Abstract

Non-phenolic oxidative coupling: The first total synthesis of the *C*-2 symmetric indole alkaloid *P*-(+)-dispegatine (**1**) is reported. A late-stage thallium(III)acetate mediated intermolecular oxidative coupling was employed to construct the C(9)-C(9') bond with complete regio- and stereocontrol. The exclusive formation of a single atropodiastereomer **12** in this critical step arises due to internal asymmetric induction, as planned. In addition, the first total synthesis of four other monomeric *sarpagine* indole alkaloids is described.

Keywords

atropodiastereomer; biaryls; indole alkaloids; oxidative coupling; thallium

The *Sarpagine-Macroline* group of indole alkaloids consists of more than 150 members and is an important class of natural products with diverse biological activity.^[1] A biogenetic link between the *Sarpagine* alkaloids and the *Ajmaline*-related alkaloids has been confirmed by Stöckigt et al.^[2] Common to these three classes of alkaloids, is the core cycloocta[b]-indole framework **I** (Figure 1A), which has recently been a subject of biology-oriented synthesis (BIOS) by Waldmann et al.,^[3] the analogues of which are promising targets for developing a novel class of potent and selective *Mycobacterium* protein tyrosine phosphatase B (MptpB) inhibitors against *Mycobacterium tuberculosis*.^[4] The 'S' configuration at C(6) and C(10) and the β -ketoester moiety were key to the inhibitory activity.

Bisphenolic, bisquaternary indole alkaloids are very rare.^[5] Of the 300 or so dimeric indole alkaloids isolated to date, the *sarpagine* alkaloid dispegatrine **1**^[6] (Figure 1B) and blumeanine^[7] are the only two dimeric indoles belonging to this class. (+)-Dispegatrine (**1**) and the monomer (+)-spegatrine (**2**) were isolated from the roots of *Rauwolfia verticillata* (Lour.) Baill var. *hainanensis* Tsiang by Yu et al.^[6] Both **1** and **2** are known to exhibit antihypertensive activity with the affinity of the dimer **1** on both the α 1- and α 2-adrenoreceptors about an order of magnitude greater than that of the monomer **2**.^[8] While the structure of dispegatrine (**1**) was assigned during isolation, the apparent axial chirality at the C(9)-C(9') biaryl axis was not determined. Although the authors attempted a semisynthesis of **1** via an oxidative phenolic coupling of **2** (Scheme 1A), the yield of the process was very low (0.25%).^[6] A number of synthetically related monomeric alkaloids such as (+)-lochneram (**3**), (+)-10-methoxyvellosimine (**4**), (+)-lochnerine (**5**) and (+)-sarpagine (**6**) have also been reported (Figure 1B).^[1c] The complex architecture combined with the promising bioactivity of **1**,^[8] **2**,^[8] and **5**^[9] rendered them very attractive targets. Herein is described the first total synthesis of the *sarpagine* alkaloids **1**, **2** and **4–6** in a stereospecific manner.

Direct biaryl bond formation can be classified into two types: (a) the reductive metal-catalyzed coupling reaction (e.g Ullmann, Suzuki, Stille, etc.) and (b) the oxidative (phenolic/non-phenolic) coupling reaction.^[10] Although the regioselectivity of the reductive coupling processes is predetermined by the use of activated coupling partners (which may have to be synthesized separately), this could mean additional steps to the synthetic route. The direct oxidative (phenolic/non-phenolic) coupling of non-activated substrates on the other hand, is the most powerful and economical method for the synthesis of biaryls.^[10,11] The lack of preactivation, however, could affect the regioselectivity of the process, especially in the intermolecular mode. For example, the presence of more than one reactive site in the phenolic substrate could lead to a mixture of products (via *ortho*- and *para*-coupling) and subsequent overoxidation to quinones either from the coupled product or the original substrate could lower the yield of the process. Atropselectivity in both cases is most commonly achieved by employing chiral catalysts^[10–12] or in a few cases by taking advantage of the existing chiral centers in the substrate^[13] and/or by double diastereodifferentiation^[14]

