Abstract—In this article, a novel millimeter-wave dual-polarized 2-D multibeam antenna array incorporating differentially fed antenna elements is proposed to achieve high cross-polarization discrimination (XPD) when the beams scan to the maximal pointing angles. The antenna element is composed of an SIW cavity with four shorted patches placed inside, and it is differentially excited for dual-polarization by a pair of feeding strips and transverse slots beneath the patches. Differential excitation is realized by a power divider designed on two laminate layers. Two Butler matrices placed perpendicularly with each other in different laminates are employed to generate four tilted beams with dual-polarization. A 2×2 dual-polarized 2-D multibeam antenna array working at 28 GHz is designed, fabricated, and measured. The operation bandwidth of the antenna is 26.8–29.2 GHz. The improvement in the XPD is experimentally demonstrated by far-field measurement. When the beams scan to 30° off the boresight, the measured XPDs are 28 dB at the center frequency and higher than 25 dB over the operation bandwidth, which confirms that the cross-polarized radiation in the 2-D multibeam antenna array is suppressed by using the differential-feeding technique. The measured gain is in the range from 7.6 to 10.5 dBi.

Index Terms—Butler matrix, cross-polarization, differential feeding, dual-polarization, millimeter-wave (mmWave), multibeam antenna, patch antenna.

I. INTRODUCTION

WIRELESS communications have experienced considerable growth in the past decade due to ever-increasing

handheld devices accessing real-time data. For 5G millimeter-wave (mmWave) applications, the multibeam antenna array that is able to steer beams in two dimensions and operate with dual-polarization is an attractive candidate to achieve multispot coverage and high channel capacity [1]–[7]. The dual-polarized antenna array is usually required to have high cross-polarization discrimination (XPD) and high isolation between ports for different polarizations so as to improve the signal-to-noise ratio and reduce channel interference. However, it is difficult to achieve good XPD in 2-D multibeam antenna arrays because high cross-polarized radiation occurs when beams scan off the boresight. In addition, the intricate beamforming networks and high integration complexity also impose challenges on designing a dual-polarized 2-D multibeam antenna array.

A number of techniques to realize beamforming networks for 2-D multibeam antenna arrays have been reported. Multibeam antennas realized using dielectric lenses and reflectors are simple, but they are bulky and expensive [8], [9]. To reduce the cost and size, the antenna arrays driven by the Butler matrices or the Rotman Lenses are more preferable in many scenarios since they can be realized with planar laminates. To generate multiple beams in two dimensions, the beamforming networks composed of the cross-connected Butler matrices or the Rotman Lenses are considered in some designs [10]–[12]. However, these designs have low integration, high loss, and high cost. In general, to design a mmWave multibeam antenna array, the slot and traditional patch antennas are frequently selected as the radiating element due to their simple structure and ease of integration [13]–[20]. As reported in [15], low sidelobe levels (SLLs) are obtained in the multibeam slot antenna array by tapering the amplitude distribution at the array ports of the beamforming network. The antenna element in [20] is realized by placing a parasitic patch over a square SIW cavity to achieve wide bandwidth. Another antenna type widely used in mmWave multibeam antenna arrays is magnetolectric (ME) dipoles due to their wide bandwidth, broad beamwidth, and symmetric radiation patterns [21]–[24]. As seen from these designs, most of the antennas are only able to steer beams in one dimension and operate with a single polarization. Particularly, cross-polarized radiation in these multibeam antenna arrays is not well suppressed, resulting in low XPDs that are less than 15 dB when beams scan off the boresight. Although the multibeam antenna array proposed in [24] is able to steer beams in two dimensions

and operate with dual-polarization, its XPDs are degraded to 10 dB when the beams are at the maximal pointing angles.

In this article, we introduce a novel dual-polarized 2-D multibeam antenna array incorporating differentially-fed antenna elements. The differential feeding technique has been widely used in modern antenna designs [25], [26] in order to achieve high port isolation, high XPD, and symmetric radiation patterns. In our design, the antenna element is composed of an SIW cavity with four shorted patches placed inside, and it is differentially excited for dual-polarization by a pair of feeding strips and transverse slots beneath the patches. Differential excitation is realized by a power divider designed on two laminate layers. Two Butler matrices placed perpendicularly with each other in different laminates are employed to generate four tilted beams with dual-polarization. A dual-polarized 2×2 2-D multibeam antenna array working at 28 GHz is designed, fabricated, and measured. It is demonstrated that the proposed design has the advantages of high XPD and simple configuration. When the beams scan to 30° off the boresight, the measured XPDs are 28 dB at the center frequency and higher than 25 dB over the operation bandwidth. The measured results confirm that the cross-polarized radiation in the 2-D multibeam antenna array is suppressed by using the differential-feeding technique.

This article is organized as follows. Section II presents the configuration, the operation mechanism, and design of the dual-polarized differentially fed antenna element. In Section III, the feeding network designs, including the Butler matrix, the differential power divider, and the interconnection structure, are presented. Section IV shows the measured results of the multibeam antenna array. Section V concludes this article.

