

## NEW CHRONOLOGICAL FRAME FOR THE YOUNG NEOLITHIC BADEN CULTURE IN CENTRAL EUROPE (4TH MILLENNIUM BC)

Eva Maria Wild<sup>1,2</sup> • Peter Stadler<sup>3,4</sup> • Mária Bondár<sup>5</sup> • Susanne Draxler<sup>1</sup> • Herwig Friesinger<sup>4</sup> • Walter Kutschera<sup>1</sup> • Alfred Priller<sup>1</sup> • Werner Rom<sup>1</sup> • Elisabeth Ruttikay<sup>3</sup> • Peter Steier<sup>1</sup>

**ABSTRACT.** The Baden Culture is a widely spread culture of the Young Neolithics in east-central Europe. In southeast Europe, several parallel cultures are found at different places. The main innovations in east-central Europe associated with the Baden Culture were traditionally thought to originate in southeast Europe, Anatolia, and the Levant. However, in recent years, doubt about this theory has arisen among archaeologists.

Here, we try to contribute to this question by increasing the radiocarbon data set available for the Baden Culture. Thirty-two age determinations of samples from different sites assigned to the Baden Culture were performed by accelerator mass spectrometry (AMS) <sup>14</sup>C dating. The new data were combined with previously published <sup>14</sup>C dates. Data from the individual cultural phases of the entire Baden period and the parallel cultures in southeast Europe (Sitagroi, Cernavoda, and Ezero) were analyzed by sum calibration. Comparison of the results indicates that the southeastern cultures cannot be synchronized with the Boleráz period, the early phase of the Baden Culture. It seems that these cultures were parallel to the Baden Classical period. This finding, which has to be verified by more data from the southeastern cultures, contradicts the theory of the east-west spreading of these cultures.

### INTRODUCTION

During the Young Neolithic period around 4250–2850 BC (according to the central European chronology) principal progress was made in various fields of cultural and economic life. In this period we find the first occurrence of wheeled vehicles, an enormous step forward in the cultural development and exchange systems. The importance of this innovation is documented by models of wagons made from ceramics found as grave goods. In central Europe, a change occurred in the species of domestic sheep to a bigger form of wool sheep that was probably raised in the Anatolian region. The decoration of ceramics originating from this period shows that typical characteristics and similar features are found in various sites throughout southeast Europe (Kalicz 1963; Němejcová-Pavúková 1981). Archaeologists had assumed that the origin of these cultural innovations was in southeast Europe, Anatolia, and the Levant. It was believed that they spread from there to east-central Europe. However, over the last few years, archaeologists have begun to doubt this theory (Breunig 1987; Maran 1998).

Using radiocarbon dating, we compared the time periods of some of the so-called parallel cultures in southeast Europe with the chronology of the Baden Culture in east-central Europe.

### The Baden Culture

The Baden Culture is a widely spread Young Neolithic culture in east-central Europe. It is named after the “Königshöhle” near Baden, Lower Austria, where the remains of this culture were discovered for the first time.

The Baden Culture is characterized by a typical design of pottery. As in the other Young Neolithic cultures, Baden people already used wheeled vehicles. Ceramic models of wagons were found in graves from the Baden period in Hungary (e.g. Foltiny 1959; Kalicz 1976). During the Baden period, the burial mode had been changed from cremation to burial of the body with funeral rites. The earliest signature of a trephination found so far in Austria was on a skull from the period of the Baden Culture (Heiling-Schmoll 1985).

### **Phases of the Baden Culture**

The Baden Culture is divided into two large phases. The earlier one is called *Baden-Boleráz* after the *locus typicus* near Trnava in Slovakia. Ceramics from this period typically have brown surfaces in different shades and are decorated with herring-bone patterns. The Baden-Boleráz phase is followed by the so-called *Baden-Classical* period. One of the main characteristics of ceramics from that period is mugs with dark surfaces and handles extending far above the rim.

Archaeological evidence shows that the two main stages were further divided into a number of consecutive phases of development (Baden Ia–c, IIa–b, III, IVa), which are characterized by, among other things, a specific design of the associated pottery (Němejcová-Pavúková 1998). The Boleráz group was thought to occur later than the Proto-Boleráz group of Šturovo (Baden Ia) in Slovakia (Kalicz 1991).

In the Boleráz period, three phases were differentiated (Baden Ib–Ic–IIa). The Baden Classical period was subdivided into three groups: Červený-Hradok (Slovakia, Baden IIb), Ossarn I (Baden III), and Ossarn II (Baden IVa), named after a site in Lower Austria (Ruttkay 1995).

