**Abstract**—We demonstrate the first multiterabit/s wavelength division multiplexing data transmission through hollow-core antiresonant fiber (HC-ARF). In total, 16 channels of 32-GBd dual-polarization Nyquist-shaped 256QAM signal channels were transmitted through a 270-m-long fiber without observing any power penalty. In a single-channel high power transmission experiment, no nonlinearity penalty was observed for up to 1 W of received power, despite the very low chromatic dispersion of the fiber ( $<2$  ps/nm/km). Our simulations show that such a low level of nonlinearity should enable transmission at 6.4 Tb/s over 1200 km of HC-ARF, even when the fiber attenuation is significantly greater than that of SMF-28. As signals propagate through hollow-core fibers at close to the speed of light in vacuum such a link would be of interest in latency-sensitive data transmission applications.

**Index Terms**—Coherent transmission, fiber nonlinearity, hollow-core antiresonant fiber, modulation, optical fiber communication.

## I. INTRODUCTION

**D**RIVEN by the continual succession of new applications and technologies the information transfer capacity of optical communication networks has grown exponentially over several decades, transforming almost every aspect of the global economy and our everyday social lives. This transformative power has come about as a result of many technological breakthroughs including the development of low-loss, single

mode transmission fiber (SMF), the erbium-doped fiber amplifier (EDFA), wavelength division multiplexing (WDM), and more recently digital signal processing (DSP) enabled coherent transmission. Throughout this technological evolution, silica-based single mode optical fiber has remained at the heart of optical communication networks. Spectacular as its impact has been, the silica optical fiber has its weakness: the Kerr nonlinearity. This ultimately degrades the quality of propagating optical signals and limits the maximum information transmission capacity. This in turn has the potential to result in a “capacity crunch” at various points in the global optical communication network [1].

In addition to traditional data transfer, new data hungry services such as machine-to-machine communications inside data centers (DCs), 5G mobile communications, and the Internet of Things are starting to dominate the network traffic. These new services place further requirements on the data transfer performance, in particular with regards to transmission latency within the network. For example, data center operators have recently specified a maximum round-trip time of less than 2.0 ms for metro inter-DC communication [2]. Emerging applications such as virtual reality, the tactile internet, and autonomous driving will impose even more stringent requirements on the maximum allowed latency, with stability of latency also now becoming an important consideration in many instances. [3].

The intrinsic problems of silica fiber (nonlinearity and latency), have triggered numerous research activities, ranging from hardware technologies through to software DSP algorithms. On the mitigation of nonlinearity-induced impairments front, digital impairment compensation techniques including digital backward propagation [4] and the nonlinear Fourier transform [5] have attracted significant research interest as they can be employed with no/ minimal changes to currently deployed fiber links. Nevertheless, they are intrinsically limited by the bandwidths and resolutions available for coherent receivers. Optical phase conjugation (OPC) promises simultaneous compensation of both dispersion and nonlinearity at the expense of building symmetric transmission links [6]. Phase sensitive amplification (PSA) can in principle achieve noise-less amplification and can even be used to regenerate signal constellations. However, it is challenging to implement PSA for wide

bandwidth WDM signals and requires precise control of chromatic dispersion [7], [8]. Effective as the above-mentioned technologies are, they can only mitigate nonlinearity impairments, not eliminate them.

In optical networks, especially in long-reach transmission systems, the data transmission delay is dominated by signal propagation in the optical fibers [9]. For this reason, network operators are increasingly looking to deploy low latency systems by installing as straight as possible fiber links between sites to support financial and other high value latency sensitive applications [10]. Researchers are also investigating new solid fiber designs for low latency transmission and a 0.3% reduction in propagation latency has been obtained by engineering/optimizing the design of solid core silica fiber [11].

By contrast hollow-core fibers (HCF)s exhibit  $\sim 30\%$  reduction of latency, a high damage threshold and more than three orders of magnitude lower nonlinear response than standard silica optical fiber. Such a combination of advantages over conventional solid-core silica fiber make them an exciting option to meet both the emerging capacity and latency needs in future optical networks [12], [13].

Broadly speaking, there are two classes of hollow-core fiber: hollow-core photonic bandgap fiber (HC-PBGF) and hollow-core antiresonant fiber (HC-ARF). The HC-PBGF guides light in a hollow core by virtue of photonic bandgap effects determined by a carefully designed glass microstructure [14]. The HC-ARFs, however, rely essentially on coherent reflections from thin and typically tubular glass membranes to confine and guide light in the hollow region [15]–[19]. These membranes behave effectively as Fabry-Perot type resonators, with their transmission signature consisting of sharp peaks (resonances) separated by high reflectivity regions referred to as antiresonance windows. Within these windows, the grazing incidence provided by the large hollow-core results in very high reflectivity for the membranes, and translates into orders of magnitude lower leakage loss. These fibers offer the flexibility of engineering low-loss transmission windows simply through the choice of membrane thickness, and numerical simulations are currently indicating that they can provide lower attenuation than almost any existing fibers at almost any wavelength [19].

