# NUMERICAL ANALYSIS OF AUGMENTED PLANE WAVE METHODS FOR FULL-POTENTIAL ELECTRONIC STRUCTURE CALCULATIONS * 

Huajie Chen ${ }^{1}$ and Reinhold Schneider ${ }^{1}$

#### Abstract

This paper investigates the augmented plane wave methods which are widely used in full-potential electronic structure calculations. These methods introduce basis functions that describe different regions using different discretization schemes. We construct a nonconforming method based on this idea and present an a priori error analysis for both linear Schrödinger type equations and nonlinear Kohn-Sham equations. Some numerical experiments are presented to support our theory.

## 1. Introduction

Electronic structure theory describes the energies and distributions of electrons, which plays a fundamental role in many different fields: materials science, biochemistry, solid-state physics, and surface physics. The most widely used technique, which achieves so far the best compromise between accuracy and efficiency, is Kohn-Sham (KS) density functional theory (DFT) [28, 32]. For a system consisting of $M$ nuclei (located at $\mathbf{R}_{k} \in \mathbb{R}^{3}$ with charge $\left.Z_{k} \in \mathbb{N}, k=1, \ldots, M\right)$ and $N$ electrons, the KS-DFT model with local density approximation (LDA) gives rise to the following KS equations

$$
\begin{equation*}
H_{\Phi} \phi_{i}=\lambda_{i} \phi_{i}, \quad i=1, \ldots, N, \tag{1.1}
\end{equation*}
$$

where the KS orbitals $\Phi=\left\{\phi_{1}, \ldots, \phi_{N}\right\} \in\left(H^{1}\left(\mathbb{R}^{3}\right)\right)^{N}$ satisfy the orthonormality conditions $\int_{\mathbb{R}^{3}} \phi_{i} \phi_{j}=\delta_{i j}$, and $\lambda_{1} \leq \lambda_{2} \leq \ldots \leq \lambda_{N}$ are the lowest $N$ eigenvalues of $H_{\Phi}$. The Hamiltonian $H_{\Phi}$ in (1.1) is given by

$$
\begin{equation*}
H_{\Phi}=-\frac{1}{2} \Delta+V_{\mathrm{eff}}\left(\rho_{\Phi}(\mathbf{r})\right) \quad \text { with } \quad V_{\mathrm{eff}}\left(\rho_{\Phi}(\mathbf{r})\right)=v_{\mathrm{ext}}(\mathbf{r})+v_{\mathrm{H}}\left(\rho_{\Phi}(\mathbf{r})\right)+v_{\mathrm{xc}}\left(\rho_{\Phi}(\mathbf{r})\right) \tag{1.2}
\end{equation*}
$$

[^0]where $\rho_{\Phi}(\mathbf{r})=\sum_{i=1}^{N}\left|\phi_{i}(\mathbf{r})\right|^{2}$ is the electron density, $v_{\text {eff }}\left(\rho_{\Phi}(\mathbf{r})\right)$ represents the effective potential, $v_{\text {ext }}(\mathbf{r})=$ $-\sum_{k=1}^{M} \frac{Z_{k}}{\left|\mathbf{r}-\mathbf{R}_{k}\right|}$ is the electrostatic potential generated by the nuclei, $v_{\mathrm{H}}\left(\rho_{\Phi}(\mathbf{r})\right)=\int_{\mathbb{R}^{3}} \frac{\rho_{\Phi}\left(\mathbf{r}^{\prime}\right)}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} \mathrm{d} \mathbf{r}^{\prime}$ is the Coulomb potential representing interactions between the electrons, and $v_{\mathrm{xc}}\left(\rho_{\Phi}(\mathbf{r})\right)$ is the exchange-correlation potential. A self-consistent field (SCF) iteration algorithm is commonly resorted to for this nonlinear problem. In each iteration of the algorithm, a Hamiltonian $H_{\tilde{\Phi}}$ is constructed from a trial electronic state $\tilde{\Phi}$, and a linear eigenvalue problem is then solved to obtain the low-lying eigenvalues. In this paper, we will focus on the periodic versions of the KS models. In the periodic setting, the simulation domain is no longer $\mathbb{R}^{3}$, but a unit cell $\Omega$ of some periodic lattice of $\mathbb{R}^{3}$. In the periodic KS framework, periodic boundary conditions are imposed to the KS orbitals at the boundary of the simulation cell $\Omega$, which is the standard method to compute condensed phase properties with a limited number of atoms in the simulation cell.

In studies of the electronic structure of periodic solids, it is nature to use plane wave basis functions which correspond to Bloch functions labeled by the $k$-vector of the first Brillouin zone. A pseudopotential approximation (see, e.g. [39]) is always combined with the plane wave method, since in full-potential calculations, an extremely large number of plane waves are needed to describe the cusps $[24,27]$ and the rapid oscillations of the electron density. The pseudopotential approximations remove the core electrons, replace them and the strong ionic potential by a smooth pseudopotential that acts on a set of pseudo wave functions rather than the true valence wave functions, and hence allow the wave functions to be expanded using a much smaller basis set. Although the pseudopotentials give satisfactory results in most cases, they sometimes fail, and to our best knowledge, a mathematical analysis of the pseudopotential approximations is still lacking. The full-potential calculations can be regarded as a benchmark for the pseudopotential calculations. Moreover, the core electrons have to be considered sometimes and are responsible for many properties. Therefore, the full-potential calculations are necessary in practice, where more efficient basis sets than plane waves shall be used.

One of the most commonly used methods in full-potential calculations is the augmented plane wave (APW) method $[39,45]$, which is among the most accurate methods of performing electronic structure calculations for crystals. The APW method was originally proposed by Slater [47] in 1937. In spite of its demanding computational cost due to the energy dependency, it has been widely and successfully used (see e.g. [20]). Several improvements of the basis set were tried to get rid of the energy dependency, the first really successful one was the linearization scheme introduced by Andersen [3] in 1975, leading to the linearized augmented plane wave (LAPW) method [31]. It was further developed by including local atomic orbitals (LAPW+lo) to have enough variational flexibility in the radial basis functions [38,44,46]. Several widely used quantum chemistry and solid-state physics softwares are based on these methods such as Exciting [54], FLEUR [53], and WIEN2k [55].

In the APW method, the unit cell $\Omega$ is partitioned into two types of regions (the so-called "muffin-tin" division [39], see Fig. 1): (i) spheres $\mathscr{C}_{i}$ centered at atomic sites $\mathbf{R}_{i}$ with radius $R_{i}$, in which the effective potential is assumed to be symmetric, i.e. $V_{\mathrm{eff}}\left(\rho_{\Phi}(\mathbf{r})\right)=V\left(\left|\mathbf{r}-\mathbf{R}_{i}\right|\right)$; (ii) the remaining interstitial region $\mathscr{D}$. The basis functions consist of augmentations of plane waves as follows

$$
|\Omega|^{-\frac{1}{2}} \mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}} \rightarrow \begin{cases}|\Omega|^{-\frac{1}{2}} e^{i \mathbf{k} \cdot \mathbf{r}} & \text { in } \mathscr{D}  \tag{1.3}\\ \sum_{l m} \alpha_{l m}^{\mathbf{k}} \chi_{l}\left(r_{i}, \varepsilon\right) Y_{l m}\left(\hat{\mathbf{r}}_{i}\right) & \text { in } \mathscr{C}_{i}\end{cases}
$$

where $\mathbf{r}_{i}=\mathbf{r}-\mathbf{R}_{i}, r=|\mathbf{r}|, \hat{\mathbf{r}}=\mathbf{r} / r, Y_{l m}(\hat{\mathbf{r}})$ denotes the spherical harmonic functions on $S^{2}, \chi_{l}(r, \varepsilon)$ is the solution of the radial Schrödinger equation at energy parameter $\varepsilon$

$$
\begin{equation*}
-\frac{1}{2 r^{2}} \frac{\mathrm{~d}}{\mathrm{~d} r}\left(r^{2} \frac{\mathrm{~d} \chi_{l}}{\mathrm{~d} r}\right)+\left(\frac{l(l+1)}{2 r^{2}}+V(r)-\varepsilon\right) \chi_{l}=0 \tag{1.4}
\end{equation*}
$$

and the coefficients $\alpha_{l m}^{\mathbf{k}}$ are determined such that each angular component of the basis function is matched through the spherical surface (see Sect. 3). The philosophy of the APW method is a procedure for solving the

Figure 1. The "muffin-tin" division of the unit cell $\Omega$ into spheres $\mathscr{C}_{i}$ centered at atoms and interstitial region $\mathscr{D}$.

KS equations of a many-electron system by introducing a basis set that is in some ways the "best of both worlds". The smoothly varying parts of the wave functions between the atoms are represented by plane waves, and the rapidly varying parts near the nuclei are represented by radial atomic functions time spherical harmonics inside the sphere around each nucleus.

The purpose of this paper is to construct a discretization method based on the idea of the (L)APW method in order to provide a numerical analysis for full-potential electronic structure calculations. As far as we know, there is no numerical analysis concerning the APW method in literature. We shall first consider linear Schrödinger type eigenvalue problems with an effective potential, which appear in each step of the SCF iterations. Afterwards we extend the analysis to the nonlinear KS equations under certain reasonable coercivity assumptions. Our analysis shows that, in principle, the (L)APW approach can provide super algebraic and nearly exponential convergence for full-potential calculations. This explains why the (L)APW codes are frequently used for sufficiently accurate electronic structure calculations from a numerical point of view.

Standard plane wave and finite element methods for numerically solving (1.1) are based on variational principles, which consist in constructing a finite dimensional subspace of the Sobolev space $H^{1}(\Omega)$. Such conforming methods have been extensively studied for linear problems (see, e.g. [5, 14]). In contrast, the (L)APW basis functions are not continuous on the spherical surface due to the truncation of angular momentums in (1.3), so the finite dimensional approximation space no longer lies in $H^{1}(\Omega)$. Therefore, one gets a nonconforming method by using the (L)APW basis functions. There are a lot of existing results on analysis of the nonconforming finite element methods for solving linear elliptic problems, see e.g. [17, 30, 36, 48]. The advantages of the nonconforming idea lie in: (i) coupling different variational discretizations so as to take profit of the efficiency of each of them; (ii) more flexible and economical adaptive procedures as the refinements can be made on the subdomain where it is needed. The nonconforming idea in the APW method is also highly related to the mortar methods, which match incompatible grids with a suitable variational operator ensuring an optimal transmission of information between adjacent subdomains (see, e.g. [8-10]).

The KS equations form a nonlinear integro-differential eigenvalue problem with multiple eigenvalues to be considered, for which the numerical analysis is a difficult task. To our best knowledge, there are only a handful of very recent works concerning this problem, see, Cancès et al. [13], Chen et al. [16] and Suryanarayana et al. [49], and none of these numerical analysis can be applied to the APW method. In this paper, we shall establish the convergence of the eigenpair approximations and obtain an a priori error estimate, using the techniques that are related to the arguments in $[13,16,34]$. The results in this paper deal with the a priori error analysis, while the a posteriori error analysis is even more challenging and shall be investigated in our future works.

An outline of this paper is as follows. In Section 2, we state the model problem and some regularity results. In Section 3, we construct a nonconforming method analogous to the (L)APW methods with a complete basis set and obtain an a priori error estimate for linear eigenvalue problems. Further, the (L)APW methods are investigated under this framework and a numerical analysis is given. In Section 4, we give an a priori error estimate for ground state solutions of the nonlinear KS equations. In Section 5, we present several numerical experiments to support our theoretical results. Finally, some concluding remarks are made in Section 6.

## 2. Preliminary

Throughout this paper, we shall use $C$ to denote a generic positive constant which may stand for different values at its different occurrences and is independent of the discretization parameters. For convenience, the symbol $\lesssim$ will be used. The notation $A \lesssim B$ means that $A \leq C B$ for some constant $C$ that is independent of the discretization parameters. For $\mathbf{r} \in \mathbb{R}^{3}$, we shall denote by $r=|\mathbf{r}|$ and $\hat{\mathbf{r}}=\mathbf{r} / r$. Moreover, we shall denote $\sum_{l=0}^{\infty} \sum_{m=-l}^{l}$ by $\sum_{l m}$, and $\sum_{l=0}^{L} \sum_{m=-l}^{l}$ by $\sum_{l m}^{L}$ for simplicity.

Let $\Omega \subset \mathbb{R}^{3}$ be the simulation domain with periodic boundary conditions. We denote by $\mathcal{R}$ the periodic lattice, and by $\mathcal{R}^{*}$ the dual lattice. For simplicity, we assume that $\Omega=\left[-\frac{\ell}{2}, \frac{\ell}{2}\right]^{3}(\ell>0), \mathcal{R}=\ell \mathbb{Z}^{3}$, and $\mathcal{R}^{*}=\frac{2 \pi}{\ell} \mathbb{Z}^{3}$. For $\mathbf{k} \in \mathcal{R}^{*}$, we denote by $e_{\mathbf{k}}(\mathbf{r})=|\Omega|^{-1 / 2} \mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}}$ the plane wave with wave vector $\mathbf{k}$. The family $\left\{e_{\mathbf{k}}\right\}_{\mathbf{k} \in \mathcal{R}^{*}}$ forms an orthonormal basis set of

$$
L_{\#}^{2}(\Omega)=\left\{u \in L_{\mathrm{loc}}^{2}\left(\mathbb{R}^{3}\right): u \text { is } \mathcal{R} \text {-periodic }\right\}
$$

For all $u \in L_{\#}^{2}(\Omega)$, we have

$$
u(\mathbf{r})=\sum_{\mathbf{k} \in \mathcal{R}^{*}} \hat{u}_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r}) \quad \text { with } \quad \hat{u}_{\mathbf{k}}=|\Omega|^{-1 / 2} \int_{\Omega} u(\mathbf{r}) \mathrm{e}^{-i \mathbf{k} \cdot \mathbf{r}} \mathrm{~d} \mathbf{r}
$$

We introduce the Sobolev spaces of $\mathcal{R}$-periodic functions

$$
H_{\#}^{s}(\Omega)=\left\{u(\mathbf{r})=\sum_{\mathbf{k} \in \mathcal{R}^{*}} \hat{u}_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r}): \sum_{\mathbf{k} \in \mathcal{R}^{*}}\left(1+|\mathbf{k}|^{2}\right)^{s}\left|\hat{u}_{\mathbf{k}}\right|^{2}<\infty\right\}
$$

where $s \in \mathbb{R}_{+}$and $k=|\mathbf{k}|$. For $K \in \mathbb{N}$, we define

$$
\mathcal{V}_{K}=\left\{v_{K} \in L_{\#}^{2}(\Omega): v_{K}(\mathbf{r})=\sum_{\mathbf{k} \in \mathcal{R}^{*},|\mathbf{k}| \leq \frac{2 \pi}{\ell} K} c_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r})\right\} .
$$

For all $s \in \mathbb{R}_{+}$and each $v \in H_{\#}^{s}(\Omega)$, the best approximation of $v$ in $\mathcal{V}_{K}$ for $H^{r}$-norm $(r \leq s)$ is

$$
\Pi_{K} v=\sum_{\mathbf{k} \in \mathcal{R}^{*},|\mathbf{k}| \leq \frac{2 \pi}{\ell} K} \hat{v}_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r})
$$

The more regular $v$, the faster the convergence of this truncated series to $v$ : for real numbers $r$ and $s$ with $0<r \leq s$, we have

$$
\begin{equation*}
\left\|v-\Pi_{K} v\right\|_{H_{\#}^{r}(\Omega)}=\min _{v_{K} \in \mathcal{V}_{K}}\left\|v-v_{K}\right\|_{H_{\#}^{r}(\Omega)} \lesssim K^{r-s}\|v\|_{H_{\#}^{s}(\Omega)} \quad \forall v \in H_{\#}^{s}(\Omega) \tag{2.1}
\end{equation*}
$$

As a model problem, we consider the following Schrödinger type linear eigenvalue problem, which can be viewed as a linearization of (1.1): find $\lambda \in \mathbb{R}$ and $u \in H_{\#}^{1}(\Omega)$ such that $\|u\|_{L^{2}(\Omega)}=1$ and

$$
\begin{equation*}
a(u, v)=\lambda(u, v) \quad \forall v \in H_{\#}^{1}(\Omega) \tag{2.2}
\end{equation*}
$$

where the bilinear form $a: H_{\#}^{1}(\Omega) \times H_{\#}^{1}(\Omega) \rightarrow \mathbb{R}$ is defined by:

$$
\begin{equation*}
a(u, v)=\frac{1}{2} \int_{\Omega} \nabla u \cdot \nabla v+\int_{\Omega} V_{\mathrm{eff}} u v \tag{2.3}
\end{equation*}
$$

with the effective potential $V_{\text {eff }}$ being a smooth potential except at the positions of nuclei (see (2.7)).

It is sufficient for us to consider the system with a single nucleus located at the origin, the algorithms and analysis of which can be easily generalized to multi-nuclei systems. Throughout this paper, we shall denote by $\mathscr{C}$ the sphere centered at the origin, by $R$ the radius of the sphere, by $\Gamma$ the spherical surface, and by $\mathscr{D}$ the interstitial region.

Note that the plane wave approximations of (2.2) can not achieve as good convergence rate as (2.1) due to the cusps of electron density at the nuclear positions (see, e.g. [22-24]). In our analysis, we rely on the regularity result in weighted Sobolev space for Schrödinger type eigenvalue problems, which is developed in [21]. This type of analysis has been introduced to investigate singularities of boundary value problems in conical domains with corners and edges, we refer to $[6,19,26]$ for more details. In our case the geometry is fairly simple, while the singular electrostatic potential generated by the nuclei fits perfectly in this treatment.

