## 1 Introduction

In this paper we consider the problem of model checking for different fragments of propositional  $\mu$ -calculus. This logic was studied by many authors [4, 8] for specifying the properties of concurrent programs. It has been shown (see [12, 10, 5]) to be as expressive of automata on infinite trees. Most of the known temporal and dynamic logics can be translated into this logic.

The model checking problem for this logic was first considered in [6]. In that paper, the authors presented an algorithm that is of complexity  $O((mn)^{l+1})$  where  $m$  is the length of the formula,  $n$  is the size of the Kripke structure and  $l$  is the number of alternations of least and greatest fixed points in the given formula. Thus the complexity of the algorithm is exponential in the length of the formula. Since then there have been other algorithms [1, 3, 11] that were presented. Although some of these algorithms have lower complexity than the original algorithm, their complexity is still exponential. Algorithms of linear complexity (both in the size of the structure and the formula) were given [2] for the case when there is no alternation of least and greatest fixed points in the given formula.

In this paper, we consider the model checking problem for different fragments of the  $\mu$ -calculus. We first consider two fragments called  $L_1, L_2$  and give model checking algorithms for these fragments which are of complexity  $O(m^2n)$  where  $m$  is the length of the formula and  $n$  is the size of the structure. The formulas in  $L_1$  and  $L_2$  allow arbitrary nesting of the least and greatest fixed points. However, they restrict how the modal operators and the boolean connectives can appear in the formula. The fragment  $L_2$  is shown to be exactly as expressive as the branching time temporal logic ECTL\* considered in [13]. ECTL\* is the extended version of CTL\* in which the path formulas have the same expressive power as  $\omega$ -regular expressions.

We also consider the model checking problem for the full  $\mu$ -calculus and show that this problem is equivalent to the non-emptiness problem of parity tree automata considered in [9, 5]. More specifically, we show that the model checking problem for  $\mu$ -calculus is reducible to the non-emptiness problem for

parity tree automata of size  $O(mn)$  where  $m$  and  $n$  are as defined above. We also show that the non-emptiness problem of parity tree automata of size  $p$  is reducible to the model checking problem for  $\mu$ -calculus in which the size of the Kripke structure is  $O(p)$  and the length of the formula is  $O(p)$ . This shows that there is an efficient algorithm for one of them iff there is such an algorithm for the other.

The paper is organized as follows. Section 2 contains definitions and notation. Section 3 presents the model checking algorithms for the logics  $L_1$  and  $L_2$ . Section 4 contains the result showing the equivalence of the model checking problem for the full  $\mu$ -calculus and non-emptiness problem for the parity tree automata.

## 2 Definitions and Notation

In this section we define the syntax and semantics of the different fragments of the logic  $\mu$ -calculus. Let  $\mathcal{P}$  and  $\mathcal{X}$  be two disjoint sets of elements. The elements of  $\mathcal{P}$  will be called *atomic propositions* and are usually denoted by  $P, Q, \dots$ . The elements of  $\mathcal{X}$  will be called *variables* and are usually denoted by  $x, y, \dots$ . The formulae of  $\mu$ -calculus are formed using the symbols from  $\mathcal{P}, \mathcal{X}$ , the propositional connectives  $\neg$  and  $\wedge$ , the modal operator  $\langle R \rangle$ , and the symbol  $\mu$ .

The set of well-formed formulae of  $\mu$ -calculus are defined inductively. The symbols **true** and **false** are well-formed formulae. Every atomic proposition and every variable are well-formed formulae. If  $f$  and  $g$  are well-formed formulae then  $\neg f$ ,  $f \wedge g$  and  $\langle R \rangle f$  are also well-formed formulae. In addition, if  $f$  is well-formed formula in which all the occurrences of the variable  $x$  are in the scope of an even number of negations then  $\mu x(f)$  is also a well-formed formula.

We say that a variable  $x$  is free variable in a formula  $f$  if there is an occurrence of  $x$  in  $f$  which is not in the scope of some  $\mu x$ . Let  $\text{free-var}(f)$  denote all the variables that are free in  $f$ . A variable which appears in  $f$  and which is not free, is called a bound variable. A formula without any free variables is called a *closed* formula. A formula that has no variables will be called a constant. We define the semantics of the formulae in  $\mu$ -calculus with respect to a *kripke structure*. A kripke structure  $K$  is a triple  $(S, R, L)$  where  $S$  is a finite set of states,  $R \subseteq S \times S$  is a total binary relation (i.e.  $\forall x \exists y(x, y) \in R$ ), and  $L : S \rightarrow 2^{\mathcal{P}}$ . With each state  $s$ ,  $L$  associates a set of atomic propositions that are true in that state. Let  $f$  be a formula with  $\text{free-var}(f) = \{x_1, \dots, x_k\}$ . An evaluation  $\rho$  for  $f$  is a mapping that associates with each variable in  $\text{free-var}(f)$  a subset of  $S$ . If  $\text{free-var}(f)$  is empty then there is a unique empty evaluation  $\epsilon$  for  $f$ . For a given kripke structure  $K$ , we define a function  $\mathcal{M}_{(K,f)}$  from the set of evaluations for  $f$  to the subsets of  $S$ , by induction on the structure of  $f$  as follows.