To date, a significant body of work has been done to demonstrate transmission in hollow-core photonic bandgap fibers, with both high capacity (73.7 Tb/s) [20] and relatively long lengths (up to 74.8 km) in a re-circulating loop demonstrated [21]. However, for HC-ARF, only single-channel 10-Gb/s on-off keyed (OOK) signal transmission over a fiber length of just 100 m has been demonstrated [15]. Compared to HC-PBGF, the key advantages of HC-ARF include an ultra-large transmission window (for example, a 1100 nm wide transmission bandwidth as shown in ref. [15]) with almost constant mode field diameter and a very high differential modal loss ( $> 10$  times higher loss in high order modes than the fundamental mode) that effectively supports single-mode transmission. Moreover, theoretical studies have identified a potential low loss ( $< 0.15$  dB/km) and a very low chromatic dispersion (CD) over almost the entire transmission window ( $< 2$  ps/(nm·km)) [20]. This potential is supported by a recent demonstration of a 0.5 km length HC-ARF with a

loss of 1.3 dB/km [22], outperforming the lowest rigorously documented loss in a HC-PBGF (1.7 dB/km) [23]. Arguably the key potential advantage of HC-ARF lies in the potential for very high transmission capacities using wide wavelength range dense wavelength division multiplexing (DWDM) and high-order modulation formats due to the anticipated very high nonlinearity tolerance. Although the prior art in [15] showed that the HC-ARF has a broad transmission window, its capability of supporting DWDM transmission (e.g., no wavelength-dependent fading or transmission impairments) has not been confirmed. Further, no study of nonlinear transmission impairments in HC-ARF has been reported to date.

In this paper, we show the significant potential of HC-ARF for optical communications by demonstrating the coherent transmission of a very high-order modulation format (256QAM) signal, over two polarizations, in a 16-channel 32 GBd DWDM system. This results in a  $> 14$  times greater spectral efficiency (14.5 bit/s/Hz) than the previous demonstration, over a 2.7 times longer (270 m) length of HC-ARF. Importantly, we demonstrate for the first time the high tolerance to nonlinearities in HC-ARF relative to SMF-28 in coherent transmission. These experiments were first reported at OFC 2017 [24]. This paper extends the conference abstract by showing the superior nonlinearity tolerance of HC-ARF relative to SMF-28 (even in experimental conditions that are deliberately biased against the HC-ARF). Moreover, through simulation, we compare the nonlinear tolerance HC-ARF to SMF-28 and large effective area solid core fibers, and investigate the potential of using HC-ARF in a 1200 km long low latency coherent communication system. Experimental characterization of the CD of the fiber is shown for the first time, essentially confirming the low values of CD predicted in [15].

## II. LOW DISPERSION ANTIRESONANT FIBER

The two HC-ARF fibers in this work were drawn from the same cane and have a non-contacting tubular geometry with seven tubes around a hollow core, as shown in the inset in Fig. 1. Their loss characterization and simulated dispersion were previously reported in [15]. Here, we experimentally measure the CD of the two fibers using the RF phase shift method [25] employing a tunable laser (1500 to 1585 nm) with a step size of 0.1 nm. The measured group delay was converted to CD using a 5-term Sellmeier fit to each raw group delay trace [26]. This measurement system allowed for an accurate CD measurement with a resolution of 0.1 ps/(nm·km). The solid and dashed lines in Fig. 1 show the measured CD for fiber A and fiber B, with core diameters of 38 and 40.2  $\mu\text{m}$ , respectively. The dotted line shows the simulation result reported in [15] for comparison. The measured CD is slightly higher than the simulation results but a very low and flat dispersion is obtained across the full measurement wavelength range. The average CD for fiber A and fiber B was 2.0 and 1.7 ps/(nm·km), respectively.

An important benefit comes with the low dispersion of HC-ARFs is the reduction of DSP complexity. For example, the number of taps for a 1200 km transmission system with SMF-28 requires 167 taps (assuming CD of 17 ps/(nm·km)), whereas

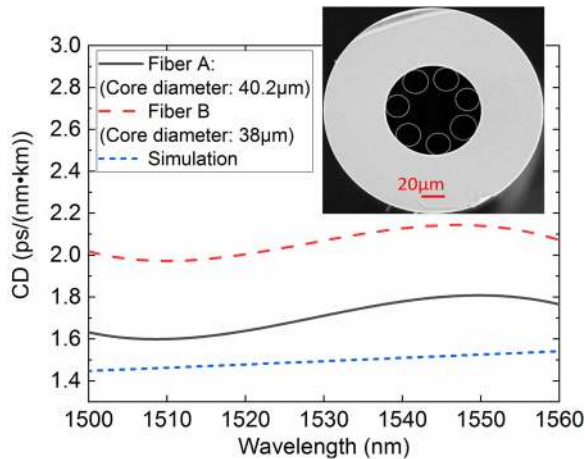

Fig. 1. Measured chromatic dispersion. Fiber A: solid black line; Fiber B: dashed red line; Simulation: dotted blue line.

