## CHAPTER 4

## NUMERICAL CALCULATION OF WIND WAVES IN SHALLOW WATER

Takeshi Ijima Dr. Eng. Prof. of Hydraulic Civil Engineering Department, Kyushyu Univ. Japan<br>Frederick L. W. Tang<br>Associate Prof. of Hydraulic Engineering<br>Department, Cheng Kung Univ. Republic of China

## SYNOPSIS

For the purpose of estimating the waves raised by typhoons approaching continental shelf and inland seas, one of the authors (I960) devised graphical method to the forecasting the waves in the fetches travelling over shallow water area in 1960. The method has been widely adopted to evaluate the waves of the bays and inland seas in Japan and the western coast of Taiwan, since it was proved that calculated results considerably agreed with measured records.

On the account of the spread of electronic computers, numerical analysis will be more expedient than graphical operations nowadays. Wilson s numerical integration method (I96I)(I962) has been extended to facilitate the calculation of the waves of shallow water area. The procedures of calculation are described and example of hindcasting of waves in typhoon by the machine run are also submitted in this paper.

PROPOSED RELATIONSHIPS
GOVERING SHALLOW WATER GENERATION
Based on the measured data of Bretschneider (I958), the sibnificant wave height $H$ and period $T$ are expressed by the following equations in shallow water.

$$
\begin{align*}
\frac{g H}{U^{2}}= & a \tanh \left[k_{s}\left(\frac{g D}{U^{2}}\right)^{3 / 4}\right] \tanh \left[\frac{k_{1}\left(g x / U^{21 / 2}\right.}{\left.\tanh k_{3}\left(g D / U^{2}\right)^{3 / 4}\right]}\right.  \tag{I}\\
& U: \text { wind velocity } \quad D: \text { water depth } \\
& g: \text { gravity } \quad k: \quad \text { fetch length } \\
& \alpha=0.26 \quad k=0.0 I \quad k=0.578
\end{align*}
$$

$$
\begin{gather*}
\frac{g T}{2 \pi U}=\beta \tanh \left[k_{4}\left(\frac{g D}{U^{2}}\right)^{3 / / 3}\right] \tanh \left[\frac{k_{2}\left(g x / U^{2}\right)^{1 / 3}}{\tanh k_{4}\left(g D / U^{2}\right)^{1 / 8}}\right] \ldots  \tag{2}\\
\beta=1.40 \quad k_{2}=0.0436 \quad k_{4}=0.520
\end{gather*}
$$

Both of the equations are approaching to Wilson's
while $D \rightarrow \infty$

$$
\begin{align*}
& \frac{\mathrm{gH}}{\mathrm{U}^{2}}=\alpha \tanh \left[\mathrm{k}_{1}\left(\frac{\mathrm{gx}}{\mathrm{U}^{2}}\right)^{1 / 2}\right]  \tag{3}\\
& \frac{\mathrm{gT}}{2 \pi \mathrm{U}}=\beta \tanh \left[\mathrm{k}_{2}\left(\frac{\mathrm{gx}}{\mathrm{U}^{2}}\right)^{1 / 3}\right] \tag{4}
\end{align*}
$$

Equations (1) and (2) are illustrated by Fig. 1 and 2.
The ratio between group velocity and wind velocity in shallow water is:

Let

$$
\begin{gather*}
\frac{G}{U}=\frac{1}{2}\left(I+\frac{4 \pi D / L}{\sinh 4 \pi D / L}\right) \frac{g T}{2 \pi U} \tanh \frac{2 \pi D}{L}  \tag{5}\\
G: \text { group velocity } \quad L: \text { wave length } \\
S=\frac{g D / U^{2}}{g T / 2 \pi U}=\frac{2 \pi D}{L_{0}}=\frac{2 \pi D}{L} \tanh \frac{2 \pi D}{L}=y \text { tanh }  \tag{6}\\
L: \text { wave length in deep water } \\
y=\frac{2 \pi D}{L}
\end{gather*}
$$

