**Figure S30:** Job's plot between  $\text{Cu}^{2+}$  and L2 in DMSO. It confirms 1:1 binding mode.

**Figure S31:** Job's plot between  $\text{Cu}^{2+}$  and L3 in DMSO. It confirms 2:1 binding mode.

### Binding constant determination by Modified Tsien equation:

The stoichiometry between  $\text{Cu}^{2+}$  ions and L3 is 2:1 which has been calculated by using Job's method. Equation 1 shows complex formation between  $\text{Cu}^{2+}$  ions (B) and L1 (A). The ratio between  $\text{Cu}^{2+}$  ions and L1 is m:n.

where  $K$  is the equilibrium constant of the reaction. According to the modified Stern-Volmer equation, the relationship between the change in the fluorescence intensities, the concentration of  $\text{Cu}^{2+}$  [B] and the total concentration of L1 [A] can be expressed as follows:

$$\frac{F_0 - F}{F} = K[A]^{n-1}B^m \quad (2)$$

suppose the change in the fluorescence intensities ( $\Delta F$ ) =  $F_0 - F$ , the equation 2 will be

$$\log(\Delta F/F) = \log k + (n - 1)\log[A] + m\log[B], \quad (3)$$

Where  $F_0$  and  $F$  represent the fluorescence intensities of L1 in the absence and in the presence of  $\text{Cu}^{2+}$ , respectively. The relative fluorescence intensity,  $\alpha$ , can be experimentally determined by measuring the fluorescence intensity,

$$\alpha = \frac{F - F_1}{F_0 - F_1} \quad (4)$$

Here,  $F$  is the fluorescence intensity of L1 in presence of different equivalent of  $\text{Cu}^{2+}$ .  $F_1$  is the maximum fluorescence intensity of L1- $\text{Cu}^{2+}$  system.  $F_0$  is the fluorescence intensity of L1 and the relationship between  $\alpha$  and  $\text{Cu}^{2+}$  concentrations can be shown by modified Tsien equation

$$[M^{n+}]^m = \frac{1}{n \cdot K} \cdot \frac{1}{[L]_T^{n-1}} \cdot \frac{1 - \alpha}{\alpha^n} \quad (5)$$

$n$  is the charge on the metal ion.  $m$  is the number of metal ion bound to the ligand. [L] is the concentration of the ligand. The response of L1 with different concentrations of  $\text{Cu}^{2+}$  has been fitted by using equation 5.

### The binding constant $K$ determination by the Benesi-Hildebrand equation

The binding constant  $K$  for L2-  $\text{Cu}^{2+}$  system was determined by the Benesi-Hildebrand equation. Based on the assumption that the fluorescence change is only induced by the formation of a 1:1 complex between L2 and metal ion (M), the equilibrium can be expressed by the following equations:

$$1/(F - F_0) = 1/\{K(F_{max} - F_0)[\text{Cu}^{2+}]\} + 1/(F_{max} - F_0) \quad (6)$$

where  $F_0$  is the fluorescence intensity of L2 in absence of  $\text{Cu}^{2+}$ ,  $F$  is the fluorescence intensity of L2 at any given  $\text{Cu}^{2+}$  concentration and  $F_{\text{max}}$  is the maximum fluorescence intensity of L2 in presence of  $\text{Cu}^{2+}$  in solution. The association constant  $K$  was evaluated graphically by plotting  $1/(F - F_0)$  against  $1/[\text{Cu}^{2+}]$ . Binding constant was obtained from the slope and intercept.

**Figure S32:** Benesi-Hildebrand plot of L2 with  $\text{Cu}^{2+}$  ions assuming 1:1 binding stoichiometry in DMSO.

**Figure S33:** Response parameter values ( $\alpha$ ) vs  $\log [\text{Cu}^{2+}]$  for L3 in DMSO.

**Figure S34:** Plot of intensity of L2 ( $75\mu\text{M}$ ) with respect to  $[\text{Cu}^{2+}]$  ( $15\text{-}135\mu\text{M}$ ).  $\lambda_{\text{ex}}$  was  $345\text{ nm}$ .

**Figure S35:** Plot of intensity of L3 ( $75\mu\text{M}$ ) with respect to  $[\text{Cu}^{2+}]$  ( $15\text{-}180\mu\text{M}$ ) in DMSO.  $\lambda_{\text{ex}}$  was  $345\text{ nm}$ .