- $\mathcal{M}_{(K,P)}(\epsilon) = \{s : P \in L(s)\}$  where  $P$  is an atomic proposition;
- $\mathcal{M}_{(K,f \wedge g)}(\rho) = \mathcal{M}_{(K,f)}(\rho') \cap \mathcal{M}_{(K,g)}(\rho'')$  where  $\rho'$  and  $\rho''$  are restrictions of  $\rho$  to the free variables of  $f$  and  $g$  respectively;
- $\mathcal{M}_{(K,\neg f)}(\rho) = S - \mathcal{M}_{(K,f)}(\rho)$ ;

- $\mathcal{M}_{(K, \langle R \rangle f)}(\rho) = \{s : \exists s' \in \mathcal{M}_{(K, f)}(\rho) \text{ such that } (s, s') \in R\}$ ;
- $\mathcal{M}_{(K, \mu x f)}(\rho) = \bigcap \{S' \subseteq S : S' = \mathcal{M}_{(K, f)}(\rho') \text{ where } \rho'(x) = S' \text{ and for all other } y \in \text{free-var}(f), \rho'(y) = \rho(y)\}$ .

In the above definition, it is to be noted that the value of  $\mathcal{M}_{(K, \mu x f)}(\rho)$  is given as a least fixed point. For a closed formula  $f$ , we say that a state  $s$  in  $K$  satisfies  $f$  (written as  $K, s \models f$ ) iff  $s \in \mathcal{M}_{(K, f)}(\epsilon)$ . We define derived connectives defined as follows:  $f \vee g \equiv \neg(\neg f \wedge \neg g)$ ,  $f \rightarrow g \equiv (\neg f \vee g)$ ,  $[R]f \equiv \neg \langle R \rangle \neg f$ ,  $\nu y f(y) \equiv \neg \mu x(\neg f(\neg x))$ . It is to be noted that while  $\mu x$  denotes the least fixed point  $\nu y$  denotes the greatest fixed point operator.

By using DeMorgan's laws, the identities  $\neg \nu y f(y) \equiv \mu x(\neg f(\neg x))$  and  $\neg [R]f \equiv \langle R \rangle \neg f$ , we can transform any formula into an equivalent formula in which all negations apply only to the atomic propositions. Such formulas will be called normalized formulas. In our paper we will be interested in these types of formulas. A formula of the form  $\mu x f$  ( resp.,  $\nu x f$ ) will be called a  $\mu$ -formula ( resp.,  $\nu$ -formula).

With a normalized formula  $f$ , we define an integer  $altdepth(f)$ . Intuitively,  $altdepth(f)$  will be the maximum number of alternations of  $\mu$ s and  $\nu$ s in  $f$ . Formally, it is defined as follows.

- For a  $\mu$ -formula  $f$ ,  $altdepth(f) = 0$  if  $f$  has no  $\nu$ -subformulas in it, otherwise  $altdepth(f) = 1 + \max\{altdepth(g) : g \text{ is a } \nu\text{-subformula of } f\}$ .
- For a  $\nu$ -formula  $f$ ,  $altdepth(f) = 0$  if  $f$  has no  $\mu$ -subformulas in it, otherwise  $altdepth(f) = 1 + \max\{altdepth(g) : g \text{ is a } \mu\text{-subformula of } f\}$ .
- For any formula  $f$ , define  $altdepth(f) = 1 + \max\{altdepth(g) : g \text{ is a } \mu\text{-subformula or a } \nu\text{-subformula of } f\}$ .

We assume throughout the paper that each variable appearing in a formula is bound at most once. This means that we can not have two subformulas of the form  $\mu x(g)$  and  $\mu x(h)$  appearing in a formula. If this property is not satisfied, then by renaming the variables we can obtain an equivalent formula that satisfies this property.

For finite kripke structures, the least fixed point can be computed by iteration starting with an empty set and iterating until a fixed point is reached. Similarly, the greatest fixed point can be computed by starting from the set containing all states and iterating until a fixed point is reached. These results are due to Tarski/Knaster.

Now, we define two fragments of the  $\mu$ -calculus  $L_1$  and  $L_2$  defined as follows. The set of  $L_1$  formulas are exactly those that are formed using the following rules:

1. All the members of  $\mathcal{P} \cup \mathcal{X}$  are  $L_1$ -formulas; i.e. all atomic propositions and all variables are  $L_1$ -formulas.
2. If  $f$  is a  $L_1$ -formula that does not have any variables appearing in it then  $\neg f$  is also an  $L_1$ -formula.
3. If  $f$  and  $g$  are  $L_1$ -formulas then  $f \vee g$ ,  $\langle R \rangle f$ ,  $\mu x(f)$  and  $\nu x(f)$  are  $L_1$ -formulas.
4. If  $f$  and  $g$  are  $L_1$ -formulas such that at most one of them has variables appearing in it, then  $f \wedge g$  is a  $L_1$ -formula.