Next, designate

$$
\begin{equation*}
M=\frac{G / U}{\left(g D / U^{2}\right)^{1 / 2}} \tag{7}
\end{equation*}
$$

From eq. (5)

$$
\begin{equation*}
M=\frac{S-S^{2}-y^{2}}{2 y S^{1 / 2}} \tag{8}
\end{equation*}
$$

If $s$ approaches to $0, y^{2}=s, M=1-S / 2$, whereas $s=\pi$, is the case of deep water wave, the ratio between group velocity and wind velocity is expressed by:

$$
\begin{equation*}
\frac{\mathrm{G}}{\mathrm{U}}=\frac{1}{2} \frac{\mathrm{gT}}{2 \pi \mathrm{U}}=\frac{\beta}{2} \tanh \left[\mathrm{k}_{2}\left(\frac{\mathrm{gx}}{\mathrm{U}^{2}}\right)^{1 / 3}\right] \tag{9}
\end{equation*}
$$

In the region of $0<S<\pi$, following equation can be approximately established

$$
\begin{array}{rlrl}
1-M & =a_{1} s+a_{2} s^{2}+\ldots+a_{6} s^{6}  \tag{10}\\
a_{1} & =0.4536 & a_{2} & =0.0931 \\
a_{3} & =-0.2745 & a_{4} & =0.17033 \\
a_{5} & =-0.04760 & a_{6} & =0.005067
\end{array}
$$

From this equation, in case $S \geq \pi, M \leqq 0.288$, and $S$ can also be expressed as follows if $M>0.288$

$$
\mathrm{b}_{7}=\text { IOI.I9046 }
$$

The group velocity and period of shallow water wave can be calculated when $S$ and $M$ are worked out.

## CALCULATION PROCEDURES

The calculation of waves in shallow water is also to be carried out by stepwise method from the lattice of wind field, only evaluating $S$ instead of calculating period or celerity directly. At the initial point of the fetch, Wilson's method will be adopted all the same. If the wave height Ha, group velocity Ga at the point " $a^{\prime \prime}$ on the space time wind field are known, the problem is to calculate the wave features of the point " $b$ " in the lattice as shown in Fig. 3.

At first, compute the velocity Ua of the wind blowing over point "a"from the lattice or by a formula $U=U(x, t)$, which can be drived from the pressure distribution of typoon or hurricane as well as its moving direction and velocity, also the water depth of this point Da is to be detemined from the lattice or some approxmate function $D=D(x, t)$.

Secondary, calculate $M a=\frac{G a}{U a} \frac{I}{(g D a / U a)^{1 / 2}}, \quad$ if $M<0.288$, the waves at this point are still to be deep water wave, and Wilson's method should be used, whereas $\mathrm{M}<0.288$ following procedures are to be adopted.

## CALCULATION IN CASE OF WAVE

DEVELOPMENT
By differentiating Eq. (I)

$$
\frac{d H}{d x}=\frac{k^{2}}{\alpha} x
$$

$\left[\alpha \tanh k_{s}\left(g D / U^{2}\right)^{1 / 4} g H / U^{2}\right] \quad\left[\alpha \tanh k_{3}\left(g D / U^{2}\right)^{\frac{1}{4}}-g H / U^{2}\right]$
$x \frac{\left[\alpha \tanh k_{3}(g D / U)^{3 / 4} g H / U\right]\left[\alpha \tanh k_{3}(g D / U)^{2 / 4}-g H / U^{2}\right]}{\left[\tanh k_{3}\left(g D / U^{2}\right)^{3 / 1}\right]\left[\ln \left(\alpha \tanh k_{3}(g D / U)^{1 / k}+g H^{2} / U^{2}\right)-\ln \left(\alpha \tanh k_{3}\left(g D / U^{2}\right)^{2 / 4} g H / U^{2}\right)\right]}$ .........(I2)
at point" $a^{\prime \prime}$, if the waves are developing, it must be that atanh $k_{j}\left(g D / U^{1 / 4}>g H / U^{2}\right.$, and the wave height $H b$ can be calculated by:

$$
H_{b}=H_{a}+\left(\frac{d H}{d x}\right)_{a} \Delta x
$$

the choosing of $\Delta x$ is the same as Wilson's method.