Let $\mathbb{p} \in L_{\#}^{2}(\Omega)$ be a continuous function such that $p(\mathbf{r})=r$ in the neighborhood of $0, \mathbb{p} \in C_{\mathrm{loc}}^{\infty}\left(\mathbb{R}^{3} \backslash S\right)$ with $S=\ell \mathbb{Z}^{3}$ being the set of singular points of $\mathbb{P}$, and $\mathbb{P}(\mathbf{r})>0$ for $\mathbf{r} \in \mathbb{R}^{3} \backslash S$. We define the $k$ th weighted Sobolev space with index $\gamma$ by

$$
\begin{equation*}
\mathcal{K}^{k, \gamma}(\Omega)=\left\{u \in L_{\#}^{2}(\Omega): \mathbb{P}^{|\alpha|-\gamma} \partial^{\alpha} u \in L_{\#}^{2}(\Omega) \quad \forall|\alpha| \leq k\right\} \tag{2.4}
\end{equation*}
$$

where $k \in \mathbb{N}$ and $\gamma \in \mathbb{R}$. Note that the difference between the Sobolev space $H^{k}(\Omega)$ and the weighted Sobolev space $\mathcal{K}^{k, \gamma}(\Omega)$ only lays in the introduction of weight function $\mathbb{p}^{|\alpha|-\gamma}$. Consider a subspace of $\mathcal{K}^{s, \gamma}(\Omega)$ consisting of functions with the asymptotic expansions

$$
\begin{equation*}
u(\mathbf{r}) \sim \sum_{j \in \mathbb{N}_{0}} c_{j}(\hat{\mathbf{r}}) r^{j} \quad \text { as } r \rightarrow 0 \tag{2.5}
\end{equation*}
$$

where $c_{j}$ belongs to the finite dimensional subspace $M_{j}=\operatorname{span}\left\{Y_{l m}, 0 \leq l \leq j,|m| \leq l\right\} \subset C^{\infty}\left(S^{2}\right)$. We define the weighted Sobolev spaces with asymptotic type (2.5) as

$$
\begin{equation*}
\mathscr{K}^{k, \gamma}(\Omega)=\left\{u \in \mathcal{K}^{k, \gamma}(\Omega): u(\mathbf{r})-\omega(r) \sum_{j=0}^{N} c_{j}(\hat{\mathbf{r}}) r^{j} \in \mathcal{K}^{k, \gamma+N}(\Omega), \forall N \in \mathbb{N}\right\} \tag{2.6}
\end{equation*}
$$

where $\omega(r)$ is a smooth cut-off function, i.e. $\omega=1$ near 0 and $\omega=0$ outside some neighborhood of 0 . More precisely, $u(\mathbf{r})-\omega(r) \sum_{j=0}^{N} c_{j}(\hat{\mathbf{r}}) r^{j}$ in Definition (2.6) should be the periodic extension of the function defined on $\Omega$ by this expression.

Definition 2.1. A function $u$ is called asymptotically well behaved if $u \in \mathscr{K}^{\infty, \gamma}(\Omega)$ for $\gamma<3 / 2$.
We shall make the assumption on the effective potential that

$$
\begin{equation*}
V_{\mathrm{eff}}(\mathbf{r})=v_{\mathrm{ext}}(\mathbf{r})+v_{\mathrm{H}}(\rho(\mathbf{r}))+v_{\mathrm{s}}(\mathbf{r}) \quad \text { with } \quad v_{\mathrm{s}} \in C_{\#}^{\infty}(\Omega) \tag{2.7}
\end{equation*}
$$

where $v_{\text {ext }}(\mathbf{r})$ is a periodic function that equals $-Z /|\mathbf{r}|(Z \in \mathbb{N})$ in the neighborhood of 0 , and belongs to $C_{\mathrm{loc}}^{\infty}\left(\mathbb{R}^{3} \backslash S\right), \rho$ is an asymptotically well behaved function, and

$$
C_{\#}^{\infty}(\Omega)=\left\{v \in C_{\mathrm{loc}}^{\infty}\left(\mathbb{R}^{3}\right): v \text { is } \mathcal{R} \text {-periodic }\right\} .
$$

Here, $v_{\mathrm{H}}(\rho(\mathbf{r}))$ denotes the $\mathcal{R}$-periodic Coulomb potential generated by the $\mathcal{R}$-periodic electron density $\rho$ :

$$
\begin{equation*}
v_{\mathrm{H}}(\rho(\mathbf{r}))=4 \pi \sum_{\mathbf{k} \in \mathcal{R}^{*} \backslash\{0\}}|\mathbf{k}|^{-2} \hat{\rho}_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r}) . \tag{2.8}
\end{equation*}
$$

The following lemma concerning the regularity of the eigenfunctions of (2.2) is heavily used in our analysis, the proof of which is given in ([21], Thms. 1, 4 and Prop. 1).

Lemma 2.2. If $u$ is an eigenfunction of (2.2) with $V_{\text {eff }}$ satisfying (2.7), then $u$ is asymptotically well behaved.

Lemma 2.3. For any $s>0$ and $k \in \mathbb{N}, k>s+\frac{3}{2}$, if $u \in \mathscr{K}^{k, \gamma}(\Omega)$ with $\gamma<3 / 2$, then the restriction of $u$ to $\mathscr{C}$ satisfies $\left.u\right|_{\mathscr{C}} \in H^{s}\left([0, R] \times S^{2}\right)$.

Proof. For any $s>0$, we take $k>s+\frac{3}{2}$, and express the function $u \in \mathscr{K}^{k, \gamma}(\Omega)$ as

$$
\begin{equation*}
u(\mathbf{r})=\omega(r) \sum_{j=0}^{m} c_{j}(\hat{\mathbf{r}}) r^{j}+\Phi_{m+1}(\mathbf{r}) \tag{2.9}
\end{equation*}
$$

where $\Phi_{m+1} \in \mathcal{K}^{k, \beta}(\Omega)$ with $\beta<\frac{3}{2}+m$. For sufficiently large $m, \Phi_{m+1} \in \mathcal{K}^{k, k}(\Omega)$. Therefore, we have from the Definition (2.4) that

$$
\sum_{|\alpha| \leq k} \int_{\mathscr{C}} \mathbb{P}^{2|\alpha|-2 k}\left|\partial^{\alpha} \Phi_{m+1}\right|^{2}<\infty
$$

This implies $\Phi_{m+1} \in H^{k}(\mathscr{C})$. According to Sobolev's lemma, we have $H^{k}(\mathscr{C}) \subset C^{s}(\mathscr{C})$ for $s<k-\frac{3}{2}$, and hence $\Phi_{m+1} \in H^{s}\left([0, R] \times S^{2}\right)$.

Note that the first part of (2.9) already belongs to $C^{\infty}\left([0, R] \times S^{2}\right)$, we obtain $\left.u\right|_{\mathscr{C}} \in H^{s}\left([0, R] \times S^{2}\right)$, which completes the proof.

The following lemma will be used in our analysis, which states the relationship between two Sobolev norms.

Lemma 2.4. If $v \in H^{1}(\mathscr{C}) \bigcap H^{1}\left([0, R] \times S^{2}\right)$, then there exists a constant $C$ such that

$$
\|v\|_{H^{1}(\mathscr{C})} \leq C\|v\|_{H^{1}\left([0, R] \times S^{2}\right)} .
$$

Proof. Since in spherical coordinates

$$
\begin{equation*}
\Delta=\frac{1}{r^{2}} \frac{\partial}{\partial r}\left(r^{2} \frac{\partial}{\partial r}\right)+\frac{1}{r^{2} \sin \theta} \frac{\partial}{\partial \theta}\left(\sin \theta \frac{\partial}{\partial \theta}\right)+\frac{1}{r^{2} \sin ^{2} \theta} \frac{\partial^{2}}{\partial^{2} \phi} \tag{2.10}
\end{equation*}
$$

where the last two terms multiplied by $r^{2}$ is $\Delta_{S^{2}}$, i.e. the Laplace-Beltrami operator on $S^{2}$. We have

$$
\begin{aligned}
\|v\|_{H^{1}(\mathscr{C})}^{2} & =-\int_{\mathscr{C}} v \Delta v+\left.\int_{\Gamma} v \frac{\partial v}{\partial r}\right|_{r=R}+\int_{\mathscr{C}} v^{2} \\
& =\int_{0}^{R} r^{2} \mathrm{~d} r \int_{S^{2}}\left(v^{2}+\left(\frac{\partial v}{\partial r}\right)^{2}\right)-\int_{0}^{R} \mathrm{~d} r \int_{S^{2}}\left(v \Delta_{S^{2}} v\right) \\
& \leq R^{2} \int_{S^{2}}\|v\|_{H^{1}([0, R])}^{2}+\int_{0}^{R}\|v\|_{H^{1}\left(S^{2}\right)}^{2} \mathrm{~d} r \\
& \leq C\|v\|_{H^{1}\left([0, R] \times S^{2}\right)}^{2}
\end{aligned}
$$

where Green's formula is used for the second equality. This completes the proof.

## 3. Error estimates for Linear Schrödinger type equations

In this section, we shall consider a nonconforming approximation of (2.2) and extend the analysis to the (L)APW methods. We introduce the broken Sobolev space

$$
\begin{equation*}
H_{\# \delta}(\Omega)=\left\{v \in L_{\#}^{2}(\Omega):\left.v\right|_{\mathscr{C}} \in H^{1}(\mathscr{C}),\left.v\right|_{\mathscr{D}} \in H^{1}(\mathscr{D})\right\} \tag{3.1}
\end{equation*}
$$

equipped with the broken Sobolev norm

$$
\|v\|_{\delta}=\|v\|_{H^{1}(\mathscr{C})}+\|v\|_{H^{1}(\mathscr{D})}
$$

Define the subspace $H_{\# L}(\Omega) \subset H_{\# \delta}(\Omega)$ by

$$
\begin{equation*}
H_{\# L}(\Omega)=\left\{v \in H_{\# \delta}(\Omega): b(v, \psi)=0, \quad \forall \psi \in M_{L}\right\} \tag{3.2}
\end{equation*}
$$

where $M_{L}=\operatorname{span}\left\{Y_{l m}, 0 \leq l \leq L,|m| \leq l\right\}$ and the bilinear form $b: L_{\#}^{2}(\Omega) \times L^{2}\left(S^{2}\right) \rightarrow \mathbb{R}$ is given by

$$
b(v, \psi)=\int_{\Gamma} \psi\left(v^{+}-v^{-}\right) \mathrm{d} \Gamma
$$

with $v^{ \pm}$being the traces of $v$ taken from outside and inside the sphere, respectively.
Note that Definition 2.1 and Lemma 2.3 imply that an asymptotically well behaved function belongs to $H^{s}\left([0, R] \times S^{2}\right)$ in the sphere and $H^{s}(\mathscr{D})$ in the interstitial region for any $s>0$. For simplicity of notation, we introduce the space

$$
\tilde{H}_{L}^{s}(\Omega)=\left\{v \in H_{\# L}(\Omega):\left.v\right|_{\mathscr{D}} \in H^{s}(\mathscr{D}),\left.v\right|_{\mathscr{C}} \in H^{s}\left([0, R] \times S^{2}\right)\right\}
$$

with the induced norm

$$
\|v\|_{\tilde{H}_{L}^{s}(\Omega)}=\|v\|_{H^{s}(\mathscr{D})}+\|v\|_{H^{s}\left([0, R] \times S^{2}\right)}
$$

### 3.1. A nonconforming method

Define the space of functions on $\mathscr{D}$ expanded in plane waves

$$
\mathcal{P}_{K}(\mathscr{D})=\left\{u \in H^{1}(\mathscr{D}): u(\mathbf{r})=\left.\sum_{|\mathbf{k}| \leq \frac{2 \pi}{L} K} c_{\mathbf{k}} e_{\mathbf{k}}(\mathbf{r})\right|_{\mathscr{D}}\right\}
$$

and the space of functions on $\mathscr{C}$ expanded in polynomial times spherical harmonics

$$
\mathcal{B}_{N L}(\mathscr{C})=\left\{u \in H^{1}(\mathscr{C}): u(\mathbf{r})=\sum_{l m}^{L} \sum_{n=0}^{N} c_{n l m} \chi_{n}(r) Y_{l m}(\hat{\mathbf{r}})\right\}
$$

where $\left\{\chi_{n}\right\}_{n=0}^{N}$ forms a basis set of the space of polynomials on $[0, R]$ with degree at most $N$. Let

$$
\begin{equation*}
\mathcal{S}_{N L}^{K}(\Omega)=\left\{u \in L_{\#}^{2}(\Omega):\left.u\right|_{\mathscr{C}} \in \mathcal{B}_{N L}(\mathscr{C}) \text { and }\left.u\right|_{\mathscr{D}} \in \mathcal{P}_{K}(\mathscr{D})\right\} \tag{3.3}
\end{equation*}
$$

and $\varrho=\min \{K, N, L\}$. We may assume throughout this paper that $\varrho \geq C \max \{K, N, L\}$.
Based on the above constructions, we have the nonconforming approximation space

$$
\begin{equation*}
V_{\varrho}(\Omega)=H_{\# L}(\Omega) \cap \mathcal{S}_{N L}^{K}(\Omega) \tag{3.4}
\end{equation*}
$$

which does not lie in $H_{\#}^{1}(\Omega)$. The nonconforming approximation of (2.2) is: find $\lambda_{\varrho}\left(=\lambda_{N L}^{K}\right) \in \mathbb{R}$ and $u_{\varrho}\left(=u_{N L}^{K}\right) \in V_{\varrho}$ such that $\left\|u_{\varrho}\right\|_{L^{2}(\Omega)}=1$ and

$$
\begin{equation*}
a_{\delta}\left(u_{\varrho}, v\right)=\lambda_{\varrho}\left(u_{\varrho}, v\right) \quad \forall v \in V_{\varrho}, \tag{3.5}
\end{equation*}
$$

where the bilinear form $a_{\delta}(\cdot, \cdot): H_{\# \delta}(\Omega) \times H_{\# \delta}(\Omega) \rightarrow \mathbb{R}$ is given by

$$
\begin{equation*}
a_{\delta}(u, v)=\frac{1}{2} \int_{\mathscr{C}} \nabla u \cdot \nabla v+\frac{1}{2} \int_{\mathscr{D}} \nabla u \cdot \nabla v+\int_{\Omega} V_{\mathrm{eff}} u v \tag{3.6}
\end{equation*}
$$

Since $v_{\text {ext }} \in L_{\#}^{2}(\Omega)$ and $\int_{\Omega} v_{\mathrm{H}}(\rho) u v \leq C_{H}\|\rho\|_{L^{2}(\Omega)}\|u\|_{L^{2}(\Omega)}\|v\|_{L^{2}(\Omega)}\left(C_{H}\right.$ is a constant, see [13], (3.17)), we have from (2.7) that for all $v \in H_{\# \delta}(\Omega)$,

$$
\begin{align*}
a_{\delta}(v, v) \geq & \frac{1}{2}\|\nabla v\|_{L^{2}(\mathscr{C})}^{2}+\frac{1}{2}\|\nabla v\|_{L^{2}(\mathscr{D})}^{2}-\left\|v_{\mathrm{ext}}\right\|_{L^{2}(\Omega)}\|v\|_{L^{2}(\Omega)}^{1 / 2}\|v\|_{L^{6}(\Omega)}^{3 / 2} \\
& -C_{H}\|\rho\|_{L^{2}(\Omega)}\|v\|_{L^{2}(\Omega)}^{2}-\left\|v_{s}\right\|_{L^{\infty}(\Omega)}\|v\|_{L^{2}(\Omega)}^{2} \\
\geq & C\|v\|_{\delta}^{2}-\nu\|v\|_{L^{2}(\Omega)}^{2} \tag{3.7}
\end{align*}
$$

where $C$ and $\nu$ are positive constants. Using a shift of the bilinear form $a_{\delta}^{\nu}(u, v)=a_{\delta}(u, v)+\nu(u, v),(3.5)$ is equivalent to

$$
a_{\delta}^{\nu}\left(u_{\varrho}, v\right)=\left(\lambda_{\varrho}+\nu\right)\left(u_{\varrho}, v\right) \quad \forall v \in V_{\varrho}
$$

with the same $\left(\lambda_{\varrho}, u_{\varrho}\right)$. Therefore, we may assume afterwards without loss of generality that there exists $C>0$, such that

$$
\begin{equation*}
a_{\delta}(v, v) \geq C\|v\|_{\delta}^{2} \quad \forall v \in H_{\# \delta}(\Omega) \tag{3.8}
\end{equation*}
$$

Note that (3.8) together with the fact $H_{\#}^{1}(\Omega) \subset H_{\# \delta}(\Omega)$ implies $a(v, v) \geq C\|v\|_{H_{\#}^{1}(\Omega)}$ for all $v \in H_{\#}^{1}(\Omega)$.
To obtain the a priori error estimate of the nonconforming approximations, we shall first construct a basis set of $V_{\varrho}$. Let $\left\{\chi_{n}\right\}_{n=0}^{N}$ be a basis set that spans the space of polynomials on $[0, R]$ with degree at most $N$ and satisfies (see, e.g. Fig. 2)

$$
\begin{equation*}
\chi_{n}(R)=0 \quad \text { for } \quad n=0, \ldots, N-1, \quad \text { and } \quad \chi_{N}(r)=\frac{r}{R} \tag{3.9}
\end{equation*}
$$

Note that the subspace $\tilde{\mathcal{B}}_{N L} \subset \mathcal{B}_{N L}$ defined by

$$
\tilde{\mathcal{B}}_{N L}=\left\{u \in H_{0}^{1}(\mathscr{C}): u(\mathbf{r})=\sum_{l m}^{L} \sum_{n=0}^{N-1} c_{n l m} \chi_{n}(r) Y_{l m}(\hat{\mathbf{r}})\right\}
$$

is a finite dimensional subspace of $H_{0}^{1}(\mathscr{C})$.
Define

$$
\omega_{\mathbf{k}}(\mathbf{r})= \begin{cases}|\Omega|^{-\frac{1}{2}} \mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}} & \text { in } \mathscr{D} \\ \sum_{l m}^{L} \beta_{l m}^{\mathbf{k}} \chi_{N}(r) Y_{l m}(\hat{\mathbf{r}}) & \text { in } \mathscr{C}\end{cases}
$$

where the coefficients

$$
\begin{equation*}
\beta_{l m}^{\mathbf{k}}=|\Omega|^{-1 / 2} 4 \pi i^{l} j_{l}(k R) Y_{l m}^{*}(\hat{\mathbf{k}}) / \chi_{N}(R) \tag{3.10}
\end{equation*}
$$

Figure 2. Schematic plots of radial basis functions $\chi_{n}(r) n=0, \ldots, N$ satisfying (3.9).
are determined by the continuity constraint in (3.2) together with the scattering expansion [40]

$$
\begin{equation*}
\mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}}=4 \pi \sum_{l m} i^{l} j_{l}(k r) Y_{l m}^{*}(\hat{\mathbf{k}}) Y_{l m}(\hat{\mathbf{r}}) . \tag{3.11}
\end{equation*}
$$

Set $\tilde{V}_{\varrho}=\tilde{\mathcal{B}}_{N L} \oplus \operatorname{span}\left\{\omega_{\mathbf{k}}(\mathbf{r}):|\mathbf{k}| \leq K\right\}$. It is obvious from the definition of $\omega_{\mathbf{k}}$ that $\tilde{V}_{\varrho} \subset V_{\varrho}$, which together with the fact

$$
\operatorname{dim}\left(V_{\varrho}\right)=\operatorname{dim}\left(\mathcal{P}_{K}\right)+\operatorname{dim}\left(\mathcal{B}_{N L}\right)-\operatorname{dim}\left(M_{L}\right)=\operatorname{dim}\left(\mathcal{P}_{K}\right)+\operatorname{dim}\left(\tilde{\mathcal{B}}_{N L}\right)=\operatorname{dim}\left(\tilde{V}_{\varrho}\right)
$$

implies $V_{\varrho}=\tilde{V}_{\varrho}$. Having a set of basis functions that span $V_{\varrho}$, we can derive the error for the best approximation in this finite dimensional space.