### **Parallel Cultures**

In southeastern Europe, cultures with characteristics similar to those of the Baden Culture are found in Romania (Cernavoda III), Greece (Sitagroi IV and Vb), and Bulgaria (Ezeroi XIII–VII). At Tell Dipsis in *Ezero*, Bulgaria, 13 strata were identified, and the culture encompassing strata XIII–VII was synchronized with the Boleráz period by Němejcová-Pavúková (1981).

*Sitagroi*—also a tell settlement—is a key archaeological site in northern Greece. The archaeological layers of this site are associated with five cultural phases (Renfrew 1971, 1986; Alram-Stern 1996). Ceramics from phases IV and Vb show similarities to the pottery from the Baden Culture and the Late Baden Culture, respectively (Breunig 1987).

In Romania, the *Cernavoda* site is archaeologically classified into the chronological sequence Cernavoda I–III–II, where the individual Roman numerals correspond to different places at the Cernavoda location. The Cernavoda III period was estimated to be parallel to the Boleráz period (Morintz and Roman 1968; Roman 1999; Maran 1998; Němejcová-Pavúková 1999).

### **<sup>14</sup>C-Dating of the Baden Culture and Parallel Cultures**

The Vienna Environmental Research Accelerator (VERA) laboratory is engaged in a larger interdisciplinary project, “Absolute Chronology for Early Civilisations in Austria and Central Europe using Accelerator Mass Spectrometry”. In the course of this project, the Baden Culture and its relation to the parallel cultures is investigated. Thirty-two samples from various sites of the Baden Culture, mainly bones but also charcoals, were selected according to archaeological evidence and <sup>14</sup>C dated by the accelerator mass spectrometry (AMS) method at VERA.

Bone samples were decalcified and gelatin was produced from the organic substance. For the pre-treatment of the samples an automatic collagen extraction apparatus similar to the one developed by Law and Hedges (1989) was used. Charcoal samples were treated manually by the standard ABA method. Further processing and measurement of the cleaned samples is described in Wild et al. (1998). Since then, we changed from mounting duplicates and triplicates (targets with identical target material) of all samples into our 40-position target wheel to the use of only two duplicates of the C-3 IAEA  $^{14}\text{C}$ -standard. The purpose of the multiple targets at different positions was to compensate for small position dependency problems, which turned out to originate from a slight eccentricity of the target wheel. We now use the two standard duplicates distributed at opposite positions around the wheel to monitor eccentricity effects. Small eccentricity effects can be corrected mathematically by using the measured  $^{14}\text{C}/^{12}\text{C}$  and the  $^{13}\text{C}/^{12}\text{C}$  ratio of the identical targets. Larger eccentricity effects require a retuning of the machine. During the measurement, data are automatically evaluated by a computer program, which allows an online check of various diagnostic marks. Details of this program are described in Puchegger et al. (2000). The  $^{14}\text{C}$  ages of the samples calculated according to Stuiver and Polach (1977) are converted to calibrated ages with the OxCal calibration program (Bronk Ramsey 2000).

With the  $^{14}\text{C}$  ages determined at VERA and the 43 ages found in the literature, a data set of 75 dates is now available for the Baden Culture period. Table 1 lists the complete data. From this data set, the data of the different phases in east-central Europe were grouped and analyzed by sum calibration with OxCal. With this option of the calibration program, the probability distributions of all events assigned to a single phase of a cultural period can be summed up, giving each event the same weight. The result is a new probability distribution that gives a best estimate of the chronological distribution of the dated events (Bronk Ramsey 1999). In other words, if the data set is sufficiently large, the 68% probability range of such a distribution means that 68% of the total events fall within this time interval. This implies that the 68% time interval of the sum calibration allows significant conclusions, whereas this is not possible for the 1- $\sigma$  interval of the calibration of single events.

Table 2 shows the 68% and 95% intervals of the sum calibration for the individual phases of the Baden culture. These results were compared with those of sum calibration performed for the south-eastern cultures displayed in Table 3.

## DISCUSSION

For interpretation of the results of the sum calibration, only the time periods corresponding to the 68% confidence level are considered. This seems to be a useful way to reduce the influence of outliers in a data set of the investigated cultural period. A few such samples in a data set of a cultural phase with ages much younger or older than the investigated period would cause a broadening of the 95% interval of the sum distribution, but would have little effect on the 68% time period. As described above, the 68% time period of the sum calibration allows a significant assessment of a cultural phase.

For the Proto-Boleráz, a 68% time period from 3630 to 3360 BC was determined. This period is nearly identical with the period determined for the Boleráz phase. Although an overlap exists between the Červený Hradok and the Boleráz time, the younger phases of the Baden-Classical period can be distinguished from the Boleráz by sum calibration.