$$
\begin{aligned}
& S=b_{1}(I-M)+b_{2}(I-M)^{2}+\ldots . .+b_{7}(I-M)^{n} \ldots .(I I) \\
& b_{1}=2.464857 \quad b_{2}=-7.35305 \\
& \mathrm{~b}_{3}=52.74583 \quad \mathrm{~b}_{4}=-\mathrm{I} 62 . \dot{2} \\
& \mathrm{~b}_{5}=275.8 \dot{3} \quad \mathrm{~b}_{6}=-247 . \dot{2}
\end{aligned}
$$

Prior to the evaluation of group velocity, calculate Sa from Ma by eq.(ll).

Since $\quad S=\frac{g D}{U^{2}} /\left(\frac{g T}{2 \pi U}\right)^{2} \quad$ from eq. (2)

$$
\begin{equation*}
S=\frac{g D}{U^{2}}\left[\beta \tanh k_{4}\left(\frac{g D}{U^{2}}\right)^{1 / 8}\right] \tanh \left[\frac{k_{2}(g x / U)^{1 / 3}}{\tanh k_{4}\left(g D / U^{2}\right)^{3 / 2}}\right] \tag{13}
\end{equation*}
$$

therefore

$$
\frac{d S}{d x}=\frac{8 k_{2}^{3}}{3 \beta} \frac{g}{U^{2}} \frac{S}{\left(1 / S \times g D / U^{2}\right)^{2}}\left[\tanh \frac{1}{\mathrm{k}_{\mu}\left(\mathrm{gD} / \mathrm{U}^{2}\right)^{3 / 2}}\right] \times
$$

$\frac{\left[\beta \tanh \left\{k_{*}\left(g D / U^{2}\right)^{3 / 8}+\left(1 / S \times g D / U^{2 / 2}\right)^{1 / 2}\right]\left[\beta \tanh \left\{k_{4}\left(g D / U^{2}\right)^{3 / 2}\right\}-\left(1 / S \times g D / U^{2 / 2}\right)^{1 / 2}\right]\right.}{\left\{\ln \left[\beta \tanh k_{4}\left(g D / U^{2}\right)^{1 / 2}\right\}-\left(1 / S \times g D / U^{2}\right)^{2 / 2}\right]^{2 / 2} \ln \left[\beta \tanh \left\{\left(g D / U^{2}\right)^{3 / 3}\right\}-\left(1 / S \times g D / U^{2}\right)^{2 / 2}\right\}^{2}}$
For developing waves, naturally $\beta \tanh \left\{k_{x}\left(g D / U^{2}\right)^{3 / 8}\right\} \cdots(14)$ $\left(1 / \mathrm{S} \times \mathrm{gD} / \mathrm{U}^{2}\right)^{1 / 2}$, and Sb will be determined by following equation,

$$
\begin{equation*}
\mathrm{Sb}=\mathrm{Sa}+\left(\frac{\mathrm{dS}}{\mathrm{dx}}\right)_{a} \Delta \mathrm{x} \tag{15}
\end{equation*}
$$

Mb can be calculated by eq.(10) and

$$
\begin{equation*}
G b=M b U_{2}\left(\frac{g D a}{U \dot{a}}\right)^{1 / 2}=M b(g D a)^{1 / 2} \tag{16}
\end{equation*}
$$

also

$$
\begin{equation*}
T b=\left(\frac{4 \pi^{2} \mathrm{Da}}{g S b}\right)^{1 / 2} \tag{17}
\end{equation*}
$$

CALCULATION IN CASE OF WAVE DECAY
If $\alpha \tanh \left\{k_{3}\left(g D / U^{2}\right)^{3 / 1 /}\right\}<g H / U^{2}$ and/or $\beta \tanh \left\{k_{4}\left(g D / U^{2}\right)^{3 / 8}\right\}<(1 / \mathrm{S} \times$ $\left.g D / U^{2 / 2}\right)^{2 r e}$ recognized at point "a", it means that the wave series whose height is Ha reaching this point with group velocity $G a$ can not grown any more under the circumstance Ua and Da. In other words, the waves have already larger than the wind Ua can generate in shallow water area of depth Da. As shown in Fig. 4, Ha is located above the curve $\mathrm{H}(\mathrm{Ua}, \mathrm{Da}$ ). In such a case, following consideration are being made.