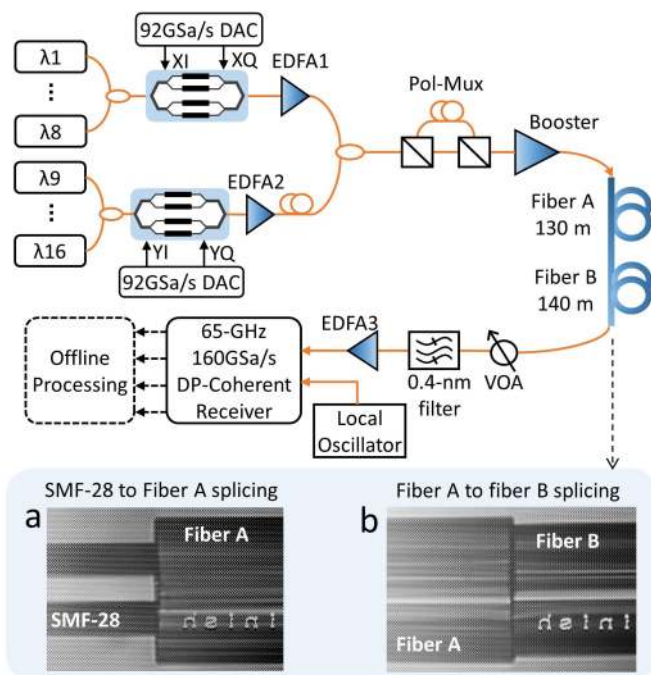

Fig. 2. Experimental setup for WDM transmission. EDFA: erbium-doped fiber amplifier; DAC: digital-to-analog converter; VOA: variable optical attenuator.

only 19 taps (assuming CD of 2 ps/(nm.km)) is needed when using HC-ARF [27]. This means that coherent system can eliminate the use of static equalizers for CD compensation, thereby reducing both the DSP complexity and processing delay.

### III. TRANSMISSION EXPERIMENT

Fig. 2 shows the experimental set-up of our WDM transmission experiment. The DWDM transmitter consists of 16 tunable external cavity lasers (ECLs, linewidth of 100 kHz) spaced between 1544.13 nm and 1550.12 nm on a 50 GHz ITU grid. The odd (and even) channels were combined through an  $8 \times 1$  coupler and subsequently modulated with a  $\text{LiNbO}_3$  IQ modulator

Fig. 3. Experimental setup for single-channel high power transmission.

driven by two 92-GS/s digital-to-analog converters (DACs). The modulated odd and even channels were amplified and decorrelated before being combined and passed through a polarization multiplexing emulation stage to form a 16-channel 32 GBd dual-polarization (DP) 256QAM signal. The power of each ECL was adjusted to yield a flat DWDM power spectrum (with less than 1 dB power variation) after the high-power EDFA. The high-power EDFA boosted the total signal power to 35 dBm (3.5 W), corresponding to 23 dBm per channel. The amplified signal was then launched into the HC-ARF transmission link via a SMF-28 to HC-ARF splice connection with a loss of 3.5 dB (due to the significant mode field mismatch) – see inset (a) in Fig. 2. The HC-ARF link comprised the two longest HC-ARF spans available, which were spliced together (inset Fig. 2b) to enable a transmission distance of 270 m. The first span (fiber A) is 130 m long and has a 40  $\mu\text{m}$  core and a 200  $\mu\text{m}$  cladding diameters. The second span (fiber B) is 140 m long and has a 38  $\mu\text{m}$  core and a 170  $\mu\text{m}$  cladding diameters. Their transmission performance were previously reported in [15]. Over the C-band it has an average loss of 41 dB/km. The second span is 140 m long and has a 38  $\mu\text{m}$  core and a 180  $\mu\text{m}$  cladding diameter. Its loss over the C-band is 58 dB/km. After transmission, the signal was coupled back from the HC-ARF to SMF-28 with a  $\sim 4$  dB loss.

The average loss of the line at the transmission wavelength region was approximately 21.5 dB, including 14 dB fiber loss and 7.5 dB coupling loss. A lower HCF to SMF-28 coupling loss could be achieved by using a mode field diameter matching buffer fiber [28], unfortunately though such a buffer fiber was not available for this experiment. The channel of interest was selected by passing the DWDM signal through a 50 GHz flat-top optical filter and was subsequently pre-amplified (EDFA3) and detected using a 65 GHz dual-polarization coherent receiver. The local oscillator (LO) laser was a 100 kHz-linewidth tunable ECL and the detected signals were then sent to four 160 GSa/s analog-to-digital converters (ADCs) for offline signal demodulation. In order to compare the result with the back-to-back performance at the same optical signal-to-noise ratio (OSNR), the fiber link was replaced with a variable optical attenuator (VOA) to emulate the loss.

