## INTRODUCTION

Figure 1 is a picture of the standard Mandelbrot set M . The article [M] by Benoit Mandelbrot, containing the first pictures and analyses of this set aroused great interest.
The set $\mathbf{M}$ is defined as follows. Let $\mathrm{P}_{c}: z \mapsto z^{2}+c$ and for each $c$ let $\mathrm{K}_{c}$ be the set of $z \in \mathbb{C}$ such that the sequence $z, \mathrm{P}_{c}(z), \mathrm{P}_{c}\left(P_{c}(z)\right), \ldots$ is bounded. A classical Theorem of Fatou [F] and Julia [J] asserts that $\mathrm{K}_{c}$ is connected if $0 \in \mathrm{~K}_{c}$ and a Cantor set otherwise ( 0 plays a distinguished role because it is the critical point of $\mathrm{P}_{c}$ ). More recent introductions to the subject are $[\mathrm{Br}]$ and $[\mathrm{Bl}]$, where this Theorem in particular is proved. The set $M$ is the set of $c$ for which $K_{c}$ is connected.

In addition to the main component and the components which derive from it by successive bifurcations, M consists of a mass of filaments (see Figs. 2 and 3) loaded with small droplets, which ressemble $\mathbf{M}$ itself. The combinatorial description of these filaments is complicated; it is sketched in $[\mathrm{D}-\mathrm{H}]$ and will be the object of a later publication.

Figure 4 concerns an apparently unrelated problem. Let $f_{\lambda}$ be the polynomial $(z-1)(z+1 / 2+\lambda)(z+1 / 2-\lambda)$, which we will attempt to solve by Newton's method, starting at $z_{0}=0$ and setting

$$
z_{n+1}=\mathrm{N}_{\lambda}\left(z_{n}\right)=z_{n}-f_{\lambda}\left(z_{n}\right) / f_{\lambda}^{\prime}\left(z_{n}\right)
$$

As we shall see, 0 is the worst possible initial guess. Color $\lambda$ blue if $z_{n} \rightarrow 1$, red if $z_{n} \rightarrow-1 / 2+\lambda$ and green if $z_{n} \rightarrow-1 / 2-\lambda$; leave $\lambda$ white if the sequence $z_{n}$ does not converge to any of the roots. Figure 4 represents a small region in the $\lambda$-plane; a sequence of zooms leading to this picture is given in chapter VI. This family has been studied independantly by Curry, Garnett and Sullivan [C-G-S] who also obtained similar figures.

If two cubic polynomials have roots which form similar triangles, the affine map sending the roots of one to the roots of the other conjugates their Newton's methods. Up to this equivalence, the family $f_{\lambda}$ contains all cubic polynomials with marked roots except $z^{3}$ and $z^{3}-z^{2}$ with 0 as first marked root. The point $z_{0}=0$ is a point of inflexion of $f_{\lambda}$ and hence a critical point of the Newton's method; it is the only critical point besides the roots.

Fig. 6

ANNALES SCIENTIFIQUES DE L'ÉCOLE NORMALE SUPÉRIEURE

If there is an attractive periodic cycle of the Newton's method other than the roots of $f$, by a Theorem of Fatou it attracts a critical point, which is necessarily 0 ; in that sense $z_{0}=0$ is the worst possible initial choice.

The white region in Figure 4 looks remarkably like M. Figures 5 and 6 show that the ressemblance extends to the finest detail. Here the coloring corresponds to speed of convergence to the roots.

We interpret this fact as follows. For a certain value $\lambda_{0}$ of $\lambda$, at the "center" of the white region, the sequence $z_{n}$ is periodic of some period $k$ (in this case 3 ) for Newton's method. Since 0 is critical for Newton's method, the periodic cycle containing 0 is superattractive, and on a neighborhood of 0 the function $N_{\lambda}^{k}$ will behave like $z \mapsto z^{2}$. If V is a small neighborhood of 0 , then $\mathrm{N}_{\lambda_{0}}^{k}(\mathrm{~V}) \subset \mathrm{V}$, but for a slightly larger neighborhood U we will have $\mathrm{N}_{\lambda_{0}}^{k}(\mathrm{U}) \supset \mathrm{U}$. For $\lambda$ close to $\lambda_{0}$ we will still have $\mathrm{N}_{\lambda}^{k}(\mathrm{U}) \supset \mathrm{U}$ but now $\mathrm{N}_{\lambda}^{k}$ will behave on U like some polynomial $z \mapsto z^{2}+c$ for some $c=\chi(\lambda)$.

Figure 8 represents basins of attraction of the roots for the polynomial $f_{\lambda}$, $\lambda=-.0100605+i .220311$ (that value of $\lambda$ is indicated with a cross on Figure 6). The shading corresponds to speed of attaction by the appropriate root; the black region is not attracted by any root. Figure 7 is a picture of $\mathrm{K}_{c}$ for $c=-.714203+i .245052$ (again indicated with a cross on Figure 3). The reader will agree that the words "behave like", although still undefined, are not excessive.

If $\chi(\lambda) \in \mathrm{M}$, then $z_{n} \in \mathrm{~V}$ for all $n$ and the sequence cannot converge to one of the roots. The remarkable fact is that $\chi$ induces a homeomorphism of $\chi^{-1}(\mathrm{M})$ onto M .

The above phenomenon is very general. If $f_{\lambda}$ is any family of analytic functions depending analytically on $\lambda$, then an attempt to classify values of $\lambda$ according to the dynamical properties of $f_{\lambda}$ will often produce copies of $\mathbf{M}$ in the $\lambda$-plane.

The object of this paper is to explain this phenomenon, by giving a precise meaning to the words "behave like", which appear in the heuristic description above. The notion of polynomial-like mapping was invented for this purpose. It was motivated by the observation that when studying iteration of polynomials, one uses the theory of analytic functions continually, but the rigidity of polynomials only rarely.

In the real case, something analoguous happens. Many results extend from quadratic polynomials to convex functions with negative Schwarzian curvature. But there is a major difference: in the real case, one is mainly interested in functions which send an interval into itself. An analytic function which sends a disc into itself is always contracting for the Poincare metric, and there is not much to say.

In the complex case, the appropriate objects of study are maps $f: \mathrm{U} \rightarrow \mathbb{C}$ where $\mathrm{U} \subset \mathbb{C}$ is a simply connected bounded domain. $f$ extends to the boundary of U and sends $\partial \mathrm{U}$ into a curve which turns several times around U , staying outside $\overline{\mathrm{U}}$. Our definition is slightly different from the above, mainly for convenience.

Many dynamic properties of polynomials extend to the framework of polynomial-like mappings. In fact, you can often simply copy the proof in the new setting. For the two following statements, however, that procedure does not go through.

$$

$$

Fig. 7

Fig. 8
ANNALES SCIENTIFIQUES DE L'ÉCOLE NORMALE SUPÉRIEURE
(a) The density of periodic points in $\mathrm{J}_{f}=\partial \mathrm{K}_{f}$, proved by Fatou for polynomials (and rational mappings) using Picard's theorem.
(b) The eventual periodicity of components of $\stackrel{\circ}{\mathrm{K}}_{f}$, proved by Sullivan [S1] using the fact that a polynomial (or a rational function) depends only on a finite number of parameters.

The Straightening Theorem $(\mathbf{1}, 1)$ allows one to deduce various properties of polynomiallike mappings from the analogous properties of polynomials. In particular, this applies to statements ( $a$ ) and (b) above.

Its proof relies on the "measurable Riemann mapping Theorem" of Morrey-AhlforsBers ([A-B], [L], [A]). A review of this Theorem, as well as a dictionary between the languages of Beltrami forms and of complex structures, will be given in $(1,3)$.

Chapter I is centered on the Straightening Theorem.
Chapters II to IV are devoted to the introduction of parameters in the situation.
Chapters V and VI give two applications. Chapter V explains the appearance of small copies of M in M . The computation is similar to one made by Eckmann and Epstein [E-E] in the real case. They were able, using our characterization of Mandelbrot-like families, to get results similar to those in chapter V in the complex case also.

Chapter VI is a study of Figure 4.
This work owes a great deal to the ideas of D. Sullivan, who initiated the use of quasiconformal mappings in the study of rational functions. It fits in with Sullivan's papers ([S1], [S2]), and the article by Mañe, Sad and Sullivan [M-S-S].

We thank Pierrette Sentenac for her help with the inequalities, particularly those in IV, 5 and V, 3 .

We also thank Homer Smith. He wrote the programs which drew the pictures in the article, and also provided expert photographic assistance.

A preliminary version of this article appeared in French as a preprint in RCP25, I.R.M.A., Strasbourg.

## CHAPTER I

## Polynomial-like mappings

1. Definitions and statement of the straightening theorem. - Let $\mathrm{P}: \mathbb{C} \rightarrow \mathbb{C}$ be a polynomial of degree $d$ and let $U=D_{R}$ be the disc of radius $R$. If $R$ is large enough then $\mathrm{U}^{\prime}=\mathrm{P}^{-1}(\mathrm{U})$ is relatively compact in U and homeomorphic to a disc, and $\mathrm{P}: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ is analytic, proper of degree $d$.

The object above will be our model.
Definition. - A polynomial-like map of degree $d$ is a triple $\left(\mathrm{U}, \mathrm{U}^{\prime}, f\right)$ where U and $\mathrm{U}^{\prime}$ are open subsets of $\mathbb{C}$ isomorphic to discs, with $\mathrm{U}^{\prime}$ relatively compact in U , and $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ $a \mathbb{C}$-analytic mapping, proper of degree $d$.

We will only be interested in the case $d \geqq 2$.

$$
4^{e} \text { SÉRIE }- \text { TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

Examples. - (1) The model above. When we refer to a polynomial $f$ as a polynomiallike mapping, a choice of U and $\mathrm{U}^{\prime}$ such that $\mathrm{U}^{\prime}=f^{-1}(\mathrm{U})$ and that $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ is polynomial-like will be understood.
(2) Let $f(z)=\cos (z)-2$ and let $\mathrm{U}^{\prime}=\left\{z| | \operatorname{Re}(z)|<2,|\operatorname{Im}(z)|<3\}\right.$. Then $\mathrm{U}=f\left(\mathrm{U}^{\prime}\right)$ is the region represented in Figure 9, and $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ is polynomial-like of degree 2.

Fig. 9
(3) Let P be a polynomial of degree $d$ and let U be open in $\mathbb{C}$, such that $\mathrm{P}^{-1}(\mathrm{U})$ has several connected components $\mathrm{U}_{1}^{\prime}, \mathrm{U}_{2}^{\prime}, \ldots, \mathrm{U}_{k}^{\prime}$ with $k \leqq d$. If $\mathrm{U}_{1}^{\prime}$ is contained and relatively compact in U , then the restriction of P to $\mathrm{U}_{1}^{\prime}$ is polynomial-like of some degree $d_{1}<d$.
In this situation, one often gets much better information about the behaviour of P in $U_{1}^{\prime}$ by considering it as a polynomial-like map of degree $d_{1}$ than as a polynomial of degree $d$, especially when $d=128$ and $d_{1}=2$ as will occur in chapter V .
(4) A small analytic perturbation of a polynomial-like mapping of degree $d$ is still polynomial-like of degree $d$. More precisely, let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ be polynomial-like of degree d. Then $f$ has $d-1$ critical points $\omega_{1}, \ldots, \omega_{d-1}$, counting with multiplicities. Choose $\varepsilon>0, \varepsilon<d\left(\mathrm{U}^{\prime}, \mathbb{C}-\mathrm{U}\right)$ and let $\mathrm{U}_{1}$ be the component of $\{z \mid d(z, \mathbb{C}-\mathrm{U})>\varepsilon\}$ containing $\mathrm{U}^{\prime}$. Suppose that $\varepsilon$ is so small that $\mathrm{U}_{1}$ contains the $f\left(\omega_{i}\right)$. Then if $g: \mathrm{U}^{\prime} \rightarrow \mathbb{C}$ is an analytic function such that $|g(z)-f(z)|<\varepsilon$ for all $z \in \mathrm{U}^{\prime}$, the set $\mathrm{U}_{1}^{\prime}=g^{-1}\left(\mathrm{U}_{1}\right)$ is homeomorphic to a disc and $g: \mathrm{U}_{\mathbf{1}}^{\prime} \rightarrow \mathrm{U}_{1}$ is polynomial-like of degree $d$.
If $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ is a polynomial-like mapping of degree $d$, we will note

$$
\mathrm{K}_{f}=\underset{n \geqq 0}{\cap} f^{-n}\left(\mathrm{U}^{\prime}\right),
$$

the set of $z \in \mathrm{U}^{\prime}$ such that $f^{n}(z)$ is defined and belongs to $\mathrm{U}^{\prime}$ for all $n \in \mathbb{N}$. The set $\mathrm{K}_{f}$ is a compact subset of $\mathbf{U}^{\prime}$, which we will call the filled-in Julia set of $f$. The Julia set $\mathbf{J}_{f}$ of
$f$ is the boundary of $\mathrm{K}_{f}$. As a dynamical system, $f$ is mainly interesting near $\mathrm{K}_{f}$; we will neglect what occurs near the boundary of $\mathrm{U}^{\prime}$.

The following statements are standard for polynomials; they are also valid for polyno-mial-like mappings. The proofs are simply copies of the classical proofs.

Proposition 1. - Every attractive cycle has at least one critical point in its immediate basin.

Proposition 2. - The set $\mathbf{K}_{f}$ is connected if and only if all the critical points of $f$ belong to $\mathrm{K}_{f}$. If none of the critical points belong to $\mathrm{K}_{f}$ then $\mathrm{K}_{f}$ is a Cantor set.

Proposition 3 and definition. - The following conditions are equivalent:
(i) Every critical point of $f$ belonging to $\mathrm{K}_{f}$ is attracted by an attractive cycle.
(ii) There exists a continuous Riemannian metric on a neigborhood of $\mathrm{J}_{f}$ and $\lambda>1$ such that for any $x \in \mathrm{~J}_{f}$ and any tangent vector $t$ at $x$ we have

$$
\left\|d_{x} f(t)\right\|_{f(x)} \geqq \lambda\|t\|_{x}
$$

If the above conditions are satisfied, fis said to be hyperbolic.
Sometimes proofs in the setting of polynomial-like mappings give slightly better results.
For instance, by Proposition 1 a polynomial-like mapping of degree $d$ has at most $d-1$ attractive cycles. One can deduce from this that if a polynomial has $n$ attractive periodic cycles and $m$ indifferent ones, then $n+m / 2 \leqq d-1$, by perturbing P so as to make half the indifferent points attractive. That is as well as one can do if the perturbation is constrained to be among polynomials of degree $d$.

However, if one is allowed to perturb among polynomial-like maps of degree $d$, it is easy to make all the indifferent points attractive, and to see that $n+m \leqq d-1$.

Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ and $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ be polynomial-like mappings. We will say that $f$ and $g$ are topologically equivalent (denoted $f \sim_{\text {top }} g$ ) if there is a homeomorphism $\varphi$ from a neighborhood of $\mathrm{K}_{f}$ onto a neighborhood of $\mathrm{K}_{g}$ such that $\varphi \circ f=g \circ \varphi$ near $\mathrm{K}_{f}$. If $\varphi$ is quasi-conformal (resp. holomorphic) we will say that $f$ and $g$ are quasi-conformally (resp. holomorphically) equivalent (denoted $f \sim_{q c} g$ and $f \sim_{\text {hol }} g$ ). We will say that $f$ and $g$ are hybrid equivalent (noted $f \sim_{h b} g$ ) if they are quasi-conformally equivalent, and $\varphi$ can be chosen so that $\bar{\partial} \varphi=0$ on $\mathbf{K}_{\boldsymbol{f}}$.

We see that

$$
f \sim_{\text {hol }} g \Rightarrow f \sim_{h b} g \Rightarrow f \sim_{q c} g \Rightarrow f \sim_{\text {top }} g .
$$

If $J_{f}$ is of measure 0 (no example is known for which this does not hold) the condition $\bar{\partial} \varphi=0$ on $\mathrm{K}_{f}$ just means that $\varphi$ is analytic on the interior of $\mathrm{K}_{f}$.

Theorem 1 (the Straightening Theorem). - (a) Every polynomial-like mapping $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ of degree $d$ is hybrid equivalent to a polynomial P of degree $d$.
(b) If $\mathrm{K}_{f}$ is connected, P is unique up to conjugation by an affine map.

Part (a) follows from Propositions 4 and 5 below and part (b) is Corollary 2 of Proposition 6.

$$
4^{e} \text { Série - TOME } 18-1985-\mathrm{N}^{0} 2
$$

2. External equivalence. - Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ and $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ be two polynomial-like mappings, with $\mathrm{K}_{f}$ and $\mathrm{K}_{g}$ connected. Then $f$ and $g$ are externally equivalent (noted $\left.f \sim_{\text {ext }} g\right)$ if there exist connected open sets $U_{1}, U_{1}^{\prime}, V_{1}, V_{1}^{\prime}$ such that

$$
\begin{gathered}
\mathrm{K}_{f} \subset \mathrm{U}_{1}^{\prime} \subset \mathrm{U}_{1} \subset \mathrm{U}, \\
\mathrm{~K}_{g} \subset \mathrm{~V}_{1}^{\prime} \subset \mathrm{V}_{1} \subset \mathrm{~V}, \\
f^{-1}\left(\mathrm{U}_{1}\right)=\mathrm{U}_{1}^{\prime}, \quad g^{-1}\left(\mathrm{~V}_{1}\right)=\mathrm{V}_{1}^{\prime}
\end{gathered}
$$

and a complex-analytic isomorphism

$$
\varphi: \quad \mathrm{U}_{1}-\mathrm{K}_{f} \rightarrow \mathrm{~V}_{1}-\mathrm{K}_{g},
$$

such that $\varphi \circ f=g \circ \varphi$.
We will associate to any polynomial-like map $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ of degree $d$ a real analytic expanding map $h_{f}: \mathrm{S}^{1} \rightarrow \mathrm{~S}^{1}$ also of degree $d$, unique up to conjugation by a rotation. We will call $h_{f}$ the external map of $f$.

