# N-PLAYER STOCHASTIC DIFFERENTIAL GAMES* 

by

Pravin Varaiya

ABSTPACT

The paper presents conditions which guarantee that the control strategies adopted by N players constitute an efficient solution, an equilibrium, or a core solution. The system dynamics are described by an Ito equation, and all players have perfect information. When the set of instantaneous joint costs and velocity vectors is convex the conditions are necessary.

The research reported here was initiated at the University of California, Berkeley, under the Joint Services Electronic Program, Contract F44260-71-c-0087, and continued at the Decision and Control Sciences Group of the M.I.T. Electronic Systems Laboratory, Cambridge, Mass., 02139, with partial support provided by AFOSR under grant 72-2273 and by NASA Ames Research Center under grant NGL-22-009-124.

N players are simultaneously controlling the evolution of a system described by the Ito equation

$$
\begin{equation*}
d z_{t}=f\left(t, z_{1}, u_{t}^{1}, \ldots, u_{t}^{N}\right) d t+d B_{t}, t \varepsilon[0,1] \tag{1}
\end{equation*}
$$

where ( $z_{t}$ ) is the state process, ( $B_{L}$ ) is Brownian motion and ( $u_{t}^{i}$ ) is the control of the ith player. player $i$ chooses this control so as to minimize the cost

$$
\begin{equation*}
J^{i}(u)=E\left[\int_{0}^{1} c^{i}\left(t, z, u_{t}^{i}\right) d t+\gamma^{i}(z)\right], \tag{2}
\end{equation*}
$$

where $u=\left(u_{t}\right)=\left(u_{t}^{1}, \ldots, u_{t}^{N}\right)$.
Different solution concepts of the resulting game are stuaied. Sufficient conditions are given which guarantee that $u^{*}=\left(u_{t}^{1 *}, \ldots, u_{t}^{N^{*}}\right)$ is a (Nash) equilibrium, a (Pareto) efficient solution, or a member of the core. When the set of admissible cost-drift vectors ( $\left.c^{1}, \ldots, c^{N}, f\right)$ possesses a certain convexity property, these sufficient conditions become necessary.

The next section gives a precise model of the game. The convexity property is stated, and its main implications are drawn out in section 3. The main results are given in section 4. A priori conditions on the $c^{i}$ and $f$ which imply the convexity property are examined in section 5.
52. THE MODEL

### 2.1 Admissible Controls

The sample paths of the state process $\left(z_{t}\right)$ are evidently continuous, hence members of the Banach space $C$ of all continuous functions $\omega:[0,1]+R^{n}$. Let $\xi_{t}$ be the evaluation functional on $C$, that is, $\xi_{t}(\omega)=\omega(t)$. Let $F_{t}$ be the $\sigma$-field of subsets of $C$ generated by $\left\{\xi_{s} \mid 0 \leq s \leq t\right\}$. Let $F_{1} F_{1}$.

For each $i$ $U_{i}$ is a compact metric space, the set of actions available to i. $A$ function $u^{i}:[0,1] \times c+U_{i}$ is an (admissible) control for if
(i) $u^{i}$ is jointly measurable,
(ii) $u_{t}^{i}=u^{i}\left(t,{ }^{i}\right)$ is $F_{t}$ measurable for all $t$.
$U_{i}$ denotes the set of controls for $i$.
Denote $U=U_{1} \not \approx \ldots x U_{N}$ with elements $u=\left(u_{1}, \ldots, u_{N}\right)$ and $U=U^{1} x \ldots x U^{N}$ with elements $u=\left(u^{1}, \ldots, u^{N}\right)$. For $u \in U$, vEU and $i$ $\varepsilon\{1, \ldots, N\}$ denote $\left(u_{\bar{i}}, v_{i}\right)=\left(u_{1}, \ldots, u_{i-1}, v_{i}, u_{i+1}, \ldots, u_{N}\right)$. More generally, for $s c\{1, \ldots, N\}$ denote $\left(u_{\vec{S}}, v_{S}\right)$ to be the $N$-tuple obtained fron $u$ upon replacing $u_{i}$ by $v_{i}$ for each ies. In exactly the same way one defines $\left(u^{\bar{i}}, v^{i}\right)$ and $\left(u^{\mathbf{S}}, v^{S}\right)$ when $u$ and $v$ are in $U$.