Lemma 3.1. If $u \in \tilde{H}_{L}^{s}(\Omega)$ for $s>3 / 2$, then there exists a constant $C$ such that

$$
\begin{equation*}
\inf _{v_{e} \in V_{e}}\left\|u-v_{\varrho}\right\|_{\delta} \leq C \varrho^{-(s-3 / 2)}\|u\|_{\tilde{H}_{L}^{s}(\Omega)} . \tag{3.12}
\end{equation*}
$$

Proof. Split $u$ into two parts $u=u_{1}+u_{2}$ such that

$$
u_{1}(\mathbf{r})=\left\{\begin{array}{l}
u(\hat{\mathbf{r}} R) \cdot \frac{r}{R} \text { in } \mathscr{C} \\
u
\end{array} \quad \text { in } \mathscr{D} \quad \text { and } \quad u_{2}=u-u_{1} \in H_{0}^{1}(\mathscr{C}),\right.
$$

where $u(\hat{\mathbf{r}} R)$ is the trace of $\left.u\right|_{\mathscr{C}}$ on $\Gamma$. We approximate these two parts separately.
To approximate $u_{1}$, we shall first extend $\left.u\right|_{\mathscr{D}}$ smoothly into the sphere $\mathscr{C}$. Note that $u$ can be represented by

$$
u(\mathbf{r})=\sum_{l m} u_{l m}(r) Y_{l m}(\hat{\mathbf{r}})
$$

around the sphere surface with $u_{l m}(r)=\int_{S^{2}} u(\mathbf{r}) Y_{l m}(\hat{\mathbf{r}})$. We can define

$$
\tilde{u}(\mathbf{r})=\left\{\begin{array}{lr}
u(\mathbf{r}) & \text { in } \mathscr{D},  \tag{3.13}\\
\sum_{l m} \varphi_{l m}(r) Y_{l m}(\hat{\mathbf{r}}) & \text { in } \mathscr{C},
\end{array}\right.
$$

where $\varphi_{l m}(r)=\tau(r) \sum_{n=1}^{\bar{s}+1} c_{n} u_{l m}\left(R+\frac{1}{n}(R-r)\right)$ with $\bar{s}$ being the ceil integer of $s, c_{n}$ being the coefficients such that $\sum_{n=1}^{\bar{s}+1}\left(-\frac{1}{n}\right)^{k} c_{n}=1(k=0,1, \ldots, \bar{s})$, and $\tau \in C^{\infty}([0, R])$ satisfying $\tau=0$ in $\left[0, \frac{R}{3}\right]$ and $\tau=1$ in $\left[\frac{2 R}{3}, R\right]$. We observe by a direct calculation that $u \in H^{s}(\mathscr{D})$ leads to $\tilde{u} \in H^{s}(\Omega)$, and

$$
\begin{equation*}
\|\tilde{u}\|_{H^{s}(\Omega)} \leq \beta_{s}\|u\|_{H^{s}(\mathscr{D})}, \tag{3.14}
\end{equation*}
$$

where the constant $\beta_{s}$ is only related to $s, R$ and $\|\tau\|_{H^{s}[0, R]}$. Let

$$
\begin{equation*}
\tilde{c}_{\mathbf{k}}=|\Omega|^{-1 / 2} \int_{\Omega} \tilde{u}(\mathbf{r}) \mathrm{e}^{-i \mathbf{k} \cdot \mathbf{r}} \mathrm{~d} \mathbf{r} \quad \text { and } \quad v_{1}=\sum_{|\mathbf{k}| \leq K} \tilde{c}_{\mathbf{k}} \omega_{\mathbf{k}} \tag{3.15}
\end{equation*}
$$

We have from (3.14) that

$$
\begin{align*}
\left\|u_{1}-v_{1}\right\|_{H^{1}(\mathscr{D})} & =\left\|\tilde{u}-\sum_{|\mathbf{k}| \leq K} \tilde{c}_{\mathbf{k}} e_{\mathbf{k}}\right\|_{H^{1}(\mathscr{D})} \leq\left\|\tilde{u}-\sum_{|\mathbf{k}| \leq K} \tilde{c}_{\mathbf{k}} e_{\mathbf{k}}\right\|_{H^{1}(\Omega)} \\
& \leq C K^{-(s-1)}\|\tilde{u}\|_{H^{s}(\Omega)} \leq C \beta_{s} K^{-(s-1)}\|u\|_{H^{s}(\mathscr{D})} . \tag{3.16}
\end{align*}
$$

Using Lemma 2.4, the definition of $\omega_{\mathbf{k}}$, and the trace theorem, we have

$$
\begin{align*}
\left\|u_{1}-v_{1}\right\|_{H^{1}(\mathscr{C})} & \lesssim\left\|u_{1}-v_{1}\right\|_{H^{1}\left([0, R] \times S^{2}\right)} \\
& =\left\|\chi_{N}(r)\left(u(\hat{\mathbf{r}} R)-\left.v_{1}(\hat{\mathbf{r}} R)\right|_{\mathscr{C}}\right)\right\|_{H^{1}\left([0, R] \times S^{2}\right)} \\
& \lesssim\left\|u-\left.v_{1}\right|_{\mathscr{C}}\right\|_{H^{1}(\Gamma)} \\
& \lesssim\left\|\left.v_{1}\right|_{\mathscr{C}}-\left.v_{1}\right|_{\mathscr{D}}\right\|_{H^{1}(\Gamma)}+\left\|u-\left.v_{1}\right|_{\mathscr{D}}\right\|_{H^{1}(\Gamma)} \\
& \lesssim L^{-(s-3 / 2)}\left\|v_{1}\right\|_{H^{s}(\mathscr{D})}+\left\|u-v_{1}\right\|_{H^{3 / 2}(\mathscr{D})} \tag{3.17}
\end{align*}
$$

Using the same argument as that in (3.16), we can derive

$$
\left\|u-v_{1}\right\|_{H^{3 / 2}(\mathscr{D})} \lesssim K^{-(s-3 / 2)}\|u\|_{H^{s}(\mathscr{D})}
$$

which together with (3.16) and (3.17) leads to

$$
\begin{equation*}
\left\|u_{1}-v_{1}\right\|_{\delta} \leq C\left(L^{-(s-3 / 2)}+K^{-(s-3 / 2)}\right)\|u\|_{H^{s}(\mathscr{D})} . \tag{3.18}
\end{equation*}
$$

For approximation of $u_{2}$, we define the projection $P_{N}: H^{1}([0, R]) \rightarrow \Psi_{N}=\operatorname{span}\left\{\chi_{n}, 0 \leq n \leq N-1\right\}$ satisfying

$$
\left(\nabla\left(v-P_{N} v\right), \nabla \psi\right)=0 \quad \forall \psi \in H^{1}([0, R])
$$

and the projection $P_{L}: L^{2}\left(S^{2}\right) \rightarrow M_{L}=\operatorname{span}\left\{Y_{l m}, 0 \leq l \leq L,|m| \leq l\right\}$ by

$$
P_{L} \varphi(\hat{\mathbf{r}})=\sum_{l m}^{L} \check{\varphi}_{l m} Y_{l m}(\hat{\mathbf{r}}) \quad \text { with } \quad \check{\varphi}_{l m}=\int_{S^{2}} \varphi(\hat{\mathbf{r}}) Y_{l m}(\hat{\mathbf{r}})
$$

Define the projection $\mathbb{P}^{N L}: H^{1}\left([0, R] \times S^{2}\right) \rightarrow \Psi_{N} \times M_{L}$ by $\mathbb{P}^{N L}=P_{N} \circ P_{L}$. Using standard error estimates for polynomial and spherical harmonics approximations, we obtain that for any $u_{2} \in H_{0}^{1}(\mathscr{C}) \cap H^{s}\left([0, R] \times S^{2}\right)$,

$$
\begin{equation*}
\left\|u_{2}-\mathbb{P}^{N L} u_{2}\right\|_{H^{1}\left([0, R] \times S^{2}\right)} \leq C\left(L^{-(s-1)}+N^{-(s-1)}\right)\left\|u_{2}\right\|_{H^{s}\left([0, R] \times S^{2}\right)} \quad \forall s>1 . \tag{3.19}
\end{equation*}
$$

Taking $v_{2}=\mathbb{P}^{N L} u_{2}$, we have from Lemmas 2.4 and (3.19) that

$$
\begin{align*}
\left\|u_{2}-v_{2}\right\|_{H^{1}(\mathscr{C})} & \leq\left\|u_{2}-v_{2}\right\|_{H^{1}\left([0, R] \times S^{2}\right)} \\
& \leq C\left(L^{-(s-3 / 2)}+N^{-(s-3 / 2)}\right)\left\|u_{2}\right\|_{H^{s-1 / 2}\left([0, R] \times S^{2}\right)} \quad \forall s>3 / 2 \tag{3.20}
\end{align*}
$$

Note that

$$
\begin{aligned}
\left\|u_{2}\right\|_{H^{s-1 / 2}\left([0, R] \times S^{2}\right)} & \leq\|u\|_{H^{s-1 / 2}\left([0, R] \times S^{2}\right)}+\left\|u(\hat{\mathbf{r}} R) \frac{r}{R}\right\|_{H^{s-1 / 2}\left([0, R] \times S^{2}\right)} \\
& \lesssim\|u\|_{H^{s-1 / 2}\left([0, R] \times S^{2}\right)}+\|u\|_{H^{s-1 / 2}(\Gamma)} \\
& \lesssim\|u\|_{H^{s}\left([0, R] \times S^{2}\right)}+\|u\|_{H^{s}(\mathscr{D})} .
\end{aligned}
$$

We can derive (3.12) by taking (3.18), (3.20) and the fact $v_{1}+v_{2} \in V_{\varrho}$ into account. This completes the proof.
Remark 3.2. We shall mention that the error estimate obtained in Lemma 3.1 may not be optimal, one would expect $\varrho^{-(s-1)}$ instead. The reason lies in that the approximation of $u$ we construct in the proof is not a direct projection onto the finite dimensional space $V_{\varrho}$. Instead, we project $\left.u\right|_{\mathscr{D}}$ onto $\mathcal{P}_{K}$, and the approximation of $\left.u\right|_{\mathscr{C}}$ in the sphere is partially determined by the approximation outside the sphere through the surface $\Gamma$. This process may lead to a loss of accuracy.

Nevertheless, if the function $u$ has sufficiently high regularity (for instance, if $u$ is asymptotically well behaved, then $s$ can be arbitrarily large by Lem. 2.2), then we may be satisfied with this convergence rate.

Define the operator $T: L_{\#}^{2}(\Omega) \rightarrow H_{\#}^{1}(\Omega)$ such that for $f \in L_{\#}^{2}(\Omega)$,

$$
\begin{equation*}
a(T f, v)=(f, v) \quad \forall v \in H_{\#}^{1}(\Omega) \tag{3.21}
\end{equation*}
$$

Then (2.2) is equivalent to the operator form $T u=\lambda^{-1} u$. We also define the operator $T_{\varrho}: L_{\#}^{2}(\Omega) \rightarrow V_{\varrho}$ such that for $f \in L_{\#}^{2}(\Omega)$,

$$
\begin{equation*}
a_{\delta}\left(T_{\varrho} f, v\right)=(f, v) \quad \forall v \in V_{\varrho} \tag{3.22}
\end{equation*}
$$

We have that (3.5) is equivalent to $T_{\varrho} u_{\varrho}=\lambda_{\varrho}^{-1} u_{\varrho}$. Note that $T$ and $T_{\varrho}$ are well-defined due to (3.8). One can prove that $T$ and $T_{\varrho}$ are self-adjoint operators on $L_{\#}^{2}(\Omega)$ and satisfy the following lemma.
Lemma 3.3. If $T f \in \tilde{H}_{L}^{s}(\Omega)$ for $s>3 / 2$ and $f \in L_{\#}^{2}(\Omega)$, then there exists a constant $C$ such that

$$
\begin{equation*}
\left\|T f-T_{\varrho} f\right\|_{\delta} \leq C \varrho^{-(s-3 / 2)}\|T f\|_{\tilde{H}_{L}^{s}(\Omega)} \tag{3.23}
\end{equation*}
$$

Proof. Let $u=T f$ and $u_{\varrho}=T_{\varrho} f$. Processing in a standard way (see, e.g. [11, 12, 42]), we get

$$
\begin{equation*}
\left\|u-u_{\varrho}\right\|_{\delta} \leq C\left(\inf _{v_{\varrho} \in V_{\varrho}}\left\|u-v_{\varrho}\right\|_{\delta}+\sup _{v_{\varrho} \in V_{\varrho}} \frac{a_{\delta}\left(u-u_{\varrho}, v_{\varrho}\right)}{\left\|v_{\varrho}\right\|_{\delta}}\right) \tag{3.24}
\end{equation*}
$$

and

$$
a_{\delta}\left(u-u_{\varrho}, v_{\varrho}\right)=b\left(v_{\varrho}, \varphi-\psi_{L}\right) \quad \forall v_{\varrho} \in V_{\varrho}, \quad \forall \psi_{L} \in M_{L}
$$

with $\varphi=\frac{\partial u}{\partial n}$, which together imply

$$
\begin{equation*}
\left\|u-u_{\varrho}\right\|_{\delta} \leq C\left(\inf _{v_{\varrho} \in V_{\varrho}}\left\|u-v_{\varrho}\right\|_{\delta}+\sup _{v_{\varrho} \in V_{\varrho}} \inf _{\psi_{L} \in M_{L}} \frac{b\left(v_{\varrho}, \varphi-\psi_{L}\right)}{\left\|v_{\varrho}\right\|_{\delta}}\right) \tag{3.25}
\end{equation*}
$$

The first term in the right-hand side of (3.25) is the best approximation error, which has been obtained in Lemma 3.1. The second term is nothing else than the consistency error, which indicates the variational crime committed by the nonconforming discretization.

For the consistency error, we have

$$
\begin{align*}
\inf _{\psi_{L} \in M_{L}} b\left(v_{\varrho}, \varphi-\psi_{L}\right) & =\inf _{\psi_{L} \in M_{L}} \int_{\Gamma}\left(v_{\varrho}^{+}-v_{\varrho}^{-}\right)\left(\varphi-\psi_{L}\right) \\
& \leq \inf _{\psi_{L} \in M_{L}}\left\|v_{\varrho}^{+}-v_{\varrho}^{-}\right\|_{H^{1 / 2}(\Gamma)}\left\|\varphi-\psi_{L}\right\|_{H^{-1 / 2}(\Gamma)} \\
& \leq C L^{-(s-1)}\left(\left\|v_{\varrho}^{+}\right\|_{H^{1}(\mathscr{C})}+\left\|v_{\varrho}^{-}\right\|_{H^{1}(\mathscr{D})}\right)\left\|\frac{\partial u}{\partial n}\right\|_{H^{s-3 / 2}(\Gamma)} \\
& \leq C L^{-(s-1)}\left\|v_{\varrho}\right\|_{\delta}\|u\|_{H^{s}(\mathscr{D})} \tag{3.26}
\end{align*}
$$

where the trace inequality is used.