Rule 2 states that negations can only be applied to formulas which are constants. Rule 4 states that if we have a conjunction only one of the conjuncts can have variables and all other conjuncts have to be constants. Due to these restrictions, when we normalize an  $L_1$ -formula, i.e. push the negations down, the resulting formula has the following property: all the [R]s only apply to constant formulas, and in any conjunction only one of the conjuncts can have variables appearing in it. This means that an  $L_1$ -formula is almost like a linear-time formula.

Let  $L_2$  be the set of formulas obtained by using rules 2a and 4a, given below, in place of 2 and 4.

**2a.** If  $f$  is a closed  $L_2$ -formula then  $\neg f$  is also an  $L_2$ -formula.

**4a.** If  $f$  and  $g$  are  $L_2$ -formulas such that at most one of them is an open formula then  $f \wedge g$  is a  $L_2$ -formula.

It is to be noted that the formula  $f$  in rule 2 should be a constant formula while in rule 2a it can be any closed  $L_2$ -formula. Similarly, in rule 4, at least one of  $f$  and  $g$  has to be a constant, while in 4a, at least one of them has to be a closed formula. As a consequence, rules 2 and 4 are special cases of rules 2a and 4a respectively. From this, it should be easy to see that  $L_1$  is a subset of  $L_2$ . The expressive power of  $L_2$  is characterized by theorem 3.2 given in the next section.

### 3 Model Checking for the restricted Logics

In this section, we present efficient procedure for model-checking for the two logics  $L_1$  and  $L_2$ . First, we consider the logic  $L_1$  and present an efficient model-checking algorithm for this logic. This algorithm, as we show later, can be easily extended to the logic  $L_2$ .

Let  $f$  be a closed normalized  $L_1$ -formula. Let  $SF(f)$  denote the set of subformulas of  $f$ . The set  $SF(f)$  can be defined inductively. Let  $K = (S, R, L)$  be a given kripke structure. We define a graph  $G_{K,f} = (V, E)$ , where  $V$  is the set of vertices and  $E$  is the set of edges, defined as follows. The node set  $V = \{(s, g) : s \in S, g \in SF(f)\}$ . Essentially, there is one node in  $V$  corresponding to each state in  $S$  and each subformula of  $f$ . The set of edges leaving the node  $(s, g)$  are, defined according to the outermost connective of the subformula  $g$ , as follows.

- If  $g = P$  or  $g = \neg P$  where  $P$  is an atomic proposition then there are no edges leaving  $(s, g)$ .
- If  $g = x$  where  $x$  is variable and  $g'$  is the largest subformula of  $f$  such that  $g' = \mu x(g')$  or  $g' = \nu x(g')$ , then there is exactly one edge leaving  $(s, g)$  and this edge is to  $(s, g')$ .
- If  $g = \mu x(g')$  or  $g = \nu x(g')$ , then there is an edge from  $(s, g)$  to  $(s, g')$  and this is the only edge from  $(s, g)$ .
- If  $g = g' \wedge g''$  or  $g = g' \vee g''$ , then there are two edges from  $(s, g)$ , to the nodes  $(s, g')$  and  $(s, g'')$ .

- If  $g = \langle R \rangle g'$  or  $g = [R]g'$ , then for each state  $s'$  such that  $(s, s') \in R$ , there is an edge from  $(s, g)$  to  $(s', g')$ .

A path in  $G_{K,f}$  is a finite sequence of nodes such that there is an edge in  $E$  from each node in the path to the succeeding node. A path starting and ending with the same node is a cycle. A subformula  $g \in SF(f)$  is called a  $\mu$ -subformula (respectively, a  $\nu$ -subformula) if  $g$  is of the form  $\mu x(f)$  (respectively,  $\nu x(f)$ ). We say that a cycle  $C$  in  $G_{K,f}$  is a  $\nu$ -cycle (respectively,  $\mu$ -cycle) if the longest subformula appearing in a node on  $C$  is  $\nu$ -subformula (respectively,  $\mu$ -subformula). A node  $(s, g)$  in  $G_{K,f}$  is called a  $\wedge$ -node if  $g$  is of the form  $g_1 \wedge g_2$  or is of the form  $[R]g_1$ ; note that in the later case  $g_1$  will be a constant. A node  $(s, g)$  is called a  $\vee$ -node if  $g$  is of the form  $g_1 \vee g_2$  or is of the form  $\langle R \rangle g_1$ .

**Observation 3.1** *The graph  $G_{K,f}$  satisfies the following properties.*

- Assume that there is an edge from  $(s, g)$  to  $(s', g')$  in  $G_{K,f}$ .
  - If  $g = \langle R \rangle g'$  or  $g = [R]g'$  then  $(s, s') \in R$ ; otherwise,  $s' = s$ .
  - If  $g$  is not a variable then  $g'$  is a subformula of  $g$ . If  $g$  is a variable then  $g$  is a subformula of  $g'$ .
- For any node  $(s, g)$  in  $G_{K,f}$ , there is a path from  $(s, g)$  to a node on a cycle iff  $g$  has at least one variable in it (i.e.  $g$  is not a constant).
- Let  $C$  be a cycle and  $(s, g)$  be a node on it such that  $g$  is the longest formula appearing in all the nodes on  $C$ . Then,  $g$  is a  $\mu$ -subformula or a  $\nu$ -subformula. In addition, all other subformulas appearing in some node on  $C$  themselves are subformulas of  $g$ .