### 2.2 Dynamics

The function $f:[0,1] \times C \times U \rightarrow R^{n}$ in (1) satisfies the following conditions:
(i) fis jointly measurable,
(ii) $f\left(t,{ }^{*}, u\right)$ is $F_{t}$ - measurable for all $t, u$ and $f\left(t, w_{*}\right)$ is continuous for all $t, w_{\text {, }}$
(iii) There is a constant $k$ such that $|f(t, \omega, u)| \leq k(1+||\omega||)$ for all $t, \omega, u$.
 uation functionals on $C$ so that $\left(z_{t}, F_{t}, P\right)$ is a n-dimensional, standard,

Brownian motion. For uell define the drift $\left(\phi_{t}{ }^{\prime}, F_{t}, p\right)$ by

$$
\phi_{t}^{u}=f(t, z, u(t, z))
$$

and the density $\left(\rho_{t^{\prime}}^{u} F_{t}, P\right)$ by

$$
\rho_{t}^{u}=\exp \left[\int_{0}^{t} \phi_{s}^{u} d z_{s}-1 /\left.2 \iint_{0}^{t} \phi_{s}^{u}\right|^{2} d s\right]
$$

Denote $p^{u}=p_{1}^{u}$. The nest result is well-known $[1,2]$. Theoren 1 (Benes) $E\left(\rho_{t}^{u}\right)=1$. Hence $p^{U}$ is a probability measure on (C,F) where.

$$
P^{u}(F)=\int_{F} \rho^{u}(z) P(d z), F \varepsilon F
$$

Furthermore, the process $\left(w_{t}{ }^{\prime}, F_{t}, p^{u}\right)$ defined by

$$
w_{t}^{u}=z_{t}-\int_{0}^{t} \phi_{s}^{u} d s
$$

is a Brownian motion.
This theorem justifies the folloring definitior. The solution of (1) corresponding to $u \in U$ is the process $\left(z_{t}, F_{t} ;{ }^{u}\right)$.

### 2.3 Solutions of the Game

Conditions analogous to those imposed on f are also imposed on the functions $c^{i}$ in (2). The functions $\gamma^{i}: C \rightarrow$ are $F$ - measurable and integrable with respect to $p^{u}$ for all $u$. In addition, the $c^{i}$ and $\gamma^{i}$ are non-negative.

The cost to player $i$ of $u \varepsilon l l$ is defined to be

$$
v^{\mathbf{j}}(u)=E^{u}\left[\int_{0}^{1} c^{i}\left(t, 0, u_{t}\right) d t+\gamma^{i}(\cdot)\right]
$$

where $E^{u}$ denotes expectation with respect to $p^{u}$
Recall the following definitions. $u^{*}=\left(u^{1^{*}} \ldots u^{N^{*}}\right)$ is
a) an equilibriumif there is no $i$ and no $u$ such that

$$
J^{i}\left(u^{\star \bar{i}}, u^{i}\right)<J^{i}\left(u^{*}\right)
$$

b) efficient if there is no $u$ such that

$$
J^{i}(u)<J^{i}\left(u^{*}\right) \text { for all } i
$$

c) in the core if there is no $S$ and no $u$ such that

$$
J^{i}\left(u^{\star \stackrel{\rightharpoonup}{S}}, u^{S}\right)<J^{i}\left(u^{*}\right) \text { for all ies }
$$

