### ABSTRACT

To better understand the risk for U.S. youth substance abuse, the results of all the follow-up surveys of the graduating high school classes of 1976 through 1994 -- taken from the Monitoring the Future study of young adults, ages 19-32 years old--is presented here. The report serves a social monitoring function, in which levels and trends in certain behaviors, attitudes, beliefs, and conditions in this population are accurately assessed. It includes trend data for the high school senior population, as well as for college students -- an important subset of the young adult population for which very little nationally representative data exists. After outlining study design and procedures, the findings are presented in six chapters: (1) "Prevalence of Drug Use among Young Adults," (2) "Trends in Drug Use among Young Adults," (3) "Attitudes and Beliefs about Drugs among Young Adults," (4) "The Social Milieu for Young Adults," (5) "Prevalence of Drug Use among College Students," and (6) "Trends in Drug Use among College Students." Overall, it was found that there were appreciable declines in the use of a number of the illicit drugs among high school seniors, with the largest declines evident among American college students and young adults. ### Chapter 1

### INTRODUCTION TO VOLUME II

This is the second volume in a two-volume set reporting the results of all surveys through 1995 from the Monitoring the Future study of American secondary school students, college students, and young adults. Monitoring the Future is a long-term research program conducted at the University of Michigan's Institute for Social Research under a series of research grants from the National Institute on Drug Abuse. It is comprised of an ongoing series of annual national surveys of American high school seniors begun in 1975—the results of which are presented in Volume I—as well as a series of annual follow-up surveys of representative samples of the previous participants from each high school senior class going back to the class of 1976. In 1991, the study also began to survey eighth and tenth grade students; the results from these surveys are included in Volume I. This second volume presents the results of the 1977 through 1995 follow-up surveys of the graduating high school classes of 1976 through 1994 as these respondents have progressed through young adulthood.

In order for this volume to stand alone, some material from Volume I is repeated here. Specifically, Chapter 2 in this volume is the same as Chapter 2, Volume I, and provides an overview of the key findings presented in both volumes. Chapter 3, Study Design and Procedures, also draws almost entirely from Volume I, Chapter 3. Therefore, the reader already familiar with Volume I will want to skip over these chapters. Otherwise, the content of the two volumes does not overlap.

### SURVEYS OF COLLEGE STUDENTS

The follow-up samples in Monitoring the Future provide very good coverage of the national college student population since 1980. College students tend to be a difficult population to study. They generally are not well covered in normal household surveys, which typically exclude dormitories, fraternities, and sororities from the universe covered. Further, the institution-based samples must be quite large to attain accurate national representation of college students because there is great heterogeneity in the types of student populations served in those institutions. There also may be problems getting good samples and high response rates within many institutions. The current study, which in essence draws the college sample in senior year of high school, has considerable advantages for generating a broadly representative sample of the college students to emerge from each graduating cohort, and it does so at very low cost. Further, it has "before" as well as "during" and "after" college measures, which permit the examination of change. For comparison, it also has similar panel data on the high school graduates who do not attend college.

As defined here, the college student population is comprised of all full-time students, one to four years post-high school, enrolled in a two- or four-year college in March during the year of the survey. More will be said about this sample definition in Chapters 3 and 8. Results on the *prevalence* of drug use among college students in 1995 are reported in Chapter 8, and results on the *trends* in substance use among college students over the past 15 surveys are reported in Chapter 9.

### SURVEYS OF YOUNG ADULTS

The young adult sample on which we report here includes the college students and is comprised of representative samples from each graduating class since 1980, all surveyed in 1995. Since 18 is the modal age of high school seniors, the young adults covered here correspond to modal ages 19 through 32. Because the study design calls for annual follow-up surveys through age 32, and then less frequent surveys beginning at age 35, the classes of 1976 through 1980 were not surveyed in 1995; the one exception was the class of 1978, members of which were sent a special "age 35" questionnaire. The results of the "age 35" survey are not included in the present volume, but will be included in future reports from the study. In this volume we have re-weighted the respondents to correct for the effects of panel attrition on measures such as drug use; however, we are less able to adjust for the absence of high school dropouts who were not included in the original high school senior sample. Because nearly all college students have completed high school, the omission of dropouts should have almost no effect on the college student estimates, but this omission does have an effect on the estimates for entire age groups. Therefore, the reader is cautioned that the omission of the 15% to 20% of each cohort who drop out of high school will make the drug use estimates given here for the various young adult age bands somewhat low for the age group as a whole. The proportional effect may be greatest for some of the most dangerous drugs such as heroin and crack, and also for cigarettes-the use of which is highly correlated with educational aspirations and attainment.

### GENERAL PURPOSES OF THE RESEARCH

The research purposes of the Monitoring the Future study are extensive and can be sketched only briefly here. One major purpose is to serve a social monitoring or social indicator function, intended to characterize accurately the levels and trends in certain behaviors, attitudes, beliefs, and conditions in the population. Another purpose is to develop knowledge which increases our understanding of why changes in these behaviors, attitudes, etc., are taking place. (In healthrelated disciplines such work is usually labeled epidemiology.) These two purposes are addressed in the current series of volumes. There are a number of other purposes for the research, however, which are addressed through other types of publications and professional products. They include: helping to determine what types of young people are at greatest risk for developing various patterns of drug abuse; gaining a better understanding of the lifestyles and value orientations associated with various patterns of drug use, and monitoring how those orientations are shifting over time; determining the immediate and more general aspects of the social environment which are associated with drug use and abuse; determining how drug use is affected by major transitions into and out of social environments (such as military service, civilian employment, college, unemployment) or social roles (marriage, pregnancy, parenthood). We also are interested in determining the life course of the various drug-using behaviors during this period of development; distinguishing such "age effects" from cohort and period effects in determining drug use; determining the effects of social legislation on various types of substance use; and determining the changing connotations of drug use and changing patterns of multiple

<sup>&</sup>lt;sup>1</sup>For a more complete listing and discussion of the study's many objectives, see Johnston, L.D., O'Malley, P.M., Bachman, J.G., and Schulenberg, J. (1996, revised). *The aims and objectives of the Monitoring the Future study and progress toward achieving them.* Monitoring the Future Occasional Paper No. 34. Ann Arbor, MI: Institute for Social Research.

drug use among youth. We believe that the differentiation of period, age, and cohort effects in substance use of various types has been a particularly important contribution of the project; its cohort-sequential research design is especially well-suited to allow such differentiation. Readers interested in publications dealing with any of these other areas, or wishing to receive a copy of a brochure listing publications from the study, should write the authors at the Institute for Social Research, The University of Michigan, Ann Arbor, Michigan, 48106-1248.

### Chapter 2

### OVERVIEW OF KEY FINDINGS

Volumes I and II of this monograph report the findings through 1995 of the ongoing research and reporting series entitled Monitoring the Future: A Continuing Study of the Lifestyles and Values of Youth. Over its twenty-one year existence, the study has consisted of in-school surveys of nationally representative samples of (a) high school seniors each year since 1975 and (b) eighth and tenth grade students each year since 1991. In addition, beginning in 1976, follow-up surveys have been conducted by mail on representative subsamples of the respondents from each previously participating twelfth grade.

Volume I of this report presents findings on the prevalence and trends in drug use and related factors for secondary school students (eighth, tenth, and twelfth graders); Volume II presents the results for young adult high school graduates 19-32 years old, as well as college students specifically. Trend data are presented for varying time intervals, covering up to the past twenty years in the case of the high school senior population. For college students, a particularly important subset of the young adult population for which very little nationally representative data exists, we present detailed prevalence and trend results covering a fifteen year interval (since 1980). The high school dropout segment of the population—about 15%-20% of an age group—is of necessity omitted from the coverage of these populations, though this omission should have a negligible effect on the coverage of college students. Appendix A to this report discusses the likely impact of omitting dropouts from the sample coverage at senior year. Very few students will have left school by eighth grade, of course, and relatively few by the end of tenth grade, so the results of the school surveys at those levels should be generalizable to the great majority of the relevant age cohorts.

A number of important findings emerge from these five national populations—eighth grade students, tenth grade students, twelfth grade students, college students, and all young adults through age 32 who are high school graduates. They have been summarized and integrated in this chapter so that the reader may quickly get an overview of the key results. Because so many populations, drugs, and prevalence intervals are discussed here, a single integrative table (Table 1) showing the 1991-1995 trends for all drugs on all five populations is included in this chapter.

### TRENDS IN ILLICIT DRUG USE

o In the previous three volumes in this series we have noted an increase in the use of a number of illicit drugs among the secondary students and some reversals among them in key attitudes and beliefs. (Beginning with the volume reporting 1992 survey results, we noted the beginning of such reversals among eighth graders, the youngest respondents surveyed in this study.) Specifically, the proportions seeing great risk in using drugs began to decline as did the proportions saying they disapproved of use. As predicted earlier, those reversals indeed presaged "... an end to the improvements in the drug situation that the nation may be taking for granted." The use of illicit drugs again rose sharply in 1995 in all three grade levels as negative attitudes and beliefs about them continued to erode.

This year's findings on illicit drug use are in many ways a continuation of the prior two years, with *marijuana* use rising sharply among secondary school students and their use of a number of *other illicit drugs* rising more gradually. The most significant change in the story is that these increases in use are now beginning to show up among American college students, as well, no doubt in large part to "generational replacement," wherein earlier graduating high school class cohorts are being replaced in the college population by more recent ones who were more drug experienced even before they left high school. The spread of this resurgence in the epidemic *up* the age spectrum is a reversal of the way the epidemic spread when it began in the 1960's. It began on the nation's college campuses and then the behavior diffused downward in age to high school students, and eventually junior high school students.

At present there still is rather little increase in illicit drug use in the young adult population, 19-28 years old, taken as a whole; but it can be predicted that generational replacement will also begin to move the numbers up for this group, as well.

- A parallel finding occurred this year for *cigarette* smoking, as well, in that college students showed a sharp increase in smoking, no doubt reflecting a generational replacement effect. (Smoking has been rising among graduating high school seniors since 1992.) This has been a more typical pattern of change for *cigarettes*, since differences among class cohorts tend to remain through much or all of the life cycle and also tend to account for much of the change in use which is observed at any given age. Whatever the cause, however, the sharp increase in 1995 in smoking among college students is also noteworthy.
- Marijuana use rose sharply in all three grade levels in 1995, the fourth year of increase for eighth graders and the third for tenth and twelfth graders. Over these intervals the annual use of marijuana (i.e., any use during the prior twelve months) more than doubled among eighth graders (from 6.2% in 1991 to 16% in 1995), nearly doubled among tenth graders (from 15% in 1992 to 29% in 1995), and grew by more than half among twelfth graders (from 22% in 1992 to 35% in 1995). Among college students and young adults, the increase from 1991 or 1992 had been much more gradual. Among college students, however, the increase in marijuana use accelerated considerably in 1995, no doubt in large part due to a "replacement effect," wherein more drug experienced high school graduates are replacing graduating college students who had used drugs less before going to college.

Daily marijuana use rose significantly for 10th and 12th graders in 1995, reaching 4.6% among seniors; that is one in every 22 students or more than one per average classroom. Still, this rate is far below the 10.7% peak figure reached in 1978. College students showed a doubling in their daily use rate, which rose from 1.8% in 1994 to 3.7% in 1995.

- Among seniors, the proportions using *any illicit drug other than marijuana* in the past year rose to 19% from a low of 15% in 1992, a rate still substantially below the 34% peak rate in 1981. There was very little change for young adults (14%) but all of the younger groups showed significant increases in 1995, including college students for the first time.
- In 1989-1991 we noted an increase among college students and young adults in the use of *LSD*, a drug most popular in the late 1960s and early 1970s. In 1992, all five populations showed an increase in annual prevalence of LSD. Then for two years modest increases persisted among the secondary school students. In 1995 there were significant increases in LSD use in all three grade levels as well as among the college students. As with marijuana, the recent increase among college students may largely be due to a "replacement effect."

Prior to the significant increase in use among seniors in 1993, there was a significant 4.3% decline in the proportion seeing great risk associated with trying LSD. A nonsignificant decline in this belief continued through 1995. The proportion disapproving LSD began to decline in 1992 and continued through 1995.

Since LSD was one of the earliest drugs to be popularly used in the overall American drug epidemic, there is a distinct possibility that young people—particularly the youngest cohorts, like the eighth graders—are not as concerned about the risks of use. They have had less opportunity to learn vicariously about the consequences of use by observing others around them, or to learn from intense media coverage of the issue. This type of "generational forgetting" of the dangers of a drug, which occurs as a result of generational replacement, could set the stage for a whole new epidemic of use. There has, in fact, been the decline in perceived harmfulness of LSD, just mentioned, which began after 1989 among seniors. These measures were first introduced for eighth and tenth graders in 1993 and both measures have been dropping since then among them as well.

• Prescription-controlled *stimulants*—one of the most widely used classes of drugs taken illicitly (i.e., outside of medical regimen)—also showed evidence of a continued increase among the 8th and 10th graders in 1995, with annual and 30-day prevalence rates gradually increasing. The 12th grade did not show this increase in 1995, although their use had increased between 1992 and 1994.

Annual prevalence rates had fallen from 20% in 1982 to 7% in 1992 among seniors, and had fallen from 21% to 4% among college students over the same interval. The increase in use (and a decrease in disapproval) began among seniors in 1993, following a sharp drop in perceived risk a year earlier. This pattern of change was consistent with our theoretical position that perceived risk can drive both use and disapproval. Perceived risk, but not disapproval, continued to decline in 1995 among seniors, while **stimulant** use leveled. College students showed an increase in **stimulant** use, but it was not large enough to reach statistical significance. Young adults showed no change in use.

### **FABLE 1**

'\*' indicates less than .05 percent but greater than 0 percent. Any apparent inconsistency between the change estimate and the prevalence estimates for the two years is '--' indicates data not available. sss = .001. ss = .01. Level of significance of difference between the two years: s = .05, due to rounding error. NOTES:

other cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, or tranquilizers not under a doctor's orders. For 8th and 10th graders For 12th graders, college students, and young adults only: Use of "any illicit drug" includes any use of marijuana, LSD, other hallucinogens, crack The use of other opiates and barbiturates has been excluded, because these younger respondents appear to overreport use (perhaps because hey include the use of nonprescription drugs in their answers).

For 12th graders, college students, and young adults only: Data based on five of six forms, N is five-sixths of N indicated for each group

Inhalants are unadjusted for underreporting of amyl and butyl nitrites; hallucinogens are unadjusted for underreporting of PCP

For 8th, 10th, and 12th graders, and young adults only. Data based on one form; N for 12th graders and young adults is one-sixth of N indicated, N for 8th and 10th graders is one-half of N indicated. Questions about nitrite use were dropped from the college student and young adult for 8th and 10th graders is one-half of N indicated. Questions about nitrite use were dropped from the college student and young adult questionnaires in 1995. Questions about smokeless tobacco use were dropped from the college student and young adult questionnaires in 1989.

For 12th graders, college students, and young adults only. Data based on four forms; N is four-sixths of N indicated for each group.

For 12th graders, college students, and young adults only: Data based on two forms; N is two-sixths of N indicated for each group.

\*In 1995, the heroin question was changed in three of six forms for 12th graders and in one of two forms for 8th and 10th graders. Separate questions were asked for use with injection and without injection. Data presented here represent the combined data from all forms. In 1996, the heroin question was changed in the remaining 8th and 10th grade form.

"Only drug use which was not under a doctor's orders is included here.

forms using the revised wording. In 1993, each line of data was based on one of two forms for the 8th and 10th graders and on three of six forms for the 12th graders. N is one half of N indicated for these groups. Data for 1994-96 were based on all forms for all grades. For college students and For 8th, 10th, and 12th graders only: In 1993, the question text was changed slightly in half of the forms to indicate that a "drink" meant "more than just a few sips." The data in the upper line for alcohol came from forms using the original wording, while the data in the lower line came from young adults, the revision of the question text resulted in rather little change in reported prevalence. The data for all forms are used to provide the most reliable estimate of change.

For 12th graders and young adults only: Data based on two of six forms; N is two-sixths of N indicated

The *inhalants* constitute another class of abusable substances where a troublesome increase continued in 1995. Inhalants are defined as fumes or gases which are inhaled to get high, including common household substances such as glues, aerosols, butane, and solvents. One class of inhalants, *amyl and butyl nitrites*, became somewhat popular in the late 1970s, but their use has been almost eliminated. For example, annual prevalence among twelfth grade students was 6.5% in 1979 but only 1.1% in 1995.

When the nitrites are removed from consideration it appears that all other inhalants taken together have had an upward trend in annual use, from 3.0% among seniors in 1976 to 8.0% in 1995. The three secondary school populations continued to show a modest increase in inhalant use in 1995, though in no case was the one-year change statistically significant. Some 13% of the 1995 eighth graders and 10% of the tenth graders indicated use in the prior 12 months, making inhalants the second most widely used class of illicitly used drugs for eighth graders (after marijuana) and the third most widely used (after marijuana and stimulants) for the tenth graders. Inhalants can and do cause death, and tragically, this often occurs among youngsters in their early teens.

• Among high school seniors the overall prevalence of *crack* cocaine leveled in 1987 at relatively low prevalence rates, even though crack use continued to spread to new communities. In 1995, annual prevalence rose slightly (not significantly) to 2.1% for seniors (up from 1.5% in 1993 but down from 3.9% in 1987). Small increases among eighth and tenth grade students in both 1994 and 1995 did reach statistical significance. Among young adults one to ten years past high school, annual prevalence was 1.0%, relatively unchanged since 1991. While it did not reach statistical significance, college students showed their first increase in *crack* use in 1995, much as happened for the other illicit drugs discussed here. In high school, annual crack prevalence among the college-bound is lower than among those not bound for college (1.7% vs. 3.0%).

We believe that the particularly intense and early media coverage of the hazards of crack cocaine likely had the effect of "capping" an epidemic early by deterring many would-be users and by motivating many experimenters to desist use. While 3.0% of seniors report ever having tried crack, only 1.0% report use in the past month, indicating noncontinuation by 67% of those who try it. The longer-term downward trend could be explained by lower initiation rates among students and by higher noncontinuation rates.

While crack use did not increase in 1993, perceived risk and disapproval dropped in all three grade levels, predicting the modest rise in use in all three grades in 1994 and 1995.

 Cocaine<sup>2</sup> in general began to decline a year earlier than crack. Between 1986 and 1987 the annual prevalence rate dropped dramatically, by roughly one fifth

<sup>&</sup>lt;sup>2</sup>Unless otherwise specified, all references to "cocaine" refer to the use of cocaine in any form, including crack.

in all three populations then studied—seniors, college students, and young adults. The decline occurred when young people began to view experimental and occasional use—the type of use in which they are most likely to engage—as more dangerous. This change had occurred by 1987, probably partly because the hazards of cocaine use received extensive media coverage in the preceding year, but almost surely in part because of the cocaine-related deaths in 1986 of sports stars Len Bias and Don Rogers. By 1992 annual prevalence of cocaine use had fallen by about two-thirds among the three populations for which long-term data are available.

In 1993, cocaine use remained stable among secondary students but continued to decline among college students and young adults. In 1994 and 1995, annual use rose among eighth, tenth, and twelfth graders and increased significantly for the first time in recent years among college students. There was no change in use among young adults. Again, the story regarding attitudes and beliefs is informative.

Having risen substantially since 1986, the perceived risk of using cocaine actually showed some (nonsignificant) decline in 1992 among seniors. In 1993, perceived risk for cocaine other than crack fell sharply in all grades and disapproval began to decline in all grades, though not as sharply as perceived risk. In 1995, perceived risk declined in all three grades. Disapproval continued its decline among eighth and tenth graders, but not among seniors.

Through 1989, there was no decline in perceived availability of cocaine among twelfth graders; in fact, it rose steadily from 1983 to 1989 suggesting that availability played no role in bringing about the substantial downturn in use. After 1989, however, perceived availability has fallen some among seniors; the decline may be explained by the greatly reduced proportions of seniors who say they have any friends who use, because friendship circles are an important part of the supply system. Since 1992 there has been rather little change in eighth and tenth grade reports of availability of powder cocaine. Among seniors, reported availability declined from 1992 to 1994, before leveling.

As with all the illicit drugs, lifetime cocaine prevalence climbs with age, exceeding 24% by age 28. Unlike all of the other illicit drugs, active use—i.e., annual prevalence or monthly prevalence—also climbs after high school.

- *PCP* use fell sharply among high school seniors between 1979 and 1982, from an annual prevalence of 7.0% to 2.2%. It reached a low point of 1.2% in 1988 and stands at 1.8% in 1995. For the young adults, the annual prevalence rate is now only 0.3%.
- The annual prevalence of *heroin* use among twelfth graders fell by half between 1975 (1.0%) and 1979 (0.5%). It then stabilized for some fifteen years until 1994 (0.6%), before rising significantly to 1.1% in 1995. Among young adults and college students as well, heroin statistics were quite stable and at low rates (about 0.1% to 0.2%) through 1994, followed by the first increase in 1995. Eighth

and tenth graders showed an increase in heroin use in both 1994 and 1995. Their annual prevalence rates are roughly double what they were in the early nineties. Two factors that very likely contribute to the recent upturn in heroin use are: (1) a long-term decline in the perceived dangers of heroin due to "generational forgetting" (the last major heroin epidemic occurred around 1970), and (2) the fact that in recent years heroin can be used without injection (making it seem safer and perhaps less addicting). Using some new questions on heroin use introduced in 1995, we are able to show that significant proportions of past year users in grades eight, ten, and twelve, are taking heroin by means other than injection. (See Chapter 4 for details.)

We take these recent increases to reflect the fact that the newer, purer heroin available on the street can be taken by means other than injection (by snorting or smoking, for example). These new modes of administration presumably are considered safer (and may well be considered less likely to lead to addiction) than intravenous injection, thus lowering a significant psychological barrier for many potential users. New questions introduced into the study in 1995 show that, indeed, a substantial proportion of recent heroin users are using by means other than injection.

The risk perceived to be associated with heroin fell for more than a decade after the study began, with 60% of the 1975 seniors seeing a great risk of trying heroin once or twice and only 46% of the 1986 seniors saying the same. Since the last major heroin epidemic occurred around 1970, we view this steady decline in perceived risk as a case of "generational forgetting" of the drug's dangers. Between 1986 and 1991 perceived risk rose from 46% to 55%, undoubtedly reflecting the new threat of HIV infection associated with heroin injection. After 1991, however, perceived risk fell again (to 51% by 1995), this time perhaps reflecting the fact that the newer heroin on the street was so much purer that it could be administered by methods other than injection.

- The use of *opiates other than heroin* had been fairly level over most of the life of the study. Seniors had an annual prevalence rate of 4% to 6% from 1975 to 1990. In 1991, however, a significant decline (from 4.5% to 3.5%) was observed. Young adults in their twenties have generally shown a very gradual decline from 3.1% in 1986 to 2.5% in 1994; college students have likewise shown a slow decrease, from 3.8% in 1982-1984 to 2.4% in 1994. Over the last one to three years, however, each of these populations has shown some increase in use. (Data are not reported for younger grade levels because we believe the students are not accurately discriminating among the drugs which should be included or excluded from this class.)
- A long and substantial decline, which began in 1977, occurred for *tranquilizer* use among high school seniors. By 1992 annual prevalence reached 2.8%, down from 11% in 1977. Since 1992, use has increased, reaching 4.4% in 1995. Reported tranquilizer use also has shown some recent, modest increase among eighth graders, from 1.8% in 1991 to 2.7% in 1995. Among tenth graders, annual prevalence remained stable between 1991 and 1994 at around 3.3%, and then

increased significantly to 4.0% in 1995. After a period of stability, college students also showed some increase in 1995. For the young adult sample, annual prevalence has been quite stable in recent years, after a long period of decline.