Taking (3.12), (3.25) and (3.26) into account, we obtain (3.23), which completes the proof.
Denote by $\vartheta(T)$ the spectrum and $\rho(T)$ the resolvent set respectively of the solution operator $T$. For any $z \in \mathbb{C}$ in $\rho(T)$, we define the resolvent operator $R_{z}(T)=(z-T)^{-1}$. Let $\lambda^{-1}$ be an eigenvalue of $T$ and $\gamma$ be a circle in the complex plane centered at $\lambda^{-1}$, which does not enclose any other point of $\vartheta(T)$. We define the operators $\mathscr{E}$ and $\mathscr{E}_{\varrho}$ by

$$
\mathscr{E}=\mathscr{E}\left(\lambda^{-1}\right)=\frac{1}{2 \pi i} \int_{\gamma} R_{z}(T) \mathrm{d} z, \quad \mathscr{E}_{\varrho}=\mathscr{E}_{\varrho}\left(\lambda^{-1}\right)=\frac{1}{2 \pi i} \int_{\gamma} R_{z}\left(T_{\varrho}\right) \mathrm{d} z
$$

If $K, N, L$ are sufficiently large, then $\mathscr{E}$ and $\mathscr{E}_{\varrho}$ are the spectral projectors (relative to $\lambda^{-1}$ ) of $T$ and $T_{\varrho}$ respectively.

To evaluate the distance between eigenspaces, we need a suitable notation. Let $X$ and $Y$ be two closed subspaces of $H_{\# L}(\Omega)$. We define (see, e.g. [41])

$$
\hat{\delta}(X, Y):=\sup _{x \in X,\|x\|_{L^{2}(\Omega)}=1} \inf _{y \in Y,\|y\|_{L^{2}(\Omega)}=1}\|x-y\|_{\delta}
$$

and denote the gap between $X$ and $Y$ by

$$
\delta(X, Y)=\max \{\hat{\delta}(X, Y), \hat{\delta}(Y, X)\}
$$

The following theorem is the main result of this section, which states the convergence rate of the nonconforming eigenpair approximations.

Theorem 3.4. Let $\lambda$ be an eigenvalue of (2.2) with $\operatorname{dim}(\mathscr{R}(\mathscr{E}))=m$, where $\mathscr{R}$ denotes the range. If (2.7) is satisfied and $\varrho$ is sufficiently large, then there exist $m$ eigenvalues $\lambda_{1, \varrho}, \ldots, \lambda_{m, \varrho}$ of (3.5) such that for any $s>3 / 2$,

$$
\begin{equation*}
\sup _{1 \leq i \leq m}\left|\lambda-\lambda_{i, \varrho}\right|+\delta\left(\mathscr{R}(\mathscr{E}), \mathscr{R}\left(\mathscr{E}_{\varrho}\right)\right) \leq C_{s} \varrho^{-(s-3 / 2)} \tag{3.27}
\end{equation*}
$$

where $C_{s}$ is a constant depending on $s$.
Proof. Similar to (2.10), we have

$$
-\frac{1}{2} \Delta+V_{\mathrm{eff}}=-\frac{1}{2 r^{2}}\left[\frac{\partial}{\partial r}\left(r^{2} \frac{\partial}{\partial r}\right)+\frac{1}{\sin \theta} \frac{\partial}{\partial \theta}\left(\sin \theta \frac{\partial}{\partial \theta}\right)+\frac{1}{\sin ^{2} \theta} \frac{\partial^{2}}{\partial^{2} \phi}-2 r^{2} V_{\mathrm{eff}}\right]
$$

in spherical coordinates. For operators of this form, one can apply the regularity results in ([19], p. 257, Thm. 9 and (8.137)). More precisely, for any $f \in L_{\#}^{2}(\Omega)$, we have $T f \in \tilde{H}_{L}^{2}(\Omega)$ and

$$
\begin{equation*}
\|T f\|_{\tilde{H}_{L}^{2}(\Omega)} \leq C\|f\|_{L^{2}(\Omega)} \tag{3.28}
\end{equation*}
$$

For any $f \in L_{\#}^{2}(\Omega)$, we have the following very rough $L^{2}$-error estimate

$$
\begin{equation*}
\left\|\left(T-T_{\varrho}\right) f\right\|_{L^{2}(\Omega)} \leq\left\|T f-T_{\varrho} f\right\|_{\delta} \lesssim \varrho^{-1 / 2}\|T f\|_{\tilde{H}_{L}^{2}(\Omega)} \lesssim \varrho^{-1 / 2}\|f\|_{L^{2}(\Omega)} \tag{3.29}
\end{equation*}
$$

where Lemmas 3.3 and (3.28) are used. Therefore, we have

$$
\begin{equation*}
\lim _{\varrho \rightarrow \infty}\left\|T-T_{\varrho}\right\|_{\mathscr{L}\left(L_{\#}^{2}(\Omega), L_{\#}^{2}(\Omega)\right)} \leq C \lim _{\varrho \rightarrow \infty} \varrho^{-1 / 2}=0 \tag{3.30}
\end{equation*}
$$

Using (3.30) and the result in Theorem 1 of [41], we have the convergence of the eigenvalues (i.e., there exist $m$ eigenvalues $\lambda_{1, \varrho}, \ldots, \lambda_{m, \varrho}$ of (3.5) such that $\left.\lim _{\varrho \rightarrow \infty}\left|\lambda-\lambda_{i, \varrho}\right|=0, i=1, \ldots, m\right)$ and

$$
\begin{equation*}
\delta\left(\mathscr{R}(\mathscr{E}), \mathscr{R}\left(\mathscr{E}_{\mathscr{Q}}\right)\right) \lesssim\left\|T-T_{\varrho}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right) .} \tag{3.31}
\end{equation*}
$$

It is now only necessary for us to estimate the right-hand side of (3.31). Using Lemma 3.3, the regularity results in Lemma 2.2, 2.3, and the fact $T v=\lambda^{-1} v$ for $v \in \mathscr{R}(\mathscr{E})$, we have

$$
\begin{align*}
\left\|T-T_{\varrho}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right)} & \leq \sup _{v \in \mathscr{R}(\mathscr{E}),\|v\|_{L^{2}(\Omega)}=1}\left\|T v-T_{\varrho} v\right\|_{\delta} \\
& \leq C \varrho^{-(s-3 / 2)} \sup _{v \in \mathscr{R}(\mathscr{E}),\|v\|_{L^{2}(\Omega)}=1}\|v\|_{\tilde{H}_{L}^{s}(\Omega)} \\
& \leq C_{s} \varrho^{-(s-3 / 2)} \quad \forall s>\frac{3}{2} . \tag{3.32}
\end{align*}
$$

This completes the estimate for $\delta\left(\mathscr{R}(\mathscr{E}), \mathscr{R}\left(\mathscr{E}_{\varrho}\right)\right)$.
For eigenvalue estimate, we obtain by a simple calculation that

$$
\begin{equation*}
\lambda_{\varrho}-\lambda=a_{\delta}\left(u-u_{\varrho}, u-u_{\varrho}\right)-\lambda\left(u-u_{\varrho}, u-u_{\varrho}\right)+2 D_{\varrho} \tag{3.33}
\end{equation*}
$$

with the consistency error

$$
\begin{align*}
\left|D_{\varrho}\right| & =\left|a_{\delta}\left(u, u_{\varrho}\right)-\lambda\left(u, u_{\varrho}\right)\right|=\left|\int_{\Gamma} \frac{\partial u}{\partial n}\left(u_{\varrho}^{+}-u_{\varrho}^{-}\right)\right| \\
& \leq \inf _{\psi_{L} \in M_{L}}\left\|\frac{\partial u}{\partial n}-\psi_{L}\right\|_{H^{-1 / 2}(\Gamma)}\left\|u_{\varrho}^{+}-u_{\varrho}^{-}\right\|_{H^{1 / 2}(\Gamma)} \\
& \leq C L^{-(s-1)}\|u\|_{H^{s}(\mathscr{D})}\left\|u_{\varrho}\right\|_{\delta}, \tag{3.34}
\end{align*}
$$

where similar argument as that in (3.26) is used.
For any eigenpair $\left(\lambda_{i, \varrho}, u_{i, \varrho}\right)$ of (3.5) with $1 \leq i \leq m$, we can find an eigenfunction $u \in \mathscr{R}(\mathscr{E})$ and $\|u\|_{L^{2}(\Omega)}=1$, such that $\left\|u_{i, \varrho}-u\right\|_{\varrho} \leq C \varrho^{-(s-3 / 2)}$. This together with (3.33) and (3.34) leads to $\left|\lambda-\lambda_{i, \varrho}\right| \leq C \varrho^{-(s-3 / 2)}$, which completes the proof of (3.27).

### 3.2. APW method

The APW method can be viewed as a modified method of the nonconforming scheme under the assumption that the effective potential is spherically symmetric inside the atomic sphere $\mathscr{C}$, say $V_{\text {eff }}(\mathbf{r})=V(r)$ for $r \leq R$. It replaces the radial basis function $\chi_{N}(r)$ by $\chi_{l}(r, E)$, which is the regular solution of the following radial Schrödinger equation with parameter $E$ :

$$
\begin{equation*}
-\frac{1}{r^{2}} \frac{\mathrm{~d}}{\mathrm{~d} r}\left(r^{2} \frac{\mathrm{~d} \chi_{l}}{\mathrm{~d} r}\right)+\left(\frac{l(l+1)}{r^{2}}+V(r)-E\right) \chi_{l}=0 \quad \forall r \in[0, R] . \tag{3.35}
\end{equation*}
$$

The approximation space is $V_{K L}^{E}=\operatorname{span}\left\{\omega_{\mathbf{k} L}^{E}\right\}_{|\mathbf{k}| \leq K}$ with

$$
\omega_{\mathbf{k} L}^{E}(\mathbf{r})= \begin{cases}|\Omega|^{-\frac{1}{2}} \mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}} & \text { in } \mathscr{D},  \tag{3.36}\\ \sum_{l m}^{L} \alpha_{l m}^{\mathbf{k}} \chi_{l}(r, E) Y_{l m}(\hat{\mathbf{r}}) & \text { in } \mathscr{C}\end{cases}
$$

where the coefficients $\alpha_{l m}^{\mathbf{k}}$ are determined by the expansion (3.11) as

$$
\begin{equation*}
\alpha_{l m}^{\mathbf{k}}=4 \pi i^{l} j_{l}(k R) Y_{l m}^{*}(\hat{\mathbf{k}}) / \chi_{l}(R, E) \tag{3.37}
\end{equation*}
$$

so that the constraint in (3.2) is satisfied. Since the effective potential is spherically symmetric, $\left\{\omega_{\mathbf{k} L}^{E}(\mathbf{r})\right\}_{|\mathbf{k}|<K}$ are solutions of the Schrödinger type equation inside the sphere, but only with the eigenvalue $E$. Consequently, $E$ must be set equal to the eigenvalue to be calculated. This leads to a nonlinear eigenvalue problem: find $\lambda_{K L} \in \mathbb{R}$ and $0 \neq u_{K L} \in V_{K L}^{\lambda_{K L}}$, such that

$$
\begin{equation*}
a_{\delta}\left(u_{K L}, v\right)=\lambda_{K L}\left(u_{K L}, v\right) \quad \forall v \in V_{K L}^{\lambda_{K L}} \tag{3.38}
\end{equation*}
$$

where $a_{\delta}(\cdot, \cdot)$ is given by (3.6). Solving (3.38) is a very computationally demanding procedure. Using the roottracing method (see, e.g. [39]), one has to choose a parameter $E$, solve the radial Schrödinger equation to obtain the APW basis functions and set up the matrix elements. The determinant has to be computed, which is expected to vanish according to (3.38) but does not with an incorrect parameter. One has to vary the trial parameters in an appropriate domain to numerically find the zeros of this determinant (see [44] or Example 2 in Sect. 5). This is the main drawback of the APW method, which works for simple systems with a few eigenvalues only.

Another, less serious, difficulty of the APW method is the so-called asymptote problem (see [45]): the eigenvalue dependent APW basis functions must be evaluated for a large number of parameters, and sometimes one might hit a parameter $E$ for which $\chi_{l}(R, E)$ equals zero at the spherical surface. Inserting this in (3.37) will yield infinite coefficients $\alpha_{l m}^{\mathbf{k}}$ and can not match the basis functions at the spherical surface. Therefore, we shall always assume that $\chi_{l}(R, E) \geq \alpha$ with some constant $\alpha>0$ for any $l \in \mathbb{N}$, which can be achieved by varying the radius of the atomic sphere.

In the following, we shall give a convergence analysis of the APW approximations. Note that we search the eigenvalue approximations in a finite domain that contains the eigenvalues to be calculated (in fact, we can derive that for each $L,\left\{\lambda_{K L}\right\}_{K \in \mathbb{N}}$ is a non-increasing sequence bounded below by $\lim _{K, N \rightarrow \infty} \lambda_{N L}^{K}$ with $\lambda_{N L}^{K}$ being the eigenvalue of (3.5)). Consequently, we have limiting points in this domain when $K$ and $L$ go to infinity. Let $\lambda_{\infty}$ be any accumulation point, i.e., there exists a subsequence of eigenpairs, which we still denote by $\left\{\left(\lambda_{K L}, u_{K L}\right)\right\}_{K, L \in \mathbb{N}}$, such that

$$
\begin{equation*}
\lim _{K, L \rightarrow \infty}\left|\lambda_{K L}-\lambda_{\infty}\right|=0 \tag{3.39}
\end{equation*}
$$

We have from (3.8) that

$$
\lambda_{K L}=a_{\delta}\left(u_{K L}, u_{K L}\right) \geq C\left\|u_{K L}\right\|_{\delta}^{2}
$$

which implies that $\left\{u_{K L}\right\}_{K, L \in \mathbb{N}}$ is bounded in $H_{\# \delta}$. Banach-Alaoglu Theorem yields that there exists a weakly convergent subsequence $\left\{u_{K_{j} L_{j}}\right\}_{j \in \mathbb{N}}$, such that

$$
\begin{equation*}
u_{K_{j} L_{j}} \rightharpoonup u_{\infty} \quad \text { in } H_{\# \delta}(\Omega) \text { as } j \rightarrow \infty \tag{3.40}
\end{equation*}
$$

for some $u_{\infty} \in H_{\#}^{1}(\Omega)$. For simplicity of notation, we shall denote the sequence $\left\{\left(\lambda_{K_{j} L_{j}}, u_{K_{j} L_{j}}\right)\right\}_{j \in \mathbb{N}}$ by $\left\{\left(\lambda_{j}, u_{j}\right)\right\}_{j \in \mathbb{N}}$ afterwards. Using Sobolev's imbedding theorem, we have that $u_{j}$ converges to $u_{\infty}$ in $L^{q}(\Omega)$ for $1 \leq q<6$, which leads to

$$
\begin{equation*}
\lim _{j \rightarrow \infty} \int_{\Omega} V_{\mathrm{eff}}(\mathbf{r})\left(u_{\infty}^{2}-u_{j}^{2}\right) \mathrm{d} \mathbf{r}=0 \tag{3.41}
\end{equation*}
$$

Therefore, we derive from (3.39) and (3.41) that $\left\|u_{j}\right\|_{\delta} \rightarrow\left\|u_{\infty}\right\|_{\delta}$, which together with (3.40) yields

$$
u_{j} \rightarrow u_{\infty} \quad \text { in } \quad H_{\# \delta}(\Omega)
$$

Theorem 3.5. If $V_{\mathrm{eff}}(\mathbf{r})$ is a spherically symmetric potential in $\mathscr{C}$ and satisfies (2.7), then the limiting pair $\left(\lambda_{\infty}, u_{\infty}\right)$ is an eigenpair of (2.2), that is

$$
\begin{equation*}
a\left(u_{\infty}, v\right)=\lambda_{\infty}\left(u_{\infty}, v\right) \quad \forall v \in H_{\#}^{1}(\Omega) \tag{3.42}
\end{equation*}
$$

Moreover, for the sequence of eigenpairs $\left\{\left(\lambda_{j}, u_{j}\right)\right\}_{j \in \mathbb{N}}$ that converges to $\left(\lambda_{\infty}, u_{\infty}\right)$, there exists a constant $C_{s}$ such that

$$
\begin{equation*}
\left|\lambda_{\infty}-\lambda_{j}\right|+\left\|u_{\infty}-u_{j}\right\|_{\delta} \leq C_{s}\left(K_{j}^{-(s-1)}+L_{j}^{-(s-1)}\right) \tag{3.43}
\end{equation*}
$$

where $s>1$ and $j$ is sufficiently large.
Proof. Since $V_{\mathrm{eff}}(\mathbf{r})=V(r)$ and $\chi_{l}\left(r, \lambda_{j}\right)$ satisfies the radial Schrödinger equation, we have that for $u_{j} \in V_{K_{j} L_{j}}^{\lambda_{j}}$, there holds

$$
\begin{equation*}
\left(-\frac{1}{2} \Delta+V_{\mathrm{eff}}\right) u_{j}=\lambda_{j} u_{j} \quad \text { in } \mathscr{C} \tag{3.44}
\end{equation*}
$$

