# ON STABLE NUMERICAL DIFFERENTIATION 

ALEXANDER G. RAMM AND ALEXANDRA B. SMIRNOVA

#### Abstract

A new approach to the construction of finite-difference methods is presented. It is shown how the multi-point differentiators can generate regularizing algorithms with stepsize $h$ being a regularization parameter. The explicitly computable estimation constants are given. Also an iteratively regularized scheme for solving the numerical differentiation problem in the form of Volterra integral equation is developed.

## 1. Introduction

The problem of numerical differentiation is known to be ill-posed in the sense that small perturbations of the function to be differentiated may lead to large errors in the computed derivative. However in many applications it is necessary to estimate the derivative of a function given the noisy values of this function. As an example we refer to the analysis of photo-electric response data (see [13], 1970). The goal of this experiment is to determine the relationship between the intensity of light falling on certain plant cells and their rate of uptake of various substances, in order to gain further information about photo synthesis. Rather than measuring the uptake rate directly, the experimenters measure the amount of each substance not absorbed as a function of time, the uptake rate being defined as minus the derivative of this function. As for the other example, one can mention the problem of finding the heat capacity of a gas $c_{p}$ as a function of temperature $T$. Experimentally one measures the heat content

$$
q(T)=\int_{T_{0}}^{T} c_{p}(\tau) d \tau
$$

and the heat capacity is determined by numerical differentiation.
A number of techniques have been developed for numerical differentiation. They fall in three categories: difference methods, interpolation methods and regularization methods. The first two categories (see, for instance, [3], [15], [24], [25] and others), especially the central difference formula that can be related to both of them, are well-known. They have the advantage of simplicity and are considered by many authors as the ones which yield satisfactory results when the function to be differentiated is given very precisely ([9], [2], [4]). In sections 1,2 of our paper the other view on these methods, based on the works [16]-[23] and [12], is presented

[^0](see also [10] where the results and ideas of [16] are used). Namely, it is shown how the multi-point difference schemes may construct stable regularizing algorithms for the process of numerical differentiation with a stepsize $h$ being a regularization parameter. The main points are:
a) $h$ must depend on $\delta$, the level of noise in the initial data,
and
b) one has to take into account a priori information about the specific class, to which the function to be differentiated belongs.

Most of the regularization procedures [4]-[7], [27], [28] that belong to the third category make use of the variational ([14], [26]) approach for solving ill-posed problems. These methods typically involve writing the derivative as the solution to an integral Volterra equation and then reducing the integral equation to a family of well-posed problems that depend on a regularization parameter. Once an optimal value of this parameter is found, the corresponding well-posed problem is solved to obtain an estimate for the derivative. Unfortunately the determination of the optimal parameter value is generally a nontrivial task.

In [6] the authors propose the quasisolution method (see [8]) for regularization, which can be described as follows: find the coefficients of the expansion of $f_{\delta}$ in the Legendre polynomials $P_{k}(x)$ :

$$
\begin{equation*}
b_{k}=\frac{2 k+1}{2} \int_{-1}^{1} f_{\delta}(x) P_{k}(x) d x, \quad k=1,2, \ldots, n+1 \tag{1.1}
\end{equation*}
$$

"choosing $n$ so that $\left\|q_{n+1}-f_{\delta}\right\| \leq \delta$ and $\sum_{k=0}^{n+1} \frac{2}{2 k+1} b_{k}^{2}>4 \delta^{2}$ ", where the quotation is from [6]. The function $q_{n+1}$ here is the approximating polynomial and $\left\|f-f_{\delta}\right\| \leq$ $\delta$. Then the estimate of the derivative of $f$ is given by

$$
\begin{equation*}
p_{\delta}=\sum_{k=1}^{n+1} \frac{b_{k}}{1+\lambda k^{2}(1+k)^{2}} P_{k}(x) . \tag{1.2}
\end{equation*}
$$

The existence and the uniform convergence of approximation (1.2) is proved in [6]. Apparently it is assumed in [6] that $f$ and $f_{\delta}$ are such that the above choice of $n$ is possible. This is not always so: if $\left\|f_{\delta}\right\|<2 \delta$, then

$$
4 \delta^{2}>\left\|f_{\delta}\right\|^{2} \geq \sum_{k=0}^{n+1} \frac{2}{2 k+1} b_{k}^{2}
$$

by Parseval's identity. In this case it is impossible to choose $n$ in such a way that $\sum_{k=0}^{n+1} \frac{2}{2 k+1} b_{k}^{2}>4 \delta^{2}$. If $n$ can be chosen, as suggested in [6], then to determine $\lambda$ one has to solve the nonlinear equation

$$
\begin{equation*}
\sum_{k=1}^{n+1} \frac{2}{2 k+1} b_{k}^{2} \frac{\lambda^{2} k^{4}(k+1)^{4}}{\left[1+\lambda k^{2}(k+1)^{2}\right]^{2}}=4 \delta^{2} \tag{1.3}
\end{equation*}
$$

In [7] the idea proposed by the authors of [6] is generalized to the case of the $k$-th order derivative, $k>1$. No results of a numerical experiment, based on procedure (1.2)-(1.3), are given in [6] as well as in [7].

One of the first regularization methods, which performed well in practice (according to the experiments illustrated in [2] and [4]) when used with noisy data,
can be found in [4]. There a variational approach to a regularization is used to obtain the following family of well-posed optimization problems:

$$
\begin{equation*}
\|A f-g\|^{2}+\left(\int_{0}^{1} f d x\right)^{2}+\alpha\left(\|f\|^{2}+\left\|f^{\prime}\right\|^{2}\right)=\min _{f \in W_{1}^{2}} \tag{1.4}
\end{equation*}
$$

The norm is understood in $L^{2}$-sense and $A f=g$ is the initial Volterra equation. Then (1.4) is reduced to the second kind Fredholm integral equation

$$
\begin{equation*}
\alpha f(x)+\int_{0}^{1} K_{0}(x, u) f(u) d u=m(x), \quad 0 \leq x \leq 1 \tag{1.5}
\end{equation*}
$$

The error contributed by variational regularization (1.4) and trapezoidal discretization of (1.5) is estimated in [4]. From this estimate it is clear that for a given $\delta$ the regularization parameter $\alpha$ has a nonzero optimal value. Although a way of choosing the regularization parameter optimally is not offered there, the later paper [2] describes a spectral interpretation of method [4] that allows one to obtain an optimal value of this parameter. However the applicability of that interpretation is restricted to the cases, when the spectrum of the data shows a clear distinction between the signal and the noise.

In the literature there were no results which give error estimates for a stable numerical differentiation algorithm such that the estimate would be suitable for a fixed $\delta>0$ and the estimation constants would be given explicitly, so that the error estimate could be used in practical computations. An exception is the result in [16] generalized and applied in [17]-[23].

In section 4 we suggest an iteratively regularized scheme for solving a Volterra equation based on the idea of continuous regularization (see [1]), which is an alternative to the variational one. This procedure avoids some of the limitations in a choice of the regularization parameter mentioned above.

In section 5 the results of the numerical experiment are discussed. The derivative of the test function $f(x)=\sin (\pi x), x \in[0,1]$, was computed in the presence of noise, whose maximum value was $10 \%$ of the maximum value of $f(x)$. The dependence of the actual and estimated errors on the regularization parameters is considered. The important practical recommendations on stable numerical differentiation with various a priori information are given.

## 2. Inequalities for the Derivatives

2.1. The main result. In this sections we investigate and answer the following questions (see [22]):
Question 2.1. Given $f_{\delta} \in L^{\infty}(\mathbb{R})$ and $f \in C^{1}(\mathbb{R})$ such that inequalities

$$
\left\|f_{\delta}-f\right\| \leq \delta, \quad\left\|f^{(m)}\right\| \leq M_{m}<\infty, \quad m=0,1
$$

hold with some known $\delta$ and unknown (or roughly estimated) $M_{m}$, can one compute $f^{\prime}$ stably?

Here

$$
\begin{equation*}
\|f\|:=\underset{x \in \mathbb{R}}{\operatorname{ess} \sup }|f(x)| \tag{2.1}
\end{equation*}
$$

In other words, does there exist an operator $T$ such that

$$
\begin{equation*}
\sup _{f \in \mathcal{K}\left(\delta, M_{m}\right)}\left\|T f_{\delta}-f^{\prime}\right\| \leq \eta(\delta) \longrightarrow 0 \quad \text { as } \quad \delta \rightarrow 0 \tag{2.2}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathcal{K}\left(\delta, M_{m}\right):=\left\{f: f \in C^{1}(\mathbb{R}),\left\|f^{(m)}\right\| \leq M_{m}<\infty,\left\|f_{\delta}-f\right\| \leq \delta\right\} \tag{2.3}
\end{equation*}
$$

$m=0$ or $m=1$ ?
Question 2.2. It is similar to Question 1 but now it is assumed that $m=1+a$, $0<a \leq 1$.

$$
\begin{equation*}
\left\|f^{(1+a)}\right\|:=M_{1+a}<\infty \tag{2.4}
\end{equation*}
$$

where

$$
\left\|f^{(1+a)}\right\|:=\underset{x, y \in \mathbb{R}}{\operatorname{esssup}} \frac{\left|f^{\prime}(x)-f^{\prime}(y)\right|}{|x-y|^{a}}
$$

