Abstract Government size, corruption, and tax policy can influence allocation towards necessity or opportunity-driven entrepreneurship. Using a comparative multi-source sample across 52 countries during 2005–2015, we apply a mixed-process estimation of the simultaneously unrelated system of equations and unpack these heterogeneous and complex effects. Interestingly, our results show that the influence of tax policy and corruption on necessity and opportunity entrepreneurship depends on government size. Our results hold for numerous robustness analyses.

Plain English summary Institutions matter for the choice of opportunity and necessity-driven entrepreneurship. Government size, the level of corruption,

and tax policy directly affect entrepreneurs' motivation and incentives. We study 52 countries during 2005–2015 to find out to what extent tax rate, corruption, and a range of government expenditure change the allocation of necessity and opportunity entrepreneurship. Our main implications are for (1) Research: Formal and informal institutions need to be considered when studying entrepreneurship allocation, particularly in an emerging and developing country context. Results suggest that the impact of the same institutional settings and informal institutions such as corruption on necessity and opportunity entrepreneurship is not uniform in size and scope and have different magnitude. The effect of government expenditure on necessity and opportunity entrepreneurship is not ubiquitous. (2) Management: The broader institutional context affects allocation of entrepreneurship, and potential entrepreneurs can consider how corruption in particular can affect them. (3) Policy: Policymakers can measure the extent to which opportunity and necessity entrepreneurship are likely to change, when they make changes to tax policy, resources for public spending, and take anti-corruption measures.

1 Introduction

Many countries have seen an increase in government size and taxes (Mueller, 2004; Tanzi & Schuknecht, 2000). A robust stream of primarily economics research has examined the influence of government size on economic development and social welfare (see Alesina et al., 2004; Asimakopoulou & Karavias, 2016; Barro, 1990) and entrepreneurship (Nyström, 2008; Audretsch & Lehmann, 2017; Audretsch et al., 2006, 2019a, b). However, there is still a paucity of knowledge in identifying how these components interact with each other to influence different types of entrepreneurial activity (van der Zwan et al., 2016). A critical gap remains in the literature: how government size and institutional environment influence different types of entrepreneurship. To address this gap in the literature, we ask the following question: How do government size, tax policy, and corruption influence entrepreneurial allocation towards necessity or opportunity entrepreneurship?. This question is an in-depth look into how government, the regulatory environment of a country, and broader institutions can influence entrepreneurial climate. Additionally, the combination of policies and the institutional climate produces the pull and push factors as the two opposing forces that contribute to different types of entrepreneurial activity (opportunity and necessity entrepreneurship) in diverse institutional contexts (Audretsch et al., 2019a, b; Block et al., 2015; Block & Sandner, 2009; Nikolaev et al., 2018; Stenholm et al., 2013; van der Zwan et al., 2016; Welter et al., 2019).

Different types of entrepreneurial activities are essential to consider because the quality of entrepreneurship dictates the technological change, structural transformation, and economic development (Amorós et al., 2019; Belda & Cabrer-Borrás, 2018; van der Zwan et al., 2016). Compared to necessity entrepreneurship, opportunity entrepreneurship occurs when entrepreneurs have other work options but still decide to pursue entrepreneurship (Acs et al., 2008; Vivarelli, 2004, 2013). While entrepreneurship contributes to economic development and social welfare, not all entrepreneurship activity contributes equally. Therefore, determining the context that promotes desired entrepreneurial activity is essential (Baumol, 1990; Baumol & Strom, 2007; Fredström et al., 2020).

The overall economic environment and governmental policies play a crucial role and govern these opposing forces (Fairlie et al., 2011). Opportunity entrepreneurs

may spend less and delay investments during high taxation and recessions, while they are also more likely to start a business when tax policy and government size are more conducive; necessity entrepreneurs, on the other hand, are forced out of the labor force and into entrepreneurship because of adverse economic conditions (Shiller, 2017).

Government size is a critical component to consider because larger government may mean a greater capacity to provide services and fund public governance activities. These supports could encourage entrepreneurship activities by providing safety nets to offset risks, high-quality inputs related to labor, and efficient capital markets. Larger government could also mean more inadequate governance if it allows overreach or inefficiency (see Afonso et al., 2005; Hauner & Kyobe, 2010), which could discourage entrepreneurship activities by complicating the business environment and putting entrepreneurs at risk for predatory behavior by government agents.

Along with government size, tax policy directly affects entrepreneurs' incentives to enter the market (Friedman et al., 2000). Government is a core dimension of any country's regulatory setup, and taxes provide revenues for public spending. Taxes, government size, and corruption are important to consider together because government requires tax revenue to operate and maintain services, which corruption can affect (see Belitski et al., 2016; O'Higgins, 2006; Pandey, 2010).

We contribute to the existing literature on entrepreneurship and public policy by demonstrating that government size, corruption, and tax policy do not have predictably consistent effects on two types of entrepreneurship. To test this article's hypotheses, we use a panel of 52 countries from 2005 to 2015. The results suggest that the direction and magnitude of government size, corruption, and tax policy on different types of entrepreneurship depend on the form of entrepreneurship.