II. DUAL-POLARIZED ANTENNA

A. Antenna Configuration

The configuration of the proposed dual-polarized antenna is illustrated in Fig. 1, which is composed of a square SIW cavity and four patches. The SIW cavity is used to prevent potential surface waves from propagating when beams steer off the boresight. Four inductive vias with a diameter of 0.3 mm and an offset position of (p_x, p_y) are used to connect the patches to the ground plane. The antenna is differentially excited for dual-polarization by different feeding structures. The feeding structure for exciting HP radiation is realized with a stepped microstrip line, which is small enough to be fitted between the patches. The feeding structure for exciting VP radiation is realized with SIWs in Sub-2. The SIW width is set to $w_2 = 4.3$ mm for avoiding higher order modes within the operation frequency of interest. To couple the input energy from the SIWs so as to excite the shorted patches in Sub-1, two transverse slots are etched on the top copper layer of Sub-2. According to the mixed-mode theory, the S -parameters of a differentially fed antenna can be obtained from the single-ended four-port S -parameters [27]. Thus, to facilitate the analysis, ports #1 and #2 are defined as the differential feeding port d1 for exciting HP radiation, and ports #3 and #4 are defined as the differential feeding port d2 for exciting

Fig. 1. Configuration of the proposed differentially fed dual-polarized antenna. (Dimensions: $w_{cav} = 6.4$ mm, $l_p = 2.2$ mm, $w_p = 2.2$ mm, $g_x = 0.15$ mm, $g_y = 0.4$ mm, $p_x = 0.425$ mm, $p_y = 0.4$ mm, $l_{st} = 1.55$ mm, $w_{st} = 0.15$ mm, $w_1 = 0.5$ mm, $w_2 = 4.3$ mm, $l_s = 3.2$ mm, $w_s = 0.3$ mm, and $p_s = 0.5$ mm.)

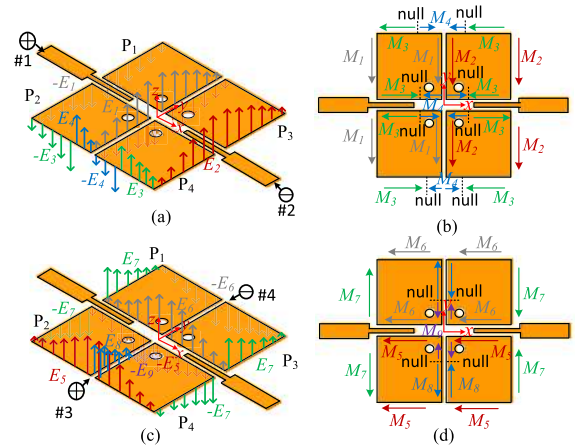

Fig. 2. (a) Electric field distribution. (b) Equivalent magnetic current when differential port d1 is excited. (c) Electric field distribution. (d) Equivalent magnetic current when differential port d2 is excited.

VP radiation. In this design, Sub-1 and Sub-2 are the Rogers 4003C laminates with a thickness of 0.508 mm, a relative permittivity of 3.55, and the loss tangent of 0.0027. All the simulations in this article are performed by using the high frequency full-wave electromagnetic solver, ANSYS Electronics Desktop HFSS.

B. Working Mechanism

Similar to the traditional patch antennas, an intuitive way of analyzing the working mechanism from the proposed antenna is based on the cavity-mode theory [28]. Fig. 2 shows the electric distribution and equivalent magnetic currents of the proposed differentially fed dual-polarized antenna. To facilitate the analysis, the antenna is viewed as an array of four shorted patches P_1 – P_4 . When signals input from the differential port d1, the shorted patches are excited for HP radiation by coupling from the feeding strips. It is seen from Fig. 2(a) that the electric fields radiated from each patch are identical. In addition, the electric field pattern from P_1 and P_2

(or P_3 and P_4) is quite similar to that of a traditional patch antenna resonating at TM_{010} mode. Thus, the antenna can be regarded as two patch antennas with the resonating length w_p and the width $(2l_p + g_y)$. As shown in Fig. 2(b), the magnetic currents M_1 and M_2 from the edges along the y -axis are in the same direction, indicating that constructive far fields are obtained in the E-plane (xoz plane, $\phi = 0^\circ$). The presence of the shorting vias helps to improve the impedance matching. However, it also makes the nulls between the magnetic currents M_3 and M_4 shift off the center of each edge. The cross polarization in the E-plane caused by these x -directed magnetic currents would be very low because these currents are antisymmetric along the x -axis. Similar observations can be found for the H-plane ($yo z$ plane, $\phi = 90^\circ$). Thus, when differential port d1 is excited, the edges along the y -axis contribute to the effective field radiation, while the edges parallel to the x -axis constitute the nonradiating edges of the antenna.

When operating with VP, the antenna is excited by couplings from the transverse slots underneath the shorted patches. As the dominant mode of the feeding SIWs in Sub-2 is TE_{10} mode, the electric fields near the shorted-end wall of the feeding SIWs are vertically polarized, which results in longitudinal electric fields across the transverse slots. Therefore, the shorted patches placed above the transverse slots can be excited subsequently. In this case, the radiating edges are those parallel to the x -axis. As shown in Fig. 2(c), the electric fields from these edges are the same as those from the radiating edges of a traditional patch antenna. In this case, the antenna can be considered as two patch antennas with the resonating length l_p and the width $(2w_p + g_x)$. Fig. 2(d) shows the magnetic currents when the antenna operates with VP. Constructive far fields are obtained in the E-plane ($yo z$ plane, $\phi = 90^\circ$) as the magnetic currents M_5 and M_6 are in the same direction. The magnetic currents M_7 – M_9 from the edges along the y -axis are slightly different from those of Fig. 2(b). In this case, no magnetic current nulls are found at the external edges, while each internal edge has a null between the magnetic currents M_8 and M_9 . In spite of this, the cross-polarization caused by the y -directed magnetic currents would be also very small as these currents are antisymmetric along the y -axis. Due to the differential feeding applied, the currents on the feeding strips are very weak when differential port d2 is excited, which ensures high isolation between the differential ports d1 and d2.

