2017).

436

438

439 4 Discussion

440

441 The aim of this systematic review was to evaluate the use of machine and deep learning for sport-
442 specific movement recognition from IMUs and, or computer vision data inputs. Overall, the search
443 yielded 52 studies, categorised as 29 which used IMUs, 22 vision-based and one study using both
444 IMUs and vision. Automation or semi-automated sport movement recognition models working in
445 near-real time is of particular interest to avoid the error, cost and time associated with manual
446 methods. Evident in the literature, models are trending towards the potential to provide optimised

447 objective assessments of athletic movement for technical and tactical evaluations. The majority of
448 studies achieved favourable movement recognition results for the main characterising actions of a
449 sport, with several studies exploring further applications such as an automated skill quality evaluation
450 or judgement scoring, for example automated ski jump error evaluation (Brock et al., 2017).

451 Experimental set-up of IMU placement and numbers assigned per participant varied between
452 sporting actions. The sensor attachment locations set by researchers appeared dependent upon the
453 specific sporting conditions and movements, presumably to gain optimal signal data. Proper fixation
454 and alignment of the sensor axes with limb anatomical axes is important in reducing signal error
455 (Fong & Chan, 2010). The attachment site hence requires a biomechanical basis for accuracy of the
456 movement being targeted to obtain reliable data. Single or multiple sensor use per person also
457 impacts model development trade-off between accuracy, analysis complexity, and computational
458 speed or demands. In tennis studies, specificity whilst using a single sensor was demonstrated by
459 mounting the IMU on the wrist or forearm of the racquet arm (Connaghan et al., 2011; Kos &
460 Kramberger, 2017; Srivastava et al., 2015; Whiteside et al., 2017). A single sensor may also be
461 mounted in a low-profile manner on sporting equipment (Groh et al., 2016, 2017, 2015; Jensen et
462 al., 2015). Unobtrusive use of a single IMU to capture generalised movements across the whole body
463 was demonstrated, with an IMU mounted on the posterior head in swimming (Jensen et al., 2016,
464 2013), lower back during running (Kobsar et al., 2014), and between the shoulder blades in rugby
465 union (Kelly et al., 2012).

466 The majority of vision-based studies opted for a single camera set-up of RGB modality. Data
467 output from a single camera as opposed to multiple minimises the volume of data to process,
468 therefore reducing computational effort. However, detailed features may go uncaptured, particularly
469 in team sport competition which consists of multiple individuals participating in the capture space at
470 one time. In contrast, a multiple camera set-up reduces limitations including occlusion and viewpoint
471 variations. However, this may also increase the complexity of the processing and model
472 computational stages. Therefore, a trade-off between computational demands and movement
473 recording accuracy often needs to be made. As stated earlier, the placement of cameras needs to suit
474 the biomechanical nature of the targeted movement and the environment situated in. Common
475 camera capture systems used in sports science research such as Vicon Nexus (Oxford, UK) and
476 OptiTrack (Oregon, USA) were not present in this review. As this review targeted studies

477 investigating during on-field or in-situation sporting contexts, efficiency in data collection is key for
478 routine applications in training and competition. A simple portable RGB camera is easy to set-up in
479 a dynamic and changing environment, such as different soccer pitches, rather than a multiple capture
480 system such as Vicon that requires calibrated precision and are substantially more expensive.

481 Data acquisition and type from an IMU during analysis appears to influence model trade-off
482 between accuracy and computational effort of performance. The use of accelerometer, gyroscope or
483 magnetometer data may depend upon the movement properties analysed. Within tennis studies,
484 gyroscope signals were the most efficient at discriminating between stroke types (Buthe et al., 2016;
485 Kos & Kramberger, 2017) and detecting an athlete's fast feet court actions (Buthe et al., 2016). In
486 contrast, accelerometer signals produced higher classification accuracies in classifying tennis stroke
487 skills levels (Connaghan et al., 2011). The authors expected lower gyroscope classification
488 accuracies as temporal orientation measures between skill levels of tennis strokes will differ
489 (Connaghan et al., 2011). Conversely, data fusion from all three individual sensors resulted in a more
490 superior model for classifying advanced, intermediate and novices tennis player strokes (Connaghan
491 et al., 2011). Fusion of accelerometer and vision data also resulted in a higher classification accuracy
492 for tennis stroke recognition (Ó Conaire et al., 2010).