- The long-term gradual decline in *barbiturate* use, which began at least as early as 1975, when the study began, halted in 1988. Annual prevalence among seniors fell from 10.7% in 1975 to 3.2% in 1988, and then hovered around 3.4% through 1991 before dropping further to 2.8% in 1992. It rose significantly to 4.1% in 1994 and in 1995 it again rose (not significantly to 4.7%). The 1995 annual prevalence of this class of sedative drugs is lower among the young adult sample (2.1%), and lower still among college students specifically (2.0%). For these groups there has been little change since 1988. Again, data are not included here for lower grades because we believe the younger students have more problems with the proper classification of relevant drugs.
- Methaqualone, another sedative drug, has shown quite a different trend pattern than barbiturates. Its use rose steadily among seniors from 1975 to 1981, when annual prevalence reached 8%. It then fell rather sharply to 0.2% by 1993 and rose significantly to 0.8% in 1994 and 0.7% in 1995. Use also fell among all young adults and among college students, which had annual prevalence rates of only 0.3% and 0.2%, respectively in 1989—the last year in which they were asked about this drug. In the late eighties, shrinking availability may well have played a role in this drop, as legal manufacture and distribution of the drug ceased. Because of its very low usage rates, only the seniors are now asked about their use of this drug.
- In sum, five classes of illicitly used drugs, *marijuana*, *cocaine*, *stimulants*, *LSD*, and *inhalants* have had an impact on appreciable proportions of young Americans in their late teens and twenties. In 1995, high school seniors showed annual prevalence rates of 35%, 4%, 9%, 8%, and 8%, respectively. Among college students in 1995, the comparable annual prevalence rates are 31%, 4%, 5%, 7%, and 4%; and for all high school graduates one to ten years past high school (young adults) the rates are 27%, 4%, 5%, 5%, and 2%. It is worth noting that LSD has climbed in the rankings because its use has not declined, or in some cases has increased, during a period in which use of cocaine, amphetamines, and other drugs declined appreciably. The inhalants have become relatively more important for similar reasons.

Clearly, cocaine is relatively more important in the older age group and inhalants are relatively more important in the younger ones. In fact, in eighth grade inhalants are second to marijuana as the most widely used of the illicit drugs.

Because of their importance among the younger adolescents, a new index of illicit drug use including inhalants was introduced in Table 1. Certainly the use of inhalants reflects a form of illicit, psychoactive drug use; its inclusion makes relatively little difference in the illicit drug index prevalence rates for the older age groups, but considerable difference for the younger ones. For example, the proportion of eighth graders reporting any illicit drug used in their lifetime,

exclusive of inhalants, in 1995 is 29%, whereas 38% report such experience if inhalants are included.

The annual prevalence among seniors of over-the-counter stay-awake pills, which usually contain caffeine as their active ingredient, nearly doubled between 1982 and 1990, increasing from 12% to 23%. Since 1990 this statistic has fallen slightly to 20% in 1995. Increases also occurred among the college-age young adult population (ages 19-22), where annual prevalence was 26% in 1989, but is now down to 18% in 1995.

The other two classes of nonprescription stimulants—the *look-alikes* and the over-the-counter *diet pills*—also showed some fall-off among both seniors and young adults in recent years, though use among seniors rose in 1995. Among seniors in 1995 some 24% of the females have tried diet pills by the end of senior year, 15% have used them in the past year, and 6% in just the past month.

### College-Noncollege Differences in Illicit Drug Use

American college students (defined here as those respondents one to four years past high school who were actively enrolled full-time in a two- or four-year college) show annual usage rates for a number of drugs which are about average for their age group, including any illicit drug, marijuana specifically, hallucinogens, LSD, and opiates other than heroin. For several categories of drugs, however, college students have rates of use which are below those of their age peers, including any illicit drug other than marijuana, cocaine, crack cocaine specifically, heroin, tranquilizers, stimulants, ice, and barbiturates.

Since college-bound seniors had below average rates of use on all of these illicit drugs while they were in high school, the eventual attainment of parity on many of them reflects some closure of the gap. As results from the study published elsewhere have shown, this college effect of "catching up" is largely explainable in terms of differential rates of leaving the parental home and of getting married. College students are more likely than their age peers to have left the parental home and its constraining influences and less likely to have entered marriage, with its constraining influences.

In general, the trends since 1980 in illicit substance use among American college students have paralleled those of their age peers not in college. Most drugs showed a period of substantial decline in use since then. Further, all young adult high school graduates through age 28, as well as college students taken separately, showed trends which were highly parallel for the most part to the trends among high school seniors up until about 1992. After 1992 a number of drugs showed an increase in use among seniors (as well as eighth and tenth graders), but not among college students and young adults. This divergence, combined with the fact that the upturn began first among the eighth graders (in 1992), suggests that cohort effects are emerging for illicit drug use.

### Male-Female Differences in Illicit Drug Use

- Regarding sex differences in three older populations (seniors, college students, and young adults), males are more likely to use most illicit drugs, and the differences tend to be largest at the higher frequency levels. Daily marijuana use among high school seniors in 1995, for example, is reported by 6.5% of males vs. 2.4% of females; among all young adults (19-32 years) by 4.4% of males vs. 2.2% of females; and among college students, specifically, by 4.6% of males vs. 3.0% of females. The only significant exception to the rule that males are more frequently users of illicit drugs than females occurs for stimulant use in high school, where females usually are at the same level or slightly higher.
- In the eighth and tenth grade samples there are fewer sex differences in the use of drugs—perhaps because the girls tend to date older boys who are in age groups considerably more likely to use drugs. There is little male-female difference in eighth and tenth grades in the use of *cocaine* and *crack*. *Stimulant* use is slightly higher among females.

### TRENDS IN ALCOHOL USE

- Several findings about *alcohol* use in these age groups are noteworthy. First, despite the fact that it is illegal for virtually all secondary school students and most college students to purchase alcoholic beverages, experience with alcohol is almost universal among them. That is, 55% of eighth graders have tried it, 71% of tenth graders, 81% of twelfth graders, and 90% of college students, and active use is widespread. Most important, perhaps, is the widespread occurrence of occasions of heavy drinking—measured by the percent reporting five or more drinks in a row at least once in the prior two-week period. Among eighth graders this statistic stands at 15%, among tenth graders at 24%, among twelfth graders at 30%, and among college students at 40%. After the early twenties this behavior recedes somewhat, reflected by the 33% found in the entire young adult sample.
- Alcohol use did not increase as use of other illicit drugs decreased among seniors, although it was common to hear such a "displacement hypothesis" asserted. This study demonstrates that the opposite seems to be true. After 1980, when illicit drug use was declining, the monthly prevalence of alcohol use among seniors also declined gradually, from 72% in 1980 to 51% in 1993. Daily use declined from a peak of 6.9% in 1979 to 2.5% in 1993; and the prevalence of drinking five or more drinks in a row (binge drinking) during the prior two-week interval fell from 41% in 1983 to 28% in 1993—nearly a one-third decline. Now that illicit drug use is starting to rise again in the nineties, there is evidence that alcohol use may, if anything, be starting to increase as well—particularly binge drinking. (Annual and 30-day use have remained fairly stable.)

### College-Noncollege Differences in Alcohol Use

- The data from college students show a quite different pattern in relation to alcohol use. They show less drop-off in monthly prevalence since 1980 (82% to 68% in 1995) and slightly less decline in daily use (6.5% in 1980 to 3.3% in 1995). There has also been little change in occasions of heavy drinking, which was at 40% in 1995—considerably higher than the 30% among high school seniors. Since both their noncollege-age peers and high school students have been showing a net decrease in occasions of heavy drinking since 1980, the college students stand out as having maintained a very high rate of binge or party drinking. Since the college-bound seniors in high school are consistently less likely to report occasions of heavy drinking than the noncollege-bound, this indicates that they are "catching up and passing" their peers in binge drinking after high school.
- In most surveys from 1980 onward, college students have had a *daily drinking* rate which was slightly lower than that of their age peers, suggesting that they were more likely to confine their drinking to weekends, when they tend to drink a lot. Again, college men have much higher rates of daily drinking than college women: 5.3% vs. 1.8% in 1995. The rate of daily drinking has fallen considerably among the noncollege group, from 8.7% in 1981 to 3.5% in 1995.

### Male-Female Differences in Alcohol Use

- There is a substantial sex difference among high school seniors in the prevalence of *occasions of heavy drinking* (23% for females vs. 37% for males in 1995); this difference generally had been diminishing very gradually since the study began.
- There are also substantial sex differences in alcohol use among college students, and young adults generally, with males drinking more. For example, 47% of college males report having five or more drinks in a row over the previous two weeks vs. 35% of college females. There had been little change in this gender difference between 1980 and 1994, but in 1995 the difference began to narrow as the rate for males dropped and the rate for females rose.

### TRENDS IN CIGARETTE SMOKING

- A number of important findings about cigarette smoking among American adolescents and young adults have emerged from the study. Despite the demonstrated health risks associated with smoking, sizeable proportions of young people still are establishing regular cigarette habits during late adolescence. In fact, since the study began in 1975, cigarettes have consistently comprised the class of substance most frequently used on a daily basis by high school students.
- At present we are in a period of clear and continuing increase in cigarette smoking among teens. Twelfth graders have shown an increase in smoking which

19 3?

began in 1992, while eighth and tenth graders have shown a steady increase since they were first surveyed in 1991. Their rates of current smoking—that is, smoking any cigarettes in the prior 30 days—rose among eighth graders by a third between 1991 and 1995, from 14% to 19%. Tenth graders' current smoking rates increased by the same proportion over the same interval, from 21% to 28%. Among seniors the current smoking rate has risen over one-fifth since 1992, from 28% to 34%. (All three changes are highly statistically significant.)

- For seniors, this upturn follows a substantial decline in smoking during the period from 1977 to 1981, a leveling for nearly a decade (through 1990) and a slight decline in 1991 and 1992.
- The dangers perceived to be associated with pack-a-day smoking differ greatly by grade level and seem to be unrealistically low at all grade levels. Only two-thirds of the seniors (66%) report that a pack-a-day smokers run a great risk of harming themselves and only half (50%) of the eighth graders say the same. All three grades showed a decrease in perceived risk in 1994 and 1995. Disapproval of cigarette smoking has been in decline longer: since 1991 among eighth and tenth graders and since 1992 among twelfth graders.

### Age and Cohort-Related Differences in Cigarette Smoking

- Initiation of daily smoking most often occurs in grades 6 through 9 (i.e., at modal ages 11-12 to 14-15), with rather little further initiation after high school, although a number of light smokers make the transition to heavy smoking in the first two years after high school. Analyses presented in this volume and elsewhere have shown that cigarette smoking shows a clear "cohort effect." That is, if a class (or birth) cohort establishes an unusually high rate of smoking at an early age relative to other cohorts, it is likely to remain high throughout the life cycle.
- As we reported in the "Other Findings from the Study" chapter in the 1986 volume in this series, some 53% of the half-pack-a-day (or more) smokers in senior year said that they had tried to quit smoking and found they could not. (The figure was 50% in 1995.) Of those who were daily smokers in high school, nearly three-quarters were daily smokers 7 to 9 years later (based on the 1985 survey), despite the fact that in high school only 5% of them thought they would "definitely" be smoking 5 years hence. Clearly, the smoking habit is established at an early age; it is difficult to break for those young people who have it; and young people greatly overrate their own ability to quit. Additional data from the eighth and tenth grade students show us that younger children are even more likely than older ones to underestimate the dangers of smoking.
- The surveys of eighth and tenth graders also show that cigarettes are almost universally available to teens. Three-quarters of eighth graders and 91% of tenth graders say that cigarettes are "fairly easy" or "very easy" for them to get, if they want them; and there has been little change in reported availability since these questions were first asked in 1992.

### College-Noncollege Differences in Cigarette Smoking

A striking difference in smoking rates exists between college-bound and noncollege-bound high school seniors. For example, smoking half-pack or more a day is more than twice as prevalent among the noncollege-bound seniors (23% vs. 9%). Among respondents one to four years past high school, those not in college show the same dramatically higher rate of smoking compared to that found among those who are in college, with half-pack-a-day smoking standing at 23% and 10%, respectively.

### Male-Female Differences in Cigarette Smoking

Since 1980, among college students, females have had slightly higher probabilities of being daily smokers, although this finding did not replicate in 1995. This long-standing sex difference has not been true of their age peers\_who are not in college.

In the 1970s, among high school seniors, females caught up to, and passed, males in their rates of *current smoking*. Both sexes then showed a decline in use followed by a long, fairly level period with use by females consistently higher. In 1990 there was another crossover due to a rising rate among males (from 1987 to 1995) and a falling rate among females (from 1987 to 1992) resulting in males having a higher rate from 1991 to 1995. Both sexes have shown increasing use since 1992.

### RACIAL/ETHNIC COMPARISONS

The three largest ethnic groupings—whites, blacks, and Hispanics taken as a group—are examined here. (Sample size limitations simply do not allow finer subgroup breakdowns unless many years are combined.) A number of interesting findings emerge in these comparisons, and the reader is referred to Chapters 4 and 5 for a full discussion of them.

- Black seniors have consistently shown lower usage rates on most drugs, licit and illicit, than white students; this also is true at the lower grade levels where little dropping out of school has occurred. In some cases, the differences are quite large.
- o Black students have a much lower prevalence of *daily cigarette smoking* than white students (6% vs. 24% in senior year, in 1995) because their smoking rate continued to decline after 1983, while the rate for whites stabilized for some years. (Smoking rates have been rising among whites since 1992 and among blacks since 1993.)
- In twelfth grade, *binge drinking* is much less likely to be reported by black students (15%) than by white (32%) or Hispanic students (27%).

- In twelfth grade, of the three racial/ethnic groups, whites have the highest rates of use on a number of drugs, including marijuana, inhalants, hallucinogens, LSD specifically, barbiturates, amphetamines, tranquilizers, opiates other than heroin, alcohol, cigarettes, and smokeless tobacco.
- However, in senior year, Hispanics have the highest usage rate for a number of the most dangerous drugs: cocaine, crack, other cocaine, and in 1994-1995 heroin use. Further, in eighth grade, Hispanics have the highest rates not only on these drugs, but on many of the others, as well. For example, in eighth grade, the annual prevalence for Hispanics is 20%, vs 14% for whites and 12% for blacks for marijuana; 4%, 4%, and 1% for hallucinogens; 22%, 21%, and 9% for 30-day prevalence of cigarettes; 22%, 14%, and 11% for binge drinking; etc. In other words, Hispanics have the highest rates of use for nearly all drugs in eighth grade, but not in twelfth, which suggests that their considerably higher dropout rate (compared to whites and blacks) may change their relative ranking by twelfth grade.
- With regard to trends, seniors in all three racial/ethnic groups exhibited the decline in *cocaine* use from 1986 through 1992, although the decline was less steep among black seniors because the earlier increase in use was not as large as that among whites and Hispanics.
- For virtually all of the illicit drugs, the three groups have tended to trend in parallel. Because white seniors had achieved the highest level of use on a number of drugs—including stimulants, barbiturates, and tranquilizers—they also had the largest declines; blacks have had the lowest rates, and therefore, the smallest declines.
- During the life of the study, important racial/ethnic differences in *cigarette* smoking have emerged among seniors. The three groups were fairly similar in their smoking rates during the late 1970s and all three mirrored the general decline in smoking from 1977-1981. Since 1981, however, a considerable divergence has emerged: Through 1992, smoking rates declined very little, if at all, for whites and Hispanics, but the rates for blacks continued to decline steadily. As a result, by 1992 the daily smoking rate for blacks was one-fifth that for whites. By 1995, both blacks and whites showed an increase in smoking, however, and in all three grade levels.

### DRUG USE IN EIGHTH GRADE

It may be useful to focus specifically on the youngest age group in the study—the eighth graders—who are about 13 to 14 years old, because the exceptional level of both licit and illicit drug use that they already have attained helps illustrate the urgent need for the nation to continue to address the problems of substance abuse among its young.

• By eighth grade 55% of youngsters report having tried *alcohol* (more than just a few sips) and a quarter (25%) say they have already been drunk at least once.

- o Nearly half of the eighth graders (46%) have tried *cigarettes*, and 19%, or nearly one in five, say they have smoked in the prior month. Only 50% say there is great risk associated with being a pack-a-day smoker.
- Smokeless tobacco has been tried by 31% of the male eighth graders, is used currently by 12% of them, and is used daily by 2.2%. Rates are far lower among the female eighth graders.
- Among eighth graders, one in five (22%) have used *inhalants*, and 6% say they have used in the past month. This is the only class of drugs for which use is substantially higher in eighth grade than in tenth or twelfth grade.
- *Marijuana* has been tried by one in every five eighth graders (20%), and has been used in the prior month by one in every eleven (9%), and these numbers are rising rapidly.
- A surprisingly large number of eighth grade students say they have tried prescription-type *stimulants* (13%); 4.2% say they have used them in the prior 30 days.
- Relatively few eighth graders say they have tried most of the other illicit drugs yet. (This is consistent with the retrospective reports from seniors.) But the proportions having at least some experience with them still is not inconsequential when one considers the fact that a 3.3% prevalence rate represent one child in every 30-student classroom on average: tranquilizers (4.5%), LSD (4.4%), other hallucinogens (2.5%), crack (2.7%), other cocaine (3.4%), heroin (2.3%), and steroids (2.0% overall, and 2.6% among males.)
- The very large numbers who have already begun use of the so-called "gateway drugs" (tobacco, alcohol, inhalants, and marijuana) suggests that a substantial number of eighth grade students are already at risk of proceeding further to such drugs as LSD, cocaine, amphetamines, and heroin.

### SUMMARY AND CONCLUSIONS

To summarize the findings on trends, over more than a decade—from the late 1970's to the early 1990's—there were appreciable declines in the use of a number of the *illicit drugs* among seniors, and even larger declines in their use among American college students and young adults. These substantial improvements—which seem largely explainable in terms of changes in attitudes, beliefs about risk of drugs, and peer norms against drug use—have some extremely important policy implications. One is that the nation does have the capacity to deal quite effectively with the drug problem. It has done it before. The second is that demand-side factors appear to have been pivotal in bringing about those changes. The availability of marijuana, as reported by high school seniors, has held fairly steady throughout the life of the study. (Moreover, abstainers and quitters rank availability and price very low on their list of reasons for not using.) And the perceived availability of cocaine actually was rising during the beginning of the sharp decline in cocaine and crack use.

However, as we have previously warned, the stall in these favorable trends in all three populations in 1985, as well as an increase in active *cocaine* use that year, should have served as a reminder that the improvements were not inevitable and should not be taken for granted. Further, during the 1980s, the use of *inhalants* other than the nitrites continued to rise.

While the general decline in use resumed in 1986 and, most importantly, was joined by the start of a decline in *cocaine* use in 1987 and *crack* use in 1988, in 1992 a number of alarm bells sounded. While the seniors continued to show improvement on a number of measures in 1992, the college students and young adults did not. Further, the attitudes and beliefs of seniors regarding drug use began to soften. Perhaps of greatest importance, the eighth graders exhibited a significant increase in use of *marijuana*, *cocaine*, *LSD*, and *hallucinogens other than LSD* that year, as well as an increase in *inhalant* use. (In fact, all five populations showed some increase on *LSD*, continuing a longer term trend for college students and young adults.)

In 1993, 1994 and again in 1995, still more alarm bells sounded. Eighth graders continued to show an increase in their use of a number of drugs, and the tenth graders and twelfth graders joined them, fulfilling predictions based on their eroding beliefs about the dangers of drugs and their attitudes about drug use. Increases occurred in a number of the so-called "gateway drugs"—marijuana, cigarettes, and inhalants—which we argued boded ill for the use of later drugs in the usual sequence of drug-use involvement. Indeed, the proportion of students reporting the use of any illicit drug other than marijuana has risen steadily since 1991 among eighth and tenth graders and since 1992 among twelfth graders. (This proportion has increased by exactly half among eighth graders [with annual prevalence rising from 8.4% in 1991 to 12.6% in 1995].) The softening attitudes about crack and other forms of cocaine also provided a basis for concern.

This study has demonstrated over the years that changes in perceived risk and disapproval have been important causes of change in the use of a number of drugs. These beliefs and attitudes surely are influenced by the amount and nature of the public attention being paid to the drug issue at the time young people are growing up. A substantial decline in attention to this issue in the past few years may help explain why the increases in perceived risk and disapproval among students ceased, and backsliding began.

Also, we seem to be seeing the beginning of a turnaround in the drug abuse situation more generally among our youngest cohorts—perhaps because they have not had the same opportunities for vicarious learning from the adverse drug experiences of people around them and people they learn about through the media. Clearly there was a danger that, as the drug epidemic subsided considerably, newer cohorts would have far less opportunity to learn through informal means about the dangers of drugs. This may mean that the nation must redouble its efforts to be sure that they learn these lessons through more formal means—from schools, parents, and focused messages in the media, for example—and that this more formalized prevention effort become institutionalized so that it will endure for the long term. Clearly, for the foreseeable future, American young people will be aware of the psychoactive potential of a host of drugs and will have access to them. That means that each new generation of young people must learn why they should not use drugs. Otherwise their natural curiosity and desires for new experiences will lead a great many of them to use.

The following facts help to put into perspective the magnitude and variety of substance use problems which remain among American young people at the present time:

- o By the end of eighth grade, over a third (38%) of American secondary school students have tried an *illicit drug* (if inhalants are included as an illicit drug). Nearly half of all tenth graders have done so (46%), and just over half of twelfth graders (52%).
- o By their late twenties, 70% of today's American young adults today have tried an *illicit drug*, including nearly half (45%) who have tried some *illicit drug* other than (usually in addition to) marijuana. (These figures do not include inhalants.)
- o Three out of ten young Americans have tried *cocaine* (29% in 1995) by the age of 30, and 6% have tried it by their senior year of high school (approximately age eighteen). One in every thirty-three seniors (3.0%) have tried the particularly dangerous form of cocaine called *crack*: in the young adult sample one in twenty-six (3.8%) have tried it.
- o Roughly one in twenty-two (4.6%) high school seniors in 1995 smoked *marijuana daily*. Among young adults aged 19 to 28, the percent is slightly less (3.3%). Among seniors in 1995, one in eight (12.1%) had ever been daily marijuana smokers at some time for at least a month, and among young adults the comparable figure is 13.9%.
- o Some 30% of seniors had consumed *five or more drinks in a row* at least once in the two weeks prior to the survey, and such behavior tends to increase among young adults one to four years past high school. The prevalence of such behavior among male college students reaches 47%.
- One-third (34%) of seniors in 1995 were current *cigarette* smokers and 22% already were current daily smokers; these numbers are rising among seniors, as well as among the younger students. In addition, many of the lighter smokers will convert to heavy smoking after they leave high school.
- O Despite the improvements between 1979 and 1991, it is still true that this nation's secondary school students and young adults show a level of involvement with illicit drugs which is greater than has been documented in any other industrialized nation in the world. Even by longer-term historical standards in this country, these rates remain extremely high. Heavy drinking also remains widespread and troublesome; and certainly the continuing initiation of a large and growing proportion of young people to cigarette smoking is a matter of the greatest public health concern.
- Finally, we note the seemingly unending capacity of pharmacological experts and amateurs to discover new substances with abuse potential that can be used to alter mood and consciousness, as well as the potential for our young people to "discover" the abuse potential of existing products, like Robitussin<sup>™</sup>, and to

# Monitoring the Future

"rediscover" older drugs, such as *LSD* and now *heroin*. While as a society we have made significant progress on a number of fronts in the fight against drug abuse, we must remain vigilant against the opening of new fronts, as well as the re-emergence of trouble on older ones. The recent rises in illicit drug use and in cigarette smoking, both of which began in the early 1980s, certainly suggests that we have not been sufficiently vigilant and/or effective.

• The drug problem is not an enemy which can be vanquished, as in a war. It is more a recurring and relapsing problem which must be contained to the extent possible on a long term, ongoing basis; and, therefore, it is a problem which requires an ongoing, dynamic response from our society—1wone which takes into account the continuing generational replacement of our children and the generational forgetting of the dangers of drugs which can occur with that replacement.