The multi-level drive signals required for the QAM format were generated from decorrelated pseudorandom binary

Fig. 4. The loss profile of the 270-m HC-ARF fiber link (black line) and spectrum of the transmitted WDM signals (blue line), measured using an OSA with a resolution of 0.1 nm.

Fig. 5. Measured SNR (square marker) and BER (circle marker) both back-to-back (open marker) and after transmission (closed maker) though the 270 m HC-ARF fiber link.

sequences (PRBSs) of length  $2^{16}$ . The transmitter-side DSP shaped the generated QAM signal using a root raised-cosine (RRC) filter with a roll-off factor of 1% to generate the 32 GBd Nyquist-shaped 256QAM signals. At the receiver side, the signal was down sampled to 2 Sa/sym before equalizing the digital signals using a 21-tap blind radially directed equalizer for polarization demultiplexing. The carrier-frequency offset and phase noise were compensated with conventional DSP algorithms as described in [29]. The demodulated symbols were used to calculate the bit error rate (BER) and signal-to-noise ratio (SNR).

In addition to the WDM experiment, we investigated the high-power, single-channel performance of a length of HC-ARF, in order to enable us to compare the nonlinearity-induced transmission penalties of HC-ARF with respect to conventional SMF-28. As shown in Fig. 3, the experimental setup for the single channel transmission was the same as the WDM experiment except that only one ECL at 1550.12 nm was used and the 270 m HC-ARF link was replaced with 100 m HC-ARF (the lowest loss sample available, with an attenuation of 40 dB/km) and a 100 m length of SMF-28. Due to the loss in the HC-ARF sample (about 4 dB) as compared to the negligible loss in SMF-28 of the same length, it is difficult to decide at which power to carry out the comparison of nonlinearity impairments. However, we decided to show the impact of nonlinearity impairment with reference to the optical power after transmission, meaning that

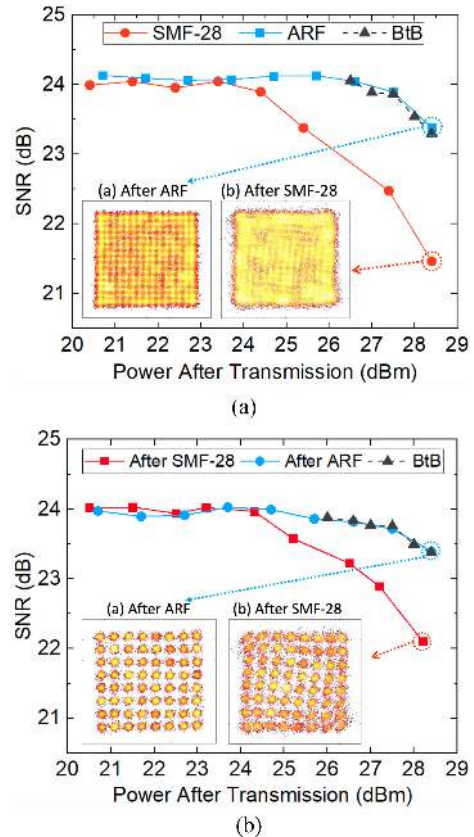

Fig. 6. SNR of the single-carrier (a) DP-256QAM and (b) DP-64QAM transmission over 100 m HC-ARF (blue square marker), 100 m SMF-28 (red circle marker), and back-to-back (black triangle marker); Constellation diagrams at the power of 28.5 dBm after HC-ARF and SMF-28 transmission.

the local power along the HC-ARF length is always higher than the power along at the equivalent point in the SMF-28. This biases the comparison in favor of the SMF-28. Limited by the maximum output power (36.5 dBm) of our high-power EDFA and the 3.5 dB input coupling loss from SMF-28 to the HC-ARF, the maximum launch power into the HC-ARF was 32.5 dBm (measured at the input of the HC-ARF), resulting in 28.5 dBm power after HC-ARF transmission. The performance of the signal was compared to an SMF-28 transmission with 28.5 dBm launch power, as plotted in Fig. 6.

## IV. EXPERIMENTAL RESULTS

### A. WDM Transmission

Fig. 4 shows the measured loss profile of the HC-ARF link and the optical spectrum of the transmitted WDM signal. The total link loss within the C-band increases smoothly from 21.2 dB to 22.2 dB for wavelengths from 1535 nm to 1565 nm. Fig. 5 shows the SNRs and BERs of the transmitted WDM DP-256QAM signals over the 270 m HC-ARF link, as closed square and circle markers, respectively. The achieved SNR values ranged from 22.8 to 23.4 dB and the pre-FEC corresponding BER values ranged from  $2.7 \times 10^{-2}$  to  $3.5 \times 10^{-2}$ . Using soft-decision decoding with 17% overhead [29], we achieved error free transmission for all channels, yielding a net data rate of 6.8 Tb/s. The back-to-back results are shown as open markers in Fig. 5.

The average SNR values for back-to-back and after transmission were 23.2 and 23.4 dB, respectively. We believe the slight difference in the SNR lies within the accuracy of our measurement.