The construction is simpler if $\mathbf{K}_{f}$ is connected; we will do it in that case first.
Let $\alpha$ be an isomorphism of $\mathrm{U}-\mathrm{K}_{f}$ onto $\mathrm{W}_{+}=\{z|1<|z|<\mathrm{R}\}(\log \mathrm{R}$ is the modulus of $\left.\mathrm{U}-\mathrm{K}_{f}\right)$ such that $|\alpha(z)| \rightarrow \mathbf{1}$ when $d\left(z, \mathrm{~K}_{f}\right) \rightarrow 0$. Set $\mathrm{W}_{+}^{\prime}=\alpha\left(\mathrm{U}^{\prime}-\mathrm{K}_{f}\right)$ and $h_{+}=\alpha \circ f \circ \alpha^{-1}: \mathrm{W}_{+}^{\prime} \rightarrow \mathrm{W}_{+}$. Let $\tau: z \mapsto 1 / \bar{z}$ be the reflection with respect to the unit circle, and set $W_{-}=\tau\left(W_{+}\right), \quad W_{-}^{\prime}=\tau\left(W_{+}^{\prime}\right), \quad W=W_{+} \cup W_{-} \cup S^{1} \quad$ and $W^{\prime}=W_{+}^{\prime} \cup W^{\prime} \cup S^{1}$.

By the Schwarz reflection principle $[\mathrm{R}], h_{+}$extends to an analytic map $h: \mathrm{W}^{\prime} \rightarrow \mathrm{W}$; the restriction of $h$ to $\mathbf{S}^{1}$ is $h_{f}$. The mapping is strongly expanding. Indeed, $\tilde{h}: \tilde{\mathbb{W}}^{\prime} \rightarrow \tilde{\mathbb{W}}$ is an isomorphism, and $\tilde{h}^{-1}: \tilde{\mathrm{W}} \rightarrow \tilde{\mathrm{W}}^{\prime} \subset \tilde{\mathrm{W}}$ is strongly contracting for the Poincare metric on $\tilde{\mathrm{W}}$. This metric restricts to a metric of the form $a|d z|$ with $a$ constant on $\mathrm{S}^{1}$.

In the general case ( $\mathrm{K}_{f}$ not necessarily connected), we begin by constructing a Riemann surface T , an open subset $\mathrm{T}^{\prime}$ of T and an analytic map $\mathrm{F}: \mathrm{T}^{\prime} \rightarrow \mathrm{T}$ as follows.

Let $\mathrm{L} \subset \mathrm{U}^{\prime}$ be a compact connected subset containing $f^{-1}\left(\overline{\mathrm{U}}^{\prime}\right)$ and the critical points of $f$, and such that $\mathrm{X}_{0}=\mathrm{U}-\mathrm{L}$ is connected. Let $\mathrm{X}_{n}$ be a covering space of $\mathrm{X}_{0}$ of degree $d^{n}, \rho_{n}: \mathrm{X}_{n+1} \rightarrow \mathrm{X}_{n}$ and $\pi_{n}: \mathrm{X}_{n} \rightarrow \mathrm{X}_{0}$ be the projections and let X be the disjoint union of the $\mathrm{X}_{n}$. For each $n$ choose a lifting

$$
f_{n}: \quad \pi_{n}^{-1}\left(U^{\prime}-L\right) \rightarrow X_{n+1}
$$

of $f$. Then T is the quotient of X by the equivalence relation identifying $x$ to $f_{n}(x)$ for all $x \in\left(\mathrm{U}^{\prime}-\mathrm{L}\right)$ and all $n=0,1, \ldots$ The open set $\mathrm{T}^{\prime}$ is the union of the images of the $\mathrm{X}_{n}, n=1,2, \ldots$, and $\mathrm{F}: \mathrm{T}^{\prime} \rightarrow \mathrm{T}$ is induced by the $\rho_{n}$.

If $\mathrm{K}_{f}$ is connected, we have just painfuly reconstructed $\mathrm{U}-\mathrm{K}_{f}$ and $f: \mathrm{U}^{\prime}-\mathrm{K}_{f} \rightarrow \mathrm{U}-\mathrm{K}_{f}$. In all cases, T is a Riemann surface isomorphic to an annulus of finite modulus, say $\log \mathrm{R}$. We can choose an isomorphism $\alpha: T \rightarrow W=\{z|1<|z|<\mathrm{R}\}$ and continue the construction as above, to construct an expanding map $h_{f}: \mathrm{S}^{1} \rightarrow \mathrm{~S}^{1}$.

If L is chosen differently, neither $\mathrm{T}, \mathrm{T}^{\prime}$ or F are changed.

Let $f_{1}: \mathrm{U}_{1}^{\prime} \rightarrow \mathrm{U}_{1}$ be a polynomial-like restriction of $f$ such that $\mathrm{U}_{1}^{\prime}=f^{-1}\left(\mathrm{U}_{1}\right)$. The surface $\mathrm{T}_{1}$ constructed from $f_{1}$ is an open subset of T and if $h_{1}$ is an external map of $f$, constructed from an isomorphism $\alpha_{1}$ of $\mathrm{T}_{1}$ onto an annulus, then $\beta=\alpha \circ \alpha_{1}^{-1}$ gives, using the Schwarz reflection principle again, a real-analytic automorphism of $S^{1}$ conjugating $h_{1}$ to $h$.

Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ and $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ be two polynomial-like mappings, and $h_{f}$ and $h_{g}$ be their external maps. If $\mathrm{K}_{f}$ and $\mathrm{K}_{g}$ are connected, the same argument as above shows that $f$ and $g$ are externally equivalent if and only if $h_{f}$ and $h_{g}$ are real-analytically conjugate.

If $\mathrm{K}_{f}$ or $\mathrm{K}_{g}$ is not connected, we take real-analytic conjugation of their external maps as the definition of external equivalence.

Remarks. - (1) If there exist open sets $\mathrm{U}_{1}, \mathrm{U}_{1}^{\prime}, \mathrm{V}_{1}, \mathrm{~V}_{1}^{\prime}$ and compact sets L and M such that

$$
\begin{gathered}
f^{-1}\left(\mathrm{U}^{\prime}\right) \subset \mathrm{L} \subset \mathrm{U}_{1}^{\prime} \subset \mathrm{U}_{1} \\
g^{-1}\left(\mathrm{~V}^{\prime}\right) \subset \mathrm{M} \subset \mathrm{~V}_{1}^{\prime} \subset \mathrm{V}_{1}, \\
\mathrm{U}_{1}^{\prime}=f^{-1}\left(\mathrm{U}_{1}\right), \quad \mathrm{V}_{1}^{\prime}=g^{-1}\left(\mathrm{~V}_{1}\right)
\end{gathered}
$$

L (resp. M) containing the critical points of $f$ (resp. g) and an isomorphism $\varphi: \mathrm{U}_{1}-\mathrm{L} \rightarrow \mathrm{V}_{1}-\mathrm{M}$ such that $\varphi \circ f=g \circ \varphi$ on $\mathrm{U}_{1}^{\prime}-\mathrm{L}$, one can easily construct using $\varphi$ an isomorphism of $\mathrm{T}_{f, 1}$ onto $\mathrm{T}_{g, 1}$ and therefore $f$ and $g$ are externally equivalent.

Unfortunately, there exist pairs $f, g$ of externally equivalent polynomial-like maps, whose equivalence cannot be realized by such a $\varphi$. However, any external equivalence can be obtained from a chain of three such realizable equivalences.
(2) Let $\tilde{h}: \mathbb{R} \rightarrow \mathbb{R}$ be a lifting of $h$ to the universal covering space. Then $h$ has a unique fixed point a with $h^{\prime}(a)=\delta>1$ and there exists a diffeomorphism $\gamma: \mathbb{R} \rightarrow \mathbb{R}$ such that $\gamma \circ \tilde{h} \circ \gamma^{-1}$ is $t \mapsto \delta$.t. The map $S: t \mapsto \gamma\left(\gamma^{-1}(t)+1\right)$ satisfies the functional equation $\mathrm{S}^{d}(t)=\delta \mathrm{S}(t / \delta)$, which is formally identical to the Cvitanovic-Feigenbaum equation. The trivial map $z \mapsto z^{d}$ leads to $h(z)=z^{d}, \delta=d$ and $S(t)=t+1$. Up to conjugation by an affine map, the class of $S$ uniquely determines the class of $h$. We do not know how to express the property that $h$ is expanding in terms of $S$.
(3) Let $h_{1}$ and $h_{2}$ be two expanding maps $\mathbf{S}^{1} \rightarrow \mathbf{S}^{1}$ of degree $d$. If $h_{1}$ and $h_{2}$ are realanalytically. conjugate, then the eigenvalues along corresponding cycles are equal. It is an open question whether the converse holds. Recently, P. Collet [C] found a partial positive answer. (*)

Proposition 4. - Let $f$ be a polynomial-like mapping of degree d. Then $f$ is holomorphically equivalent to a polynomial if and only iff is externally equivalent to $z \mapsto z^{d}$.

Proof. - Let $\mathbf{P}$ be a polynomial. Then $\mathbf{P}$ is analytically conjugate to $z \mapsto z^{d}$ in a neighborhood of infinity. Therefore if $U$ is chosen sufficiently large, and $L$ is chosen sufficiently large in $\mathrm{U}^{\prime}=\mathrm{P}^{-1}(\mathrm{U})$, the Riemann surface T constructed will be isomorphic to the one for $z \mapsto z^{d}$, by an isomorphism which conjugates P to $z \mapsto z^{d}$. This proves "only if".
(*) Added in proof: The answer is yes (Sullivan, unpublished).

$$

$$

Now let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ be a polynomial-like mapping, and $\mathrm{F}: \mathrm{T}^{\prime} \rightarrow \mathrm{T}$ be constructed from $f$ as above. If $f$ is externally equivalent to $\mathrm{P}_{0}: z \mapsto z^{d}$, there exists an open subset $\mathrm{T}_{1}$ of $T$ containing $X_{n}$ for $n$ sufficiently large, and an isomorphism $\varphi$ of $T_{1}$ onto $W_{1}=V_{1}-\bar{D}$, where $V_{1}$ is an open neigborhood of $\overline{\mathrm{D}}$ in $\mathbb{C}$, such that $\varphi \circ \mathrm{F}=\mathrm{P} \circ \varphi$ on $\mathrm{T}_{1}^{\prime}=\mathrm{F}^{-1}\left(\mathrm{~T}_{1}\right)$.

Lemma. - The mapping $\varphi$ extends to an analytic embedding of T into $\mathbb{C}-\overline{\mathrm{D}}$, satisfying $\varphi \circ \mathrm{F}=\mathrm{P}_{0} \circ \varphi$ on $\mathrm{T}^{\prime}$.

Proof of lemma. - The map F: $\mathrm{T}^{\prime} \rightarrow \mathrm{T}$ is a covering map of degree $d . \quad$ Let $\sigma: \mathrm{T}^{\prime} \rightarrow \mathrm{T}^{\prime}$. be the automorphism induced by the canonical generator of $\pi_{1}(\mathrm{~T})=\mathbb{Z}$, and let $\sigma_{0}$ be the automorphism $z \mapsto e^{2 \pi i / d} z$ of $\mathbb{C}-\widehat{\mathrm{D}}$. Then $\varphi \circ \sigma=\sigma_{0} \circ \varphi$ on $\mathrm{X}_{n}$ for $n$ sufficiently large, hence on any connected subset of $X$ to which $\varphi$ extends analytically. Therefore, if $\varphi$ is defined on $\mathrm{X}_{n}$ for some $n>0$, it can be extended to $\mathrm{X}_{n-1}$ by the formula $\varphi(x)=\mathrm{P}_{0}\left(\varphi\left(\mathrm{~F}^{-1}(x)\right)\right)$.

End of proof of the Proposition. - Consider the Riemann surface S obtained by gluing U and $\overline{\mathbb{C}}-{ }^{\varphi}(\mathrm{L})$ using $\left.\varphi\right|_{\mathrm{x}_{0}}$, and the map $g: \mathrm{S} \rightarrow \mathrm{S}$ given by $f$ on $\mathrm{U}^{\prime}$ and $\mathrm{P}_{0}$ on $\overline{\mathbb{C}}-{ }^{\varphi}(\mathrm{L})$. The surface S is homeomorphic to the Riemann sphere, and is therefore analytically isomorphic to it by the uniformization Theorem. Let $\Phi: S \rightarrow \overline{\mathbb{C}}$ be an isomorphism such that $\Phi(\infty)=\infty$, and let $\mathrm{P}=\Phi \circ g \circ \Phi^{-1}$. The map $\mathrm{P}: \overline{\mathbb{C}} \rightarrow \overline{\mathbb{C}}$ is analytic, therefore a rational function. Since $\mathrm{P}^{-1}(\infty)=\infty, \mathrm{P}$ is a polynomial. The map $\Phi \varphi$ defines an analytic equivalence between $f$ and P .
Q.E.D.
3. The Ahlfors-Bers Theorem. - We will use the "measurable Riemann mapping Theorem", which can be stated as follows:
If $\mu=u(z) d \bar{z} / d z$ is a Beltrami form on $\mathbb{C}$ with $\sup |u(z)|<1$, then there exists a quasiconformal homeomorphism $\varphi: \mathbb{C} \rightarrow \mathbb{C}$ such that $\bar{\partial} \varphi / \partial \varphi=\mu$.

This Theorem can also be stated as follows:
Any measurable almost complex structure $\sigma$ on a Riemann surface X which has bounded dilatation ratio with respect to the initial complex structure $\sigma_{0}$ is integrable.

As the two statements above show, Beltrami forms and almost complex structures are two ways of speaking of the same objects. In this paper we use both, according to convenience, with a preference for the language of almost complex structures, which is more geometric. A dictionary is as follows.
To provide an oriented surface X with an almost complex structure $\sigma$ means to choose, for each $x \in \mathrm{X}$ (sometimes almost every $x \in \mathrm{X}$ ), a multiplication by $i$ in $\mathrm{T}_{x} \mathrm{X}$ which makes $\mathrm{T}_{x} \mathrm{X}$ into a complex vector space, in a way compatible with the orientation.

An $\mathbb{R}$-differentiable map $f: \mathrm{X} \rightarrow \mathbb{C}$ is holomorphic at $x$ for $\sigma$ if $\mathrm{T}_{x} f: \mathrm{T}_{x} \mathrm{X} \rightarrow \mathbb{C}$ is $\mathbb{C}$ linear for the complex structure $\sigma_{x}$ on $\mathrm{T}_{x} \mathrm{X}$ and the standard structure on $\mathbb{C}$.

An almost complex structure $\sigma$ defined almost everywhere on X is called integrable if, for any $x \in \mathrm{X}$, there is an open neighborhood U of $x$ in X and a homeomorphism $\varphi: \mathrm{U} \rightarrow \mathrm{V}$ with V open in $\mathbb{C}$, which is in the Sobolev space $\mathrm{H}^{1}(\mathrm{U})$ [i. e. such that the distributional derivatives are in $\mathrm{L}^{2}(\mathrm{U})$ ], and holomorphic for $\sigma$ at almost every point of U. Such maps can then be used as charts for an atlas which makes X into a $\mathbb{C}$-analytic manifold.

An almost complex structure is best visualized as a field of infinitesimal ellipses: to each $x \in \mathrm{X}$, assign an ellipse $u^{-1}\left(\mathrm{~S}^{1}\right) \subset \mathrm{T}_{x} \mathrm{X}$ where $u: \mathrm{T}_{x} \mathrm{X} \rightarrow \mathbb{C}$ is $\mathbb{C}$-linear for the structure $\sigma_{x}$.

Any field of infinitesimal ellipses defines an almost complex structure; two fields $\left(\mathrm{E}_{x}\right)_{x \in X}$ and $\left(\mathrm{E}_{\mathbf{X}}^{\prime}\right)_{x \in X}$ define the same almost complex structure if and only if $\mathrm{E}_{x}^{\prime}$ is $\mathbb{R}-$ homothetic to $\mathrm{E}_{x}$ for almost all $x$.

If X and $\mathrm{X}^{\prime}$ are oriented surfaces and $\varphi: \mathrm{X}^{\prime} \rightarrow \mathrm{X}$ is $\mathrm{C}^{1}$, an almost complex structure $\sigma$ on $X$ can be pulled back into an almost complex structure $\varphi^{*} \sigma$ on the open set $W^{\prime} \subset X^{\prime}$ on which $\operatorname{Jac}(\varphi)>0$, as follows. If $\sigma$ is defined by a field of infinitesimal ellipses ( $\mathrm{E}_{x}$ ), then $\varphi^{*} \sigma$ is defined by $\left(\mathrm{E}_{x^{\prime}}^{\prime}\right)_{x^{\prime} \in W^{W}}$, where $\mathrm{E}_{x^{\prime}}^{\prime}=\left(\mathrm{T}_{x^{\prime}} \varphi\right)^{-1} \mathrm{E}_{\varphi\left(x^{\prime}\right)}$

If $f$ is holomorphic at $x=\varphi\left(x^{\prime}\right)$ for $\sigma$, then $f \circ \varphi$ is holomorphic at $x^{\prime}$ for $\varphi^{*} \sigma$.
Let $U$ be an open set in $\mathbb{C}$ and denote $\sigma_{0}$ its initial complex structure. A new almost complex structure on $\sigma$ on U can be defined by its Beltrami form $\mu=u d \bar{z} / d z$. For each $x$, one has

$$
\mathrm{u}(\mathrm{x})=(\partial f / \partial \bar{z}(x)) /(\partial f / \partial z(x)),
$$

where $f$ is any function holomorphic at $x$ for $\sigma$. The correspondance between Beltrami forms and ellipses is as follows: the argument of $u(x)$ is twice the argument of the major axis of $\mathrm{E}_{x}$, and $|u(x)|=(K-1) /(K+1)$, where $K \geqslant 1$ is the ratio of the lengths of the axes. This ratio K is the dilatation ratio of $\sigma$ at $x$ with respect to the standard structure $\sigma_{0}$.

Let U and $\mathrm{U}^{\prime}$ be two open sets in $\mathbb{C}$ and $\varphi: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ be a $\mathrm{C}^{1}$-diffeomorphism. If $\sigma$ is the almost complex structure defined on U by a Beltrami form $\mu=u d \bar{z} / d z$, the structure $\sigma^{\prime}=\varphi^{*} \sigma$ is defined by $\varphi^{\prime} \mu=\mu^{\prime}=v d \bar{w} / d w$, where $v=\lambda(u+a) /(1+\bar{a} u)$, with

$$
\lambda=\overline{(\partial \varphi / \partial w)} /(\partial \varphi / \partial w) \quad \text { and } \quad a=(\partial \varphi / \partial \bar{w}) /(\partial \varphi / \partial w) .
$$

If $\varphi$ is holomorphic for the original structure, then $\sigma$ and $\sigma^{\prime}$ have the same dilatation ratio.