C. Antenna Optimization

Due to constrained space and high design complexity, it is usually difficult to design a mmWave antenna array incorporating differentially fed antenna elements. To better illustrate the design process of the developed antenna, the reference antennas (Ant-1 and Ant-2) are shown in Fig. 3. As shown in Fig. 3(a), Ant-1 is realized with two patch antennas placed inside the SIW cavity, and the differential feeding pairs are perpendicularly placed for dual-polarization. The antenna can be considered as an inset-fed patch antenna when operating with HP. To improve the impedance matching, two inductive vias are placed beside the centerline. The length of the patch l_p decides the resonance frequency, and the width of the patch w_p

Fig. 3. Design process of the proposed differentially fed dual-polarized antenna. (a) Ant-1. (b) Ant-2. (c) Proposed antenna.

Fig. 4. Simulated results of the antennas in the design process.

affects the input impedance. The preliminary simulation shows that to achieve good impedance matching, the patch length should be 0.9λ . However, it makes the patch nonresonant when the antenna operates with VP. As can be seen from Fig. 4, signals input from the differential port d2 are totally reflected. To investigate the resonance characteristics of the proposed antenna when operating with VP, Ant-2 is developed by placing the patches above the coupling slots. The feeding strips for exciting HP radiation are located between the two patches. The antenna can be considered as a slot-coupled patch antenna when operating with VP. The simulated results presented in Fig. 4 show that good impedance matching is achieved at differential port d2. However, in this case, strong reflection is observed at the differential port d1. To realize good impedance matching at both differential ports, the proposed antenna is designed by splitting the patch into four elements. The proposed antenna can be taken as a combination of Ant-1 and Ant-2. The dimension of each patch element is $2.6 \text{ mm} \times 2.6 \text{ mm}$ ($\approx 0.39\lambda \times 0.39\lambda$), which enables the antenna to resonate when it is excited at the differential port d1 or d2. As shown in Fig. 4, the splitting of the patch has no influence on the performance of this differentially fed antenna. Thus, the proposed antenna is an inset-fed patch antenna when it operates with HP and a slot-coupled patch antenna when it operates with VP.

Fig. 5 shows the simulated performance of the proposed antenna. The overlapped impedance bandwidth for S_{dd11} and S_{dd22} less than -10 dB is 8.6% from 26.8 to 29.2 GHz. The antenna exhibits high port isolation, which is higher than 68 dB. The stable gain is achieved over the operation bandwidth, which is in the range of 6.2–7 dBi. The simulated radiation patterns in E- and H-planes are shown in Fig. 6. It is observed from Fig. 6(a) that the proposed antenna has symmetrical radiation patterns in the E-plane and the H-plane when the differential port d1 is excited. The -3 dB beamwidth

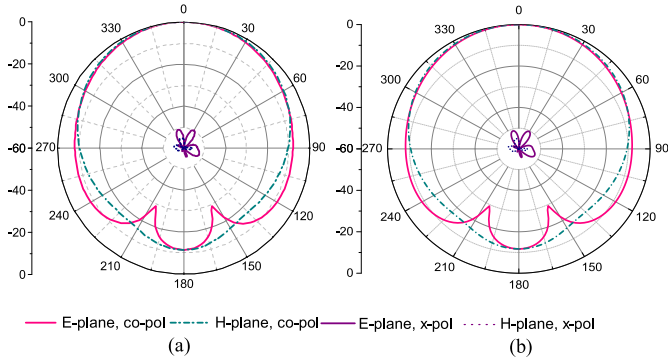

Fig. 6. Simulated radiation patterns of the proposed antenna at 28 GHz. (a) Differential port d1 is excited (HP). (b) Differential port d2 is excited (VP).

Fig. 7. (a) Simulated S -parameters with or without the shorting vias. (b) Simulated S_{dd11} by varying the length of the feeding strip.

of the radiation patterns is 86° in both planes, and the XPD is higher than 46 dB within the beamwidth. As shown in Fig. 6(b), similar radiation patterns are also obtained when the differential port d2 is excited.

The shorting via connecting the patch elements to the ground plane helps to improve the impedance matching of the proposed antenna. As shown in Fig. 7(a), the performance of S_{dd11} and S_{dd22} is very sensitive to the introduced vias. The resonant frequency increases with the presence of the shorting vias when differential port d1 is excited. Without introducing the shorting vias, no resonance is observed over the bandwidth when differential port d2 is excited. In addition, the impedance matching at differential port d1 is also affected by the feeding strip length l_{strip} . As shown in Fig. 7, the resonance shifts to the lower frequency with the increase of strip length because the inset feeding leads to longer electric current path for the patch antenna. When the strip length l_{strip} increases

Fig. 8. Configuration of the proposed dual-polarized 2-D multibeam array antenna.

to 1.2 mm, the resonance frequency shifts to 28 GHz with $S_{dd11} < -30$ dB. The presence of feed strips almost has no effect on S_{dd22} due to high isolation between the differential ports d1 and d2.