### B. High Power Single-Channel Transmission

Fig. 6 shows the SNRs of the transmitted single-channel 32 GBd DP-256QAM (Fig. 6a) and DP-64QAM (Fig. 6b) signals for various optical powers as measured at the output of the 100 m HC-ARF and the 100 m SMF-28, respectively. As mentioned earlier, this comparison is biased against HC-ARF as the optical power propagating in the HC-ARF is at all points higher than in the SMF-28. In Fig. 6 we can observe that the back-to-back performance degrades as the input power is increased above about 26 dBm. This is due to nonlinear impairments generated within the high-power EDFA, which was operated at output powers up to 36.5 dBm. The high-power EDFA used was designed for CW operation and was not optimized for high power data signal amplification.

In the back-to-back case, the maximum achieved SNR was 24.2 dB due to the electronic noise limitations of the transceiver [30]. The SNR of the demodulated 256QAM signal remained about 24 dB before the post transmission power reached 26.5 dBm (corresponding to an EDFA output power of 34 dBm). The blue circle markers show the SNR obtained after transmission over the HC-ARF link. The performance was identical to the back-to-back case, confirming that no nonlinearity impairment occurred in the HC-ARF transmission. In contrast, SMF-28 fiber nonlinearity further degraded performance for post transmission powers above 25 dBm. The SNR of the demodulated signal dropped from 24.0 dB to 21.5 dB as the power was increased from 23.5 dBm to 28.5 dBm, corresponding to an increase in BERs from  $2 \times 10^{-2}$  to  $5 \times 10^{-2}$ .

The constellation diagrams corresponding to a transmission power of 28.5 dBm are shown as insets to Fig. 6. At 28.5 dBm, the SNR obtained after SMF-28 transmission was 2 dB lower than in the case of the HC-ARF transmission, highlighting the superior nonlinear tolerance of HC-ARF compared to SMF-28. A similar experiment was repeated for a single-channel 32 GBd DP-64QAM signal. The constellation diagrams in Fig. 6b clearly show the nonlinear phase distortion after 100 m SMF-28 transmission, while no significant distortion was observed after HC-ARF transmission even at the maximum post transmission power of 28.5 dBm.

The above results clearly evidenced that HC-ARFs have ultra low nonlinearity and the capability of handling very high optical powers. In HC-ARFs based optical communication systems, it is possible to launch high optical powers beyond the limitations of conventional SMF-28 based systems.

## V. SIMULATION

### A. Performance Comparison of HC-ARF with Different Solid Core Fibers

We conducted simulations to compare the high HC-ARF nonlinearity tolerance to that of various types of commonly-used solid core fibers including large effective area solid core silica fiber and non-zero dispersion shifted fiber. We first simulated

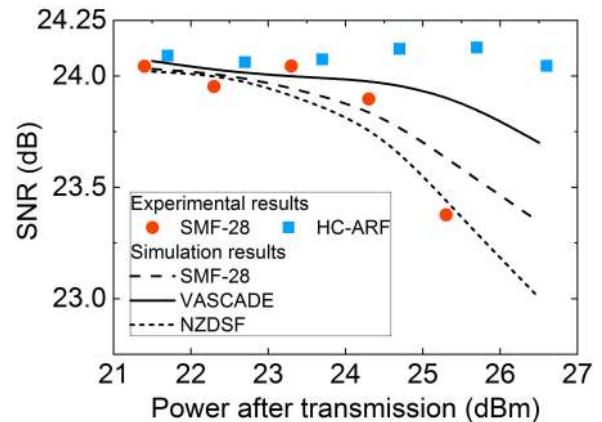

Fig. 7. Experimental and simulation results of the single-carrier 32-GBd DP-256QAM signal.

TABLE I  
FIBER PARAMETERS IN SIMULATION

Parameters	SMF-28	Corning VASCADE EX3000 [31]	Corning non-zero dispersion shifted fiber [32]
Attenuation at 1550 nm (dB/km)	0.2	0.158	0.19
CD (ps/nm•km)	17	20.8	5
Effective area ( $\mu\text{m}^2$ )	80	150	72

the transmission performance of 32 GBd DP-256QAM over a 100 m length of SMF-28 using the split step Fourier method with a step size of 1 m. By setting the transceiver noise limit to the experimentally-obtained value of 24.2 dB, the simulated SNR values at different optical powers showed good agreement with the experimental results as shown by the dashed line in (Fig. 7), which confirms the accuracy of our simulation. Subsequently, we changed the fiber parameters by assuming 100 m of Corning Vascade Ex3000 fiber (large effective area fiber) and non-zero dispersion shifted fiber (NZDSF), whose key parameters are listed in Table I.