Concerning the dependence on parameters, we shall use the two following results: Let U be a bounded open set in $\mathbb{C}$.
(a) Let $\left(\mu_{n}\right)=\left(u_{n} d \bar{z} / d z\right)$ be a sequence of Beltrami forms on U and $\mu=u d \bar{z} / d z$ be another Beltrami form. Suppose that there is a $m<1$ such that $\|u\|_{\infty} \leqq m$ and $\left\|u_{n}\right\|_{\infty} \leqq m$ for each $n$, and that $u_{n} \rightarrow u$ in the $\mathrm{L}^{1}$ norm. Let $\varphi: \mathrm{U} \rightarrow \mathrm{D}$ be a quasi-conformal homeomorphism such that $\bar{\partial} \varphi / \partial \varphi=\mu$. Then there exists a sequence $\left(\varphi_{n}\right)$ of quasi-conformal homeomorphisms $\mathrm{U} \rightarrow \mathrm{D}$ such that $\bar{\partial} \varphi_{n} / \partial \varphi_{n}$ for each $n$ and that $\varphi_{n} \rightarrow \varphi$ uniformly on $\mathrm{U}([\mathrm{A}],[\mathrm{L}-\mathrm{V}])$.
(b) Let $\Lambda$ be an open set in $\mathbb{C}^{n}$ and $\left(\mu_{\lambda}=u_{\lambda} d \bar{z} / d z\right)_{\lambda \in \Lambda}$ be a family of Beltrami forms. Suppose $\lambda \mapsto u_{\lambda}(z)$ is holomorphic for almost each $z \in \mathrm{U}$, and that there is a $m<1$ such that $\left\|u_{\lambda}\right\|_{\infty} \leqq m$ for each $\lambda \in \Lambda$. For each $\lambda$, extend $\mu_{\lambda}$ to $\mathbb{C}$ by $\mu_{\lambda}=0$ on $\mathbb{C}-\mathrm{U}$, and let $\varphi_{\lambda}: \mathbb{C} \rightarrow \mathbb{C}$ be the unique quasi-conformal homeomorphism such that $\bar{\partial} \varphi_{\lambda} / \partial \varphi_{\lambda}=\mu_{\lambda}$ and $\varphi(z)-z \rightarrow 0$ when $|z| \rightarrow \infty$. Then $(\lambda, z) \mapsto\left(\lambda, \varphi_{\lambda}(z)\right)$ is a homeomorphism of $\Lambda \times \mathbb{C}$ onto itself, and for each $z \in \mathbb{C}$ the map $\lambda \mapsto \varphi_{\lambda}(z)$ is $\mathbb{C}$-analytic.

$$

## 4. Mating a hybrid class with an external class.

Proposition 5. - Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ be a polynomial-like mapping, and $h: \mathrm{S}^{1} \rightarrow \mathrm{~S}^{1}$ be an $\mathbb{R}$-analytic expanding map of the same degree $d$. There then exists a polynomial-like mapping $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ which is hybrid equivalent to $f$ and whose exterior class is $h$.

Proof. - Let $\mathrm{A} \subset \mathrm{U}$ be a compact manifold with $\mathrm{C}^{1}$-boundary, homeomorphic to $\overline{\mathrm{D}}$, and containing $\mathrm{K}_{f}$ in its interior. Moreover, we require that $\mathrm{A}^{\prime}=f^{-1}(\mathrm{~A})$ be homeomorphic to $\overline{\mathrm{D}}$ and that $\mathrm{A}^{\prime} \subset \AA$. Set $\mathrm{Q}_{f}=\mathrm{A}-\AA^{\prime}$.

The mapping $h$ extends to an analytic map $V^{\prime} \rightarrow V$ where $V^{\prime}$ and $V$ are neighborhoods of $S^{1}$ in $\mathbb{C}$. If $V^{\prime}$ is chosen sufficiently small, there exists $R>1$ such that $\mathrm{B}=\left\{z|1<|z| \leqq \mathrm{R}\}\right.$ is contained in V and $\mathrm{B}^{\prime}=h^{-1}(\mathrm{~B})$ is homeomorphic to B and contained in B . Set $\mathrm{Q}_{h}=\mathrm{B}-\mathrm{B}^{\prime}$.

Let $\psi_{0}$ be an orientation-preserving $C^{1}$-diffeomorphism of $\partial \mathrm{A}$ onto $\partial \mathrm{B}$. Since $\partial \mathrm{A}^{\prime}$ and $\partial \mathrm{B}^{\prime}$ are $d$-fold covers of $\partial \mathrm{A}$ and $\partial \mathrm{B}$ respectively, there exists a diffeomorphism $\psi_{1}: \mathrm{A}^{\prime} \rightarrow \mathrm{B}^{\prime}$ such that $\psi_{0} \circ f=h^{\circ} \psi_{1}$. Let $\psi: \mathrm{Q}_{f} \rightarrow \mathrm{Q}_{h}$ be a diffeomorphism inducing $\psi_{0}$ on $\partial \mathrm{A}$ and $\psi_{1}$ on $\partial \mathrm{A}^{\prime}$.

Call $\sigma_{0}$ the standard complex structure of $\mathbb{C}$ and $\sigma_{1}$ the complex structure $\psi^{*} \sigma_{0}$ on $\mathrm{Q}_{f}$. Define the complex structure $\sigma$ on A by taking $\left(f^{n}\right)^{*}\left(\sigma_{1}\right)$ on $f^{-n}\left(\mathrm{Q}_{f}-\partial \mathrm{A}^{\prime}\right)$ and $\sigma_{0}$ on $K_{f}$. This complex structure is not defined at inverse images of the critical points $\omega_{i}$ (if $\omega_{i} \varepsilon / \mathrm{K}_{f}$ ); it is discontinuous along the curves $f^{-n}\left(\partial \mathrm{~A}^{\prime}\right)$ although these discontinuities could be avoided by a more careful choice of $\psi$. However, the much nastier discontinuities along $\partial \mathrm{K}_{f}$ cannot be avoided.

Since $f$ is holomorphic, the dilatation of $\sigma$ is equal to that of $\sigma_{1}$, hence bounded since $\psi$ was chosen of class $C^{1}$. By the measurable Riemann mapping Theorem, $\sigma$ defines a complex structure on $A$, and there exists a homeomorphism $\varphi: \AA \rightarrow D$ which is holomorphic for $\sigma$ on $\AA$ and $\sigma_{0}$ on D.

Set $g=\varphi \circ f \circ \varphi^{-1}: \varphi\left(\AA^{\prime}\right) \rightarrow \mathrm{D}$. Clearly $g$ is holomorphic, hence polynomial-like of degree $d$. The mapping $\varphi$ is a hybrid equivalence of $f$ with $g$ and $\psi \circ \varphi^{-1}$ is an exterior equivalence of $h$ and $g$.
Q.E.D.
5. Uniquess of the mating. - Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ and $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ be two polynomial-like mappings of degree $d>1$, with $K_{f}$ and $K_{g}$ connected. Let $\varphi: \mathrm{U}_{1} \rightarrow \mathrm{~V}_{1}$ be a hybrid equivalence and $\psi: U_{2}-K_{f} \rightarrow V_{2}-K_{g}$ an external equivalence. Define $\Phi: U_{2} \rightarrow V_{2}$ by $\Phi=\psi$ on $U_{2}-K_{f}$ and $\Phi=\varphi$ on $K_{f}$.

We will give a topological condition making $\Phi$ continuous, and show that if this condition is satisfied, then $\Phi$ is in fact holomorphic.

One way to state the condition is to require that $\varphi$ and $\psi$ operate the same way on the $d-1$ prime ends of $K_{f}$ that are fixed by $f$. We shall restate the condition so as to avoid the theory of prime ends.

Note that the condition is void if $d=2$.
Let Q be a space having the homotopy type of an oriented circle; let $f: \mathbf{Q} \rightarrow \mathrm{Q}$ and $\alpha: Q \rightarrow Q$ have degree $d$ and 1 respectively and satisfy $\alpha \circ f=f \circ \alpha$. Define

[^0]$[\alpha ; f] \in \mathbb{Z} /(d-1)$ as follows. Let $\tilde{f}: \widetilde{\mathrm{Q}} \rightarrow \widetilde{\mathrm{Q}}$ and $\tilde{\alpha}: \widetilde{\mathrm{Q}} \rightarrow \widetilde{\mathrm{Q}}$ be liftings to the universal covering space, and $\tau: \widetilde{\mathrm{Q}} \rightarrow \widetilde{\mathrm{Q}}$ be the automorphism giving the generator of $\pi_{1}(\mathrm{Q})$ specified by the orientation.

Clearly, $\tilde{f} \circ \tilde{\alpha}=\tau^{i} \circ \tilde{\alpha} \circ \tilde{f}$ for some $i$; if we replace $\tilde{f}$ by $\tau \circ \tilde{f}$ then $i$ does not change, whereas replacing $\tilde{\alpha}$ by $\tau \circ \tilde{\alpha}$ changes $i$ to $i+d-1$.

Therefore the class $[\alpha, f]$ of $i$ in $\mathbb{Z} /(d-1)$ is independant of the choices.
We will require the above invariant in a slightly more general context. Let $Q_{1}$ and $Q_{2}$ be two spaces having the homotopy type of an oriented circle, and $Q_{1}^{\prime}, Q_{2}^{\prime}$ subsets such the inclusions are homotopy equivalences.

Let $f: \mathrm{Q}_{1}^{\prime} \rightarrow \mathrm{Q}_{1}$ and $g: \mathrm{Q}_{2}^{\prime} \rightarrow \mathrm{Q}_{2}$ be maps of degree $d$ and $\varphi, \psi: \mathrm{Q}_{1} \rightarrow \mathrm{Q}_{2}$ be maps of degree 1 , mapping $Q_{1}^{\prime}$ into $Q_{2}^{\prime}$, and satisfying $g \circ \varphi=\varphi \circ f$ and $g \circ \psi=\psi \circ f$.

Define $[\varphi, \psi ; f, g] \in \mathbb{Z} /(d-1)$ as follows: construct $\tilde{\varphi}, \tilde{\psi}, \widetilde{f}, \tilde{g}$ by lifting to the universal covering spaces. Then

$$
\tilde{\varphi} \circ f=\tau^{i} \circ \tilde{g} \circ \tilde{\varphi}
$$

and

$$
\tilde{\psi} \circ f=\tau^{j} \circ \tilde{g} \circ \tilde{\psi}
$$

for some $i$ and $j$. The class of $j-i$ in $\mathbb{Z} /(d-1)$ is independant of the choices and will be noted $[\varphi, \psi ; f, g]$.

If $\mathrm{Q}_{1}^{\prime}=\mathrm{Q}_{1}$ and $\varphi$ is a homeomorphism, then $[\varphi, \psi ; f, g]=\left[\varphi^{-1} \psi ; f\right]$.
Proposition 6. - Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ and $g: \mathrm{V}^{\prime} \rightarrow \mathrm{V}$ be two polynomial-like mappings of degree $d>1$, with $\mathrm{K}_{f}$ and $\mathrm{K}_{g}$ connected. Let $\varphi: \mathrm{U}_{1} \rightarrow \mathrm{~V}_{1}$ be a hybrid equivalence and $\psi: \mathrm{U}_{2}-\mathrm{K}_{f} \rightarrow \mathrm{~V}_{2}-\mathrm{K}_{g}$ be an external equivalence. If $[\varphi, \psi ; f, g]=0$ then the map $\Phi$ which agrees with $\varphi$ on $\mathrm{K}_{f}$ and with $\psi$ on $\mathrm{U}_{2}-\mathrm{K}_{f}$ is a holomorphic equivalence between $f$ and $g$.

Lemma 1. - The map $\Phi$ is a homeomorphism.
Proof. - Let $\alpha=\psi^{-1} \circ \varphi$; we must show that $\alpha$ is close to the identify near $K_{f}$.
Let $\rho(z)|d z|$ be the Poincare metric of $U-K_{f}$ and let $d_{\mathrm{P}}$ be the associated distance; $d$ will denote the Euclidian distance. There is a constant $M$ such that $\rho(z) \geqq \mathbf{M} / d\left(z, K_{f}\right)$.

The mapping $f: \mathrm{U}^{\prime}-\mathbf{K}_{f} \rightarrow U-\mathbf{K}_{f}$ on covering spaces is bijective; let $h$ be its inverse. Then $h$ is contracting for $d_{\mathrm{P}}$.

Choose a compact set $\mathrm{C} \subset \mathrm{U}-\mathrm{K}_{f}$ such that the union

$$
\bigcup_{i>0} \bigcup_{j} h^{i}\left(\tau^{j}(\mathrm{C})\right)
$$

is the inverse image in $\mathrm{U}-\mathrm{K}_{f}$ of a neighborhood of $\mathrm{K}_{f}$; let $m=\sup _{x \in \mathrm{C}} d_{\mathrm{P}}(\tilde{\alpha}(x), x)$.

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

The map $h$ commutes with $\tilde{\alpha}$ because of the hypothesis $[\varphi, \psi ; f, g]=0$; and $\tau$ is an isometry. It follows that

$$
\begin{aligned}
d_{\mathrm{P}}\left(\tilde{\alpha}\left(h^{i}\left(\tau^{j}(x)\right), h^{i}\left(\tau^{j}(x)\right)\right)=d_{\mathbf{P}}( \right. & \left.h^{i}\left(\tilde{\alpha}\left(\tau^{j}(x)\right)\right), h^{i}\left(\tau^{j}(x)\right)\right) \\
& <d_{\mathbf{P}}\left(\tilde{\alpha}\left(\tau^{j}(x)\right), \tau^{j}(x)\right)=d_{\mathrm{P}}\left(\tau^{j}(\tilde{\alpha}(x)), \tau^{j}(x)\right)<m
\end{aligned}
$$

for $x \in \mathrm{C}$.
Therefore $d(\tilde{\alpha}(x), x) \rightarrow 0$ as $x \rightarrow \mathrm{~K}_{f}$. This shows that $\Phi$ is continuous; to show that $\Phi^{-1}$ is continuous, you repeat the proof above exchanging $\varphi$ and $\psi$.

```
Q.E.D.
```

Lemma 2 ( S . Rickman [Ri]). - Let $\mathrm{U} \subset \mathbb{C}$ be open, $\mathrm{K} \subset \mathrm{U}$ be compact, $\varphi$ and $\Phi$ be two mappings $\mathrm{U} \rightarrow \mathbb{C}$ which are homeomorphisms onto their images. Suppose that $\varphi$ is quasi-conformal, that $\Phi$ is quasi-conformal on $\mathrm{U}-\mathrm{K}$ and that $\varphi=\Phi$ on K . Then $\Phi$ is quasi-conformal, and $\mathrm{D} \Phi=\mathrm{D} \varphi$ almost everywhere on K .

Proof. - We may assume that $\Phi(\mathrm{U})$ and $\varphi(\mathrm{U})$ are bounded. We need to show that $\Phi$ is in the Sobolev space $\mathrm{H}^{1}(\mathrm{U})$, and find bounds for the excentricity of its derivative.

Since $\varphi$ is in $H^{1}(\mathrm{U})$ it is enough to show that $u=\operatorname{Re}(\Phi-\varphi) \in \mathrm{H}^{1}(\mathrm{U})$ [and similarly for $\operatorname{Im}(\Phi-\varphi)]$.

Let $\eta_{n}: \mathbb{R} \rightarrow \mathbb{R}$ be a $\mathbf{C}^{1}$-function such that

$$
\begin{gathered}
\eta_{n}(x)=x-1 / n \quad \text { for } \quad x>2 / n, \\
\eta_{n}(x)=x+1 / n \quad \text { for } \quad x<-2 / n, \\
\eta_{n}(x)=0 \quad \text { for } \\
\eta_{n}^{\prime}(x)<1
\end{gathered} \quad \text { for } \quad x \in \mathbb{R} .
$$

The sequence $u_{n}=\eta_{n} \circ u$ is a Cauchy sequence in $\mathrm{H}^{1}$, with limit $u$. Since $u_{n}=0$ on a neighborhood of K for all $n, \mathrm{D} u=0$ almost everywhere on K .

> Q.E.D:

Proposition 6 is now immediate: we have to show that $\Phi$ satisfies the Cauchy-Riemann equations almost everywhere. On $\mathrm{K}_{f}, \mathrm{D} \Phi=\mathrm{D} \varphi$ almost everywhere, and on $\mathrm{U}_{2}-\mathrm{K}_{f}, \Phi$ is holomorphic.

## Q.E.D.

Corollary 1. - Let $f$ and $g$ be two polynomial-like mappings of degree 2 with $\mathrm{K}_{f}$ and $K_{g}$ connected. If $f$ and $g$ are hybrid equivalent and externally equivalent, then they are holomorphically equivalent.

Corollary 2. - Let P and Q be two polynomials with $\mathrm{K}_{f}$ and $\mathrm{K}_{g}$ connected. If P and Q are hybrid equivalent, then they are conjugate by an affine map.

Proof. - If P is a polynomial of degree $d$, there is an external equivalence $\psi_{\mathrm{P}}: \mathbb{C}-\mathrm{K}_{\mathrm{P}} \rightarrow \mathbb{C}-\mathrm{D}$ between P and $z \mapsto z^{d}$ defined on $\mathbb{C}-\mathrm{K}_{\mathrm{P}}$. Then $\psi_{\mathrm{P}, \mathrm{Q}}=\psi_{\mathrm{Q}}{ }^{-1}{ }^{\circ} \psi_{\mathrm{P}}$ is an isomorphism of $\mathbb{C}-\mathrm{K}_{\mathbf{P}}$ onto $\mathbb{C}-\mathrm{K}_{\mathrm{Q}}$, and the map $\Phi$ constructed in Proposition 4 is an isomorphism of $\mathbb{C}$ onto itself, therefore affine.

Corollary 3. - Let $c_{1}$ and $c_{2}$ be two points of M. If the polynomials $z \mapsto z^{2}+c_{1}$ and $z \mapsto z^{2}+c_{2}$ are hybrid equivalent, then $c_{1}=c_{2}$.
6. Quasi-conformal equivalence in degree 2.

Proposition 7. - Suppose $c_{1}$ and $c_{2}$ are in $\mathbb{C}$, with $c_{1}$ in $\partial \mathrm{M}$. If the polynomials $\mathrm{P}_{1}: z \mapsto z^{2}+c_{1}$ and $\mathrm{P}_{2}: z \mapsto z^{2}+c_{2}$ are quasi-conformally equivalent, then $c_{1}=c_{2}$.

Proof. - Let $\varphi: \mathrm{U} \rightarrow \mathrm{V}$ be a quasi-conformal equivalence of $\mathrm{P}_{1}$ with $\mathrm{P}_{2}$. If $\mathrm{K}_{\mathrm{P}_{1}}$ is of measure zero, then $\varphi$ is a hybrid equivalence, and the result follows from Corollary 3 to Proposition 6.