1) If the wind of velocity Ua blew over deep water area, the wave height would increase $\Delta H_{1}$, while the fetch was being prolonged $\Delta x, \Delta H_{1}$, can be calculated by

$$
\begin{align*}
& \Delta H_{1}=\left(\frac{d H}{d x}\right)_{a} \Delta x \\
= & \frac{k^{2}}{a} \frac{\left(\alpha+g H a / U a^{2}\right)\left(\alpha-g H a / U a^{2}\right)}{\ln \left(a+g H a / U a^{2}\right)-\ln \left(a-g H a / U a^{2}\right)} \Delta x \tag{18}
\end{align*}
$$

2) Actually the waves should decrease their height for being suffered by bottom friction at shallow water of depth Da. It is necessary to evaluate the wind velocity U'a which makes the fully arisen wave height just equals $\mathrm{H}_{a}$ in depth $\mathrm{D}_{a}$ as shown by the curve OM in Fig. 4 , from eq. (1), let

$$
\begin{equation*}
\frac{\mathrm{gH}_{a}}{\mathrm{Ua}^{\prime 2}}=a \tanh \left\{k_{3}\left(\frac{\mathrm{gDa}}{\mathrm{Ua} a^{2}}\right)^{3 / 4}\right\} \tag{19}
\end{equation*}
$$

$\mathrm{U}_{a}^{\prime}$ can be found out by Newton's method then, $\Delta \mathrm{H}_{2}$ can be calculated as follows

$$
\begin{equation*}
\Delta H_{2}=\frac{k_{1}^{2}}{a} \frac{\left(\alpha+\mathrm{gHa} / U_{a}^{2}\right)\left(\alpha-g H a / U_{a}^{\prime}\right)}{\ln \left(\alpha+\mathrm{gH} a / \mathrm{U}^{\prime 2}\right)-\ln \left(\alpha-\mathrm{gH} a / U_{a}^{2}\right)} \Delta x \tag{20}
\end{equation*}
$$

While the wind of velocity U' is acting on a wave series with a height $H a$ over $\Delta x$ length in deep water, the height should be increased $\Delta H_{2}$, however, in shallow water of depth $\mathrm{D} a$, the wave height remain constant, the energy obtained from the wind and lost due to bottom friction are in equilibrium, namely, the lost height of wave series of height $\mathrm{H} a$ travelling over $\Delta x$ is $\Delta \mathrm{H}_{2}$. So that Hb is:

$$
\mathrm{H}_{b}=\mathrm{Ha}+\Delta \mathrm{H}_{1}-\Delta \mathrm{H}_{2} \quad \ldots \ldots(21)
$$

The same consideration can be applied for evaluating group velocity, calculate $\Delta G$, from following equation first.
$\Delta G_{1}=\frac{8}{3} \frac{k_{2}^{3}}{\beta} \frac{g}{U a} \frac{(\beta / 2+G a / U a)(\beta / 2-G a / U a)}{[\ln (\beta 2+G a / U a)-\ln (\beta / 2-G a / U a)]^{2}} \Delta x$
The relationship of $G / U$ and $g D / U^{2}$ when $x \rightarrow \infty$ can be approximately expressed as bellow:

$$
\begin{array}{ll}
\mathrm{gD} / \mathrm{U}^{2}>0.06 & \frac{\mathrm{G}}{\mathrm{U}}=\frac{\beta}{2} \tanh \left\{\mathrm{k}_{5}\left(\frac{\mathrm{gD}}{\mathrm{U}^{2}}\right)^{1 / 3}\right\} \\
\mathrm{gD} / \mathrm{U}^{2} \leqq 0.06 & \frac{\mathrm{G}}{\mathrm{U}}=\frac{\beta}{3}\left(\frac{\mathrm{gD}}{\mathrm{U}^{2}}\right)^{2 / 5}
\end{array}
$$