Now, we label the nodes of  $G_{K,f}$  as follows. With each node  $u \in V$ , we maintain a variable  $label(u)$  that denotes the label of the node  $u$ . Each of these variables takes one of the three values—true, false,  $NIL$ , and is initialized to the value  $NIL$ . During the execution of the algorithm, the values of these variables will be set to true or false. When once a variable is set to one of these two values, it will never be changed. Furthermore, for any node  $u = (s, g)$ , at the end of the execution of the algorithm,  $label(s, g) = \text{true}$  iff  $K, s \models g$ .

At any time during the execution of the algorithm, if  $label(u) = NIL$  then we say that node  $u$  is *unlabeled* at that time. We say that a path is unlabeled if all the nodes on the path are unlabeled. Let  $n$  be the length of the formula  $f$ . We execute the following algorithm on the graph  $G_{K,f}$ .

1. For each node  $u \in V$ ,  $label(u) \leftarrow NIL$ .
2. For each  $g \in SF(f)$  in increasing lengths of  $g$ , and for each  $s \in S$ , update  $label(u)$ , where  $u = (s, g)$ , as follows.
  - $g = P$ : If  $P \in L(s)$  then  $label(u) \leftarrow \text{true}$  else  $label(u) \leftarrow \text{false}$ .
  - $g = \neg P$ : If  $P \notin L(s)$  then  $label(u) \leftarrow \text{true}$  else  $label(u) \leftarrow \text{false}$ .
  - $g = g' \wedge g''$  or  $g = [R]g'$ :  
 If for all successors  $u'$  of  $u$  it is the case that  $label(u') = \text{true}$  then  $label(u) \leftarrow \text{true}$ ;  
 If for some successor  $u'$  of  $u$  such that  $label(u') = \text{false}$  then  $label(u) \leftarrow \text{false}$ . In other cases,  $label(u)$  is unchanged (i.e. =  $NIL$ ).

–  $g = g' \vee g''$  or  $g = \langle R \rangle g'$  :

If for some successor  $u'$  of  $u$   $label(u') = true$  then  $label(u) \leftarrow true$ ;

If for all successors  $u'$  of  $u$  it is the case that  $label(u') = false$  then  $label(u) \leftarrow false$ .

In other cases,  $label(u)$  is unchanged.

– None of the above:  $label(u)$  is unchanged.

3. For each unlabeled node  $u \in V$ , if there exists an unlabeled path from  $u$  to an unlabeled  $\nu$ -cycle then  $label(u) \leftarrow true$ .
4. For each unlabeled node  $u$ ,  $label(u) \leftarrow false$ .

**Theorem 3.1** *After the execution of the above algorithm, for any node  $u = (s, g)$  in  $G_{K,f}$  where  $g$  is a closed subformula,  $label(u) = true$  iff  $K, s \models g$ .*

In order to prove the above theorem, we need some lemmas. First, it is to be noted that after the execution of step 2 of the above algorithm, the following conditions are satisfied. For all nodes  $u$  in  $G_{K,f}$  such that there is no path connecting  $u$  to a node on a cycle,  $label(u) \neq NIL$ . Hence, for each node  $u = (s, g)$  where  $g$  is a constant,  $label(u) \neq NIL$ . For this case, it should be easy to see that  $label(s, g) = true$  iff  $K, s \models g$ . Also, for every node  $u = (s, g)$  such that  $label(s, g) = NIL$ , there is at least one successor node  $u'$  such that  $label(u') = NIL$ . In addition, if  $g = g' \wedge g''$ , then for one successor  $u'$ ,  $label(u') = true$  and for the other successor  $u''$ ,  $label(u'') = NIL$ . Consider any node  $(s, g)$  such that  $label(s, g) \neq NIL$ . For any evaluation  $\rho$  over the free variables of  $g$ , the following property holds:  $s \in \mathcal{M}_{K,g}(\rho)$  iff  $label(s) = true$ . For any node  $(s, g)$  where  $g$  is a  $\mu$ -formula or a  $\nu$ -formula,  $label(s, g) = NIL$ .

In step 3 of the algorithm, all nodes lying on unlabeled  $\nu$ -cycles or all nodes that have unlabeled paths to such cycles will be labeled true. Now, we prove that step 3 of the above algorithm is sound. To do this, we need the following lemmas.

**Lemma 1.** *Let  $u_0, u_1, \dots, u_k$  be a path in  $G_{K,f}$  after execution of step 2 of the above algorithm where for each  $i = 0, 1, \dots, k-1$ ,  $u_i$  is a  $\wedge$ -node or a  $\vee$ -node. Also, let  $u_i = (s_i, g_i)$ . Then, each  $g_i$  is a subformula of  $g_0$ , and for any evaluation  $\rho$  on the free-var( $g_0$ ), if  $s_k \in \mathcal{M}_{K,g_k}(\rho')$  where  $\rho'$  is a restriction of  $\rho$  to free-var( $g_k$ ), then  $s_0 \in \mathcal{M}_{K,g_0}(\rho)$ .*

The above lemma can be proved by a simple induction on the length of  $g_0$ .