# Chapter 3

# STUDY DESIGN AND PROCEDURES

This chapter presents the research design, sampling plans, and field procedures used in both the in-school surveys of the eighth, tenth, and twelfth grade students, and the follow-up surveys of young adults. Related methodological issues such as response rates, population coverage, and the validity of the measures will also be discussed. We begin with a description of the design which has been used consistently over 20 years to survey high school seniors; then the much more recently instituted design for eighth and tenth graders is described. Finally, the designs for the *follow-up* surveys of former twelfth graders, and former eighth and tenth graders are described.<sup>3</sup>

#### RESEARCH DESIGN AND PROCEDURES FOR THE SURVEYS OF SENIORS

The universe to be represented by each year's sample consists of all seniors enrolled in a public or private high school in the coterminous United States at the time of data collection. The data from high school seniors are collected during the spring of each year; data collection began with the class of 1975. Each year's data collection takes place in approximately 125 to 140 public and private high schools selected to provide an accurate representative cross-section of high school seniors throughout the coterminous United States.

The population under study. There are several reasons for choosing the senior year of high school as an optimal point for monitoring the drug use and related attitudes of youth. First, the completion of high school represents the end of an important developmental stage in this society, since it demarcates both the end of universal public education and, for many, the end of living in the parental home. Therefore, it is a logical point at which to take stock of the cumulated influences of these two environments on American youth. Further, the completion of high school represents the jumping-off point from which young people diverge into widely differing social environments and experiences so senior year represents a good time at which to take a "before" measure upon which to calculate changes which may be attributable to the many environmental and role transitions which occur in young adulthood<sup>4</sup>. Finally, there are some important practical advantages to building a system of data collections around samples of high school seniors. The need for systematically repeated, large-scale samples from which to make reliable estimates of change requires that considerable stress be laid on cost efficiency as well as feasibility. The last year of high school constitutes the final point at which a reasonably good national sample of an age-specific cohort can be drawn and studied economically.

The omission of dropouts. One limitation in the design to date has been that it did not include in the target population those young men and women who drop out of high school before

<sup>&#</sup>x27;See, for example, Bachman et al. (1997). Smoking, drinking, and drug use in young adulthood: The impacts of new freedoms and new responsibilities. Mahwah, NJ: Lawrence Erlbaum Associates.

<sup>&</sup>lt;sup>3</sup>For a more detailed description of the study design, See Bachman, J.G., Johnston, L.D., & O'Malley, P.M. (1996). *Monitoring the Future project after twenty-two years: Design and procedures*. (Monitoring the Future Occasional Paper 38.) Ann Arbor, MI: Institute for Social Research.

graduation—between 15 and 20 percent of each age cohort nationally, according to U.S. Census statistics. The omission of high school dropouts does introduce biases in the estimation of certain characteristics of the entire age group; however, for most purposes, the small proportion of dropouts sets outer limits on the bias. Further, since the bias from missing dropouts should remain just about constant from year to year, their omission should introduce little or no bias in change estimates. Indeed, we believe the changes observed over time for the great majority who finish high school are likely to parallel the changes for dropouts in most instances. Appendix 1 in Volume I addresses the likely effects of the exclusion of dropouts on estimates of prevalence of drug use and trends in drug use among the entire age cohort; the reader is referred to it for a more detailed discussion of this issue.

Sampling procedures. A multi-stage random sampling procedure is used for securing each nationwide sample of high school seniors. Stage 1 is the selection of particular geographic areas, Stage 2 the selection (with probability proportionate to size) of one or more high schools in each area, and Stage 3 the selection of seniors within each high school. This three-stage sampling procedure has yielded the numbers of participating schools and students shown in Table 2 of Volume I. Sample weights, scaled to sum to the actual sample size, are then used in all analyses; these adjust for any differential selection probabilities that may have occurred at any stage.

Questionnaire administration. About ten days before the administration, the seniors are given flyers explaining the study. The actual questionnaire administrations are conducted by the local Institute for Social Research representatives and their assistants, following standardized procedures detailed in a project instruction manual. The questionnaires are administered in classrooms during a normal class period whenever possible; however, circumstances in some schools require the use of larger group administrations. Eighth and tenth graders are surveyed between mid-February and mid-May, while twelfth graders are surveyed between mid-March and the end of May.

Questionnaire format. Because many questions are needed to cover all of the topic areas in the study, much of the questionnaire content intended for seniors is divided into six different questionnaire forms which are distributed to participants in an ordered sequence that ensures six virtually identical subsamples. (Five questionnaire forms were used prior to 1989.) About one-third of each questionnaire form consists of key or "core" variables which are common to all forms. All demographic variables, and nearly all of the drug use variables included in this report, are contained in this core set of measures. Many of the questions dealing with attitudes, beliefs, and perceptions of relevant features of the social environment are included in a single form only, and are thus based on one-sixth as many cases (approximately 2,600) in 1989-1995 or one-fifth as many cases in 1975-1988 (approximately 3,300). All tables in this report give the sample sizes upon which the statistics are based, stated in terms of weighted numbers of cases (which are roughly equivalent to the actual numbers of cases for the in-school samples).

# RESEARCH DESIGN AND PROCEDURES FOR THE SURVEYS OF LOWER GRADES

Beginning in 1991 the study was expanded to include nationally representative samples of eighth and tenth grade students. Our intention was to conduct surveys on an annual basis, as we do with seniors, and to conduct follow-up surveys of representative sub-samples from each year's sample. The first such follow-ups were implemented in 1993.

In general, the procedures used for the annual surveys of eighth and tenth grade students closely parallel those used for high school seniors, including the procedures for selecting schools and students, questionnaire administrations, and questionnaire formats. A major exception is that only two different questionnaire forms are used, rather than the six used with seniors. Identical forms are used for both eighth and tenth grades, and, for the most part, questionnaire content is drawn from the twelfth grade questionnaires. Thus, key demographic variables and measures of drug use and related attitudes and beliefs are generally identical for all three grades. The two forms used in both eighth and tenth grades have a common core (Parts B and C) that parallels the core used in twelfth grade, and each form has somewhat different questions in Parts A and D. Many fewer questions about attitudes and values are included in these forms than in the twelfth grade forms, in part because we think that many of these attitudes are more likely to be formed by twelfth grade, and therefore are best monitored there. For the national survey of eighth graders, approximately 18,000 to 19,000 students are surveyed in approximately 160 schools. For the tenth graders, approximately 15,000 students are surveyed in about 125 schools.

Our original research plan called for follow-up surveys of subsamples of the eighth and tenth graders participating in the study, carried out at two-year intervals, similar to the senior follow-up samples. This plan influenced the design of the cross-sectional studies of eighth and tenth graders in some important ways. First, in order to "capture" many of the eighth grade participants two years later in the normal tenth grade cross-sectional study for that year, we selected the eighth grade schools by first drawing a sample of high schools and then selecting a sample of their feeder schools which contain eighth graders. This extra stage in the sampling process meant that many of the eighth grade participants in, say, the 1991 cross-sectional survey were also participants in the 1993 cross-sectional survey of tenth graders. Thus, a fair amount of panel data was generated with no additional cost. However, after the 1993 data collection, we concluded that the savings in follow-up costs did not justify the complexities in sampling, administration, and interpretation. Therefore, we returned to a more simplified design, beginning in 1995, in which eighth grade schools are drawn independently of the tenth grade school sample. Because the follow-ups of eighth and tenth graders did not yield so many dropouts as we had hoped, we decided not to initiate follow-ups on any further cohorts. However, the cohorts first surveyed as eighth and tenth graders in 1991, 1992, and 1993 are still being followed by means of mail surveys.

It should be noted that the eighth, tenth, and twelfth grade samples are all nationally representative, and are all drawn independently of each other. Therefore, to the extent that they yield similar results (in drug use trends, for example), they amount to independent replications of one another's findings.

# RESEARCH DESIGN AND PROCEDURES FOR THE FOLLOW-UP SURVEYS OF SENIORS

Beginning with the graduating class of 1976, each senior class has been followed up annually after high school on a continuing basis, for seven follow-up data collections, which corresponds to their reaching a modal age of 32. From the roughly 15,000 to 17,000 seniors originally participating in a given class, a representative sample of 2,400 individuals is chosen for follow-up. In order to ensure sufficient numbers of drug users in the follow-up surveys, those fitting certain criteria of current drug use (that is, those reporting 20 or more uses of marijuana, or any use of any of the other illicit drugs, in the previous 30 days) are selected with higher probability (by a factor of 3.0) than the remaining seniors. Differential weighting then is used in all follow-up analyses to compensate for the differential sampling probabilities. Because those in the drug-using stratum receive a weight of only .33 in the calculation of all statistics to compensate for their over representation, the actual numbers of follow-up cases are somewhat larger than the weighted numbers reported in the tables.

The 2,400 target respondents selected from each class are randomly assigned to one of two matching groups of 1,200 each; one group is surveyed on even-numbered calendar years, while the other group is surveyed on odd-numbered years. This two-year cycle is intended to reduce respondent burden, and thus yield a better retention rate across the years. After the seventh follow-up, which occurs at age 31 or 32, respondents are sent questionnaires at five-year intervals, starting at age 35. The first of these "age 35" follow-ups occurred in 1993 for all the respondents in the Class of 1976 (no distinction is made between the two half-samples); the third occurred in 1995 for the Class of 1978.

Follow-up procedures. Using information provided by respondents at the time of the senior survey (name, address, phone number, and the name and address of someone who would always know how to reach them), mail contacts are maintained with those selected for inclusion in the follow-up panels. Newsletters are sent each year, and name and address corrections are requested. Follow-up questionnaires are sent by certified mail in the spring of each year to one of the two alternating half-samples. A check made payable to the respondent is attached to the front of each questionnaire. Prior to 1992, the checks were for \$5.00; in 1992, the payment was changed to \$10.00 to compensate for the effects of inflation. (A controlled experiment indicated that the increased payment was justified based on the increased panel retention that was achieved.) Reminder letters and postcards go out at fixed intervals thereafter; finally, those not responding receive a prompting phone call from the Survey Research Center's phone interviewing facility in Ann Arbor. If requested, a second copy of the questionnaire is sent; but no questionnaire content is administered by phone.

**Panel retention rates.** To date the panel retention rates have remained quite high. In the first follow-up after high school, about 79% of the original panel have returned questionnaires. The retention rate for each panel reduces with time, as would be expected. The 1995 panel retention from the class of 1981—the oldest of the panels discussed here, and now aged 32 (14 years past their first data collection in high school)—was 60% in 1995.

Corrections for panel attrition. Since attrition is modestly associated with drug use, we have introduced corrections into the prevalence estimates presented here for the follow-up panels. These raise the prevalence estimates from what they would be uncorrected, but only slightly.

We believe the resulting estimates to be the most accurate obtainable for the population of high school senior graduates but still low for the age group as a whole, due to the omission of dropouts and absentees from the population covered by the original panels.<sup>5</sup>

Follow-up questionnaire format. The questionnaires used in the follow-up surveys are very much like those used in the senior year. They are optically scanned; they contain a core section on drug use and background and demographic factors common to all forms; and they have questions about a wide range of topics at the beginning and ending sections, many of which are unique to each questionnaire form. Many of the questions asked of seniors are retained in the follow-up questionnaires, and respondents are consistently mailed the same version of the questionnaire that they first received in senior year, so that changes over time in their behaviors, attitudes, experiences, and so forth can be measured. Questions specific to high school status and experiences are dropped in the follow-up, of course, and questions relevant to post-high school statuses and experiences are added. Thus, there are questions about college, military service, civilian employment, marriage, parenthood, and so on.

For most follow-up cohorts, the numbers of cases on single-form questions are only one-fifth the size of the total follow-up sample. The core questions are based on the full sample. Beginning with the Class of 1989, a sixth form was introduced in senior year, so single-form data from the more recent classes have N's one-sixth the total follow-up sample size. In the follow-up studies, single-form samples from a single cohort are too small to make reliable estimates; therefore, in those cases where they are reported, the data from several adjacent cohorts (and, therefore, age groups) are combined.

#### REPRESENTATIVENESS AND VALIDITY

School participation. Schools are invited to participate in the study for a two-year period. With very few exceptions, each school from the original sample participating in the first year has agreed to participate for the second. Each year thus far, from 58% to 80% of the high schools invited to participate initially in the surveys of their seniors have agreed to do so; for each school refusal, a similar school (in terms of size, geographic area, urbanicity, etc.) is recruited as a replacement. The selection of replacement schools almost entirely removes problems of bias in region, urbanicity, and the like, that might result from certain schools refusing to participate. Other potential biases could be more subtle, however. If, for example, it turned out that most schools with "drug problems" refused to participate, that would seriously bias the sample. And if any other single factor were dominant in most refusals, that also might suggest a source of serious bias. In fact, however, the reasons given for a school refusing to participate are varied and are often a function of happenstance events specific to that particular year; only a very

The intent of the weighting process is to correct for the effects of differential attrition on follow-up drug use estimates. Different weights are used for different substances. Cigarettes, alcohol, and marijuana each have one weight for every follow-up of each graduating class. The weights are based on the observed differences in the distribution on an index of use in senior year of the relevant substance based on the follow-up sample compared to the distribution based on the full base-year sample. For example, the distribution on the index of marijuana use in senior year in the 1988 follow-up of approximately 1,000 respondents from the class of 1976 was compared to the original 1976 base-year distribution for the entire participating base-year class of 17,000 respondents; and weights were derived which, when applied to the base-year data for only those participating in the 1988 follow-up, would reproduce the original base-year frequency distribution. A similar procedure is used to determine a weight for all illicits other than marijuana combined. In this case, however, an average weight is derived across graduating classes. Thus, the same weight is applied, for example, to all respondents in the follow-up of 1988, regardless of when they graduated from high school.

small proportion specifically object to the drug content of the survey. Thus we feel quite confident that school refusals have not seriously biased the surveys.

Schools are selected in such a way that half of each year's sample in each grade level is comprised of schools which participated the previous year, and half is comprised of schools which will participate the next year. This staggered half-sample design is used to check on possible errors due to school turnover in the year-to-year trend estimates. For example, separate sets of one-year trend estimates are computed for seniors using first that half-sample of schools which participated in both 1990 and 1991, then the half-sample which participated in both 1991 and 1992, and so on. Thus, each one-year trend estimate derived in this way is based on a constant set of at least 65 schools. When the resulting trend data (examined separately for each class of drugs) are compared with the corresponding one-year trends based on the total samples of schools, the results are highly similar, indicating that the trend estimates are little affected by turnover or shifting refusal rates in the school samples. The absolute prevalence estimates for a given year are not as accurate using just the half-sample, however.

Student participation. In 1995, completed questionnaires were obtained from 89% of all sampled students in eighth grade, 88% in tenth grade, and 84% in twelfth grade. The single most important reason that students are missed is absence from class at the time of data collection; in most cases, it is not workable to schedule a special follow-up data collection for absent students. Students with fairly high rates of absenteeism also report above-average rates of drug use; therefore, there is some degree of bias introduced into the prevalence estimates by missing the absentees. Much of that bias could be corrected through the use of special weighting based on the reported absentee rates of the students who did respond; however, we decided not to use such a weighting procedure because the bias in overall drug use estimates was determined to be quite small, and because the necessary weighting procedures would have introduced greater sampling variance in the estimates. Appendix A of one of our earlier reports provides a discussion of this point, and Appendix A of Volume I of this report shows trend and prevalence estimates which would result if corrections for absentees had been included. Because absentee rates have remained very constant, the slopes of the trend lines are virtually unaffected by the omission of absentees.

Of course, some students are not absent from class, but simply refuse when asked to complete a questionnaire. However, the proportion of explicit refusals amounts to less than 1% of the target sample.

#### VALIDITY OF THE MEASURES OF SELF-REPORTED DRUG USE

The question always arises whether sensitive behaviors like drug use are honestly reported. Like most studies dealing with sensitive behaviors, we have no direct, totally objective validation of the present measures; however, the considerable amount of inferential evidence that exists strongly suggests that the self-report questions produce largely valid data. A more

<sup>&</sup>lt;sup>6</sup>Johnston, L.D., O'Malley, P.M., & Bachman, J.G. (1984). *Drugs and American high school students: 1975-1983*. DHHS (ADM) 85-1374. Washington, D.C.: U.S. Government Printing Office.

complete discussion of the contributing evidence which leads to this conclusion may be found in other publications; here we will only briefly summarize the evidence.<sup>7</sup>

First, using a three-wave panel design, we established that the various measures of self-reported drug use have a high degree of reliability-a necessary condition for validity.8 In essence, this means that respondents were highly consistent in their self-reported behaviors over a three- to four-year time interval. Second, we found a high degree of consistency among logically related measures of use within the same questionnaire administration. Third, the proportion of seniors reporting some illicit drug use by senior year has reached two-thirds of all respondents in peak years and nearly as high as 80% in some follow-up years, which constitutes prima facie evidence that the degree of under reporting must be very limited. Fourth, in the aggregate the seniors' reports of use by their unnamed friends-about which they would presumably have less reason to distort-has been highly consistent with self-reported use in terms of both prevalence and trends in prevalence (see Volume I of this report). Fifth, we have found self-reported drug use to relate in consistent and expected ways to a number of other attitudes, behaviors, beliefs, and social situations-in other words, there is strong evidence of "construct validity." Sixth, the missing data rates for the self-reported use questions are only very slightly higher than for the preceding nonsensitive questions, in spite of an explicit instruction to respondents to leave blank those drug use questions they felt they could not answer honestly. And seventh, the great majority of respondents, when asked, say they would answer such questions honestly if they were users.

This is not to argue that self-reported measures of drug use are valid in all cases. In the present study we have gone to great lengths to create a situation and set of procedures in which students feel that their confidentiality will be protected. We have also tried to present a convincing case as to why such research is needed. We think the evidence suggests that a high level of validity has been obtained. Nevertheless, insofar as there exists any remaining reporting bias, we believe it to be in the direction of under reporting. Thus, we believe our estimates to be lower than their true values, even for the obtained samples, but not substantially so.

One procedure we undertake to help assure the validity of our data is worth noting. We check for logical inconsistencies in the triplets of answers about the use of each drug (i.e., about lifetime, past year, and past 30-day use), and if a respondent exceeds a minimum number of inconsistencies, his or her drug use data are deleted. Similarly, we check for improbably high rates of use of multiple drugs and delete the drug data of such cases, on the assumption that the respondents are not taking the task seriously. Relatively few cases are eliminated in this way.

# Monitoring the Future

Consistency and the measurement of trends. One final point is perhaps the most important in this discussion of the validity of the findings. The Monitoring the Future project is designed to be sensitive to changes from one time period to another. Accordingly, the measures and procedures have been standardized and applied consistently across each data collection. To the extent that any biases remain because of limits in school and/or student participation, and to the extent that there are distortions (lack of validity) in the responses of some students, it seems very likely that such problems will exist to much the same extent from one year to the next. In other words, biases in the survey estimates will tend to be consistent from one year to another, which means that our measurement of trends should be affected very little by any such biases. The smooth and consistent nature of most trend curves reported for the various drugs provides rather compelling empirical support for this assertion.

#### Chapter 4

# PREVALENCE OF DRUG USE AMONG YOUNG ADULTS

As described in more detail in the preceding chapter, the Monitoring the Future study conducts ongoing panel studies on representative samples from each graduating class, beginning with the class of 1976. Two matched panels, of roughly 1,200 seniors each, are selected from each graduating class—one panel is surveyed every even-numbered year after graduation, the other is surveyed every odd-numbered year. Thus, in a given year, the study encompasses one of the panels from each of the last fourteen senior classes previously participating in the study. In 1995, this meant that representative samples of the classes of 1981 through 1994 were surveyed by mail. Because the study design calls for an end of biennial follow-ups of these panels after they reach approximately age 32 (i.e., seven follow-ups for each half-panel), the classes of 1976 through 1980 were not included in the standard 1995 follow-up surveys. They are surveyed at age 35 and at five-year intervals thereafter. In 1995, the class of 1978 received the "age 35" follow-up questionnaire; the findings from this special questionnaire will be provided in future reports.

In this section, we present the results of the 1995 follow-up survey, which should accurately characterize approximately 85% of young adults in the class cohorts one to fourteen years beyond high school (modal ages 19 to 32). The remaining 15% or so, the high school dropout segment, was missing from the senior year surveys and, of course, is missing from all of the follow-up surveys, as well.

Figures 1 through 19 contain the 1995 prevalence data by age, corresponding to those respondents one to fourteen years beyond high school (modal ages 19 to 32). Later figures contain the trend data for each age group, including seniors and graduates who are up to fourteen years past high school (modal age 32). With the exception of the seniors, age groups have been paired into two-year intervals in both sets of figures in order to increase the number of cases, and thus the reliability, for each point estimate. The trends are based on fairly narrow age bands in order to cover more years. For obvious reasons, trends on the youngest age bands can be calculated for the longest period of time.

# A NOTE ON LIFETIME PREVALENCE ESTIMATES

In Figures 1 through 19, two different estimates of lifetime prevalence are provided. One estimate is based on the respondent's most recent statement of whether he or she ever used the drug in question (second bar from the left). The other estimate takes into account the respondent's answers regarding lifetime use gathered in *all* of the previous data collections in which he or she participated (the left-most bar). To be categorized as one who has used the drug based on all past answers regarding that drug, the respondent has either (a) to have reported past use in the most recent data collection and/or (b) to have reported some use in his or her lifetime on at least two earlier occasions. Because respondents in the age groups of 18 and 19-20 cannot have their responses adjusted on the basis of two earlier occasions, adjusted

prevalences are reported only for ages 21 and older. The unadjusted estimate is most commonly presented in epidemiological studies, since it can be made based on the data from a single cross-sectional survey. An adjusted estimate of the type used here is possible only when panel data have been gathered and a respondent can be classified as having used a drug at sometime in his or her life, based on earlier answers, even though he or she no longer indicates lifetime use in the most recent survey.

The divergence of these two estimates as a function of age shows that there is more inconsistency as time passes. Obviously, there is more opportunity for inconsistency as the number of data collections increases. Our judgment is that "the truth" lies somewhere between the two estimates: the lower estimate may be depressed by tendencies to forget, forgive, or conceal earlier use, and the upper estimate may include earlier response errors or incorrect definitions of drugs which respondents appropriately corrected in later surveys. It should be noted that a fair proportion of those giving inconsistent answers across time had earlier reported having used only once or twice in their lifetime. As we have reported elsewhere, cross-time stability of self-reported usage measures, which take into account the number of occasions of self-reported use, is still very high.

It also should be noted that the divergence between the two lifetime prevalence estimates is greatest for the psychotherapeutic drugs and for the derivative index of "use of an illicit drug other than marijuana," which is heavily affected by the psychotherapeutic estimates. We believe this is due to the greater difficulty of accurately categorizing psychotherapeutic drugs (usually taken in pill form) with a high degree of certainty—especially if one has used them only once or twice. We expect higher inconsistency across time when the event—and in many of these cases, a single event—is reported with a relatively low degree of certainty at quite different points in time. Those who have gone beyond simple experimentation with one of these drugs would undoubtedly be able to categorize them with a higher degree of certainty. Also, those who have experimented more recently, in the past month or year, should have a higher probability of recall, as well as fresher information for accurately categorizing the drug.

We provide both estimates to make clear that a full use of respondent information provides a possible range for lifetime prevalence estimates, not a single point. However, by far the most important use of the prevalence data is to track *trends* in *current* (as opposed to lifetime) use. Thus, we are much less concerned about the nature of the variability in the lifetime estimates than we might otherwise be. The lifetime prevalence estimates are primarily of importance in showing the degree to which a drug class has penetrated the general population.<sup>10</sup>

### PREVALENCE OF DRUG USE AS A FUNCTION OF AGE

For virtually all drugs, available age comparisons show a much higher lifetime prevalence for the older age groups. In fact, the figures reach impressive levels among young adults in their early thirties.

o In 1995 the adjusted lifetime prevalence figures among 31 to 32 year olds reach 81% for any illicit drug; 60% for any illicit drug other than marijuana; 76% for marijuana; and 37% for cocaine. Put another way, among young Americans who graduated high school in 1981 and 1982-near the peak of the larger drug epidemic-only one-fifth (19%) have never tried an illegal drug.

The 1995 survey responses, unadjusted for previous answers, show somewhat lower lifetime prevalence: 73% for any illicit drug, 46% for any illicit drug other than marijuana, 70% for marijuana, and 32% for cocaine.