The simulation results are plotted as lines (NZDSF: dotted; VASCADE: solid) in Fig. 7 together with the experimental results for SMF-28 (red circles) and HC-ARF (blue squares). Although the NZDSF fiber has a smaller dispersion, it underperforms compared to SMF-28 due to the smaller effective area. The simulation results show that the VASCADE fiber outperforms SMF-28 for optical powers higher than 23 dBm. However, the SNRs start to degrade as we further increase the power past 25 dBm, showing a 0.3 dB SNR penalty at 26.5 dBm. Similar to the experiment, this comparison is biased against the HC-ARF in that the optical power along the fiber is always higher than the solid core fibers, indicating that HC-ARF has a much higher nonlinearity tolerance than the state-of-the-art large effective area solid core fiber, though its CD is 10 times smaller. The combination of ultra-low nonlinearity and dispersion enable

Fig. 8. Simulation results. Center channel SNR of the 15-channel WDM transmission over 1200 km HC-ARF link at launch powers of 20 (black square), 22 (red circle), 24 (blue triangle), and 26 dBm (green diamond).

operation at high optical powers and reduces the DSP-generated latency.

### B. ARF-Based Long-Haul Transmission

Current HC-ARF research is focused on reducing the fiber attenuation and increasing the fiber length. Recent work has demonstrated a HC-ARF with less than 1.5 dB/km attenuation over 65 nm [22]. In our simulation, we investigate the performance of HC-ARF in long-reach coherent communications by considering 15 channels of 50 GBd Nyquist-shaped DP-16QAM signals. The optical channels centered at 1550 nm with a 100 GHz channel spacing. The effective nonlinear coefficient ( $\gamma$ ) of the HC-ARF was assumed to be  $0.01 \text{ W}^{-1}\text{km}^{-1}$  [33]. The in-line EDFAs were assumed to have 30 dB gain and a 7 dB noise figure.

Fig. 8 shows the simulated SNRs of the center channel with respect to different fiber attenuation values after transmission over a 1200 km HC-ARF link. The corresponding span length for different fiber attenuation levels is depicted as the upper-x axis. Different markers are used to indicate the SNRs at launch powers of 20 (square), 22 (circle), 24 (triangle), and 26 (diamond) dBm. Since the launch powers are significantly lower than those used in the experiment, we assume there is no non-linearity in the EDFAs. As a result, the signal performance is limited mainly by the amplified spontaneous emission (ASE) noise of the EDFAs.

The solid line shows the forward error correction (FEC) free SNR (22.5 dB) required for DP-16QAM signal transmission over the simulated link to achieve a BER of  $10^{-9}$  (under the assumption of Additive White Gaussian Noise, AWGN), which indicates that the system can support FEC-free operation with a fiber attenuation of 0.77 dB/km when the launch power is higher than 26 dBm, achieving a data rate of 400 Gb/s per channel after 31 spans (39 km per span). The required SNR threshold FEC-free QPSK (15.6 dB, BER of  $10^{-9}$ ) are also shown in Fig. 8 as the dotted blue line. It shows that the system can achieve a

net rate of 200 Gb/s even with 6 dB/km loss HC-ARF when the launch power to each span is higher than 26 dBm. Obviously, if the loss of HC-ARF can be reduced below 1 dB/km, the system can readily support FEC-free transmission at a launch power of around 16 dBm with a relatively low number of spans.

Although it is possible to achieve high throughput transmission using high attenuation HC-ARF, it would be at a high system cost and power consumption due to the large number of spans. However, the recently demonstrated 1.3 dB/km low loss HC-ARF (together with the theoretical predictions of even up to two orders of magnitude lower loss) show the potential of employing HC-ARF in long-haul communications. Such systems have an unprecedented advantage of low latency. For example, assuming a 40 m fiber length in each EDFA and a DSP processing latency of  $20 \mu\text{s}$ , a 1200 km transmission link with 240 spans (considering 6 dB/km fiber attenuation) would have a latency of about 4.1 ms, which is 1.9 ms lower than that of an equivalent-length SMF-28 based transmission link. Similarly, for a 100 km link, a HC-ARF based system would have a latency of about  $340 \mu\text{s}$ , providing a  $150 \mu\text{s}$  reduction relative to SMF-28. In addition to the latency reduction, the hollow core fiber would have a more stable latency due to its significantly lower thermal coefficient [34], which benefits system stability in latency-sensitive real-time applications.

## VI. CONCLUSION

We have presented 6.8 Tb/s coherent data transmission over 270 m of HC-ARF. The excellent quasi single mode behavior of the fiber allowed us to transmit dual-polarization-256QAM signals in a coherent 16-channel WDM system with negligible SNR penalty, and to achieve the highest data rate transmitted through an HC-ARF to date. We have also experimentally confirmed that the fiber can handle high optical powers (up to 36.5 dBm, giving it 2 dB SNR advantage over SMF-28 in a comparison that is deliberately biased against the HC-ARF, using a power after transmission of up to 28.5 dBm. Our simulations show that HC-ARF has a clear advantage over different types of solid core fibers in terms of insensitivity to nonlinearities, even though its CD is significantly smaller. These results, together with inherently lower and more stable latency and potential for significant further loss reduction make HC-ARF a most promising transmission medium for future low-latency, ultra-high capacity data transmission applications.

