

**NOTE ON THE TIGHTNESS OF THE METRIC ON THE SET OF
 COMPLETE SUB σ -ALGEBRAS OF A PROBABILITY SPACE**

BY J. NEVEU

University of Paris

The purpose of this note is to show that the usual metric on the set of complete sub σ -algebras of a probability space is very tight; a recent result from E. B. Boylan on equi-convergence of martingales follows and is thereby, we believe, better understood.

Given a probability space (Ω, \mathcal{A}, P) , a metric can be introduced on the set S of all complete sub σ -algebras \mathcal{B} of \mathcal{A} by letting (see [1])

$$d(\mathcal{B}_1, \mathcal{B}_2) = \sup_{B_1 \in \mathcal{B}_1} \inf_{B_2 \in \mathcal{B}_2} P(B_1 \triangle B_2) + \sup_{B_2 \in \mathcal{B}_2} \inf_{B_1 \in \mathcal{B}_1} P(B_1 \triangle B_2)$$

where \triangle denotes symmetric difference of sets as usual; here a sub σ -algebra \mathcal{B} of \mathcal{A} is said to be complete (relatively to \mathcal{A}) if every set $A \in \mathcal{A}$ of probability zero belongs to \mathcal{B} . The following proposition is then the main result of this note.

PROPOSITION. *Let $\mathcal{B}, \mathcal{B}'$ be two complete sub σ -algebras of \mathcal{A} in (Ω, \mathcal{A}, P) such that $\mathcal{B} \subset \mathcal{B}'$. Then there exists a set $A \in \mathcal{B}$ such that*

$$P(A^c) \leq 4d(\mathcal{B}, \mathcal{B}') \quad \text{and} \quad A \cap \mathcal{B}' = A \cap \mathcal{B}.$$

Conversely if $A \in \mathcal{B}'$ is such that $A \cap \mathcal{B}' = A \cap \mathcal{B}$, then $d(\mathcal{B}, \mathcal{B}') \leq P(A^c)$.

When $A \in \mathcal{A}$ and $\mathcal{B} \in S$, we denote by $A \cap \mathcal{B}$ the σ -algebra of subsets of A which are of the form $A \cap B$ for a $B \in \mathcal{B}$; when $A \in \mathcal{B}$, then this class $A \cap \mathcal{B}$ is also the σ -algebra of subsets of A belonging to \mathcal{B} .

PROOF.

(a) When $\mathcal{B} \subset \mathcal{B}'$, the distance $d(\mathcal{B}, \mathcal{B}')$ can be characterized as the smallest positive real number d for which the following implication holds

$$B' \in \mathcal{B}', P^{\mathcal{B}}(B') \leq \frac{1}{2} \text{ a.s.} \implies P(B') \leq d,$$

where $P^{\mathcal{B}}(B')$ denotes the conditional expectation of the indicator function $1_{B'}$ of B' with respect to \mathcal{B} . This is easily proved as follows.

Because $P(B \triangle B') = E[|P^{\mathcal{B}}(B') - 1_B|]$ when $B \in \mathcal{B}$ and $B' \in \mathcal{B}'$, we have for every $B' \in \mathcal{B}'$

$$\begin{aligned} \inf_{B \in \mathcal{B}} P(B \triangle B') &= \inf_{B \in \mathcal{B}} E[|P^{\mathcal{B}}(B') - 1_B|] \\ &= E\{\min[P^{\mathcal{B}}(B'), 1 - P^{\mathcal{B}}(B')]\} \end{aligned}$$

the infimum being for instance achieved by the \mathcal{B} -set $\{P^{\mathcal{B}}(B') > \frac{1}{2}\}$. Hence

$$d(\mathcal{B}, \mathcal{B}') = \sup_{B' \in \mathcal{B}'} E\{\min[P^{\mathcal{B}}(B'), 1 - P^{\mathcal{B}}(B')]\}.$$

Received November 24, 1971.

Now we use the hypothesis $\mathcal{B} \subset \mathcal{B}'$ to assert that for every $B' \in \mathcal{B}'$, the set $B^* = B' \triangle \{P^{\mathcal{B}}(B') > \frac{1}{2}\}$ is also in \mathcal{B}' ; since

$$P^{\mathcal{B}}(B^*) = \min[P^{\mathcal{B}}(B'), 1 - P^{\mathcal{B}}(B')] \leq \frac{1}{2}$$

it is not hard to see that

$$d(\mathcal{B}, \mathcal{B}') = \sup[P(B''); B'' \in \mathcal{B}', P^{\mathcal{B}}(B'') \leq \frac{1}{2}]$$

as announced.

(b) If $\mathcal{B}, \mathcal{B}' \in \mathcal{S}$ still verify $\mathcal{B} \subset \mathcal{B}'$, let A be a \mathcal{B} -atom of \mathcal{B}' [i.e. a set $A \in \mathcal{B}'$ such that $A \cap \mathcal{B}' = A \cap \mathcal{B}$] with largest possible conditional expectation $P^{\mathcal{B}}(A)$; the existence of such a set has been proved in [2], Theorem 1, page 258. Let us show now that $P(A^c) \leq 4d(\mathcal{B}, \mathcal{B}')$.