Second, we contribute to the literature on entrepreneurship and institutions by demonstrating that engagement in opportunity and necessity entrepreneurship is shaped by both the regulatory environment (tax), informal institutions (corruption), and government size. The study results suggest not all regulatory and institutional settings have a similar effect on entrepreneurship.

The remainder of the paper is structured as follows. In Section 2, we present the relevant literature and

develop our hypotheses on the direct and moderating effects of government size, tax policy, and corruption on entrepreneurship. In Section 3, we discuss our data, method, and identification strategy. We report results in Section 4, followed by discussing implications and next steps for scholars, entrepreneurs, and policymakers in Section 5.

2 Theoretical background and hypotheses

2.1 Government size and opportunity and necessity entrepreneurship

Government size can determine how, where, and what resources are allocated in an economy, and this resource allocation can influence entrepreneurship (Williamson, 2000), shaping protections (or lack of) for entrepreneurs (Aidis et al., 2012). Large government size could mean improved ability to provide services by the government and better inputs for entrepreneurs, such as skilled workers coming out of effective education systems (Audretsch et al., 2015) and social services/benefits that the government generally provides, like health and public schools, can boost human capital and quality of life (Berry & Lowery, 1987). Existing research suggests that human capital is associated with improved cognitive skills related to opportunity recognition and exploitation (Lofstrom, 2013).

Opportunity entrepreneurship requires access to established infrastructure such as the Internet, roads, and access to electricity (Audretsch et al., 2015), and government with resources can better develop these infrastructures than their counterpart. Well-developed infrastructures allow entrepreneurs access to information, mobility, and connectivity. A large government is also better able to invest in systems like land and property rights, and intellectual property protections that can be costly to set up by the individual entrepreneurs and divert necessary resources from the venture activity, yet these types of protections help opportunity entrepreneurs (Desai et al., 2013; Estrin et al., 2013).

Large governments can also offer social security and welfare programs that can mitigate risk and lower the opportunity cost of going into business instead of wage employment. Such programs could generate more security and encourage risk-taking. For example, if private health insurance is expensive, wage employment could

be more attractive (see Fairlie et al., 2011; Holtz-Eakin et al., 1996). Health insurance costs can be a constraint on entrepreneurs, depending on the health insurance system's reach and scope (Fossen & König, 2017). An expanded safety net could reduce the pressure for a person to generate income, encouraging risk-taking (Henrekson, 2005), particularly for welfare programs associated with monetary transfers (Heinemann, 2008). Therefore, we hypothesize that:

Hypothesis 1a(H1a): Larger government size has a positive effect on opportunity entrepreneurship.

Potential problems that could accompany larger government are discussed further, when we hypothesize on corruption. Here, we consider that if larger government means effective and efficient services and programs, it could also mean better quality of inputs, resources, and conditions for entrepreneurship. Government size can increase entrepreneurial activity by pushing individuals to undertake entrepreneurship. Many developed countries have unemployment insurance (UI) and active labor market programs (ALMP) to promote entrepreneurship by pushing unemployed individuals to undertake entrepreneurship (Agwu et al., 2017; Fadahunsi & Rosa, 2002; Laffineur et al., 2017). Unemployed individuals may be forced to undertake entrepreneurship since they do not have any other option. While the safety net provisions may serve the unemployed person's need for the short term, these programs will not support them for an extended period. The need for income generation over the longer term will push individuals to undertake necessity entrepreneurship.

Hypothesis 1b(H1b): Larger government size has a positive effect on necessity entrepreneurship.

2.2 Corruption and opportunity and necessity entrepreneurship

Corruption in the public sector is a de facto reality in many countries (Estrin et al., 2013; Rose-Ackerman, 1999, 2007). Corruption is commonly conceptualized as the use of public office for personal benefit (Mauro, 1995; Rose-Ackerman, 2007, 1999). On one hand, corruption could have a "greasing" effect for entrepreneurs by providing a way to circumvent cumbersome regulations by paying bribes (Méon & Weill, 2010); on the

other hand, it could have a “sanding” effect for those who cannot pay (Shleifer & Vishny, 2002) because new ventures may have limited resources (Choi & Thum, 2005; Tonoyan et al., 2010).

Opportunity entrepreneurs need financial resources for opportunity exploitation, and corruption can increase constraints on critically important resources (see Dreher & Gassebner, 2013). Besides, corruption imposes several types of costs on opportunity entrepreneurs beyond just the obvious financial cost. It can increase the business financial costs by charging additional unseen fees on top of what is already anticipated, and redirect funds away from productivity-enhancing investments by cutting into the total volume of funding available for the business. Corruption also creates costs in terms of non-financial resources, shifting the entrepreneur’s time to negotiating bribes and managing relationships with bureaucrats instead of engaging in value creation activity (see Tonoyan et al., 2010).

Opportunity entrepreneurs are likely to formally enter the marketplace through registration and obtaining required licenses to gain legitimacy. This legitimization process can help the opportunity entrepreneurs to get financial resources. However, corrupt government officials may use this as an exploitation opportunity by refusing to issue a permit or process a transaction without receiving a bribe (see Dreher & Gassebner, 2013). Even after obtaining the required permissions and licenses, opportunity entrepreneurs can be vulnerable to continued exploitation by corrupt public agents (see Dreher & Gassebner, 2013). Entrepreneurs may face consequences if they seek recourse and try to access protections offered by law. Bureaucrats can repeatedly exploit entrepreneurs, and each act of corruption further raises their vulnerability in a system where government agents make the laws and enforce them.