**Zhixin Liu** (M'12–SM'17) received the B.Eng. degree in information engineering and the B.B.A. degree in business administration from Tianjin University, Tianjin, China, in 2006, the M.S. degree in electrical engineering from Shanghai Jiao Tong University, Shanghai, China, in 2009, and the Ph.D. degree in information engineering from the Chinese University of Hong Kong, Hong Kong, in 2012.

He joined the Optoelectronics Research Centre, University of Southampton, Southampton, U.K., in 2013. In 2016, he joined the Department of Electronics and Electrical Engineering at UCL. His current research includes high-speed direct modulation and coherent optical signal processing with focus on phase locking, advance modulation formats, advanced multiplexing/demultiplexing schemes, and their system applications.

Dr. Liu is a Senior Member of OSA.

**Boris Karanov** (S'16) received the B.Sc. degree in telecommunication engineering from Technical University of Sofia, Sofia, Bulgaria, in 2014, and the joint M.Sc. degrees in photonic networks engineering from Aston University, Birmingham, U.K.; Osaka University, Osaka, Japan; and Technical University of Berlin, Berlin, Germany, in 2016, under the Erasmus Mundus Masters framework. His master thesis was developed in Fraunhofer Heinrich-Hertz-Institute, Germany. He is currently working toward the Ph.D. degree with the Optical Networks Group, University College London, London, U.K., and Nokia Bell Labs, Stuttgart, Germany under the Marie Skłodowska-Curie Innovative Training Network project COIN. During the B.Sc. and M.Sc. degrees, he had internships in the Bulgarian Academy of Sciences and Mitsubishi Electric, Japan and worked under MC-IRSES scheme with Jiaotong University, Shanghai, China. His research interests include nonlinear fiber effects, impact of spectral broadening on nonlinearity compensation, and deep learning of optical communications.

**Lidia Galdino** (M'13) received the M.Sc. and Ph.D. degrees in electronic and electrical engineering from the University of Campinas, Campinas, Brazil, in 2008 and 2013, respectively. She subsequently joined the Optical Networks Group, University College London to work as a Research and Senior Research Associate. She is currently a Lecturer and a Royal Academy of Engineering Research Fellow on the topic of "Capacity-approaching, Ultra-Wideband Nonlinear Optical Fibre Transmission System." She is a co-investigator in the EPSRC TRANSNET program grant. She currently serves as Associated Vice President of IEEE's Women in Photonics and she is with technical program committees of IEEE Photonics Conference and European Conference on Optical Communication. She was a co-recipient of the RAEng Colin Campbell Mitchell Award in 2015 for pioneering contributions to optical communications technology and named as one of the 2017 "Top 50 Women in Engineering under 35" by The Telegraph and Women in Engineering Society which features the U.K.'s top rising female stars of engineering.

**John R. Hayes** received the Ph.D. degree from the Optoelectronics Research Centre (ORC), Southampton, U.K., for his development of highly innovative microstructured fibers. He joined the ORC in 2003 from industry, where he was with Pirelli developing the vapor axial deposition (VAD) method for the high volume manufacture of single-mode telecoms fibers. He was part of a team that initially transferred VAD technology from Sumitomo Electric Industries in Japan and established a U.K. fiber manufacturing facility, and later became the head in a team of engineers that supported its 24/7 operation. Since joining the ORC, he has created a diverse range of novel microstructured fibers and has coauthored more than 110 conference and journal papers. He is a member of the Optical Society of America.

**Domanij Lavery** (M'13) received the M.Phys. degree in theoretical physics from Durham University, Durham, U.K., in 2009, and the Ph.D. degree in electronic and electrical engineering from University College London, London, U.K., in 2013.

He commenced a Royal Academy of Engineering Research Fellowship in December 2016 on the topic of "Simplified Transceiver Architectures for High Capacity Optical Networks," having previously worked as a Postdoctoral Research Associate on the EPSRC UNLOC project, investigating digital signal processing for optical fiber communications. He is a co-investigator in the EPSRC TRANSNET project, a multidisciplinary research program investigating intelligent resource allocation in dynamic optical networks.

Dr. Lavery is a member of the Optical Access Networks (N4) subcommittee for OFC (2015–2017, chair 2019) and, additionally, has served on the technical program committee for ECOC since 2018. He was awarded the IEEE Photonics Society Graduate Student Fellowship in 2012, and the Marconi Society's Paul Baran Young Scholar Award in 2013.

**Kari Clark** received the B.Sc. and M.Phys. degrees in physics from the University of Warwick, Coventry, U.K., in 2013. He received the Ph.D. degree in optical communications from the Optical Networks Group, University College London. His doctoral research focuses on using central optical synchronization to achieve subnanosecond clock and data recovery times in optically switched data center networks. In 2016, he completed a 9-month internship at Microsoft Research Cambridge, applying his research in an industrial context. He is the overall winner of the 2018 EPSRC Connected Nation Pioneers.