493 Supervised learning approaches were dominant across IMU and vision-based studies. This
494 is a method which involves a labelled ground truth training dataset typically manually annotated by
495 sport analysts. Labelled data instances were recorded as up to 15, 000 for vision-based (Victor et al.,
496 2017) and 416, 737 for sensor-based (Rassem et al., 2017) studies. Generation of a training data set
497 for supervised learning can be a tedious and labour-intensive task. It is further complicated if multiple
498 sensors or cameras are incorporated for several targeted movements. A semi-supervised or
499 unsupervised learning approach may be advantageous as data labelling is minimal or not required,
500 potentially reducing human errors in annotation. An unsupervised approach could suit specific
501 problems to explain key data features, via clustering (Mohammed et al., 2016; Sze et al., 2017).
502 Results computed by an unsupervised model (Kos, Ženko, Vlaj, & Kramberger, 2016) for tennis
503 serve, forehand and backhand stroke classification compared favourably well against a proposed
504 supervised approach (Connaghan et al., 2011).

505 Recognition of sport-specific movements was primarily achieved using conventional
506 machine learning approaches, however nine studies implemented deep learning algorithms. It is

507 expected that future model developments will progressively feature deep learning approaches due to
508 development of better hardware, and the advantages of more efficient model learning on large data
509 inputs (Sze et al., 2017). Convolutional Neural networks (CNN) (LeCun, Bottou, Bengio, & Haffner,
510 1998) were the core structure of five of the seven deep learning study models. Briefly, convolution
511 applies several filters, known as kernels, to automatically extract features from raw data inputs. This
512 process works under four key ideas to achieve optimised results: local connection, shared weights,
513 pooling and applying several layers (LeCun et al., 2015; J. B. Yang et al., 2015). Machine learning
514 classifiers modelled with generic hand-crafted features, were compared against a CNN for
515 classifying nine beach volleyball actions using IMUs (Kautz et al., 2017). Unsatisfactory results were
516 obtained from the machine learning model, and the CNN markedly achieved higher classification
517 accuracies (Kautz et al., 2017). The CNN model produced the shortest overall computation times,
518 requiring less computational effort on the same hardware (Kautz et al., 2017). Vision-based CNN
519 models have also shown favourable results when compared to a machine learning study baseline
520 (Karpathy et al., 2014a; Nibali et al., 2017; Victor et al., 2017). Specifically, consistency between a
521 swim stroke detection model for continuous videos in swimming which was then applied to tennis
522 strokes with no domain-specific settings introduced (Victor et al., 2017). The authors of this training
523 approach (Victor et al., 2017) anticipate that this could be applied to train separate models for other
524 sports movement detection as the CNN model demonstrated the ability to learn to process continuous
525 videos into a 1-D signal with the signal peaks corresponding to arbitrary events. General human
526 activity recognition using CNN have shown to be a superior approach over conventional machine
527 learning algorithms using both IMUs (Ravi et al., 2016; J. B. Yang et al., 2015; Zebin et al., 2016;
528 Zeng et al., 2014; Zheng, Liu, Chen, Ge, & Zhao, 2014) and computer vision (Ji et al., 2013;
529 Krizhevsky et al., 2012; LeCun et al., 2015). As machine learning algorithms extract heuristic
530 features requiring domain knowledge, this creates shallower features which can make it harder to
531 infer high-level and context aware activities (J. B. Yang et al., 2015). Given the previously described
532 advantages of deep learning algorithms which apply to CNN, and the recent results of deep learning,
533 future model developments may benefit from exploring these methods in comparison to current
534 bench mark models.

535 Model performance outcome metrics quantify and visualise the error rate between the
536 predicted outcome and true measure. Comparatively, a kernel form of an SVM was the most common

537 classifier implemented and produced the strongest machine learning approach model prediction
538 accuracies across both IMU (Adelsberger & Tröster, 2013; Brock & Ohgi, 2017; Buthe et al., 2016;
539 Groh et al., 2016, 2017, 2015; Jensen et al., 2016; Pernek et al., 2015; Salman et al., 2017; Schuldhaus
540 et al., 2015; Whiteside et al., 2017) and vision-based study designs (Horton et al., 2014; Kasiri-
541 Bidhendi et al., 2015; Kasiri et al., 2017; Li et al., 2018; Reily et al., 2017; Shah et al., 2007; Zhu et
542 al., 2006). Classification accuracy was the most common reported measure followed by confusion
543 matrices, as ways to clearly present prediction results and derive further measures of performance.
544 Further measures included sensitivity (also called recall), specificity and precision, whereby results
545 closer to 1.0 indicate superior model performance, compared to 0.0 or poor model performance. The
546 F1-score (also called a F-measure or F-score) conveys the balances between the precision and
547 sensitivity of a model. An in-depth analysis performance metrics specific to human activity
548 recognition is located elsewhere (Minnen, Westeyn, Starner, Ward, & Lukowicz, 2006; Ward,
549 Lukowicz, & Gellersen, 2011). Use of specific evaluation methods depends upon the data type.
550 Conventional performance measures of error rate are generally unsuitable for models developed from
551 skewed training data (Provost & Fawcett, 2001). Using conventional performance measures in this
552 context will only take the default decision threshold on a model trained, if there is an uneven class
553 distribution this may lead to imprecision (Provost & Fawcett, 2001; Seiffert, Khoshgoftaar, Van
554 Hulse, & Napolitano, 2008). Alternative evaluators including Receiver Operating Characteristics
555 (ROC) curves and its single numeric measure, Area Under ROC Curve (AUC), report model
556 performances across all decision thresholds (Seiffert et al., 2008). Making evaluations between study
557 methodology have inherent complications due to each formulating their own experimental parameter
558 settings, feature vectors and training algorithms for movement recognition. The No-Free-Lunch
559 theorems are important deductions in the formation of models for supervised machine learning
560 (David H. Wolpert, 1996), and search and optimisation algorithms (D H Wolpert & Macready, 1997).
561 The theorems broadly reference that there is no ‘one model’ that will perform optimally across all
562 recognition problems. Therefore, experiments with multiple model development methods for a
563 particular problem is recommended. The use of prior knowledge about the task should be
564 implemented to adapt the model input and model parameters in order to improve overall model
565 success (Shalev-Shwartz & Ben-David, 2014).