Overlaps of the individual time intervals are found for the sequence Červený Hradok–Ossarn I–Ossarn II. This sequence cannot be resolved with the sum calibration of the  $^{14}\text{C}$  ages. The calibration curve shows a small plateau in this time period. We must also note that for the Červený Hradok and Ossarn II phases, only five samples were analyzed. A larger data set for these two phases would be more informative.

Table 1 Currently available data for the Baden and the parallel cultures. For more detailed information on these data, see Stadler et al. (2000).

Table 3 Sum calibration for the southeastern parallel cultures

Group name	Nr of samples	Baden Culture phase	68.2% – time interval of sum calibration	95.4% – time interval of sum calibration
Ezero XIII-VII	7	I	3090 BC ( 2.1%) 3060 BC 3030 BC (41.8%) 2840 BC 2820 BC (24.3%) 2670 BC	3350 BC (95.4%) 2450 BC
Sitagroi	7	I	3330 BC (17.1%) 3220 BC 3180 BC ( 2.6%) 3150 BC 3120 BC (48.5%) 2880 BC	3550 BC (95.4%) 2650 BC
Cernavoda I	4	?	3550 BC (68.2%) 2850 BC	3700 BC (95.4%) 2600 BC

The time intervals determined by sum calibration for the southeastern parallel cultures indicate that the Ezero and the Sitagroi Cultures—formerly synchronized with the Boleráz period—should be paralleled with the phases of the Classical Baden Culture. The sum calibration of the data from the Cernavoda I Culture gives a relative large time span, which is coeval with the whole Baden period, i.e. the Baden Boleráz and the Baden Classic period.

## CONCLUSION

We can deduce the following about the chronological sequence of these cultures, based on the sum calibration results of the  $^{14}\text{C}$  data from the individual phases of the Baden culture.

1. The Boleráz period cannot be distinguished from the Proto-Boleráz period by the sum calibration of the available  $^{14}\text{C}$  dates. For the Šturovo-Proto-Boleráz the same time period was determined as for the Boleráz Culture. The younger phases of the Baden-Classical period (III and IVa) can be well distinguished from the Boleráz period.
2. The data from Cernavoda indicate that already the Cernavoda I period was coeval with the Baden culture. Previously, the Cernavoda III period was assumed to be contemporary with the Boleráz period, and according to archaeological evidence, the Cernavoda III period was later than Cernavoda I (Roman 1999). Thus, if the older Cernavoda I period is coeval with the Baden Culture, the subsequent Cernavoda III phase cannot be associated with the Boleráz time. It must

be noted that the Cernavoda I–III–II sequence may be verified in the future. The analysis of the Cernavoda I data is very tentative, because only four  $^{14}\text{C}$  dates (three of them determined in the 1960s) exist for this culture. For the Cernavoda II and III phases, no age determinations are available. Therefore, more  $^{14}\text{C}$  data are urgently needed for a better chronological assessment of the Cernavoda phases. New typological investigations reconfirm the connection between Boleráz and Cernavoda III (Němejcová-Pavúková 1999).

3. The two other cultures from southeast Europe, Ezero XIII–VII and Sitagroi IV, seem to be parallel to the Baden Classical culture.

The problem of synchronizing the Sitagroi phase IV with the Boleráz stage of the Baden Culture, and of synchronizing Sitagroi Va and b with the Classical Baden is described by Breunig (1987). The  $^{14}\text{C}$  data from both Sitagroi stages were too young for this synchronization, which was established by Němejcová-Pavúková (1981). Breunig also pointed out that difficulties arise in the synchronization of Cernavoda III and Ezero XIII–VII with the Boleráz phase when the  $^{14}\text{C}$  ages (only a few at this time) are considered.

According to these results it seems that—against former assumptions—the Baden Culture developed in central Europe and spread to the southeastern parts of Europe. The idea of a west–east spread of the Baden culture is also supported by the assumption of Maran (1998). However, before jumping to definite conclusions, more data for the southeastern groups are needed to verify our results. If this hypothesis is true, it would lead to a completely new view of the rate of cultural exchange along the Danube valley, and as another consequence, the theory that wheeled vehicles developed in the Middle East should be scrutinized.

#### ACKNOWLEDGMENT

This work was supported by the Austrian Science Fund, Project P12253-PHY: “Absolute Chronology for Early Civilizations in Austria and Central Europe using  $^{14}\text{C}$  Dating with Accelerator Mass Spectrometry”.