In the general case, consider the Beltrami form $\mu=\bar{\partial} \varphi / \partial \varphi$ and let $\mu_{0}$ be the form which agrees with $\mu$ on $\mathrm{K}_{\mathbf{P}_{1}}$ and with 0 on $\mathbb{C}-\mathrm{K}_{p_{1}}$. Set $k=\left\|\mu_{0}\right\|_{\theta}$; certainly $k<1$. For any $t \in \mathrm{D}_{1 / k}$ there exists a unique quasi-conformal homeomorphism $\Phi_{i}: \mathbb{C} \rightarrow \mathbb{C}$ such that

$$
\bar{\partial} \Phi_{t} / \partial \Phi_{t}=t \mu_{0}
$$

$\Phi_{t}(0)=0$ and $\Phi_{t}(z) / z \rightarrow 1$ as $z \rightarrow \theta$.
Then $\Phi_{t} \circ \mathrm{P}_{1} \circ \Phi_{t}^{-1}$ is a polynomial of the form $z \mapsto z^{2}+u(t)$, where $u: \mathrm{D}_{1 / k} \rightarrow \mathbb{C}$ is holomorphic. Since $u(0)=c_{1} \in \partial \mathrm{M}$ and $u(t)$ is in M for all $t$, the function $u$ is constant, in particular $u(1)=c_{1}$. Then $\varphi \circ \Phi_{1}^{-1}$ is a hybrid equivalence of $P_{1}$ and $P_{2}$, and the Proposition follows from Corollary 3 of Proposition 6.

## CHAPTER II

## Analytic families of polynomial-like mappings

## 1. Definitions.

Definition. - Let $\Lambda$ be a complex analytic manifold and $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)_{\lambda \in \Lambda}$ be a family of polynomial-like mappings. Set $\mathscr{U}=\left\{(\lambda, z) \mid z \in \mathbf{U}_{\lambda}\right\}, \mathscr{U}{ }^{\prime}=\left\{(\lambda, z) \mid z \in \mathbf{U}_{\lambda}^{\prime}\right\}$ and $f(\lambda, z)=\left(\lambda, f_{\lambda}(z)\right)$. Then $\mathbf{f}$ is an analytic family if the following conditions are satisfied:
(1) $\mathscr{U}$ and $\mathscr{U}^{\prime}$ are homeomorphic over $\Lambda$ to $\Lambda \times \mathrm{D}$.
(2) The projection from the closure of $\mathscr{U}^{\prime}$ in $\mathscr{U}$ to $\Lambda$ is proper.
(3) The mapping $f: \mathscr{U}^{\prime} \rightarrow \mathscr{U}$ is complex-analytic and proper.

For such a family the degree of $f_{\lambda}$ is independant of $\lambda$ if $\Lambda$ is connected; we will call it the degree of $\mathbf{f}$. Set $\mathbf{K}_{\lambda}=\mathbf{K}_{f_{\lambda}}, \mathrm{J}_{\lambda}=\mathrm{J}_{f_{\lambda}}$ and $\mathscr{K}_{\mathbf{f}}=\left\{(\lambda, z) \mid z \in \mathrm{~K}_{\lambda}\right\}$. The set $\mathscr{K}_{\mathbf{f}}$ is closed in $\mathscr{U}$ and the projection of $\mathscr{K}_{\mathbf{f}}$ onto $\Lambda$ is proper, since $\mathscr{K}_{\mathbf{f}}=\bigcap_{n} f^{-n}\left(\mathscr{U}^{\prime}\right)$. Let $\mathbf{M}_{\mathbf{f}}$ denote the set of $\lambda$ for which $K_{\lambda}$ is connected.

By the straightening Theorem, if $\mathbf{f}$ is an analytic family of polynomial-like mappings of degree $d$, we can find for each $\lambda$ a polynomial $P_{\lambda}$ of degree $d$ and a homeomorphism $\varphi_{\lambda}: V_{\lambda} \rightarrow W_{\lambda}$, where $V_{\lambda}$ and $W_{\lambda}$ are neighborhoods of $K_{\lambda}$ and $K_{P_{\lambda}}$ respectively, which

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{0} 2
$$

defines a hybrid equivalence between $f_{\lambda}$ and $P_{\lambda}$. In this chapter, we will investigate whether $P_{\lambda}$ and $\varphi_{\lambda}$ can be chosen continuous, or even analytic in $\lambda$.
2. Tubings. - Choose $\mathrm{R}>1$; set $\mathrm{R}^{\prime}=\mathrm{R}^{1 / d}$ and $\mathrm{Q}_{\mathrm{R}}=\left\{z\left|\mathrm{R}^{\prime} \leqq|z| \leqq \mathrm{R}\right\}\right.$.

Proposition 8 and definition. - Let $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)$ be an analytic family of polyno-mial-like mappings of degree $d$, with $\Lambda$ contractible. Then there exists a $\mathrm{C}^{1}$-embedding $\mathrm{T}:(\lambda, x) \mapsto\left(\lambda, \mathrm{T}_{\lambda}(x)\right)$ of $\Lambda \times \mathrm{Q}_{\mathbf{R}}$ into $\mathscr{U}$ such that $\mathrm{T}\left(\Lambda \times \mathrm{Q}_{\mathrm{R}}\right)$ is of the form $\mathscr{A}-\mathscr{A}^{\prime}$ with $\mathscr{A}$ and $\mathscr{A}^{\prime}$ homeomorphic over $\Lambda$ to $\Lambda \times \mathrm{D}, \mathscr{K}_{\mathrm{f}} \subset \mathscr{A}^{\prime} \subset \mathscr{A}^{\prime}$ and $\mathrm{T}_{\lambda}\left(x^{d}\right)=f_{\lambda}\left(\mathrm{T}_{\lambda}(x)\right)$ for $|x|=\mathrm{R}^{\prime}$.

Such a mapping will be called a tubing for $\mathbf{f}$.
Proof. - Let $\Xi^{\prime}$ be the set of $(\lambda, z) \in \mathscr{U}^{\prime}$ for which $z$ is a critical point of $f_{\lambda}$ and let $\Xi=f\left(\Xi^{\prime}\right)$. The projections of $\Xi$ and $\Xi^{\prime}$ onto $\Lambda$ are proper. Let $\varphi:(\lambda, x) \mapsto\left(\lambda, \varphi_{\lambda}(x)\right)$ be a diffeomorphism of $\Lambda \times D$ onto $\mathscr{U}$ and $\eta: \Lambda \rightarrow] 0,1\left[\right.$ a $C^{1}$-function such that $\varphi_{\lambda}\left(D_{\eta(\lambda)}\right)$ contains $\overline{\mathrm{U}}_{\lambda}^{\prime}$ and the critical values of $f_{\lambda}$ for all $\lambda \in \Lambda$.

Define the embedding $\mathrm{T}^{0}:(\lambda, x) \mapsto\left(\lambda, \mathrm{T}_{\lambda}^{0}(x)\right)$ of $\Lambda \times \mathrm{S}_{\mathrm{R}}^{1}$ into $\mathscr{U}$ by

$$
\mathrm{T}_{\lambda}^{0}(x)=\varphi_{\lambda}\left(\frac{\eta(\lambda)}{r} \cdot x\right)
$$

For each $\lambda$, the curve $\Gamma_{\lambda}=\mathrm{T}_{\lambda}^{0}\left(\mathrm{~S}_{\mathrm{R}}^{1}\right)$ ) encloses the critical values of $f$, and therefore $\Gamma_{\lambda}^{\prime}=f_{\lambda}^{-1}\left(\Gamma_{\lambda}\right)$ is homeomorphic to a circle. Then there exists a diffeomorphism $\mathrm{T}_{\lambda}^{1}: \mathrm{S}_{\mathrm{R}^{\prime}}^{1} \rightarrow \Gamma_{\lambda}^{\prime}$ such that $f_{\lambda}\left(\mathrm{T}_{\lambda}^{1}(x)\right)=\mathrm{T}_{\lambda}^{0}\left(x^{d}\right)$ for $|x|=\mathbf{R}^{\prime}$; the region bounded by $\Gamma_{\lambda}$ and $\Gamma_{\lambda}^{\prime}$ is an annulus and there exists an embedding $T_{\lambda}$ of $Q_{R}$ into $U_{\lambda}$ inducing $T_{\lambda}^{0}$ and $T_{\lambda}^{1}$.

In order to find $T_{\lambda}^{1}$ and $T_{\lambda}^{0}$ depending continuously or differentiably on $\lambda$, one must find a continuous or a $C^{1}$-section of a principal fibration over $\Lambda$, with fiber principal under the group $\mathscr{D}$ of diffeomorphisms of $\mathrm{Q}_{\mathrm{R}}$ inducing the identity on $\mathrm{S}_{\mathrm{R}}^{1}$ and a rotation $x \mapsto e^{2 \pi i p / d} x$ on $\mathrm{S}_{\mathrm{R}}^{1} . \quad$ Since $\Lambda$ is assumed contractible, there is such a section.

## Q.E.D.

Remark. - According to a Theorem of Cerf, $\mathscr{D}$ can be written $\mathbb{Z} \times \mathscr{D}_{0}$, with $\mathscr{D}_{0}$ contractible. Therefore the hypothesis " $\Lambda$ contractible" can be replaced by " $\Lambda$ simply connected". One can even do better. If instead of

$$
\mathrm{T}_{\lambda}^{0}(x)=\varphi_{\lambda}\left(\frac{\eta(\lambda)}{r} \cdot x\right)
$$

we require only that T be of the form

$$
\varphi_{\lambda}\left(u(\lambda) \cdot \frac{\eta(\lambda)}{r} \cdot x\right)
$$

with $u: \Lambda \rightarrow S^{1}$ of class $C^{1}$, then the space of possible $\left(T_{\lambda}^{0}, T_{\lambda}^{1}, T_{\lambda}\right)$ is homeomorphic to the space $\mathscr{D}^{\prime}$ of diffeomorphisms of $\mathrm{Q}_{\mathrm{R}}$ inducing

$$
\begin{array}{ll}
x \mapsto u, x & \text { on } \mathrm{S}_{\mathrm{R}}^{1} \\
x \mapsto v, x & \text { on } \mathrm{S}_{\mathrm{R}^{\prime}}^{1}
\end{array}
$$

ANNALES SCIENTIFIQUES DE L'ÉCOLE NORMALE SUPÉRIEURE
with $v \in \mathrm{~S}^{1}$ and $u=v^{d}$. The space $\mathscr{D}^{\prime}$ can be written $\mathbb{Z} /(d-1) \times \mathscr{D}_{0}^{\prime}$ with $\mathscr{D}_{0}^{\prime}$ contractible. Therefore the only obstruction to finding a section to the corresponding fiber bundle is in $\mathrm{H}^{1}(\Lambda ; \mathbb{Z} /(d-1))$.
The hypothesis " $\Lambda$ contractible" can be replaced by " $\mathrm{H}^{1}(\Lambda ; \mathbb{Z} /(d-1))=0$ ", and in particular be omitted altogether if $d=2$.

We will be primarily interested in cases where $\Lambda$ is homeomorphic to $D$.
A tubing $T$ of $\mathbf{f}$ will be called horizontally analytic if the map $\lambda \mapsto \mathrm{T}_{\lambda}(x)$ is complexanalytic for all $x \in \mathrm{Q}_{\mathrm{R}}$.

Proposition 9. - For any $\lambda_{0} \in \Lambda$, there exists a neighborhood $\Lambda^{\prime}$ of $\lambda_{0}$ in $\Lambda$ and $a$ horizontally analytic tubing of $\left(f_{\lambda}\right)_{\lambda \in \Lambda^{\prime}}$.

Proof. - Let $\tau^{0}$ be a $C^{1}$-embedding of a neighborhood $V_{1}$ of $S_{R}^{1}$ into $\mathrm{U}_{\lambda_{0}}-\bar{U}_{\lambda_{0}}^{\prime}$, enclosing the critical values of $f_{\lambda_{0}}$. There exists an embedding $\tau^{1}$ from a neighborhood $V_{1}^{\prime}$ of $S_{R^{\prime}}^{1}$ into $U_{\lambda_{0}}^{\prime}$ such that $f_{\lambda_{0}}\left(\tau^{1}(x)\right)=\tau^{0}\left(x^{d}\right)$ for $x \in V_{1}$, and a $C^{1}$-embedding $\tau$ of a neighborhood $V$ of $Q_{R}$ into $U_{\lambda_{0}}$ that agrees with $\tau^{0}$ near $S_{R}^{1}$ and with $\tau^{1}$ near $S_{\mathbf{R}^{\prime}}^{1}$.

Define $\tilde{\tau}: \Lambda^{\prime \prime} \times V_{1} \rightarrow \mathscr{U}^{\prime}$ by $\tilde{\tau}_{\lambda}(x) \in f_{\lambda}^{-1}\left(\tau\left(x^{d}\right)\right)$, the choice in this finite set being imposed by continuity, the requirement that $\tilde{\tau}_{\lambda_{0}}=\left.\tau\right|_{V^{\prime}}$, and that $\Lambda^{\prime \prime}$ be a neighborhood of $\lambda_{0}$ in $\Lambda$.

Let $h: V \rightarrow \mathbb{R}_{+}$be a $C^{1}$-function, with support in $V_{1}$ and equal to 1 on a neighborhood of $\mathrm{S}_{\mathrm{R}^{\prime},}^{1} \quad$ Set $\mathrm{T}(\lambda, x)=\left(\lambda,(1-h(x)) . \tau(x)+h(x) . \tilde{\tau}_{\lambda}(x)\right)$. Then T is a $\mathrm{C}^{1}$-mapping above $\Lambda^{\prime \prime}$, inducing $\tau$ over $\lambda_{0}$ and therefore an embedding of $\Lambda^{\prime} \times Q_{R}$ for some neighborhood $\Lambda^{\prime}$ of $\lambda_{0}$. The mapping T is horizontally analytic and satisfies $\mathrm{T}\left(\lambda, x^{d}\right)=f(\mathrm{~T}(\lambda, x))$ for all $(\lambda, x) \in \Lambda^{\prime} \times S_{R^{\prime}}^{1} . \quad$ So $T$ is a horizontally analytic tubing.
Q.E.D.

Remark. - Let R and $\mathrm{R}_{1}$ be any two numbers $>1$ and $\mathrm{T}: \Lambda \times \mathrm{Q}_{\mathrm{R}} \rightarrow \mathscr{U}$ a tubing of $f$. Define $\alpha: \mathrm{Q}_{\mathrm{R}_{1}} \rightarrow \mathrm{Q}_{\mathrm{R}}$ by $\alpha\left(r e^{i t}\right)=r^{\mathscr{L}} e^{i t}$, where $l=\log \mathrm{R} / \log \mathrm{R}_{1}$. Then $\mathrm{T}_{1}=\mathrm{T} \circ\left(\mathbf{1}_{\Lambda} \times \alpha\right)$ is a tubing of $f$ using $\mathrm{Q}_{\mathbf{R}_{1}}$. If T is horizontally analytic, so is $\mathrm{T}_{1}$. Therefore the choice of $R$ is unimportant.
3. Review and statements. - In the remainder of this chapter we will assume we have an analytic family $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)_{\lambda \in \Lambda}$ of polynomial-like mappings of degree d. We will suppose $\Lambda$ contractible, and that a tubing $T$ of $f$ has been chosen.

Define $\quad \mathscr{A}=\mathrm{T}\left(\Lambda \times \mathrm{D}_{\mathrm{R}}\right), \quad \mathscr{A}^{\prime}=\mathrm{T}\left(\Lambda \times \mathrm{D}_{\mathrm{R}}\right) \quad$ and $\quad \mathrm{Q}_{\mathrm{f}}=\mathscr{A}-\mathscr{A}^{\prime}=\mathrm{T}\left(\Lambda \times \mathrm{Q}_{\mathrm{R}}\right) ; \quad$ set $\Psi=\mathrm{T}^{-1}$. By repeating the constructions which prove Propositions 4 and 5 , we find for each $\lambda$ a polynomial $P_{\lambda}$ of degree $d$, monic and without a term of degree $d-1$, and a hybrid equivalence $\varphi_{\lambda}$ of $f_{\lambda}$ with $\mathrm{P}_{\lambda}$, defined on $\AA_{\lambda}$.

If $d=2$, the polynomial $\mathrm{P}_{\lambda}$ is of the form $z \mapsto z^{2}+\chi(\lambda)$, and this defines a mapping $\chi: \Lambda \rightarrow \mathbb{C}$.

Let us go through the steps of the construction:
(1) Consider the Beltrami form

$$
\mu_{\lambda, 0}=\bar{\partial} \psi_{\lambda} / \partial \psi_{\lambda}
$$

[^1]defined on $Q_{\lambda}$.
(2) Let
$$
\mu_{\lambda, n}=\left(f_{\lambda}^{n}\right)^{*} \mu_{\lambda, 0}
$$
be the corresponding Beltrami form on
$$
\mathrm{Q}_{\lambda, n}=f_{\lambda}^{-n}\left(\mathrm{Q}_{\lambda}\right)
$$
(3) Define the Beltrami form $\mu_{\lambda}$ on $\AA_{\lambda}$ by setting
$$
\mu_{\lambda}(z)=\mu_{\lambda, n}(z) \quad \text { if } \quad z \in Q_{\lambda, n}
$$
and
$$
\mu_{\lambda}(z)=0 \quad \text { if } \quad z \in K_{\lambda} .
$$
(4) Using the measurable Riemann mapping Theorem, the form $\mu_{\lambda}$ defines a complex structure $\sigma_{\lambda}$ on $A_{\lambda}$; the mapping $\psi_{\lambda}: \mathrm{Q}_{\lambda} \rightarrow \mathrm{Q}_{\mathrm{R}}$ is holomorphic for $\sigma_{\lambda}$ in the domain and $\sigma_{0}$ in the range.
(5) Glue $\AA_{\lambda}$ with the structure $\sigma_{\lambda}$ to $\overline{\mathbb{C}}-\bar{D}_{\mathbf{R}}$ using $\psi_{\lambda}$; you get a Riemann surface $\Sigma_{\lambda}$ homeomorphic to $\mathrm{S}^{2}$. The maps $f_{\lambda}$ and $\mathrm{P}_{0}: z \mapsto z^{d}$ patch together to give an analytic $\operatorname{map} g_{\lambda}: \Sigma_{\lambda} \rightarrow \Sigma_{\lambda}$.
(6) Using the uniformization Theorem, there exists a unique isomorphism $\Phi_{\lambda}: \Sigma_{\lambda} \rightarrow \overline{\mathbb{C}}$ tangent to the identity at infinity and such that the polynomial
$$
P_{\lambda}=\Phi_{\lambda} \circ g_{\lambda} \circ \Phi_{\lambda}^{-1}
$$
has no term of degree $d-1 ; \varphi_{\lambda}$ is the restriction of $\Phi_{\lambda}$ to $\AA_{\lambda}$.
The step which causes problems is step 3 . The mapping $\lambda \mapsto \mu_{\lambda}$ is not necessarily continuous, even for the weak topology on $L^{\infty}$. In general, the map is discontinuous at points where $f_{\lambda}$ has a rationally indifferent non-persistent cycle. This is closely related to the fact that the mapping $\lambda \mapsto K_{\lambda}$ is not continuous at such points for the Hausdorff topology. We will analyse a counter-example in chapter III.