III. MULTIBEAM ANTENNA ARRAY

A. Configuration of the Multibeam Antenna Array

Fig. 8 shows the configuration of the proposed dual-polarized 2-D multibeam antenna array. It consists of 2×2 antenna elements, two SIW Butler matrices, eight differential power dividers, and four interconnection structures. The two Butler matrices are placed perpendicularly to each other in different layers so as to generate four tilted beams with dual-polarization. The vertical Butler matrix connected to ports #1–#4 is used to excite VP beams, and the horizontal Butler matrix connected to ports #5–#8 is used to excite HP beams. The Butler matrices for HP and VP are designed in the bottom laminate (Sub-2) and the top laminate (Sub-1), respectively. The differential power divider is used to differentially excite the antenna elements. In order to avoid the intersection, an interconnection structure is located between the Butler matrix and the differential power divider. The signal paths when port #1 is excited are also shown in Fig. 8. The signals traveling in Sub-1 is denoted by the solid arrows, and the signals in Sub-2 are denoted by the dotted arrows. To better illustrate the path of signals from the power divider to each antenna element, the detailed layouts of the differential power divider and the 2×2 antenna array are illustrated in Fig. 9. The differential power divider is designed in two laminate layers, and interlayer signal transmission is achieved by a coupling slot etched on the ground plane. Because the feeding port of the antenna element for exciting VP is located in Sub-2, the differential power divider connected with port #1 is antisymmetric with

 Fig. 9. Layout of the 2×2 antenna array and the differential power dividers.

Fig. 10. Layout of the designed Butler matrix.

the one that is connected with port #2. The antenna element spacing in x - and y -directions is chosen as 7.5 mm ($0.7\lambda_0$).

B. Butler Matrix

Fig. 10 presents the structure of the designed Butler matrix, which consists of four hybrid couplers. No additional phase shifters are needed in this Butler matrix structure. Ideally, fixed phase differences ($\pm 90^\circ$, $\pm 90^\circ$) can be obtained between the output ports in x - and y -directions. For details, Table I gives the theoretical phase responses at ports #5 and #6 when ports #1–#4 is excited, respectively. A hybrid coupler can be considered as an equal power divider having a 90° phase difference between the direct port and coupling port [29]. Fig. 11 shows the layout and the simulated results of the designed hybrid coupler. The simulated operation bandwidth for $S_{11} < -15 \text{ dB}$ is from 26 to 30 GHz. The transmission

 Fig. 11. Layout and S -parameters of the designed hybrid coupler. (Dimensions: $l_{c1} = 3.7 \text{ mm}$, $t = 0.65 \text{ mm}$, and $l_{c2} = 5.4 \text{ mm}$.)

coefficients from port #1 to ports #2 and #3 are in the range of $3.2 \pm 0.4 \text{ dB}$, and the obtained phase difference of signals output from ports #2 and #3 is $90 \pm 0.5^\circ$ over the bandwidth. Port #4 is well isolated from port #1 within the bandwidth.

Fig. 12 shows the simulated results of the designed Butler matrix. The impedance bandwidth for $S_{11} < -20 \text{ dB}$ is wider than 14% (from 26.3 to 29.8 GHz). Besides, the isolation between any two input ports is higher than 15 dB over the bandwidth. The insertion loss of this Butler matrix is less than 1.6 dB from 26.8 to 29.2 GHz. The simulated phase responses of the designed Butler matrix are also included in Fig. 12. The phase differences between the output ports are in the range of $-90^\circ \pm 1^\circ$ from 26 to 30 GHz, which are very close to the theoretical values.

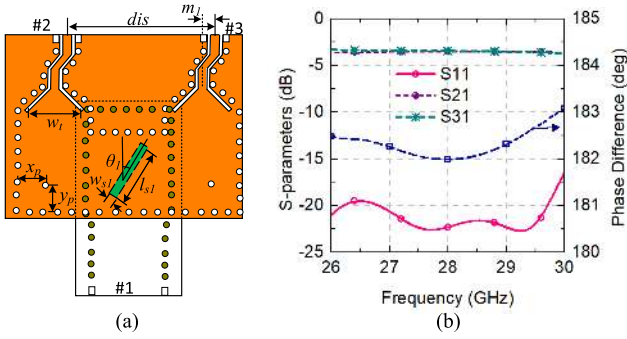

Fig. 13. Differential power divider. (a) Layout ($w_t = 3.6$ mm, $x_p = 1.66$ mm, $y_p = 1.46$ mm, $l_{s1} = 3.17$ mm, $w_{s1} = 0.3$ mm, $\theta_1 = 33.56^\circ$, $m_1 = 0.7$ mm, and $dis = 6.8$ mm). (b) Simulated performance.

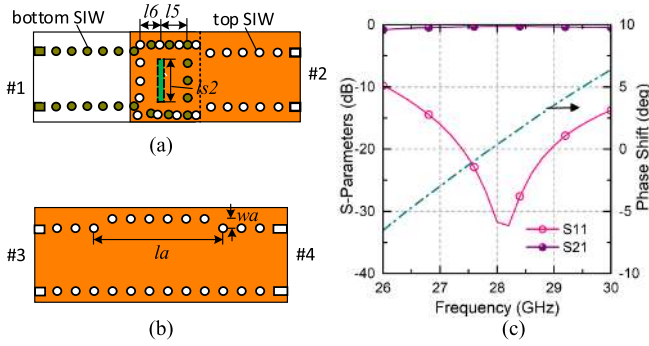

Fig. 14. (a) Interconnection ($l_5 = 3$ mm, $l_6 = 0.89$ mm, and $l_{s2} = 3.63$ mm). (b) Reference SIW ($l_a = 6.27$ mm and $w_a = 0.2$ mm). (c) Simulated results.