By Theorem 2 of [2], we may find a set $C \in \mathcal{B}'$ such that

$$P^{\mathcal{B}}(C) \leq \frac{1}{2} \leq P^{\mathcal{B}}(C) + P^{\mathcal{B}}(A).$$

Then we let

$$D = C\{P^{\mathcal{B}}(A) \leq \frac{1}{4}\} + A\{\frac{1}{4} < P^{\mathcal{B}}(A) \leq \frac{1}{2}\} + A^c\{P^{\mathcal{B}}(A) > \frac{1}{2}\}.$$

This set D belongs to \mathcal{B}' and is such that

$$\frac{1}{4}[1 - P^{\mathcal{B}}(A)] \leq P^{\mathcal{B}}(D) \leq \frac{1}{2} \quad \text{a.s.}$$

as is easily checked on each of the three sets $\{P^{\mathcal{B}}A \leq \frac{1}{4}\}$, $\{\frac{1}{4} < P^{\mathcal{B}}A \leq \frac{1}{2}\}$ and $\{\frac{1}{2} < P^{\mathcal{B}}(A)\}$ on which respectively $P^{\mathcal{B}}(D) = P^{\mathcal{B}}(C)$, $P^{\mathcal{B}}(A)$, or $1 - P^{\mathcal{B}}(A)$. The properties of this set D imply with the aid of (a) that

$$d(\mathcal{B}, \mathcal{B}') \geq P(D) \geq \frac{1}{4}[1 - P(A)].$$

The direct part of the proposition is thus proved. The converse is immediate; indeed if $A \in \mathcal{B}'$ is such that $A \cap \mathcal{B}' = A \cap \mathcal{B}$, then for every $B' \in \mathcal{B}'$ there exists a $B \in \mathcal{B}$ for which $AB' = AB$ and then $P(B \triangle B') \leq P(A^c)$; hence $d(\mathcal{B}, \mathcal{B}') \leq P(A^c)$. \square

The following easy corollary has an interest only for equi-integrable sets of functions (for which $\delta_H(a) \downarrow 0$ as $a \nearrow \infty$).

COROLLARY. *Let H be a set of real integrable functions defined on a probability space (Ω, \mathcal{A}, P) and let $\mathcal{B}, \mathcal{B}'$ be two sub σ -algebras of \mathcal{A} such that $\mathcal{B} \subset \mathcal{B}'$. Then the following inequality holds*

$$\sup_{f \in H} \|E^{\mathcal{B}}(f) - E^{\mathcal{B}'}(f)\|_1 \leq 16ad(\mathcal{B}, \mathcal{B}') + 4\delta_H(a)$$

for every real $a > 0$, provided one lets

$$\delta_H(a) = \sup_{f \in H} \int_{\{|f| > a\}} |f| dP.$$

PROOF. Let A be a set with the properties stated in the preceding proposition and let f be a \mathcal{B}' -integrable function. Then it is easily checked (see Lemma 2, page 257 of [2]) that $E^{\mathcal{B}}(f1_A) = fP^{\mathcal{B}}(A)$ a.s. on A ; hence

$$\begin{aligned} \|E^{\mathcal{B}}(f1_A) - f1_A\|_1 &= \int_{A^c} |E^{\mathcal{B}}(f1_A)| dP + \int_A |f|[1 - P^{\mathcal{B}}(A)] dP \\ &\leq \int_{\Omega} E^{\mathcal{B}}(|f|)[1_{A^c} + P^{\mathcal{B}}(A^c)] dP \\ &= 2 \int_{\Omega} |f| P^{\mathcal{B}}(A^c) dP . \end{aligned}$$

On the other hand

$$\|E^{\mathcal{B}}(f1_{A^c}) - f1_{A^c}\|_1 \leq 2\|f1_{A^c}\|_1 = 2 \int_{\Omega} |f| 1_{A^c} dP .$$

The addition of the two inequalities gives that

$$\|E^{\mathcal{B}}(f) - f\|_1 \leq 2 \int |f|[P^{\mathcal{B}}(A^c) + 1_{A^c}] dP$$

for every \mathcal{B}' -integrable function f ; the inequality remains valid for every integrable f , if $E^{\mathcal{B}'}(f)$ is substituted for f in the first member and then

$$\begin{aligned} \|E^{\mathcal{B}}f - E^{\mathcal{B}'}(f)\|_1 &\leq 2 \int_{\Omega} |f|[P^{\mathcal{B}}(A^c) + 1_{A^c}] dP \\ &\leq 4aP(A^c) + 4 \int_{\{|f|>a\}} |f| dP \\ &\leq 16ad(\mathcal{B}, \mathcal{B}') + 4 \int_{\{|f|>a\}} |f| dP . \end{aligned}$$

By taking the supremum of the extreme members over H , we obtain the formula of the corollary. \square

Boylan has recently proved [1] that for any equi-integrable subset H of $L^1(\Omega, \mathcal{A}, P)$ and for any monotone sequence $(\mathcal{B}_n, n \in N)$ of sub σ -algebras of \mathcal{A} the L^1 -convergence $\lim_{n \rightarrow \infty} E^{\mathcal{B}_n}(f) = E^{\mathcal{B}_\infty}(f)$ holds *uniformly* on H , provided \mathcal{B}_∞ denotes the limiting σ -algebra of the increasing or decreasing sequence $(\mathcal{B}_n, n \in N)$ and provided $d(\mathcal{B}_n, \mathcal{B}_\infty) \rightarrow 0$ as $n \uparrow \infty$. This theorem can be readily obtained from the preceding corollary, since by this result

$$\begin{aligned} \sup_H \|E^{\mathcal{B}_n}(f) - E^{\mathcal{B}_\infty}(f)\| &\leq 16ad(\mathcal{B}_n, \mathcal{B}_\infty) + 4\delta_H(a) \\ &\rightarrow 0 \end{aligned}$$

when $n \nearrow \infty$ and then $a \nearrow \infty$.