The basic results of this section are summerized in Theorem 2.1 below.
Theorem 2.1. There does not exist an operator $T: L^{\infty}(\mathbb{R}) \rightarrow L^{\infty}(\mathbb{R})$ such that inequality (2.2) holds if $m=0$ or $m=1$. There exists such an operator if $m>1$. This operator is given by (2.11) with $h=h_{1+a}(\delta)$ defined in (2.13). The error of the corresponding differentiation formula (2.11) is presented in (2.13).
Proof. Consider

$$
\begin{equation*}
f_{1}(x):=-\frac{M}{2} x(x-2 h), \quad 0 \leq x \leq 2 h \tag{2.5}
\end{equation*}
$$

Extend $f_{1}(x)$ to the whole real axis in such a way that the norms $\left\|f_{1}^{(m)}\right\|, m=$ $0,1,2$, are preserved. Define $f_{2}(x):=-f_{1}(x)$. Note that

$$
\begin{equation*}
\sup _{x \in R}\left|f_{k}(x)\right|=\frac{M h^{2}}{2}, \quad k=1,2 . \tag{2.6}
\end{equation*}
$$

Take

$$
\begin{equation*}
\frac{M h^{2}}{2}=\delta \tag{2.7}
\end{equation*}
$$

then for $f_{\delta}(x) \equiv 0$ it follows the estimate $\left\|f_{k}-f_{\delta}\right\| \leq \delta, \quad k=1,2$. Let $\left(T f_{\delta}\right)(0)=$ $(T 0)(0):=b$. If $\left\|f_{k}^{(m)}\right\| \leq M_{m}, \quad k=1,2$ one has

$$
\begin{gathered}
\gamma_{m}(\delta):=\inf _{T} \sup _{f \in \mathcal{K}\left(\delta, M_{m}\right)}\left\|T f_{\delta}-f^{\prime}\right\| \geq \inf _{T} \max _{k=1,2}\left\|T f_{\delta}-f_{k}^{\prime}\right\| \\
\geq \inf _{T} \max _{k=1,2}\left\|T f_{\delta}(0)-f_{k}^{\prime}(0)\right\|=\inf _{b \in R} \max \{|b-M h|,|b+M h|\}=M h .
\end{gathered}
$$

By $(2.7) h=\sqrt{\frac{2 \delta}{M}}, M h=\sqrt{2 \delta M}$.
If $m=0$, then (2.6) implies that $f_{k} \in \mathcal{K}\left(\delta, M_{0}\right), \quad k=1,2$, with $M_{0}:=\frac{M h^{2}}{2}=\delta$. Since for any fixed $\delta>0$ and $M_{0}=\delta$ the constant $M$ in (2.5) can be chosen arbitrary, inequality (2.8) proves that (2.2) is false in the class $\mathcal{K}\left(\delta, M_{0}\right)$ and in fact $\gamma_{0}(\delta) \rightarrow \infty$ as $M \rightarrow \infty$.

Estimate (2.2) is also false in the class $\mathcal{K}\left(\delta, M_{1}\right)$. Indeed,

$$
\begin{equation*}
\left\|f_{1}^{\prime}\right\|=\left\|f_{2}^{\prime}\right\|=\sup _{0 \leq x \leq 2 h}|M(x-h)|=M h=\sqrt{2 \delta M} \tag{2.9}
\end{equation*}
$$

Thus, for given $\delta, M_{1}>0$ one can find $M$ such that (2.7) holds and $M_{1}=\sqrt{2 \delta M}$. For this $M$ the functions $f_{k} \in \mathcal{K}\left(\delta, M_{1}\right), \quad k=1,2$. By (2.8) one obtains:

$$
\begin{equation*}
\gamma_{1}(\delta) \geq M_{1}>0 \quad \text { as } \quad \delta \rightarrow 0 \tag{2.10}
\end{equation*}
$$

so that (2.2) is false.
Let us assume now that (2.4) holds. Take

$$
\begin{equation*}
T_{h} f_{\delta}:=\frac{f_{\delta}(x+h)-f_{\delta}(x-h)}{2 h}, \quad h>0 \tag{2.11}
\end{equation*}
$$

One gets, using the Lagrange formula,

$$
\begin{align*}
\left\|T_{h} f_{\delta}-f^{\prime}\right\|= & \left\|T_{h}\left(f_{\delta}-f\right)\right\|+\left\|T_{h} f-f^{\prime}\right\| \\
& \leq \frac{\delta}{h}+\left\|\frac{f(x+h)-f(x-h)-2 h f^{\prime}(x)}{2 h}\right\| \\
& \leq \frac{\delta}{h}+\left\|\frac{\left[f^{\prime}(y)-f^{\prime}(x)\right] h+\left[f^{\prime}(z)-f^{\prime}(x)\right] h}{2 h}\right\| \\
& \leq \frac{\delta}{h}+M_{1+a} h^{a}:=\varepsilon_{1+a}(\delta, h) . \tag{2.12}
\end{align*}
$$

where $y$ and $z$ are the intermediate points in the Lagrange formula.
Minimizing the right-hand side of (2.12) with respect to $h \in(0, \infty)$ yields

$$
\begin{equation*}
h_{1+a}(\delta)=\left(\frac{\delta}{a M_{1+a}}\right)^{\frac{1}{1+a}}, \quad \varepsilon_{1+a}(\delta)=\frac{a+1}{a^{\frac{a}{1+a}}} M_{1+a}^{\frac{1}{1+a}} \delta^{\frac{a}{1+a}}, \quad 0<a \leq 1 \tag{2.13}
\end{equation*}
$$

Theorem 2.1 is proved.
Remark 2.2. By formula (2.12) one can see that if $M_{1+a}$ is not known a priori then one chooses $h(\delta)=O\left(\delta^{\gamma}\right), 0<\gamma<1$, where $\gamma$ is a constant and $\epsilon_{1+a}\left(\delta, \delta^{\gamma}\right) \rightarrow 0$ as $\delta \rightarrow 0$. However, since in most cases in practice $\delta>0$ is fixed, and the choice of $h=O\left(\delta^{\gamma}\right)$ is not quite determined (it gives only asymptotics of $h$ as $\delta \rightarrow 0$ and does not determine the constant factor), this choice does not yield a practically computable error estimate for the formula of stable numerical differentiation. This is in sharp contrast with the practically computable error estimate given in (2.13).
2.2. The best estimate for $m=2$. It is significant to mention that $\varepsilon_{1+a}(\delta)$ obtained in (2.13) can be improved if $a=1(m=2)$. In this subsection we will give the optimal error estimate for functions of one or several variables in the class $\mathcal{K}_{n}\left(\delta, M_{2}\right), n \geq 1$ defined as follows:

$$
\begin{align*}
\mathcal{K}_{n}\left(\delta, M_{2}\right):= & \left\{f: f \in C^{2}\left(\mathbb{R}^{n}\right), \quad\left|\left(d^{2} f(x) k, k\right)\right| \leq M_{2}|k|^{2},\right. \\
& \left.\forall x, k \in \mathbb{R}^{n}, \quad\left\|f_{\delta}-f\right\| \leq \delta\right\}, \tag{2.14}
\end{align*}
$$

where

$$
\begin{gather*}
\left(d^{2} f(x) k, k\right)=\sum_{i, j=1}^{n} f_{x_{i} x_{j}}(x) k_{i} k_{j},  \tag{2.15}\\
|k|^{2}=\sum_{i=1}^{n}\left|k_{i}\right|^{2}, \quad\|f\|:=\underset{x \in \mathbb{R}^{n}}{\operatorname{ess} \sup }|f(x)| .
\end{gather*}
$$

We want to approximate the directional derivative $D_{v} f(x)=\nabla f(x) \cdot v$, where $v$ is a unit vector. Define

$$
\begin{equation*}
T_{h} f_{\delta}:=\frac{f_{\delta}(x+h v)-f_{\delta}(x-h v)}{2 h}, \quad h>0 \tag{2.16}
\end{equation*}
$$

Theorem 2.3. [17] If $h_{2}(\delta)=\left(\frac{2 \delta}{M_{2}}\right)^{\frac{1}{2}}$ and $\varepsilon_{2}(\delta)=\left(2 \delta M_{2}\right)^{\frac{1}{2}}$ then

$$
\begin{equation*}
\left\|T_{h_{2}(\delta)} f_{\delta}-D_{v} f\right\| \leq \varepsilon_{2}(\delta) \tag{2.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\gamma_{2}(\delta):=\inf _{T \in \mathcal{A}} \sup _{f \in \mathcal{K}_{n}\left(\delta, M_{2}\right)}\left\|T f_{\delta}-D_{v} f\right\|=\varepsilon_{2}(\delta) \tag{2.18}
\end{equation*}
$$

Here $\mathcal{A}$ is the set of all operators $T: L^{\infty}\left(\mathbb{R}^{n}\right) \rightarrow L^{\infty}\left(\mathbb{R}^{n}\right)$.
Proof. For any $x \in \mathbb{R}^{n}$ and $h>0$

$$
\begin{align*}
\left\|T_{h} f_{\delta}-D_{v} f\right\| & \leq\left\|T_{h} f_{\delta}-T_{h} f\right\|+\left\|T_{h} f-D_{v} f\right\| \\
& \leq\left\|T_{h}\left(f_{\delta}-f\right)\right\|+\frac{M_{2} h}{2} \\
& \leq \frac{\delta}{h}+\frac{M_{2} h}{2} \tag{2.19}
\end{align*}
$$