Another cost of corruption is indirect, resulting from diverted or lost public spending. These funds could be spent on education and training programs that improve the labor market, infrastructures like roads and ports, health services, and security. The diversion of funds may not have an immediate tangible effect on an entrepreneur, but this shapes and raises costs in the broader economic context in which the entrepreneur must operate. For example, corruption has been found to reduce government spending on education (Mauro, 1998); this underinvestment in training the labor market can raise costs for entrepreneurs who internalize the costs of

training or acquiring skilled labor, i.e., higher salaries because of fewer local hires or costs to recruit from abroad.

Hypothesis 2a (H2a): Corruption has a negative effect on opportunity entrepreneurship.

A corrupt government agent and an entrepreneur both participate in the corrupt transaction, and government agents have the upper hand because entrepreneurs rely on them to obtain licenses and permits (Pfeffer & Salancik, 1978). The relationship may be coercive if the entrepreneur has no other option but to engage with the bribe-seeking government agent. For necessity entrepreneurs, who might not be able to afford the registration and licensing fees or may not be willing to register, they may react to the corrupt environment by staying in the informal sector.

Corruption can raise uncertainty over time because the entrepreneur is unsure how many future transactions will require bribes or the number of future bribes. This uncertainty fundamentally affects how an individual entrepreneur can reliably plan for costs and calculate expected profits. Engagement in the entrepreneurial activity itself has significant uncertainty, and necessity entrepreneurs might avoid engaging with corrupt officials by remaining in the informal sector and by reducing the cost of formal payments and regulation. In the long run, it increases costs, vulnerability, and is a barrier to business growth. Also, it creates uncertainty and increases the opportunity costs of staying in necessity entrepreneurship. Thereby, we hypothesize that:

Hypothesis 2b (H2b): Corruption has a negative effect on necessity entrepreneurship.

2.3 Tax and opportunity and necessity entrepreneurship

A large body of literature has found mixed results related to the relationship between the tax rate and entrepreneurship. An overly simplified interpretation could be that paying taxes discourages entrepreneurs who seek to maximize profits. However, the relationship appears to be far more nuanced and complex because tax policy affects entrepreneurs beyond simply their profit margins.

Tax policy can affect entrepreneurs through three channels: income shifting, risk subsidy, and risk-

sharing (Cullen & Gordon, 2007). First, income shifting occurs when tax policy redistributes income from high-income individuals to low-income individuals. This income transfer could provide more capital to entrepreneurs with less access to financial resources or in low-income households to start a business. At the same time, this could relieve some of the pressures that push underresourced people to become necessity entrepreneurs, and mean that fewer people need to do so.

Tax policy could induce a risk subsidy effect by providing welfare services that might encourage potential entrepreneurs to take on more significant risks and forego immediate income because welfare programs could meet basic needs. Henrekson et al. (2010) argued that taxes could generate an insurance effect by offsetting total losses by serving as an insurance policy for the entrepreneur and reducing risk.

Tax policy can have a risk-sharing effect by alleviating some of the financial burdens on entrepreneurs and providing some fallback if the business fails. Domar and Musgrave (1944) described the tax system as a way for entrepreneurs to share risk under adverse conditions. If an entrepreneur can share the risk, this could encourage entrepreneurs to take on greater risk. This could mean that very successful businesses might offset costs of failure for other businesses; in this way, higher taxes could be seen by opportunity entrepreneurs as cutting deeply into their profits if they become very successful, lowering their returns to entrepreneurship, which could discourage them. Based on this discussion, we hypothesize:

Hypothesis 3a(H3a): Tax rate has a negative effect on opportunity entrepreneurship.

Hypothesis 3b(H3b): Tax rate has a negative effect on necessity entrepreneurship.

2.4 Tax, government size and opportunity entrepreneurship and necessity entrepreneurship

Taxes and government size are interrelated (Bergh & Henrekson, 2011). Scholars in the “spend-and-tax” school of thought suggest that higher taxes mean more spending (Goedhuys & Sleuwaegen, 2010; Tybout, 2000). Large government and high taxes could positively influence entrepreneurship by creating and providing the necessary services and public goods (Goedhuys & Sleuwaegen,

2010; Tybout, 2000). For example, infrastructure is an essential component for entrepreneurs to build a successful business and this resource may be more important for opportunity entrepreneurs than necessity entrepreneurs. A high quality of transportation and communication should make it easier for an individual to engage in opportunity entrepreneurship to grow and reach customers outside the region or the country..

The government can act as a “benevolent dictator” by helping to address market failure by providing public goods otherwise not provided by the private sector and aiming to maximize social welfare (Musgrave, 1959; Pigou, 1928). Public provision such as safety are necessary for an entrepreneur to be confident about investing in entrepreneurship activity. As these new ventures grow, tax revenue generated from successful entrepreneurs can be redistributed to support public works (Henrekson, 2005).