C. Differential Power Divider

Fig. 13(a) shows the layout of the designed differential power divider. Port #1 is the input port, and ports #2 and #3 are the output ports. The differential power divider can be taken as an equal power divider that enables the signals out from ports #2 and #3 to be out-of-phase. In this design, the structure of the power divider is realized by using two laminate layers. Interlayer signal transmission is achieved by etching a coupling slot on the ground plane. To improve the impedance matching at port #1, the slot is slanted with an angle of θ_1 . The meandered three-stage grounded coplanar waveguides, which is $m_1 = 0.7$ mm away from the centerline, are used to avoid overlapping between two neighboring differential power dividers. Fig. 13(b) shows the simulated results of the designed differential power divider. The impedance bandwidth for $S_{11} < -20$ dB is from 26 to 29.7 GHz. The received power at ports #2 and #3 is -3.3 ± 0.15 dB lower than the input power at port #1 over the bandwidth. The phase difference between the two output ports is in the range of $182.5^\circ \pm 0.5^\circ$ over the bandwidth, which indicates that differential excitation to the antenna element is achieved.

D. Interconnection

To make the feeding networks for different polarizations separated in different layers without intersection, an interconnection structure is designed, as shown in Fig. 14(a). The interconnection consists of two SIWs situated in different layers. To realize interlayer transmission, a transverse slot is etched at the common ground plane of the two SIWs. High

Fig. 15. Top and bottom views of the fabricated array antenna.

Fig. 16. Measured and simulated return losses for ports #1 and #5.

coupling efficiency can be obtained by tuning lengths l_5 and l_6 . As shown in Fig. 14(b), an equal-length unequal-width reference SIW is designed to compensate for the additional phase introduced by the interconnection. The desired 0° phase shift between the interconnection and the reference SIW can be obtained by varying the length l_a and width w_a . Fig. 14(c) shows the simulated S -parameters of the interconnection and its phase shift relative to the reference SIW. The operation bandwidth for $S_{11} < -10$ dB is 14.3% (from 26 to 30 GHz). Within this bandwidth, the insertion loss is from -0.52 to -0.28 dB. The phase difference with a deviation of $0.2 \pm 6.6^\circ$ is achieved over the operation bandwidth.

IV. MEASURED RESULTS

A. Return Loss and Port Isolation

The fabricated prototype of the proposed multibeam antenna array is given in Fig. 15. The laminate layers are tightly pressed by two aluminum fixtures to ensure good interlayer transmission. The network analyzer Anritsu 37397C is used to perform the S -parameter measurement. Fig. 16 presents the simulated and measured return losses ($|S_{11}|$ and $|S_{55}|$) at ports #1 and #5, which are in good agreement. The measured impedance bandwidth for return loss higher than 10 dB is 14.3% from 26 to 30 GHz. Due to the presence of the feeding networks, the measured and simulated bandwidths of the multibeam antenna array are slightly wider than the bandwidth of the antenna element.

The measured and simulated isolations between port #1 and ports #2–#8 are presented in Fig. 17. It can be seen that the measured and simulated results are in good agreement. High port isolations are achieved in this antenna array. The measured isolations between the ports for exciting radiated waves

with the same polarization, $|S_{21}|$ to $|S_{41}|$, are higher than 21 dB over the operation bandwidth 26.8–29.2 GHz. The measured isolations between the ports for exciting the radiated waves with different polarization, $|S_{51}|$ to $|S_{81}|$, are higher than 46 dB over the bandwidth. Due to the symmetrical structure of the proposed multibeam array antenna, the performance of other ports is similar to the abovementioned results.

B. Radiation Patterns and XPD

The theoretical beam pointing angles for 2-D beam scanning antenna arrays in the spherical coordinate are given by

$$\theta_p = \text{asin} \sqrt{\left(\frac{\phi_x}{kd_x}\right)^2 + \left(\frac{\phi_y}{kd_y}\right)^2}, \quad \phi_p = \text{atan} \left(\frac{\phi_x d_x}{\phi_y d_y}\right) \quad (1)$$

where ϕ_x and ϕ_y are the fixed phase differences in x - and y -directions, which are listed in Table I. d_x and d_y are the element spacing in x - and y -directions, and they are 7.5 mm ($\approx 0.7\lambda_0$) in this design. k is the wavenumber in free space. The designed multibeam antenna array generates four 2-D radiation patterns for HP or VP polarization corresponding to four input ports. The calculated maximal beam pointing angles are $(30^\circ, 45^\circ)$, $(30^\circ, 135^\circ)$, $(30^\circ, 225^\circ)$, and $(30^\circ, 315^\circ)$ in the spherical coordinate when ports #1–#4 are excited, respectively. By using the definitions of quasi-E-plane and quasi-H-plane presented in [30], the measured and simulated radiation patterns of the fabricated multibeam antenna array at 26.8, 28, and 29.2 GHz are obtained. Fig. 18 shows the radiation patterns when port #1 is excited for VP, and Fig. 19 shows the radiation pattern when port #5 is excited for HP. The measured results are in reasonable agreement with the simulations. It is seen that the radiation patterns

are stable at different frequencies when the beams scan to the maximal pointing angles, and the radiation patterns with different polarizations are very similar to each other. At 28 GHz, the measured beam pointing angle is $(28^\circ, 41^\circ)$ when port #1 is excited, and the measured beam pointing angle is $(34^\circ, -43^\circ)$ when port #5 is excited. The measured pointing angles are slightly different from the theoretical ones ($\pm 30^\circ, \pm 45^\circ$) due to fabrication tolerance and the presence of the large ground plane introduced by the feeding network.