The wind velocity $U \hat{a}$ which makes the fully arisen group velocity at depth $D a$ just equals $G a$ can be worked out by solving eq. (23) or (24) and $\Delta G$ is

$$
\begin{equation*}
\Delta G_{2}=\frac{8}{3} \frac{k_{2}^{3}}{\beta} \frac{g}{U} \frac{\left(\beta / 2+G a / U^{\prime \prime} a\right)\left(\beta / 2-G a / U^{\prime \prime} a\right)}{\left[\ln \left(\beta / 2+G a / U^{\prime \prime} a\right)-\ln \left(\beta / 2+G a / U^{\prime \prime} a\right)\right]^{2}} \ldots( \tag{25}
\end{equation*}
$$

Gb will be calculated by

$$
\begin{equation*}
G_{b}=G_{a}+\Delta G_{1}-\Delta G_{2} \tag{26}
\end{equation*}
$$

The period can be calculated as follows.

$$
\begin{aligned}
\mathrm{M}_{b}= & \frac{\mathrm{G}_{b}}{\mathrm{U} a} \frac{1}{(\mathrm{gDa} / \mathrm{U} a)^{1 / 2}} \ldots(27) \quad \mathrm{T}_{b}=\left(\frac{4 \mathrm{~T}^{2} \mathrm{D} a}{\mathrm{gS} b}\right)^{1 / 2} \\
\mathrm{~S}=\mathrm{b}(1-\mathrm{M})+\mathrm{b}(1-\mathrm{M})^{2}+\ldots+\mathrm{b}(1-\mathrm{M})^{\prime} & \ldots(28)
\end{aligned}
$$

The position of point ' $b$ ' on the lattice are deter mined by following equations.

$$
\begin{aligned}
& \text { if } G a>\lambda / 2 \quad \Delta x=\lambda \quad \Delta t=\lambda / G a \quad .(30) \\
& \text { if } \quad G a<\lambda / r \quad \Delta t=r \quad \Delta x=G a z \ldots .(31) \\
& x_{b}=x_{a}+\Delta x \quad t_{b}=t_{a}+\Delta t \quad \ldots \text { (32) }
\end{aligned}
$$

Same Procedures will be applied to calculate waves of Point " $c$ " from point " $b$ ". The flow chart is to be used for Programming as Fig.5.

## DISCUSSION ON THE EFFECT OF REFRACTION

The refraction effect of waves in shallow water must not be neglected. In following examples, calculations on refraction have been made by amending the contour line to
be parallel. The difference is only a few percent both the wave height, group velocity and wave propagation line in comparison with the result of calculation without considering refraction. It is not unnatural because the refraction of waves is caused by decreasing of celerity as the waves advancing to shallow water, however, in this calculation, the decremènt in wave celerity owing to shoaling is almost balanced by the increase from wind effect. The wave celerity remains nearly constant, therefore the refraction effect seems not to be appeared. This is very noticeable phenomenon in wind waves of shallow water, further investigations are needed.

CALCULATION EXAMPLE
The waves along the northern coast of Seto Inland sea raised by typhoons "Suō" (Aug. I946) "Ruth" (Oct.I95I) "Doya" (Sept. I954) as well as the waves attacked western coast of Taiwan caused by Typhoon "Parmela" (Sept. I96I) have been hindcasted by this method. The result of the calculation of typhoon "Suö" is submitted here.

## FOUNDAMENTAL CONDITIONS

The route of typhoon and topographical features of western part of Seto Inland Sea are described in Fig. 6, the fetch length of various direction of every calculated point are also shown in the same figure.

Along this coast, the tidal range is rather large, extraordinary hightide will be recognized as the typhoon center approaching, in this calculation, the deviation of water level by the extrahightide has been considered and added into water depth.