The government can also help with the supply side of opportunity-driven and growth-oriented entrepreneurs (Estrin et al., 2013) by creating programs that support entrepreneurial activity and redistributing tax income in a way to sponsor high-quality and society-oriented businesses (Cooper, 2003; Cumming et al., 2018; Lerner & Kegler, 2000). Many countries have funding programs that help generate high-growth entrepreneurial activity (Cooper, 2003; Lerner & Kegler, 2000). Therefore, although we expected higher taxes to discourage opportunity entrepreneurs directly, if a combination of larger government and taxes effectively produces conducive conditions where opportunity entrepreneurs have greater access to resources, we hypothesize:

Hypothesis 4a (H4): Government size and tax jointly increase opportunity entrepreneurship.

For necessity entrepreneurs, a high tax rate and a large government can create a complex governance mechanism that could reduce entrepreneurs’ incentives to register their businesses (Estrin et al., 2013) formally. In their study of 47 countries, Aidis et al. (2012) found that a larger government sector negatively influences entrepreneurial activity. Parker (2018) argued that a large government sector could discourage entrepreneurship by reducing its payoffs because of higher taxes and will be particularly difficult for necessity-driven entrepreneurs with the lack of resources. Entrepreneurs generally seek to maximize profit (Baumol, 1990), and taxes take away a portion of profits generated by their

efforts. A large government size also increases administrative expenditure requiring a larger budget. To support these increased expenses, in most cases, higher taxes are needed (Acemoglu, 2005). Therefore, government size and taxation can create a virtuous circle.

Necessity entrepreneurs may also enjoy the benefit of a big government, such as well-established infrastructures, subsidizing housing, and social security, which reduces the supply of necessity-driven entrepreneurs. Based on this, we hypothesize that:

Hypothesis 4b (H4): Government size and tax jointly decrease necessity entrepreneurship.

2.5 Corruption, government size and necessity and opportunity entrepreneurship

Government size can be related to whether there is an environment for corrupt behavior and rent-seeking by authorities (Belitski et al., 2016; Bruton et al., 2010). If larger government means more or more complex regulations to comply with, this could create the opportunity for corruption. Alesina and Angeletos (2005, p. 1241) argued that a big government could increase corruption since self-serving government agents can use regulations to extract rents from entrepreneurs (Djankov et al., 2002; Peltzman, 1976; Tullock, 1967).

As government size grows, it can crowd out private resources' efficient allocation (see Aidis et al., 2012) and redirect investing in the business, affecting both necessity and opportunity entrepreneurs. This can be accelerated by decentralization, which can emerge due to expanding government, giving public officials more opportunity to use discretion in implementing policies (Fisman & Gatti, 2002), especially at the local level. A key argument in favor of decentralization is that it allows for "closer" governance and responsiveness to local needs, there by increasing public officials' accountability. However, proximity to local populations, particularly in areas where political and economic power may be entrenched, could raise vulnerability to exploitation (see Fisman & Gatti, 2002). While decentralization can create additional administration layers that require greater engagement with the government (Fan et al., 2009), creating more opportunities to seek bribes from entrepreneurs (Chowdhury et al., 2019), opportunity entrepreneurs who are likely to have more

access to resources may try to gain advantages by paying the bribes.

Taxpayers in corrupt countries are likely to have lower trust that revenues will be used to provide quality public services. Trust in government can bolster tax morale and deter tax evasion (see Hammar et al., 2009; Torgler, 2003), encouraging compliance with tax requirements (see Scholz & Lubell, 1998), while mistrust reshapes incentives for entrepreneurship (Audretsch et al., 2021) and higher corruption redistributes government expenditure for corrupt needs and rent-seeking. When faced with high corruption and a low level of government trust, both potential necessity and opportunity entrepreneurs may be wary of exposure to rent-seeking.

Subsidy programs are another area where government officials can exercise discretion, and in corrupt countries, government expenditure and support may be directed in ways that provide little benefit for the community and region. Corruption can affect the allocation of resources and social programs targeting appropriate places (Blackburn & Forgues-Puccio, 2007), with both types of entrepreneurs losing from high corruption and larger government. Paying bribes could limit entrepreneur's growth and make them withdraw from the market, while high uncertainty and the tax burden could prevent new entry, including necessity-driven entrepreneurs. For the reasons discussed above, we thus consider that:

Hypothesis 5a(H5a): Large government and high corruption will reduce opportunity entrepreneurship.

Hypothesis 5b(H5b): Large government and high corruption will reduce necessity entrepreneurship.

3 Data and method

3.1 Data

We construct our sample by matching data from the following sources at the country level for 2005-2015: World Bank Group Entrepreneurship Snapshot (WBGES), World Development Indicators (WDI), Doing Business (DB) Database, Global Entrepreneurship Monitor (GEM) National Expert Survey and Adult Population survey, and the Worldwide Governance Indicators (WGI) and Internationally Monetary Fund.

The WBGES provides an internationally comparable indicator of new business registrations at the country level worldwide, based on business registrar information. The WDI is a compilation of comparable national statistics on a wide range of economic trends, including poverty and development. The DB Project tracks business regulations at the national and subnational levels, using several indicators to capture different regulatory dimensions. The GEM is a cross-national comparative data effort that uses general population surveys (Adult Population Survey) to measure the nature and level of entrepreneurial activity and expert-based surveys (National Expert Survey) to track the conditions in the environment for entrepreneurship. GEM data has been used extensively in the entrepreneurship literature to understand various phenomena related to entrepreneurship. The WGI report on governance indicators at the country level, based on a combination of the businesses, citizens, and expert survey respondents' views.