The formation of the biaryl bond in a large number of bisphenolic biaryl natural products is assumed and in some cases proven to be a result of an oxidative phenolic coupling.^[15] The existence of **1** as a single atropodiastereomer both in nature and during semisynthesis, suggests the simultaneous formation of the biaryl bond with internal asymmetric induction by the *sarpagine* framework of the monomer **2**. We based the strategy on these reports. The retrosynthetic analysis of **1** is illustrated in Scheme 1B. A potentially biomimetic intermolecular biaryl coupling could be employed to construct the C(9)-C(9') bond in **1**. Since oxidative phenolic coupling of **2**,^[6] yielded only a trace amount of **1**, a non-phenolic Scholl-type oxidative coupling^[16] of the *sarpagine* alkaloid (+)-lochnerine (**5**) could be attempted to this end. We have been interested in the total synthesis of *sarpagine* indole alkaloids and a general route for the synthesis of related alkaloids via the asymmetric Pictet-Spengler reaction has been developed. Our strategy toward the synthesis of the monomers **2–6** and in turn **1** relied on this approach.^[1a]

Analogous to the previous work of Zhao et al., in the N_a -Me series,^[17] the 5-methoxy- N_a -H-D(+)-tryptophan ethyl ester **7** was converted to the key tetracyclic core **8** in six steps via the asymmetric Pictet-Spengler approach. Attempts to effect the key enolate mediated palladium catalyzed cyclization of **8** under the modified conditions [Pd₂(dba)₃/DPEphos/*t*-BuONa]^[18] furnished the pentacyclic ketone **9** in lower yields (50%), accompanied by acetylene byproduct (not shown). This problem was circumvented by subjecting the vinyl iodide **8** to

the much milder conditions of Bonjoch et al.^[19] which furnished the pentacyclic ketone **9** in 73% yield (Scheme 2). Wittig reaction of **9**, followed by a hydrolysis/epimerization sequence provided the more stable α -aldehyde in (+)-10-methoxyvellosimine (**4**). Reduction of the aldehyde **4** with NaBH₄/EtOH furnished (+)-lochnerine (**5**) in 90% yield. Demethylation of **5** with BBr₃/CH₂Cl₂ furnished the phenolic monomer (+)-sarpagine (**6**) in 80% yield. Subsequent quaternization of the N_b-nitrogen function in **6** at room temperature with excess methyl iodide provided the N_b-methiodide salt, which on stirring with silver chloride in ethanol^[20] furnished (+)-spiegatine chloride (**2**). The spectral data of synthetic **2** and **4–6** were in excellent agreement to that reported for the natural products and resulted in the first total synthesis of the alkaloids.^[1c]

Intermolecular non-phenolic oxidative dimerizations of complex aryl substrates are very rare.^[21] A majority of the documented examples constitute simpler aromatic systems or substrates with no competing reactive sites.^[10d, 22] In order to test the feasibility of such an intermolecular oxidative coupling on the electron-rich indole alkaloid (+)-lochnerine (**5**) [with two possible reactive sites, C(9) and C(11)], it was decided to first carry out a model reaction on a more robust substrate. The N_a-methyl beta-carboline **10**, synthesized earlier^[17] was employed for this purpose. In the absence of a chiral catalyst, such a model reaction could also provide an insight into the possible substrate-dependent atropselectivity of the process.

Of the various combinations documented,^[10d] the hypervalent iodine(III) mediated coupling conditions developed by Kita et al.^[22b, 23] and the thallium(III) mediated conditions of Taylor et al.^[22c, 24] seemed best suited to the substrates under study here. As illustrated in Scheme 3, β -carboline **10** when subjected to iodine(III) or thallium(III) mediated oxidative coupling afforded a mixture of the atropodiastereomers **11a** and **11b** with complete regioselectivity. In general, the hypervalent iodine mediated oxidations [phenyliodine(III)bis(trifluoroacetate) (PIFA) or phenyliodine diacetate (PIDA) at –78 °C to 0 °C] generated a number of highly colored baseline impurities. At best a combined yield of 30% (**11a** : **11b** = 4 : 1) was obtained with a combination of PIFA (0.8 equiv), BF₃·Et₂O (3 equiv) at –40 °C. However, with the thallium(III) salt [Tl(OCOCH₃)₃ or Tl(OCOCH₃)₃] as the oxidant, the reaction was much cleaner with very little baseline material. Upon optimization, the milder thallium(III) acetate (0.7 equiv), BF₃·Et₂O (3 equiv) at –40 °C provided a combined yield of 67% (b.r.s.m.), in favor of **11b**. Upon chromatographic separation, the lower R_f atropodiastereomer **11b** was recrystallized from EtOH. X-ray analysis determined the axial chirality of **11b** as P(S).^[25] Based on the results of the model reaction, oxidative dehydrodimerization of **5** was next attempted.