Fig. 20 shows the minimum XPDs of the designed multibeam array antenna at different frequencies. High XPDs are achieved in the fabricated antenna array when the beams scan to the maximal pointing angles. Within the operation frequency band, the XPDs are higher than 25 dB. The measured XPD at the center frequency is 28.3 dB. The minimum measured XPD at 26.8 GHz is 25.1 dB when port #1 or #5 is excited. The slight decrease of XPD off the center frequency is mainly because the phase error introduced by the interconnection is not well compensated at the edge frequencies. The measured results confirm that the cross-polarized radiation in the 2-D multibeam antenna array is suppressed by using the differential-feeding technique.

C. Gain

The measured and simulated gain and directivity of the designed dual-polarized multibeam array antenna are illustrated in Fig. 21. When port #1 is excited, the simulated gain increases from 8.4 to 10.8 dBi over the frequency range from 26.8 to 29.2 GHz, while the measured one is in the range of 7.6–10.5 dBi. The simulated directivity over the bandwidth is increased from 10.5 to 12.1 dBi. The simulated efficiency at the center frequency is approximately 55%. The efficiency is mainly degraded by the high loss laminates Rogers 4003C and the fabrication tolerance. In addition, the losses from the connectors are not calibrated. The change in gain and directivity when port #5 is excited has a similar tendency to the results of port #1 under excitation. The slight difference between the measured and simulated gain is mainly caused by the uncertainty of the dielectric loss of the used laminates.

D. Comparison and Discussion

A comparison between this article and the reported 2-D multibeam array antennas is carried out in Table II. The antenna array in [15] has low SLLs but suffers very narrow bandwidth and low XPDs. The antenna arrays in [19], [20],

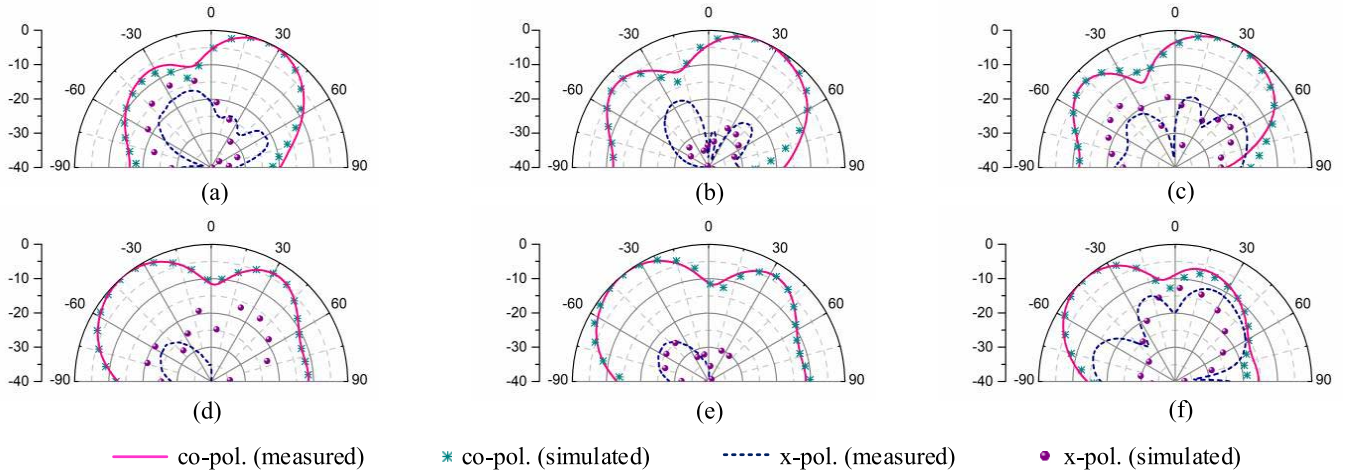

Fig. 18. Simulated and measured radiation patterns of the proposed multibeam array antenna with VP when port 1 is excited. (a) 26.8 GHz at quasi-E-plane. (b) 28 GHz at quasi-E-plane. (c) 29.2 GHz at quasi-E-plane. (d) 26.8 GHz at quasi-H-plane. (e) 28 GHz at quasi-H-plane. (f) 29.2 GHz at quasi-H-plane.