Despite the higher levels of lifetime use among older age groups, they generally show levels of annual or current use which are no higher than such use among today's high school seniors. In fact, for a number of drugs the levels reported by older respondents are lower, suggesting that the incidence of quitting more than offsets the incidence of initiation after high school.

In analyses published elsewhere, we looked closely at patterns of change in drug use, and identified some post-high school experiences which contribute to declining levels of annual or current use as respondents grow older. For example, the likelihood of marriage increases with age, and we have found that marriage is consistently associated with declines in alcohol use in general, heavy drinking in particular, marijuana use, and use of other illicit drugs. 11

- For the use of any illicit drug, lifetime prevalence is 81% among 31 to 32 year olds vs. "only" 48% among the 1995 high school seniors. Annual prevalence, however, is highest among the seniors (39%) with progressively lower rates among the older age groups (see Figure 1). Current (30-day) prevalence shows much the same pattern with seniors having the highest rate (24%), and the rate declining gradually for each older age groups, reaching 13% among the 31 to 32 year-olds.
- A similar pattern exists for marijuana; a higher lifetime prevalence as a function of age, but somewhat lower annual and 30-day prevalence rates during the late 20s. Current daily marijuana use shows the least variation across age (see Table 6). Still, it falls from 4.7% among twelfth graders, down to 2.3% among 25-26 year olds, before rising to 3.1% among 31-32 year olds. This curvilinear pattern suggests that a "cohort effect" may be working here. 12

See O'Malley, P.M., Bachman, J.G., & Johnston, L.D. (1988). Period, age, and cohort effects on substance use among young

- Statistics on the use of any illicit drug other than marijuana (Figure 2) have a similar pattern. Like marijuana and the any-illicit-drug-use index, corrected lifetime rates on this index also show an appreciable rise with age, reaching 60% among the 31 to 32 year old age group. Current use shows less variation across all age bands, ranging from 4% to 10%. Annual use declines gradually with increased age of the respondent, in fact, most of the drugs that constitute this category show a decline with age in annual prevalence. One exception is cocaine.
- Several classes of drugs show rates of current use among the older age groups proportionately much lower than among seniors. For example, annual prevalence rates for *hallucinogens* fall sharply from 9%-10% among high school seniors and 19-20 year olds to 1% by age 31-32 (Figure 7). *Inhalants* (Figure 10) also show a sharp drop off in annual and 30-day use after senior year and again after age 20.
- For stimulants, lifetime prevalence is again much higher among the older age groups—reflecting the addition of many new initiates in their early twenties (Figure 4). (There is also a considerable divergence between the corrected lifetime prevalence vs. the contemporaneously reported lifetime prevalence, as is true for most of the psychotherapeutic drugs.) However, more recent use as reflected in the annual prevalence figure is now lower among the older age groups. This has not always been true; the present pattern is the result of a sharper decline in use among older respondents than has occurred among seniors. These trends are discussed in the next section.
- Questions on the use of *crystal methamphetamine* (ice), are contained in two of the six questionnaire forms, making the estimates less reliable than those based on all six. Among the 19 to 32 year old respondents *combined*, 1.0% reported some use in the prior year-lower than the 2.4% reported by seniors (Figure 15).
- Barbiturates are similar to stimulants in that lifetime prevalence is appreciably
  higher in the older ages and annual use appreciably lower; one difference is that
  active nonmedical use of barbiturates after high school always has been lower
  than such use during high school (Figure 11). At present, current usage rates are
  quite low in all age groups, therefore 30-day use varies rather little by age.
- Opiates other than heroin show age differences very similar to those seen for barbiturates—somewhat higher lifetime prevalence as a function of age, annual prevalence declining modestly with age, and 30-day use varying little with age (Figure 12).
- *Tranquilizer* use, on the other hand, remains fairly stable for both 30-day and annual prevalence rates across the full age band even though lifetime prevalence increases considerably with age (Figure 13).

<sub>38</sub> 56

- Cocaine generally has presented a unique case among the illicit drugs in that lifetime, annual, and current use all tended to be higher among the older age groups (Figure 5). By 1994 30-day cocaine use had reached such low levels that it varied rather little by age, and by 1995 annual and current use are fairly similar across all age groups.
- Lifetime prevalence of crack reached 7% to 9% among those in their late 20s and early 30s, vs. 3% among seniors. This no doubt reflects not only an age effect but also something of a cohort effect due to the rather transient popularity of crack in the early- to mid-1980s. Current prevalence is very low at all ages. On average, the follow-up respondents one to fourteen years out of high school have an annual prevalence of 1.1% vs. 2.1% among seniors, and a 30-day prevalence of 0.3% vs. 1.0% among seniors. Clearly the follow-up respondents have a higher rate of noncontinuation than seniors, as is true for most other drugs.

However, we believe that the omission of high school dropouts is likely to have a greater than average impact on the prevalence estimates for crack (as is the case with the senior data).

- o In the case of *alcohol*, all prevalence rates generally increase for the first four years after high school, through age 21 or 22 (Figure 18a). After that, prevalence rates vary slightly for the different age groups. Lifetime prevalence, due in large part to a "ceiling effect," changes very little after age 21 to 22. Current (30-day) alcohol use is considerably higher at age 21-22 (70%) than among seniors (51%); it stays fairly steady thereafter, at least through age 26, perhaps declining slightly thereafter. Current *daily drinking* varies very little by age; it is at 3%-5% between ages 18 and 32 (Figure 18b).
- Occasions of heavy drinking in the two weeks prior to the survey show the largest differences among the age groups (Figure 18b). There is a fair difference between 18 year-olds (30%) and 21 to 22 year-olds, who have the highest prevalence of such heavy drinking (39%). Then there is a fall-off with each subsequent age group, reaching 25% by ages 31 to 32. We have interpreted this curvilinear relationship as reflecting an age effect (not a cohort effect), because it seems to replicate across different graduating classes or cohorts, and also because it has been linked directly to age-related events such as leaving the parental home (which increases heavy drinking) and marriage (which decreases it)<sup>13</sup>.
- Cigarette smoking also shows an unusual pattern of age-related differences (Figure 19). On the one hand, current (30-day) smoking is about the same among those in their 20s as among high school seniors, reflecting the fact that relatively few new people are recruited to smoking after high school. On the other hand, smoking at heavier levels—such as smoking half-a-pack daily—is somewhat higher

<sup>13</sup> O'Malley, P.M., Bachman, J.G., & Johnston, L.D. (1988). Period, age, and cohort effects on substance use among young Americans: A decade of change, 1976-1986. American Journal of Public Health, 78, 1315-1321. See also Bachman et al., (1997). Smoking, drinking, and drug use in young adulthood: The impacts of new freedoms and new responsibilities. Mahwah, NJ: Lawrence Erlbaum Associates.

among the older age groups, reflecting the fact that many previously moderate smokers move into a pattern of heavier consumption after high school<sup>14</sup>. While slightly more than a third (37%) of the current smokers in high school smoke at the rate of half-pack a day or more, almost three-quarters (71%) of the current smokers in the 31 to 32 age group do so.

• In 1989, MDMA (ecstasy) was added to two of the six forms of the follow-up surveys to assess how widespread its use had become among young adults. (Questions about its use were not asked of high school students, primarily because we were concerned that its alluring name might have the effect of stimulating interest.)

Relatively few 1995 follow-up respondents report any use of MDMA (Figure 14). Among all 19 to 32 year olds combined, 4.5% say they have ever tried it, with the highest rates of use for those respondents in their late 20s. Annual and current (30-day) use levels are much lower, at 1.2% and 0.3%, respectively.

• Questions about use of *steroids* were added in 1989 to one form only, making it difficult to determine age-related differences with much accuracy. Overall, 1.3% of 19 to 32 year olds in 1994 reported having used steroids in their lifetime. Annual and 30-day use levels were very low, at 0.3% and 0.2%, respectively. (See Tables 3 to 5.)

# PREVALENCE COMPARISONS FOR SUBGROUPS OF YOUNG ADULTS

#### Sex Differences

Statistics on usage rates for the group of young adults one to fourteen years beyond high school (modal ages 19 to 32), are given for the total sample and separately for males and females in Tables 2 to 6. In general, most of the sex differences in drug use which pertained in high school may be found in this young adult sample as well.

• Somewhat more males than females report using any illicit drug during the prior year (30% vs. 25%). Males have higher annual prevalence rates in most of the specific illicit drugs—with the highest ratios (all greater than 2) pertaining for steroids, LSD, hallucinogens, ice, , and inhalants. For example, among the 19 to 32 year olds, LSD was used by 5.4% of males vs. 2.5% of females during the prior twelve months.

Because age is confounded with class cohort, and because we have established that cigarette smoking shows strong cohort effects (enduring differences among cohorts), one must be careful in interpreting age-related differences in a cross-sectional sample as if they were due only to age effects, i.e., changes with age consistently observable across cohorts. However, multivariate analyses conducted on panel data from multiple cohorts do show a consistent age effect of the type mentioned here (O'Malley, Bachman, & Johnston, (1988), op. cit.).

- o Both *crack* and *cocaine* in general were used by more males than females in the past year. Crack use was reported by 1.5% of the males and 0.8% of the females; cocaine by 5.9% of the males and 3.1% of the females.
- Other large sex differences are found in *daily marijuana use* (4.4% for males vs. 2.2% for females in 1995), *daily alcohol use* (6.8% vs. 1.9%), and occasions of drinking *five or more drinks in a row* in the prior two weeks (42% vs. 22%). This sex difference in occasions of heavy drinking is greater among young adults than among high school seniors, where it is 37% for males vs. 23% for females.

## Alcohol: Two-Week Prevalence of Five or More Drinks in a Row and Thirty-Day Prevalence of Daily Use Among Young Adults, 1995 by Age Group

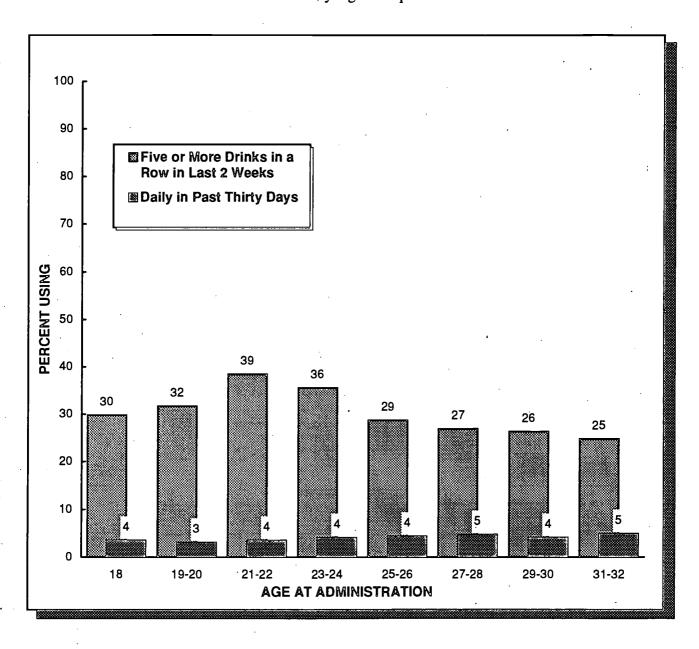

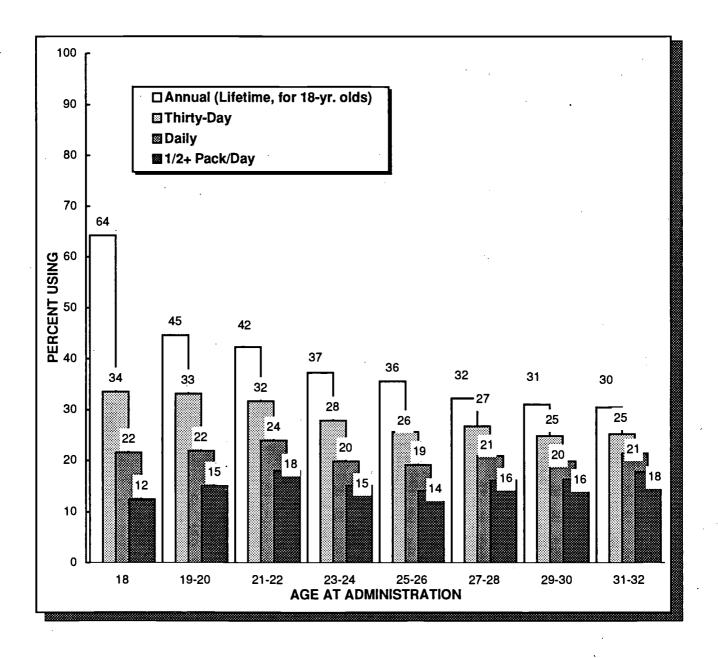

Figure 19

Cigarettes: Annual, Thirty-Day, Daily, and Half-Pack-a-Day Prevalence

Among Young Adults, 1995

by Age Group

- The use of *stimulants*, which is now about equivalent among males and females in high school, is also fairly similar for both sexes in this post-high school period (annual prevalence 4.4% vs. 3.5%, respectively).
- Crystal methamphetamine (ice) is used by small percentages of both males (1.6% annual prevalence) and females (0.5%).
- In the 1980s, there were few differences between males and females in rate of cigarette use. In the 1990s however, small differences have emerged resulting in slightly higher rates of use by males in 1995. Among high school seniors, past month prevalence is 35% for males, compared to 32% for females. Daily use rates are 22% and 21%, respectively, and half-pack or more use rates are 13% and 11%. These differences are similar among the 19 to 32 year olds. Males are slightly more likely to have smoked in the past month (30% vs. 27%), to have smoked daily (22% vs. 20%), and to have smoked half-a-pack or more per day (17% vs. 15%).
- Steroid use among young adults is much more prevalent among males than females, as is true for seniors. Among seniors, 2.4% of the males reported steroid use in the past year vs. 0.6% of the females. These statistics are much lower among the 19 to 32 year olds-0.7% vs. 0.1%- but males still account for nearly all steroid use.
- MDMA (ecstasy) is higher among males than females in the young adult sample (annual prevalence 1.7% vs. 0.9%, respectively).

## Regional Differences

Follow-up respondents are asked in what state they currently reside. States are then grouped into the same regions used in the analysis of the high school data (see Figure 5, Volume I and Appendix B, Volume I). Tables 3 through 6 present regional differences in lifetime prevalence, annual prevalence, 30-day prevalence, and current daily prevalence, for the 19 to 32 year olds combined.

- Regional differences in use are not very large for *marijuana*, except that the South is lower than the other regions, as is true among seniors. The South is also somewhat lower in the proportion using *any illicit drug*.
- The Northeast and West show slightly higher rates of annual *cocaine* use than the North Central and the South; these regional differences are smaller on 30-day prevalence. In previous years, these regional differences were much larger, and this is reflected in part in the lifetime prevalence statistics.
- *Crack* shows no significant differences based on region for either young adults or seniors in 1995, though use is highest in the West.
- The annual use of **stimulants** is lowest in the Northeast, again consistent with the high school results. At present use is highest in the West.

- The use of *crystal methamphetamine* (ice) by 19 to 32 year olds is concentrated primarily in the Western region of the country, 3.5% annual prevalence vs. 0.1%-0.7% for all other regions. This is also the case for high school seniors.
- *Hallucinogen* use is fairly evenly distributed across all regions as is true *LSD* specifically.
- For the *remaining illicit drugs* the annual and 30-day prevalence rates tend to be very low, at or under 4% and 1.5%, respectively, making regional differences small in absolute terms (see Tables 4 and 5).
- The annual and 30-day prevalence rates for *alcohol* are somewhat higher in the Northeast and North Central regions than in the Southern and Western parts of the country, as is true for seniors. *Occasional heavy drinking* shows the same pattern: 34%, 37%, 27% and 26%, respectively for the Northeast, North Central, South, and West (see Table 6).
- As with alcohol, *cigarette smoking* among young adults highest in the Northeast and North Central, as it is among seniors. It is lowest in the West.

## Differences Related to Population Density

Population density is measured by asking respondents to check which of a number of listed alternatives best describes the size and nature of the community where they lived during March of that year. The major answer alternatives are listed in Table 3 and the population size given to the respondent to help define each level is provided in a footnote. An examination of the 1987 and 1988 drug-use data for the two most urban strata revealed that the modest differences in prevalence rates between the suburbs and the corresponding cities were not worth the complexity of reporting them separately; accordingly, these categories have been merged. See Tables 4 through 6 for the relevant results discussed below.

- Differences in illicit drug use by population density tend to be very modest, perhaps more modest than is commonly supposed. This is not to deny that certain drug problems are more common in highly urban areas—injection drug use and addictive use of crack cocaine, for example, are likely concentrated in inner-city urban areas. Among the general population, however, use of most illicit drugs is fairly broadly distributed among all areas from rural to urban. To the extent that there are variations, almost all of the associations are positive, with rural/country areas having the lowest levels of use, and small towns having the next lowest. Medium-sized cities, large cities, and very large cities tend to be higher, with only small variations among these three categories. The modest positive association, based on annual prevalence, is true for any illicit drug use, marijuana, hallucinogens, MDMA, and cocaine (but not crack).
- Among young adults, the lifetime, annual, and 30-day alcohol use measures all show a slight positive association with population density. Occasions of heavy drinking are about the same across all strata except farm/country, which has

<del>6</del> آ

a slightly lower rate (see Table 6). Daily use stands between 3.4% and 4.8% for all community size strata.

In contrast, a negative association with population density exists for daily cigarette smoking which is highest in the farm/country stratum and lowest in the very large cities (daily prevalences of 25% and 18%, respectively).

Source: The Monitoring the Future Study, the University of Michigan.

<sup>&</sup>lt;sup>h</sup>Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants.

<sup>&</sup>lt;sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

<sup>&</sup>lt;sup>b</sup>This drug was asked about in five of the six questionnaire forms. Total N is approximately 7100.

<sup>&</sup>lt;sup>c</sup>Unadjusted for known underreporting of certain drugs. See text for details.

<sup>&</sup>lt;sup>d</sup>This drug was asked about in one of the six questionnaire forms. Total N is approximately 1400.

<sup>&</sup>lt;sup>e</sup>This drug was asked about in four of the six questionnaire forms. Total N is approximately 5700.

<sup>&</sup>lt;sup>f</sup>This drug was asked about in two of the six questionnaire forms. Total N is approximately 2800.

<sup>&</sup>lt;sup>8</sup>Only drug use which was not under a doctor's orders is included here.

-Use of "any illicit drug" includes any use of manjuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

\*Unadjusted for known underreporting of certain drugs. See text for details.

This drug was asked about in five of the six questionnaire forms. Total N is approximately 7100. This drug was asked about in one of the six questionnaire forms. Total N is approximately 1400.

This drug was asked about in two of the six questionnaire forms. Total N is approximately 2800.

A small town is defined as having less than 50,000 inhabitants; a medium city as 50,000-100,000; a large city as 100,000-500,000; and a very large city as having over 500,000 residents. Within each level of population density, suburban and urban respondents are combined.

<sup>\*</sup>A small town is defined as having less than 50,000 inhabitants; a medium city as 50,000-100,000; a large city as 100,000-500,000; and a very large city as having over 500,000 residents. Within each level of population density, suburban and urban respondents are combined.

## Chapter 5

## TRENDS IN DRUG USE AMONG YOUNG ADULTS POST-HIGH SCHOOL

Beginning in 1993, we observed large and important increases in the use of a number of substances among secondary school students. (In fact, among 8th graders the upturn began a year earlier.) Among the issues to be addressed in this chapter are whether such increases are occurring only among adolescents or among young adults as well, and whether recent graduating classes are carrying their higher levels of drug use in high school with them into young adulthood.

Trends in the use of the various licit and illicit drugs by all high school graduates who are between one to fourteen years beyond high school are presented here. Figures 20 through 34 plot separate trend lines for two-year age strata (that is, 1-2 years beyond high school, 3-4 years beyond high school, etc.) in order to damp down the random fluctuations which would be seen with one-year strata. (Strictly speaking, these two-year strata are not age-strata, because they are based on all respondents from adjacent high school classes, and they do not take account of the minor differences in individual respondents' ages; however, they are close approximations to age-strata, and we characterize them by the modal age of the respondents, as age 19 to 20, 21 to 22, and so on.) Each data point in these figures is based on approximately 1200 weighted cases drawn from two adjacent high school classes; actual (unweighted) numbers of cases are somewhat higher. For the 1995 data, the 19 to 20 year old stratum is comprised of participating respondents from the classes of 1994 and 1993, respectively, the 21 to 22 year old stratum contains data from the classes of 1992 and 1991, and so on.

Tables 7 through 11 are derived from the same data but are presented in tabular form for 19 to 28 year olds combined. Data are given for each year in which they are available for that full age band (i.e., from 1986 onward). Those aged 29 to 32 are omitted because their inclusion would shorten the time period over which trends can be examined. However, the full data for them are contained in Figures 20 through 34.

### TRENDS IN PREVALENCE: YOUNG ADULTS

To repeat, trends in use by young adults may be found in Tables 7 through 11 (for the age group 19-28), as well as in Figures 20 through 34 (for ages 19-32). The results are as follows:

• Longer term declines for a number of drugs appeared to level in 1992 (see Table 8). Among the 19 to 28 year old young adult sample this was true for the use of any illicit drug, any illicit drug other than marijuana, marijuana, stimulants, and crack. In 1993 and 1994, annual prevalence for most drugs remained steady. Cocaine other than crack leveled in 1993 after a period of substantial decline. In 1995 there was a very modest though often statistically significant increase in the annual prevalence of a number of drugs; these changes were a percentage point or less for all drug classes.

Thus, it appears that the broad increase seen among secondary school students is beginning to be observed among young adults ages 19-28. A careful look at Figure 20, however, shows that this is due to generational replacement, because the strata containing the recent graduates account for virtually all the change.

- Marijuana remained at about 25% annual prevalence in 1992, 1993, and 1994, following a 1.4% increase in 1992 (not statistically significant) after years of steady decline. In 1995, however, it rose by exactly one percentage point, and again this increase is due entirely to increases in the two youngest strata (i.e., those one to four years past high school) who are from the recent high school classes which showed a sharp jump in marijuana use (see Figure 22a).
- Use of *LSD* increased modestly between 1989 and 1992 among young adults, but did not continue to increase after that, with annual prevalence remaining at about 4%, and 30-day prevalence at 1% (Tables 8 and 9). Use of *PCP* remained at a very low level (0.3% annual prevalence in 1995).
- Over the longer term, trends in use of most drugs among the older age groups have pretty much paralleled the changes among seniors discussed in Chapter 5, Volume I. Many of the changes thus have been secular trends—that is, they are observable in all the age groups under study. This was generally true for the longer term declines in the use of any illicit drug, marijuana, any illicit drug other than marijuana, stimulants, crack, and tranquilizers. LSD and opiates other than heroin began to level out in 1987, barbiturates and methaqualone in 1988. However, their trends have not been parallel in the last few years, suggesting that the recent change is due more to cohort effects—differences between class cohorts which remain across a range of ages/dates.
- Several of these drug classes actually exhibited a faster decline in use among the older age groups than among high school seniors during the earlier period of decline (see Figures 20-34). These included any illicit drug, any illicit drug other than marijuana, stimulants, hallucinogens (until 1987), LSD (through 1989), and methaqualone.
- In fact there was a crossover for some drugs when seniors are compared to young adult graduates. In earlier years, seniors had lower usage levels but in recent years have higher ones than post-high school respondents for use of any illicit drug, any illicit drug other than marijuana, marijuana, hallucinogens, LSD, tranquilizers, and stimulants.
- With regard to inhalants, the large separation of the age band lines in Figure 23 shows that use consistently has dropped sharply with age. In fact, of all of the populations covered in this study, the eighth graders (not shown in Figure 23) have had the highest rate of use. Figure 23 also shows that there has been a long-term gradual increase in annual inhalant use (unadjusted for under reporting of nitrite inhalants) among the youngest two age groups shown (seniors, and those one to two years past high school). Respondents five or more

years past high school, who historically have had a negligible rate of use, did not exhibit the same increase in use as the younger respondents.