Our sample captures variance across both developed and developing countries for 2005–2015, and our final dataset covers 52 countries and comprises 272 observations. We use unbalanced panel data with missing values for several countries (see Appendix, Table 4 for details).

It is essential to acknowledge the heterogeneity that characterizes both the explanatory and dependent variables in our study, which we argue is a core to gaining a more accurate understanding of the nuances embedded in the relationships being tested (see Audretsch et al., 2019b).

3.2 Dependent variables

We use two measures for entrepreneurship. These measures are taken from GEM's Adult Population Survey: necessity entrepreneurship and opportunity entrepreneurship, which are calculated as a subset of total entrepreneurial activity (TEA), defined as the percentage of the population that is either a nascent entrepreneur actively involved in starting a new venture or an owner-manager of a new business less than 42 months old. *Necessity entrepreneurship* is measured as the percentage of total entrepreneurial activity that reported no other option for work. *Opportunity entrepreneurship* is measured as the percentage of total entrepreneurial activity driven by opportunity, reporting that the main driver for being involved in entrepreneurship is to be independent or increase (rather than maintain) income

(Reynolds et al., 2005). This distinction has allowed scholars to observe the impact of economic and socio-cultural factors on entrepreneurial motivation (Hechavarria & Reynolds, 2009).

3.3 Explanatory variables

We include various types of government expenditures (as a percentage of GDP) from the IMF Government Finance Statistics (GFS, 2021) to measure the link between government size and entrepreneurship types. Based on Estrin et al. (2013) and Aidis et al. (2012), we use a range of public expenditure measures, such as expenditure on public order and safety to GDP, expenditure on economic affairs to GDP, expenditure on housing and community amenities to GDP, expenditure on recreation, culture, and religion to GDP, education expenditure to GDP, and social security expenditure to GDP. We also include a measure of public administration expenditure in total government expenditure, which is predicted to negatively affect entrepreneurship (Bruton et al., 2010).

Corruption is taken from the WGI, reflecting the extent to which public power is exercised for private gain, including petty and grand forms of corruption and the capture of the state elites and private interests (Anokhin & Schulze, 2009). Country scores range from -2.5 (high corruption) to 2.5 (low corruption). We reversed the measure by multiplying by -1 so that 2.5 corresponds to high corruption, and -2.5 corresponds to low corruption.

Our measure for the tax rate is the percentage of taxes and mandatory contributions payable by businesses after deductions and exemptions in commercial profits (Djankov et al., 2010; Kaufmann et al., 2009; World Bank, 2004, 2007). Recent research suggests that the complexity of paying taxes, in addition to the tax rate, matters (Braunerhjelm et al., 2021; Djankov et al., 2010), so we also include tax time from the DB database, measured as the number of days needed to prepare and pay taxes (Belitski et al., 2016).

3.4 Control variables

Several control variables reflect vital trends that could affect entrepreneurship in our study. Economic development is an essential consideration for entrepreneurship (Parker, 2004) and is measured as GDP per capita (constant 2010 USD), taken from WDI. We use GDP

per capita to construct a binary variable “rich” that takes the value of one if a country’s GDP per capita is greater or equal to 25,000 USD (constant 2010 USD), zero otherwise. GDP per capita is highly correlated with corruption, while “rich” is not and could be included in the model. Human capital can take different forms and is a typical theoretical lens to study entrepreneurship (see Marvel et al., 2016); our measure for human capital is the percentage of the population enrolled in tertiary education, taken from WDI.

We account for information about private credit bureau, taken from DB, and measured as a private credit registry that gathers information about individuals and firms listed by a private credit bureau with information on their borrowing history from the past 5 years (a percentage of the population). The availability of credit is measured by domestic credit given to the private sector by the banks (% of GDP) was taken from WDI (Chowdhury et al., 2019).

We account for unemployment in a country because it can motivate some individuals to seek entrepreneurial activity (Wennekers et al., 2005) and can be useful to understand necessity and opportunity entrepreneurship outcomes. Unemployment was measured as the percentage of the labor force available for and seeking employment, but without employment, taken from WDI. We also account for labor force participation by including labor force participation, gathered from WDI, reflecting the percentage of the total population participating in the labor force.

We control for entrepreneurs’ perceptions of the environment in which they are embedded (Edelman & Yli-Renko, 2010). Therefore, we include government support for entrepreneurship, measured as the extent to which public policies support entrepreneurship collected from GEM. This variable is expected to have a positive effect on entrepreneurship activity.

Definitions and data sources for all variables in our study are provided in Table 1.

4 Empirical strategy

We first check correlations among our variables: Necessity and opportunity entrepreneurship are negatively correlated (-0.75). Government safety expenditure, expenditure on housing, and economic affairs are positively associated with necessity entrepreneurship, while

they are negatively associated with opportunity entrepreneurship (see Table 2).

Corruption is positively correlated with necessity entrepreneurship (0.68) and negatively with opportunity entrepreneurship (-0.60).

Our first concern was the covariance structure of the control variable matrix. We are unlikely to estimate partial effects without bias, as several variables included in the model are causally related; this is not a multicollinearity issue but an endogeneity issue. First, government size can be a function of the tax base’s size and government programs, including those serving businesses and the unemployed.