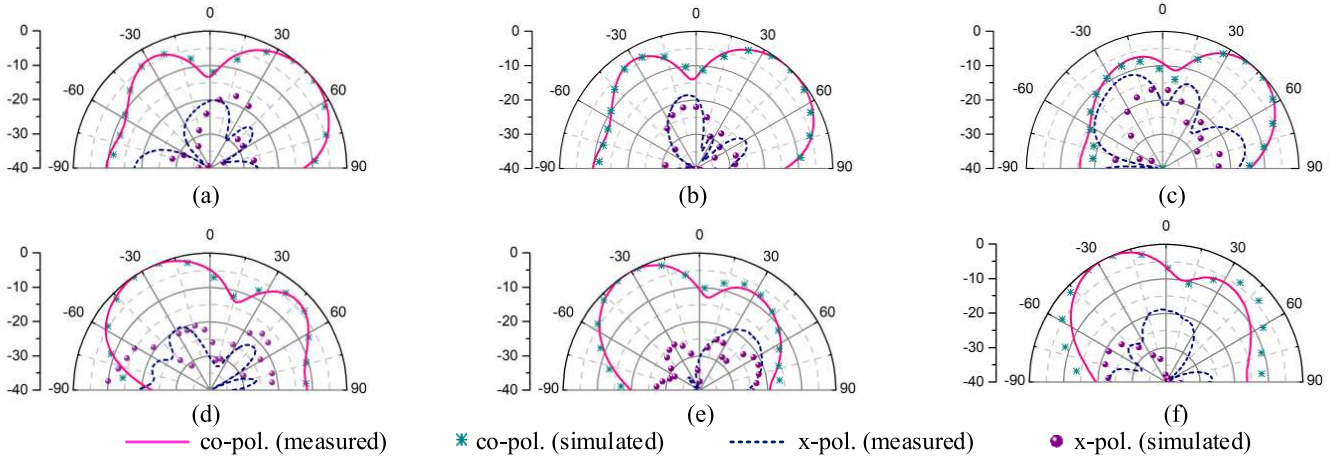

Fig. 19. Simulated and measured radiation patterns of the proposed multibeam array antenna with HP when port 5 is excited. (a) 26.8 GHz at quasi-E-plane. (b) 28 GHz at quasi-E-plane. (c) 29.2 GHz at quasi-E-plane. (d) 26.8 GHz at quasi-H-plane. (e) 28 GHz at quasi-H-plane. (f) 29.2 GHz at quasi-H-plane.

Fig. 20. Minimum XPDs at different frequencies when ports #1 and #5 are excited.

Fig. 21. Simulated gain, directivity, and measured gain when ports #1 and #5 are excited, respectively.

and [23] have wide bandwidth, but they are only able to operate with a single polarization, and their XPDs are lower than 15 dB. Both dual-polarization and wide bandwidth are achieved in the antenna array reported in [24]. However, this antenna also suffers low XPD, which is only 10 dB when the beams scan off the boresight. In comparison, the proposed 2-D multibeam antenna array is able to work with dual-polarization while maintaining high XPD when the beams scan to the maximal beam pointing angles. In addition, the designed

array antenna can be realized with only two PCB laminates, as the multibeam feeding network for VP is designed with the antenna array aperture on the same laminate layer. Hence, the proposed antenna array also has the advantages of easy fabrication and low cost. Due to the low profile of the antenna with a thickness of only 0.09λ (λ is the wavelength in the laminate), the developed antenna array is not a wideband antenna. The bandwidth can be improved by increasing the thickness and lowering the permittivity of the laminate as the

designs reported in [19], [20], [23] and [24]. As the antenna element separation is designed as $0.7\lambda_0 \times 0.7\lambda_0$, the SLLs are degraded when the beams scan to the maximal pointing angles. This could be mitigated by decreasing the element distance and optimizing the excitation if low SLLs are required in some application scenarios.

V. CONCLUSION

This article presents a novel design of mmWave dual-polarized 2-D multibeam array antenna. The differentially driven cavity-backed shorted patch is employed as the antenna element in the design of dual-polarized multibeam array antennas for the first time. The SIW power dividers designed on two laminate layers are used to achieve differential excitations to the antenna elements. Two Butler matrices placed perpendicularly with each other in different laminates are used to generate four tilted beams with dual-polarization. An antenna prototype working from 26.8 to 29.2 GHz is fabricated and measured. The whole structure is realized by using only two laminates. The measured results and simulated results agree well. When the beams scan to the maximal pointing angles, the measured XPDs in our design are higher than 25 dB within the operation bandwidth. The measured results confirm that the cross-polarizations are effectively suppressed in this 2-D multibeam antenna array. Compared with the reported works, the proposed dual-polarized 2-D multibeam antenna array has the advantages of high XPDs, low profile, ease of fabrication, and low cost.

Qingling Yang received the M.S. degree from the University of Electronic Science and Technology of China (UESTC), Chengdu, China, in 2017. He is currently pursuing the Ph.D. degree with the University of Kent, Canterbury, U.K.

His research interests include millimeter-wave antennas, multibeam antennas, and phased array antennas.

Steven Gao received the Ph.D. degree from Shanghai University, Shanghai, China, in 1999.

He is currently a Professor and the Chair of RF and Microwave Engineering, and the Director of Post-graduate Research with the School of Engineering and Digital Arts, University of Kent, Canterbury, U.K. He has coedited or coauthored three books, including *Space Antenna Handbook* (Wiley, 2012), *Circularly Polarized Antennas* (Wiley-IEEE, 2014), *Low-Cost Smart Antennas* (Wiley, 2019), and more than 300 articles. He holds eight patents. His current

research interests include smart antennas, phased array, multi-in multi-out (MIMO), broadband and multiband antennas, small antennas, RF front ends, FSS, and their applications to 5G mobile communications, satellite communication, small satellites, radars, energy harvesting, and medical systems.