Waves diffracted from outer sea have not been considered in this calculation. All waves to be calculated are generated in shallow water area.

## CALCULATION CONDITIONS

In general, the pressure distribution in typhoon cycle is as below.

$$
\begin{equation*}
P=P C+a \exp \left(-\frac{r}{r_{0}}\right) \tag{33}
\end{equation*}
$$

Pc: pressure at typhoon center (m b)
$r$ : distance from typhoon center (km)
$r_{0}$ : radius of the largest gradient wind velocity circle (km)
P : pressure at the circle with radius $x$
a : constant
a and $r$ are different in each typhoon.

The gradient wind velocity Vg is

$$
\begin{aligned}
V=\sqrt{a} \frac{r}{r} & \exp \left(-\frac{r_{0}}{2 r}\right)-\frac{f r}{2} \\
: & \text { air density } \\
f & =2 \omega \sin \phi: \text { Coriolis coefficient }
\end{aligned}
$$

Actual wind in typhoon is the resultant of symetrical wind $U^{\prime}$ and wind of field $U^{\prime \prime}$, taking typhoon center as the origin, wind velocity of the point ( $x, y$ ) can be calculated from the following equations.

| $U x=U x+U x, \quad U y=U y+U y$ | (35) |
| :---: | :---: |
| $U_{x}=-0.6(V g r)(x \sin \alpha+y \cos \alpha)$ | . (36) |
| $U^{\prime} y=0.6(V g r)(x \cos \alpha+y \sin \alpha)$ | . .... (37) |
| $U^{\prime \prime} \times=(0.6 \mathrm{Vgmax}) \mathrm{Vg} \cdot \mathrm{Vx}$ | .... (38) |
| $U y=(0.6 \mathrm{Vgmax}) \mathrm{Vg} \mathrm{Vy}$ | . . . . (39) |

a is the angle of symetrical wind direction and the tangent of isobar. It will be different in lattitude, in this calculation $\alpha=30^{\circ}$ is adopted. $V x$, Vy are the components of progressing velocity of typhoon.

The origin of fixed coordinate is set at I3I E and $33^{\circ} 4 \mathrm{~N}, \mathrm{EW}$ and NS direction are taken as $X-Y$ - axes respectively. If the linear fetch is at an angle of to the $X$ axis the component of wind velocity can be calculated by following equation

$$
\mathrm{U}=\mathrm{U} x \cos \theta+\mathrm{Uysin} \theta \quad \ldots \ldots \cdot(40)
$$

The positions of the center of typhoon "Suo", when she was in the vicinity of Seto Inland Sea at every hour, are listed below

| Date | hour | X(km) | $Y(\mathrm{~km})$ |
| :---: | :---: | :--- | :--- |
| Aug.27 | I4 | - IOI | -207 |
|  | I5 | -88.5 | -I 65.5 |
|  | I6 | -89.5 | -I 25.5 |
|  | I7 | -89.5 | -9 I |
|  | I8 | -9 I | -65 |
|  | I9 | -85 | -24.5 |
|  | 20 | -77.75 | $I 5.5$ |
|  | 21 | -72.25 | 55.5 |
|  | 22 | -32.50 | IO5 |
|  | 23 | -25.0 | I47 |
| Aug. 28 | 0 | $-I 8.50$ | 201.5 |

During calculation, the unit distance $\lambda$ on lattice of wind diagram is to be 2 km windward and 1 km in the region of depth less than 10 m leeward, but the time unit 2 is remaining 30 minutes.

## CALCULATION RESULTS

Wave which attacked the estuary of Yoshida river and other point from various direction have been calculated by
the electronic computor. Fig. 7,8 illustruted the waves on the SE fetch of Yoshida estuary.

In addition, for the purpose of investigating the distribution of waves over the west part of Seto Inland Sea, a number of parallel linear fetch with a distance of lokm have been set as shown in Fig. 6. Waves on such fetch lines have been calculated and the contour of wave heights and periods are to be delineated for every hour as shown in Fig. 9 and 10.