The alcohol trends for the older age groups (see Figures 33a-d) have been somewhat different than for the younger age groups. The declines during the 1980s in 30-day prevalence and occasions of heavy drinking had been greater for the two youngest age strata (seniors and those one to two years past high school) than for the older age groups. These differential trends are due in part to the effects of changes in minimum drinking age laws in many states, which would be expected to affect only the younger age groups. However, because similar (though weaker) trends were evident among high school seniors in states that have maintained a constant minimum drinking age of 21, the changed laws cannot account for all the downward trends suggesting that there was also a more general downward secular trend in alcohol consumption during the eighties. By 1994 these declines in 30-day prevalence had slowed or discontinued for virtually all age groups.

Those three to four years past high school stand out for showing the smallest long-term downward trend in *binge drinking*. One important segment of that age stratum is comprised of college students, who showed practically no downward trend.

The older age groups in general have shown only a modest long-term decline in annual prevalence rates, and no recent decline in 30-day prevalence rates or in binge drinking. Note that the binge-drinking trend lines for different age groups (Figure 33d) are more spread out on the vertical dimension than is usually the case, reflecting large and persisting age differentials (age effects) in this behavior. The college-age group shows the highest rates of binge drinking. Rates of daily drinking have fallen by larger proportions than annual and 30-day rates for binge drinking.

In Figure 33b, dealing with 30-day prevalence of *alcohol* use, note the sharp drop among seniors between 1987 and 1992, and then among those 1-2 years past high school between 1989 and 1992. This may reflect some lasting cohort effects resulting from fewer adolescents drinking in high school (perhaps due to the change in drinking age laws).

o The prevalence rates for *cigarette smoking* show more complex trends than other substances, due to the presence of both cohort and age effects, plus slightly different patterns of such effects on different measures of smoking in the past 30 days (one or more cigarettes per month, one or more cigarettes per day, and halfpack or more cigarettes per day).

While the curves are of the same general shape for each age band (Figures 34a-c), each curve tends to be displaced to the right of the immediately preceding age

<sup>&</sup>lt;sup>15</sup>O'Malley, P.M., & Wagenaar, A.C. (1991). Minimum drinking age laws on alcohol use, related behaviors, and traffic crash involvement among American youth: 1976-1987. *Journal of Studies on Alcohol*, 52, 478-491.

group, which is two years younger. The pattern is clearest in Figure 34c (halfpack plus per day). This pattern is very similar to the one described in Volume I for lifetime smoking rates for various grade levels *below* senior year; it is the classic pattern exhibited by cohort effect—that is, when cohorts (in this case, class cohorts) differ from other cohorts in a consistent way across much or all of the life span. We interpret the cigarette data as reflecting just such a cohort effect of and we believe that the persisting cohort differences are due to the dependence-producing characteristics of cigarette smoking.

The declining levels of cigarette smoking across cohorts at age 18, which were observed when the classes of 1978 through 1981 became high school seniors, were later observable in the early-30s age band, as those same high school graduating classes reached their early 30s (see Figures 34b and c). This was true at least through about 1991. Since then, there has been some convergence of rates across age groups, largely because of few cohort differences among senior classes who have graduated since the early to mid-1980s. For example, smoking at lighter levels has shown little cohort differences since about 1981 (see Figure 34a, age 18 senior year data). Figure 34c shows that heavier use, half-pack or more per day, continued to show modest further decline through about 1986.

In addition to these cohort differences, there is a differential age trend in which, as respondents grow older, the proportion smoking at all in the past 30 days declines some, while the proportion smoking half-pack per day actually increases. Put another way, many of the light smokers in high school either become heavy smokers or quit smoking. In 1995, the age relationship with prevalence of smoking one or more cigarettes in the past 30 days is clearly negative, going from 34% among 18 year olds to 25% among 31 to 32 year olds. On the other hand, the age relationship with prevalence of half-pack plus per day is clearly positive, ranging from 12% among 18 year olds to 18% among 31 to 32 year olds. (The age relationship at the intermediate level, of one or more cigarettes per day, is essentially flat, ranging only 5 percentage points, unsystematically, from 19% to 24% across the various age groups.) In previous years these age relationships often were different because big cohort differences were superimposed upon the age differences. The small large cohort differences at senior year across time indicate the cross-age differences now observed across the age band 18 to 32 reflect primarily the age effects of light use declining with age and heavy use increasing with age.

• Apart from cigarettes, none of the other drugs included in the study showed a clear long-term pattern of enduring cohort differences, despite wide variations in their use by different cohorts at a given age. There is one exception: A modest cohort effect was observable for daily marijuana use during the late 1970s and early 1980s. (But as more recent classes leveled at low rates of use, evidence for the cohort effect has faded.) The cohort effect for daily marijuana use may be

<sup>&</sup>lt;sup>16</sup>O'Malley, P.M., Bachman, J.G., & Johnston, L.D. (1988). Period, age, and cohort effects on substance use among young Americans: A decade of change, 1976-1986. *American Journal of Public Health*, 78, 1315-1321.

ŻΩ

attributable, in part, to the strong association between that behavior and regular cigarette smoking. As we discussed earlier in this chapter, some new cohort differences for a number of other drugs, particularly marijuana, seem to be emerging in recent years.

- The annual prevalence for *MDMA* (ecstasy) among the young adult sample was at about 1.5% in 1989 and 1990; after 1991 it dropped to around 0.8% for several years, before rising significantly in 1993 to 1.6%. (See Table 8.) MDMA is not included in the surveys of secondary students.
- The important downturn in *cocaine*, observed for the first time among all age groups in 1987, decelerated sharply by 1992 in the age groups encompassed here (see Figure 27), and almost completely stopped in 1994. The proportion of 19 to 28 year olds combined who reported any *cocaine* use in the prior year held steady (at 4.4%) in 1995, and seniors showed some modest increase. For many years, that the older age bands have been consistently higher than the younger ones, illustrating an age effect in the use of this drug. In 1995, however, there was no further systematic difference by age because use by the younger age groups leveled some, and then began to climb.
- The decline in *crack* use ended in 1991 among seniors, and by 1994 the decline ended among young adults (see Figure 28 and Table 8). Among 19 to 28 year olds the annual prevalence rate has held at about 1%, which is down by nearly two-thirds from the peak levels of just over 3% in 1986 through 1988.
- Stimulant use showed a long and substantial decline between 1981 and 1991, and has been relatively flat among the young adult sample since then (Figure 30). As Table 8 shows, 19 to 28 year olds' annual prevalence rate has ranged from 4.0% to 4.5% since 1991. (Use by adolescents, however, increased in 1993 and 1994.) It should be noted, that use by those one to two years past high school jumped in 1995, apparently reflecting the earlier increases when they were seniors.
- The use of *crystal methamphetamine* (ice) has remained at fairly low rates since it was first measured in 1990. However its annual prevalence has risen from 0.4% in 1992 to 1.2% by 1995 (Table 8).
- Among young adults age 19 to 28, annual prevalence of LSD averaged slightly under 3% in the late 1980s (1986-1989). Use rates rose slightly between 1989 and 1992, reaching 4.3%; in 1995 annual prevalence is 4.6% (Figure 25 and Table 8). Clearly the younger age groups have had the highest rates of LSD use in recent years and have shown the greatest increase in use. Among high school seniors, the average annual prevalence in the late 1980s was slightly under 5%, but has risen to 8.4% in 1995.
- Use of *heroin* increased significantly in 1995 for both seniors and young adults (Tables 1 and 8). Among young adults use had previously been quite stable at least as far back as 1986. Among 19 to 28 year olds, the use of *opiates other*

than heroin leveled after 1991, following a period of slow, long-term decline (Figure 29).

• In sum, except for *cigarettes* and *alcohol* (and more recently for *LSD*), substance use among high school seniors and young adults have shown *longer-term* trends which were highly parallel. Although divergent trends would not necessarily demonstrate a lack of validity in either set of data (because such a divergence could occur as the result of cohort differences), we believe that the high degree of *convergence* provides an important source of validation of the trends reported earlier for the seniors. In fact, each of these sets of data have helped to validate the trend story reported by the other.

After 1992, however, there has been some divergence in trends between the adolescents and the young adults on a number of drugs, as use among adolescents has risen (and subsequently risen among the 19-20 year olds). This divergence indicates a new cohort effect, quite possibly reflecting an "intergenerational forgetting" of the dangers of drugs by the youngest cohorts.

## TRENDS FOR IMPORTANT SUBGROUPS OF YOUNG ADULTS

Four-year age-bands have been used here to examine subgroup trends in order to have sufficiently large numbers of cases to make reliable estimates for the various subgroups being examined. Subgroup data for respondents of each sex, and for respondents from communities of different sizes, are available for 19 to 22 year olds since 1981, 23 to 26 year olds since 1985, and 27 to 30 year olds since 1989. Beginning with the 1987 follow-up questionnaires, information on state of residence was included so we have been able to obtain trend data for the four regions of the country. These data are not presented in tables here because of space limitations.

## Sex Differences in Trends

- Over the long term, sex differences narrowed for some drugs, primarily because of a steeper decline in use among males (who generally had higher rates of use) than among females. The overall picture, though, is one of parallel trends, with use among males remaining higher for most drugs, including the indexes of any illicit drug use in the prior year and any illicit drug use other than marijuana (see Table 11, for example).
- Between 1980 and 1989, the downward trend in *marijuana* use among 19 to 22 year olds was sharper among males than females, narrowing the gap between the two groups. Annual prevalence fell by 22 percentage points (to 34%) among males, compared to a drop of 14 percentage points (to 31%) among females. Since then the gap widened some, particularly as use has begun to rise modestly in this age band (but not the older ones) since 1993.

TABLE 7

Trends in Lifetime Prevalence of Various Types of Drugs Among Respondents of Modal Age 19-28

(Entries are percentages)

## FOOTNOTES FOR TABLES 7-10

aUse of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (until 1990), or tranquilizers not under a doctor's orders.

bThis drug was asked about in four of the five questionnaire forms in 1986-89, and five of the six questionnaire forms in 1990-1995. Total N is approximately 5300 in 1995.

cAdjusted for underreporting of amyl and butyl nitrites, except in 1995, when questions about nitrite use were dropped.

dThis drug was asked about in one questionnaire form. Total N in 1995 is approximately 1100.

eAdjusted for underreporting of PCP.

<sup>f</sup>This drug was asked about in two of the five questionnaire forms in 1987-89, and in all six questionnaire forms in 1990-1995.

gThis drug was asked about in one of the five questionnaire forms in 1987-89, and in four of the six questionnaire forms in 1990-1995. Total N in 1995 is approximately 4300.

hThis drug was asked about in two of the five questionnaire forms in 1989, and in two of the six questionnaire forms in 1990-1995. Total N in 1995 is approximately 2100.

Only drug use which was not under a doctor's orders is included here.

jBased on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants.

kIn 1993 and 1994, the question text was changed slightly in three of the questionnaire forms to indicate that a "drink" meant "more than just a few sips." Because this revision resulted in rather little change in reported prevalence in the surveys of high school graduates, the data for all forms are used in order to provide the most reliable estimate of change.

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

<sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (until 1990), or tranquilizers not under a doctor's orders.

Also, between 1980 and 1993 *daily marijuana use* for this age group fell more steeply, from 13% to 3% among males, versus from 6% to 2% among females, again narrowing the gap considerably. However, there was a significant increase among males in 1994 (to 5%), and an increase among females a year later (to 3%).

- Following a period of decline, by 1993 rates had stabilized for the proportion of both males and females in the two older age bands using any illicit drug other that marijuana. Among the 19 to 22 year olds, however, there has been an increase for males since 1993 and for females since 1994.
- For *LSD*, the male-female differences tended to diminish as use declined (1980-1985), and tended to increase as use increased (1985-1992). As of 1995, the sex differences are fairly large, with males at least twice as likely to be users in the past year across all age bands.
- During the period of sharp decline in annual *cocaine* prevalence (1986-1993), use dropped more among males than females. In the 19 to 22 year age band, annual prevalence for males declined by 16 percentage points (to 4.5%) vs. 13 percentage points among females (to 2.8% in 1993). In the 23 to 26 year old age band there was also a narrowing of the sex difference between 1986 and 1993, with annual prevalence down 19 percentage points (to 6.9%) among males and 13 percentage points (to 4.2%) among females. Since 1988, when data are first available, use among males in the 27 to 30 year old group also dropped faster (down 11.5% vs. 6.4% for females) between 1986 and 1993. In sum, during the period of sharp decline in cocaine use overall, the sex differences—which had been fairly large—narrowed considerably in all age bands.
- As *barbiturate* use declined after 1980, the modest sex differences were virtually eliminated in all three age bands; annual prevalence stands between 1.0% and 3.4% for both sexes in all three age groups. Since 1993 there has been a modest increase for both sexes among the 19 to 22 year olds.
- The annual prevalence figures for *heroin* dropped among males in the 19 to 22 year old category between 1980 and 1986 (from 0.6% to 0.2%) before leveling through 1994. Rates for females remained very low, between 0.1% to 0.3% throughout the period through 1994. In 1995 use increased in the two younger age bands among both males and females.
- Both sexes have shown some decline in recent years in the use of *opiates other* than heroin, with a near elimination of previous sex differences by 1992. In 1994, use by males began to rise slightly in all three age bands, while use by females began to rise slightly in all three age bands in 1995. Again, the largest increases occurred in the 19 to 22 year old band.
- e Between 1981 and 1991, rates of *stimulant* use were similar for males and females, and showed substantial and parallel downward trends for both sexes. Among the 19 to 22 year olds, use for males dropped 22 percentage points in annual prevalence (to 5.2% in 1991), and females dropped 21 percentage points

(to 4.7% in 1991). Since 1991, there have been small increases in annual prevalence for both sexes in the 19 to 22 year age group, where the prevalence rate now stands at 7.3% for males and 5.7% for females.

- For *tranquilizers* both sexes have shown a long, gradual decline (and very similar rates of use) since 1980. In recent years, rates hovered between 2% and 5% annual prevalence for both sexes in all three age groupings. In 1995 use increased for both sexes in the 19 to 22 year old group only, again reflecting generational replacement.
- Inhalant use has been consistently higher among males than females in all three age groups. It has also been stable for both sexes in the older two age groups, but the 19 to 22 year olds (who have the highest prevalence rate in general) showed a gradual upward drift from 1980 to 1988 for both sexes, similar to the trend pattern among high school seniors. Rates then remained stable through 1994, before increasing slightly again among the 19 to 22 year old males. In the two older age bands use among males also drifted upward over the past couple of years.
- For *alcohol*, 30-day prevalence rates have shown a long, gradual, parallel decline from 1981 through 1992 for both sexes in the 19 to 22 year old age group. Thirty-day prevalence fell from 83% to 72% among males and from 75% to 62% among females by 1992. In the older two age bands, there had also been a modest, parallel decline for both sexes, after 1985 in the case of 23 to 26 year olds, and at least since 1988 (when data were first available) in the case of the 27 to 30 year olds. After 1992 both sexes in all three age bands showed level use.

There also has been a general long term decline in *daily drinking*. There is still a large sex difference for daily drinking among the 19 to 22 year old age group in 1995: 5.5% for males vs. 1.5% for females; but not nearly as large as it was in 1981 (11.8% vs. 4.0%). The sex differences have been larger for the older age groups (in 1995, for example, 7.0% vs. 2.4% among 27 to 30 year olds), and there has been less evidence of convergence.

There also are long-established and large sex differences in all age groups on occasional heavy drinking or "binge drinking" (i.e., having five or more drinks in a row at least once in the past two weeks). However, 19 to 22 year old males have shown some longer-term decline in this statistic, from 54% in 1986 to 45% in 1995, thus narrowing the gender gap (from 24% in 1986 to 17% in 1995). Among females in this age group, there has been only a slight change in the rate of binge drinking since 1985, when use was 30%, to 1995 (28%). In the two older age bands, there is little evidence of a change in binge drinking rates by either sex.

All three age groups showed a long-term decline in daily smoking rates for both males and females since data were first available for each—at least through 1990: 19 to 22 year olds from 1980 to 1990; 23 to 26 year olds from 1984 to 1992; and

27 to 30 year olds from 1988 to 1994. Their smoking rates have also been very close.

There have been some increases in recent years in daily smoking rates, particularly among the younger groups, and especially among the males. For example, 19 to 22 year old males increased significantly from 20% in 1993 to 24% in 1995. Because smoking rates in high school graduating classes since 1992 have been on the rise, and because we know that class cohorts tend to maintain their relative differences over time, we would predict a continuation of the increase in smoking among 19 to 22 year olds in the coming years, and eventually in the older age bands as the recent heaver-smoking high school class cohorts grow older.

## Regional Differences in Trends

The respondent's current state of residence was first asked in the 1987 follow-up survey, so trend data by region exist only for the interval since then. Changes have been examined for all 19 to 28 year olds combined to increase the reliability of the estimates. (All regions are represented by between 1100 and 2300 cases in all years.) In general, the changes which have occurred since 1987 have been pretty consistent across regions, particularly in terms of the direction of the change.

- There were substantial drops in all four regions between 1987 (the initial measurement point) and 1991 for any illicit drug, marijuana, cocaine, crack, and stimulants. Since 1991 there has been a leveling or increase in the use of these drugs in most or all regions, with the exception of cocaine which has continued to decline.
- The proportion of 19 to 28 year olds using any illicit drug has been consistently lowest in the South and highest in the West and Northeast. For marijuana use, the South stands out as being consistently lowest, until 1995, when an increase in use observed in all three age groups nearly closed the gap. Generally, the other three regions have been fairly close to one another. For the use of any illicit drug other than marijuana, the West has stood out as highest and the other three regions have been nearly identical since 1990. As will be discussed below, in recent years the West has had the highest rates of use among young adults of LSD (at least until 1995, when use dropped in the West), hallucinogens other than marijuana, (again, until 1995, when use dropped in the West and rose in all other regions), and ice. In fact, in this age band (19 to 28), most of the reported ice use occurs in the West. (In 1995, the annual prevalence was 3.9% in the West, 0.9% in the North Central, 0.4% in the South, and 0.1% in the Northeast.)
- The declines in *cocaine* use observed in all regions between 1987 and 1991, were greatest in the two regions which had attained the highest levels of use by the mid-1980s—the West and the Northeast. In 1992 these declines stalled in all regions except the Northeast, which was similar to the finding for seniors. Much less regional variability remains in 1995 than in 1987, but the West and

Northeast still have the highest annual prevalence rates (5.8% and 4.9%, respectively, for 19 to 28 year olds), while the South and North Central regions are lower (4.0% and 3.4%, respectively).

- All four regions also exhibited an appreciable drop in crack use between 1987 and 1991, with the greatest declines in the West and Northeast, where prevalence had been the highest. Use has leveled in all regions. As was true for cocaine generally, prevalence rates among the regions have converged and now stand at about 1% for all regions.
- Through 1994 rates of *inhalant* use remained relatively stable and quite low in all four regions among 19 to 28 year olds. In 1995, however, use increased in the Northeast and North Central.
- Questions about MDMA (ecstasy) were added to the surveys in 1989; use rates in both 1989 and 1990 were higher in the West and the South and lower in the Northeast and North Central. In 1991 and 1992 use fell (non-significantly) in all regions except the West, where annual prevalence rose significantly in 1992 (from 0.9% to 3.1%). Since 1992, the West has continued to have a high rate relative to the other regions. In 1995, use in the South rose to the same level as the West.
- LSD use rose in all four regions between 1989 and 1992, though more in the West than elsewhere. Since 1992 rates have remained fairly level, with some convergence occurring in 1995. Annual prevalence of LSD now stands at 4% to 5% for all regions. Use of hallucinogens other than LSD also is quite level across regions in 1995 at 2% to 3% annual prevalence.
- Questions about the use of *ice* were added in 1990. Three of the regions have shown negligible rates since then (from 0.1% to 0.9% annual prevalence) with the West showing a consistently higher rate (from 1.4% to 3.9%) and evidence of an increase in use between 1991 (0.9%) and 1995 at about 3.9%.
- The use of *barbiturates* has remained flat, and at about equivalent levels, in all four regions of the country since 1987, when regional data were first available.
- With respect to *alcohol* use, there were modest declines in all four regions between 1987 (when the first measurement was available for 19 to 28 year olds) and 1992 in both 30-day prevalence and daily drinking. Since then rates have leveled. *Occasional heavy drinking* has remained fairly level in all regions since 1987. The rates generally have been appreciably higher in the North Central (37% in 1995) and the Northeast (34%) than in the South (27%) and the West (26%).
- There have been highly consistent regional differences in *cigarette smoking* since regional data were first available in 1987—and they exist for monthly, daily and the half-pack-daily prevalence rates. The West consistently has had the lowest rates (e.g., 16% daily prevalence in 1995), the South the next lowest (21%)

in 1995), the Northeast the second highest (24% in 1995) and the North Central the highest (24% in 1995).

## Trend Differences Related to Population Density

The analyses presented here for population density return to the use of four-year age groupings, which allows a longer time interval to be examined for the younger strata.

- In general, the proportion of young adults using any illicit drug declined substantially over the long term in communities of all sizes. (Among the young adults, five levels of population density are distinguished.) Among 19 to 22 year olds, this decline began in 1980 (when data were first available) and continued through 1991; rates then stabilized for a couple of years among the 19 to 22 year olds in all areas before increasing modestly. In the two older age groups rates have remained steady in all areas since about 1991 or 1992. In general, the farm/country and small town strata continue to have lower use than all of the other strata. In 1995 the proportions of 19 to 22 year olds reporting use of an illicit drug in the past year were 27% for the farm/country strata, 34% for small town, 35% for medium-sized cities, 34% for large cities, and 37% for very large cities. (The absolute differences among these strata narrowed as usage rates fell, and remain narrow with the more recent rise.) For young adults aged 23 to 26, the difference also has become smaller in recent years (a difference of only 13 percentage points in 1995 between the rural and most urban strata vs. 23 percentage points in 1985). Among the 27 to 30 year olds, the difference has averaged about 9% between the rural and large city strata.
- The use of any illicit drug other than marijuana tells a similar story: A long period of fairly parallel decline before leveling, and some convergence of usage rates among the strata. While the very large cities tended to have the highest rates on both indexes, they generally have been only slightly higher than the other urban areas.
- *Marijuana* use began to decline in 1981 or 1982 among the 19 to 22 year olds in all community-size categories until about 1991 when prevalence rates stabilized, before trending upward again in 1994 and 1995. Still, the four largest urban strata have declined by 19 to 23 percentage points since 1980, and the farm/country by 16 percentage points.
- Among the 19 to 22 year olds (the age group with by far the highest rates of *LSD* use of the young adults) *LSD* use in communities of all sizes declined appreciably in the 1980s. Since around 1989 there has been some increase in use in all strata. There also was some increase after 1989 among 23 to 26 year olds in the more urban areas, though their rate of use has remained fairly stable since 1991 or 1992.

The use of *hallucinogens other than LSD*, taken as a class, fell in communities of all sizes among the young adults between 1980 and about 1988. Since then there has been some modest increase in use among all strata in the 19 to 22 year

old age band. In the 23 to 26 year old group, there was a general but modest increase for a year or two, which generally ended by 1992.

- The important drop in *cocaine* use since 1986 slowed considerably after 1992 or 1993 in all three age strata and in communities of all sizes. Usage rates among the strata tended to converge a bit during the period of decline, and this convergence remains, with the large and very large cities still showing rates of cocaine use slightly higher than the less densely populated areas.
- Crack use among all age groups peaked in 1987 or 1988 and, after declining, appears to have bottomed out in all population-density strata since about 1990.
   The crack use reported in these young adult samples bears little systematic association with community size.
- Stimulant use showed large drops after 1981 among 19 to 22 year olds in communities of all sizes; after 1984 (the first time point available) among the 23 to 26 year olds; and, to a lesser extent, after 1988 (first time point available) among the 27 to 30 year olds. After 1991 use tended to level at relatively low prevalence rates in all strata and age groups, although use has been gradually rising since 1992 or 1993 for all strata—undoubtedly as a result of generational replacement by the heavier-using adolescents.
- **Methaqualone** use, which in 1981 was rather strongly associated (positively) with population density, dropped to annual prevalence rates of 0.8% or below in all size strata for all three age bands by 1989. Its use is no longer measured in the study.
- The use of *barbiturates* also fell to very low rates by 1989 before stabilizing. Annual prevalence in 1995 is less than 3% in all community-size strata for the two older age bands. Among the 19 to 22 year olds, however, use has begun to rise again since 1992 or 1993. Unlike methaqualone, barbiturates have never shown much correlation with urbanicity, at least as far back as 1980.
- Tranquilizer use among young adults has had little or no association with population density over this time interval either. Among the 19 to 22 year olds it declined by half in most strata from 1980 to about 1985, to just over 4% annual prevalence. Since 1985 some further, rather modest declines have occurred, resulting in annual prevalence rates of between 2% and 4% in all community-size strata for all three age bands. Once again, however, use has begun to rise among the 19 to 22 year olds only, since 1993 or 1994.
- Annual *heroin* prevalence in 1994 stands at less than 1.0%—usually much less—in all strata for all three age bands, and shows little systematic relationship with urbanicity. In the early 1980s it did tend to be a bit more concentrated in cities than in the small-town and farm/country strata among the 19 to 22 year olds. There was a slight upturn in use in 1995, which seems to be concentrated in the more urban areas.