Second, corruption can be associated with entry regulation, taxes, licensing, and many other regulations (Belitski et al., 2016; Méon & Sekkat, 2005; Rose-Ackerman, 2007). Third, government expenditure could create more opportunities for corruption, such as through public procurement. Unobserved factors that affect government size could also affect corruption and taxes.

Because these variables are causally related to each other, the effects of interrelated variables are being mediated (moderated) by others, and they cannot be included together in the same regressions (Angrist & Pischke, 2008), this makes it difficult to assess the independent effect of any one of the variables. We control for this interdependency effect using an alternative modeling strategy by fitting four models jointly.

First, we combine four equations in a mixed-process model, incorporating both continuous responses (entrepreneurship type, government size) and ordinal responses (corruption). We modeled a simultaneous system of equations: first for necessity entrepreneurship, second for opportunity entrepreneurship, third for government size, and fourth for corruption. Second, the *cmp* framework in Stata 15 allows for the different observations to enter each equation in the model, with available observations being used to estimate each equation parameter.

Given the potential interdependence between the four equations, they should be estimated simultaneously. The FIML estimates produced by *cmp* estimation can handle this form of simultaneity (Baum et al., 2017). A maximum likelihood estimator of a seemingly unrelated equation (SUR) system (Zellner, 1962) can consistently estimate parameters in an essential subclass of mixed-process simultaneous systems: those are recursive and simultaneous (Roodman 2011). Government size is

Table 1 Variable descriptions, sources, and descriptive statistics

Variable	Description	Source	Mean	Std. dev.	Min	Max
Necessity entrepreneurship	Percentage of those involved in Total early-stage Entrepreneurial Activity (TEA) who claim they had no other options for work and just to maintain their income. TEA—the percentage of 18–64 population who are either a nascent entrepreneur or owner-manager of a new business.	GEM	22.44	12.31	4.00	61.00
Opportunity entrepreneurship	Percentage of those involved in TEA who claim to be driven by opportunity, and who indicate the main driver for being involved is being independent or increasing their income	GEM	51.10	13.19	10.00	82.00
Rich	Binary variable = 1 for countries with GDP per capita in 2010 USD constant prices greater or equal 25,000USD, zero otherwise	WDI	0.47	0.50	0.00	1.00
Private credit bureau	Private credit registry coverage: individuals and firms listed by a private credit bureau with information on their borrowing history from the past 5 years (% of population)	DB	12.66	21.22	0.00	100.00
Human capital	Total enrollment in tertiary education (ISCED 5 and 6), regardless of age, 5-year age group following on from secondary school leaving (% of total population)	WDI	55.70	19.77	4.00	97.97
Tax rate	The amount of taxes and mandatory contributions payable by businesses after accounting for allowable deductions and exemptions as a share of commercial profits.	DB	43.94	17.91	8.30	107.70
Corruption	Perceptions of the extent to which public power is exercised for private gain, including both petty and grand forms of corruption, as well as “capture” of the state by elites and private interests. The score ranges from – 2.5 to 2.5. We reversed the order by multiplying by – 1 (2.5 = most corrupt, – 2.5 = least corrupt).	WGI	– 0.67	1.01	– 2.55	1.09
Tax time	Time required to prepare and pay taxes (hours)	DB	289.50	333.40	12.00	2600.00
Credit	Domestic credit to private sector by banks (% GDP) refers to financial resources provided to the private sector by other depository corporations (deposit taking corporations except central banks).	WDI	82.40	53.33	10.10	312.15
Entry density	New business density (new firm registrations per 1000 people ages 15–64)	WBGES	4.06	4.46	0.04	28.12
Unemployment	Unemployment refers to the share of the labor force that is without work but available for and seeking employment (% of total labor force).	WDI	7.89	5.20	0.70	32.20
Government support	The extent to which public policies support entrepreneurship. (a) Entrepreneurship as a relevant economic issue and (b) taxes or regulations are either size-neutral or encourage new and SMEs (scale 1–5)	GEM	2.55	0.45	1.65	4.55
Labor force	Labor force participation rate, % of total population (modeled ILO estimate)	WDI	61.04	7.60	42.36	82.24
Government expenditure indicators						
Public services expenditure	Expenditure on general public services, % GDP	IMF	6.38	2.09	3.23	17.11
Safety expenditure	Expenditure on public order and safety, % GDP	IMF	1.72	0.46	0.82	3.70
Economic affair expenditure	Expenditure on economic affairs, % GDP	IMF	5.14	2.34	1.78	25.04
Housing expenditure	Expenditure on housing and community amenities, % GDP	IMF	0.88	0.68	-0.13	3.57
Culture expenditure	Expenditure on recreation, culture, and religion, % GDP	IMF	1.30	0.55	0.34	3.57
Education expenditure	Expenditure on education, % GDP	IMF	5.19	1.12	3.21	8.09
Social security expenditure	Expenditure on social protection, % GDP	IMF	15.70	4.34	4.58	24.84
Public administration share	Share of public administration expenditure in total government expenditure	IMF	14.09	3.50	7.96	24.65

likely to influence corruption and vice versa and is associated with several explanatory factors hypothesized to influence government size, corruption, and entrepreneurship. There is potentially a more efficient approach as it allows estimation of possible cross-equation correlations for each country between equations with entrepreneurship types as dependent variables and equations with the institutional environment as dependent variables. Besides, we controlled for the year and country-specific effects.