Denote by $a_{\mathscr{C}}(w, v)=\frac{1}{2} \int_{\mathscr{C}} \nabla w \cdot \nabla v+\int_{\mathscr{C}} V_{\mathrm{eff}} w v$ and $a_{\mathscr{D}}(w, v)=\frac{1}{2} \int_{\mathscr{D}} \nabla w \cdot \nabla v+\int_{\mathscr{D}} V_{\mathrm{eff}} w v$. For any $v \in C_{\#}^{\infty}(\Omega)$, we have

$$
\begin{aligned}
a_{\delta}\left(u_{j}, v\right)-\lambda_{j}\left(u_{j}, v\right) & =a_{\delta}\left(u_{j}, v_{j}\right)-\lambda_{j}\left(u_{j}, v_{j}\right)+a_{\delta}\left(u_{j}, v-v_{j}\right)-\lambda_{j}\left(u_{j}, v-v_{j}\right) \\
& =a_{\mathscr{C}}\left(u_{j}, v-v_{j}\right)+a_{\mathscr{D}}\left(u_{j}, v-v_{j}\right)-\lambda_{j}\left(u_{j}, v-v_{j}\right) \\
& =\frac{1}{2} \int_{\Gamma} \frac{\partial u_{j} \mid \mathscr{C}}{\partial n}\left(v-\left.v_{j}\right|_{\mathscr{C}}\right)+a_{\mathscr{D}}\left(u_{j}, v-v_{j}\right)-\lambda_{j} \int_{\mathscr{D}} u_{j}\left(v-v_{j}\right) \\
& \lesssim\left(\left\|v-v_{j}\right\|_{H^{1}(\mathscr{D})}+\left\|\left.v_{j}\right|_{\mathscr{C}}-\left.v_{j}\right|_{\mathscr{D}}\right\|_{H^{1 / 2}(\Gamma)}\right)\left\|u_{j}\right\|_{\delta} \quad \forall v_{j} \in V_{K_{j} L_{j}}^{\lambda_{j}},
\end{aligned}
$$

where (3.44) is used for the third equality. Note that for any $v \in C_{\#}^{\infty}(\Omega)$, we can find $v_{j} \in V_{K_{j} L_{j}}^{\lambda_{j}}$ such that $\left\|v-v_{j}\right\|_{H^{1}(\mathscr{D})} \rightarrow 0$ as $j \rightarrow \infty$. This together with the fact $\lim _{j \rightarrow \infty}\left\|\left.v_{j}\right|_{\mathscr{C}}-\left.v_{j}\right|_{\mathscr{D}}\right\|_{H^{1 / 2}(\Gamma)}=0$ leads to

$$
\begin{equation*}
\lim _{j \rightarrow \infty} a_{\delta}\left(u_{j}, v\right)-\lambda_{j}\left(u_{j}, v\right)=0 \quad \forall v \in C_{\#}^{\infty}(\Omega) \tag{3.45}
\end{equation*}
$$

Since $C_{\#}^{\infty}(\Omega)$ is dense in $H_{\#}^{1}(\Omega)$, we have that (3.45) holds for all $v \in H_{\#}^{1}(\Omega)$.
Note that

$$
\begin{aligned}
& \left|a\left(u_{\infty}, v\right)-\lambda_{\infty}\left(u_{\infty}, v\right)\right|=\left|a_{\delta}\left(u_{\infty}, v\right)-\lambda_{\infty}\left(u_{\infty}, v\right)\right| \\
\leq & \left|a_{\delta}\left(u_{\infty}-u_{j}, v\right)\right|+\left|\lambda_{\infty}\left(u_{\infty}-u_{j}, v\right)\right|+\left|\left(\lambda_{j}-\lambda_{\infty}\right)\left(u_{j}, v\right)\right|+\left|a_{\delta}\left(u_{j}, v\right)-\lambda_{j}\left(u_{j}, v\right)\right| \\
\lesssim & \left\|u_{\infty}-u_{j}\right\|_{\delta}+\left|\lambda_{\infty}-\lambda_{j}\right|+\left|a_{\delta}\left(u_{j}, v\right)-\lambda_{j}\left(u_{j}, v\right)\right| \quad \forall v \in H_{\#}^{1}(\Omega) .
\end{aligned}
$$

Using (3.45), the convergence of $u_{j} \rightarrow u_{\infty}$ in $H_{\# \delta}(\Omega)$ and $\lambda_{j} \rightarrow \lambda_{\infty}$, we can conclude (3.42).
Define the operator $T_{j}: L_{\#}^{2}(\Omega) \rightarrow V_{K_{j} L_{j}}^{\lambda_{j}}$ such that for $f \in L_{\#}^{2}(\Omega)$,

$$
\begin{equation*}
a_{\delta}\left(T_{j} f, v\right)=(f, v) \quad \forall v \in V_{K_{j} L_{j}}^{\lambda_{j}} \tag{3.46}
\end{equation*}
$$

Let $\gamma$ be a circle in the complex plane centered at $\lambda_{\infty}^{-1}$, which does not enclose any other point of $\vartheta(T)$. Define the spectral projector of $T_{j}$ by

$$
\mathscr{E}_{j}=\mathscr{E}_{j}\left(\lambda_{\infty}^{-1}\right)=\frac{1}{2 \pi i} \int_{\gamma} R_{z}\left(T_{j}\right) \mathrm{d} z
$$

Note that the convergence of eigenvalues implies that any open set in the complex plane containing $\vartheta(T)$ contains $\vartheta\left(T_{j}\right)$ for sufficiently large $j$. Therefore, $R_{z}\left(T_{j}\right)$ is well defined and bounded on $\gamma$ for sufficiently large $j$. Since

$$
R_{z}(T)-R_{z}\left(T_{j}\right)=R_{z}\left(T_{j}\right)\left(T-T_{j}\right) R_{z}(T),
$$

we have from the definition of spectral projector that

$$
\left\|\mathscr{E}-\mathscr{E}_{j}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right)} \leq C\left\|T-T_{j}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right)} .
$$

Therefore it is now only necessary for us to estimate $\left\|T-T_{j}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right) \text {. For simplicity of notation, we will }}$ denote $\left(\lambda_{\infty}, u_{\infty}\right)$ by $(\lambda, u)$ in the following.

Let $\tilde{u}$ be the extension of $\left.u\right|_{\mathscr{D}}$ given as in (3.13) and $\tilde{c}_{\mathbf{k}}=|\Omega|^{-1 / 2} \int_{\Omega} \tilde{u}(\mathbf{r}) \mathrm{e}^{-i \mathbf{k} \cdot \mathbf{r}} \mathrm{~d} \mathbf{r}$. Define

$$
\begin{equation*}
I_{j, \lambda} u=\sum_{|\mathbf{k}| \leq K_{j}} \tilde{c}_{\mathbf{k}} \omega_{\mathbf{k} L_{j}}^{\lambda} \quad \text { and } \quad I_{j, \lambda_{j}} u=\sum_{|\mathbf{k}| \leq K_{j}} \tilde{c}_{\mathbf{k}} \omega_{\mathbf{k} L_{j}}^{\lambda_{j}} . \tag{3.47}
\end{equation*}
$$

Since $T u=\lambda^{-1} u$ for $u \in \mathscr{R}(\mathscr{E})$, we obtain from (3.24) that

$$
\begin{equation*}
\left\|T u-T_{j} u\right\|_{\delta} \lesssim\left\|u-I_{j, \lambda_{j}} u\right\|_{\delta}+\sup _{v_{j} \in V_{K_{j} L_{j}}^{\lambda_{j}}} \frac{a\left(T u-T_{j} u, v_{j}\right)}{\left\|v_{j}\right\|_{\delta}} . \tag{3.48}
\end{equation*}
$$

The first term on the right-hand side of (3.48) is estimated by

$$
\begin{equation*}
\left\|I_{j, \lambda_{j}} u-u\right\|_{\delta} \leq\left\|I_{j, \lambda_{j}} u-u\right\|_{H^{1}(\mathscr{D})}+\left\|I_{j, \lambda_{j}} u-I_{j, \lambda} u\right\|_{H^{1}(\mathscr{C})}+\left\|I_{j, \lambda} u-u\right\|_{H^{1}(\mathscr{C})} . \tag{3.49}
\end{equation*}
$$

Using similar arguments as those in the proof of Lemma 3.1, we have

$$
\begin{equation*}
\left\|I_{j, \lambda_{j}} u-u\right\|_{H^{1}(\mathscr{D})} \leq C K_{j}^{-(s-1)}\|u\|_{H^{s}(\mathscr{D})} . \tag{3.50}
\end{equation*}
$$

Note that similar to (3.44), $I_{j, \lambda} u$ and $I_{j, \lambda_{j}} u$ satisfy the following equations

$$
\begin{equation*}
\left(-\frac{1}{2} \Delta+V_{\mathrm{eff}}\right) I_{j, \lambda} u=\lambda I_{j, \lambda} u \quad \text { and } \quad\left(-\frac{1}{2} \Delta+V_{\mathrm{eff}}\right) I_{j, \lambda_{j}} u=\lambda_{j} I_{j, \lambda_{j}} u \quad \text { in } \mathscr{C} . \tag{3.51}
\end{equation*}
$$

Since (3.47) implies that $I_{j, \lambda} u=I_{j, \lambda_{j}} u$ on $\Gamma$ from both inside and outside the sphere, we have

$$
\left\{\begin{array}{rlrl}
\left(-\frac{1}{2} \Delta+V_{\text {eff }}-\lambda_{j}\right)\left(I_{j, \lambda} u-I_{j, \lambda_{j}} u\right) & =\left(\lambda-\lambda_{j}\right) I_{j, \lambda} u \text { in } \mathscr{C},  \tag{3.52}\\
I_{j, \lambda} u-I_{j, \lambda_{j}} u & =0 & \text { on } \partial \mathscr{C} .
\end{array}\right.
$$

From the assumption on the asymptote problem, we have that $\lambda_{j}$ is not an eigenvalue of the problem

$$
\left\{\begin{aligned}
\left(-\frac{1}{2} \Delta+V_{\text {eff }}\right) v & =\lambda v \quad \text { in } \mathscr{C}, \\
\left.v\right|_{\partial \mathscr{C}} & =0 .
\end{aligned}\right.
$$

Therefore, we have from (3.52) that

$$
\begin{equation*}
\left\|I_{j, \lambda} u-I_{j, \lambda_{j}} u\right\|_{H^{1}(\mathscr{C})} \lesssim\left|\lambda-\lambda_{j}\right|\left\|I_{j, \lambda} u\right\|_{L^{2}(\mathscr{C})} \lesssim\left|\lambda-\lambda_{j}\right|\left(\|u\|_{L^{2}(\mathscr{C})}+\left\|I_{j, \lambda} u-u\right\|_{L^{2}(\mathscr{C})}\right) . \tag{3.53}
\end{equation*}
$$

Similarly, we have from $\left(-\frac{1}{2} \Delta+V_{\text {eff }}-\lambda\right)\left(I_{j, \lambda} u-u\right)=0$ in $\mathscr{C}$ that

$$
\begin{align*}
\left\|I_{j, \lambda} u-u\right\|_{H^{1}(\mathscr{C})} & \leq C\left\|\left.I_{j, \lambda} u\right|_{\mathscr{C}}-u\right\|_{H^{1 / 2}(\Gamma)} \\
& \leq C\left(\left\|u-\left.I_{j, \lambda} u\right|_{\mathscr{D}}\right\|_{H^{1 / 2}(\Gamma)}+\left\|\left.I_{j, \lambda} u\right|_{\mathscr{C}}-\left.I_{j, \lambda} u\right|_{\mathscr{D}}\right\|_{H^{1 / 2}(\Gamma)}\right) \\
& \leq C\left(K_{j}^{-(s-1)}+L_{j}^{-(s-1)}\right)\|u\|_{H^{s}(\mathscr{D})} . \tag{3.54}
\end{align*}
$$

Therefore, we obtain from (3.49), (3.50), (3.53) and (3.54) that

$$
\begin{equation*}
\left\|I_{j, \lambda_{j}} u-u\right\|_{\delta} \lesssim\left(K_{j}^{-(s-1)}+L_{j}^{-(s-1)}+\left|\lambda-\lambda_{j}\right|\right)\left(\|u\|_{H^{s}(\mathscr{D})}+\|u\|_{L^{2}(\mathscr{C})}\right) \tag{3.55}
\end{equation*}
$$

For the second term on the right-hand side of (3.48), we can obtain

$$
\begin{equation*}
\sup _{v_{j} \in V_{K_{j} L_{j}}^{\lambda_{j}}} \frac{a\left(T u-T_{j} u, v_{j}\right)}{\left\|v_{j}\right\|_{\delta}} \lesssim L_{j}^{-(s-1)}\|u\|_{H^{s}(\mathscr{D})} \tag{3.56}
\end{equation*}
$$

by using similar argument as that in (3.26). Taking the regularity results of Lemma 2.2, 2.3, (3.48), (3.55) and (3.56) into account gives rise to

$$
\begin{equation*}
\left\|T-T_{j}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right)} \leq C\left(K_{j}^{-(s-1)}+L_{j}^{-(s-1)}+\left|\lambda-\lambda_{j}\right|\right) \tag{3.57}
\end{equation*}
$$

Using (3.33), we have $\left|\lambda-\lambda_{j}\right| \lesssim\left\|T-T_{j}\right\|_{\mathscr{L}\left(\mathscr{R}(\mathscr{E}), H_{\# \delta}(\Omega)\right)}^{2}+D_{j}$, where $\left|D_{j}\right| \lesssim L_{j}^{-(s-1)}$ can be obtained by using the same argument as that in (3.34). This together with (3.57) and the fact $\lambda_{j} \rightarrow \lambda$ leads to (3.43), which completes the proof.

Remark 3.6. In contrast to the basis functions we construct in Section 3.1, the APW method uses different radial basis functions for different angular components by solving (3.35). With this type of basis functions, we see from Theorem 3.5 that a half order is not lost in the estimate compared with Lemma 3.3 and Theorem 3.4.

Remark 3.7. When the radius $R$ is well chosen, the assumption of spherically symmetric potential is reasonable for a lot of systems, e.g. close-packed crystals [39]. That is why the APW method has been successfully used in many computations.

### 3.3. LAPW (+lo) methods

We shall discuss LAPW (+lo) methods in this subsection. Since the accuracies of LAPW ( + lo methods depend heavily on the parameters chosen by experience, we can not prove the convergence of numerical approximations but only provide some conjectures on the error estimates.

The LAPW method uses the combination of $\chi_{l}(r, E)$ and its energy derivative $\dot{\chi}_{l}(r, E)$ with a fixed parameter $E$ as the radial basis function. The energy derivative is defined by

$$
\dot{\chi}_{l}(r, E)=\left.\frac{\partial}{\partial \varepsilon} \chi_{l}(r, \varepsilon)\right|_{\varepsilon=E}
$$

where $\chi_{l}$ is kept normalized to the same value in the sphere (the properties of $\dot{\chi}_{l}(r, E)$ can be read in $[3,39,45]$ ). The approximation space is $\widetilde{V}_{K L}^{E}=\operatorname{span}\left\{\widetilde{\omega}_{\mathbf{k} L}^{E}\right\}_{|\mathbf{k}| \leq K}$ with

$$
\widetilde{\omega}_{\mathbf{k} L}^{E}(\mathbf{r})=\left\{\begin{array}{lr}
|\Omega|^{-\frac{1}{2}} \mathrm{e}^{i \mathbf{k} \cdot \mathbf{r}} & \text { in } \mathscr{D}  \tag{3.58}\\
\sum_{l m}^{L}\left[\alpha_{l m}^{\mathbf{k}} \chi_{l}(r, E)+\beta_{l m}^{\mathbf{k}} \dot{\chi}_{l}(r, E)\right] Y_{l m}(\hat{\mathbf{r}}) \text { in } \mathscr{C}
\end{array}\right.
$$

The coefficients $\alpha_{l m}^{\mathbf{k}}$ and $\beta_{l m}^{\mathbf{k}}$ are determined by (3.11) requiring that the basis functions match both the value and slope (in the weak sense of (3.2)). The LAPW method provides flexible basis functions to properly describe eigenfunctions that correspond to eigenvalues near $E$. In contrast to the APW method, this scheme allows us to obtain all eigenvalues by solving a linear eigenvalue problem.

Using the result of Theorem 3.5, it is only necessary for us to estimate the error introduced by linearization, say, the difference between the LAPW radial basis function with fixed parameter $E$

$$
\begin{equation*}
\tilde{\chi}_{l}(r, E)=\alpha_{l} \chi_{l}(r, E)+\beta_{l} \dot{\chi}_{l}(r, E) \tag{3.59}
\end{equation*}
$$

and the APW radial basis function $\chi_{l}\left(r, \lambda_{K L}\right)$. This is done by assuming that the APW radial basis functions $\chi_{l}\left(r, \lambda_{K L}\right)$ and the LAPW combination (3.59) have the same logarithmic derivatives with respect to $r$ at the spherical surface (see $[3,31,39]$ ), i.e.

$$
\begin{equation*}
\left.\frac{\chi_{l}^{\prime}\left(r, \lambda_{K L}\right)}{\chi_{l}\left(r, \lambda_{K L}\right)}\right|_{r=R}=\left.\frac{\tilde{\chi}_{l}^{\prime}(r, E)}{\tilde{\chi}_{l}(r, E)}\right|_{r=R} \tag{3.60}
\end{equation*}
$$

Let $\sigma=\left|\lambda_{K L}-E\right|$. It has been analyzed in $[3,31]$ that under the Assumption (3.60), the difference between $\tilde{\chi}_{l}(r, E)$ and $\chi_{l}\left(r, \lambda_{K L}\right)$ is of order $\sigma^{2}$, i.e.

$$
\left\|\tilde{\chi}_{l}(r, E)-\chi_{l}\left(r, \lambda_{K L}\right)\right\|_{H^{1}([0, R])} \lesssim \sigma^{2}
$$

Using similar arguments as those in the proof of Theorem 3.5 , we may obtain the following a priori error estimate of LAPW approximations ( $\left.\widetilde{\lambda}_{K L}, \widetilde{u}_{K L}\right)$

$$
\begin{gather*}
\left\|u-\widetilde{u}_{K L}\right\|_{\delta} \leq C_{s}\left(K^{-(s-1)}+L^{-(s-1)}+\sigma^{2}\right)  \tag{3.61}\\
\left|\lambda-\widetilde{\lambda}_{K L}\right| \leq c_{s}\left(K^{-(s-1)}+L^{-(s-1)}+\sigma^{4}\right) \tag{3.62}
\end{gather*}
$$

for some eigenpair $(\lambda, u)$ of (2.2) and any $s>1$.
Remark 3.8. The a priori error estimates (3.61) and (3.62) rely on the Assumption (3.60), which has not been proved (see a comment in [33]). Nevertheless, the numerical experiments in Section 5 support the exponential convergence rates.