To avoid confusion it should be pointed out that the definitions b) and c) are not the standard ones. Usually, $u^{*}$ is said to be efficient if there is no $u$ such that $J^{i}(u) \because J^{i}\left(u^{*}\right)$ fox all $i$ with the strict inequality holding for at least one $i$. If one adopts this definition, then the observation at the beginning of section 4.3 below needs to be modified and so do the subsequent results; these modifications are slight but clunsy, and the definition given here avoics the clunsiness. In any case the difference is slight. The core is usually defined only for games where comparison of inter-personal utilities is permitted and where side payments are allowed. For games where such comparison is not permitted, as is the normal posture in mathematical economics, one is naturally led to the definition given here.
53. THE CONVEXITY PROPERTY

Let $g(t, z, u)=\left(c^{1}(t, z, u), \ldots, c^{N}(t, z, u), f(t, z, u)\right)$. $g$ is an $(N+n)-$ dimensional vector.

The game is said to have the convexity property if for all $t, z$

$$
\{g(t, z, u) \mid u \in u\}
$$

is a convex set. It is said to have the strong convexity property if for all $t, z, u$ and for all $s$

$$
\left\{g\left(t, z_{,}\left(u_{\vec{s}}, v_{S}\right)\right) \mid v \in u\right\}
$$

is a convex set.
In [1] and [2] it is shown that the convexity property implies that the set of densities obtained by using all possible admissible controls is convex. The two lemmas below follow readily from these results.

Lemma 1 Suppose the game has the convexity property. Then

$$
J=\left\{\left(J^{1}(u), \ldots, J^{N}(u) \mid u \in u\right\}\right.
$$

is a convex subset of $\mathrm{R}^{\mathrm{N}}$.
Lemma 2 Suppose the game has the strong convexity property. Let uell and S C $\{1, \ldots, N\}$. Then

$$
J\left(u^{\overline{\mathbf{S}}}\right)=\left\{\left(J^{1}\left(u^{\overline{\mathbf{S}}}, v^{\mathbf{S}}\right), \ldots, J^{N}\left(u^{\overline{\mathbf{S}}}, v^{\mathbf{S}}\right) \mid v \varepsilon \|\right\}\right.
$$

is a convex subset of $\mathrm{R}^{\mathrm{N}}$.

## 54. THE MATN RESULTS

4.1 A Result from Control Theory

Suppose $N=1$ so that the game is simply an optimal control problem.
Dropping superscripts and subscripts, the control problem is to find $u * \in U$ so as to minimize

$$
\left.J(u)=\mathrm{E}_{0}^{u} \int_{0}^{1} \mathrm{f}\left(t, \cdot u_{t}\right) d t+\gamma(\cdot)\right]
$$

A minimizing control is said to be optimal.
The result below has been proved in [3] in a slightly more restrictive form than necessary.

Theorem $2 u^{*}$ is an optimal control if and only if there exist a constant $J^{*}$, and processes $\left(\Lambda V_{t}\right),\left(\nabla V_{t}\right)$ with values in $R, R^{n}$ respectively such that
(i) $J^{\star}+\int_{0}^{1} \Lambda v_{t} d t+\int_{0}^{1} \nabla v_{t} d z_{t}=\gamma$ a.s.
(ii) $\Lambda V_{t}+\operatorname{Min}_{u \varepsilon U}\left\{\nabla V_{t} f(t, z, u)+c(t, z, u)\right\}=0$,
and the minimum is achieved at $u^{*}(t, z)$ for almost all $t, z$. Furthermore, $J^{*}=J\left(u^{*}\right)$ is the minimum cost; in fact,

$$
J^{*}+\int_{0}^{t} \Lambda V_{s} d s+\int_{0}^{t} \nabla V_{s} d z_{s}=\operatorname{Min}_{\| \in U} E^{U}\left\{\int_{t}^{1}\left(s, z, u_{s}\right) d s+\gamma^{i} \mid F_{t}\right\}
$$