Given the panel structure of the data, the equation was estimated using the observations from the various datasets that could be matched by country and year. The entire sample includes 272 observations for 52 countries. We used the fixed-effects (FE) estimator as it concentrates on differences that, over time, characterize a country. This is why the FE estimator is also referred to as the “within” estimator. It explains to what extent a given country’s change in a variable of interest affects its entrepreneurship rates. Our estimates are “within” effect, allowing us to identify the factors that explain the differences between the countries in the panel and control for country-specific unobserved characteristics

over time. Thus, the FE estimates should provide a more exhaustive scenario of the drivers of entrepreneurship than random effect estimation, which follows a stronger assumption. The use of the FE estimator also resolves a simultaneity bias induced by unobservable factors and is preferred.

The model with country and time-fixed effects is as follows:

$$E_{i,t} = \beta_0 + \sum_{i=1}^n \beta_{11}x_{i,t-1} + \sum_{j=1}^n \beta_{12}z_{i,t-1} + \rho_{li} + \lambda_{lt} + u_{1(i,t-1)}$$

where $E_{i,t}$ is a necessity (opportunity) entrepreneurship in a country i at time t . We deal with panel data for each dependent and independent variable. $X_{i,t-1}$ is a vector of explanatory variables—the size of government (variety of government expenditures), corruption, and tax rate of country i at time t . $Z_{i,t-1}$ is a vector of control exogenous variables for a country i at time t . Moreover, we include two additional vectors of fixed country effects: ρ_i , controlling for unobserved heterogeneity of a country i over time t , and λ_t is a vector of time-fixed (entity invariant) effects over each period t across all

countries i . The error term is denoted by $u_{i,t-1}$ for a country i , at time t .

We lagged all explanatory and control variables by 1 year for robustness checks and to rule out possible endogeneity in all equations. There could be a time lag for tax policy, government spending, and corruption to affect and shape entrepreneurs' behavior. For example, a new tax rate could be passed in 1 year but enforced in the following year, or it could take several months for entrepreneurs to learn about new government programs. It is plausible to assume that regulatory changes and government expenditure will affect outcomes in the next financial year, as they cannot be immediately applied.

5 Results

The results of our fixed-effects panel data estimations are reported in Table 3. Results are grouped as follows: specifications 1–4 are for necessity entrepreneurship, and specifications 5–8 are for opportunity entrepreneurship.

In hypotheses 1a and 1b, we posited that government size and both types of entrepreneurship have a positive relationship. Our results do not support H1a that government size increases opportunity entrepreneurship; an increase in economic affairs expenditure by 1% to GDP reduces opportunity entrepreneurship by $(\beta = -0.77, p < 0.05)$. An increase in culture and recreation expenditure by the government reduces opportunity entrepreneurship by 8.79% $(\beta = -8.79, p < 0.01)$, while an increase in social security expenditure reduces opportunity entrepreneurship by 2.20% $(\beta = -2.20, p < 0.01)$. Interestingly, an increase of public administration share in total government expenditure reduces opportunity entrepreneurship by 1.51% $(\beta = -1.51, p < 0.001)$, which could be associated with a negative effect of bureaucratic government (Aidis et al., 2012; Estrin et al., 2013). With regard to hypothesis 1b, while we find that social security expenditure is positively associated with necessity entrepreneurship $(\beta = 1.55, p < 0.05)$, supporting H1b, we find that safety-related expenditure

reduces necessity entrepreneurship $(\beta = -12.50, p < 0.01)$.

We find strong support for H2a and H2b—corruption has a negative effect on both necessity $(\beta = -5.87, p < 0.05)$ (spec. 2, Table 3) and opportunity $(\beta = -10.49, p < 0.05)$ (spec. 6, Table 3). Given the confidence intervals' distribution, corruption's negative effect on opportunity entrepreneurship is twice as strong as on necessity entrepreneurship, demonstrating that opportunity entrepreneurship is worse affected by corruption.

In H3a and H3b, we posited that the tax rate has a negative impact on both necessity and opportunity entrepreneurship. We find support for both H3a and H3b: an increase of 1% in tax will reduce necessity entrepreneurship by 0.43% $(\beta = -0.43, p < 0.01)$ (spec. 2, Table 3) and opportunity by 0.45% $(\beta = -0.45, p < 0.01)$ (spec. 6, Table 3). The effect of the tax change on both types of entrepreneurs is very similar (see Braunerhjelm et al., 2021).

In H4a and H4b, we posited that an increase in government size and tax rate increases opportunity entrepreneurship and reduces necessity entrepreneurship, respectively. When we consider opportunity entrepreneurship (spec 7, Table 3), we note that only an increase in tax rate and public administration expenditure share adds to opportunity entrepreneurship $(\beta = 0.11, p < 0.01)$, while the effect of public administration expenditure share remains negative and statistically significant, partly supporting H4a. Other interaction coefficients in spec. 7 (Table 3) are insignificant, which means that an increase in tax rate and government size does not change opportunity entrepreneurship. We found a negative effect of housing government expenditure on necessity entrepreneurship $(\beta = -0.44, p < 0.01)$ (spec. 3, Table 3) supporting H4b. Other interactions remain insignificant (spec.3, Table 3).