**Lemma 2.** *Let  $u_0, u_1, \dots, u_k$  be an unlabeled path in  $G_{K,f}$  after the execution of step 2 of the above algorithm satisfying the following conditions: for each  $i > 0$ ,  $u_i = (s_i, g_i)$ ,  $g_i$  is a strict subformula of  $g_0$  and  $g_k \in \text{free-var}(g_0)$ . Then, for any evaluation  $\rho$  over free-var( $g_0$ ), if  $s_k \in \rho(g_k)$  then  $s_0 \in \mathcal{M}_{K,g_0}(\rho)$ .*

The following lemma shows that step 3 of the above algorithm is sound.

**Lemma 3.** *Let*

- $u_0, u_1, \dots, u_k = u_0$  be an unlabeled  $\nu$ -cycle in  $G_{K,f}$  after execution of step 2 of the above algorithm;
- $u_i = (s_i, g_i)$  for  $0 \leq i < k$ , where  $g_0 = \nu x(g')$  is the longest subformula appearing in any node of the cycle;
- $S' = \{s_i : 0 \leq i < k, g_i = g_0\}$ .

*Then, for any evaluation  $\rho$  on the free-var( $g_0$ ),  $S' \subseteq \mathcal{M}_{K,g_0}(\rho)$ .*

The remainder of the proof of theorem 3.1 and the proofs of the lemmas will be given in an extended version of this paper.

### Complexity and Expressiveness

Below, we discuss the complexity of the above algorithm. First, it is to be noted that the number of vertices in  $G_{K,f}$ , i.e.  $|V|$ , is  $O(|S||f|)$ . The number of edges in  $G_{K,f}$ , i.e.  $|E| = O(|R||f| + |S||f|)$ . It is not difficult to see that steps 1, 2, 4 and 5 can all be implemented in time linear in  $(|V| + |E|)$ .

Step 3 can be implemented using an algorithm of complexity  $O(|f|(|V| + |E|))$ . This algorithm works as follows: It first identifies all nodes that lie on unlabeled  $\nu$ -cycles. This is done as follows.

For each  $\nu$ -subformula  $g$  of  $f$  and in the increasing lengths of  $g$ , consider the restriction of  $G_{K,f}$  to unlabeled nodes of the form  $(s, g')$  where  $g'$  is a subformula of  $g$ . For each strongly connected component  $C$  of the restricted graph, find the type of the longest subformula in any node of  $C$ ; if this formula is a  $\nu$ -formula then mark all the nodes of  $C$  as nodes lying on a  $\nu$ -cycle.

In the full paper we will show that the above algorithm correctly identifies all the nodes that lie on unlabeled  $\nu$ -cycles. After this, it is straightforward to find nodes that have unlabeled paths to such cycles. Each iteration of the above algorithm can be implemented using an algorithm of complexity  $O(|V| + |E|)$ . Hence, all the iterations together take time  $O(|f|(|V| + |E|))$ .

Thus, the overall complexity of the algorithm is  $O(|f|(|V| + |E|))$ . Substituting for  $|V|$  and  $|E|$  in terms of  $|S|$  and  $|R|$ , we see that the overall complexity of the above algorithm is  $O(|f|^2(|S| + |R|))$ .

The above algorithm can be naturally be extended to the logic  $L_2$  with the same complexity. We will present this in the full paper. Thus, model checking for  $L_2$  can also be done in time  $O(|f|^2(|S| + |R|))$ .

We compare the expressive power of the logics to well known branching time temporal logics. Consider the branching time temporal logic CTL\*. Let the ECTL\* (given in [13]) denote the extended version of the logic CTL\* where each path formula can be as expressive as  $\omega$ -regular expressions.

**Theorem 3.2** *The logic  $L_2$  is as expressive as ECTL\*.*

**Proof** We give an outline of the proof. First, we show that any ECTL\* formula of the form  $E(p)$  where  $E$  is the existential path quantifier and  $p$  is an  $\omega$ -regular expression can be translated in to the logic  $L_1$ . To achieve this, we translate

$p$  into a Buchi automaton  $A$  on infinite strings. It is well known that linear  $\mu$ -calculus, i.e.  $\mu$ -calculus interpreted over infinite strings is as expressive as Buchi automaton on infinite strings. The logic  $L_1$  is similar to the linear  $\mu$ -calculus. We can apply the same techniques used as in the case of linear  $\mu$ -calculus, to show that for any Buchi automaton  $A$  we can obtain a formula  $f$  in  $L_1$  such that  $f$  is satisfied at a state in a Kripke structure iff there exists an infinite path from that state that is accepted by  $A$ . Applying this translation inductively, we can show that any formula of the logic ECTL\* can be translated in to the logic  $L_2$ .