Consider the right-hand side of (2.19) as a function of $h$. As before, this function has an absolute minimum $\varepsilon_{2}(\delta)$ at $h=h_{2}(\delta)$. Thus $\left\|T_{h_{2}(\delta)} f_{\delta}-D_{v} f\right\| \leq \varepsilon_{2}(\delta)$. Let

$$
f_{1}(x)=\frac{1}{2} M_{2} \sum_{i=1}^{n} x_{i}^{2}-M_{2} h_{2}(\delta) \sum_{i=1}^{n} v_{i} x_{i}
$$

for $x$ inside the ball centered at $\left(h_{2}(\delta) v_{1}, \ldots, h_{2}(\delta) v_{n}\right)$ with radius $h_{2}(\delta)$. Note that $f_{1}(x)=0$ on the boundary of this ball, $f_{1}$ has an absolute minimum value $-\delta$ at $x=\left(h_{2}(\delta) v_{1}, \ldots, h_{2}(\delta) v_{n}\right)$ and $\left|\left(d^{2} f_{1}(x) k, k\right)\right|=M_{2}|k|^{2}$. Also one gets

$$
\begin{aligned}
D_{v} f_{1}(0) & =-M_{2} h_{2}(\delta) \sum_{i=1}^{n} v_{i}^{2}=-M_{2} h_{2}(\delta) \\
& =-\left(2 \delta M_{2}\right)^{\frac{1}{2}}=-\varepsilon_{2}(\delta)
\end{aligned}
$$

Continue $f_{1}$ on $\mathbb{R}^{n}$ in such a way that

$$
\begin{equation*}
\left|\left(d^{2} f_{1}(x) k, k\right)\right|=M_{2}|k|^{2}, \quad\left\|f_{1}\right\| \leq \delta \quad \forall x \in \mathbb{R}^{n} \tag{2.20}
\end{equation*}
$$

The continuation is possible since in the above ball conditions (2.20) are satisfied. Set $f_{2}=-f_{1}, f_{\delta}=0$. Following the proof of Theorem 2.1 (formula (2.8)) one obtains

$$
\begin{equation*}
\varepsilon_{2}(\delta) \leq \gamma_{2}(\delta) \tag{2.21}
\end{equation*}
$$

On the other hand,

$$
\begin{equation*}
\gamma_{2}(\delta) \leq \sup _{f \in \mathcal{K}_{n}\left(\delta, M_{2}\right)}\left\|T_{h} f_{\delta}-D_{v} f\right\| \leq \varepsilon_{2}(\delta) \tag{2.22}
\end{equation*}
$$

From (2.21) and (2.22) one gets (2.18).

## 3. Multi-Point finite difference formulas

3.1. Finite-difference methods in the class $\mathcal{K}\left(\delta, M_{m}\right), m>2$. Assume that $f(x)$ has derivatives up to order $m$ and $\left\|f^{(m)}\right\| \leq M_{m}, m>2$. Let $f_{\delta} \in L^{\infty}(\mathbb{R})$ be given such that $\left\|f-f_{\delta}\right\| \leq \delta$, where the norm is calculated by (2.1). Suppose that $m>2$ is odd and define (see [17], [19])

$$
\begin{equation*}
T_{h}^{Q} f_{\delta}:=h^{-1} \sum_{j=-Q}^{Q} A_{j}^{Q} f_{\delta}\left(x+\frac{j h}{Q}\right) \tag{3.1}
\end{equation*}
$$

where the numbers $A_{j}^{Q}(j=-Q, \ldots, Q)$ are to be determined. One has:

$$
\begin{align*}
& \left|T_{h}^{Q} f_{\delta}-f^{\prime}\right| \leq\left|T_{h}^{Q}\left(f_{\delta}-f\right)\right|+\left|T_{h}^{Q} f-f^{\prime}\right| \leq \frac{\delta}{h} \sum_{j=-Q}^{Q}\left|A_{j}^{Q}\right|+\left\lvert\, \frac{f(x)}{h} \sum_{j=-Q}^{Q} A_{j}^{Q}\right. \\
& +f^{\prime}(x)\left[\sum_{j=-Q}^{Q}\left(\frac{j}{Q}\right) A_{j}^{Q}-1\right]+\sum_{p=2}^{m-1} \frac{f^{(p)}(x) h^{p-1}}{p!} \sum_{j=-Q}^{Q}\left(\frac{j}{Q}\right)^{p} A_{j}^{Q} \\
& 2)  \tag{3.2}\\
& \left.\quad+\frac{h^{m-1}}{m!} \sum_{j=-Q}^{Q} f^{(m)}(\xi)\left(\frac{j}{Q}\right)^{m} A_{j}^{Q} \right\rvert\,, \quad m>2 .
\end{align*}
$$

If one requires the order of smallness (as $h \rightarrow \infty$ ) for $\left\|T_{h}^{Q} f_{\delta}-f^{\prime}\right\|$ to be minimal one gets the following system of equations for the coefficients $A_{j}^{Q}$ :

$$
\sum_{j=-Q}^{Q}\left(\frac{j}{Q}\right)^{l} A_{j}^{Q}=\delta_{1 l}, \quad 0 \leq l \leq 2 Q, \quad \delta_{1 l}:= \begin{cases}0, & \text { if } \quad l \neq 1  \tag{3.3}\\ 1, & \text { if } \quad l=1\end{cases}
$$

This is a linear system of $m$ equations with $2 Q+1$ unknowns. When $m=2 Q+1$ system (3.3) has a nonsingular (Vandermonde) matrix. So it is uniquely solvable for $A_{j}^{Q}$. For the first few values of $Q$ one obtains (see [19] and [12]):

$$
\begin{gather*}
A_{0}^{1}=0, \quad A_{ \pm 1}^{1}= \pm \frac{1}{2} \\
A_{0}^{2}=0, \quad A_{ \pm 1}^{2}= \pm \frac{4}{3}, \quad A_{ \pm 2}^{2}=\mp \frac{1}{6}, \\
A_{0}^{3}=0, \quad A_{ \pm 1}^{3}= \pm \frac{9}{4}, \quad A_{ \pm 2}^{3}=\mp \frac{9}{20}, \quad A_{ \pm 3}^{3}= \pm \frac{1}{20} \\
A_{0}^{4}=0, \quad A_{ \pm 1}^{4}= \pm \frac{16}{5}, \quad A_{ \pm 2}^{4}=\mp \frac{4}{5}, \quad A_{ \pm 3}^{4}= \pm \frac{16}{105}, \quad A_{ \pm 4}^{4}=\mp \frac{1}{70} \tag{3.4}
\end{gather*}
$$

With this choice of the coefficients $A_{j}^{Q}$, from (3.2) one gets

$$
\begin{align*}
\mid T_{h}^{Q} f_{\delta}-f^{\prime} & \leq \frac{\delta}{h} \sum_{j=-Q}^{Q}\left|A_{j}^{Q}\right|+h^{m-1} \frac{M_{m}}{m!} \sum_{j=-Q}^{Q}\left|\left(\frac{j}{Q}\right)^{m} A_{j}^{Q}\right| \\
& \equiv \frac{\delta}{h} \alpha_{m}+h^{m-1} M_{m} \beta_{m} \tag{3.5}
\end{align*}
$$

The right-hand side of (3.5) as a function of $h$ has an absolute minimum $\varepsilon_{m}(\delta)$ when

$$
\begin{equation*}
h=h_{m}(\delta)=\left[\frac{\alpha_{m} \delta}{(m-1) M_{m} \beta_{m}}\right]^{\frac{1}{m}} \tag{3.6}
\end{equation*}
$$

the coefficients $\alpha_{m}, \beta_{m}$ are defined in (3.5) and

$$
\begin{equation*}
\varepsilon=\varepsilon_{m}(\delta)=m\left[\frac{\alpha_{m}^{m-1} M_{m} \beta_{m} \delta^{m-1}}{(m-1)^{m-1}}\right]^{\frac{1}{m}} \tag{3.7}
\end{equation*}
$$

Remark 3.1. In [19] and [12] multi-point formulas for two-dimensional case are also investigated.
3.1.1. Best possible estimates of $f^{\prime}$ and $f^{\prime \prime}$ in the class $\mathcal{K}\left(\delta, M_{3}\right)$. It is shown above that the minimal order of smallness for the approximation error $\left\|T_{h}^{Q} f_{\delta}-f^{\prime}\right\|$ is attained when $m=2 Q+1$ and $A_{j}^{Q}$ are the solutions to (3.3). According to (3.1), (3.4) and (3.6) for $m=3$ one gets the central difference derivative.

$$
\begin{equation*}
T_{h_{3}(\delta)}^{1} f_{\delta}=\frac{f_{\delta}\left(x+h_{3}(\delta)\right)-f_{\delta}\left(x-h_{3}(\delta)\right)}{2 h} \tag{3.8}
\end{equation*}
$$

with

$$
\begin{equation*}
h_{3}(\delta)=\left(\frac{3 \delta}{M_{3}}\right)^{\frac{1}{3}} \tag{3.9}
\end{equation*}
$$

As a simple consequence of this observation we state the following proposition.
Proposition 3.2. Among all linear and nonlinear operators $T: L^{\infty}(\mathbb{R}) \rightarrow L^{\infty}(\mathbb{R})$ the operator $T_{h_{3}(\delta)}^{1}$ defined by (3.8), (3.9) gives the best possible estimate of $f^{\prime}$ in the class of all functions $f \in \mathcal{K}\left(\delta, M_{3}\right)$ (see (2.3)) and

$$
\begin{equation*}
\gamma_{3}(\delta):=\inf _{T} \sup _{f \in \mathcal{K}\left(\delta, M_{3}\right)}\left\|T f_{\delta}-f^{\prime}\right\|=\frac{3}{2}^{\frac{2}{3}} M_{3}^{\frac{1}{3}} \delta^{\frac{2}{3}}=\varepsilon_{3}(\delta) \tag{3.10}
\end{equation*}
$$