Although the error of the eigenvalue approximation relies on the choice of $E$, the high order of $\sigma$ in (3.62) results in that the LAPW method forms a good basis set over a relatively large eigenvalue region. In most materials, it is quite adequate to choose $E$ near the center of the region of eigenvalues to be computed. However, in a few instances, there is no single choice of $E$ that is adequate for all the eigenvalues that must be considered. Then the eigenvalue region may be divided into a few windows and separate computations with different parameters should be carried out for each.

In order to have enough variational flexibility in the radial basis functions, the LAPW + lo method adds new local basis functions to the LAPW method. The approximation space is spanned by $\left\{\widetilde{\omega}_{\mathbf{k} L}^{E}\right\}_{|\mathbf{k}| \leq K}$ given in (3.58) and local orbitals $\left\{\varphi_{i}\right\}_{1 \leq i \leq N}$ as

$$
\varphi_{i}(\mathbf{r})=\left\{\begin{array}{lr}
0 & \text { in } \mathscr{D}  \tag{3.63}\\
\sum_{l m}^{L}\left[\alpha_{i, l m} \chi_{\varepsilon_{i}}\left(r, \varepsilon_{i}\right)+\beta_{i, l m} \dot{\chi}_{\varepsilon_{i}}\left(r, \varepsilon_{i}\right)\right] Y_{l m}(\hat{\mathbf{r}}) & \text { in } \mathscr{C}
\end{array}\right.
$$

where the coefficients $\alpha_{i, l m}$ and $\beta_{i, l m}$ do not depend on $\mathbf{k}$, but are determined by the requirement that $\varphi_{i}$ is zero at the sphere boundary and normalized. Note that different parameters $\varepsilon_{i}$ can be chosen so that different states can be described simultaneously.

As shown by the numerical experiments in [38], the LAPW+lo method converges practically to identical result as the LAPW method, but allows a significantly smaller basis set (up to $50 \%$ ) and thus reduces the computational cost drastically.

## 4. Error estimates for Kohn-Sham equations

We have given an a priori error estimate for linear Schrödinger type eigenvalue problems in the previous section. In this section, we shall investigate the nonlinear KS equations (1.1), considering the convergence and a priori error estimate of the nonconforming approximations.

We shall introduce some notations first. For $\mathfrak{k} \in \mathbb{R}^{N \times N}$, we denote its Frobenius norm by $|\mathbb{c}|$. Define

$$
\mathcal{H} \equiv\left(H_{\#}^{1}(\Omega)\right)^{N}=\left\{\left(\phi_{1}, \phi_{2}, \ldots, \phi_{N}\right): \phi_{i} \in H_{\#}^{1}(\Omega), i=1,2, \ldots, N\right\}
$$

which is a Hilbert space associated with the induced norm $\|\Phi\|_{1, \Omega}=\left(\sum_{i=1}^{N}\left\|\phi_{i}\right\|_{H^{1}(\Omega)}^{2}\right)^{1 / 2}$. In our discussion, we shall use the following spaces:

$$
\mathcal{S}^{N \times N}=\left\{M \in \mathbb{R}^{N \times N}: M^{T}=M\right\}, \quad \mathcal{A}^{N \times N}=\left\{M \in \mathbb{R}^{N \times N}: M^{T}=-M\right\},
$$

and

$$
\mathbb{Q}=\left\{\Phi \in \mathcal{H}:\left\langle\Phi^{T} \Phi\right\rangle=I^{N \times N}\right\} \quad \text { with } \quad\left\langle\Phi^{T} \Psi\right\rangle=\left(\int_{\Omega} \phi_{i} \psi_{j}\right)_{i, j=1}^{N} \in \mathbb{R}^{N \times N}
$$

For any $\Phi \in \mathcal{H}$, we may decompose $\mathcal{H}$ into a direct sum of three subspaces (see, e.g. [18, 37]):

$$
\begin{equation*}
\mathcal{H}=\mathcal{S}^{\Phi} \oplus \mathcal{A}^{\Phi} \oplus \mathcal{T}^{\Phi} \tag{4.1}
\end{equation*}
$$

where $\mathcal{S}^{\Phi}=\Phi \mathcal{S}^{N \times N}, \mathcal{A}^{\Phi}=\Phi \mathcal{A}^{N \times N}$, and $\mathcal{T}^{\Phi}=\left\{\Psi \in \mathcal{H}:\left\langle\Psi^{T} \Phi\right\rangle=0 \in \mathbb{R}^{N \times N}\right\}$.
For the nonconforming framework, we define $\mathcal{H}_{L}=\left(H_{\# L}(\Omega)\right)^{N}$ with the induced norm $\|\cdot\|_{\delta, \Omega}$, and $\mathbb{Q}_{L}=$ $\left\{\Phi \in \mathcal{H}_{L}:\left\langle\Phi^{T} \Phi\right\rangle=I^{N \times N}\right\}$. For any $\Phi \in \mathcal{H}_{L}$, the space $\mathcal{H}_{L}$ can be decomposed into three subspaces like (4.1)

$$
\begin{equation*}
\mathcal{H}_{L}=\mathcal{S}_{L}^{\Phi} \oplus \mathcal{A}_{L}^{\Phi} \oplus \mathcal{T}_{L}^{\Phi} \tag{4.2}
\end{equation*}
$$

We also need the discrete space $\mathcal{V}_{\varrho}=\left(V_{\varrho}(\Omega)\right)^{N} \subset \mathcal{H}_{L}$, where $\varrho$ and $V_{\varrho}$ are defined in Section 3.1.
Remark 4.1. Following [18, 43], we can use Grassmann manifold to interpret the equivalence classes of orthonormal bases spanning the same $N$-dimensional subspace. Define the equivalence class of $\Phi$ by

$$
[\Phi]=\left\{\Psi \in \mathbb{Q}_{L}: \Psi=\Phi U, U \text { is an orthogonal matrix }\right\}
$$

$\mathcal{T}_{L}^{\Phi}$ is the tangent space of the Grassmann manifold at $[\Phi]$.

### 4.1. Abstract Kohn-Sham model and nonconforming discretization

The ground state solutions of the periodic KS-LDA model can be obtained by minimizing the KS energy functional

$$
\begin{equation*}
E(\Phi)=\frac{1}{2} \sum_{i=1}^{N} \int_{\Omega}\left|\nabla \phi_{i}(x)\right|^{2} \mathrm{~d} x+\int_{\Omega} v_{\mathrm{ext}}(x) \rho_{\Phi}(x) \mathrm{d} x+\frac{1}{2} D\left(\rho_{\Phi}, \rho_{\Phi}\right)+\int_{\Omega} \mathcal{E}\left(\rho_{\Phi}(x)\right) \mathrm{d} x \tag{4.3}
\end{equation*}
$$

with respect to KS orbitals $\Phi=\left\{\phi_{i}\right\}_{i=1}^{N} \in \mathcal{H}$ under the orthogonality constraints $\left\langle\Phi^{T} \Phi\right\rangle=I^{N \times N}$. The function $\mathcal{E}(\rho)$ denotes the exchange-correlation energy per unit volume in an electron gas with density $\rho$ and $\mathcal{E}^{\prime}(t)=v_{\mathrm{xc}}(t)$. $D\left(\rho_{\Phi}, \rho_{\Phi}\right)$ models the periodic electron-electron Coulomb energy, where

$$
D(f, g)=4 \pi \sum_{\mathbf{k} \in \mathcal{R}^{*} \backslash\{0\}}|\mathbf{k}|^{-2} \hat{f}_{\mathbf{k}}^{*} \hat{g}_{\mathbf{k}}
$$

The existence of a minimizer of the energy functional can be found in $[1,35]$. The Euler-Lagrange equation associated with the minimization problem is

$$
\left\{\begin{align*}
\left(H_{\Phi} \phi_{i}, v\right) & =\left(\sum_{j=1}^{N} \lambda_{i j} \phi_{j}, v\right) \quad \forall v \in H_{\#}^{1}(\Omega), \quad i=1,2, \ldots, N  \tag{4.4}\\
\int_{\Omega} \phi_{i} \phi_{j} & =\delta_{i j}
\end{align*}\right.
$$

where $\Lambda \equiv\left(\lambda_{i j}\right)_{i, j=1}^{N}=\left(\int_{\Omega} \phi_{j} H_{\Phi} \phi_{i}\right)_{i, j=1}^{N}$ is the Lagrange multiplier and

$$
\left(H_{\Phi} u, v\right)=\frac{1}{2} \int_{\Omega} \nabla u \cdot \nabla v+\int_{\Omega}\left(v_{\mathrm{ext}}(\mathbf{r})+v_{\mathrm{H}}\left(\rho_{\Phi}(\mathbf{r})\right)+v_{\mathrm{xc}}\left(\rho_{\Phi}(\mathbf{r})\right)\right) u v
$$

with $v_{\mathrm{H}}\left(\rho_{\Phi}(\mathbf{r})\right)$ defined by (2.8). Note that the Lagrange multiplier $\Lambda$ can be diagonalized since the energy functional and the Hamiltonian are invariant under any unitary transform of the KS orbitals, i.e., for any $\Phi \in \mathbb{Q}$,

$$
\begin{equation*}
E(\Phi)=E(\Phi U) \quad \forall U=\left(u_{i j}\right)_{i, j=1}^{N} \in \mathcal{O}^{N \times N} \tag{4.5}
\end{equation*}
$$

where $\mathcal{O}^{N \times N}$ is the set of orthogonal matrices.
To obtain the a priori error estimate of the nonconforming approximations, we shall represent the KS equation in the following setting. Define

$$
Y=\mathbb{R}^{N \times N} \times \mathcal{H}
$$

with the associated norm $\|(\Lambda, \Phi)\|_{Y}=|\Lambda|+\|\Phi\|_{1, \Omega}$ for $(\Lambda, \Phi) \in Y$. We may rewrite (4.4) as a nonlinear problem:

$$
\begin{equation*}
F((\Lambda, \Phi))=0 \in Y^{*} \tag{4.6}
\end{equation*}
$$

where $F: Y \rightarrow Y^{*}$ is given by

$$
\begin{equation*}
\langle F((\Lambda, \Phi)),(\mathfrak{k}, \Gamma)\rangle=\sum_{i=1}^{N}\left(H_{\Phi} \phi_{i}-\sum_{j=1}^{N} \lambda_{i j} \phi_{j}, \gamma_{i}\right)+\sum_{i, j=1}^{N} \chi_{i j}\left(\int_{\Omega} \phi_{i} \phi_{j}-\delta_{i j}\right) \tag{4.7}
\end{equation*}
$$

with $\mathbb{y}=\left(\chi_{i j}\right)_{i, j=1}^{N} \in \mathbb{R}^{N \times N}$ and $\Gamma=\left(\gamma_{1}, \gamma_{2}, \ldots, \gamma_{N}\right) \in \mathcal{H}$. The Fréchet derivative of $F$ at $(\Lambda, \Phi): Y \rightarrow Y^{*}$ is defined by

$$
\begin{equation*}
\left\langle F_{(\Lambda, \Phi)}^{\prime}((\mu, \Psi)),(\mathbb{X}, \Gamma)\right\rangle=a_{(\Lambda, \Phi)}(\Psi, \Gamma)-\sum_{i, j=1}^{N}\left(\mu_{i j} \phi_{j}, \gamma_{i}\right)+\sum_{i, j=1}^{N} \chi_{i j} \int_{\Omega}\left(\psi_{i} \phi_{j}+\phi_{i} \psi_{j}\right) \tag{4.8}
\end{equation*}
$$

with $(\mu, \Psi) \in Y\left(\mu=\left(\mu_{i j}\right)_{i, j=1}^{N} \in \mathbb{R}^{N \times N}, \Psi=\left(\psi_{1}, \psi_{2}, \ldots, \psi_{N}\right) \in \mathcal{H}\right),(\mathfrak{y}, \Gamma) \in Y$, and

$$
\begin{align*}
a_{(\Lambda, \Phi)}(\Psi, \Gamma)= & \sum_{i=1}^{N}\left(\frac{1}{2}\left(\nabla \psi_{i}, \nabla \gamma_{i}\right)+\left(V_{\mathrm{ext}} \psi_{i}, \gamma_{i}\right)+\left(\mathcal{E}^{\prime}\left(\rho_{\Phi}\right) \psi_{i}, \gamma_{i}\right)+D\left(\rho_{\Phi}, \psi_{i} \gamma_{i}\right)\right. \\
& \left.-\left(\sum_{j=1}^{N} \lambda_{i j} \psi_{j}, \gamma_{i}\right)+\left(2 \phi_{i} \mathcal{E}^{\prime \prime}\left(\rho_{\Phi}\right) \sum_{j=1}^{N} \phi_{j} \psi_{j}, \gamma_{i}\right)+\sum_{j=1}^{N} 2 D\left(\phi_{j} \psi_{j}, \phi_{i} \gamma_{i}\right)\right) \tag{4.9}
\end{align*}
$$

We shall then address the nonconforming form of (4.6). Let

$$
Y_{L}=\mathbb{R}^{N \times N} \times \mathcal{H}_{L}
$$

with the associated norm $\|(\mu, \Psi)\|_{Y_{L}}=|\mu|+\|\Psi\|_{\delta, \Omega}$ and $F_{L}: Y_{L} \rightarrow Y_{L}^{*}$ be the operator defined by

$$
\begin{align*}
\left\langle F_{L}\left(\left(\Lambda_{L}, \Phi_{L}\right)\right),\left(\mathbb{K}_{L}, \Gamma_{L}\right)\right\rangle= & \frac{1}{2} \sum_{i=1}^{N}\left(\int_{\mathscr{C}} \nabla \phi_{L, i} \nabla \gamma_{L, i}+\int_{\mathscr{D}} \nabla \phi_{L, i} \nabla \gamma_{L, i}\right) \\
& +\sum_{i=1}^{N}\left(\left(v_{\mathrm{ext}}+v_{H}\left(\rho_{\Phi_{L}}\right)+v_{\mathrm{xc}}\left(\rho_{\Phi_{L}}\right)\right) \phi_{L, i}, \gamma_{L, i}\right)-\sum_{i=1}^{N}\left(\sum_{j=1}^{N} \lambda_{L, i j} \phi_{L, j}, \gamma_{L, i}\right) \\
& +\sum_{i, j=1}^{N} \chi_{L, i j}\left(\int_{\Omega} \phi_{L, i} \phi_{L, j}-\delta_{i j}\right) \quad \forall\left(\Lambda_{L}, \Phi_{L}\right),\left(\mathbb{K}_{L}, \Gamma_{L}\right) \in Y_{L} \tag{4.10}
\end{align*}
$$

We denote the derivative of $F_{L}$ at $\left(\Lambda_{L}, \Phi_{L}\right) \in Y_{L}$ by $F_{L,\left(\Lambda_{L}, \Phi_{L}\right)}^{\prime}: Y_{L} \rightarrow Y_{L}^{*}$ as

$$
\begin{align*}
\left\langle F_{L,\left(\Lambda_{L}, \Phi_{L}\right)}^{\prime}\left(\left(\mu_{L}, \Psi_{L}\right)\right),\left(\mathbb{K}_{L}, \Gamma_{L}\right)\right\rangle= & a_{\left(\Lambda_{L}, \Phi_{L}\right)}^{\delta}\left(\Psi_{L}, \Gamma_{L}\right)-\sum_{i, j=1}^{N}\left(\mu_{L, i j} \phi_{L, j}, \gamma_{L, i}\right) \\
& +\sum_{i, j=1}^{N} \chi_{L, i j} \int_{\Omega}\left(\psi_{L, i} \phi_{L, j}+\phi_{L, i} \psi_{L, j}\right) \quad \forall\left(\mu_{L}, \Psi_{L}\right),\left(\mathbb{K}_{L}, \Gamma_{L}\right) \in Y_{L}, \tag{4.11}
\end{align*}
$$

where the bilinear form $a_{(\Lambda, \Phi)}^{\delta}(\Psi, \Gamma)$ is defined as (4.9) by replacing $\left(\nabla \psi_{i}, \nabla \gamma_{i}\right)$ with $\int_{\mathscr{C}} \nabla \psi_{i} \nabla \gamma_{i}+\int_{\mathscr{D}} \nabla \psi_{i} \nabla \gamma_{i}$.
For numerical discretization of (4.6), let

$$
Y_{\varrho}=\mathbb{R}^{N \times N} \times \mathcal{V}_{\varrho}
$$

and $F_{\varrho}: Y_{\varrho} \rightarrow Y_{\varrho}^{*}$ be defined as the restriction of $F_{L}$ to $Y_{\varrho}$ :

$$
\left\langle F_{\varrho}\left(\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)\right),\left(\mathbb{K}_{\varrho}, \Gamma_{\varrho}\right)\right\rangle=\left\langle F_{L}\left(\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)\right),\left(\mathbb{K}_{\varrho}, \Gamma_{\varrho}\right)\right\rangle \quad \forall\left(\Lambda_{\varrho}, \Phi_{\varrho}\right),\left(\mathbb{K}_{\varrho}, \Gamma_{\varrho}\right) \in Y_{\varrho} .
$$

The nonconforming approximation of (4.6) can be written as

$$
\begin{equation*}
F_{\varrho}\left(\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)\right)=0 \in Y_{\varrho}^{*} \tag{4.12}
\end{equation*}
$$

We denote the derivative of $F_{\varrho}$ at $\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)$ by $F_{\varrho,\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)}^{\prime}: Y_{\varrho} \rightarrow Y_{\varrho}^{*}$, which is the restriction of $F_{L,\left(\Lambda_{\varrho}, \Phi_{\varrho}\right)}^{\prime}$ to $Y_{\varrho}$.
Note that there are infinitely many solutions of (4.6) and (4.12) due to (4.5). We shall define

$$
\mathbb{Q}_{L}^{\Phi}=\left\{\Psi \in \mathbb{Q}_{L}:\|\Psi-\Phi\|_{0, \Omega}=\min _{U \in \mathcal{O}^{N \times N}}\|\Psi U-\Phi\|_{0, \Omega}\right\} \quad \text { for } \Phi \in \mathbb{Q}
$$

to get rid of the redundancy (see [13]). In our analysis, the following lemma will be used, whose proof is given in $[13,37]$.
Lemma 4.2. If $\Phi \in \mathbb{Q}$, then $\Psi \in \mathbb{Q}_{L}^{\Phi}$ can be represented by

$$
\Psi=\Phi+\Phi S+W
$$

with $W \in \mathcal{T}_{L}^{\Phi}$ and $S \in \mathcal{S}^{N \times N}$.