- o Similarly, the annual use of *opiates other than heroin* had some positive association with degree of population density in the early 1980s; however, it has shown rather little association since then, due to a greater decline in use in several urban strata. For each of the strata, annual prevalence stands at between 1.2% and 4.3% for all community-size strata in all three age groups. Among the 19 to 22 year olds only, all strata showed some modest increase in use in 1995.
- o While the absolute levels of *inhalant* use still remain low in these age groups, during the mid- to late-1980s there was a gradual increase among 19 to 22 year olds in all community-size strata. There has been no strong or consistent association with population density though the urban areas generally have tended to have higher rates than the non-urban areas among 19 to 22 year olds. (Prevalence rates are all extremely low thereafter.)
- o In the first four years for which data on *MDMA* (ecstasy) were available (1989-1992), use was generally lower in the farm/country and small town strata than in the three urban strata. In recent years, use levels have been very low, and not systematically related to population density.
- o Prevalence rates for the use of *ice* or crystal methamphetamine have been very low since questions about its use were introduced into the study in 1990, and there has been no systematic relationship with urbanicity. In 1995 among the 19 to 22 year olds there was some modest increase in use in all strata.
- o In the six years between 1984 and 1990, 30-day prevalence of alcohol use declined modestly in almost all community-size strata for both the 19 to 22 and the 23 to 26 age groups. (The same happened among 27 to 30 year olds living in the very large cities from 1988, when data were first available, to 1991.) Since then, there has been little systematic change. The same is true for occasional heavy drinking. The association between community size and alcohol use has remained a slightly positive one for 30-day prevalence and for occasions of heavy drinking among all age groups. The farm/country stratum has stood apart fairly consistently as having the lowest monthly prevalence of drinking and the lowest prevalence of occasional heavy drinking in all age bands.
- Cigarette smoking has been slightly negatively associated with urbanicity in all three age strata, without much evidence of differential trends related to degree of urbanicity.

#### Chapter 6

## ATTITUDES AND BELIEFS ABOUT DRUGS AMONG YOUNG ADULTS

Over the past twenty years we have observed substantial changes in 12th graders' attitudes and beliefs about the use of drugs, in particular the perceived risk of harm associated with marijuana and cocaine, and personal disapproval of use of marijuana, cocaine, and amphetamines. Further, the importance of these shifts in attitudes and beliefs in explaining changes in actual drug-using behavior has been demonstrated in earlier volumes in this series and elsewhere.<sup>17</sup> In this chapter we review trends since 1980 in the same attitudes and beliefs among young adults.

#### PERCEIVED HARMFULNESS OF DRUGS

Table 12 provides trends in the perceived risks associated with differing usage levels of various licit and illicit drugs. These questions are contained in one questionnaire form only, limiting the numbers of follow-up cases; accordingly, we use four-year age bands in order to increase the available sample size (to about 500-600 weighted cases per year for each age band) and thus, to improve the reliability of the estimates. (The actual case counts are given at the end of Table 12.) Still, these are small sample sizes compared to those available for eighth, tenth, and twelfth graders, so the change estimates are more labile. Because of the nature of the Monitoring the Future design, trend data are available for a longer period for 19 to 22 year olds (since 1980) than for 23 to 26 year olds (since 1984), or for 27 to 30 year olds (since 1988). Also displayed in this table are comparison data for seniors, shown here as 18 year olds, for 1980 onward.

#### Beliefs About Harmfulness Among Young Adults

- Table 12 illustrates considerable differences in the degree of risk young adults associate with various drugs. In general, the results closely parallel those observed among seniors.
- o *Marijuana* is seen as the least risky of the illicitly used drugs, although sharp distinctions are made between different levels of use: In 1995, experimental use is perceived as being of "great risk" by only 13%-16% of high school graduates (in

Bachman, J.G., Johnston, L.D., O'Malley, P.M., & Humphrey, R.H. (1988). Explaining the recent decline in marijuana use: Differentiating the effects of perceived risks, disapproval, and general lifestyle factors. Journal of Health and Social Behavior, 29, 92-112; Bachman, J.G., Johnston, L.D., & O'Malley, P.M. (1990). Explaining the recent decline in cocaine use among young adults: Further evidence that perceived risks and disapproval lead to reduced drug use. Journal of Health and Social Behavior, 31, 173-184; Johnston, L.D. (1981). Frequent marijuana use: Correlates, possible effects, and reasons for using and quitting. In R. deSilva, R. Dupont, & G. Russell (Eds.), Treating the Marijuana Dependent Person (pp. 8-14). New York: The American Council on Marijuana; Johnston, L.D. (1985). The etiology and prevention of substance use: What can we learn from recent historical changes? In C.L. Jones & R.J. Battjes (Eds.), Etiology of Drug Abuse: Implications for Prevention (NIDA Research Monograph No. 56, pp. 155-177). (DHHS Publication No. (ADM) 85-1335). Washington, DC: U.S. Government Printing Office.

the age band 19 to 30), whereas regular use is perceived to be that risky by about two-thirds (62%-69%) of them.

It is interesting to note that in the mid-1980s and early 1990s fewer of the older age groups saw great risk, particularly with experimental and occasional use of marijuana, than the younger age bands. Indeed, there was a quite regular negative ordinal relationship between age and perceived risk for some years. This could have reflected an age effect, but we interpreted it as a cohort effect: The younger cohorts initially perceived marijuana as more dangerous and persisted in this belief as they grew older than did preceding cohorts. Newer cohorts however, have become more relaxed in their attitudes—1995 high school seniors are less likely to perceive marijuana use as dangerous than their predecessors in the late 1980s and early 1990s, reflecting what we have called generational forgetting," a phenomenon wherein younger replacement cohorts no longer carry the knowledge, and perhaps the direct or vicarious experience on which the knowledge is based, that the older cohorts had when they were that age. This recent change of beliefs had been happening primarily among 18 year olds (and younger ages), not among the older age bands. In 1995, the 19 to 22 year olds had a significant drop in perceived risk of experimental and occasional marijuana use, we think as a direct result of generational replacement of older cohorts by the more recent less concerned ones. In fact, the relationship between perceived risk and age reversed by 1995. Now, the older the respondents, the more likely they are to see marijuana as dangerous. In 1995, only 61% of seniors thought regular marijuana use carried great risk, vs. 69% of the 27 to 30 year olds. This reversal of the relationship with age is consistent with an underlying cohort effect and inconsistent with the notion of a regular change with age in these attitudes.

- Use of any of the other illicit drugs is seen as distinctly more risky than marijuana. Even the experimental use of amphetamines and barbiturates is perceived as risky by about 31%-37% of young adults aged 19 to 30, and 40%-53% think trying LSD or MDMA (ecstasy) involves great risk. Trying cocaine powder is seen as dangerous by 48%-56%, while using crack or heroin once or twice is seen as dangerous by 59%-66%.
- In recent years, the older age groups have been more likely than the younger age groups to see *LSD*, *heroin*, and *barbiturates* as dangerous. These age distinctions have become sharper in recent years as perceived risk has declined more in the younger age groups than the older ones-again indicating some important cohort changes in these attitudes.
- There is a modest age-related difference in experimental and occasional use of *cocaine*; the older groups (23 and over) perceive less risk than the younger groups (18 to 22) who have had less experience with cocaine. However, with regard to regular cocaine use, the three older age groups are *more* likely to see that behavior as dangerous than the seniors. It should be noted that among the 19 to 22 year old age band, the risks perceived to be associated with *cocaine*

**powder** and **crack** began to fall in 1995, undoubtedly reflecting the effects of generational replacement.

- Questions about perceived risk of crystal methamphetamine (ice) use were introduced in 1990, and the results show what may be an important reason for its lack of rapid spread. More than half of all seniors and young adults perceive it as a quite dangerous drug, perhaps because it has been likened to crack in most media accounts. Both drugs are burned and the fumes inhaled, both are stimulants, and both can produce a strong dependence. There is rather little difference in these attitudes by age.
- o MDMA (ecstasy) questions were introduced in 1989, and have not been asked of seniors. Young adults see it as a fairly dangerous drug, even for experimentation; between 48% and 50% say there is "great risk" involved. This puts it close to cocaine powder in its level of perceived risk.
- o As was true for high school seniors, only a minority of the young adults see *heavy* drinking on weekends as dangerous (38%-45%); however, about three-fourths of young adults (and two-thirds of seniors) feel that way about daily heavy drinking.
- o Approximately three-quarters (72%-76%) of the young adults perceive regular pack-a-day *cigarette smoking* as entailing high risk, higher than the 66% of seniors who hold that belief and much higher than the 50% of eighth graders who do so. Unfortunately an understanding of the risks comes too late for many who have initiated use (and often heavy use) in their teen years.
- The use of **smokeless tobacco** is seen as dangerous by many fewer, 42%-47% of young adults and 33% of seniors.

#### Trends in Perceived Harmfulness Among Young Adults

- Nearly all of the important trends observed among seniors in perceived harmfulness can also be seen among young adults. (See Table 12.)
- The long-term increase in the perceived risk of *regular marijuana use* documented among seniors between 1980 and 1989 also occurred among young adults. The proportion of 19 to 22 year olds reporting "great risk" rose dramatically from 44% in 1980 (the first data point available) to 75% in 1989. Among seniors the shift over the same interval was from 50% to 78%. (Daily marijuana use dropped appreciably during this time in all of these age groups.) In 1992 however, the perceived dangers of regular marijuana use declined among seniors, 19 to 22 year olds, and the 23 to 26 year olds. These declines continued through 1995, and the youngest two age groups perceived risk is at its lowest point since the early 1980s. Since 1991, the younger the age group, the larger the decline in perceived risk. This resulted in the reversal of the relationship between perceived risk and age, discussed above.

TABLE 12 **Trends in Perceived Harmfulness of Drugs** Young Adults in Modal Age Groups of 18, 19-22, 23-26, and 27-30 (Entries are percentages)

NOTES: Level of significance of difference between the two most recent years: s=.05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

<sup>&#</sup>x27;NA' indicates data not available.

a Answer alternatives were: (1) No risk, (2) Slight risk, (3) Moderate risk, (4) Great risk, and (5) Can't say, drug unfamiliar.

- In general, young adults have been more cautious about *heroin* use than high school seniors. Among the seniors, there had been a downward shift from 1975 to 1986 in the proportion seeing great risk associated with trying heroin; then there was a sharp upturn in 1987, followed by a leveling through 1991, followed by some gradual decline since. Young adults, although the data do not extend back as far, also seem to have shown an increased caution about heroin use in the latter half of the 1980s, followed by some fall off in concern in the 1990s. These various trends may reflect respectively, (a) the lesser attention paid to heroin by the media during the late seventies and early eighties than previously, (b) the subsequent great increase in attention paid to intravenous heroin use in the latter half of the 1980s because of its important role in the spread of AIDS, and (c) the emergence in the 1990s of heroin so pure that people no longer needed to use a needle to administer it.
  - Among seniors and the young adult age groups, the danger associated with cocaine use on a regular basis grew considerably between 1980 and 1986. However, these changed beliefs did not translate into changed behavior until the perceived risk associated with experimental and occasional use began to rise sharply after 1986. When these two measures rose, a sharp decline in actual use occurred. We hypothesized that respondents see only these lower levels of use as relevant to them (nobody starts out planning to be a heavy user; further, cocaine was not believed to be addictive in the early 1980s). Based on this hypothesis, we included the additional question about occasional use in 1986, just in time to capture a sharp increase in perceived risk which occurred that year, largely in response to the growing media frenzy about cocaine and crack cocaine, in particular, and the widely publicized, cocaine-related deaths of Len Bias and others. After stabilizing for a few years, perceived risk began to fall off among seniors after 1991, but not among the older age groups. A decline may have begun among the 19 to 22 year olds starting in 1995, likely as the result of generational replacement with the high school seniors who had come to see cocaine as less dangerous.
- Trend data on the risks perceived to be associated with *crack* (available since 1987) show increases in the 1987-1990 interval for all age groups, followed by relatively little change. Had data been available a year or two earlier, they undoubtedly would have shown an even larger shift.
  - Since 1992 the seniors have shown decreases in the perceived risk of experimental or occasional use of crack, leaving them as perceiving considerably less risk than the other age groups. In 1995, the 19 to 22 year olds showed a decline on these two measures as well, perhaps reflecting the onset of "generational forgetting."
- Perceived risk of harm from *occasional heavy drinking* (that is, having five or more drinks once or twice each weekend) increased among 12th graders from 36% in 1980 to 49% in 1992; it has since declined to 45% in 1995. The older groups have shown smaller changes, though all increased slightly between 1988 and 1992 (by 2-5 percentage points), and then changed very little between 1992 and

1995 (decreased among 19 to 22 years old from 42% to 40%) or not at all (the 23 to 26 and 27 to 30 groups remained at 38% and 45%, respectively).

Self-reported rates of occasional heavy drinking among 12th graders shifted in corresponding ways to shifts in perceived risk over the longer term from 1980 to 1995. The smaller increases in perceived risk between 1988 and 1995 among the older groups have been accompanied by decreases in use.

- In the late 1980s and early 1990s, the data available from the young adult samples showed a modest increase in the proportions associating great risk with regular smoking. For example, over the nine-year interval from 1984 to 1993, 12th graders, 19 to 22 year olds, and 23 to 26 year olds all showed an increase of 6 or 7 percentage points in the proportion seeing great risk in pack-a-day smoking. However, all three groups showed (nonsignificant) declines in 1994 and remain stable in 1995. Substantial proportions still do not see such behavior as being risky (between 24% and 34%). In recent years the 18 year olds consistently showed the lowest perceived risk (10th graders are lower, 8th graders lower still). Clearly, an age effect plays a role in young people's growing understanding of the dangers from smoking. Unfortunately, it appears that much of the learning occurs after the proverbial "horse is out of the barn" when many young people already have become addicted.
- Between 1986 (when questions about *smokeless tobacco* were first included) and 1993, there was a fair increase in perceived risk among 12th graders, 19 to 22 year olds, and 23 to 26 year olds. The lower the age, the larger the increase, which had the effect of narrowing the age-related differences among young adults. In 1995, however, there was a significant drop among high school seniors in the perceived dangers of smokeless tobacco use, again setting them apart from the high school graduate population.

#### PERSONAL DISAPPROVAL OF DRUG USE

The questions asked of high school seniors concerning the extent to which they personally disapprove of various drug-using behaviors also are asked of follow-up respondents, in one of the six questionnaire forms. Trends in the answers of young adults aged 19 to 22, 23 to 26, and 27 to 30 are contained in Table 13. Comparison data for 12th graders are also provided for 1980 onward. (See also Table 22 in Chapter 8 of Volume I, for the longer-term trends in high school seniors' attitudes and beliefs about drugs.)

#### Extent of Disapproval by Young Adults

• In general, the attitudes of young adults related to the various drug-using behaviors, both licit and illicit, are highly similar to those held by 12th graders. This means that the great majority disapprove of using, or even experimenting with, all of the *illicit drugs other than marijuana*. For example, regular use of each of the following drugs is disapproved by 97% or more of young adults: *LSD*, cocaine, amphetamines, barbiturates, and heroin. Even

experimentation with each of these drugs is disapproved by 83% to 96% of the young adults.

- These attitudes seem to differ little as a function of age, except that disapproval of experimental use of *cocaine* declines after age 22: among seniors (90%), 19 to 22 year olds (94%), 23 to 26 year olds (92%), and 27 to 30 year olds (87%). These differences are consistent with age-related differences in actual use.
- Even for *marijuana*, more than half of young adults now disapprove experimentation, between 68% and 73% disapprove occasional use, and nearly 90% disapprove regular use.
- Rates of disapproval for the various patterns of *alcohol* use listed are quite close to those observed among seniors. Seniors are more likely to disapprove of experimentation: 27% for seniors vs. 17% to 22% for the three older groups.
- Obsapproval for *cigarette smoking* at the rate of a pack per day or more showed a slight positive association with age in 1993, 1994, and 1995; in prior years that was not the case (see Table 13).

#### Trends in Disapproval by Young Adults

Prior to 1991, some important changes occurred in American young adults' attitudes, with a declining proportion finding the use of the various drugs acceptable, even for adult use. However, since 1990 there has been rather little further systematic change in these attitudes. The rates of disapproval have remained fairly constant (in many cases at very high levels) and generally have not reversed, even though such a change has been occurring among secondary school students. (See Volume I.) The major exception occurs for the 19 to 22 year olds, where drops in disapproval of *marijuana* and *alcohol* use occurred for the first time in 1995.

- o Prior to 1991, the largest upward shift occurred for *marijuana*; the proportion of 19 to 22 year olds disapproving even experimentation with marijuana rose from 38% in 1980 to 60% in 1990. (It was 64% in 1994.) Although data are available for a shorter period for the 23 to 26 year olds, this group also increased in disapproval of experimenting with marijuana—from 41% in 1984 to 59% in 1991. Since then, disapproval rates for this age group declined to 52% in 1995. High school seniors began to show a sharp decline in disapproval after 1992, and the 19 to 22 year olds showed the first evidence of such a change in attitude after 1994.
- Between 1990 and 1995, there has been some decline in disapproval of *LSD* use among seniors and 19 to 22 year olds, but not among the older age groups.
- Most of the 1995 disapproval statistics for *heroin* use, at all three levels of use, have remained at very high and stable throughout the life of the study. There has, however been a little slippage in heroin disapproval rates during the 1990s among seniors.

**TABLE 13** Trends in Proportions Disapproving of Drug Use Young Adults in Modal Age Groups of 18, 19-22, 23-26, and 27-30 (Entries are percentages)

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

<sup>&#</sup>x27;Answer alternatives were: (1) Don't disapprove, (2) Disapprove, and (3) Strongly disapprove. Percentages are shown for categories (2) and (3) combined.

- Among the 19 to 22 year olds, disapproval of regular *cocaine* use rose gradually from about 92% in 1982 to 99% in 1990, where it has remained since (98% in 1995). All three young adult age bands (but not seniors) are now near the ceiling of 100%. Young adults 19 to 22, like seniors, showed a sizeable increase in their disapproval of experimental use of cocaine, with the proportion disapproving rising from 70% in 1982 to 94% in 1995; most of the increase occurred since 1986. Disapproval also rose among 23 to 26 year olds—from 70% in 1984 (when data were first available) to 92% in 1995. Only among seniors has there been some fall-off in disapproval, from 94% in 1991 to 90% in 1995.
- There were significant increases in disapproval of experimental use of amphetamines and barbiturates. Trying amphetamines once or twice was disapproved by 73%-74% of 19 to 26 year olds in 1984, compared to 84% by 1990, and the corresponding figures for trying barbiturates were 84%-85% in 1984 compared to 89%-91% in 1990. There has been little systematic change in these attitudes since then; disapproval of amphetamine and barbiturate use remains quite high among young adults as well as among seniors.
- The story for alcohol has become quite complicated. Between 1980 and 1992, an increasing proportion of high school seniors favored total abstention, with the percent disapproving even drinking once or twice rising from 16% in 1980 to 33% in 1992. This figure has fallen back to 27% in 1995. Among 19 to 22 year olds was a modest increase from 15% to 22% disapproving between 1985 and 1989, with no discernible trend since then. For the two oldest age groups there has been little change in these attitudes. These differing trends may reflect the fact that the drinking age in all states has been raised to age 21; this would have the greatest effect on seniors, who may be incorporating the legal restrictions into their normative structure, and as they enter the second age band, bring these new norms with them. Put another way, these changes could reflect a cohort effect resulting from the laws that were prevailing when the cohort passed through late adolescence.

Daily drinking (of one or two drinks) had become more disapproved in the three youngest age bands (seniors through 26 year olds) until about 1990, but disapproval has declined some since then in the three younger strata. Occasional heavy drinking showed a considerable increase in disapproval since the early 1980s for the three youngest age groups (who started out the most tolerant) and this continued through 1992. The levels of disapproval of occasional heavy drinking have remained fairly stable since then, except for some fall-off among the seniors. As Figure 33d illustrates, occasional heavy drinking declined substantially among seniors and 19 to 22 year olds between 1981 and the early 1990s, as norms became more restrictive. There was little or no change in the older age strata.

• From 1984 through 1992 there was very little change in the proportions of high school seniors disapproving *cigarette smoking* at the rate of a pack or more per day (73% vs. 74%), but there has been some decline in disapproval since then. Among the young adults, disapproval rose only very slightly during the 1980s and

has changed little in the last three or four years dropping 3% for the 19 to 22 year olds and rising by the same amount for the 27 to 30 year olds.

# A FURTHER COMMENT: COHORT DIFFERENCES AND IMPLICATIONS FOR PREVENTION AND THEORY

It was noted above that the older age respondents are more likely than younger ones to see the use of crack, LSD, heroin, and barbiturates as dangerous, just the opposite of the situation with marijuana. We have offered the framework for a theory of drug epidemics in which direct learning (from personal use) and vicarious learning (from observing use by others in both the immediate and mass media environments) play an important role in changing these key attitudes. 18 To the extent that the current data on perceived risk represent cohort effects (enduring differences between class cohorts), these findings would be consistent with this theoretical perspective. Clearly, use of these particular drugs was greater when the older cohorts were growing up, and public attention and concern regarding the consequences of these drugs was greatest in the 1970s and early 1980s. In the early 1970s, LSD was alleged to cause brain damage and chromosomal damage, as well as bad trips, flashbacks, and behavior which could prove dangerous. Methamphetamine was discouraged with the slogan "speed kills." There was a serious epidemic of heroin use in the early 1970s, and so on. The youngest cohorts in our study were not exposed to these experiences, but the older cohorts were. While there may have been a secular trend toward greater perceived risk for drugs in general, in the case of LSD there may also have been a cohort effect (younger cohorts seeing less danger) that was enough to offset the secular trend among seniors, who have shown little change in perceived risk since 1980.

This vicarious learning process has a very practical importance for national strategy for preventing future epidemics. As future cohorts of youngsters grow up with less opportunity for such vicarious learning, because fewer in their immediate social circles and fewer public role models are using these drugs and exhibiting the adverse consequences of use, the less opportunity youngsters have to learn about the adverse consequences of these drugs in the normal course of growing up. Unless those hazards are convincingly communicated to them in other ways—say through school prevention programs and public service advertising—they will become more susceptible to a new epidemic of use of the same or similar drugs.

Volume I, the companion volume to the present one, reports an increase in use of several drugs in all three grades in 1994 and 1995, suggesting that this form of "generational forgetting"-in which replacement cohorts lose some of the knowledge held by their predecessors and thus become more vulnerable to using drugs-already may be taking place.

Johnston, L.D. (1991). Toward a theory of drug epidemics. In R.L. Donohew, H. Sypher, & W. Bukoski (Eds.), Persuasive communication and drug abuse prevention. Hillsdale, NJ: Lawrence Erlbaum. pp. 93-132.

#### Chapter 7

## THE SOCIAL MILIEU FOR YOUNG ADULTS

In Volume I we examined the extent to which secondary school students are exposed to drug use of various kinds, their perceptions of the relevant norms in their peer groups, and the extent to which they perceive various drugs to be available to them. In this chapter the same issues are addressed for the young adult population, many of whom are in social environments quite different from the ones to which they were exposed during their high school years.