**Kai Shi**, biography not available at the time of publication.

**Daniel J. Elson**, biography not available at the time of publication.

**Benn C. Thomsen** (M'06) joined Microsoft Research in 2017 where he works on optical systems for networking and storage in next generation cloud computing systems.

Before joining Microsoft, he was a reader in optical communications with University College London from 2004–2017. His research was in physical layer implementation of dynamic optical networks and optical transmission systems including digital signal processing for burst mode optical receivers, optical networking for data centers, and the use of MIMO techniques for transmission over multimode optical fibers.

**Marco N. Petrovich** (M'11–SM'12) received the Laurea degree in physics from the University of Padua, Padua, Italy, in 1998, and the Ph.D. degree in optoelectronics from the University of Southampton, Southampton, U.K., in 2003. He joined the Optoelectronics Research Centre in 1999 as the recipient of a prestigious Ph.D. studentship awarded by Pirelli Cables Ltd. He has been involved ever since in the development and fabrication of special fibers. Since 2003, he has been working on silica microstructured fibers. His research interests include the development of novel fiber structures, particularly hollow core photonic bandgap and antiresonant fibers, and their application in telecommunications, gas sensing, and power delivery. In 2016, he co-founded Lumenity Ltd. He is a Senior Member of the Optical Society of America, an Associate Editor of the IEEE SENSORS JOURNAL, has co-authored more than 210 publications in journals and conference proceedings and is a frequent Invited Speaker at international conferences and meetings.

**David J. Richardson** (F'15) received the B.Sc. and Ph.D. degrees in fundamental physics from Sussex University, Brighton, U.K., in 1985 and 1989, respectively.

He joined the Optoelectronics Research Centre (ORC), Southampton University in 1989 and was awarded a Royal Society University Fellowship in 1991 in recognition of his pioneering work on short pulsed fiber lasers. He is now a Deputy Director of the ORC with responsibility for the ORC's fiber related activities. His current research interests include amongst others optical fiber communications, microstructured optical fibers, and pulsed high-power fiber lasers. He is a prominent figure in the international photonics community and has published more than 900 conference and journal papers and produced more than 20 patents.

Prof. Richardson is a Fellow of the Optical Society of America, the Institute of Engineering and Technology and was made a Fellow of the Royal Academy of Engineering in 2009 and Fellow of Royal Society in 2018.

**Francesco Poletti** (M'05) received the Laurea degree in electronics engineering from the University of Parma, Parma, Italy, in 2000, and the Ph.D. degree from the Optoelectronics Research Centre (ORC), Southampton, U.K., in 2007.

He is currently a Professor with the ORC. He has worked for three years on optical network design with Marconi Communications and for more than ten years on the development of new generations of microstructured optical fibers with ORC. He has coauthored more than 100 journal and 200 conference publications and produced 8 patents. His research interests include the design of photonic bandgap and antiresonant fibers, the development of fiber-optic characterization techniques, and the fabrication of silica and nonsilica-based fibers and devices. He is the recipient of a Royal Society University Fellowship and a European Research Fellowship Consolidator Grant.

**Radan Slavík** (M'07–SM'07) received the M.A.Sc. and Ph.D. degrees in optics and optoelectronics from the Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, in 1996 and 2000, respectively. He received the D.Sc. degree from Academy of Sciences, Prague, Czech Republic, in 2009.

In 1995–2000 and 2004–2009, he was with the Institute of Photonics and Electronics, Czech Academy of Sciences. In 2000–2003, he was with the Centre d'optique, photonique et laser, Université Laval, Québec, Canada, as a Postdoctoral Research Fellow. Since 2009, he has been with Optoelectronics Research Centre, University of Southampton, Southampton, U.K. His research interests focus in optical and optics-assisted signal processing.

Dr. Slavík is a Fellow of OSA. In 2006, he received Otto Wichterle Award and in 2007, he received The Visegrad Group Academies Young Researcher Award.

**Polina Bayvel** (F'10) received the B.Sc. (Eng) and Ph.D. degrees in electronic and electrical engineering from University of London, London, U.K., in 1986 and 1990, respectively. In 1990, she was with the Fiber Optics Laboratory, General Physics Institute, Moscow, Russia (formerly USSR, now Russian Academy of Sciences). During 1994–2004, she held a Royal Society University Research Fellowship with the University College London, and in 2002, she was appointed to a Chair in Optical Communications and Networks. She is a Fellow of the Royal Society, Royal Academy of Engineering, Optical Society of America, the UK Institute of Physics, and the Institute of Engineering and Technology. She was the recipient of the Royal Society Wolfson Research Merit Award (2007–2012), 2013 IEEE Photonics Society Engineering Achievement Award, 2014 Royal Society Clifford Patterson Prize Lecture and Medal and in 2015 together with 5 members of her group, received the Royal Academy of Engineering Colin Campbell Mitchell Award for "pioneering contributions to optical communications technology." She was awarded CBE (Commander of the Order of the British Empire) in the 2017 New Year's Honours List for services to engineering.