566 Acquisition of athlete specific information, including statistics on number, type and intensity
567 of actions, may be of use in the monitoring of athlete load. Other potential applications include
568 personalised movement technique analysis (M. O'Reilly et al., 2017), automated performance
569 evaluation scoring (Reily et al., 2017) and team ball sports pass quality rating (Horton et al., 2014).
570 However, one challenge lies in delivering consistent, individualised models across team field sports
571 that are dynamic in nature. For example, classification of soccer shots and passes showed a decline
572 in model performance accuracy from a closed environment to a dynamic match setting (Schuldhaus
573 et al., 2015). A method to overcome accuracy limitations in dynamic team field sports associated
574 with solely using IMUs or vision may be to implement data fusion (Ó Conaire et al., 2010).
575 Furthermore, vision and deep learning approaches have demonstrated the ability to track and classify
576 team sport collective court activities and individual player specific movements in volleyball (Ibrahim
577 et al., 2016), basketball (Ramanathan et al., 2015) and ice hockey (Tora et al., 2017). Accounting for
578 methods from experimental set-up to model evaluation, previous reported models should be
579 considered and adapted based on the current problem. Furthermore, the balance between model
580 computational efficiency, results accuracy and complexity trade-offs calculations are an important
581 factor.

582 In the present study, meta-analysis was considered however variability across developed
583 model parameter reporting and evaluation methods did not allow for this to be undertaken. As this
584 field expands and further methodological approaches are investigated, it would be practical to review
585 analysis approaches both within and between sports. This review was delimited to machine and deep
586 learning approaches to sport movement detection and recognition. However, statistical or parametric
587 approaches not considered here such as discriminative functional analysis may also show efficacy
588 for sport-specific movement recognition. However, as the field of machine learning is a rapidly
589 developing area shown to produce superior results, a review encompassing all possible other methods
590 may have complicated the reporting. Since sport-specific movements and their environments alter
591 the data acquisition and analysis, the sports and movements reported in the present study provide an
592 overview of the current field implementations.

596 This systematic review reported on the literature using machine and deep learning methods to
597 automate sport-specific movement recognition. In addressing the research questions, both IMUs and
598 computer vision have demonstrated capacity in improving the information gained from sport
599 movement and skill recognition for performance analysis. A range of methods for model
600 development were used across the reviewed studies producing varying results. Conventional machine
601 learning algorithms such as Support Vector Machines and Neural Networks were most commonly
602 implemented. Yet in those studies which applied deep learning algorithms such as Convolutional
603 Neural Networks, these methods outperformed the machine learning algorithms in comparison.
604 Typically, the models were evaluated using a leave-one-out cross validation method and reported
605 model performances as a classification accuracy score. Intuitively, the adaptation of experimental
606 set-up, data processing, and recognition methods used are best considered in relation to the
607 characteristics of the sport and targeted movement(s). Consulting current models within or similar to
608 the targeted sport and movement is of benefit to address bench mark model performances and identify
609 areas for improvement. The application within the sporting domain of machine learning and
610 automated sport analysis coding for consistent uniform usage appears currently a challenging
611 prospect, considering the dynamic nature, equipment restrictions and varying environments arising
612 in different sports.

56
613 Future work may look to adopt, adapt and expand on current models associated with a
614 specific sports movement to work towards flexible models for mainstream analysis implementation.
615 Investigation of deep learning methods in comparison to conventional machine learning algorithms
616 would be of particular interest to evaluate if the trend of superior performances is beneficial for sport-
617 specific movement recognition. Analysis as to whether IMUs and vision alone or together yield
618 enhanced results in relation to a specific sport and its implementation efficiency would also be of
619 value. In consideration of the reported study information, this review can assist future researchers in
620 broadening investigative approaches for sports performance analysis as a potential to enhancing upon
621 current methods.