To prove that every formula in  $L_2$  can be translated into ECTL\*, it is enough to show that  $L_1$  can be translated into ECTL\*. This translation can be applied inductively, to show that any formula of  $L_2$  can also be translated into ECTL\*. Given a formula  $f$  in  $L_1$ , we can construct a Buchi automaton  $A$  on infinite strings, and from this obtain an equivalent ECTL\* formula of the form  $E(p)$  where  $p$  is an  $\omega$ -regular expression. ■

We can also use the following alternate approach for model-checking for formulas in  $L_1$  which will have the same complexity. We briefly describe this method. The proof of Theorem 3.2 shows that for each formula  $f$  in  $L_1$  there exists a formula of the form  $E(p)$  in ECTL\*, where  $p$  is a path formula, such that  $f$  is equivalent to  $E(p)$ . In fact, from  $f$ , we can construct a parity string automaton  $A_f$  (see the next section for the definition of parity automaton) with the following property:  $f$  is satisfied at a node  $s_0$  in a Kripke structure iff there exists an infinite path from  $s_0$  that is accepted by  $A_f$ . The number of states in the automaton  $A_f$  will be  $O(|f|)$  and the number of sets in the accepting condition will be  $O(|f|)$ . Now to check if the formula  $f$  is satisfied at state  $s_0$  of  $K$ , we simply consider  $K$  as a string automaton and construct the product automaton of  $A_f$  and  $K$ , and check for non-emptiness of this product automaton. The size of the product automaton, which will also be a parity string automaton, will be  $O((|S|+|R|)|f|)$ , and the number of sets in the accepting condition will be  $O(|f|)$  (in fact, the graph  $G_{K,f}$  constructed in our algorithm is itself can be considered as the product automaton). Checking non-emptiness for parity string automaton can be done using a procedure, similar to the one used for step 3 of the previous algorithm, of complexity linear in the product of the size of the automaton and the number of sets in the acceptance condition. The complexity of this method will also be  $O(|f|^2(|S| + |R|))$ .

## 4 Relationship between Model Checking and Automata

In this section we explore the relationship between the model checking problem for  $\mu$ -calculus and the emptiness problem for automata on infinite trees. More specifically, we show that the model checking problem for the complete logic  $\mu$ -calculus is equivalent under linear reductions to the emptiness problem of a particular type of automata on infinite trees, called parity automata. This shows that there is an efficient model checking algorithm for  $\mu$ -calculus iff there is an efficient algorithm for checking emptiness of parity automata.

A corollary of the above result is that the model checking problem for formulas of  $\mu$ -calculus which are of the form  $\nu y(g)$  where  $g$  is in normal form and  $\mu$  is the only fixed point operator appearing in  $g$ , is equivalent to the non-emptiness problem for Buchi tree automata

First, we define parity tree automata (introduced in [5, 9]). A parity tree automaton  $A$  on infinite binary tree is a 5-tuple  $(\Sigma, Q, q_0, \delta, F)$  where  $\Sigma$  is the input alphabet,  $Q$  is the set of automaton states,  $q_0$  is the initial states,  $\delta : (Q \times \Sigma) \rightarrow 2^{Q \times Q}$  is the next move relation and  $F = (F_0, F_1, \dots, F_k)$  where  $F_0, F_1, \dots, F_k$  is a sequence of mutually disjoint subsets of  $Q$ .  $F$  is called the acceptance condition. Note that, for any  $a \in \Sigma$  and  $q \in Q$ ,  $\delta(q, a)$  is a set of pairs of the form  $(q', q'')$  where  $q'$  and  $q''$  are automaton states; Intuitively, if the automaton is in state  $q$  and reads input  $a$  in the current node then the state of the automaton on the left child is going to be  $q'$  and its state on the right child is going to be  $q''$ . We denote the infinite binary tree by the set  $\{0, 1\}^*$ . The empty string denotes the root of the tree and the two children of  $x$  are  $x0$  and  $x1$ . An infinite path  $\sigma$  in the tree is an infinite sequence of nodes starting with root node and such that each succeeding node is a child of the preceding node.

An input to the automaton is a marked infinite binary tree which is a function  $\tau : \{0, 1\}^* \rightarrow \Sigma$ . A run of  $r$  of  $A$  on input  $\tau$  is a function  $r : \{0, 1\}^* \rightarrow Q$ , associating a state of the automaton with each node of the tree, such that  $r(\epsilon) = q_0$ , and for any  $x \in \{0, 1\}^*$   $(r(x0), r(x1)) \in \delta(r(x), \tau(x))$ . For a run  $r$  and an infinite path  $\sigma = \sigma_0, \sigma_1, \dots, \sigma_i, \dots$ , we let  $r(\sigma)$  denote the infinite sequence of automaton states  $r(\sigma_0), \dots, r(\sigma_i), \dots$ . The run  $r$  is accepting if for every infinite path  $\sigma$ , the following condition is satisfied: there exists an even number  $l$ ,  $0 \leq l \leq k$ , such that some state in  $F_l$  appears infinitely often in  $r(\sigma)$  and each of the states in the set  $(\bigcup_{l < j \leq k} F_j)$  only appears finitely often in  $r(\sigma)$ . We say that the automaton  $A$  accepts an input  $\tau$  iff there exists an accepting run  $r$  of the automaton on the input  $\tau$ .