For people who dislike cut and paste techniques, steps 4,5 and 6 can be restated as follows. Extends $\psi_{\lambda}$ to a diffeomorphism $\psi_{\lambda}$ of $\AA_{\lambda}$ onto $D_{R}$. Let $\theta_{\lambda}$ be the complex structure on $\mathrm{D}_{\mathrm{R}}$ gotten by transporting $\mu_{\lambda}$ by $\Psi_{\lambda}$. Let $v_{\lambda}$ be the Beltrami form on $\overline{\mathbb{C}}$ defining $\theta_{\lambda}$ on $\mathrm{D}_{\mathbf{R}}$, and extended by 0 . There exists a unique quasi-conformal homeomorphism $\Phi_{\lambda}: \mathbb{C} \rightarrow \mathbb{C}$ such that

$$
\bar{\partial} \Phi_{\lambda} / \partial \varphi_{\lambda}=v_{\lambda}
$$

and

$$
\Phi_{\lambda}(z)-z \rightarrow z \rightarrow 0 \quad \text { as }|z| \rightarrow \theta
$$

Define $g_{\lambda}: \mathbb{C} \rightarrow \mathbb{C}$ by

$$
g_{\lambda}=\Psi_{\lambda} \circ f_{\lambda} \circ \Psi_{\lambda}^{-1} \quad \text { on } \mathrm{D}_{\mathrm{R}^{\prime}}
$$

and

$$
g_{\lambda}(z)=z^{d} \quad \text { on } \mathbb{C}-\mathbf{D}_{\mathbf{R}}
$$

Then

$$
\varphi_{\lambda}=\Phi_{\lambda} \circ \Psi_{\lambda}
$$

and

$$
P_{\lambda}=\Phi_{\lambda} \circ g_{\lambda} \circ \Phi_{\lambda}^{-1}
$$

up to conjugation by a translation.
In this chapter we will prove the following Theorems.
Theorem 1. - Let $\mathscr{R}$ be the open subset of the first Mañe-Sad-Sullivan decomposition of $\Lambda$ (cf. II, 4). Then $\varphi_{\lambda}$ and $\mathrm{P}_{\lambda}$ depend continuously on $\lambda$ for $\lambda \in \mathscr{R}$, and $\mathrm{P}_{\lambda}$ depends analytically on $\lambda$ for $\lambda \in \mathscr{R} \cap \dot{M}_{\mathbf{f}}$.

The first part is Proposition 12 and the second is Corollary 1 to Proposition 13.
Theorem 2. - If $d=2$, the mapping $\chi: \Lambda \rightarrow \mathbb{C}$ is continuous on $\Lambda$, and analytic on $\dot{\mathrm{M}}_{\mathrm{f}}$. Continuity is Proposition 14 and analyticity is Corollary 1 of Proposition 13.
4. The first Mañe-Sad-Sullivan decomposition. - Let $\left(P_{\lambda}\right)_{\lambda \in \Lambda}$ be an analytic family of polynomials (or rational functions). In [M-S-S], Mañe, Sad and Sullivan describe two decomposition of $\Lambda$ into a dense open set and a closed complement. For the first decomposition, the open set is the set of $\lambda$ for which $P_{\lambda}$ is structurally stable on a neighborhood of the Julia set; for the second decomposition structural stability of $P_{\lambda}$ is required on the whole Riemann sphere.

In this paragraph we will review the first decomposition in the framework of polyno-mial-like mappings.

Let $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathbf{U}_{\lambda}\right)_{\lambda \in \Lambda}$ be an analytic family of polynomial-like mappings.
An indifferent periodic point $z_{0}$ of $f_{\lambda_{0}}$ is called persistent if for each neighborhood V et $z_{0}$ there is a neighborhood W of $\lambda_{0}$ such that, for each $\lambda \in \mathrm{W}$, the function $f_{\lambda}$ has in V an indifferent periodic point of the same period.

Let $\mathscr{I}$ be the set of $\lambda$ for which $f_{\lambda}$ has a non-persistent indifferent periodic point, $\mathscr{F}=\overline{\mathscr{I}}$, and $\mathscr{R}=\Lambda-\mathscr{F}$ the complementary open set.

Proposition 10. - (a) The open set $\mathscr{R}$ is dense in $\Lambda$.
(b) For any $\lambda_{0}$, there exists a neighborhood W of $\lambda_{0}$ in $\mathscr{R}$, a neighborhood V of $\mathrm{J}_{\lambda_{0}}$ in $\mathrm{U}_{\lambda_{0}}$ and an embedding $\tau:(\lambda, z) \mapsto\left(\lambda, \tau_{\lambda}(z)\right)$ of $\mathrm{W} \times \mathrm{V}$ into $\mathscr{U}$ such that:
(i) $\tau(\lambda, z)$ is holomorphic in $\lambda$ and quasi-conformal in $z$, with dilatation ratio bounded by a constant independant of $\lambda$.
(ii) The image of $\tau$ is a neighborhood of $\mathscr{I}_{\mathrm{W}}=\left\{(\lambda, z) \mid \lambda \in \mathrm{W}, z \in \mathrm{~J}_{\lambda}\right\}$, which is closed in $\mathscr{U} \cap(\mathbf{W} \times \mathbb{C})$.
(iii) The map $\tau_{\lambda_{0}}$ is the identity of V , and for all $\lambda \in \mathrm{W}$ we have $f_{\lambda} \circ \tau_{\lambda}=\tau_{\lambda} \circ f_{\lambda_{0}}$.

The proofs of [M-S-S], completed by [S-T] (see also [B-R]) for the case of persistent Siegel discs, can simply be copied in the setting of polynomial-like mappings.

Corollary. - Let W be a connected component of $\mathscr{R}$. If $\lambda_{1}, \lambda_{2} \in \mathrm{~W}$, then $\mathrm{K}_{\lambda_{1}}$ and $\mathrm{K}_{\lambda_{2}}$ are homeomorphic. In particular, either $\mathrm{W} \subset \mathrm{M}_{\mathbf{f}}$ or $\mathrm{W} \cap \mathrm{M}_{\mathbf{f}}=\varnothing$.

$$
4^{e} \text { SÉRIE }- \text { TOME } 18-1985-N^{0} 2
$$

Proposition 11. $-(a) \stackrel{\circ}{\mathbf{M}}_{\mathbf{f}} \subset \mathscr{R}$.
(b) If $d=2$, then $\mathscr{R}=\Lambda-\partial \mathbf{M}_{\mathbf{f}}$.

Proof. - (a) Choose $\lambda_{0} \in \dot{\mathbf{M}}_{\mathbf{f}}$. By contradiction, suppose $f_{\lambda_{0}}$ has a non-persistent indifferent periodic point $\alpha_{0}$ of period $k$. There then exists a neighborhood V of 0 in $\mathbb{C}$, an analytic map $t \mapsto \lambda(t)$ of V into $\Lambda$ and analytic maps

$$
\alpha, \quad \omega_{1}, \ldots, \omega_{d-1}
$$

of V into $\mathbb{C}$ with $\lambda(0)=\lambda_{0}, \alpha(0)=\alpha_{0}$, such that $\alpha(t)$ is a periodic point of $f_{\lambda(t)}$ of period $k$ and eigenvalue $\rho(t)$, where $\rho: \mathrm{V} \rightarrow \mathbb{C}^{*}$ is a non-constant holomorphic function, and such that

$$
\omega_{1}(t), \ldots, \omega_{d-1}(t)
$$

are the $(d-1)$ critical points of $f_{\lambda(t)}$ for $t \in \mathrm{~V}$.
Let $\left(t_{n}\right)$ be a sequence in $V$ converging to 0 , such that $\left|\rho\left(t_{n}\right)\right|<1$ for all $n$. For each $n, \alpha\left(t_{n}\right)$ is an attractive periodic point, so there exist $i, j$ such that

$$
f_{\lambda\left(t_{n}\right)}^{k p+i}\left(\omega_{j}\left(t_{n}\right)\right)
$$

converges to $\alpha\left(t_{n}\right)$ without reaching it as $p \rightarrow \infty$. By choosing a subsequence we can assume $i$ and $j$ independant of $n$.

Since $\lambda(t) \in \mathrm{M}_{\mathbf{f}}$ for all $t \in \mathrm{~V}$, we can define a sequence ( $u_{p}$ ) of analytic functions on V by

$$
u_{p}(t)=f_{\lambda(t)}^{k p+i}\left(\omega_{j}(t)\right)
$$

This sequence is bounded on any compact subset of V since $u_{p}(t) \in \mathrm{U}_{\lambda}^{\prime}$. . If a subsequence converges to a function $h: \mathrm{V} \rightarrow \mathbb{C}$, then $h\left(t_{0}\right)=\alpha\left(t_{n}\right)$ for all $n$, so $h=\alpha$. Therefore $u_{p}(t) \rightarrow \alpha(t)$ for all $t \in \mathrm{~V}$.

But in V there are points $t^{*}$ such that $\left|\rho\left(t^{*}\right)\right|>1$ and $u_{p}\left(t^{*}\right) \neq \alpha\left(t^{*}\right)$ for all $p$. The point $\alpha\left(t^{*}\right)$ is a repulsive periodic point and cannot attract the sequence $u_{p}\left(t^{*}\right)$.
(b) By the Corollary to Proposition $10, \mathscr{R} \subset \Lambda-\partial \mathbf{M}_{\mathbf{f}}$, and $\stackrel{\circ}{\mathbf{f}}_{\mathbf{f}} \subset \mathscr{R}$ by (a). We will use the hypothesis $d=2$ to prove $\Lambda-\mathbf{M}_{\mathbf{f}} \subset \mathscr{R}$. For any $\lambda \in \Lambda$, the map $f_{\lambda}$ has a unique critical point $\omega(\lambda)$. If $\lambda \in \Lambda-\mathbf{M}_{\mathbf{f}}$, then $\omega(\lambda) \in \mathrm{U}^{\prime}-\mathrm{K}_{\lambda}$, so $f_{\lambda}$ is hyperbolic and all periodic points are repulsive. Therefore $\left(\Lambda-\partial \mathbf{M}_{\mathbf{f}}\right) \cap \mathscr{I}$ is empty, and since $\Lambda-\mathbf{M}_{\mathbf{f}}$ is open, $\Lambda-\mathbf{M}_{\mathbf{f}} \subset \mathscr{R}$.
Q.E.D.

## 5. Continuity on $\mathscr{R}$.

Proposition 12. - On the open set $\mathscr{R}$ both $\varphi_{\lambda}$ and $\mathrm{P}_{\lambda}$ depend continuously on $\lambda$.
Proof. - Using the notations of 3 , clearly $\left\|\mu_{\lambda}\right\|_{\infty}=\left\|\mu_{\lambda, 0}\right\|_{\infty}$ is bounded on any compact subset of $\Lambda$ by a constant $<1$. According to $I, 3$, we need to show that $\mu_{\lambda} \rightarrow \mu_{\lambda_{0}}$ as $\lambda \rightarrow \lambda_{0}$ in the $\mathrm{L}^{1}$-norm.

Since $\mu_{\lambda}=\lim \hat{\mu}_{\lambda, n}$ pointwise, where

$$
\begin{aligned}
\hat{\mu}_{\lambda, n} & =\mu_{\lambda, i} \quad \text { on } \quad f^{-i}\left(\mathrm{Q}_{\lambda}\right) \quad \text { for } i \leqq n \\
& =0 \quad \text { on } \quad \mathrm{A}_{\lambda, n}=f_{\lambda}^{-n-1}\left(\mathrm{~A}_{\lambda}\right)
\end{aligned}
$$

and since for each $n$ the form $\hat{\mu}_{\lambda, n}$ depends continuously on $\lambda$ for the $L^{1}$-norm, it is enough to show that $\left\|\hat{\mu}_{\lambda, n}-\mu_{\lambda}\right\|_{1}$ tends to 0 uniformly on any compact subset of $\mathscr{R}$.

This will follow from the statement that the area of $A_{\lambda, n}-K_{\lambda}$ tends to zero uniformly on every compact subset of $\mathscr{R}$.
Note that this is false on any open subset of $\Lambda$ which meets $\mathscr{F}$. Indeed, for every $n$ the area of $A_{\lambda, n}$ depends continuously on $\lambda$, but the area of $K_{\lambda}$ is discontinuous for every value of $\lambda$ for which $f_{\lambda}$ has a non-persistent rationally indifferent fixed point.

Choose $\lambda_{0} \in \mathscr{R}$, and using the notations of Proposition 10 set $\tau_{\lambda}(z)=\tau(\lambda, z), V_{\lambda}=\tau_{\lambda}(\mathrm{V})$, $\mathrm{B}_{\lambda}=\mathrm{V}_{\lambda} \cup \mathrm{K}_{\lambda}$ and $\mathrm{B}_{\lambda, n}=f_{\lambda}^{-n}\left(\mathrm{~B}_{\lambda}\right)$. There exists a neighborhood $\mathrm{W}^{\prime}$ of $\lambda_{0}$ with compact closure in W and $p \in \mathbb{N}$ such that $\mathrm{A}_{\lambda, p} \subset \mathrm{~B}_{\lambda}$ for all $\lambda \in \mathrm{W}^{\prime}$. Then $\mathrm{A}_{\lambda, n+p} \subset \mathrm{~B}_{\lambda, n}$, so it is enough to show that the area $m_{n}(\lambda)$ of $B_{\lambda, n}-K_{\lambda}$ tends to 0 uniformly on any compact subset of $\mathrm{W}^{\prime}$.

Clearly

$$
\mathbf{m}_{n}(\lambda)=\int_{\mathbf{B}_{\lambda_{0}, n}-K_{\lambda_{0}}} \operatorname{Jac}\left(\tau_{\lambda}\right)
$$

Set

$$
\mathbf{n}_{n(\lambda)}=\int_{\mathbf{B}_{\lambda_{0, n}}-K_{\lambda_{0}}}\|D \tau\|^{2} .
$$

The functions $\mathbf{n}_{n}$ form a decreasing sequence of plurisubharmonic functions. There exist numbers $a, b$, with $0<a<b<\infty$ such that on $\mathrm{W}^{\prime}$

$$
a \mathbf{n}_{n}(\lambda)<\mathbf{m}_{n}(\lambda)<b \mathbf{n}_{n}(\lambda)
$$

since the $\tau_{\lambda}$ are quasi-conformal with bounded dilatation ratio.
Since $\mathbf{m}_{n}(\lambda) \rightarrow 0$ pointwise, $\mathbf{n}_{n}(\lambda) \rightarrow 0$ pointwise, hence $\mathbf{n}_{n}(\lambda) \rightarrow 0$ uniformly on any compact subset of $\mathrm{W}^{\prime}$, so $\mathbf{m}_{n}(\lambda) \rightarrow 0$ uniformly on any compact subset of $\mathrm{W}^{\prime}$.
Q.E.D.

## 6. The locus of hybrid equivalence.

Proposition 13. - Let $\mathbf{f}=\left(f_{\lambda}: \mathbf{U}_{\lambda}^{\prime} \rightarrow \mathbf{U}_{\lambda}\right)$ and $\mathbf{q}=\left(g_{\lambda}: \mathbf{V}_{\lambda}^{\prime} \rightarrow \mathbf{V}_{\lambda}\right)$ be two analytic families of polynomial-like mappings of degree $d$ parametrized by the same manifold $\Lambda$. Let $\mathscr{R}$ be the open subset of $\Lambda$ given by the first Mañe-Sad-Sullivan decomposition for $\mathbf{f}$ and let $\mathbf{W}$ be a connected component of $\mathscr{R}$ contained in $\mathbf{M}_{\mathbf{f}}$. Then the set $\Gamma \subset \mathbf{W}$ of those $\lambda$ for which $f_{\lambda}$ and $g_{\lambda}$ are hybrid equivalent is a complex-analytic subset of W .

Addendum if $d>2$. - Let $\mathrm{T}_{\mathbf{f}}$ and $\mathrm{T}_{\mathbf{g}}$ be tubings of $\mathbf{f}$ and $\mathbf{g}$ respectively, defined on $\mathrm{W} \times \mathrm{Q}_{\mathrm{R}}$, and with images $\mathrm{Q}_{\mathrm{f}}=\mathscr{A}-\mathscr{\mathscr { A }}^{\prime}$ and $\mathrm{Q}_{\mathrm{g}}=\mathscr{B}-\mathscr{B}^{\prime}$ respectively. Since $\mathrm{K}_{f_{\lambda}}$ is connec-

```
4e}\mp@subsup{}{}{e}\mathrm{ SÉRIE - TOME 18-1985 - No 2
```

ted for all $\lambda \in \mathrm{W}$, $\mathrm{T}_{\mathbf{f}}$ can be extended to a homeomorphism $\hat{\mathrm{T}}_{\mathbf{f}}: \mathrm{W} \times\left(\overline{\mathrm{D}}_{\mathrm{R}}-\overline{\mathrm{D}}\right) \rightarrow \mathscr{A}-\mathscr{K}_{\mathrm{f}}$. Choose $\lambda \in \Gamma$ and let $\alpha$ be a hybrid equivalence of $f_{\lambda}$ and $g_{\lambda}$. Since this requires that $\mathrm{K}_{g_{\lambda}}$ be connected, $\mathrm{T}_{g_{\lambda}}$ can be extended to $\hat{T}_{g_{\lambda}}: \overline{\mathrm{D}}_{\mathrm{R}}-\overline{\mathrm{D}} \rightarrow \mathrm{B}_{\lambda}-\mathrm{K}_{g_{\lambda}}$.

Set $\mathbf{i}(\alpha)=\left[\hat{\mathrm{T}}_{g_{\lambda}} \circ \hat{\mathrm{T}}_{f}^{-1}, \alpha ; f_{\lambda}, g_{\lambda}\right] \in \mathbb{Z} /(d-1)$, (cf. $\left.\mathrm{I}, 4\right)$.
Then $\Gamma$ is the union of subsets $\Gamma_{i}$ for $i \in \mathbb{Z} /(d-1)$, where $\Gamma_{i}$ is the set of $\lambda \in \mathrm{W}$ for which there exists a hybrid equivalence $\alpha$ of $f_{\lambda}$ and $g_{\lambda}$ with $\mathbf{i}(\alpha)=i$.