Proof. By (3.5)-(3.7) one obtains $\gamma_{3}(\delta) \leq \varepsilon_{3}(\delta)$. To prove that

$$
\begin{equation*}
\gamma_{3}(\delta) \geq \varepsilon_{3}(\delta) \tag{3.11}
\end{equation*}
$$

take

$$
\begin{equation*}
f_{1}(t):=-\frac{M_{3}}{6} t^{3}+\varepsilon_{3}(\delta) t, \quad t \in\left[0,\left(\frac{6 \varepsilon_{3}(\delta)}{M_{3}}\right)^{\frac{1}{2}}\right] \tag{3.12}
\end{equation*}
$$

It is clear that $f_{1}(0)=f_{1}\left(\left(\frac{6 \varepsilon_{3}(\delta)}{M_{3}}\right)^{\frac{1}{2}}\right)=0$ and

$$
\begin{equation*}
\left|f_{1}^{(3)}(t)\right|=M_{3}, \quad f_{1}^{\prime}(0)=\varepsilon_{3}(\delta), \quad\left|f_{1}(t)\right| \leq \delta \tag{3.13}
\end{equation*}
$$

Continue $f_{1}(t)$ on $\mathbb{R}$ in such a way that (3.13) are satisfied for any $t \in \mathbb{R}$. Let $f_{2}(t)=f_{1}(t), f_{\delta}=0$. Thus, following the proof of Theorem 2.1 once again (formula (2.8)) one derives (3.11) and completes the proof.

Similar result can be proved for the second derivative operator in the class $\mathcal{K}\left(\delta, M_{3}\right)$. Introduce

$$
\begin{equation*}
R_{\delta} f_{\delta}:=\frac{f_{\delta}\left(x-g_{3}(\delta)\right)-2 f_{\delta}(x)+f_{\delta}\left(x+g_{3}(\delta)\right)}{g_{3}^{2}(\delta)} \tag{3.14}
\end{equation*}
$$

$$
\begin{equation*}
g_{3}(\delta):=2\left(\frac{3 \delta}{M_{3}}\right)^{\frac{1}{3}} \tag{3.15}
\end{equation*}
$$

Proposition 3.3. Among all linear and nonlinear operators $T: L^{\infty}(\mathbb{R}) \rightarrow L^{\infty}(\mathbb{R})$ the operator $R_{\delta}$, defined by (3.14)-(3.15), gives the best possible estimate of $f^{\prime \prime}$ in the class $\mathcal{K}\left(\delta, M_{3}\right)$ and

$$
\begin{equation*}
\beta_{3}(\delta):=\inf _{T} \sup _{f \in \mathcal{K}\left(\delta, M_{3}\right)}\left\|T f_{\delta}-f^{\prime \prime}\right\|=3^{\frac{1}{3}} M_{3}^{\frac{2}{3}} \delta^{\frac{1}{3}}:=\alpha_{3}(\delta) \tag{3.16}
\end{equation*}
$$

Proof. Using the Taylor formula one gets:

$$
\begin{equation*}
\left\|R_{\delta} f_{\delta}-f^{\prime \prime}\right\| \leq \frac{4 \delta}{g_{3}^{2}(\delta)}+\frac{M_{3} g_{3}(\delta)}{3} \tag{3.17}
\end{equation*}
$$

The function $G(g):=\frac{4 \delta}{g^{2}}+\frac{M_{3} g}{3}$ has an absolute minimum $\alpha_{3}(\delta)$ if $g=g_{3}(\delta)$ (see formulas $(3.16),(3.15)$ respectively). Therefore $\beta_{3}(\delta) \leq \alpha_{3}(\delta)$. To obtain the inequality

$$
\begin{equation*}
\beta_{3}(\delta) \geq \alpha_{3}(\delta) \tag{3.18}
\end{equation*}
$$

we consider the following function

$$
f(t)=-\frac{M_{3}}{6} t^{3}+\frac{\alpha_{3}(\delta)}{2} t^{2}-\delta
$$

This function has three real roots: $t_{1}<0<t_{2}<t_{3}$. One can also check that on the interval $\left[t_{1}, t_{3}\right]$

$$
\begin{equation*}
\left|f^{(3)}(t)\right|=M_{3}, \quad f^{\prime \prime}(0)=\alpha_{3}(\delta), \quad|f(t)| \leq \delta \tag{3.19}
\end{equation*}
$$

The last inequality is true because $f(t)$ attains its global maximum on the interval $\left[t_{1}, t_{3}\right]$ at $\hat{t}=\frac{2 \alpha_{3}(\delta)}{M_{3}}$, its global minimum on the above interval at $\tilde{t}=0$ and $|f(\hat{t})|=$ $|f(\tilde{t})|=\delta$.

Suppose that $f_{1}(t)=f(t)$ for $t \in\left[t_{1}, t_{3}\right]$ and continue $f_{1}(t)$ on $\mathbb{R}$ so that (3.19) holds for any $t \in \mathbb{R}$. Let $f_{2}(t)=-f_{1}(t), f_{\delta}(t) \equiv 0$. If one estimates $\beta_{3}(\delta)$ from below following the idea used in (2.8) then one arrives at (3.18) and the proof is completed.
3.2. Finite difference methods in the class $\mathcal{K}\left(\sigma, M_{2}\right)$. Here we consider the family of the operators (see [17], [19] and [23])

$$
\begin{equation*}
T_{h}^{Q} f_{\sigma}:=h^{-1} \sum_{j=-Q}^{Q} A_{j}^{Q} f_{\sigma}\left(x+\frac{j h}{Q}\right) \tag{3.20}
\end{equation*}
$$

under the assumption that $f$ is twice differentiable and $\left\|f^{\prime \prime}\right\| \leq M_{2}$. We assume also that the approximation $f_{\sigma}(x)=f(x)+e_{\sigma}(x)$, where the error $e_{\sigma}(x)$ is independent and identically distributed with zero mean value and variance $\sigma^{2}$. We will call the class of functions $f \in C^{2}(\mathbb{R})$ with the above properties $\mathcal{K}\left(\sigma, M_{2}\right)$.

We wish to determine the coefficients $A_{j}^{Q}$ which minimize the mean square error:

$$
\begin{equation*}
E\left[\left(T_{h}^{Q} f_{\sigma}-f^{\prime}\right)^{2}\right]=\min \tag{3.21}
\end{equation*}
$$

and

$$
\begin{equation*}
E\left[T_{h}^{Q} f_{\sigma}\right]=f^{\prime} \tag{3.22}
\end{equation*}
$$

where $E$ denotes the mean value. By Taylor's formula one gets:

$$
\begin{align*}
& T_{h}^{Q} f_{\sigma}-f^{\prime}=h^{-1} \sum_{j=-Q}^{Q} A_{j}^{Q}\left[f_{\sigma}\left(x+\frac{j h}{Q}\right)-f\left(x+\frac{j h}{Q}\right)\right] \\
& +\frac{f(x)}{h} \sum_{j=-Q}^{Q} A_{j}^{Q}+f^{\prime}(x)\left[\sum_{j=-Q}^{Q}\left(\frac{j}{Q}\right) A_{j}^{Q}-1\right]+h \sum_{j=-Q}^{Q} \frac{f^{\prime \prime}\left(\xi_{j}\right)}{2}\left(\frac{j}{Q}\right)^{2} A_{j}^{Q} . \tag{3.23}
\end{align*}
$$

It follows from (3.21)-(3.23) (see [19] and [23]) that

$$
\begin{gather*}
\sum_{j=-Q}^{Q} A_{j}^{Q}=0, \quad \sum_{j=-Q}^{Q}\left(\frac{j}{Q}\right) A_{j}^{Q}=1  \tag{3.24}\\
\frac{\sigma^{2}}{h^{2}} \sum_{j=-Q}^{Q}\left(A_{j}^{Q}\right)^{2}+h^{2}\left(\sum_{j=-Q}^{Q}\left|A_{j}^{Q}\right|\left(\frac{j}{Q}\right)^{2} \frac{M_{2}}{2}\right)^{2}=\min . \tag{3.25}
\end{gather*}
$$

Let us find $A_{j}^{Q}$ satisfying conditions (3.24) and the condition

$$
\sum_{j=-Q}^{Q}\left(A_{j}^{Q}\right)^{2}=\min
$$

Then we will minimize (3.25) with respect to $h$. Using Lagrange multipliers $\lambda$ and $\nu$, one has:

$$
\begin{equation*}
2 A_{j}^{Q}-\lambda-\nu\left(\frac{j}{Q}\right)=0, \quad-Q \leq j \leq Q \tag{3.26}
\end{equation*}
$$

System (3.26) together with (3.24) imply

$$
\lambda=0, \quad \nu=\frac{6 Q}{(Q+1)(2 Q+1)}
$$

So,

$$
\begin{equation*}
A_{j}^{Q}=\frac{\nu j}{2 Q}=\frac{3 j}{(Q+1)(2 Q+1)} \tag{3.27}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{j=-Q}^{Q}\left(A_{j}^{Q}\right)^{2}=\frac{18}{[(Q+1)(2 Q+1)]^{2}} \sum_{j=1}^{Q} j^{2}=\frac{3 Q}{(Q+1)(2 Q+1)} \tag{3.28}
\end{equation*}
$$