A Buchi automaton is a parity tree automaton in which the accepting condition  $F$  is of length one, i.e. it has only one set. Note that this definition is equivalent to the standard definition of Buchi tree automaton.

**Theorem 4.1** *Given a kripke structure  $K = (S, R, L)$  and any  $\mu$ -calculus formula  $f$  and a state  $s_0 \in S$ , we can obtain a parity tree automaton  $A$  of size  $O((|S| + |R|)|f|)$  in time  $O((|S| + |R|)|f|)$  such that*

- *the number of sets in the acceptance condition of  $A$  is less than or equal to  $\text{altdepth}(f) + 1$ , and*
- *$A$  accepts at least one input iff  $K, s_0 \models f$ .*

**Proof** We briefly sketch the proof here. Let  $f$  be the given  $\mu$ -calculus formula and  $K$  be the given Kripke structure. First we construct the graph  $G_{K,f} = (V, E)$  as given in the previous section. Recall that each node in  $V$  is of the form  $(s, h)$  where  $s \in S$  and  $h$  is a subformula of  $f$ . The edge set  $E$  is as defined in the previous section. For example, when  $h$  is of the form  $[\mathbf{R}]h'$ , then for each  $(s, s') \in R$  there is an edge from  $(s, h)$  to  $(s, h')$  in  $E$ . We call a node  $(s, h)$  in  $V$  to be an  $\wedge$ -node if  $h$  is of the form  $h_1 \wedge h_2$  or is of the form  $[\mathbf{R}]h_1$  and  $(s, h)$

has at least two successors (i.e. edges to two distinct nodes); we call it to be an atomic node if  $h$  is  $P$  or  $\neg P$  for some atomic proposition  $P$  and all other nodes in  $V$  are called  $\vee$ -nodes. Note that if  $(s, h)$  is an  $\vee$ -node then  $h$  can be a variable, or a  $\mu$ -subformula, or a  $\nu$ -subformula, or a subformula of the form  $[R]h'$  and  $(s, h)$  has only one successor. We make the following assumption. Any non-atomic node has at most two successors, i.e. two edges leaving it. If this condition is not satisfied, we can introduce new intermediate nodes and edges so that this property is satisfied; actually, for each node  $u$  with  $k$  successors, if  $k > 2$  then we introduce  $k - 2$  additional new nodes and  $k - 2$  additional edges. As a consequence, the size of  $G_{K,f} = |V| + |E|$  at most doubles. The type of a new node that is introduced in the previous step is same as that of  $u$ , i.e. it is a  $\wedge$ -node if  $u$  is a  $\wedge$ -node, etc. After this, each  $\wedge$ -node has exactly two successors, while a  $\vee$ -node has either one or two successors.

The automaton  $A = (\Sigma, Q, q_0, \delta, F)$  is defined as follows. The states set  $Q$  of the automaton is simply  $V$ , the initial state  $q_0$  is  $(s_0, f)$ , the input alphabet  $\Sigma$  has only one symbol, say symbol  $a$ . The transitions of  $A$  are defined as follows. For any node  $u = (s, h)$ ,  $\delta(u, a)$  consists of the following pairs: if  $u$  is an atomic node (i.e.  $h = P$  or  $h = \neg P$ ) then  $\delta(u, a) = \{(u, u)\}$ ; if  $h$  is  $\vee$ -node then  $\delta(u, a) = \{(v, v) : (u, v) \in E\}$ ; if  $h$  is a  $\wedge$ -node then  $\delta(u, a) = \{(v, v') : v \text{ and } v' \text{ are the successors of } u\}$ .

We define the acceptance condition  $F = (F_0, F_1, \dots, F_{(k-1)})$  as follows. Let  $T$  be the set of all of  $g \in SF(f)$  such that  $g$  is  $\mu$ -subformula or is a  $\nu$ -subformula. First, arrange the members of  $T$  into a sequence so that for any two distinct  $h, g$  in  $T$  where  $h$  is a subformula of  $g$ ,  $h$  appears before  $g$ . After this, group all subformulas of same type that appear contiguously in the above sequence into one set and obtain a sequence  $C_0, C_1, \dots, C_{(l-1)}$  of sets of subformulas that forms a partition of  $T$  satisfying the following properties:

- Each  $C_i$  contains subformulas of the same type, i.e. all of them are  $\mu$ -subformulas or all of them are  $\nu$ -subformulas. In addition, for each  $i < (l-1)$ ;  $C_i$  and  $C_{(i+1)}$  contain different types of formulas.
- For any  $g, h \in T$  where  $g$  and  $h$  are of different type and  $g$  is a subformula of  $h$ , if  $g$  appears in some set  $C_i$  then  $h$  appears in a later set, i.e.  $h$  appears in  $C_j$  for some  $j > i$ .

We define  $F = (F_0, F_1, \dots, F_{(k-1)})$  according to the following three cases.