#### PEER NORMS AS PERCEIVED BY YOUNG ADULTS

Table 14 gives the current status and trends in peer norms for the same three age bands discussed in Chapter 5: namely, 19 to 22 year olds, 23 to 26 year olds, and 27 to 30 year olds. For these three age bands, trend data are available since 1980, 1984, and 1988, respectively. Table 14 also includes comparable data from high school seniors surveyed in those same years.

The questions about how their close friends feel use the same answer scale (stated in terms of degree of disapproval of the use of the various drugs at different levels of use) as do the questions which ask about the respondent's own attitudes about those behaviors (discussed in Chapter 6). The list of drug-using behaviors is shorter here, and the questions appear on a different questionnaire form (and therefore have a different set of respondents). However, the results for perceived peer norms are generally quite consistent with those for personal disapproval; i.e., the proportion saying that they personally disapprove of a drug-using behavior tends to approximate the proportion saying that their close friends would disapprove of that same behavior. The major exceptions are *marijuana*, where friends' attitudes have consistently been reported as more disapproving than their own attitudes, and *binge drinking*, where friends' attitudes have consistently been seen as less disapproving than their own attitudes.

### Current Perceptions of Friends' Attitudes

- The peer norms reported by young adults one to twelve years past high school are similar to those reported by high school seniors. That is, for each of the *illicit drugs other than marijuana* the great majority think that their close friends would disapprove of their even trying such drugs once or twice (85% for *amphetamines*, 86% for *LSD* and 95% for *cocaine*).
- Nearly two-thirds of the young adults (about 63%) now think their friends would disapprove of their even trying *marijuana*, while almost three-fourths (70%) think they would disapprove of occasional use and about 86% think they would disapprove of regular use.

TABLE 14 Trends in Proportions of Friends Who Disapprove of Drug Use Young Adults in Modal Age Groups of 18, 19-22, 23-26, and 27-30 (Entries are percentages)<sup>a</sup>

Source: The Monitoring the Future Study, the University of Michigan.

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

Answer alternatives were: (1) Don't disapprove, (2) Disapprove, and (3) Strongly disapprove. Percentages are shown for categories (2) and (3) combined.

- Over two-thirds (68%) of young adults say their friends would disapprove if they were *daily drinkers*, and over 9 out of 10 (91%) if they were *heavy daily drinkers*, defined as taking four or five drinks nearly every day.
- o Friends' disapproval of *heavy weekend drinking* is distinctly lower. Only 56% to 62% of any age group thinks their friends would disapprove of their having five or more drinks once or twice each weekend. The 19 to 22 year olds, who exhibit the highest rate of such drinking, have the lowest level of perceived friends' disapproval; the level rises with age thereafter.
- Peer disapproval of cigarette smoking is reasonably high in all four age bands: 69% of seniors say their friends would disapprove of pack-a-day smoking, 71% of the 19 to 22 year olds, 79% of the 23 to 26 year olds, and 83% of the 27 to 30 year olds say so. Clearly anti-smoking attitudes are weakest among younger people.

#### Trends in Peer Norms for Young Adults

- o Important changes in the social acceptability of drug-using behaviors among young adults' peers have occurred over the life of this study. Since 1980, peer disapproval of *marijuana* use has grown substantially in all of the young adult age bands. For example, among the 19 to 22 year olds the proportion thinking their friends would disapprove if they even tried marijuana rose from 41% in 1980 to 65% in 1992. That figure remained stable through 1994 (64%) before dropping in 1995 to 59%. While the two older age bands showed some slippage in peer norms against marijuana use, the most important change occurred among the 19 to 22 year olds.
- There was a more gradual increase in peer disapproval levels for *amphetamine* use through 1994, and in 1995 norms against use weakened among 19 to 22 years olds.
- LSD has generally showed little change through 1991, but disapproval among the 18 year olds and the 19 to 26 year olds has edged downward in the past few years—in particular since 1992.
- Perceived peer norms regarding *cocaine* use were first measured in 1986. During the next five years self-reported cocaine use declined substantially and peer norms shifted considerably toward disapproval. By 1994, 95% of the 19 to 22 year olds thought their friends would disapprove of their even trying cocaine (vs. 76% in 1986); however, this statistic slipped back to 92% in 1995. In the two older age bands, peer norms against use have grown and have held.
- While peer norms among seniors regarding alcohol use became somewhat more restrictive between 1981 and 1991, there was less change among the young adults.
- Peer norms regarding cigarette smoking became somewhat more restrictive among high school seniors in the early years of this study, peer disapproval rose

from 64% in 1975 to 73% in 1979. There was little further change through 1994 when friends' disapproval stood at 72%. There was little change for some years among the older groups. Between 1985 and 1993, peer disapproval among 19 to 22 year olds hovered around 79%, before dropping to 71% by 1995. Among 23 to 26 year olds it increased a bit from 74% in 1984, to 83% by 1993 but dropped back to 79% by 1995. Despite recent publicity about changing norms and new laws restricting smoking, there was little change in rates of perceived peer disapproval of cigarette smoking for some years, particularly among those of high school and college ages; now rates of disapproval show clear evidence of a decline. There is little evidence of change in perceived peer disapproval in the oldest age stratum since 1988, when such data were first gathered.

#### EXPOSURE TO DRUG USE BY FRIENDS AND OTHERS

Exposure to drug use is measured by two sets of questions, each appearing on a (different) single questionnaire form. The first set asks each respondent what proportion-of-his or-her-close friends use each drug, while the second asks how often the respondent has been around people using each of a list of drugs "to get high or for kicks." The same questions are asked of high school seniors and their results also have been included in Tables 15 and 16 for comparison purposes. We continue to deal with four-year age bands to increase the reliability of the change scores. At the end of each table is a summary of the numbers of cases upon which each annual estimate is based.

#### Exposure to Drug Use among Young Adults

- Relatively high proportions of young adults have at least some friends who use some illicit drugs (Table 15). In 1995, the proportion is highest for high school seniors (79%), falls to 72% among 19 to 22 year olds, 65% for the 23 to 26 year olds, and 59% for the 27 to 30 year olds. About 13% of the 19 to 22 year olds, and between 6% and 8% of the two older groups, say that most or all of their friends use one or more of the illicit drugs. Since 1985 high school seniors have the highest proportion, saying that most or all of their friends use drugs-fully 22% in 1995, about double the 1992 figure. There was a more modest increase among the 19 to 22 year olds, from 9% in 1992 to 13% in 1995, and little change for the older age groups.
- With regard to *illicit drugs other than marijuana*, taken as a whole, considerably fewer report *any* of their friends so involved: 54% for seniors, 46% for 19 to 22 year olds, 40% for 23 to 26 year olds, and 38% for 27 to 30 year olds. (Note again the descending rates with increasing age after high school.) High school seniors also have the highest proportion saying that *most or all* of their friends use (8% vs. 2%-4% among the young adult strata).
- With respect to individual drugs, exposure among young adults age 19 to 30 is greatest for *marijuana*, with around two-thirds of 19 to 26 year olds reporting that some friends use, and over half of the 27 to 30 year olds doing so. The next

- highest exposures are for *cocaine* (22%-26%), *LSD* (27% among 19 to 22 year olds, declining to 12% among 27 to 30 year olds), and *amphetamines* (14%-22%).
- o The proportions who have friends who use all exceed 10% in at least one age group: steroids (8%-17%), inhalants (4%-14%), hallucinogens other than LSD (8%-15%), crack cocaine (10%-14%), MDMA (ecstasy, 7%-17%), tranquilizers (10%-14%), and barbiturates (7%-13%).
- For several substances, the proportion of young adults having any friends who use decreases with age, consistent with the age-related differences in self-reported use. The steepest declines occur with *inhalants*, *heroin*, *quaaludes*, *MDMA*, *LSD*, *opiates other than heroin*, *and steroids*.
- Cocaine is the one illicit drug that shows a significant increase in active use with age. Consequently, there is a slight increase associated with age in having friends who use (22%-26% for all three young adult age groups).
- For *crack*, however, the story is different. Use now descends sharply with age, although this was not true in the mid 1980s, when measures of crack use were first included in the surveys.
- o In general it appears that even some respondents who report that friends use illicit drugs are not directly exposed to use themselves, judging by the differences in proportions saying they have some friends who use (Table 15), and the proportions who say they have not been around people who were using during the prior year (Table 16).
- o With respect to *alcohol* use, the great majority of young adults have at least some friends who *get drunk at least once a week*, although this differs by age: 79% of the high school seniors, 83% of the 19 to 22 year olds, 73% of the 23 to 26 year olds, and 67% of the 27 to 30 year olds. The proportions who say *most or all* of their friends get drunk once a week differ more substantially by age: 27% of the seniors, 28% of the 19 to 22 year olds, 15% of the 23 to 26 year olds, and only 8% of the 27 to 30 year olds. In terms of direct exposure during the past year to people who were drinking alcohol "to get high or for 'kicks'," having some such exposure is almost universal in these four age groups: 91%, 93%, 92%, and 89%, respectively. (See Table 16.)
- In each of these four age groups, nearly all (85%-89%) also have at least a few friends who *smoke cigarettes*, with little difference by age. At the other end of the scale, over one-quarter of each of the younger two groups state that *most or all* of their friends smoke, while only 14% of the 23 to 26 year olds and 12% of the 27 to 30 year olds say the same. This reduction in the segregation of smokers probably reflects the gradual dissolution of self-selected affiliation groups in high school and the formation of more heterogeneous work-based and neighborhood-based friendship networks after high school.

#### **TABLE 15** Trends in Proportions of Friends Using Drugs Young Adults in Modal Age Groups of 18, 19-22, 23-26, and 27-30 (Entries are percentages)

Source: The Monitoring the Future Study, the University of Michigan.

NOTES: Level of significance of difference between the two most recent years: s = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding. 'NA' indicates data not available.

These estimates were derived from responses to the questions listed above. For the young adult sample, "any illicit drug" includes all of the drugs listed except cigarettes and alcohol.

#### Trends in Exposure to Drug Use by Young Adults

Tables 15 and 16 also provide trend data on the proportions of friends using and directly exposed to use. Once again, trends are available for the 19 to 22 year olds since 1980, for the 23 to 26 year olds since 1984, and for the 27 to 30 year olds since 1988. Data for high school seniors since 1980 also have been included in these tables for comparison purposes.

- An examination of Table 16 will show that exposure to illicit drug use gets progressively lower with advancing age for any illicit drug, as well as for a number of specific drugs. Some of the largest declines in exposure to use with age occur for marijuana, LSD, other hallucinogens, heroin, other narcotics and steroids. These differences replicate across different historical periods.
- Until 1992, young adults' trends in exposure to use tended to parallel those observed for 12th graders. Between 1980 and 1992, that meant a decreasing number of respondents being exposed to any illicit drug use (Table 16), or reporting any such use in their own friendship circle (Table 15). Since 1992, however, some divergence in the trends has emerged; 12th graders showed a significant increase in both friends' use and exposure to use (and in self-reported use), but the young adults generally did not show such a systematic trend, although the 19 to 22 year olds show some upturn, no doubt as a result of generational replacement.
- With regard to *marijuana*, it is particularly noteworthy that, while 34% of the 19 to 22 year olds in 1980 said *most or all* of their friends used marijuana, only 9% said the same in 1993. That number was up to 13% by 1995. Clearly the number of friendship groupings in which marijuana use is widespread dropped dramatically over the long term.
- The proportion exposed to use of any illicit drugs other than marijuana, by way of contrast, did not change much between 1980 and 1986, but between 1986 and 1991 there was a drop in such exposure in all four age groups. This drop appears to be due to drops in exposure to the use of cocaine and amphetamine use, particularly, although there were decreases for barbiturates, and tranquilizers as well. The levels have not changed a great deal since 1991 or 1992, however, except among 12th graders, whose exposure has increased.
- Between 1977 and about 1992, there was a considerable drop in the proportion
  of all four age groups who said they had any friends who used crack. (Selfreported use declined in the same period.) The rates have pretty much leveled
  since then.
- For all four age groups there were some modest declines between 1987 and 1992 in the proportion saying that most or all of their friends drink *alcohol*, but the only change in the proportion saying that most or all of their friends *get drunk* once a week occurred among the seniors and 19 to 22 year olds. The latter measure has shown slight increases between 1992 and 1995 among young adults.

- o Among high school seniors, the proportion who said most or all of their friends smoked cigarettes declined appreciably between 1975 and 1981, during the same period that self-reported use declined, after which neither measure showed much change until about 1992. Thereafter, substantial increases in both measures have occurred. Among 19 to 22 year olds a decline in friends' use occurred between 1980 (or possibly earlier) and 1985, followed by a leveling, through 1994. In 1995, there was a significant increase in the percentage saying most friends smoke, reaching the highest level since 1980. Among 23 to 26 year olds a downturn was evident between at least 1984 (the first year for which data are available) and 1988, then leveled. These staggered changes illustrate that the "cohort effects" are moving up the age spectrum along with the cohorts.
- Nearly all of these changes parallel changes in self-reported use by these four age groups, reinforcing our trust in the validity of the self-report data.

#### PERCEIVED AVAILABILITY OF DRUGS

Young adults participating in the follow-up survey receive identical questions to those asked of high school seniors about how difficult they think it would be to get each of the various drugs if they wanted them. The questions are contained in only one of the six questionnaire forms, yielding a weighted sample size for each four-year age band of about 400 to 600 cases per year. The data for the follow-up samples, which are grouped into four-year age bands, are presented in Table 17, along with the data for the 12th graders.

#### Perceived Availability for Young Adults

- As was true with the high school seniors, substantial proportions of the American young adult population have access to the various illicit drugs. (We do not ask about access to alcohol and cigarettes, since we assume it to be universal.)
- o *Marijuana* is the most available, with 83%-88% of the young adult age strata saying it would be "fairly easy" or "very easy" to get. About the same proportion of 12th graders (89%) have access.
- o Stimulants (amphetamines) are the next most available (54%-60%), and they are even more available to 12th graders (63%).
- o Powdered cocaine, with 46%-53% saying it would be fairly easy to get, ranks next. Crack is available to somewhat smaller proportions than powdered cocaine-from 41%-45% for all four age strata.
- LSD shows a high degree of availability among high school seniors (54%), then decreases with age to 36% for the 27 to 30 year olds.
- o Hallucinogens other than LSD are reported as less available than LSD; 29%-32% in the three young adult strata, and 36% among 12th graders say they could get it fairly easily. Again, availability descends with age.

#### TABLE 16 Trends in Exposure to Drug Use

Young Adults in Modal Age Groups of 18, 19-22, 23-26, and 27-30 (Entries are percentages)

Q. During the LAST 12

| Q. During the LAST 12 MONTHS how often have you been around people who were taking each of the following to get high or for "kicks"?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Age<br><u>Group</u> | <u>1980</u> | <u>1981</u>  | <u>1982</u>  | <u>1983</u>  | 1984         | <u>1985</u>  | <u>1986</u>  | <u>1987</u>  | <u>1988</u>  | 1989          | 1990         | <u> 1991</u> | <u>1992</u>  | 1993         | 1994            | <u>1995</u>  | '94-'95<br><u>change</u> |

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

These estimates were derived from responses to the questions listed above. For the young adult sample, "any illicit drug" includes all of the drugs listed except cigarettes and alcohol.

43

- Two other classes of drugs which are reported as available by sizeable proportions of young adults are barbiturates and tranquilizers. Some 40%-43% say they could get barbiturates (compared with 42% of seniors), and 40%-45% say they could get tranquilizers (vs. 38% of seniors). While the availability of barbiturates declines a bit with age, the availability of tranquilizers seems to increase in the mid- to late-20s.
- Almost a third of young adults (29%-35%) say they could get *heroin* fairly easily (vs. 35% of 12th graders), and availability drops slightly for those over age 22.
- More than a third of young adults (33%-39%) say they can get other narcotics (vs. 40% of high school seniors).
- Even a drug as exotic as *ice* is perceived to be available by at least one-quarter of all age groups (25%-27%).
- Steroids show descending availability with increasing age, ranging from 46% among high school seniors down to 33% among the 27 to 30 year olds.

#### Trends in Perceived Availability for Young Adults

- Marijuana has been almost universally available to all these age groups throughout the historical periods covered by the available data (for up to 20 years in the case of high school seniors). There had been a slight decrease among high school seniors since the peak year of 1979, and a slightly larger decrease since 1980 among 19 to 22 year olds. Availability has risen some in nearly all strata since 1993, though by very little among the young adults. Perceived availability is now a bit higher for the younger age groups (89% for seniors, 83% for those age 27 to 30).
- Cocaine availability moved up among all three age groups over the 1985 to 1988 intervals, reaching historic highs in 1987 and 1988. (High school seniors showed a rise in availability in earlier years-from 1975 to 1980-followed by a leveling between 1980 and 1985. Availability was level during the latter period among young adults, also.) From a policy perspective, it is worth noting that in all three age bands for which we had data, the perceived availability of cocaine increased in 1987-the same year that use actually dropped sharply. Between 1988 and 1989, in the two younger age strata (aged 18, and 19 to 22) the proportions who believed cocaine to be easily available were still increasing, whereas in the older age strata the proportions were beginning to decrease. In 1990 and 1991, all four groups reported decreased availability-quite likely because the number who had friends who were users dropped substantially and then leveled in 1992, when usage rates also leveled. Perceived availability of cocaine dropped to between 49% and 57% for all four age groups in 1993, with the declines ranging from 4 to 7 percentage points. These declines were statistically significant among all but the 19 to 22 year olds. There were no statistically significant changes in 1994 or 1995.

144 187

- o Crack availability increased between 1987 (when such data were first collected) and 1989, then declined a bit until leveling (or perhaps increasing slightly) in 1992. After 1992, it remained level. Since 1987, between 40% and 50% of 18 to 30 year olds have reported that crack would be fairly easy for them to obtain, with no systematic differences in availability across these age groups.
- The trends in *LSD* availability among young adults have some parallels to those for 12th graders. Among 12th graders there was a drop of about 10 percentage points in the mid 1970s and a later drop in the interval 1980 to 1986. The latter drop, at least, was paralleled in the early data for 19 to 22 year olds. Then, since 1986, availability has increased considerably in all age bands. In fact, it is at its highest level since these questions were introduced.
- In the early 1980s there was a fair decline among all age groups in the availability of *hallucinogens other than LSD*; there was little additional change until 1993, when high school seniors reported a significant increase in availability, but the young adult strata did not. There have been modest increases since then in all age groups.
- The availability of *MDMA* (ecstasy) has risen since the questions were first introduced in 1989 and 1990, particularly for the high school seniors. Reported availability of this drug now stands at its highest level for all age groups, with a fair increase occurring in 1995.
- e *Heroin* availability varied within a fairly narrow range from 1980 to 1986, but then showed a modest increase among both high school seniors and the 19 to 26 year olds through 1990. After leveling for a couple of years, the availability of heroin again began to increase, and continued to do so in 1995.
- The availability of *narcotics other than heroin* slowly rose among all age groups between 1980 and 1989, followed by some decline among young adults, but not among 12th graders. Between 1993 and 1995 reported availability was up for all age groups, except the 23 to 26 year olds, and it has returned to its highest level for those three age groups.
- The reported availability of *amphetamines* peaked in 1982 for both 12th graders and 19 to 22 year olds, since then it has fallen by 8 percentage points among 12th graders and 12 percentage points among the 19 to 22 year olds. Since 1987 there has been a decline of 9 percentage points among the 23 to 26 year olds, as well. For the 27 to 30 year olds, reported availability is about the same as it was in 1988, when data for them first became available. All four age bands showed some increase in availability in 1995.
- Barbiturates exhibited a decline in availability since about 1981 or 1982 in the two younger groups—by 13 percentage points among high school seniors and 18 percentage points among 19 to 22 year olds. Since 1984, when data were first available for 23 to 26 year olds, availability has declined by 11 percentage points.

There also has been a decline for 27 tp 30 year olds of about 6 percentage points since 1989. These declines did not continue in 1995 among the young adults.

- Tranquilizer availability has been declining gradually among high school seniors from 72% in 1975 to 38% in 1995. From 1980, when data were first available for 19 to 22 year olds, through 1992, availability declined more sharply and from a higher level (from 67% to 41% in 1992) than among seniors, such that previous differences in availability between them have been eliminated since 1992. The older age groups also showed an overall decline in the availability of tranquilizers through 1991, with little change since then.
- Data on *steroid* availability were first gathered in 1990, and there was little systematic change in any age group through 1992. In 1993, however, all showed some drop in availability, though no one of them reached statistical significance. Since then, availability has been fairly flat. It drops with age, from 46% among seniors to 33% among 27 to 30 year olds, but, considering that steroids are used primarily by males, these are quite high levels of availability.

#### Chapter 8

#### PREVALENCE OF DRUG USE AMONG COLLEGE STUDENTS

The follow-up design of the Monitoring the Future project generates an excellent national sample of college students—better in many ways than the more typical design which first samples colleges and then samples students within them, because in the present sample the students are not clustered in a limited number of colleges. Given the greater diversity in post-secondary institutions than in high schools, the use of a clustered sample would place far greater limitations on sample accuracy at the college level than at the high school level. (Note that the absence of dropouts in the high school senior sample should have practically no effect on the college sample, since very few dropouts go on to college.)

Perhaps the major limitation of the present design for the purpose of characterizing college students is that it limits the age range of the college sample. For trend estimation purposes, we have decided to limit the age band to the most typical one for college attendance, i.e., one to four years past high school, which corresponds to the modal ages of 19 to 22 years old. According to statistics from the United States Bureau of the Census, 19 this age band should encompass about 73% of all undergraduate college students enrolled full-time in 1993, down slightly from the 79% covered in 1989. Although extending the age band to be covered by an additional two years would cover 81% of all enrolled college students, it would also reduce by two years the interval over which we could report trend data. Some special analyses conducted earlier indicated that the differences in prevalence estimates under the two definitions were extremely small. The annual prevalence of all drugs except cocaine shifted only about one- or two-tenths of a percent, based on comparisons made in 1985. Cocaine, which has the greatest amount of age-related change, would have had an annual prevalence rate only 0.8% higher if the six-year age span were included rather than the four-year age span. Thus, for purposes of estimating all prevalence rates except lifetime prevalence, the four-year and six-year intervals are nearly interchangeable.

On the positive side, controlling the age band may be desirable for trend estimation purposes, because it controls for the possibility that the age composition of college students changes much with time. Otherwise, college students characterized in one year might represent a non-comparable segment of the population when compared to college students surveyed in another year.

College students are defined here as those follow-up respondents one to four years past high school who say they were registered as full-time students in a two- or four-year college at the beginning of March in the year in question. Thus, the definition encompasses only those who are one to four years past high school and are active full-time undergraduate college students in the year in question. It excludes those who previously may have been college students or may have completed college.

<sup>&</sup>lt;sup>19</sup>U.S. Bureau of the Census. (Telephone communication, unpublished data: 1997).

Prevalence rates for college students and their same-age peers are provided in Tables 18 to 22. Having statistics for both groups makes it possible to see whether college students are above or below their age peers in terms of their usage rates. The college-enrolled sample now constitutes half (50%) of the entire follow-up sample one to four years past high school. Note that any difference between the two groups likely would be enlarged if data from the missing high school dropout segment were available for inclusion as part of the noncollege segment; therefore, any differences observed here are only an indication of the direction and relative size of differences between the college and the entire noncollege-enrolled populations, not an absolute estimate of them.

#### PREVALENCE OF DRUG USE: COLLEGE STUDENTS VS. THOSE NOT IN COLLEGE

For many drugs, lifetime use among college students now tends to be lower than among their age-peers, but the degree of difference varies considerably by drug as Table 18 shows. However, there are very few differences between them on annual or thirty-day prevalence rates (Tables 19 and 20).