### 4.2 Conditions for Equilibrium

The controls $u^{*}=\left(u *^{1} \ldots, u^{*}\right)$ constitute an equilibrium if and only if for each $i u^{*}{ }^{i}$ minimizes $J^{i}\left(u^{\star} \bar{i}^{\bar{i}} u^{i}\right)$ over the set $u^{i}$. Theorem 2 , therefore, immediately yields the next result.
Theorem $3 u^{*}=\left(u^{*}{ }^{i} \ldots, u^{* N}\right)$ is an equilibrium if and only if for each $i$ there exist a constant $J \star^{i}$, and processes $\left(A V_{t}^{i}\right),\left(\nabla V_{t}^{i}\right)$ such that
(i) $\quad J^{\star}+\int_{0}^{1} n v_{t}^{i} d t+\int_{0}^{1} \nabla v_{t}^{i} d z_{t}=\gamma^{i}$ a.s.
(ii)

$$
\Lambda v_{t}^{i}+\operatorname{Min}_{u_{i} \varepsilon U_{i}}\left\{\nabla v_{t}^{1} f\left(t, z,\left(u^{*^{\bar{i}}}(t, z), u_{i}\right)\right)+c^{i}\left(t, z,\left(u^{\bar{i}}(t, z), u_{i}\right)\right)\right\}=0
$$ and the minimum is achieved at $u^{\star}(t, z)$ a.s. Furthermore, $J^{\star^{i}}=J^{i}\left(u^{\star}\right)$.

### 4.3 Conditions for Efficiency

Consider the set $J=\left\{J(u)=\left\{J^{l}(u), \ldots, J^{N}(u)\right) \mid u \varepsilon u\right\}$, the set of attainable cost vectors. Suppose there exists a non-negative vector $\lambda=\left(\lambda_{1}, \ldots, \lambda_{N}\right) \neq 0$ and $a^{*}$ such that

$$
\begin{equation*}
\lambda J\left(u^{*}\right) \leq \lambda J \text { for all } J \varepsilon J \tag{3}
\end{equation*}
$$

It is then immediate that $u^{*}$ is an efficient solution. It is also wellknown that (3) is a necessary condition in the event that $J$ is a convex set. This observation, in conjunction with Theorem 2 and Lemma 1, imply the next result.

Theorem 4 a) $u^{*}$ is an efficient solution if there exist $\lambda \geq 0, \lambda \neq 0$, and for each $i$ a constant $J \star^{i}$, and processes $\left(\Lambda V_{t}^{i}\right),\left(\nabla V_{t}^{i}\right)$ such that
(i) $\quad \Sigma \lambda_{i}\left[J^{\star^{i}}+\int_{0}^{1} \Lambda v_{t}^{i} d t+\int_{0}^{l} \nabla v_{t}^{i} d z_{t}\right]=\Sigma \lambda_{i} \gamma^{i}$ a.s.
(ii) $\Sigma \lambda_{i} \Lambda V_{t}^{i}+\operatorname{Min}_{u \in U} \Sigma \lambda_{i}\left\{\nabla V_{t}^{i} f(t, z, u)+c^{i}(t, z, u)\right\}=0$,
and the minimum is achieved at $u^{*}(t, z)$ a.s.
b) If the game has the convexity property, then the conditions above are necessary for efficiency.