We shall show that for each $i \in \mathbb{Z} /(d-1)$ the set $\Gamma_{i}$ is an analytic subset of W . By changing $\mathrm{T}_{f}$ or $T_{g}, \mathbf{i}(\alpha)$ is can be changed to any element of $\mathbb{Z} /(d-1)$, so we only need to show that $\Gamma_{0}$ is analytic.

Proof. - Choose $\lambda_{0} \in \mathrm{~W}$ and let $\Lambda^{\prime}$ be a neighborhood of $\lambda_{0}$ in W . Choose $\mathrm{T}_{g}: \Lambda^{\prime} \times \mathrm{Q}_{\mathrm{R}} \rightarrow \mathscr{V}$ a horizontally analytic tubing of $\mathbf{g}$ and $\tau: \Lambda^{\prime} \times \check{\mathrm{U}} \rightarrow \mathscr{U}$ an M-S-S trivialisation of $\mathbf{f}(c f$. Proposition 10).

Let $\mathrm{T}_{f_{\lambda_{0}}}: \mathrm{Q}_{\mathrm{R}} \rightarrow \mathrm{U}_{\lambda_{0}}$ be a tubing of $f_{\lambda_{0}}$, whose image is contained in $\check{\mathrm{U}}$ (since $\mathrm{K}_{f_{\lambda}}$ is connected, there are no critical values of $f_{\lambda_{0}}$ in $\mathrm{U}_{\lambda_{0}}-\mathrm{K}_{\lambda_{0}}$ ). Now define a horizontally analytic tubing $T_{f}$ of $f$ over $\Lambda^{\prime}$ by $T_{f, \lambda}=\tau_{\lambda} \circ T_{f_{\lambda_{0}}}$. The images $Q_{f}$ and $Q_{g}$ of $T_{f}$ and $T_{g}$ are respectively of the form $\mathscr{A}-\mathscr{A}^{\prime}$ and $\mathscr{B}-\mathscr{B}^{\prime}$, where $\mathscr{A}$ and $\mathscr{B}$ are homeomorphic to $\Lambda^{\prime} \times \mathrm{D}$.

For any $\lambda \in \Lambda^{\prime}$, set

$$
\gamma_{\lambda}=\mathrm{T}_{g, \lambda} \circ \mathrm{~T}_{f, \lambda}^{-1}: \mathrm{Q}_{\mathbf{f}, \lambda} \rightarrow \mathrm{Q}_{\mathbf{g}, \lambda}
$$

and

$$
\tilde{\gamma}_{\lambda}=\tau_{\lambda} \circ \gamma_{\lambda}: Q_{f, \lambda_{0}} \rightarrow Q_{g, \lambda}
$$

and define the Beltrami forms

$$
v_{\lambda, 0}=\bar{\partial} \gamma_{\lambda} / \partial \gamma_{\lambda} \quad \text { on } \quad \mathrm{Q}_{\mathbf{f}, \lambda}
$$

and

$$
\tilde{v}_{\lambda, 0}=\bar{\partial} \tilde{\gamma}_{\lambda} / \partial \tilde{\gamma}_{\lambda} \quad \text { on } \quad \mathrm{Q}_{f, \lambda_{0}}
$$

Further define $v_{\lambda}$ on $A_{\lambda}$ and $\tilde{v}_{\lambda}$ on $A_{\lambda_{0}}$ by

$$
\begin{array}{cccl}
v_{\lambda}=\left(f^{n}\right)_{v_{\lambda, 0}}^{*} & \text { on } Q_{f_{\lambda}, n}, & v=0 & \text { on } K_{f_{\lambda}} \\
\tilde{v}_{\lambda}=\left(f^{n}\right)_{v_{\lambda, 0}}^{*} & \text { on } Q_{f_{\lambda_{0}, n}}, & \tilde{v}=0 & \text { on } K_{f_{\lambda_{0}}} .
\end{array}
$$

Call $\theta_{\lambda}$ and $\tilde{\theta}_{\lambda}$ the complex structures on $A_{\lambda}$ and $A_{\lambda_{0}}$ defined by $v_{\lambda}$ and $\tilde{v}_{\lambda}$ respectively. The map $\lambda \mapsto \widetilde{v}_{\lambda}$ is a complex analytic map of $\Lambda^{\prime}$ into $L^{\infty}\left(A_{\lambda_{0}}\right)$, so there exists a unique complex structure $\tilde{\theta}$ on $\Lambda^{\prime} \times A_{0}$ inducing $\tilde{\theta}$ on $\{\lambda\} \times A_{\lambda_{0}}$ for each $\lambda \in \Lambda^{\prime}$ and such that $\Lambda^{\prime} \times\{x\}$ is an analytic submanifold for each $x \in \mathrm{~A}_{\lambda_{0}}(c f, \mathrm{I}, 3)$.

Let $\theta=\tau_{*}(\widetilde{\theta})$ be the corresponding complex structure on $\check{\mathscr{U}}=\tau\left(\Lambda^{\prime} \times \check{\mathrm{U}}\right)$; it induces $\theta_{\lambda}$ on $\tau_{\lambda}(\breve{\mathrm{U}})$ for each $\lambda$ and the $\tau\left(\Lambda^{\prime} \times\{x\}\right)$ are complex analytic submanifolds of $\check{\mathscr{U}}$.

Since $\theta=\sigma_{0}$ on $\mathscr{K} \cap \mathscr{U}$, it can be extended to $\mathscr{K} \cup \mathscr{U}$ by setting $\theta=\sigma_{0}$ on $\mathscr{K}$. Proposition 13 now follows from the following two Lemmas.

Lemma 1. - For any $\lambda \in \Lambda^{\prime}$, the following conditions are equivalent:
(i) $\lambda \in \Gamma_{0}$.
(ii) There exists an isomorphism

$$
\alpha: \quad\left(\AA_{\lambda}, \theta_{\lambda}\right) \rightarrow\left(\dot{\mathbf{B}}_{\lambda}, \sigma_{0}\right)
$$

extending $\gamma_{\lambda}$, and such that $\alpha \circ f_{\lambda}=g_{\lambda} \circ \alpha$ on $\mathrm{A}_{\lambda^{\prime}}$.
(iii) There exists a map $\alpha: \AA_{\lambda} \rightarrow \mathbb{C}$, holomorphic with respect to $\theta_{\lambda}$ and extending $\gamma_{\lambda}$.

Lemma 2. - Let $\boldsymbol{\Omega}$ be a complex analytic manifold, $\pi: \Omega \rightarrow \Lambda$ be a submersion, and $\boldsymbol{\Omega}^{\prime}$ be open in $\Omega$. Suppose both $\Omega$ and $\Omega^{\prime}$ are homeomorphic over $\Lambda$ to $\Lambda \times \mathrm{D}$, and that $\mathrm{Q}=\Omega-\bar{\Omega}^{\prime}$ is homeomorphic over $\Lambda$ to $\Lambda \times \mathrm{Q}_{\mathrm{R}} . \quad$ Let $h: \mathrm{Q} \rightarrow \mathbb{C}$ be a holomorphic function, and call $h_{\lambda}$ the restriction of $h$ to $\mathrm{Q}_{\lambda}=\mathrm{Q} \cap \pi^{-1}(\lambda)$. Then the set of $\lambda$ for which $h_{\lambda}$ extends to a holomorphic function on $\Omega_{\lambda}=\pi^{-1}(\lambda)$ is a closed analytic subset of $\Lambda$.

Proof of Lemma 1. - Clearly (ii) implies both (i) and (iii). To see that (i) implies (ii), let $\beta$ be a hybrid equivalence of $f_{\lambda}$ and $g_{\lambda}$ such that

$$
\mathbf{i}(\beta)=\left[\check{\mathrm{T}}_{g_{\lambda}} \circ \check{\mathrm{T}}_{f_{\lambda}}^{-1}, \beta ; f_{\lambda}, g_{\lambda}\right]=0
$$

Define $\alpha: \mathrm{A}_{\lambda} \rightarrow \mathrm{B}_{\lambda}$ by $\alpha=\check{\mathrm{T}}_{g_{\lambda}} \circ \check{\mathrm{T}}_{f_{\lambda}}^{-1}$ on $\mathrm{A}_{\lambda}-\mathrm{K}_{f_{\lambda}}$ and $\alpha=\beta$ on $\mathrm{K}_{f_{\lambda}}$. By Proposition 6 (I,4), $\alpha$ is an isomorphism of $\AA_{\lambda}$ with the complex structure $\theta_{\lambda}$ onto $\dot{B}_{\lambda}$ with the complex structure $\sigma_{0}$.
Next we show that (iii) implies (ii). For any $z \in \mathrm{~B}_{\lambda}^{\prime}$, the cardinal of $\alpha^{-1}(z)$, counted with multiplicity, is the winding number of a loop $\left.\alpha\right|_{\Gamma}$ around $z$, where $\Gamma$ is a loop in $\AA_{\lambda}$ near $\partial \mathrm{A}_{\lambda}^{\prime}$; it is 1 . If we had chosen $z$ in $\mathbb{C}-\mathrm{B}_{k}$, we would have found 0 . Therefore $\alpha$ is bijective from $\AA_{\lambda}$ onto $\mathbf{B}_{\lambda}$, and hence an isomorphism of $\left(\AA_{\lambda}, \theta_{\lambda}\right)$ onto ( $\left.\mathbf{B}_{\lambda}, \sigma_{0}\right)$.

The function $\alpha \circ f_{\lambda}-g_{\lambda} \circ \alpha$ is continuous on $A_{2}$, analytic on $\AA_{\lambda}$ for the structure $\theta_{\lambda}$ and vanishes on the boundary, so it vanishes on $A_{\lambda}$.

## Q.e.d. Lemma 1.

Proof of Lemma 2. - Let $\lambda_{0}$ be a point of $\Lambda, \zeta_{0}$ be an isomorphism of $\Omega_{\lambda_{0}}=\pi^{-1}\left(\lambda_{0}\right)$ onto D and let A be a closed disc embedded in $\Omega_{\lambda_{0}}$ containing $\bar{\Omega}_{\lambda_{0}}^{\prime}$. According to a Theorem of Grauert, there exists a Stein neighborhood $U$ of A in $\Omega$ and a holomorphic function $\zeta: \mathrm{U} \rightarrow \mathbb{C}$ extending $\zeta_{0}$.
We can find neighborhoods $\Lambda^{\prime}$ of $\lambda_{0}$ in $\Lambda$ and $W$ of $A$ in $U$, and an open subset $\mathrm{V} \subset \mathbb{C}$ such that

$$
\varphi: x \mapsto(\pi(x), \zeta(x))
$$

is an isomorphism of W onto $\Lambda^{\prime} \times \mathrm{V}$. Set $\Gamma=\zeta_{0}(\hat{\partial} \mathrm{~A})$ and $\Gamma_{\lambda}=\varphi^{-1}(\{\lambda\} \times \Gamma)$.

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

By restriction W if necessary, we may assume that $\Gamma_{\lambda} \subset \dot{Q}_{\lambda}$ for all $\lambda \in W$. The function $h_{\lambda}$ extends to an analytic function on $Q_{\lambda}$ if and only if the integrals

$$
\int_{\Gamma_{\lambda}} h_{\lambda} \zeta_{\lambda}^{n} d \zeta_{\lambda}
$$

vanish for all $n \geqq 0$. Since these integrals are analytic functions of $\lambda$, the set defined by these conditions is analytic.
Q.E.D.

Corollary 1. - Using the notations of II, 3, $\mathbf{P}_{\lambda}$ depends analytically on $\lambda$ for $\lambda$ in $\dot{\mathrm{M}}_{\mathbf{f}}$.
Proof. - By Proposition 11 (a) and Proposition 12, the map $\lambda \mapsto P_{\lambda}$ from $M_{f}$ into the affine space E of monic polynomials of degree $d$ with no term of degree $d-1$ is continuous. According to Proposition 6 , its graph is the set of $(\lambda, P) \in \Lambda \times E$ for which there is a hybrid equivalence $\alpha$ of $f_{\lambda}$ with $\mathrm{P}_{\lambda}$ such that $i(\lambda)=0$. This is an analytic subspace.

Corollary 2. - Suppose $d=2$ and let $c$ be a point of the standard Mandelbrot set M. The set $\chi^{-1}(c)$ is analytic.

Proof. - Let $\mathbf{p}$ be the constant family $p_{\lambda}=\mathrm{P}_{c}: z \mapsto z^{2}+c$. The set $\mathscr{R}$ for $\mathbf{p}$ is all of $\Lambda$. Corollary 2 follows by applying Proposition 13 to $p$ and $f$.
7. Continuity of $\chi$ in degree 2.

Lemma (valid for any degree). - Choose $\lambda_{0} \in \Lambda$ and let $\left(\lambda_{n}\right)$ be a sequence in $\Lambda$ converging to $\lambda_{0}$. Then there exists a subsequence $\left(\lambda_{k}^{*}\right)=\left(\lambda_{n_{k}}\right)$ such that the $\mathrm{P}_{\lambda_{k}^{*}}$ converge to a polynomial $\tilde{\mathrm{P}}$ and such that the $\varphi_{\lambda_{k}^{*}}$ converge uniformly on every compact subset of $\mathrm{A}_{\lambda_{0}}$ to a quasi-conformal equivalence $\tilde{\varphi}$ of $f_{\lambda_{0}}$ with $\widetilde{\mathrm{P}}$.

Remarks. - (1) If $\lambda_{0} \in \mathscr{R}$, then the Lemma follows from Proposition 12, with $\widetilde{\mathrm{P}}=\mathrm{P}_{\lambda_{0}}$.
(2) If $\lambda_{0} \in \mathscr{F}$, then $\bar{\partial} \tilde{\varphi}$ may fail to vanish on $\mathrm{K}_{\lambda_{0}}$, even if $d=2$. If $d \geqq 3$, the polynomial $\widetilde{\mathbf{P}}$ is not necessarily hybrid equivalent to $f_{\lambda_{0}}$, and may depend on the choice of the subsequence. We will show examples of all these pathologies in chapter III.

Proof of Lemma. - Since all the $\varphi_{\lambda_{n}}$ are quasi-conformal with the same dilatation ratio, they form an equicontinuous family. Moreover, any compact subset of $A_{\lambda_{0}}$ is contained in all but finitely many of the $A_{\lambda_{n}}$. The Lemma follows by Ascoli's Theorem.

Proposition 14. - If $d=2$, the map $\chi: \Lambda \rightarrow \mathbb{C}$ is continuous.
Proof. - By Proposition 12, $\chi$ is continuous on $\mathscr{R}$. It is therefore enough to show that for any sequence ( $\lambda_{n}$ ) in $\Lambda$ converging to a point $\lambda_{0} \in \mathscr{F}$ you can choose a subsequence $\lambda_{k}^{*}=\lambda_{n_{k}}$ such that the $\chi\left(\lambda_{k}^{*}\right)$ converge to $\chi\left(\lambda_{0}\right)$.

First let us show that $c_{0}=\chi\left(\lambda_{0}\right)$ belongs to $\partial \mathrm{M}$. Let $\left(\mu_{n}\right)$ be a sequence in $\mathscr{I}$ converging to $\lambda_{0}$. By the preceding Lemma, you can choose a subsequence $\mu_{k}^{*}$ such that $\chi\left(\mu_{k}^{*}\right)$ converge to a point $\tilde{c}^{\prime}$ for which $\tilde{\mathrm{P}}^{\prime}: z \rightarrow z^{2}+\tilde{c}^{\prime}$ is quasi-conformally equivalent to $\mathrm{P}_{0}: z \rightarrow z^{2}+c_{0}$.

ANNALES SCIENTIFIQUES DE L'ÉCOLE NORMALE SUPÉRIEURE

For any $n$, the point $c_{n}^{\prime}=\chi\left(\mu_{n}\right)$ belongs to $\partial \mathbf{M}$ since $\mathrm{P}_{n}^{\prime}: z \rightarrow z^{2}+c_{n}^{\prime}$ has an indifferent periodic point, like $f_{\mu_{n}}$. Therefore $\tilde{c}^{\prime}=\lim c_{n}^{\prime}$ belongs to $\hat{\delta} \mathbf{M}$, and $c_{0}=\tilde{c}^{\prime}$ by Proposition 7 (I,5).

Now let $\left(\lambda_{n}\right)$ be an arbitrary sequence of points of $\Lambda$ converging to $\lambda_{0}$. According to the Lemma, a subsequence ( $\lambda_{k}^{*}$ ) can be chosen so that $\chi\left(\lambda_{k}^{*}\right)$ converges to a point $\tilde{c}$ such that $\tilde{\mathrm{P}}: z \mapsto z^{2}+\tilde{c}$ is quasi-conformally equivalent to $\mathrm{P}_{0}$. By Proposition 7, $\tilde{c}=c_{0}$, so $c_{0}=\lim \chi\left(\lambda_{k}^{*}\right)$.
Q.E.D.

## CHAPTER III

## Negative results

1. Non-analyticity of $\chi$. - Let $f=\left(f_{\lambda}\right)_{\lambda_{\in \Lambda}}$ be an analytic family of polynomial-like mappings of degree 2 , and $\chi: \Lambda \rightarrow \mathbb{C}$ be the map defined in section II, 3. The following example shows that $\chi$ is not generally analytic on a neighborhood of $\partial \mathbf{M}_{\mathbf{f}}$.

Let $f:\left(f_{\lambda}\right)_{\lambda \in \Lambda}$ be an analytic family of polynomial-like mappings of degree 2. Let $\omega_{\lambda}$ be the critical point of $f_{\lambda}$; we will assume that $\Lambda$ is a neighborhood of 0 in $\mathbb{C}$, and that there is an analytic map $\lambda \mapsto \alpha_{\lambda}$ such that $\alpha_{\lambda}$ is a repulsive fixed point of $f_{\lambda}$ for all $\lambda \in \Lambda$, and that $f_{0}^{k}\left(\omega_{0}\right)=\alpha_{0}$. Set $\rho(\lambda)=f_{\lambda}^{\prime}\left(\alpha_{\lambda}\right)$.