- There is little difference between those enrolled in college vs. their fellow high school graduates who are one to four years past high school in annual prevalence of an overall index of *any illicit drug use* (college students at 33.5%, others at 34.0%), and college students are only slightly lower in their annual prevalence of *any illicit drug other than marijuana* (16% vs. 18%).
- Annual marijuana use is actually slightly higher among college students than among their fellow high school graduates of the same age (31% vs. 29%). However, their rate of current daily marijuana use is lower (3.7% vs. 4.5%). (See Table 21 for the prevalence of current daily use.)
- *Stimulants* show the largest absolute difference in annual prevalence among the illicit drugs, 5.4% for college students vs. 7.5% for those not in college.
- The next largest absolute difference after stimulants occurs for *barbiturates*, with 2.0% of the college students vs. 4.0% of the others reporting use in the past year.
- *Tranquilizers* were used by fewer college students (2.9% annual prevalence) than 19-22 year olds not in college full-time (4.4%) in 1995.
- Annual use of *ice* is also lower among college students than among their noncollege age peers, at 1.1% vs. 2.2%, respectively.
- In 1995, use of *heroin* in the past year among college students is half that among those respondents not in college (0.3% vs. 0.7%).
- College students are slightly below their noncollege age peers in annual usage rates for *cocaine* (3.6% vs. 4.5%), and *crack* (1.1% vs. 1.5%).

- Usage rates for *inhalants* and *MDMA* (ecstasy) are slightly higher among college students than among the noncollege group. (See Table 19.)
- Usage rates for *hallucinogens*, *LSD* specifically, and *opiates other than heroin* all are nearly identical for the two groups.
- In 1995, college students and their age peers have equal prevalence rates for lifetime use of *alcohol* (88%-89%). However, college students report slightly higher rates of annual use (83% vs. 81%) and monthly use (68% vs. 62%). The most important difference lies in the prevalence of *occasions of heavy drinking* (five or more drinks in a row in the past two weeks), which is 39% among college students vs. 31% among their age peers. (As noted in the next section, this difference appears primarily because heavy drinking is relatively low among noncollege females.) In sum, college students participate in more of what is probably heavy weekend drinking, but they have a slightly lower rate of daily drinking (3.0%) than their peers (3.4%).
- By far the largest absolute difference between college students and others their age occurs for *cigarette smoking*. For example, their prevalence of daily smoking is only 16% vs. 30% for high school graduates the same age who are currently not full-time college students. Smoking at the rate of half-pack a day stands at 10% vs. 23% for these two groups, respectively. Recall that the high school senior data show the college-bound to have much lower smoking rates in high school than the noncollege-bound: thus, these substantial differences observed at college age actually preceded college attendance.<sup>20</sup>

#### SEX DIFFERENCES IN PREVALENCE AMONG COLLEGE STUDENTS

Tabular data are provided separately for male and female college students, and their same age-peers, in Tables 18 to 22.

- Most of the sex differences among college students replicate those discussed earlier for all young adults one to fourteen years past high school, which in turn replicated sex differences among secondary school students for the most part. That means that among college students, males have higher annual prevalence rates for most of the illicit drugs. The absolute differences for use of any illicit drug are 36.1% vs. 31.7%, for any illicit drug other than marijuana, 19.5% vs. 13.3%, and for marijuana (34.1% vs. 29.0%). Large gender differences occur for hallucinogens (11.9% for males vs. 5.5% for females), and LSD specifically (9.7% vs. 4.9%).
- **Daily marijuana use** is higher among male college students (4.6%) than among females (3.0%).

Bachman, J.G., Wadsworth, K.N., O'Malley, P.M., Johnston, L.D., & Schulenberg, J. (1997). Smoking, drinking, and drug use in young adulthood: The impacts of new freedoms and new responsibilities. Mahwah, NJ: Lawrence Erlbaum Associates.

• The annual prevalence rate for *alcohol* is only slightly higher for male than for female college students (85% vs. 82%), but the 30-day rate is somewhat higher (71% vs. 65%). Males are much higher on *daily drinking* (5.0% vs. 1.5%), and *occasional heavy drinking* (47% vs. 33%).

Male college students also have higher rates of *occasional heavy drinking* (47%) than their male counterparts who are not in college (42%). This difference occurs also for females (33% and 22%, respectively).

• One substance-using behavior that in the past reflected a gender difference among college students different from that observed in the sample of all young adults is *cigarette smoking*. While the noncollege segment of this age group generally has shown a slightly higher rate of smoking among males than among females (e.g., in 1995, 24% of noncollege males smoked a half-pack or more per day compared to 23% of noncollege women), in the past, college women were as likely to be current smokers as college men. This year, however, males have higher rates of monthly prevalence (28.7% vs. 25.4%), slightly higher rates of daily use (16.7% vs. 15.2%), and higher rates of smoking a half-a-pack or more per day (11.7% vs. 9.1%).

NOTE: 'NA' indicates data not available.

<sup>&</sup>lt;sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

bThis drug was asked about in five of the six questionnaire forms. Total N in 1995 for college students is approximately 1210.

<sup>&</sup>lt;sup>c</sup>This drug was asked about in two of the six questionnaire forms. Total N in 1995 for college students is approximately 485.

dOnly drug use which was not under a doctor's orders is included here.

<sup>&</sup>lt;sup>e</sup>Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants.

<sup>&</sup>lt;sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates or tranquilizers not under a doctor's orders.

#### Chapter 9

#### TRENDS IN DRUG USE AMONG COLLEGE STUDENTS

Beginning in the mid-1960s, illicit drug use increased dramatically among American college students, then spread quickly to their noncollege-age peers, and eventually down the age spectrum to high school students, and even to middle school students. College students were thus the leading edge of social change in illicit drug use. As we shall see in this chapter, that role at the present time seems to have shifted to secondary school students.

We continue to use the same definition of college students: high school graduates one to four years past high school who are enrolled full time in a two-year or four-year college at the beginning of March in the year in question. For comparison purposes trend data are provided on the remaining follow-up respondents who are also one to four years past high school. (See Figures 35 through 48.) Because the rate of college enrollment declines steadily with number of years beyond high school, the comparison group is slightly older on the average than the college-enrolled group.

The reader is reminded that the difference between the enrolled and other group shows the degree to which college students are above or below average for other high school *graduates* in this age band. Were we able to include the high school dropout segment in the "other" calculation, many differences with the college-enrolled likely would be accentuated.

For each year there are approximately 1,100-1,500 weighted respondents constituting the college student sample (see Table 27 for N's per year) and roughly 1,500-1,700 respondents constituting the "other" group one to four years past high school. Comparisons of the trends for these two groups are given below. Because it was not until 1980 that enough follow-up years had accrued to characterize young people one to four years past high school, the comparisons begin with that year.

#### TRENDS IN PREVALENCE 1980-1995: COLLEGE STUDENTS VS. THOSE NOT IN COLLEGE

• The proportion of college students using **any illicit drug** in the twelve months prior to the survey (i.e., the annual prevalence rate) dropped fairly steadily between 1980 to 1991 (from 56% to 29%). (See Table 24.) In other words, illicit drug use fell by nearly half over the 11-year period 1980-1991. Since 1991, there has been a slight increase (to 31% by 1994) which accelerated a bit in 1995, with annual prevalence reaching 34%. The rise among high school seniors has been distinctly sharper, as Figure 35 illustrates.

Source: The Monitoring the Future Study, the University of Michigan.

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding. 'NA' indicates data not available.

This drug was asked about in four of the five questionnaire forms in 1980-89, and in five of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is 1210. <sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (until 1990), or tranquilizers not under a doctor's orders.

<sup>1</sup>This drug was asked about in two of the five questionnaire forms in 1989, and in two of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is 480. Phis drug was asked about in two of the five questionnaire forms in 1987-89, and in all six questionnaire forms in 1990-1995.

Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants. <sup>2</sup>Only drug use which was not under a doctor's orders is included here.

This drug was asked about in two of the six questionnaire forms. Total N in 1995 (for college students) is 480.

resulted in rather little change in reported prevalence in the surveys of high school graduates, the data for all forms are used in order to provide the most reliable estimate of change. In 1993 and 1994, the question text was changed slightly in three of the questionnaire forms to indicate that a "drink" meant "more than just a few sips." Because this revision

# Trends in Annual Prevalence of Various Types of Drugs Among College Students 1-4 Years Beyond High School

Source: The Monitoring the Future Study, the University of Michigan.

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding. \*\* indicates a percentage of less than 0.05%. 'NA' indicates data not available.

aUse of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (until 1990), or tranquilizers not under a doctor's orders.

This drug was asked about in four of the five questionnaire forms in 1980-89, and in five of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is 1210. This drug was asked about in two of the five questionnaire forms in 1989, and in two of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is 480. This drug was asked about in one of the five questionnaire forms in 1986, two of the five questionnaire forms in 1987-89, and in all six questionnaire forms in 1990-1995.

Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants. Only drug use which was not under a doctor's orders is included here.

This drug was asked about in two of the six questionnaire forms. Total N in 1995 (for college students) is 480.

resulted in rather little change in reported prevalence in the surveys of high school graduates, the data for all forms are used in order to provide the most reliable estimate of change. In 1993 and 1994, the question text was changed slightly in three of the questionnaire forms to indicate that a "drink" meant "more than just a few sips." Because this revision

## Trends in Thirty-Day Prevalence of Various Types of Drugs Among College Students 1-4 Years Beyond High School (Entries are percentages)

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding. '\*' indicates a percentage of less than 0.05%. 'NA' indicates data not available. aUse of "any illicit drug" includes any use of manjuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, methaqualone (until 1990), or tranquilizers not under a doctor's orders.

Phis drug was asked about in four of the five questionnaire forms in 1980-89, and in five of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is <sup>o</sup>This drug was asked about in two of the five questionnaire forms in 1987-89, and in all six questionnaire forms in 1990-1995. 1210.

This drug was asked about in two of the five questionnaire forms in 1989, and in two of the six questionnaire forms in 1990-1995. Total N in 1995 (for college students) is 480.

Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants. <sup>e</sup>Only drug use which was not under a doctor's orders is included here.

This drug was asked about in two of the six questionnaire forms. Total N in 1995 (for college students) is 480.

resulted in rather little change in reported prevalence in the surveys of high school graduates, the data for all forms are used in order to provide the most reliable estimate of change. hin 1993 and 1994, the question text was changed slightly in three of the questionnaire forms to indicate that a "drink" meant "more than just a few sips." Because this revision

Source: The Monitoring the Future Study, the University of Michigan.

NOTES: For all drugs not included here (but in tables 23-25), thirty-day prevalence of daily use is below 0.05% in all years. Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

<sup>&#</sup>x27;\*' indicates a percentage of less than 0.05%.

<sup>&#</sup>x27;NA' indicates data not available.

Aonly drug use which was not under a doctor's orders is included here.

<sup>&</sup>lt;sup>b</sup>Based on the data from the revised question, which attempts to exclude the inappropriate reporting of non-prescription stimulants.

Cln 1993 and 1994, the question text was changed slightly in three of the questionnaire forms to indicate that a "drink" meant "more than just a few sips." Because this revision resulted in rather little change in reported prevalence in the surveys of high school graduates, the data for all forms are used in order to provide the most reliable estimate of change

TABLE 27
Trends in Lifetime, Annual, and Thirty-Day Prevalence of an Illicit Drug Use Index<sup>a</sup>
Among College Students 1-4 Years Beyond High School, by Sex

(Entries are percentages)

NOTES: Level of significance of difference between the two most recent years: s = .05, ss = .01, sss = .001. Any apparent inconsistency between the change estimate and the prevalence estimates for the two most recent years is due to rounding.

bRevised questions about stimulant use were introduced in 1982 to exclude more completely the inappropriate reporting of non-prescription stimulants. The data in italics are therefore not strictly comparable to the other data.

190

<sup>&</sup>lt;sup>a</sup>Use of "any illicit drug" includes any use of marijuana, hallucinogens, cocaine, or heroin, or any use of other opiates, stimulants, barbiturates, or tranquilizers not under a doctor's orders.

- O Use of any illicit drugs other than marijuana declined fairly steadily among college students between 1980 and 1994, with annual prevalence dropping gradually from 32% to 12% (Table 24). This generally paralleled the trend for the noncollege group, but not the trend for high school seniors, whose use began to rise after 1992 (Figure 36). Not until 1995 did an upturn among college students appear—no doubt reflecting the replacement of the college student population with more recent, heavier-using classes of high school seniors. This statistic jumped from 12.2% in 1994 to 15.9% in 1995.
- In general, for *most individual classes of illicit drugs*, the trends during the 1980s, among those enrolled in college tended to parallel those for the noncollege group, as well as the trends observed among seniors. That is, for most drugs there was a decline in use until 1991. In 1992, a number of drugs leveled, and possibly increased in use, among college students. (There was no significant one-year change in annual use of illicit drugs among college students between 1992 and 1995.) Again, noncollege respondents' use generally paralleled that of their college-aged peers. However, among high school seniors the use of most drugs began to increase after 1992 (and among 8th graders after 1991). This divergence in the 1990s was most sharp in the case of *marijuana* use (see Figure 37a).
- The annual prevalence of *marijuana* use among college students decreased steadily from 1981 through 1991, dropping by nearly half from 51% to 26.5%. Their noncollege peers showed a comparable decline over the same time interval (Figure 37a). Since 1991 annual prevalence has increased by nearly five percentage points among college students and by less than three percentage points among other young adults.
- Daily marijuana use among college students (Figure 37b) fell significantly between 1980 and 1986, from 7.2% to 2.1%, as it did for those not in college and among high school seniors. (The latter two groups showed sharper declines because they started higher than the college students in 1980.) After 1986 the decline decelerated and after 1990 it ceased. The rate stood at 1.8% in 1994, the same rate as in 1991. In sum, the proportion of American college students who actively smoked marijuana on a daily basis dropped by about three-fourths between 1980 and 1991, before leveling for several years. The other two groups showed significant increases after 1993 and a sharp rise began among college students after 1994.
- An appreciable and ongoing decline occurred for *stimulant* use between 1980 and 1991 (Figure 44). Annual prevalence dropped by more than eight-tenths, from 21% in 1982 to 4% in 1991. Proportionately this was a larger drop than among high school seniors, but fairly parallel to the overall change among age-peers not in college. Use among college students and their noncollege-age peers leveled for a year before beginning to increase in both groups after 1992 and 1993, respectively. Over the years, those not in college have consistently reported a higher rate of stimulant use than the college students, and since the mid-1980s high school seniors have reported higher rates still.

- During the early 1980s, one of the largest proportional declines observed among college students was for LSD. Annual prevalence fell from 6.3% in 1982 to 2.2% in 1985. Since 1985, use has increased, reaching 5.7% in 1992, before falling (nonsignificantly) to 5.1% in 1993, and leveling at 5.2% in 1994. Annual prevalence then rose to 6.9% in 1995. Similar trends have been observed in those young adults not in college (Figure 40), and among high school seniors, when use in both groups increased between 1985 and 1995. Use among noncollege young adults increased from 4.1% to 6.8%, and use among high school seniors increased from 4.4% to 8.4%.
- Barbiturate use already was quite low among college students in 1980 (at 2.9% annual prevalence) but it fell by more than half to 1.3% by 1985. This proportional decline was, once again, sharper than among high school students, and less sharp than among the young adults not in college. Annual prevalence remained essentially unchanged between 1985 and 1993 among all three groups (see Figure 45). All three groups also have shown some increase in use since 1993 (or 1994 in the case of the college students).
- Figure 46 shows that the annual prevalence of *tranquilizer* use among college students dropped by half in the period 1980-1984, from 6.9% to 3.5%, remained fairly level until 1988, when it declined again (to 3.1%).<sup>21</sup> It was down to 1.8% by 1994, after a slow uneven decline. Use in the noncollege segment dropped more sharply, leaving very small subgroup differences. Tranquilizer use also dropped steadily among seniors, from 10.8% in 1977 to 2.8% in 1992, before rising to 4.4% by 1995. In 1995, use among both college students and their noncollege-age peers began to rise.
- In 1994, the use of *opiates other than heroin* by college students was about half what it was in 1980 (2.4% in 1994 vs. 5.1% in 1980) as a result of gradual decline over the interval. This trend closely parallels use among noncollege young adults and high school seniors (Figure 43). As with a number of other drugs, use among seniors began to rise after 1992, but use among college students did not begin to increase until after 1994.
- Like the high school seniors, college students showed a relatively stable pattern of *cocaine* use between 1980 and 1986, followed by a substantial decline in annual prevalence from 17% in 1986 to 2% in 1994—a drop of nearly nine-tenths (Figure 42). Their noncollege counterparts also showed a large decline from 19% in 1986 to 5.1% in 1994. Use among college students has dropped more sharply than among high school seniors, with the result that, since 1990, there has been little or no difference between high school seniors and college students in annual prevalence rates for cocaine. Cocaine does show a continuing decline in 1994 among college students, but not in the other two groups. Between 1994 and 1995 annual cocaine prevalence for college students increased significantly, from a 14-year low of 2.0% in 1994 to 3.6% in 1995.

<sup>&</sup>lt;sup>21</sup>The use of barbiturates and tranquilizers very likely was dropping also during the latter half of the 1970s, judging by the trends among high school seniors.

o It is in regard to alcohol use that college students appear to be showing some shifts in use which are different from those observed either among their age peers not in college or among high school seniors. The noncollege segment and the seniors have shown fairly substantial declines since 1981 in the prevalence of having five or more drinks in a row during the two weeks prior to the survey. College students, however, have shown less decline (Figure 47c). Between 1981 (when all three populations were very close in use) and 1992, this measure of heavy drinking dropped by 14 percentage points for high school seniors, by 11 percentage points for the noncollege 19 to 22 year olds, but by only 2 percentage points among college students. Since 1992 there has been no further divergence between college students and the other two groups. In fact, since 1993, binge drinking has risen a few percent among high school seniors and fallen a few percent among college students and their noncollege-age peers.

It is interesting to conjecture about why college students did not show much decline in heavy drinking while their noncollege peers and high school seniors did. One possibility is that campuses provided some insulation to the effects of changes in the drinking age laws. Also, in college, individuals who are under the legal drinking age are mixed in with peers who are of legal age to purchase alcohol in a way that is no longer true in high schools and less true, perhaps, for those 19 to 22 who are not in college. Finally, a lot of alcohol advertising is directed at the college student population.

On the other hand, college students generally have had slightly lower rates of daily drinking than their age group taken as a whole, though by the early 1990s such differences nearly disappeared (Figure 47b). Daily drinking among the young adults not enrolled in college declined from 8.7% in 1981 to 6.5% in 1984, remained essentially unchanged through 1988, and since then has declined further (to 3.4% in 1995). The daily drinking estimates for college students—which appear a little less stable, perhaps due to smaller sample sizes in the 1980s—showed little or no decline between 1980 and 1984, but some considerable decline since then. Daily prevalence was 6.5% in 1980 and 6.6% in 1984, before declining to 3.0% by 1995; less than half the level first observed in 1980. High school seniors also showed a large decline in daily drinking, but showed a reversal in 1995.

Cigarette smoking among American college students declined modestly in the first half of the 1980s. Thirty-day prevalence fell from 26% to 22% between 1980 and 1985, remained fairly stable through 1990, then increased to 27% in 1995. The daily smoking rate fell from 18.3% in 1980 to 12.7% in 1986 as the cohorts who had lower initiation rates by senior year replaced the earlier, heavier smoking cohorts. It remained fairly level through 1990 (12.1%), then rose to 15.8% in 1995.

While the rates of smoking are dramatically lower among college students than among those not in college, their trends were quite parallel up to 1986, after which smoking rates stabilized among college students and continued to decline among young adults not in college (Figure 48a). Both groups have shown an

increase in their smoking rates in more recent years. (Recall that smoking among seniors began to increase after 1992.)

- In sum, the trends in substance use among American college students have generally paralleled quite closely those occurring among their age group as a whole. One important exception occurred for occasions of *heavy drinking*, which fell off among those not enrolled full-time in college (as well as among high school seniors) but remained fairly constant among college students.
- For many drugs (stimulants, barbiturates, tranquilizers, LSD, and daily marijuana use) differences between college students and their noncollege age peers narrowed over the years. Much of this is due to overall declines in usage rates generally, but some may also reflect the increasing proportion of the age group going to college.<sup>22</sup>

The overall drug use trends among college students are also parallel, for the most part, to the trends among high school seniors, although declines in many drugs over the decade of 1980 to 1990 were proportionately larger among college students, and for that matter among all young adults of college age, than among high school seniors. Despite parallel trends to the early 1990s, the high school seniors have shown a larger, and often earlier increase in the use of a number of drugs in the years since; and as indicated in Volume I, the eighth and tenth graders in secondary school showed increases a year earlier than the seniors. It is clear that this most recent upsurge or "relapse phase" in the illicit drug epidemic did not originate on the nation's campuses, as did the original epidemic. It originated among secondary school children, and young ones at that.

#### SEX DIFFERENCES IN TRENDS AMONG COLLEGE STUDENTS

One trend which is not obvious from the figures included here is the fact that the proportion of college students who are female has been rising slowly. Females constituted 50% of our 1980 sample of college students and 58% of our 1995 sample. Given that substantial sex differences exist in the use of some drugs, we have been concerned that apparent long-term trends in the levels of drug use among college students might actually be attributable to changes in the sex composition of that population. For that reason, in particular, we have consistently presented separate trend lines for the male and female segments of the college student population. Differences in the trends observed for these two groups are illustrated in the lower panels of Figures 35 through 48, and are discussed below.

In general, trends in the use of the various drugs, and in the overall drug use indexes, have been highly parallel for male and female college students, as an examination of the relevant figures will show. The most noteworthy exceptions are mentioned below.

<sup>&</sup>lt;sup>22</sup>The proportion of respondents one to four years past high school who report being enrolled full-time in a two- or four-year college rose from 38% in 1980 to 50% in 1992, where it has remained since.

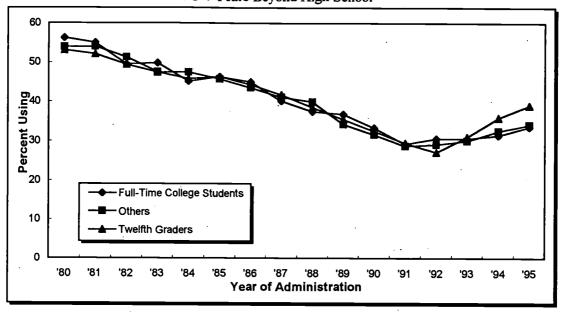

- Certain drug use measures showed a convergence of usage levels between the sexes, mainly because they were converging toward zero. *Daily marijuana use* is one such example, with the decline among males between 1980 and 1986 narrowing the gap between the sexes. Since 1986 there has been no further narrowing, however. In 1995 the rates were 4.6% vs. 3.0% for male and female college students, respectively. (See Figure 37b.)
- After 1986, *cocaine* use dropped more steeply for males than for females in general, and among male *college students* in particular, narrowing the gap between the sexes considerably (see Figure 42). However, in 1995 there was a sharp increase among males, widening the gap between the sexes.
- In fact, the male college students in 1995 showed a sharp uptick in their use of a number of drugs, including *inhalants*, *hallucinogens*, *LSD* specifically, *other hallucinogens*, *cocaine*, and *opiates other than heroin*.
- Like a number of other drugs, *methaqualone* also showed a convergence in use through 1989, with males declining more (no figure given).
- Stimulant use (Figure 44) also showed some convergence in the early 1980s due to a greater decline among males. In fact, male and female college student use has been essentially equal for the past six years, though males showed some increase in use in 1993 and the resultant gap continues through 1995.
- The annual prevalence of *alcohol* use has been virtually identical for the two sexes throughout the period (Figure 47a), but males have consistently had higher rates of daily drinking and binge drinking (Figures 47b-c). Since 1989, *binge drinking* among college females decreased very slightly; heavy drinking among college males has fluctuated more, but appears to have declined some from a high point in 1986 (see Figure 47c).
- Between 1980 and 1992, the 30-day prevalence of *cigarette smoking* was consistently higher among females than males in college, despite decreases for both sexes during the first half of the decade and increases for both sexes from 1989 to 1993 (Figures 48a-c). However, between 1980 and 1989 the gap in 30-day prevalence narrowed, because use by female college students declined some, while use by male college students did not. Since 1989, the gap has remained quite small, but the sexes have reversed position, with males catching up to, and passing females, in their rate of smoking by 1995. (A similar reversal occurred among seniors a few years earlier.)