As illustrated in Scheme 4, a combination of thallium(III)acetate (0.65 equiv) and BF₃·Et₂O (3.0 equiv) in acetonitrile at –40 °C afforded the key C(9)-C(9') biaryl **12** as the sole atropodiastereomer in 60% yield (b.r.s.m) with complete regioselectivity in agreement with the retrosynthetic analysis. Formation of a small amount of the aryl-thallium byproduct **A** (8%) at C(9), is in accordance with the mechanistic studies by Kochi et al.^[26] The free indole N_a-H and the primary hydroxyl function at C(17) remained unaffected. Attempts to achieve complete conversion of the starting material **5** by increasing the equivalents of Tl(OCOCH₃)₃ led to increased formation of the arylthallium adduct (**A**) and baseline impurities. Column chromatographic purification of the dimer **12**, followed by recrystallization from methanol provided white crystals for X-ray analysis, which established the axial configuration as P(S).^[27] As anticipated, the rigid *sarpagine* framework and the existing stereogenic centers in **5** exerted complete atropselection in the key biaryl coupling step, thereby forming a single atropodiastereomer **12**. This would be in agreement with a potential biomimetic coupling in the plant since the other atropodiastereomer of **1** was not reported there or observed by us.

With the axial chirality established in the key intermediate **12**, the total synthesis of dispegatrine (**1**) was completed in two steps as illustrated in Scheme 4. The C(10)-C(10') methoxy groups were demethylated with 11 equiv of BBr₃/CH₂Cl₂ at -78 °C to furnish the bisphenol. N_b-quaternization of the highly polar bisphenol required heating of the reaction mixture in a sealed tube at 40 °C with a large excess of MeI to provide the methiodide salt. Further treatment with AgCl/MeOH at room temperature completed the total synthesis of *P*-dispegatrine (**1**). Spectral analysis (¹H NMR and HRMS) of the synthetic (+)-dispegatrine (**1**) were in good agreement with the literature values,^[6] except the proton chemical shifts for H-5,5'. In order to obtain better spectroscopic data, the bismethyl ether **13** was synthesized by carrying out the the N_b-quaternization of **12** with MeI/MeOH at rt or 40 °C. Analogous to blumeanine (isolated as its diacetate),^[7] chromatographic purification and isolation of the bisquaternary salt **13** proved to be much easier in comparison to (+)-dispegatrine (**1**). The 2D NMR correlation experiments (see Supporting Information) on the dimer **13** established the position of the H-3,3' and H-5,5' protons. In the absence of an authentic sample^[28] [for circular dichroism (CD) analysis or thin layer chromatography (TLC) comparison], it is impossible to unequivocally report that synthetic **1** is identical to the natural product even though the ¹H NMR is in good agreement.^[29] However the fact that the biomimetic coupling by Yu et al.^[6] gave only the natural isomer and our oxidative coupling gave the *P*-atropodiastereomer from similar scaffolds strongly suggests that they presumably are the same.

In summary, a general approach to the ring-A oxygenated N_a-H *sarpagine* indole alkaloids has led to the first asymmetric total synthesis of the dimeric indole alkaloid *P*-(+)-dispegatrine (**1**) as well as the monomers **2**, **4**–**6**. The synthesis is notable especially for execution of the direct oxidative dimerization of (+)-lochnerine (**5**), in the presence of the free indole N_a-H, highly basic N_b-nitrogen atom and the C(17) hydroxyl group. To the best of our knowledge, this is the first report of a direct intermolecular oxidative nonphenolic coupling of highly functionalized and sensitive substrates (**5** and **10**) and has expanded the scope of the thallium(III)-mediated oxidative coupling reaction in heteroaromatic biaryl synthesis. Additionally an indirect alternative to the less predictable phenolic coupling, especially in complex aryl substrates is presented. Further work to understand the mechanism of the key biaryl coupling reaction is in progress and will be reported in due course.