Thus (3.25) becomes

$$
\begin{gather*}
\varphi(h):=\frac{\sigma^{2} a_{Q}}{h^{2}}+h^{2} M_{2}^{2} b_{Q}=\min  \tag{3.29}\\
a_{Q}:=\frac{3 Q}{(Q+1)(2 Q+1)},  \tag{3.30}\\
b_{Q}:=\frac{9}{Q^{4}(Q+1)^{2}(2 Q+1)^{2}}\left(\sum_{j=1}^{Q} j^{3}\right)^{2}=\frac{9(Q+1)^{2}}{16(2 Q+1)^{2}} \tag{3.31}
\end{gather*}
$$

Minimizing with respect to $h$, we find:

$$
\begin{equation*}
-2 \sigma^{2} a_{Q} h^{-3}+2 h^{2} M_{2}^{2} b_{Q}=0, \quad h(\sigma)=\left(\frac{\sigma}{M_{2}}\right)^{\frac{1}{2}}\left(\frac{a_{Q}}{b_{Q}}\right)^{\frac{1}{4}} . \tag{3.32}
\end{equation*}
$$

Let $\varphi(h(\sigma))=\varepsilon_{2}^{2}(\sigma)$. Then

$$
\begin{equation*}
\varepsilon_{2}^{2}(\sigma)=\sigma^{2} a_{Q} \frac{M_{2}}{\sigma}\left(\frac{b_{Q}}{a_{Q}}\right)^{\frac{1}{2}}+M_{2}^{2} b_{Q} \frac{\sigma}{M_{2}}\left(\frac{a_{Q}}{b_{Q}}\right)^{\frac{1}{2}}=2 \sigma M_{2} \sqrt{a_{Q} b_{Q}} \tag{3.33}
\end{equation*}
$$

Thus the standard deviation of the optimal estimate is

$$
\begin{equation*}
\sqrt{E\left[\left(T_{h}^{Q} f_{\sigma}-f^{\prime}\right)^{2}\right]} \leq \sqrt{2 \sigma M_{2}}\left(a_{Q} b_{Q}\right)^{\frac{1}{4}} \tag{3.34}
\end{equation*}
$$

Note that

$$
\begin{equation*}
\left(a_{Q} b_{Q}\right)^{\frac{1}{4}}=\left(\frac{27 Q(Q+1)}{16(2 Q+1)^{3}}\right)^{\frac{1}{4}} \approx \frac{0.67}{Q^{\frac{1}{4}}}, \quad Q \rightarrow \infty \tag{3.35}
\end{equation*}
$$

Let $Q$ be 16. Then $\varepsilon_{2}(\sigma) \leq \sqrt{2 \sigma M_{2}} \cdot 0.34$. Therefore there is a gain in accuracy compared with (2.17). Estimates (3.34) and (3.35) show that, in principle, it is possible to attain an arbitrary accuracy of the approximation by taking $Q$ sufficiently large.

Remark 3.4. It follows from (3.20), (3.27) that the multi-point differentiator can be written as:

$$
\begin{equation*}
T_{h}^{Q} f_{\sigma}:=\frac{3}{h(Q+1)(2 Q+1)} \sum_{j=-Q}^{Q} j f_{\sigma}\left(x+\frac{j h}{Q}\right) \tag{3.36}
\end{equation*}
$$

or in the equivalent form:

$$
\begin{equation*}
T_{\tilde{h}}^{Q} f_{\sigma}:=\frac{\sum_{j=-Q}^{Q} j f_{\sigma}(x+j \tilde{h})}{2 \tilde{h} \sum_{j=-Q}^{Q} j^{2}}, \quad \tilde{h}:=\frac{h}{Q} \tag{3.37}
\end{equation*}
$$

which coincides with the least squares differentiator derived by Lanczos ([11]) and also investigated by Anderssen and de Hoog ([3]). However, neither in [11] nor in [3] the special choice of $h$ by formula (3.32) was proposed to guarantee a better accuracy of the approximations.
3.2.1. Construction of finite-difference methods without using the a priori estimate of $M_{2}$. To calculate $h$ by formula (3.32) one needs to know $\sigma^{2}$ and $M_{2}$. If the constants $\sigma^{2}$ and $M_{2}$ cannot be found a priori then one can use the following considerations. By (3.29), (3.30) and (3.31) for small $h$ and large $Q \geq 1$ one has

$$
\begin{equation*}
E\left[\left(T_{h}^{Q} f_{\sigma}-f^{\prime}\right)^{2}\right] \leq \frac{3 \sigma^{2} Q}{h^{2}(Q+1)(2 Q+1)}+\frac{h^{2} M_{2}^{2}}{2} \sim \frac{3 \sigma^{2}}{2 h^{2} Q} \tag{3.38}
\end{equation*}
$$

which means that the right-hand side of (3.38) is bounded if

$$
\begin{equation*}
h^{2} Q \longrightarrow \infty \quad \text { as } \quad h \rightarrow 0 \tag{3.39}
\end{equation*}
$$

The condition $h \rightarrow 0$ guarantees that the term $\frac{h^{2} M_{2}^{2}}{2}$ neglected in (3.38) is small. If it is assumed that $Q=h^{-p}$, then (3.39) holds if $p>2$. Therefore the simple strategy in the case when $\sigma^{2}$ and $M_{2}$ are not available, is to ignore the choice of $h$ by (3.32), to take $h$ sufficiently small and then to choose $Q$ in such a way that
(3.39) holds. There is no efficient error estimate (with explicitly given estimation constants as in (2.12)-(2.13)) in this case.

## 4. Continuous regularization and numerical differentiation in the class $\mathcal{G}(\delta)$

4.1. Statement of the problem. Suppose that $f$ is the function to be differentiated and $z$ is its unknown derivative. Then $z$ satisfies the following Volterra equation

$$
\begin{equation*}
\int_{a}^{x} z(s) d s=f(x), \quad a \leq x \leq b<\infty, \quad z \in L^{2}[a, b] \tag{4.1}
\end{equation*}
$$

Below we assume that $f(a)=0$. If $f(a) \neq 0$, then (4.1) is inconsistent, but the problem is essentially unchanged, since the derivative of a constant is zero.

In this section we make use of the approach developed in [1] for solving nonlinear operator equations

$$
\begin{equation*}
A(z)=f, \quad A: H \rightarrow H \tag{4.2}
\end{equation*}
$$

where $H$ is a Hilbert space and the Fréchet derivative of $A$ is not assumed to be boundedly invertible. To deal with the ill-posedness of (4.2) the following Cauchy problem

$$
\begin{equation*}
\dot{z}(t):=\frac{d z}{d t}=\Phi(z(t), t), \quad z(0)=z_{0} \in H, \quad \Phi: H \times[0,+\infty) \rightarrow H \tag{4.3}
\end{equation*}
$$

is considered and a general theorem on a continuous regularization in form (4.3) is proved (see Theorem 2.4, [1]). As a consequence of this theorem different types of the operators $\Phi$ are investigated in [1]. In particular, it is shown that for monotone operators $A$ one can write $\Phi$ as follows:

$$
\begin{equation*}
\Phi(z(t), t):=-\left[A(z(t))-f+\varepsilon(t)\left(z(t)-z_{0}\right)\right], \quad \varepsilon(t)>0 \tag{4.4}
\end{equation*}
$$

Let $\rightharpoonup$ denote weak convergence in a Hilbert space $H$. To state the main asymptotic property of the solution to (4.3)-(4.4) we will need the following definition.
Definition 4.1. The operator $A$ in a Hilbert space $H$ is said to be monotone if $(A(z)-A(y), z-y) \geq 0$ for all $z$ and $y$ in the domain of definition of $A$.
Theorem 4.2. ([1]) If

1. problem (4.2) has a unique solution $y \in H$;
2. A is monotone;
3. $A$ is continuously Fréchet differentiable and

$$
\begin{equation*}
\left\|A^{\prime}(x)\right\| \leq N_{1}, \quad \forall x \in H \tag{4.5}
\end{equation*}
$$

4. $\varepsilon(t)>0$ is continuously differentiable and tends to zero monotonically as $t \rightarrow+\infty$, and $\lim _{t \rightarrow+\infty} \frac{\dot{\varepsilon}(t)}{\varepsilon^{2}(t)}=0$.
Then Cauchy problem (4.3)-(4.4) has a unique solution $z(t)$ for all $t \in[0,+\infty)$ and

$$
\begin{equation*}
\lim _{t \rightarrow+\infty}\|z(t)-y\|=0 \tag{4.6}
\end{equation*}
$$

in the norm of a Hilbert space $H$.

Remark 4.3. One can see that for linear operator

$$
\begin{equation*}
A(z):=\int_{a}^{x} z(s) d s, \quad H=L^{2}[a, b] \tag{4.7}
\end{equation*}
$$

conditions 2 and 3 of Theorem 4.2 hold. Indeed,

$$
(A h, h)=\int_{a}^{b}\left(\int_{a}^{x} h(\tau) d \tau\right) h(x) d x=\frac{1}{2} \int_{a}^{b}\left[\left(\int_{a}^{x} h(\tau) d \tau\right)^{2}\right]^{\prime} d x \geq 0
$$

Here ( , ) denotes the inner product in a real Hilbert space $L^{2}[a, b]$. Also since $A$ is bounded the constant $N_{1}=\|A\| \leq(b-a) / \sqrt{2}$. The proof is immediate:

$$
\|A\|^{2}=\int_{a}^{b}\left[\int_{a}^{x} z(s) d s\right]^{2} d x \leq \int_{a}^{b} \int_{a}^{x} z^{2}(s) d s \int_{a}^{x} d s d x \leq\|z\|^{2} \frac{(b-a)^{2}}{2}
$$

Finally note that equation (4.1) is uniquely solvable if $f$ is absolutely continuous and $f^{\prime} \in L^{2}[a, b]$ and it is not solvable otherwise.