Dr. Gao is a fellow of the Royal Aeronautical Society and the IET. He received the 2016 IET Premium Award for the Best Paper in the *IET Microwave, Antennas and Propagation* and the 2017 CST University Publication Award for a paper in the *IEEE TRANSACTIONS ON ANTENNAS AND PROPAGATION*. He was the General Chair of the 2013 Loughborough Antenna and Propagation Conference. He is an Associate Editor of several journals, including the *IEEE TRANSACTIONS ON ANTENNAS AND PROPAGATION*, *Radio Science*, *Electronics Letters*, *IEEE ACCESS*, and the *IET Circuits, Devices and Systems*, the Editor-in-Chief of Wiley Book Series on Microwave and Wireless Technologies, an Editorial Board Member of many international journals, the Guest Editor of the *PROCEEDINGS OF THE IEEE* for Special Issue on Small Satellites in 2018, the Guest Editor of the *IEEE TRANSACTIONS ON ANTENNAS AND PROPAGATION* for Special Issue on Antennas for Satellite Communication in 2015, and the Guest Editor of the *IET Circuits, Devices and Systems* for Special Issue in Photonic and RF Communications Systems in 2014. He was a Distinguished Lecturer of the IEEE Antennas and Propagation Society. He was an invited speaker in many international conferences.

Qi Luo (Senior Member, IEEE) was born in Chengdu, China, in 1982. He received the M.Sc. degree (Hons.) from the University of Sheffield, Sheffield, U.K., in 2006, and the Ph.D. degree (Hons.) from the University of Porto, Porto, Portugal, in 2012.

From 2012 to 2013, he was with Surrey Space Centre, Guildford, U.K., as a Research Fellow. He is currently with the School of Engineering and Digital Arts, University of Kent, Canterbury, U.K., as a Research Fellow. He has authored or coauthored two books *Circularly Polarized Antennas* (Wiley-IEEE, 2014) and *Low-Cost Smart Antennas* (Wiley, 2019). He also authored a book chapter in *Handbook of Antenna Technologies* (Singapore: Springer, 2014). His current research interests include smart antennas, circularly polarized antennas, reflect array, transmit array, multiband microstrip antennas, and electrically small antenna design.

Dr. Luo has been serving as a reviewer for a number of technical journals and international conferences and was awarded as the Outstanding Reviewer for the *IEEE TRANSACTIONS ON ANTENNAS AND PROPAGATION* in 2015.

Lehu Wen received the M.S. degree from Xidian University, Xi'an, China, in 2011. He is currently pursuing the Ph.D. degree with the University of Kent, Canterbury, Kent, U.K.

His current research interests include base station antennas, mobile terminal antennas, and tightly coupled array antennas.

Yong-Ling Ban (Member, IEEE) was born in Henan, China. He received the B.S. degree in mathematics from Shandong University, Jinan, China, in 2000, the M.S. degree in electromagnetics from Peking University, Beijing, China, in 2003, and the Ph.D. degree in microwave engineering from the University of Electronic Science and Technology of China (UESTC), Chengdu, China, in 2006.

In July 2006, he joined the Xi'an Mechanical and Electric Information Institute, Xi'an, China, as a Microwave Engineer. He then joined Huawei Technologies Company, Ltd., Shenzhen, China, where he designed and implemented various terminal antennas for 15 data cards and mobile phone products customized from leading telecommunication industries like Vodafone. From September 2010 to July 2016, he was an Associate Professor with UESTC, where he is currently a Professor. From May 2014 to April 2015, he visited the Queen Mary University of London, London, U.K., as a Scholar Visitor. He holds 20 granted and pending Chinese and overseas patents. His research interests include wideband small antennas for 4G/5G handset devices, MIMO antennas, and millimeter-wave antenna arrays. He has authored over 110 referred journal and conference papers on these topics.

Xiaofei Ren is working with the China Research Institute of Radiowave Propagation, Xinxiang, Henan, China.

Jian Wu is working with the China Research Institute of Radiowave Propagation, Xinxiang, Henan, China.

Xuexia Yang (Senior Member, IEEE) received the B.S. and M.S. degrees from Lanzhou University, Lanzhou, China, in 1991 and 1994, respectively, and the Ph.D. degree in electromagnetic field and microwave technology from Shanghai University, Shanghai, China, in 2001.

From 1994 to 1998, she was a Teaching Assistant and a Lecturer with Lanzhou University. From 2001 to 2008, she was a Lecturer and an Associate Professor with Shanghai University. She is currently a Professor and the Head of the Antennas and Microwave Research and Development Center, Shanghai University. She has authored or coauthored more than 180 technical journal and conference papers. She is also a frequent reviewer for more than ten scientific journals. Her current research interests include antennas theory and technology and computational electromagnetic and microwave power transmission.

Dr. Yang is currently a member of the Committee of Antenna Society of the China Electronics Institute and a Senior Member of the China Electronics Institute. She is currently an Associate Editor for the *Journal of Shanghai University* (Science Edition).

Ying Liu (Senior Member, IEEE) received the M.S. and Ph.D. degrees in electromagnetics from Xidian University, Xi'an, China, in 2001 and 2004, respectively.

From 2006 to 2007, she was a Post-Doctoral Researcher with Hanyang University, Seoul, South Korea. She is currently a Full Professor and the Director of the National Key Laboratory of Science and Technology on Antennas and Microwaves, Xidian University. She has authored or coauthored over 100 refereed journal papers and has authored *Prediction and Reduction of Antenna Radar Cross Section* (Xi'an: Xidian University Press, 2010) and *Antennas for Mobile Communication Systems* (Beijing: Electronics Industry Press, 2011). Her current research interests include antenna theory and technology, prediction, and control of antenna RCS.

Dr. Liu is a Senior Member of the Chinese Institute of Electronics. She was a recipient of the New Century Excellent Talents in the University of the Ministry of Education for China in 2011. She is a reviewer for several international journals and serves as a TPC member or the session chair for several IEEE flagship conferences.