### 4.2. A priori error estimates of the nonconforming approximations

Given $(\Lambda, \Phi) \in \mathcal{S}^{N \times N} \times \mathbb{Q}$, we define

$$
X_{\Phi}=\mathcal{S}^{N \times N} \times\left(\mathcal{S}_{L}^{\Phi} \oplus \mathcal{T}_{L}^{\Phi}\right) \subset Y_{L}
$$

and

$$
X_{\Phi, \varrho}=\mathcal{S}^{N \times N} \times\left(\mathcal{V}_{\varrho} \cap\left(\mathcal{S}_{L}^{\Phi} \oplus \mathcal{T}_{L}^{\Phi}\right)\right) \subset Y_{\varrho}
$$

We assume here and hereafter that $y_{0} \equiv\left(\Lambda_{0}, \Phi_{0}\right)$ is a ground state solution of (4.4), where $\Lambda_{0}=\left(\lambda_{0, i j}\right)_{i, j=1}^{N}$ and $\Phi_{0}=\left(\phi_{0,1}, \ldots, \phi_{0, N}\right)$. We shall derive the existence of a unique local discrete solution $y_{\varrho} \in X_{\Phi_{0}, \varrho}$ of (4.12) in the neighborhood of $y_{0}$ and further obtain the a priori error estimate.

Our analysis will be carried out under the following two assumptions:
A1. There exists a constant $\alpha \in(0,1]$ such that $\left|\mathcal{E}^{\prime \prime}(t)\right|+\left|t \mathcal{E}^{\prime \prime \prime}(t)\right| \lesssim 1+t^{\alpha-1} \quad \forall t>0$.
A2. There exists a positive constant $\gamma$ depending on $\left(\Lambda_{0}, \Phi_{0}\right)$ such that for any $L$,

$$
\begin{equation*}
a_{\left(\Lambda_{0}, \Phi_{0}\right)}^{\delta}(\Psi, \Psi) \geq \gamma\|\Psi\|_{\delta, \Omega}^{2} \quad \forall \Psi \in \mathcal{T}_{L}^{\Phi_{0}} \tag{4.13}
\end{equation*}
$$

Remark 4.3. The assumption A2 is true for a symmetric bilinear form $\tilde{a}(u, v)=(A u, v)$ if the operator $A$ has $N$ lowest eigenvalues $\lambda_{1}, \ldots, \lambda_{N}$ and there is a gap between the lowest $N$ th eigenvalue and the $(N+1)$ th eigenvalue (see, e.g. [13, 43]).

Under the framework of Grassmann manifold [18, 43], the assumption A2 can be viewed as imposing the elliptic condition on $a_{\left(\Lambda_{0}, \Phi_{0}\right)}^{\delta}(\cdot, \cdot)$ on the tangent space.

The following lemma will be used in our analysis, which can be proved under the assumption A1 by using the same arguments as those in ([13], Lem. 4.6 and [16], Lem. 2.1).

Lemma 4.4. Let $y_{1}=\left(\Lambda_{1}, \Phi_{1}\right)$ and $y_{2}=\left(\Lambda_{2}, \Phi_{2}\right) \in Y_{L}$ satisfy $\left\|y_{1}\right\|_{Y_{L}}+\left\|y_{2}\right\|_{Y_{L}} \leq \bar{C}$. If the assumption A1 is satisfied, then there exists a constant $C_{F}$ depending on $\bar{C}$ such that

$$
\begin{equation*}
\left\|F_{L}\left(y_{1}\right)-F_{L}\left(y_{2}\right)\right\|_{Y_{L}^{*}} \leq C_{F}\left\|y_{1}-y_{2}\right\|_{Y_{L}} \quad \forall y_{1}, y_{2} \in Y_{L} \tag{4.14}
\end{equation*}
$$

Moreover, there is a constant $C_{F}^{\prime}$ such that

$$
\begin{equation*}
\left\|F_{L, y_{1}}^{\prime}-F_{L, y_{2}}^{\prime}\right\|_{\mathscr{L}\left(Y_{L}, Y_{L}^{*}\right)} \leq C_{F}^{\prime}\left(\left\|y_{1}-y_{2}\right\|_{Y_{L}}^{\alpha}+\left\|y_{1}-y_{2}\right\|_{Y_{L}}^{2}\right) \quad \forall y_{1}, y_{2} \in Y_{L} \tag{4.15}
\end{equation*}
$$

Lemma 4.5. If the assumption $\mathbf{A 2}$ is satisfied, then $F_{L, y_{0}}^{\prime}: X_{\Phi_{0}} \rightarrow X_{\Phi_{0}}^{*}$ is an isomorphism.
Proof. It is sufficient to prove that equation

$$
\begin{equation*}
F_{L, y_{0}}^{\prime}((\mu, \Psi))=(\mathfrak{\eta}, g) \tag{4.16}
\end{equation*}
$$

is uniquely solvable in $X_{\Phi_{0}}$ for every $(\mathfrak{\eta}, g) \in X_{\Phi_{0}}^{*}$. To this end we define the following bilinear forms $a_{\Phi_{0}}$ : $\mathcal{H}_{L} \times \mathcal{H}_{L} \rightarrow \mathbb{R}$ and $b_{\Phi_{0}}, c_{\Phi_{0}}: \mathcal{H}_{L} \times \mathbb{R}^{N \times N} \rightarrow \mathbb{R}$ by

$$
\begin{aligned}
a_{\Phi_{0}}(\Psi, \Gamma) & =a_{\left(\Lambda_{0}, \Phi_{0}\right)}^{\delta}(\Psi, \Gamma), \\
b_{\Phi_{0}}(\Psi, \mathfrak{\chi}) & =\sum_{i, j=1}^{N} \chi_{i j}\left(\phi_{0, i}, \psi_{j}\right), \\
c_{\Phi_{0}}(\Psi, \mathfrak{\chi}) & =\sum_{i, j=1}^{N} \chi_{i j}\left(\left(\phi_{0, i}, \psi_{j}\right)+\left(\phi_{0, j}, \psi_{i}\right)\right) .
\end{aligned}
$$

Using (4.11), we may rewrite (4.16) as follows: find $\mu \in \mathcal{S}^{N \times N}$ and $\Psi \in \mathcal{S}_{L}^{\Phi_{0}} \oplus \mathcal{T}_{L}^{\Phi_{0}}$ such that

$$
\left\{\begin{array}{rlrl}
a_{\Phi_{0}}(\Psi, \Gamma)-b_{\Phi_{0}}(\Gamma, \mu) & =(g, \Gamma) & \forall \Gamma \in \mathcal{S}_{L}^{\Phi_{0}} \oplus \mathcal{T}_{L}^{\Phi_{0}}  \tag{4.17}\\
c_{\Phi_{0}}(\Psi, \mathfrak{\chi}) & =\sum_{i, j=1}^{N} \chi_{i j} \eta_{i j} & & \forall \mathfrak{x} \in \mathcal{S}^{N \times N}
\end{array}\right.
$$

For any given $\mathfrak{\chi} \in \mathcal{S}^{N \times N}$, we can choose $\tilde{\Psi}=\Phi_{0 \mathfrak{\chi}}$, and thus

$$
\begin{equation*}
c_{\Phi_{0}}(\tilde{\Psi}, \mathfrak{\chi})=2 \sum_{i, j=1}^{N}\left|\chi_{i j}\right|^{2} \tag{4.18}
\end{equation*}
$$

where $\left\langle\Phi_{0}^{T} \Phi_{0}\right\rangle=I^{N \times N}$ is used. Note that a simple calculation leads to

$$
\begin{equation*}
\|\tilde{\Psi}\|_{\delta, \Omega}=\left\|\Phi_{0 \chi}\right\|_{1, \Omega} \lesssim\left(\sum_{i, j=1}^{N}\left|\chi_{i j}\right|^{2}\right)^{1 / 2}\left\|\Phi_{0}\right\|_{1, \Omega} \tag{4.19}
\end{equation*}
$$

By taking into account (4.18), (4.19) and the fact $\left\|\Phi_{0}\right\|_{1, \Omega} \leq C$, we obtain

$$
\begin{equation*}
\inf _{\mathfrak{X} \in \mathcal{S}^{N \times N}} \sup _{\Psi \in \mathcal{S}_{L}^{\Phi_{0}}} \frac{c_{\Phi_{0}}(\Psi, \mathfrak{X})}{\|\Psi\|_{\delta, \Omega}|\mathfrak{X}|} \geq \kappa_{c} \tag{4.20}
\end{equation*}
$$

with $\kappa_{c}>0$. Hence, there exists a unique solution $\Psi_{S} \in \mathcal{S}_{L}^{\Phi_{0}}$ such that

$$
c_{\Phi_{0}}\left(\Psi_{S}, \mathfrak{\chi}\right)=\sum_{i, j=1}^{N} \chi_{i j} \eta_{i j} \quad \forall \mathfrak{\chi} \in \mathcal{S}^{N \times N} .
$$

Therefore (4.17) is equivalent to: find $\Psi_{0} \in \mathcal{T}_{L}^{\Phi_{0}}$ such that

$$
\begin{equation*}
a_{\Phi_{0}}\left(\Psi_{0}, \Gamma\right)=(g, \Gamma)-a_{\Phi_{0}}\left(\Psi_{S}, \Gamma\right) \quad \forall \Gamma \in \mathcal{T}_{L}^{\Phi_{0}} \tag{4.21}
\end{equation*}
$$

The unique solvability of (4.21) is a direct consequence of (4.13).
Using similar arguments as those from (4.18) to (4.20), we get

$$
\inf _{\mathfrak{x} \in \mathcal{S}^{N} \times N} \sup _{\Psi \in \mathcal{S}_{L}^{\Phi_{0}}} \frac{b_{\Phi_{0}}(\Psi, \mathfrak{\chi})}{\|\Psi\|_{\delta, \Omega}|\mathfrak{X}|} \geq \kappa_{b}
$$

with $\kappa_{b}>0$. This implies that equation

$$
b_{\Phi_{0}}(\Gamma, \mu)=a_{\Phi_{0}}\left(\Psi_{0}+\Psi_{S}, \Gamma\right)-(g, \Gamma) \quad \forall \Gamma \in \mathcal{S}_{L}^{\Phi_{0}}
$$

has a unique solution $\mu_{S} \in \mathcal{S}^{N \times N}$.
We have proved that for any $(\mathfrak{q}, g) \in X_{\Phi_{0}}^{*}$, (4.17) has a unique solution ( $\left.\mu_{S}, \Psi_{0}+\Psi_{S}\right)$. This indicates that $F_{L, y_{0}}^{\prime}$ is an isomorphism from $X_{\Phi_{0}}$ to $X_{\Phi_{0}}^{*}$ and completes the proof.

Before giving a discrete counterpart of Lemma 4.5, we shall introduce two projections. First, we define the projection $\tilde{\Pi}_{\varrho}: \mathbb{Q} \rightarrow \mathcal{V}_{\varrho} \cap \mathbb{Q}$ such that

$$
\left\|\tilde{\Pi}_{\varrho} \Phi-\Phi\right\|_{\delta, \Omega}=\min _{\Psi \in \mathcal{V}_{\varrho} \cap \mathbb{Q}}\|\Psi-\Phi\|_{\delta, \Omega} \quad \forall \Phi \in \mathbb{Q} .
$$

To project further onto $X_{\Phi, \varrho}$, we then define $\Pi_{\varrho}: \mathcal{S}^{N \times N} \times \mathbb{Q} \rightarrow X_{\Phi, \varrho}$ by

$$
\Pi_{\varrho}(\Lambda, \Phi)=\left(\Lambda,\left(\tilde{\Pi}_{\varrho} \Phi\right) \tilde{U}\right) \quad \forall(\Lambda, \Phi) \in \mathcal{S}^{N \times N} \times \mathbb{Q}
$$

where

$$
\tilde{U}=\arg \min _{U \in \mathcal{O}^{N \times N}}\left\|\left(\tilde{\Pi}_{\varrho} \Phi\right) U-\Phi\right\|_{0, \Omega}
$$

From Lemma 4.2, we see that $\Pi_{\varrho}: \mathcal{S}^{N \times N} \times \mathbb{Q} \rightarrow X_{\Phi, \varrho}$ is well-defined. We obtain by a direct estimate (see [16], proof of Lem. 3.3) that for any $y=(\Lambda, \Phi) \in \mathcal{S}^{N \times N} \times \mathbb{Q}$,

$$
\begin{equation*}
\left\|\Pi_{\varrho} y-y\right\|_{Y_{L}} \lesssim \inf _{\Psi \in \mathcal{V}_{\varrho}}\|\Psi-\Phi\|_{\delta, \Omega} . \tag{4.22}
\end{equation*}
$$

Note that $F_{L, y_{0}}^{\prime}: X_{\Phi_{0}} \rightarrow X_{\Phi_{0}}^{*}$ being an isomorphism is equivalent to the following inf-sup condition

$$
\begin{equation*}
\inf _{y_{1} \in X_{\Phi_{0}}} \sup _{y_{2} \in X_{\Phi_{0}}} \frac{\left\langle F_{L, y_{0}}^{\prime} y_{1}, y_{2}\right\rangle}{\left\|y_{1}\right\|_{Y_{L}}\left\|y_{2}\right\|_{Y_{L}}}=\beta>0 \tag{4.23}
\end{equation*}
$$

with the constant satisfying $\beta^{-1}=\left\|F_{L, y_{0}}^{\prime-1}\right\|_{\mathscr{L}\left(X_{\Phi_{0}}^{*}, X_{\Phi_{0}}\right)}$. We can derive from (4.22) (see [16]) that for sufficiently large $\varrho$,

$$
\inf _{y_{1} \in X_{\Phi_{0}, e}} \sup _{y_{2} \in X_{\Phi_{0}, e}} \frac{\left\langle F_{Q, y_{0}}^{\prime} y_{1}, y_{2}\right\rangle}{\left\|y_{1}\right\|_{Y_{L}}\left\|y_{2}\right\|_{Y_{L}}} \geq \frac{\beta}{2},
$$

which together with the fact that $F_{\varrho, y_{0}}^{\prime}$ satisfies the following inequality analogous to (4.15)

$$
\left\|F_{\varrho, y_{0}}^{\prime}-F_{\varrho, \Pi_{e} y_{0}}^{\prime}\right\|_{\mathscr{L}\left(Y_{Q}, Y_{\varrho}^{*}\right)} \lesssim\left\|y_{0}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}^{\alpha}+\left\|y_{0}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}^{2}
$$

leads to the following discrete counterpart of Lemma 4.5.
Lemma 4.6. If the Assumption $\mathbf{A 1}$ and $\mathbf{A 2}$ are satisfied, then there exists $n_{0} \in \mathbb{N}$ such that $F_{\varrho, \Pi_{\rho} y_{0}}^{\prime}: X_{\Phi_{0}, \varrho} \rightarrow$ $X_{\Phi_{0}, \varrho}^{*}$ is an isomorphism for all $\varrho \geq n_{0}$. Moreover, there is a constant $M>0$ such that

$$
\| F_{\varrho, \Pi_{e} y_{0}}^{\prime} y_{\mathscr{L}\left(X_{\Phi_{0}, e}^{*}, X_{\Phi_{0}, \varrho}\right)}^{-1} \leq M \quad \forall \varrho \geq n_{0} .
$$

Now we have the main result of this section as follows.
Theorem 4.7. Let $y_{0} \equiv\left(\Lambda_{0}, \Phi_{0}\right)$ be a ground state solution of (4.4). If the Assumptions A1 and A2 are satisfied, then there exist $\sigma>0$ and $n_{1} \in \mathbb{N}$ such that (4.12) has a unique local solution

$$
y_{\varrho}=\left(\Lambda_{\varrho}, \Phi_{\varrho}\right) \in X_{\Phi_{0}, \varrho} \cap B_{\sigma}\left(y_{0}\right)
$$

for all $\varrho \geq n_{1}$. Moreover, we have the following a priori error estimate

$$
\begin{equation*}
\left|\Lambda_{0}-\Lambda_{\varrho}\right|+\left\|\Phi_{0}-\Phi_{\varrho}\right\|_{\delta, \Omega} \leq C\left(\inf _{\Psi \in \mathcal{V}_{\varrho}}\left\|\Phi_{0}-\Psi\right\|_{\delta, \Omega}+\varrho^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})}\right) . \tag{4.24}
\end{equation*}
$$

Proof. The idea of this proof is to construct a contractive mapping whose fixed point is $y_{\varrho}$. We rewrite (4.12) as

$$
\begin{equation*}
F_{\varrho}\left(y_{\varrho}\right)-F_{\varrho}\left(\Pi_{\varrho} y_{0}\right)=-F_{\varrho}\left(\Pi_{\varrho} y_{0}\right) . \tag{4.25}
\end{equation*}
$$