Let us use Euler's method to solve Cauchy problem (4.3)-(4.4) numerically.

$$
\begin{gather*}
p_{n+1}=p_{n}-h_{n}\left[A\left(p_{n}\right)-f_{\delta}+\varepsilon_{n}\left(p_{n}-z_{0}\right)\right], \quad n=0,1,2, \ldots,  \tag{4.8}\\
p_{0}:=z_{0}, \quad \varepsilon_{n}:=\varepsilon\left(t_{n}\right), \quad t_{n}:=\sum_{i=1}^{n} h_{i}, \quad h_{n}>0 \tag{4.9}
\end{gather*}
$$

where $f_{\delta} \in H$ and $\left\|f-f_{\delta}\right\| \leq \delta$ in $H$-norm.
4.2. Convergence and stability analysis. The goal of this subsection is to prove that under the assumptions of Theorem 4.2 and under the assumptions on $h_{n}, \varepsilon_{n}$ and $\delta$, listed in Theorem 4.5, one gets

$$
\begin{equation*}
\lim _{\delta \rightarrow 0}\left\|p_{n(\delta)}-z\left(t_{n(\delta)}\right)\right\|=0 \tag{4.10}
\end{equation*}
$$

The steps of the proof are:

1) we prove inequality (4.18) below,
2) we prove (4.22) for the solution to a difference inequality (4.20),
$3)$ we apply (4.20) and (4.22) to (4.18).
The limit in (4.10) is understood in the sense of $H$-norm and $n(\delta) \rightarrow \infty$ as $\delta \rightarrow$ 0 . Equalities (4.6) and (4.10) together imply that (4.8)-(4.9) generate a stable numerical scheme for solving (4.2), which in particular can be applied in the case of equation (4.1) if $f \in \mathcal{G}(\delta)$, where

$$
\begin{equation*}
\mathcal{G}(\delta):=\left\{f: f \text { is absolutely continuous, } f^{\prime} \in L^{2}[a, b],\left\|f-f_{\delta}\right\| \leq \delta\right\} \tag{4.11}
\end{equation*}
$$

In (4.11) $L^{2}$-norm is taken. Note that if the function $z(t)$ satisfies (4.3)-(4.4) one has

$$
\begin{aligned}
& z\left(t_{n+1}\right)=z\left(t_{n}\right)+h_{n} \dot{z}\left(t_{n}\right)+\frac{h_{n}^{2}}{2} \ddot{z}\left(\xi_{n}\right)=z\left(t_{n}\right)-h_{n}\left[A\left(z\left(t_{n}\right)\right)-f\right. \\
& \left.\quad+\varepsilon\left(t_{n}\right)\left(z\left(t_{n}\right)-z_{0}\right)\right]-\frac{h_{n}^{2}}{2}\left\{[ A ^ { \prime } ( z ( \xi _ { n } ) ) + \varepsilon ( \xi _ { n } ) I ] \cdot \left[A\left(z\left(\xi_{n}\right)\right)-f\right.\right.
\end{aligned}
$$

$$
\begin{equation*}
\left.\left.+\varepsilon\left(\xi_{n}\right)\left(z\left(\xi_{n}\right)-z_{0}\right)\right]+\dot{\varepsilon}\left(\xi_{n}\right)\left(z\left(\xi_{n}\right)-z_{0}\right)\right\} \tag{4.12}
\end{equation*}
$$

Denote

$$
\begin{equation*}
z_{n}:=z\left(t_{n}\right), \quad \tilde{z}_{n}:=z\left(\xi_{n}\right), \quad \tilde{\varepsilon}_{n}:=\varepsilon\left(\xi_{n}\right) \tag{4.13}
\end{equation*}
$$

Then

$$
\begin{gather*}
\left\|z_{n+1}-p_{n+1}\right\| \leq\left\|z_{n}-p_{n}-h_{n}\left[A\left(z_{n}\right)-A\left(p_{n}\right)+\varepsilon_{n}\left(z_{n}-p_{n}\right)\right]\right\| \\
+h_{n} \delta+\frac{h_{n}^{2}}{2}\left\{\left\|A^{\prime}\left(\tilde{z}_{n}\right)+\tilde{\varepsilon}_{n} I\right\| \cdot\left\|A\left(\tilde{z}_{n}\right)-f+\tilde{\varepsilon}_{n}\left(\tilde{z}_{n}-z_{0}\right)\right\|\right. \\
\left.+\left|\dot{\varepsilon}\left(\xi_{n}\right)\right| \cdot\left\|\tilde{z}_{n}-z_{0}\right\|\right\} . \tag{4.14}
\end{gather*}
$$

Suppose that conditions of Theorem 4.2 are fulfilled. Introduce the notation

$$
\begin{equation*}
\lambda_{n}:=\left(N_{1}+\tilde{\varepsilon}_{n}\right)\left\|A\left(\tilde{z}_{n}\right)-f+\tilde{\varepsilon}_{n}\left(\tilde{z}_{n}-z_{0}\right)\right\|+\left|\dot{\varepsilon}\left(\xi_{n}\right)\right| \cdot\left\|\tilde{z}_{n}-z_{0}\right\| \tag{4.15}
\end{equation*}
$$

Since $A(y)=f$, by Theorem 4.2 one gets

$$
\begin{gather*}
\lim _{n \rightarrow \infty} \lambda_{n} \leq \lim _{n \rightarrow \infty}\left\{\left(N_{1}+\tilde{\varepsilon}_{n}\right)\left(N_{1}\left\|\tilde{z}_{n}-y\right\|+\tilde{\varepsilon}_{n}\left\|\tilde{z}_{n}-z_{0}\right\|\right)\right. \\
\left.+\left|\dot{\varepsilon}\left(\xi_{n}\right)\right| \cdot\left\|\tilde{z}_{n}-z_{0}\right\|\right\}=0 \tag{4.16}
\end{gather*}
$$

If $h_{n} \varepsilon_{n} \leq 1$ then from the monotonicity of $A$ one obtains:

$$
\begin{align*}
& \left\|z_{n+1}-p_{n+1}\right\| \leq\left\{\left\|z_{n}-p_{n}\right\|^{2}\left(1-h_{n} \varepsilon_{n}\right)^{2}-2 h_{n}\left(1-h_{n} \varepsilon_{n}\right)\left(A\left(z_{n}\right)-A\left(p_{n}\right), z_{n}-p_{n}\right)\right. \\
& \left.+h_{n}^{2}\left\|A\left(z_{n}\right)-A\left(p_{n}\right)\right\|^{2}\right\}^{\frac{1}{2}}+h_{n} \delta+\frac{h_{n}^{2} \lambda_{n}}{2} \leq\left\{\| z _ { n } - p _ { n } \| ^ { 2 } \left(1-2 h_{n} \varepsilon_{n}\right.\right. \\
& \left.\left.\quad+h_{n}^{2} \varepsilon_{n}^{2}+h_{n}^{2} N_{1}^{2}\right)\right\}^{\frac{1}{2}}+h_{n} \delta+\frac{h_{n}^{2} \lambda_{n}}{2} \tag{4.17}
\end{align*}
$$

Applying the elementary estimate

$$
(a+b)^{2} \leq\left(1+h_{n} \varepsilon_{n}\right) a^{2}+\left(1+\frac{1}{h_{n} \varepsilon_{n}}\right) b^{2}
$$

to the right-hand side of (4.17) with

$$
a:=\left\{\left\|z_{n}-p_{n}\right\|^{2}\left(1-2 h_{n} \varepsilon_{n}+h_{n}^{2} \varepsilon_{n}^{2}+h_{n}^{2} N_{1}^{2}\right)\right\}^{\frac{1}{2}}
$$

and

$$
b:=h_{n} \delta+\frac{h_{n}^{2} \lambda_{n}}{2}
$$

one gets:

$$
\begin{equation*}
\left\|z_{n+1}-p_{n+1}\right\|^{2} \leq\left(1-h_{n} \varepsilon_{n}+c h_{n}^{2}\right)\left\|z_{n}-p_{n}\right\|^{2}+d \frac{h_{n}\left(\delta+h_{n}\right)^{2}}{\varepsilon_{n}} \tag{4.18}
\end{equation*}
$$

Here we assume that $h_{n}$ tends to zero monotonically as $n \rightarrow \infty$,

$$
\begin{equation*}
c:=\left(1+h_{0} \varepsilon_{0}\right)\left(\varepsilon_{0}^{2}+N_{1}^{2}\right), \quad d:=\left[\max \left\{1, \frac{1}{2} \sup _{n} \lambda_{n}\right\}\right]^{2}\left(1+h_{0} \varepsilon_{0}\right) \tag{4.19}
\end{equation*}
$$

To state the result we need the following lemma on recursive numerical sequences.
To make the paper self-contained we include the proof.