Fron a game-theoretic viewpoint an efficient solution is of interest only insofar as it is also an equilibrium. The combination of the results above gives the first intriguing result. Its proof is given in the Appendix. Theorem 5 a) $u^{*}$ is an efficient equilibrium if there exist for each $i$ a constant $J \star^{i}$, and procenses $\left(\Lambda V_{t}^{i}\right)$, $\left(\nabla V_{t}^{i}\right)$ such that
(i)

$$
J *^{i}+\int_{0}^{1} \Lambda V_{t}^{i} d t+\int / V_{0}^{i} d z_{t}=\gamma^{i} \text { a.s. }
$$

$$
\begin{equation*}
\Lambda_{t}^{i}+u_{i}^{M i} B_{i}\left\{\nabla V_{t}^{i} f\left(t, z,\left(u^{\bar{i}}(t, z), u_{i}\right)\right)+c^{i}\left(t, z,\left(u^{\bar{i}}(t, z), u_{i}\right)\right)\right\}=0 \tag{ii}
\end{equation*}
$$ and the minimum is achieved at $u^{*^{i}}(t, z)$ a.s.,

(iii) there exist $\lambda \geq 0, \lambda \neq 0$ such that
$\sum \lambda_{i}\left\{\nabla V_{t}^{i} f\left(t, z, u^{*}(t, z)\right)+c^{i}\left(t, z, u^{*}(t, z)\right)\right\}=\operatorname{lin}_{u \in U} \sum \lambda_{i}\left\{W_{t}^{i} f(t, z, u)+c^{i}(t, z, u)\right\}$ a.s.
b) If the game has the convexity property, then the conditions above are also necessary.

Remark Define the Hamiltonian $H^{i}(t, z, u)=\nabla V_{t}^{i} E(t, z, u)+c^{i}(t, z, u)$. Condition (ii) above says that ith Hamiltonian must be minimized along the ith "coordinate" $u_{i}$. Condition (iii) says that in order that the "private" minimization (implied in the equilibrium concept) also be "socially" efficient this private minimization should lead to the "global" minimization of the social cost obtained as a weighted combination of the private costs. The intriguing part of the result is that these weights, the $\lambda_{i}$, are constant, that is, they do not depend on time $t$ or the random state $z$.

### 4.4 Conditions for the Core

The result for the core follows in the same way as Theorem 5. Theorem 6 a) $u^{*}$ is in the core if there exist for each i a constant $J^{*^{i}}$, and processes $\left(\Lambda V_{t}^{i}\right),\left(\nabla V_{t}^{i}\right)$ such that
(i) $\quad J^{i}+\int_{0}^{1} A V_{t}^{i} d t+\int_{0}^{1} \Gamma_{t}^{i} d z_{t}=\gamma^{i}$ a.s.
(ii) $A V_{t}^{i}+\operatorname{Min}_{u_{i} \varepsilon U_{i}}\left\{W_{t}^{i} f\left(t, z,\left(u^{*}(t, z), u_{i}\right)+c^{i}\left(t, z,\left(u^{*} \bar{i}(t, z), u_{i}\right)\right)\right\}=0\right.$,
and the minimum is achieved at $u^{i}(t, z)$ a.s.
(iii) for each $S$ there exist constants $\lambda_{i}^{S} \geq 0$, iES, not all zero,
such that

$$
\begin{aligned}
\sum_{i \varepsilon S} \lambda_{i}^{S}\left\{\nabla V_{t}^{i} f\left(t, z, u^{*}(t, z)\right)+c^{i}\left(t, z, u^{*}(t, z)\right)\right\} & =\operatorname{Min}_{u \in U} \sum_{i \in S} \lambda_{i}^{S}\left\{\nabla V _ { t } ^ { i } f \left(t, z,\left(u^{*} \bar{S}^{\mathbf{S}}(t, z), u_{S}\right)\right.\right. \\
& +c^{i}\left(t, z,\left(u^{x^{S}}(t, z), u_{S}\right)\right\} \text { a.s. }
\end{aligned}
$$

b) If the game has the strong convexity property, then the conditions above are also necessary.

Remark It may appear reasonable, at first sight, to conjecture that the weights, $\lambda_{i}^{S}$, should not depend upon $S$. However, upon further reflection, the reader should become convinced that this is unlikely. Thus the waights associated with different players will vary with the coalition $s$ in which they are being considered as members.