Using the fact that $\left(\Lambda_{0}, \Phi_{0}\right)$ is a ground state solution and similar argument to that in (3.26), we have that for any $\mathfrak{\chi} \in \mathbb{R}^{N \times N}$ and $\Gamma=\left(\gamma_{1}, \ldots, \gamma_{N}\right) \in \mathcal{V}_{\varrho}$,

$$
\left\langle F_{\varrho}\left(\left(\Lambda_{0}, \Phi_{0}\right)\right),(\mathfrak{\chi}, \Gamma)\right\rangle=\sum_{i=1}^{N} \int_{\Gamma} \frac{\partial \phi_{0, i}}{\partial n}\left(\gamma_{i}^{+}-\gamma_{i}^{-}\right) \leq C L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{O})}\|\Gamma\|_{\delta, \Omega},
$$

which together with (4.14) leads to

$$
\begin{aligned}
\left\|F_{\varrho}\left(\Pi_{\varrho} y_{0}\right)\right\|_{Y_{\varrho}^{*}} & \leq\left\|F_{\varrho}\left(\Pi_{\varrho} y_{0}\right)-F_{\varrho}\left(y_{0}\right)\right\|_{Y_{\varrho}^{*}}+\left\|F_{\varrho}\left(y_{0}\right)\right\|_{Y_{\varrho}^{*}} \\
& \leq\left\|F_{L}\left(\Pi_{\varrho} y_{0}\right)-F_{L}\left(y_{0}\right)\right\|_{Y_{L}^{*}}+\sup _{\left(\mathfrak{K}_{\varrho}, \Gamma_{\varrho}\right) \in X_{\Phi_{0}, \varrho}} \frac{\left\langle F_{\varrho}\left(\left(\Lambda_{0}, \Phi_{0}\right)\right),\left(\chi_{\varrho}, \Gamma_{\varrho}\right)\right\rangle}{\left\|\left(\mathfrak{K}_{\varrho}, \Gamma_{\varrho}\right)\right\|_{Y_{L}}} \\
& \lesssim\left\|\Pi_{\varrho} y_{0}-y_{0}\right\|_{Y_{L}}+L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})} .
\end{aligned}
$$

From (4.25) and Lemma 4.6, we may define the map $\mathcal{N}: B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho} \rightarrow X_{\Phi_{0}, \varrho}$ by

$$
\begin{equation*}
F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}\left(\mathcal{N}(x)-\Pi_{\varrho} y_{0}\right)=-F_{\varrho}\left(\Pi_{\varrho} y_{0}\right)-\left(x-\Pi_{\varrho} y_{0}\right) \int_{0}^{1}\left(F_{\varrho, \Pi_{\varrho} y_{0}+t\left(x-\Pi_{\varrho} y_{0}\right)}^{\prime}-F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}\right) \mathrm{d} t \tag{4.26}
\end{equation*}
$$

when $\varrho \geq n_{0}$. We will show that $\mathcal{N}$ is a contraction from $B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$ into $B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$ if $R$ is chosen sufficiently small and $\varrho$ is large enough.

First, we prove that $\mathcal{N}$ maps $B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$ to $B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$ for sufficiently small $R$. For each $x \in B_{R}\left(\Pi_{\varrho} y_{0}\right)$ and $\varrho>n_{0}$, we have $\mathcal{N}(x)-\Pi_{\varrho} y_{0} \in X_{\Phi_{0}, \varrho}$ and

$$
\begin{aligned}
\left\|\mathcal{N}(x)-\Pi_{\varrho} y_{0}\right\|_{Y_{L}} & \leq M\left(\left\|F_{\varrho}\left(\Pi_{\varrho} y_{0}\right)\right\|_{Y_{\varrho}^{*}}+R \int_{0}^{1}\left\|F_{\varrho, \Pi_{\varrho} y_{0}+t\left(x-\Pi_{\varrho} y_{0}\right)}^{\prime}-F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}\right\| \mathrm{d} t\right) \\
& \leq C M\left(\left\|\Pi_{\varrho} y_{0}-y_{0}\right\|_{Y_{L}}+R\left(R^{\alpha}+R^{2}\right)+L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})}\right)
\end{aligned}
$$

Since $C M\left(\left\|\Pi_{\varrho} y_{0}-y_{0}\right\|_{Y_{L}}+R^{1+\alpha}+R^{3}+L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})}\right)$ can be estimated by $R$ when $R$ is sufficiently small and $\varrho$ is sufficiently large, we have that $\mathcal{N}(x) \in B_{R}\left(\Pi_{\varrho} y_{0}\right)$.

Next, we show that $\mathcal{N}$ is a contraction on $B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$. If $x_{1}, x_{2} \in B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$, then

$$
F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}\left(\mathcal{N}\left(x_{1}\right)-\mathcal{N}\left(x_{2}\right)\right)=\left(x_{1}-x_{2}\right) \int_{0}^{1}\left(F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}-F_{\varrho, x_{1}+t\left(x_{2}-x_{1}\right)}^{\prime}\right) \mathrm{d} t
$$

Thus, $\left\|\mathcal{N}\left(x_{1}\right)-\mathcal{N}\left(x_{2}\right)\right\|_{Y_{L}}$ can be estimated as

$$
\begin{aligned}
\left\|\mathcal{N}\left(x_{1}\right)-\mathcal{N}\left(x_{2}\right)\right\|_{Y_{L}} & \leq M\left\|x_{1}-x_{2}\right\|_{Y_{L}} \int_{0}^{1}\left\|F_{\varrho, \Pi_{\varrho} y_{0}}^{\prime}-F_{\varrho, x_{1}+t\left(x_{2}-x_{1}\right)}^{\prime}\right\| \mathrm{d} t \\
& \leq C M\left(R^{\alpha}+R^{2}\right)\left\|x_{1}-x_{2}\right\|_{Y_{L}}
\end{aligned}
$$

We obtain that $C M\left(R^{\alpha}+R^{2}\right)<1$ for sufficiently small $R$ and hence $\mathcal{N}$ is a contraction on $B_{R}\left(\Pi_{\varrho} y_{0}\right)$.
We are now able to use Banach's Fixed Point Theorem to obtain the existence and uniqueness of a fixed point $y_{\varrho}$ of the $\operatorname{map} \mathcal{N}: B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho} \rightarrow B_{R}\left(\Pi_{\varrho} y_{0}\right) \cap X_{\Phi_{0}, \varrho}$, which is the solution of $F_{\varrho}\left(y_{\varrho}\right)=0$.

Take $x=y_{\varrho}$ in (4.26), we have

$$
\begin{aligned}
\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}} \lesssim & \left\|y_{0}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}+L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})} \\
& +\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}\left(\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}^{\alpha}+\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}^{2}\right)
\end{aligned}
$$

which together with the fact that $\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}$ can be arbitrary small implies

$$
\begin{equation*}
\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}} \lesssim\left\|y_{0}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}+L^{-(s-1)}\left\|\Phi_{0}\right\|_{H^{s}(\mathscr{D})} \tag{4.27}
\end{equation*}
$$

Using (4.22), (4.27) and the triangle inequality

$$
\left\|y_{\varrho}-y_{0}\right\|_{Y_{L}} \leq\left\|y_{\varrho}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}+\left\|y_{0}-\Pi_{\varrho} y_{0}\right\|_{Y_{L}}
$$

we can obtain (4.24). This completes the proof.
Remark 4.8. Note that Lemma 2.2 can not be applied to KS equations directly due to the singularity of the exchange-correlation potential $v_{\mathrm{xc}}$. If the KS orbitals $\left\{\phi_{i}\right\}_{i=1}^{N}$ are assumed to be asymptotically well behaved, then we get from Theorems 3.2 and 4.7 that

$$
\left|\Lambda_{0}-\Lambda_{\varrho}\right|+\left\|\Phi_{0}-\Phi_{\varrho}\right\|_{\delta, \Omega} \leq C_{s} \varrho^{-(s-3 / 2)} \quad \forall s>\frac{3}{2}
$$

Remark 4.9. The arguments in this section are related to the techniques in $[13,16,34,51]$. We shall point out that $[13,16,34]$ are also devoted to the DFT models, nevertheless, the theory in $[13,16]$ can not be applied to nonconforming methods, and [34] analyzes the orbital-free DFT models which consider the lowest eigenvalue only.

Figure 3. Eigenvalue errors of plane wave and nonconforming approximations.

Figure 4. Eigenvalue errors of nonconforming approximations with different spherical radius.

## 5. Numerical experiments

In this section, we shall test our theoretical results by some numerical experiments. Since the analytical solutions of the eigenvalue problems are not available, we use the numerical solutions on the finest discretizations as references to calculate the approximation errors.

Example 1. We solve the linear eigenvalue problem: find $\lambda \in \mathbb{R}$ and $u \in H_{\#}^{1}(\Omega)$ such that

$$
-\frac{1}{2} \Delta u+V_{\mathrm{ext}} u=\lambda u
$$

where $\Omega=[-5.0,5.0]^{3}$ and the periodic external potential is

$$
V_{\mathrm{ext}}(\mathbf{r})= \begin{cases}-\frac{1}{r}-\frac{1}{2 r_{0}-r} & \text { if } r<r_{0} \\ -\frac{2}{r_{0}} & \text { if } r \geq r_{0}\end{cases}
$$

in $\Omega$ with $r_{0}=3.0$. We consider only the lowest eigenvalue of this problem.
We compare the eigenvalue errors of the plane wave approximations and our nonconforming approximations in Figure 3. It is observed that the convergence rate is significantly improved by our nonconforming method. The numerical errors obtained by different choices of atomic spheres are presented in Figure 4. We observe not only the exponential decay of the eigenvalue errors but also a faster decay with a larger atomic sphere. In fact, the eigenfunctions in the interstitial region with a larger sphere are less varying and hence more propitious to plane wave approximations. The eigenfunction on the $x$-axis is displayed in Figure 5, from which we observe that the nonconforming approximation can catch the cusp at the origin while the plane wave approximation can not.

We also present in Figure 6 the eigenvalue errors as a function of the order of polynomial radial basis functions. We observe that given a sufficiently large $K$, the errors of eigenvalue approximations converge exponentially. We mention that the condition of Lemma 2.2 is not strictly satisfied for this example since the potential $V_{\text {ext }}$ is only continuous up to the first order derivative on the sphere with $r=r_{0}$. Nevertheless, we still have exponential decay of the numerical errors, which supports the theoretical results in this paper.

The numerical results of the following two examples are presented in atomic unit (a.u.).

Figure 5. Eigenfunctions on $x$-axis obtained by plane wave and nonconforming methods.

Figure 6. Eigenvalue errors of nonconforming approximations with respect to the order of polynomials with fixed $K=6$.

Example 2. We consider the computation of the ground state of a hydrogen atom by the APW method in the supercell $\Omega=[-5.0,5.0]^{3}$ with periodic boundary condition.

Since the APW basis functions depend on the eigenvalues and lead to nonlinear equations, the eigenvalues are normally solved by the "root tracing" technique that determines the eigenvalues by varying the parameter $\varepsilon$ numerically to satisfy the condition

$$
\operatorname{det}\left(H_{\varepsilon}-\varepsilon M_{\varepsilon}\right)=0
$$

where $H_{\varepsilon}$ and $M_{\varepsilon}$ are Hamilton matrix and mass matrix generated by the basis set given in (3.36). Instead of calculating the determinant of $H_{\varepsilon}-\varepsilon M_{\varepsilon}$ (which varies strongly in this example and is difficult for root interpolation), we here compute the eigenvalues of $M_{\varepsilon}^{-1} H_{\varepsilon}$ for each parameter $\varepsilon$, and calculate the difference between the parameter and its closest eigenvalue $\lambda_{\varepsilon}$, say $\lambda_{\varepsilon}-\varepsilon$. The eigenvalues of the nonlinear problem can be found where the difference is 0 by interpolation (see Fig. 7). The errors on the lowest eigenvalue of plane wave and APW approximations are compared in Figure 8, from which we observe that the APW method is much more accurate.

We shall mention that the computational cost of this nonlinear problem is very large even for medium size systems. In contrast, LAPW (+lo) bases can result in straightforward linear eigenvalue problems and reduce the computational cost significantly.

Example 3. To examine the performance of LAPW approximations, we use the package Exciting [54] to calculate the aluminium $(\mathrm{Al})$ and lithium-fluorine (LiF) crystals. Exciting is a full-potential DFT package based on the LAPW + lo methods and use a SCF iteration for solving the nonlinear KS equations. The numerical errors of the ground state energy approximations are presented in Figures 9 and 10, from which we observe exponential convergence rates with respect to both $K$ and $L$.

Moreover, we compare the full-potential computations by using package Exciting and the pseudopotential computations by using package Abinit $[25,52]$ for the LiF crystal. We plot in Figure 11 the electron density on a plane (the structure is presented in the left of the figure) obtained by these two methods, from which we see that the true density including the core electrons is obtained by full-potential calculations, whereas the pseudopotential calculations can only have a pseudo electron density of valence electrons.

Figure 7. Search the eigenvalues of the nonlinear problem generated by APW basis set.

Figure 8. Eigenvalue errors of plane wave and APW approximations.

Figure 10. Errors on the ground state energy with respect to the angular momentum cut-off $L$ for Al and LiF using the package Exciting.

## 6. CONCLUDING REMARKS

In this paper, we analyze the (L)APW methods which are widely used in full-potential electronic structure calculations. The (L)APW methods enable highly accurate and reliable electronic structure calculations, since they avoid the use of pseudopotentials that might be a source of modeling errors difficult to control. We introduce a nonconforming method based on the idea of the (L)APW methods, which use different types of basis functions inside and outside the atomic spheres. We obtain an a priori error estimate of the nonconforming approximations for both linear Schrödinger type equations and nonlinear KS equations, and present some numerical results to support our theory. Due to the fast convergence rate, which is the central result of this paper, the (L)APW methods provide high precision using only approximately the same number of degrees of freedom, or even less, than usually done in the plane wave codes.

Figure 11. Electron density of LiF obtained by the packages Exciting and Abinit. Left: the structure of the plane. Middle: result of Abinit. Right: result of Exciting.

In order to set up the Galerkin system matrices and the overlap matrices, one has to integrate plane waves over a complicated interstitial region $\mathscr{D}$ where the atomic spheres are excluded from the unit cell $\Omega$. These integrals are computed by integrating over the whole unit cell and subtracting the integrals over the spheres. The explicit formulas for these integrals can be found in, e.g. $[16,39]$. However, there arise some discretization errors when calculating these integrals numerically. In this paper, we have not considered this issue but assume that the integrals can be computed exactly. The numerical errors arising from the integrations may be investigated in our future works.

Instead of polynomials, more physically meaningful basis functions like Gaussian or Slater type functions may be incorporated in this nonconforming framework. However, the difficulties lie in that all $\chi_{i}$ do not vanish at the spherical surface, which may generate too many basis functions in computations. The discontinuous Galerkin (DG) methods may be a proper way to handle this problem, in which different areas can be approximated by completely separate basis functions and matched together by DG schemes [15].

Similar to the APW method, the Muffin-tin orbital (MTO) approach $[3,4,39]$ is another type of atomic sphere methods. It exploits the same idea that divides the simulation domain and provides efficient representations for atomic-like features that are rapidly varying near each nucleus and smoothly varying between the atoms. The MTO method reformulates the multiple-scattering (MST, also called KKR since it was invented independently by Korringa et al. [39]) method, and leads to physically meaningful descriptions of the electronic states in terms of a small basis set of localized, augmented functions.

The MTO basis functions depend on the parameters $\kappa$ and $\varepsilon$,

$$
\omega_{l m}^{\mathrm{MTO}}(\mathbf{r})=i^{l} Y_{l m}(\hat{\mathbf{r}}) \begin{cases}\chi_{l}(r, \varepsilon)+\kappa \cot \left(\eta_{l}(\varepsilon)\right) j_{l}(\kappa r) & \text { in } \mathscr{C},  \tag{6.1}\\ \kappa n_{l}(\kappa r) & \text { in } \mathscr{D},\end{cases}
$$

where $\chi_{l}(r, \varepsilon)$ is the solution of (3.35), $j_{l}$ and $n_{l}$ are spherical Bessel and Neumann functions respectively (for negative energies, the Neumann functions are replaced by Hankel functions), and the coefficients $\eta_{l}$ are determined by requiring that the basis functions match the value and slope at the spherical surface. The equations for many-atom systems can be derived using an expansion theorem and the tail cancelation condition, which expresses the tail of a MTO basis extending into another sphere in terms of functions centered on that sphere (see, e.g. $[4,39]$ ). This amounts to a transformation of the KKR method and (the eigenvalue-dependent basis set) would lead to a nonlinear eigenvalue problem. Since the solutions obtained by the MTO method satisfy the equation both inside and outside the spheres, the convergence of the MTO approximations can be proven using similar arguments as those in this paper (the detail proof will be given elsewhere), and the error is only determined by the truncation of angular momentum $L$.

For the linearized Muffin-tin orbital (LMTO) method (see, e.g. [39]), the error estimate is far too difficult compared with the LAPW method. The errors of the LAPW approximations are mainly induced by linearization, while the numerical integrations of basis functions can be done quite accurately both inside and outside the
atomic spheres. In contrast, the numerical integrations for the LMTO method are much more complicated, which apply the atomic sphere approximation (ASA) and use the space-filling cells (Wigner-Seitz cells, see, e.g. $[3,39]$ ) neglecting the interstitial region. These error analyses shall be investigated in our future works.

Acknowledgements. We are indebted to two anonymous referees for carefully reading the original manuscript and for suggesting a number of corrections and improvements. The research for this paper has been enabled by the Alexander von Humboldt Foundation, whose support for the long term visit of H. Chen at Technische Universität Berlin is gratefully acknowledged.