- $C_0$  contains  $\nu$ -subformulas: In this case  $k = l$ .  $F_0 = (S \times C_0) \cup U$  where  $U$  is the set of all atomic nodes  $u$  such that  $u$  is of the form  $(s, P)$  and  $P \in L(s)$ , or is of the form  $(s, \neg P)$  and  $P \notin L(s)$ . For  $0 < i < k$ ,  $F_i = S \times C_i$ .
- $C_0$  contains  $\mu$ -subformulas and  $l > 1$ : In this case  $k = l - 1$ .  $F_0 = (S \times C_1) \cup U$  where  $U$  is same as in the previous case. For  $0 < i < k$ ,  $F_i = S \times C_{i+1}$ .
- $C_0$  contains  $\mu$ -subformulas and  $l = 1$ , or  $T$  is empty: In this case  $k = 1$ .  $F_0 = U$  where  $U$  is as in the previous cases.

The last of the above cases occurs if the formula has no  $\nu$ s. It can be shown that the automaton  $A$  accepts at least one input iff  $K, s_0 \models f$ . It is also not

difficult to see that the size of the automaton, which is the sum of the number of states, the total number of transitions and the sum of the cardinalities of all sets in  $F$ , is  $O((|S| + |R|)|f|)$ . ■

**Theorem 4.2** *Given a parity tree automaton  $A = (\Sigma, Q, q_0, \delta, F)$ , we can obtain a Kripke structure  $K$  whose size is linear in the size of  $A$  and a  $\mu$ -calculus formula  $f$  which is linear in the length of the acceptance condition, and a state  $s_0$  in  $K$ , such that*

- *altdepth( $f$ ) = 1 + the number of sets in  $F$ , and*
- *$A$  accepts at least one input iff  $K, s_0 \models f$ .*

**Proof** This theorem follows from the results of [5]. However, for the sake of completeness, we outline the major steps of the proof.

Without loss of generality, we can assume that the alphabet of  $A$  is a singleton consisting of the symbol  $a$ . Let the acceptance condition  $F$  be given by  $(F_1, F_2, \dots, F_{k-1})$  (note that index of the first set in  $F$  is 1). Let  $F_0 = Q - \bigcup_{1 \leq i < k} F_i$ . Now, consider the sets  $F_0, F_1, \dots, F_{k-1}$ . Corresponding to each  $F_i$ , we use an atomic proposition  $P_i$ . We give the informal description of the Kripke structure  $K = (S, R, L)$ .  $S$  has the following elements. We call each element of  $S$  as a node and each element of  $R$  as an edge. Corresponding to each automaton state  $s$ , there is one node in  $S$  which is also denoted by  $s$ . For such a node  $s$ , if  $s \in F_i$ , for some  $i < k$ , then  $L(s) = \{P_i\}$ , otherwise  $L(s)$  is the empty set.

Corresponding to each pair of states  $(s_1, s_2)$ , such that  $(s_1, s_2) \in \delta(s, a)$  for some state  $s$ ,  $S$  has a node which we denote by the triple  $(s, s_1, s_2)$  and  $L((s, s_1, s_2)) = L(s)$ .  $R$  has the following edges. Corresponding to the above transition, there is an edge from the node  $s$  to the node  $(s, s_1, s_2)$  and there are edges from  $(s, s_1, s_2)$  to  $s_1$  and to  $s_2$ .  $f$  is given by the following formula:

$$\lambda_{k-1}x_{k-1}\lambda_{k-2}x_{k-2}\dots\lambda_0x_0(\bigvee_{0 \leq i < k} P_i \wedge \langle R \rangle [R.] x_i)$$

where  $\lambda_{k-1}\dots\lambda_0$  is an alternating sequence  $\mu s$  and  $\nu s$  ending with  $\mu$ . Now, take  $s_0 = q_0$ . From the results of [5], it follows that  $K, s_0 \models f$  iff  $A$  accepts at least one input. ■

**Corollary 4.** *The model checking problem for formulas of the form  $\nu x f$  where  $f$  is in normalized form and has no further  $\nu s$  appearing in it is equivalent to checking non-emptiness of Buchi tree automata.*

**Theorem 4.3** *The model checking problem for the full  $\mu$ -calculus is in  $NP \cap co-NP$ . Formally, the set of encodings of all triples  $(K, s_0, f)$  satisfying the following condition is in  $NP \cap co-NP$ :  $K$  is a Kripke structure,  $s_0$  is a state in  $K$  and  $f$  is a  $\mu$ -calculus formula such that  $K, s_0 \models f$ .*

## 5 Conclusion

In this paper we considered two different fragments of  $\mu$ -calculus, logics  $L_1$  and  $L_2$ . We gave model checking algorithms for logics  $L_1$  and  $L_2$  which are of com-

plexity  $O(m^2n)$  where  $m$  is the length of the formula and  $n$  is the size of the structure. We have shown that the logic  $L_2$  is as expressive as ECTL\* given in [13]. In additions to these results, we have shown that the model checking problem for the  $\mu$ -calculus is equivalent to the non-emptiness problem of parity tree automata.

It will be interesting to investigate if there is a model checking algorithm for the logics  $L_1$  and  $L_2$  which is only of complexity  $O(mn)$  instead of  $O(m^2n)$ . Of course, determining if the model checking problem for the full  $\mu$ -calculus is in P or not, is also an open problem.