## §5. RANDOMIZED STRATEGIES

The convexity property is evidently quite restrictive. However, if one permits randomized controls, then converity is guaranteed. To see this, define $M_{i}$ as the set of all probability measures on $U_{i} . U_{i}$ can then be regarded as a subset of $M_{i}$ and the function $f$ can be extenced to the comain $[0,1] \times C \times M_{1} \times \ldots \times M_{N}$ by setting

$$
\begin{equation*}
f\left(t, z, m_{1} \ldots, m_{N}\right)=\int_{U_{1}} \ldots \int_{U_{N}} f\left(t, z, u_{1}, \ldots, u_{N}\right) m_{1}\left(d u_{1}\right) \ldots m_{N}\left(d u_{N}\right) \tag{4}
\end{equation*}
$$

The cost functions $c^{i}$ can be extended analogously. The spaces $M_{i}$ can be made compact and metrizable in a standard manner and $f(t, z, \cdot)$ remains continuous on $M=M_{1} \times \ldots x M_{N}$. The controls for $i$ are now randomized controls that is functions $m_{i}^{i}:[0,1] \times \quad C \rightarrow M_{i}$. The previous results continue to hold for this "extended" game. But notice from (4) that this extended game enjoys the convexity property and if joint randomization is allowed it also enjoys the strong convexity property.

## APPENDLTX

## Proof of Theorem 5

Part a of the theorem follows immediately from theorem 3 and Part a of theorem 4. Hence it only remains to prove Part b.

By theorem 3 there exist for each $i J *^{i}$, and processes $\left(\Lambda V_{t}^{i}\right),\left(W_{t}^{i}\right)$ such that

$$
\begin{align*}
& J^{\star_{i}}+\int_{0}^{1} \Lambda V_{t}^{i} d t+\int_{0}^{1} \nabla V_{t}^{i} d z_{t}=\gamma^{i} \text { a.s. }  \tag{A.2}\\
& \Lambda V_{t}^{i}+\operatorname{Min}_{u_{i} \varepsilon U_{i}}\left\{\nabla V_{t}^{i} f\left(t, z,\left(u^{*} \bar{i}(t, z), u_{i}\right)\right)+c^{i}\left(t, z,\left(u^{*^{i}}(t, z), u_{i}\right)\right)\right\}=0
\end{align*}
$$

and the minimum is achieved at $u_{i}^{*}(t, z)$. On the other hand, by Part $b$ of theorem 4 there exist $\lambda \geq 0, \lambda \neq 0$ and for each $i r^{*}$, and processes $\left(\| v_{t}^{i}\right.$ ), $\left(\nabla \|_{t}^{i}\right)$ such that

$$
\begin{aligned}
& \Sigma \lambda_{i}\left[K *^{i}+\int_{0}^{1} \Lambda W_{t}^{i} d t+\int_{0}^{1} \nabla W_{t}^{i} d z_{t}\right]=\Sigma \lambda_{i} \gamma^{i} a . s . \\
& \Sigma \lambda_{i} A W_{t}^{i}+\operatorname{Min}_{u \varepsilon U} \Sigma \lambda_{i}\left\{\nabla W_{t}^{i} f(t, z, u)+c^{i}(t, z, u)\right\}=0
\end{aligned}
$$

and the minimum is acnieved at $u^{*}(t, z)$ a.s.
Comparison of these two sets of conditions reveals that it is enough to show that whenever (A1) and (A2) are both satisfied, then (A2) is also satisfied by choosing

$$
K \star^{i}=J \star^{i}, \Lambda w_{t}^{i}=\Lambda V_{t}^{i}, \text { and } \nabla w_{t}^{i}=\nabla v_{t}^{i}
$$