Let $g_{\lambda}$ be a branch of $f_{\lambda}^{-1}$ defined near $\alpha_{\lambda}$, and such that $g_{\lambda}\left(\alpha_{\lambda}\right)=\alpha_{\lambda}$. Choose a sequence of analytic functions $\lambda \mapsto \alpha_{\lambda, n}$, restricting $\Lambda$ if necessary, so that:
(i) $\alpha_{\lambda, 0}=\alpha_{\lambda}$ and $\alpha_{\lambda, 1} \neq \alpha_{\lambda}$.
(ii) $f\left(\alpha_{n, n+1}\right)=\alpha_{n, n}$.
(iii) $g\left(\alpha_{\lambda, n}\right)=\alpha_{\lambda, n+1}$ for $n$ sufficiently large.

If $\lambda \mapsto f_{\lambda}^{k}\left(\omega_{\lambda}\right)-\alpha_{\lambda}$ has a simple zero at $\lambda=0$, there exists a sequence $\left(\lambda_{n}\right)_{n \leqq n_{0}}$ converging to 0 , such that $f_{\lambda_{n}}^{k}\left(\omega_{\lambda_{n}}\right)=\alpha_{\lambda_{n}, n}$; and the ratios $\lambda_{n+1} / \lambda_{n}$ converge to $1 / \rho(0)$.

Using the notations of II,4, set $c_{0}=\chi(0), a_{c 0}=\varphi_{0}\left(\alpha_{0}\right)$ and $a_{c 0, n}=\varphi_{0}\left(\alpha_{0, n}\right)$. For $c$ near $c_{0}$, the polynomial $\mathbf{P}_{c}: z \mapsto z^{2}+c$ has a repulsive fixed point $a_{c}$ near $a_{c 0}$, and we may define analytic functions $a_{c, n}$ of $c$ such that $a_{c, 0}=a_{c}$ and $a_{c, n+1}=\mathbf{P}_{c}^{-1}\left(a_{c, n}\right)$.
If the zero of $c \mapsto \mathrm{P}_{c}^{k}(0)-a_{c}$ at $c_{0}$ is simple (which in fact it always is), there exists a sequence $\left(c_{n}\right)_{n \geqq n_{0}}$ converging to $c_{0}$ such that $\mathrm{P}_{c_{n}}^{k}(0)=a_{c_{n}, n}$; the ratios

$$
\frac{c_{n+1}-c_{0}}{c_{n}-c_{0}}
$$

converge to $1 / \mathrm{P}_{c_{0}}^{\prime}\left(a_{c 0}\right)$.
There exists a neighborhood V of $c_{0}$ such that for $n \geqq n_{1}, c_{n}$ is the only point of V such that $\mathrm{P}_{c_{n}}^{k}(0)=a_{c_{n}, n}$, therefore $\chi\left(\lambda_{n}\right)=c_{n}$ for all $n$ sufficiently large. If $\rho(0)=f_{0}^{\prime}\left(\alpha_{0}\right) \neq P_{c_{0}}^{\prime}\left(a_{c_{0}}\right)$, the ratios $\lambda_{n+1} / \lambda_{n}$ and

$$
\frac{c_{n+1}-c_{0}}{c_{n}-c_{0}}
$$

will have different limits. Therefore $\chi$ is not analytic near 0 .

$$
4^{e} \text { SERIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

Remark. - The reader who examines Figures 3 and 6 carefully will observe that the "trunk of the elephant" is more open in Figure 6. This can be understood as an example of the above computation. In both pictures, the tip of the trunk corresponds to a mapping for which the critical point lands on the $12^{\prime}$ th move on a repulsive cycle of length 2. Moreover, the tree which describes the combinatorics of the mappings [D-H] is the same. However, the eigenvalues of the cycles in the two drawings are different.
2. Non-CONTINUity of $\lambda \mapsto \varphi_{\lambda}$ in degree 2. - Let $\left(f_{\lambda}\right)_{\lambda \in \Lambda}$ be an analytic family of polynomial-like mappings of degree 2 . We will take $\Lambda$ a neighborhood of 0 in $\mathbb{C}, \mathrm{U}_{\lambda}^{\prime}$ and $\mathrm{U}_{\lambda}$ symmetrical with respect to $\mathbb{R}$ and we will assume that $f_{\lambda}(z)=f_{\lambda}(z)$ for all $\Lambda \in \mathbb{R}$. Choose for each $\lambda$ a hybrid equivalence $\varphi_{\lambda}: \mathrm{V}_{\lambda} \rightarrow \mathbb{C}$ of $f_{\lambda}$ with a polynomial $\mathrm{P}_{\lambda}: z \rightarrow z^{2}+\chi(\lambda)$, with the $\varphi_{\lambda}$ all quasi-conformal, of dilatation ratio bounded by a constant independant of $\lambda$. Suppose that all $V_{\lambda}$ contain a fixed neighborhood of $K_{0}$, are symmetric with respect to $\mathbb{R}$ and that $\varphi_{\lambda}(\bar{z})=\overline{\varphi_{\lambda}(z)}$ for $\lambda \in \mathbb{R}$. (We are not assuming that the $\varphi_{\lambda}$ are obtained from a tubing.)

If $\left(\lambda_{n}\right)$ is a sequence converging to 0 , there is a subsequence $\left(\lambda_{n_{k}}\right)$ such that the $\left(\varphi_{\lambda_{n_{k}}}\right)$ converge to a limit $\tilde{\varphi}$, which is a quasi-conformal equivalence of $f_{0}$ with a polynomial $\widetilde{\mathrm{P}}: z \rightarrow z^{2}+\tilde{c}$.

Suppose that $f_{0}$ has a fixed point $\alpha_{0}$ with $f^{\prime}\left(\alpha_{0}\right)=1$, and that for $\lambda>0$ the map $f$ has two conjugate fixed points $\alpha_{\lambda}$ and $\bar{\alpha}_{\lambda}$ which are then necessarily repulsive. Then $\chi(0)=1 / 4$, and $\chi(\lambda)>1 / 4$ for $\lambda>0$.

Proposition 15. - If $\lambda_{n}>0$ for all $n$, then $\tilde{\varphi}=\varphi_{0}$ only if $f_{0}$ is holomorphically equivalent to $z \rightarrow z^{2}+1 / 4$.

Proof. - If $\mathrm{G} \subset \mathrm{U}$ is open, $\mathrm{G} / f_{\lambda}$ will be the quotient of G by the equivalence relation generated by setting $x$ equivalent to $f_{\lambda}(x)$ whenever both $x$ and $f_{\lambda}(x)$ are in G. Pick $u>0$ and for $\lambda \geqq 0$ let $G_{\lambda}$ (resp. $H_{\lambda}$ ) denote the disc centered at $\operatorname{Re}\left(\alpha_{\lambda}\right)-u\left[\operatorname{resp} . \operatorname{Re}\left(\alpha_{\lambda}\right)+u\right]$, the edge of which contains $\alpha_{\lambda}$ and $\bar{\alpha}_{\lambda}$. Set $X_{\lambda}=G_{\lambda} / f_{\lambda}$ and $Y_{\lambda}=H_{\lambda} / f_{\lambda}$. If $u$ and $\lambda$ are sufficiently small, then both $X_{\lambda}$ and $Y_{\lambda}$ are isomorphic to the cylinder $\mathbb{C} / \mathbb{Z}$. For $\lambda>0$ both $X_{\lambda}$ and $Y_{\lambda}$ can be identified to $\left(G_{\lambda} \cup H_{\lambda}\right) / f_{\lambda}$, and this induces an isomorphism $E_{\lambda}: X_{\lambda} \rightarrow Y_{\lambda}$. There is no mapping $E_{0}$ but if $\left(\lambda_{n}\right)$ is a sequence of positive numbers converging to zero, then a subsequence ( $\lambda_{n_{k}}$ ) can be chosen so that the $\mathrm{E}_{\lambda_{n_{k}}}$ converge to an isomorphism $\tilde{E}: X_{0} \rightarrow Y_{0}$.

The Beltrami form $\mu_{\lambda}=\bar{\partial} \varphi_{\lambda} / \partial \varphi_{\lambda}$ is $f$-invariant for all $\lambda$, so for all $\lambda>0$ we find Beltrami forms $\mu_{\lambda}^{\mathbf{X}}$ and $\mu_{\lambda}^{\mathbf{Y}}$ on $X_{\lambda}$ and $Y_{\lambda}$ respectively. For $\lambda>0$ we have $\mu_{\lambda}^{\mathbf{X}}=\mathrm{E}_{\lambda}^{*} \mu_{\lambda}^{\mathbf{Y}}$. Therefore if $\left(\lambda_{n}\right)$ is a sequence for which the $\left(\varphi_{\lambda_{n}}\right)$ and the $E_{\lambda_{n}}$ ) have limits $\tilde{\varphi}$ and $\tilde{E}$, set $\tilde{\mu}=\bar{\partial} \tilde{\varphi} / \partial \tilde{\varphi}$, and we get $\tilde{\mu}^{\mathbf{X}}=\tilde{\mathrm{E}}^{*} \mu_{0}^{\mathbf{Y}}$. If $\tilde{\varphi}=\varphi_{0}$, we get $\mu_{0}^{\mathbf{X}}=\tilde{\mathrm{E}}^{*} \mu_{0}^{\mathbf{Y}}$, but $\mu_{0}^{\mathrm{X}}=0$, at least if $\omega_{0}<\alpha_{0}$ and if $u$ is sufficiently small, for in that case $G_{0} \subset \dot{K}_{0}$. So $\mu_{0}^{Y}=0$, and $\mu_{0}=0$ on $H_{0}$.

Since $K_{0} \cup H_{0}$ is a neighborhood of $\alpha_{0}$ which is in the Julia set, and since $\mu_{0}$ is $f_{0}$ invariant, we find that $\mu_{0}$ vanishes on a neighborhood of $K_{0}$. This is just another way of saying that $\varphi_{0}$ is a holomorphic equivalence of $f_{0}$ and $\mathrm{P}_{0}$ (Fig. 10).

4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

3. A family of polynomials. - In this paragraph we will study a family of polynomials of degree 3 , the properties of which will be used in section 4 to construct a third counterexample.

For any $a \in \mathbb{R}_{+}$, define $\mathrm{Q}=\mathrm{Q}_{a}$ by

$$
\mathrm{Q}_{a}(z)=z+a z^{2}-z^{3}
$$

This polynomial has two real critical points $\omega$ and $\omega^{\prime}$ with $\omega<0<\omega^{\prime}$, and the point $\alpha=0$ is an indifferent fixed point with $\mathrm{Q}^{\prime}(\alpha)=1$. Set $\omega_{i}=\mathrm{Q}^{i}(\omega)$ and $\omega_{i}^{\prime}=\mathrm{Q}^{i}\left(\omega^{\prime}\right)$; the $\omega_{i}$ are for each $a$ an increasing sequence tending to 0 , and each $\omega_{i}$ is an increasing function of $a$.

There is a value $a_{\infty}$ of a for which $\omega_{2}^{\prime}=0$; for $a \geqq a_{\infty}$ the point $\omega_{2}^{\prime}$ is a decreasing function of $a$. Thus there is a decreasing sequence $\left(a_{n}\right)$ tending to $a_{\infty}$ such that $\omega_{2}^{\prime}=\omega_{n}$ for $a=a_{n}$. Set $\mathrm{I}=\left[a_{0}, a_{\infty}\left[\right.\right.$ and $\mathrm{I}_{n}=\left[a_{n}, a_{n+1}\right]$.

For $a \in \mathrm{I}$, the graph of $\left.\mathrm{Q}\right|_{\mathbb{R}}$ and the Julia set of Q look as Figures 11-12.
There exists a neighborhood of 0 on which $Q$ is polynomial-like of degree 2, hybrid equivalent to $z \rightarrow z^{2}+1 / 4$. If $a$ and $b$ are both in $\left.\mathrm{I}_{n}=\right] a_{n}, a_{n+1}\left[\right.$, the polynomials $\mathrm{Q}_{a}$ and $\mathrm{Q}_{b}$ are quasi-conformally conjugate; if $a$ and $b$ are simply in I , by [M-S-S] and Proposition 4 there exists a quasi-conformal homeomorphism $\psi_{a, b}: \mathbb{C} \rightarrow \mathbb{C}$, holomorphic on $\mathbb{C}-\mathrm{K}_{a}$, conjugating $\mathrm{Q}_{a}$ to $\mathrm{Q}_{b}$ on a neighborhood of $\mathrm{J}_{a}$ and on $\mathbb{C}-\mathrm{K}_{a}$. The $\psi_{a, b}$ can be chosen to depend continuously on $a, b$ and with dilatation ratio bounded on compact subsets of $\mathrm{I} \times \mathrm{I}$; let $\kappa_{n}$ be a bound for $(a, b) \in \mathrm{I}_{n} \times \mathrm{I}_{n}$.

We shall now describe an invariant of the $\mathrm{Q}_{a}$ as $a$ varies in $\mathrm{I}_{n}$.
A polynomial-like mapping $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ will be of real type if U and $\mathrm{U}^{\prime}$ are symmetrical with respect to the real axis, and $f(\bar{z})=\overline{f(z)}$. Let $f: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ be a polynomial-like mapping of real type, quasi-conformally equivalent to some $\mathrm{Q}_{a}$ with $a \in \mathrm{I}$. We will define an invariant $\theta(f) \in \mathbb{T}=\mathbb{R} / \mathbb{Z}$.

The map $f$ has an indifferent fixed point $\alpha$ with $f^{\prime}(\alpha)=1$, and two critical points $\omega=\omega_{f}$ and $\omega^{\prime}=\omega_{f}^{\prime}$. By a change of variables we may assume $\alpha=0, f^{\prime \prime}(\alpha)>0$ and $\omega<0<\omega^{\prime}$.

Let $G$ and $H$ be open discs of radius a small number $u$, centered at $-u$ and $u$ respectively. Set $\mathrm{X}=\mathrm{G} / f$ and $\mathrm{Y}=\mathrm{H} / f$, and let $\omega^{\mathrm{X}}$ and $\omega^{\prime \mathrm{X}}$ be the points of X given by the orbits of $\omega_{f}$ and $\omega_{f}^{\prime}$ respectively. More generally, if F is an $f$-invariant subset of U we will call $F^{\mathbf{X}}$ (resp. $\mathrm{F}^{\mathbf{Y}}$ ) the image of $\mathrm{F} \cap \mathrm{G}$ in X (resp. the image of $\mathrm{F} \cap \mathrm{H}$ in Y ).

The manifolds $X$ and $Y$ are isomorphic to the cylinder $\mathbb{C} / \mathbb{Z}$. If $x$ and $y$ are two points of X , let $x-y$ be the point $h(x)-h(y)$ of $\mathbb{C} / \mathbb{Z}$, where $h$ is an isomorphism of X onto $\mathbb{C} / \mathbb{Z}$ respecting the orientation of the equator. Clearly $x-y$ does not depend on the choice of $h$. If $x$ and $y$ are in $Y$, we may similarly define $x-y$. More generally, if $\mu$ is an $f$-invariant Beltrami form on U and $x, y \in \mathrm{X}$, we set

$$
[x-y]_{\mu}=h_{\mu}(x)-h_{\mu}(y)
$$

where $h: X \rightarrow \mathbb{C} / \mathbb{Z}$ is a quasi-conformal homeomorphism such that $\bar{\partial} h / \partial h=\mu^{\mathbf{X}}$.

Set $\theta(f)=\omega^{\prime \mathbf{X}}-\omega^{\mathbf{X}}$. If $f \sim_{h b} g$, then $\theta(f)=\theta(g)$. Indeed, $\mathrm{G} \subset \mathrm{K}_{f}$, and therefore a hybrid equivalence of $f$ with $g$ gives an analytic isomorphism of $\mathrm{X}_{f}$ onto $\mathrm{X}_{g}$.

If $\mu$ is an $f$-invariant Beltrami form on $U$ (or even on $K_{f}$ ), set $\theta_{\mu}(f)=\left[\omega^{\prime X}-\omega^{\mathbf{X}}\right]_{\mu}$.
4. Non-continuity of $\lambda \mapsto P_{\lambda}$ in degree 3.

Proposition 16. - There exists an analytic family $\left(f_{\lambda}\right)_{\lambda_{\in \Lambda}}$ of polynomial-like mappings of degree 3 , and a sequence $\left(\lambda_{n}\right)$ of points of $\mathbf{M}_{\mathbf{f}} \subset \Lambda$, converging to a point $\lambda_{0}$ such that the polynomials $\mathrm{P}_{\lambda_{n}}$ constructed in $\mathrm{II}, 3$ have a limit $\widetilde{\mathrm{P}}$ which is not affine conjugate to $\mathrm{P}_{\lambda_{0}}$.

Our construction will give polynomials $\widetilde{\mathrm{P}}$ and $\mathrm{P}_{\lambda_{0}}$ which will be affine conjugate to elements of the family $\left(\mathrm{Q}_{a}\right)_{a \in I}$ studied in paragraph 2. (In order to have actual elements of that family, we would have to change the convention that they be monic.) We will see that $P_{\lambda_{0}}$ and $\tilde{P}$ are not affine conjugate by showing that $\theta\left(P_{\lambda_{0}}\right) \neq \theta(\widetilde{\mathrm{P}})$.

We will use the counter-example of section 2 . Our $\Lambda$ will be a neighborhood of 0 in $\mathbb{C}, \lambda_{0}=0$, and all constructions will be equivariant under $z \mapsto \bar{z}$.

We will start from a polynomial $\mathrm{Q}=\mathrm{Q}_{a}$ with $a \in \mathrm{I}$, an isomorphism $\mathrm{E}: \mathrm{X}_{\mathrm{Q}} \rightarrow \mathrm{T}_{\mathrm{Q}}$ and a Beltrami form $v$ defined on a neighborhood $\mathrm{U}_{\mathrm{Q}}$ of $\mathrm{K}_{\mathrm{Q}}$. We will assume that $\mathrm{U}_{\mathrm{Q}}$ is homeomorphic to D , that $\mathrm{U}_{\mathrm{Q}}^{\prime}=\mathrm{Q}^{-1}\left(\mathrm{U}_{\mathrm{Q}}\right)$ (necessarily homeomorphic to D ) is relatively compact in $\mathrm{U}_{\mathrm{Q}}$, and that $\mathrm{Q}^{*} v=\left.v\right|_{\mathrm{U}^{\prime}}$ and $\mathrm{E}^{*} v^{\mathbf{Y}}=v^{\mathbf{X}}$ (we will say that $v$ is invariant by Q and E).

We will require more of $Q$ and $E$. Set $J_{Q}=\partial K_{Q}$; in this case $J_{Q}^{Y} \cap \mathbb{R}$ is infinite, in fact a Cantor set.