Lemma 4.4. Let the sequence of positive numbers $\nu_{n}$ satisfy the inequality

$$
\begin{equation*}
\nu_{n+1} \leq\left(1-\alpha_{n}\right) \nu_{n}+\beta_{n} \tag{4.20}
\end{equation*}
$$

where

$$
\begin{equation*}
0<\alpha_{n} \leq 1, \quad \sum_{n=0}^{\infty} \alpha_{n}=\infty, \quad \lim _{n \rightarrow \infty} \frac{\beta_{n}}{\alpha_{n}}=0 \tag{4.21}
\end{equation*}
$$

Then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \nu_{n}=0 \tag{4.22}
\end{equation*}
$$

Proof. Inequality (4.20) yields

$$
\begin{align*}
\nu_{n+1} & \leq\left(1-\alpha_{n}\right)\left(1-\alpha_{n-1}\right) \nu_{n-1}+\left(1-\alpha_{n}\right) \beta_{n-1}+\beta_{n} \\
\leq \ldots & \leq \prod_{j=0}^{n}\left(1-\alpha_{j}\right) \nu_{0}+\sum_{i=0}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)+\beta_{n} \tag{4.23}
\end{align*}
$$

By (4.21) $\lim _{n \rightarrow \infty} \prod_{j=0}^{n}\left(1-\alpha_{j}\right)=0$ and $\lim _{n \rightarrow \infty} \beta_{n}=0$. Thus we have to show that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \sum_{i=0}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)=0 \tag{4.24}
\end{equation*}
$$

Without loss of generality one may assume that $\beta_{n} \geq 0$ for any $n$ : if $\beta_{n}<0$ then (4.20) holds with $\left|\beta_{n}\right|$ replacing $\beta_{n}$. To get (4.24) we will use the representation:

$$
\begin{equation*}
\sum_{i=0}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)=\sum_{i=0}^{m} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)+\sum_{i=m+1}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right) \tag{4.25}
\end{equation*}
$$

Here $m$ is an arbitrary integer less than $n$. The first term in the right-hand side of (4.25) can be estimated as follows

$$
\begin{align*}
& \sum_{i=0}^{m} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)=\sum_{i=0}^{m} \frac{\beta_{i}}{\alpha_{i}}\left[\prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)-\prod_{j=i}^{n}\left(1-\alpha_{j}\right)\right] \\
& \quad \leq \zeta\left[\prod_{j=m+1}^{n}\left(1-\alpha_{j}\right)-\prod_{j=0}^{n}\left(1-\alpha_{j}\right)\right] \leq \zeta \exp \left(-\sum_{j=m+1}^{n} \alpha_{j}\right) \tag{4.26}
\end{align*}
$$

where $\frac{\beta_{i}}{\alpha_{i}} \leq \zeta, i=0,1,2, \ldots$. Introduce the notation $\varrho_{m, n}:=\max _{m+1 \leq i \leq n-1} \frac{\beta_{i}}{\alpha_{i}}$. For the second term in (4.25) one obtains

$$
\begin{gather*}
\sum_{i=m+1}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right) \leq \varrho_{m, n} \sum_{i=m+1}^{n-1}\left[\prod_{j=i+1}^{n}\left(1-\alpha_{j}\right)-\prod_{j=i}^{n}\left(1-\alpha_{j}\right)\right] \\
=\varrho_{m, n}\left[1-\alpha_{n}-\prod_{j=m+1}^{n}\left(1-\alpha_{j}\right)\right] \leq \varrho_{m, n} \tag{4.27}
\end{gather*}
$$

Therefore

$$
\begin{align*}
& \lim _{n \rightarrow \infty} \sum_{i=0}^{n-1} \beta_{i} \prod_{j=i+1}^{n}\left(1-\alpha_{j}\right) \leq \limsup _{m \rightarrow \infty}\left\{\lim _{n \rightarrow \infty}\left[\zeta \exp \left(-\sum_{j=\tilde{n}+1}^{n} \alpha_{j}\right)+\varrho_{m, n}\right]\right\} \\
& 28) \quad \leq \limsup _{m \rightarrow \infty}\left(0+\sup _{m+1 \leq n} \frac{\beta_{n}}{\alpha_{n}}\right)=\limsup _{n \rightarrow \infty} \frac{\beta_{n}}{\alpha_{n}}=0 \tag{4.28}
\end{align*}
$$

The last conclusion is a consequence of the last assumption in (4.21). From (4.28), (4.24) and (4.23) one concludes that (4.22) holds.

Finally we present the convergence theorem.
Theorem 4.5. Assume that conditions of Theorem 4.2 hold. Let

1. $\delta$ be the level of noise in (4.8): $\left\|f-f_{\delta}\right\| \leq \delta$;
2. $n=n(\delta)$ be chosen in such a way that $\lim _{\delta \rightarrow 0} n(\delta)=\infty$;
3. $h_{n(\delta)}$ tend to zero monotonically as $\delta \rightarrow 0,0<h_{n(\delta)} \varepsilon_{n(\delta)}-c h_{n(\delta)}^{2} \leq 1$ with $c$ defined by (4.19);
4. $\sum_{n=1}^{\infty} h_{n} \varepsilon_{n}=\infty, \quad \lim _{\delta \rightarrow 0} \frac{h_{n(\delta)}}{\varepsilon_{n}(\delta)}=0, \quad \lim _{\delta \rightarrow 0} \frac{\delta}{\varepsilon_{n(\delta)}}=0$.

Then

$$
\begin{equation*}
\lim _{\delta \rightarrow 0}\left\|p_{n(\delta)}-y\right\|=0 \tag{4.29}
\end{equation*}
$$

in the norm of a Hilbert space $H$, where $\left\{p_{n(\delta)}\right\}$ is defined by (4.8)-(4.9) and $y$ is the solution to (4.2).

Proof. Let us take $\nu_{n}:=\left\|z_{n}-p_{n}\right\|^{2}, \alpha_{n}:=h_{n} \varepsilon_{n}-c h_{n}^{2}$ and $\beta_{n}:=d \frac{h_{n}\left(\delta+h_{n}\right)^{2}}{\varepsilon_{n}}$. Inequality (4.29) is an immediate consequence of (4.18) and Lemma 4.4.

Thus it is shown that under the assumptions of Theorem 4.5 procedure (4.8)(4.9) can be used for stable numerical differentiation of a function from the class $\mathcal{G}(\delta)$, which is defined in (4.11).

## 5. Numerical aspects

5.1. Multi-point formulas in the class $\mathcal{K}\left(\delta, M_{m}\right), m>2$. MATLAB programs were written to investigate the practicability of the methods described above. The derivative of the function $f(x)=\sin (\pi x), x \in[0,1]$, was computed in the presence of noise functions

$$
\begin{equation*}
e_{1}(x)=\delta x, \quad e_{2}(x)=\delta \cos (3 \pi x), \quad e_{3}(x)=\delta \cos (7 \pi x) \tag{5.1}
\end{equation*}
$$

and their combinations. The constant $\delta$ in (5.1) changes from 0.01 to 0.1 .
Our first experiment makes use of formulas (3.1), (3.6) with the numbers $A_{j}^{Q}$ $(j=-Q, \ldots, Q)$ defined by (3.4) and $m=2 Q+1$. The goals of the test are the following ones:

1. To compare numerical results obtained by (3.1), (3.6) with $Q=1,2,3,4$; to consider the dependence of estimated error (3.7) and of the computed error on $Q$ (on $m$ ). Note that $Q=1,2,3,4$ correspond to $m=3,5,7,9$ respectively.
2. To evaluate the dependence of the computed and estimated errors on the perturbations of $M_{m}$ (see (3.5)-(3.7)), since in practice only the approximate bounds on $L^{\infty}$-norm of $f^{(m)}$ might be available.
3. To study the dependence of the results on $\delta$, because the optimal stepsize $h_{m}(\delta)$ and the estimated error $\varepsilon_{m}(\delta)$ are the functions of $\delta$.
Figures 1 and 2 represent the errors obtained in the process of numerical differentiation by formula (3.1) with $Q=1$ and $h=h_{3}(\delta)$ being chosen by (3.6). The function to be differentiated is $f_{\delta}(x)=f(x)+e_{3}(x)$. The upper surface on Figure 2 is the estimated error. Note that $f(x)=\sin (\pi x)$ belongs to the class $\mathcal{K}\left(\delta, M_{3}\right)$ for $M_{3} \geq \pi^{3} \approx 31.0063$. So if one uses $20 \leq M_{3}<\pi^{3}$, then $h_{3}(\delta)$ found by (3.6) is not optimal and cannot guarantee error (3.7). Therefore the computed error in some regions, where $20 \leq M_{3}<\pi^{3}$, is greater then the estimated one.

Figures 3 and 4 illustrate the same experiment with $Q=2$. There is a little gain in accuracy for both estimated and computed errors. The optimal stepsize $h_{5}(\delta)$ is approximately three times as big as $h_{3}(\delta)$.