Now, by the last part of theorem 2 ,

$$
J^{\hbar^{i}}+\int_{0}^{t} \Lambda V_{t}^{i} d s+\int_{0}^{t} \nabla V_{t}^{i} \mathrm{~d} z_{s}
$$

$$
\begin{aligned}
& =\min _{u \varepsilon U} E^{\prime \prime}\left\{\int_{t}^{1} c^{i}\left(s, z_{s},\left(u_{s}^{*}, u_{s}^{i}\right) d s+\gamma^{i} \mid F_{t}\right\}\right. \\
& =E^{u^{*}}\left\{\int_{t}^{l} c^{i}\left(s, z_{s}, u_{t}^{*}\right)+\gamma^{i} \mid F_{t}\right\}
\end{aligned}
$$

and similarly,

$$
\begin{aligned}
& \Sigma \lambda_{i}\left[K^{*^{i}}+\int_{0}^{t} \Lambda w_{s}^{i} d s+\int_{0}^{t} \nabla w_{s}^{i} d s_{s}\right\} \\
& =E^{\mu l^{*}}\left\{\Sigma \lambda_{i}\left[\int_{t}^{1} c^{i}\left(s, z_{s}, \mu_{t}^{*}\right)+\gamma^{i}\right] \mid F_{i}\right\}
\end{aligned}
$$

Hence,
$\Sigma \lambda_{i}\left[J *^{i}+\int_{0}^{t} \Lambda V_{s}^{i} d s+\int_{0}^{t} \nabla V_{s}^{i} d z_{s}\right]=\Sigma \lambda_{i}\left[K *^{i}+\int_{0}^{t} \Lambda W_{s}^{i} d s+\int_{0}^{t} \nabla v_{s}^{i} d z_{s}\right]$
Setting $t=0$, gives $\Sigma \lambda_{i} J^{*^{i}}=\sum \lambda_{i} x^{*^{i}}$ and so

$$
\int_{0}^{t}\left(\Sigma \lambda_{i} v_{s}^{i}-\Sigma \lambda_{i} w_{s}^{i}\right) d s=\int_{0}^{t}\left(\Sigma \lambda_{i} \nabla v_{s}^{i}-\Sigma \lambda_{i} \nabla V_{s}^{i}\right) d z_{s}
$$

But, under the measure $p\left(z_{t}\right)$ is a Brownian motion so that the term on the right is a continuous martingale whereas the term on the left is a process with integrable variation. It follows that both terms must vanish so that $\Sigma \lambda_{i} V_{s}^{i}=\Sigma \lambda_{i} V_{s}^{i}$ and $\Sigma \lambda_{i} \nabla V_{s}^{i}=\Sigma \lambda_{i} \nabla v_{s}^{i}$ and the result follows.

## §6. CONCLUSTOMS

These remarks are mainly suggestions for further research.
It is known that for deterministic differential games the condition that the weights $\lambda_{i}$ are constant is suificient but not necessary even when the game has the convexity property. The results presented here therefore convey surprise. However, it is not evident that these results should be regarded as curiosities or as significant. To decice this it is necessary to clarify the precise rôle played by the Brownian motion in (l). Such clarification should also aid.in restoring a measure of unity to the currently disparate traditions in the literature on deterministic and stochastic differential ganes. In the cases of control problems and two-player zero-sun games this has been achieved by the important work of Fleming $[4,5]$ and subsequent work of Danskin [6] and Friedman [7], but it is not clear that these directions will prove useful for the many-player games.

This paper is not addressed to the important question of existence of solutions. For efficient controls, this question is immediately settled by known results on existence of optimal controls. I recent study [8] has nicely resolved the problem of existence of saddle points and value for two-player, zero-sum, stcchastic differential games. It seems likely that the methods used in that study combined with the usual fixed-point arguments will help in proving existence of equilibrium solutions and the core.

Finally, the condition of complete information is a serious a priori. restriction on the family of games considered in this paper. It is likely that results similar to those obtained here hold when all players have the same information even if it is incomplete [9]. The game is enormously
more complicated when different players have different information. In the context of static games many important insights are provided by the results reported in $[10,11]$.