Finally, we found that an increase in social security expenditure in countries with high corruption increases necessity $(\beta = 1.34, p < 0.05)$ (spec. 4, Table 3) entrepreneurship and reduces opportunity entrepreneurship $(\beta = -1.04, p < 0.05)$ (spec. 8, Table 3). An increase in government size related to economic affairs expenditure facilitates necessity entrepreneurship by 1.31%, which contrasts our

hypothesized relationship. Safety expenditure reduces necessity entrepreneurship ($\beta = -7.17$, $p < 0.01$) (spec. 4, Table 3) and increases opportunity entrepreneurship ($\beta = 18.39$, $p < 0.01$) (spec. 8, Table 3). The evidence for H5 is mixed and demonstrates that not all government expenditure has a ubiquitous effect on the type of entrepreneurship activity.

Overall, our findings illustrate the importance of considering the heterogeneity of entrepreneurship. We find mixed support for all our hypotheses.

The results for our control variables are as follows. Economic development proxied by “rich” is not associated with necessity and opportunity entrepreneurship, highlighting that both types of

entrepreneurs can exist in countries with different levels of economic development. The private credit bureau is negatively associated with necessity entrepreneurship but positively with opportunity. A share of the population with tertiary education increases opportunity entrepreneurship and is not associated with necessity entrepreneurship. Government support has no direct effect on the type of entrepreneurship activity, while the effect changes when we control for interaction effects. We find that unemployment is negatively associated with opportunity entrepreneurship (spec. 6, Table 3) and is not associated with necessity entrepreneurship (spec. 2, Table 3).

6 Discussion and conclusion

Entrepreneurship activity is vital for economic development, so policymakers and scholars are interested in determining components that positively influence these activities and understanding entrepreneurial motivation to enter the market. This paper has examined how tax policies, government size, and corruption influence necessity and opportunity entrepreneurship. We use a 2005–2015 country-level panel data matching five distinctive datasets for 52 countries and show that a high corruption and tax will negatively affect both types of entrepreneurs, while government size effect on necessity and opportunity is distinctive and conditional on different types of government expenditures. Our results suggest that different types of entrepreneurship require different types of policies. Not all kinds of entrepreneurship contribute equally to society or in the same way (Block & Sandner, 2009; Reynolds et al., 2005; Vivarelli, 2004; Vivarelli, 2013) and policy makers can consider how to support the type of entrepreneurship they want to prioritize. Our empirical approach enables us to provide detailed new insights. This approach is appropriate for research on the complex institutional environment when one-size-fits-all government expenditure is not enough (Levie & Autio, 2011).

Our results suggest that the impact of the same institutional settings (corruption) on necessity and opportunity entrepreneurship is not uniform (see Levie & Autio, 2011) as the size of the effect varies between types of government expenditure. Additionally, while corruption may not discourage a share of necessity entrepreneurs, the overall result remains negative. Entrepreneurs are constantly engaging in activities to help their ventures and in some cases may seek to leverage corruption to their advantage, but both the necessity and opportunity entrepreneurs are adversely affected by corruption.

When it comes to the interaction effect of corruption and government size on opportunity and necessity entrepreneurship as the direction of the relationship depends on the type of government expenditure (i.e., safety, economic affairs, housing, education, social security, public administration). Our results indicate that investing in economic affairs and increasing social security can support necessity entrepreneurs, and safety

expenditure can support opportunity entrepreneurs. We are not able to test if there is a shift or transition between people who become necessity and opportunity entrepreneurship when government spending changes. Our study results also reveal that, in many cases, the effects of taxes and corruption in combination with heterogeneous government expenditure are not the same for opportunity and necessity entrepreneurship. For taxes and corruption, the effect depends on what government invests in and whether it targets to increase the supply of entrepreneurs or increase the demand for entrepreneurs. To increase entrepreneurial activity in a country, government plays an important role. However, government investment may have a different effect on necessity entrepreneurs and opportunity entrepreneurs, who may also leverage the government's services differently.

6.1 Study limitations and future research

While we included time lags in our model, there may be an endogeneity between government size, corruption, and entrepreneurship activity which in the future research may require instruments and longitudinal data with longer lags for robustness check. The GEM entrepreneurship-related measures also have their limitations, notably the entrepreneurship measures' low comparability between developed and developing countries (Reynolds et al., 2002). It should be noted that we controlled for time-invariant systematic measurement errors using country-level fixed-effects, which helps reduce concerns about these measurements.

We provide fresh empirical insights to the importance of considering heterogeneous institutions and heterogeneous entrepreneurship outcomes. We add to recent studies that found institutional conditions can play a role in shaping the nature and quality of entrepreneurship activity. Chowdhury et al. (2019) and Sutter et al. (2017), for instance, assert that regulation matters for net entrepreneurship productivity score, and it can play a role in shaping cognitive and informal economy dimensions. Future research can examine how policymakers can formulate policies to target specific types of entrepreneurship outcomes that are salient in their contexts, for example if they wanted to support more opportunity entrepreneurs.