One can see on Figures 5-8 that for $Q=3(m=7)$ and $Q=4(m=9)$ the results are not accurate. The reason is that the constant $\beta_{m}$ (see (3.5)), which does not depend on $f$, decreases very fast as $m=2 Q+1$ changes from 5 to 9 :

$$
\beta_{5} \approx 3.47 \cdot 10^{-3}, \quad \beta_{7} \approx 3.07 \cdot 10^{-5}, \quad \beta_{9} \approx 1.50 \cdot 10^{-7}
$$

Since $\beta_{m}$ appears in the denominator of (3.6), one has to take $M_{m}$ large, otherwise $h_{m}(\delta)$ becomes so big that it cannot be used on the interval $[0,1]$. Namely, for $M_{7}=\pi^{7}, M_{9}=\pi^{9}$ and $\delta=0.01$ one gets

$$
h_{7} \approx 0.7185, \quad h_{9} \approx 1.0985
$$

For the same $M_{7}, M_{9}$ and $\delta=0.1$

$$
h_{7} \approx 0.9986, \quad h_{9} \approx 1.4188
$$

The ratio $\frac{\alpha_{m}}{m-1}$ (see (3.6)) also grows as $m$ increases:

$$
\frac{\alpha_{5}}{4} \approx 0.75, \quad \frac{\alpha_{7}}{6} \approx 0.92, \quad \frac{\alpha_{9}}{8} \approx 1.042
$$

Thus to obtain $h_{7}(\delta)$ and $h_{9}(\delta)$ approximately at the same level as $h_{3}(\delta)$ for $20 \leq$ $M_{3} \leq 40$ one needs $M_{7} \sim 10^{8}$ and $M_{9} \sim 10^{10}$. The estimated errors $\varepsilon_{7}(\delta), \varepsilon_{9}(\delta)$ for these $M_{7}$ and $M_{9}$ are much greater then $\varepsilon_{3}(\delta)$ : one can compare the upper surfaces on Figures 6, 8 and 2. The computed errors are less then the estimated ones, but even they are almost $100 \%$ for $\delta=0.1$. Figures 5 and 7 show the errors for $f_{\delta}(x)=f(x)+e_{2}(x)$. On Figures 6 and 8 the lower surfaces correspond to $f_{\delta}(x)=f(x)+e_{2}(x)$ and $f_{\delta}(x)=f(x)+e_{2}(x)+e_{3}(x)$.

The conclusion is: practically one does not have a good reason to use formulas (3.1), (3.6) for $m>5$ in many cases. Besides even for $m=5$ sometimes the best possible constant $M_{5}$ is rather small and together with small $\beta_{5}$ they make $h_{5}(\delta)$ larger then it is appropriate on a specific interval. Therefore one has to increase the constant $M_{5}$, which in turn increases $\varepsilon_{5}(\delta)$ in (3.7). Then one can compare $\varepsilon_{5}(\delta)$ with $\varepsilon_{3}(\delta)$ and make a choice between (3.1), (3.6) for $m=3$ and (3.1), (3.6) for $m=5$.
5.2. Multi-point formulas in the class $\mathcal{K}\left(\delta, M_{2}\right)$. In our second experiment we investigate multi-point differentiator (3.20) with $h$ satisfying (3.32). Here we use the statistical nature of noise assuming zero mean value and varance $\sigma^{2}$. The perturbated function $f_{\sigma}(x)=\sin (\pi x)+\sqrt{2} \sigma \cos (2 \pi x), x \in[0,1]$, is to be differentiated. The goal is to consider the dependence of the computed and estimated errors on $Q, M_{2}$ and $\sigma$.

Figures 9 and 10 illustrate the results obtained with $Q=1$. The function $f(x)=\sin (\pi x)$ belongs to the class $\mathcal{K}\left(\sigma, M_{2}\right)$ for $M_{2} \geq \pi^{2} \approx 9.8696$. That is the reason why the computed errors on Figures 10, 12, 14 and 16 are greater then the estimated ones in some areas, where $0.1 \leq M_{2}<\pi^{2}$.

Figures 11 and 12 correspond to the case $Q=7$. One can see that both the estimated and the computed errors are less then for $Q=1$.

Theoretically by formula (3.34) one can attain an arbitrary accuracy of the approximation by taking $Q$ sufficiently large. However in practice we do not recommend using $Q>50$. Indeed, denote $\mu(Q):=\sqrt{2 \sigma M_{2}}\left(a_{Q} b_{Q}\right)^{\frac{1}{4}}$, where $a_{Q}$ and $b_{Q}$ satisfy (3.30) and (3.31) respectively. Then for $\sigma=0.1, M_{2}=20$ one has:

$$
\mu(50) \approx 0.50843, \quad \mu(75) \approx 0.45981, \quad \mu(100) \approx 0.42808, \quad \mu(150) \approx 0.38698
$$

Thus the accuracy decreases slowly as $Q$ grows. The estimated errors for $Q=75$ (see Figure 13) and $Q=150$ (see Figure 15) are almost identical because of the roundoff error. For $Q=200$ the estimated error is even bigger then the one for $Q=150$.
5.3. Numerical solution of regularized Volterra equation. Our last numerical experiment on reconstruction of the derivative is based on Euler's method (4.8)(4.9) for solving Cauchy problem (4.3)-(4.4). The operator $A$ in (4.4) is defined by (4.7) with $a=0$ and $b=1$. We assume that the function to be differentiated is

$$
f_{\delta}(x)=\sin (\pi x)+\delta \cos (3 \pi x)
$$

As in the previous subsections we take $\delta \in[0.01,0.1]$, which corresponds to the level of noise $1 \%-10 \%$ of the maximum value of $f(x)=\sin (\pi x)$. The choice of the parameters $h_{n}$ and $\varepsilon_{n}$ in (4.8)-(4.4) is dictated by condition 4 of Theorem 4.2 and by condition 4 of Theorem 4.5. Therefore we use

$$
h_{n}=h_{0}(n+1)^{-0.5}, \quad \varepsilon_{n}=\varepsilon_{0}(n+1)^{-0.4}
$$

Figures 17-20 contain the exact derivative $f^{\prime}(x)=\pi \cos (\pi x)$ and the derivatives computed by (4.8)-(4.9) with $\delta=0.01,0.05$ and 0.1 . The argument $x$ changes from 0 to 1 along the horizontal axis, eps $s_{n}$ on Figures $17-20$ denotes $\varepsilon_{n}$. The results in these figures correspond to the initial guess $p_{0}=0$, the number of iterations $N=10$ and $h_{0}=100$. Actually any $h_{0} \in[0.5,100]$ provides convergence for $\delta \in[0.01,0.1]$, the difference is in its rate. If $h_{0}=100$ and $\delta=0.01$ then the discrepancy after 10 iterations is $\sim 10^{-17}$. As one can see from Figures 17 and 18 for the levels of noise $1 \%$ and $5 \%$ the computed derivatives are found with $\varepsilon_{0}=0$. The use of $\varepsilon_{0} \neq 0$ does not give any gain in accuracy here. The reason for such a phenomenon is probably the self-regularization of Volterra equations in the process of their discrete approximation. This means that Volterra integral equations allow one to generate stable numerical methods by application of quadrature formula directly to the initial equation and the following theorem holds.

Theorem 5.1. ([29]) Let

$$
\begin{equation*}
\int_{a}^{x} K(x, s) z(s) d s=f_{\delta}(x), \quad\left\|f_{\delta}-f\right\|_{C[a, b]} \leq \delta, \quad a \leq x \leq b \tag{5.2}
\end{equation*}
$$

and assume

1. $\min _{a \leq x \leq b}|K(x, x)|>0, \quad K_{x}^{\prime}(x, s) \in C(\Delta), \quad K_{x s}^{\prime \prime}(x, s) \in C(\Delta)$, where

$$
\Delta:=\{x, s: a \leq s \leq x \leq b\}
$$

2. $f(x) \in C^{(1)}[a, b], \quad f_{\delta}(x) \in C[a, b], \quad f(a)=f_{\delta}(a)=0$.

Then

$$
\begin{equation*}
\max _{1 \leq i \leq k}\left|\hat{y}\left(x_{i}\right)-\tilde{y}_{i}\right| \leq c_{1} \tau+c_{2} \frac{\delta}{\tau} \tag{5.3}
\end{equation*}
$$

Here $\hat{y}(x)$ is the unique solution to (5.2); $\tilde{y}=\left(\tilde{y}_{1}, \tilde{y}_{2}, \ldots, \tilde{y}_{k}\right)$ is a unique solution to the linear system

$$
\begin{equation*}
\tau \sum_{j=1}^{i} K\left(x_{i}, x_{j}\right) z\left(x_{j}\right)=f_{\delta}\left(x_{i}\right), \quad i=1,2, \ldots, k \tag{5.4}
\end{equation*}
$$

$x_{i}=a+i \tau, \quad \tau=\frac{b-a}{k} ;$ the constants $c_{1}, c_{2}$ do not depend on $\tau$ and $\delta$.
The right-hand side of (5.3) tends to 0 as $\delta \rightarrow 0$ if $h(\delta)=c \delta^{\gamma}, 0<\gamma<1$. Note that in our case the functions $f(x)$ and $f_{\delta}(x)$ satisfy condition 2 of Theorem 5.1. The fact that the assumption $f(a)=f_{\delta}(a)=0$ is natural is briefly explained below formula (4.1).

For $\delta=0.1$ the result obtained with $\varepsilon_{0}=0$ is worse then the result obtained with $\varepsilon_{0} \in\left[10^{-3}, 10^{-2}\right]$. One can compare Figures 19 and 20 . The main difficulty occurs in the neighborhood of 0 , and $\varepsilon_{0} \in\left[10^{-3}, 10^{-2}\right]$ helps to get better approximation.

Scheme (4.8)-(4.9) can be realized without knowledge (and even existence) of the constants $M_{m}$, since the regularization parameter $\varepsilon_{n}$ is the function of $\delta$ only. This is an advantage of the approach based on (4.8)-(4.9). However this approach does not give the explicitly computable estimation constants. Such estimates can be found under the additional assumptions on $p_{0}$ (see [1]).