Lemma 1. - Q and E can be chosen so that $\omega^{\mathrm{x}}$ and $\omega^{\prime X}$ are different points of $\mathrm{E}^{-1}\left(\mathrm{~J}_{\mathrm{Q}}^{\mathrm{Y}}\right)$.

Proof of Lemma. - When $a$ varies in I , the set $\mathrm{J}_{\mathrm{Q}}$ remains homeomorphic to itself, as do $J_{\mathrm{Q}}^{\mathrm{Y}}$ and $\mathrm{J}_{\mathrm{Q}}^{\mathrm{Y}} \cap \mathbb{R}^{\mathrm{Y}}$; the $\mathrm{J}_{\mathrm{Q}_{a}}$ (and the $\mathrm{J}_{\mathrm{Q}_{a}}^{\mathrm{Y}}$ and the $\mathrm{J}_{\mathrm{Q}_{a}}^{\mathrm{Y}} \cap \mathbb{R}^{\mathbf{Y}}$ ) are the fibers of a trivial fibration over $I$.

Thus there exist two continuous maps $a \mapsto x(a)$ and $a \mapsto y(a)$ such that $x(a)$ and $y(a)$ are distinct points of $\mathrm{J}_{\mathrm{Q}_{a}}^{\mathrm{Y}} \cap \mathbb{R}^{\mathrm{Y}}$. For any $a \in \mathrm{I}$, choose $\mathrm{E}_{a}$ so that $\mathrm{E}_{a}\left(\omega_{a}^{\mathrm{X}}\right)=x(a)$. Then for any $n \in \mathbb{N}$, there exists $a_{n} \in \mathrm{I}$ such that $\mathrm{Q}^{2}\left(\omega^{\prime}\right)=\mathrm{Q}^{n}(\omega)$ when $a=a_{n}$. As a varies from $a_{n}$ to $a_{n+1}$, the angle $\omega_{a}^{\mathbf{X}}-\omega_{a}^{\mathrm{X}}$ makes one complete revolution. Therefore there exists $a \in] a_{n}, a_{n+1}\left[\right.$ for which $\mathrm{E}_{a}\left(\omega_{a}^{\prime \mathrm{X}}\right)=y(a)$.

## Q.E.D.

Proof of the Proposition. - We will assume that Q and E have been chosen so as to satisfy Lemma 1. Choose a neighborhood $\mathrm{U}_{\mathrm{Q}}$ of $\mathrm{K}_{\mathrm{Q}}$ as above, and a Beltrami form $v$ on $\mathrm{U}_{\mathrm{Q}}$, invariant by Q and E .

We shall take $f_{0}$ to be the mapping $\mathrm{Q}: \mathrm{U}_{\mathrm{Q}}^{\prime} \rightarrow \mathrm{U}_{\mathrm{Q}}$, with $\mathrm{U}_{\mathrm{Q}}$ and $\mathrm{U}_{\mathrm{Q}}^{\prime}$ carrying the complex structure defined by $v$. More precisely, let $\psi$ be a quasi-conformal diffeomorphism of $\mathrm{U}_{\mathrm{Q}}$ onto an open subset $\mathrm{U}_{0} \subset \mathbb{C}$, such that $\bar{\partial} \psi / \partial \psi=v$ and $\psi(0)=0$. Set $f_{0}=\psi \circ \mathrm{Q}^{\circ} \psi^{-1}: \mathrm{U}_{0}^{\prime} \rightarrow \mathrm{U}_{0}$, where $\mathrm{U}_{0}^{\prime}=\psi\left(\mathrm{U}_{\mathrm{Q}}^{\prime}\right)$. We may normalize $\psi$ so that $f_{0}(z)=z+z^{2}+O\left(|z|^{3}\right)$ near 0 .

For any $\lambda \in \mathbb{C}$ set $f_{\lambda}(z)=f_{0}(z)+\lambda$. In a neighborhood $\Lambda$ of 0 the mapping $f_{\lambda}$ is polynomial-like of degree 3 from $\mathrm{U}_{0}^{\prime}$ onto $\mathbf{U}=\mathrm{U}_{0}+\lambda$. For $\lambda \in \mathbb{R}_{+} \cap \Lambda$, the mapping $f_{\lambda}$

$$
4^{\mathrm{c}} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

has two conjugate repulsive fixed points $\alpha$ and $\bar{\alpha}$ close to 0 . The interval $\left[\omega_{2}, f_{\lambda}\left(\omega^{\prime}\right)\right]$ is sent into itself, so $\omega_{\lambda}$ and $\omega_{\lambda}^{\prime}$ both belong to $\mathrm{K}_{\lambda}$, hence $\mathrm{K}_{\lambda}$ is connected and the polynomial $\mathrm{P}_{\lambda}$ obtained by straightening $f_{\lambda}$ does not depend on the choice of a tubing.

Clearly $\theta\left(\mathbf{P}_{0}\right)=\theta\left(f_{0}\right)=\theta_{v}(\mathrm{Q})$. We will show that for appropriate choices of $v$ and of the sequence $\left(\lambda_{n}\right)$ in $\Lambda \cap \mathbb{R}_{+}^{*}$, the $\mathrm{P}_{\lambda_{n}}$ have a limit $\tilde{\mathrm{P}}$ such that $\theta(\tilde{\mathrm{P}}) \neq \theta_{\mathrm{v}}(\mathrm{Q})$.

As in section III,3, define for each $\lambda \in \Lambda \cap \mathbb{R}_{+}^{*}$ cylinders $X_{\lambda}$ and $Y_{\lambda}$, and an isomorphism $E_{\lambda}: X_{\lambda} \rightarrow Y_{\lambda}$. As before there is no $E_{0}$, but $E^{\psi}=\psi^{Y} \circ E \circ\left(\psi^{X}\right)^{-1}$ is an isomorphism of $\mathrm{X}_{0}$ onto $\mathrm{Y}_{0}$.

Lemma 2. - There exists a sequence $\left(\lambda_{n}\right)$ in $\Lambda \cap \mathbb{R}_{+}^{*}$ converging to 0 , such that the $\mathrm{E}_{\lambda_{n}}$ converge to $\mathrm{E}^{\psi}$.

Proof. - Let $u$ and $v$ be two points of $\mathrm{U}_{0}^{\prime} \cap \mathbb{R}$ close to 0 , such that $u<0<v$ and $\mathrm{E}^{\psi}\left(u^{\mathrm{X}}\right)=v^{\mathrm{Y}}$. For any integer $n \geqq 1$, the mapping $g_{n}: \lambda \mapsto f_{\lambda}^{n}(u)$ is increasing for $\lambda$ in some interval $\left[0, \lambda_{n}^{+}\right]$, with $g_{n}(0)<0$ and $g_{n}\left(\lambda_{n}^{+}\right)>v$, therefore there exists $\left.\lambda_{n} \in\right] 0, \lambda_{n}^{+}[$such that $g_{n}\left(\lambda_{n}\right)=v$ (Fig. 13).

Fig. 13
Then $\mathrm{E}_{\lambda_{n}}\left(u^{\mathrm{X}}\right)=v^{\mathrm{Y}}$, and so the $\mathrm{E}_{\lambda_{n}}$ have the limit $\mathrm{E}^{\psi}$. For all $\lambda>0$, there exists an $n$ for which $g_{n}(\lambda)>v$, so the sequence $\left(\lambda_{n}\right)$ converges to 0 .
Q.E.D.

Proposition 16 now follows from Lemmas 3 and 4.
Lemma 3. - If $\left(\lambda_{n}\right)$ satisfies the conditions of Lemma 2 and if a subsequence $\left(\lambda_{k}^{*}\right)$ is chosen so that the $\mathrm{P}_{\lambda_{k}^{*}}$ have a limit $\tilde{\mathrm{P}}$, there exists a Beltrami form $\delta$ on $\mathbb{C}$, invariant under Q and E , vanishing on $\mathbb{C}-\mathrm{K}_{\mathrm{Q}}$, and such that $\theta(\widetilde{\mathrm{P}})=\theta_{\dot{\delta}}(\mathrm{Q})$.
Proof. - The mapping $\psi$ is a quasi-conformal equivalence of Q with $f_{0}$ and $v=\widetilde{\partial} \psi / \partial \psi . \quad$ Let

$$
\mathrm{T}_{\mathbf{Q}}: \quad \overline{\mathrm{D}}_{\mathrm{R}}-\mathrm{D}_{\mathrm{R}^{\prime}} \rightarrow \mathrm{A}_{\mathrm{Q}}-\AA_{\mathrm{Q}^{\prime}}^{\prime}
$$

be an analytic tubing of Q (since $\mathrm{K}_{\mathrm{Q}}$ is connected, this is possible by Proposition 4), and choose a tubing $\mathrm{T}=\left(\mathrm{T}_{\lambda}\right)$ of $f$ such that $\mathrm{T}_{0}=\psi \circ \mathrm{T}_{\mathrm{Q}}$. Construct $\left(\varphi_{\lambda}\right)$ and $\left(\mathrm{P}_{\lambda}\right)$ from T as in II,3. By the Lemma of II,7 there is a subsequence $\left(\lambda_{k}^{*}\right)$ such that the $\varphi_{\wedge_{k}}$ converge to a quasi-conformal equivalence $\tilde{\varphi}$ of $f_{0}$ with $\tilde{\mathrm{P}}_{0}$.

Then $\tilde{\mu}=\bar{\partial} \tilde{\varphi} / \partial \tilde{\varphi}$ is a Beltrami form on $\mathrm{U}_{0}$, invariant under $f_{0}$ and E , which agrees on $\mathrm{A}-\AA^{\prime}$ with $\bar{\partial} \psi^{-1} / \partial \psi^{-1}$. The mapping $\Phi=\tilde{\varphi}^{\circ} \psi$ is a quasi-conformal equivalence of Q with $\widetilde{\mathrm{P}}$, and $\delta=\bar{\partial} \Phi / \partial \Phi$ is a Beltrami form on a neighborhood of $\mathrm{K}_{\mathrm{Q}}$, invariant under Q and $E$ and vanishing on $A_{Q}-K_{Q}$. Set $\mu=0$ on $\mathbb{C}-K_{Q}$ to get a Beltrami form on C. Then $\theta(\widetilde{\mathrm{P}})=\theta_{\boldsymbol{o}}(\mathrm{Q})$.
Q.E.D.

Lemma 4. - Let Q and E satisfy the conditions of Lemma 1.
(a) For any $\varepsilon>0$, there exists a Beltrami form v on a neigborhood of $\mathrm{K}_{\mathrm{Q}}$, invariant under Q and E , such that $0<\theta_{\mathrm{v}}(\mathrm{Q})<\varepsilon$.
(b) There exists $m>0$ such that any Beltrami form $\delta$ on $\mathbb{C}$, invariant under Q and E and vanishing on $\mathbb{C}-\mathrm{K}_{\mathrm{Q}}$, satisfies $\theta_{\mathrm{v}}(\mathrm{Q}) \in[m, 1-m]$.

Proof of $(a)$. - The polynomial Q is $\mathrm{Q}_{a}$ for a in some $\mathrm{I}_{n}$. Choose $\varepsilon>0$, and let $\varepsilon^{\prime}$ be such that for any quasi-conformal homeomorphism $h: \mathbb{C} / \mathbb{Z} \rightarrow \mathbb{C} / \mathbb{Z}$ of dilatation ratio $\leqq \kappa_{n}$ ( $\kappa_{n}$ is defined in II.2), $d(h(u), h(v))<\varepsilon$ if $d(u, v)<\varepsilon^{\prime}$.

Choose a quasi-conformal homeomorphism $\Psi$ of $Y_{Q}$ onto itself, holomorphic on a neighborhood of $K_{\mathrm{Q}}^{\mathrm{Y}}$, and such that

$$
0<\Psi\left(\mathrm{E}\left(\omega^{\prime}\right)\right)-\Psi(\mathrm{E}(\omega))<\varepsilon^{\prime}
$$

Set $\mu_{0}=\bar{\partial} \Psi / \partial \Psi$, and let $\mu$ be the corresponding Beltrami form on $K_{Q} \cup H$, vanishing on $\mathrm{K}_{\mathrm{Q}}$ and invariant under $\left.\mathrm{Q}^{-1}\right|_{\mathrm{H}}$. Let $\mathrm{V}_{\mathrm{O}}$ be a neighborhood of $\mathrm{K}_{\mathrm{Q}}$ with $\mathrm{V}_{1}=\mathrm{Q}^{-1}\left(\mathrm{~V}_{0}\right)$ relatively compact in $\mathrm{V}_{0}$.

There then exists a unique Beltrami form $v_{0}$, invariant under $Q$, agreeing with $\mu$ on $\left(V_{0}-V_{1}\right) \cap H$, and vanishing on $\left(V_{0}-V_{1}\right)-H$ and on $K_{Q}$. In general, $v_{0}^{Y} \neq \mu_{0}$, but if $v_{n}$ is the Beltrami form on $V_{n}=Q^{-n}\left(V_{0}\right)$ defined in the same way, then $\left\|v_{n}^{Y}\right\|_{\infty}<\left\|\mu_{0}\right\|_{\infty}$ for all $n$, and $v_{n}^{Y} \rightarrow 0$ in $L^{1}$. So $0<\left[\mathrm{E}\left(\omega^{\prime}\right)-\mathrm{E}(\omega)\right]_{v_{n}}<\varepsilon^{\prime}$ for sufficiently large $n$.

Let $v$ be the Beltrami form on $V_{n}$, invariant under $Q$ and $E$ and agreeing with $v_{n}$ on $\mathrm{V}_{n}-\mathrm{K}_{\mathrm{Q}}$. There is a quasi-conformal equivalence $\Phi$ of $\mathrm{Q}=\mathrm{Q}_{a}$ with a polynomial $\mathrm{Q}_{b}$, $b \in I_{n}$, such that

$$
\bar{\partial} \Phi / \partial \Phi=v \quad \text { on } \quad K_{Q}
$$

and

$$
=0 \quad \text { on } \quad \mathbb{C}-\mathrm{K}_{\mathrm{Q}}
$$

and $\Phi$ agrees with $\psi_{a, b}$ on $\mathrm{J}_{\mathrm{Q}}$.
Let $v^{*}$ be the form which agrees with $v$ (and hence with $v_{n}$ ) on $\mathrm{V}_{n}-\mathrm{K}_{\mathrm{Q}}$ and with $\bar{\partial} \psi_{a, b} / \partial \psi_{a, b}$ on $\mathrm{K}_{\mathrm{Q}}$. Then

$$
\theta_{v}(\mathrm{Q})=\left[\mathrm{E}\left(\omega^{\prime}\right)-\mathrm{E}(\omega)\right]_{v}=\left[\mathrm{E}\left(\omega^{\prime}\right)-\mathrm{E}(\omega)\right]_{v}^{*}
$$

However, the identity of $Y$, taken with the structure defined by $v_{n}$ in the domain and that defined by $v^{*}$ in the range, is quasi-conformal with dilatation ratio bounded by $\kappa_{n}$. Considering how $\varepsilon^{\prime}$ was chosen, we see that $\theta_{\mathrm{v}}(\mathrm{Q})<\varepsilon$.

```
4* SÉRIE - TOME 18-1985 - No 2
```

Proof of part (b). - The polynomial Q is $\mathrm{Q}_{a}$ for some $a \in \mathrm{I}_{n}$, and some $n \in \mathbb{N}$. Let $\Phi$ be a quasi-conformal homeomorphism of $\mathbb{C}$ such that $\bar{\partial} \Phi / \partial \Phi=\delta, \Phi(z) / z \rightarrow 1$ as $z \rightarrow \infty$ and $\Phi(0)=0$.

Then $\Phi \circ Q \circ \Phi^{-1}$ is $\mathrm{Q}_{b}$ for some $b \in \mathrm{I}_{n}$, and there exists $\Psi_{a, b}$, quasi-conformal of dilatation ratio $\leqq \kappa_{n}$, holomorphic on $\mathbb{C}-K_{a}$ and conjugating $Q_{a}$ to $Q_{b}$ there. On $\mathbb{C}-K_{a}$, $\Phi$ and $\psi_{a, b}$ agree, since they are both holomorphic and conjugate $Q_{a}$ to $Q_{b}$. By continuity, they also agree on $\mathrm{J}_{a}$.

Using $\Phi$ we define $\Phi^{\mathrm{X}}: \mathrm{X}_{a} \rightarrow \mathrm{X}_{b}$ and $\Phi^{\mathrm{Y}}: \mathrm{Y}_{a} \rightarrow \mathrm{Y}_{b}$; then $\mathrm{E}_{b}=\Phi^{\mathrm{Y}} \circ \mathrm{E} \circ\left(\Phi^{\mathrm{X}}\right)^{-1}$ is an isomorphism of $X_{b}$ onto $Y_{b}$ since $\delta$ is E-invariant.

Let $\omega$ and $\omega^{\prime}$ be the critical points of $\mathrm{Q}=\mathrm{Q}_{a}$; then
$\theta_{\delta}(\mathrm{Q})=\Phi^{\mathrm{X}}\left(\omega^{\prime \mathrm{X}}\right)-\Phi^{\mathrm{X}}\left(\omega^{\mathrm{X}}\right)=\mathrm{E}_{b}\left(\Phi^{\mathrm{X}}\left(\omega^{\prime \mathrm{X}}\right)\right)-\mathrm{E}_{b}\left(\Phi^{\mathrm{X}}\left(\omega^{\mathrm{X}}\right)\right)=\Phi^{\mathrm{Y}}\left(\mathrm{E}\left(\omega^{\prime \mathrm{X}}\right)\right)-\Phi^{\mathrm{Y}}\left(\mathrm{E}\left(\omega^{\mathrm{X}}\right)\right)$.
The mapping $\Psi_{a, b}$ conjugates $\mathrm{Q}_{a}$ to $\mathrm{Q}_{b}$ on $\mathrm{J}_{a}$, so we can consider

$$
\Psi_{b}^{\mathbf{Y}}=\left.\psi_{a, b}\right|_{J} ^{Y}: \mathbf{J}_{a}^{\mathrm{Y}} \rightarrow \mathbf{J}_{b}^{\mathrm{Y}} .
$$

Similarly we can define

$$
\psi_{b^{\prime}}^{\mathbf{Y}}=\left.\psi_{a, b^{\prime}}\right|_{{ }_{J}} ^{\mathbf{Y}}
$$

for any $b^{\prime} \in \mathrm{I}_{n}$, and these mappings form an equicontinuous family. Therefore if $u$ and $v$ are two distinct points of $\mathrm{J}_{a}^{Y}$, we have

$$
m_{u, v}=\inf _{b^{\prime} \in \mathrm{I}_{n}}\left|\psi_{b^{\prime}}^{\mathrm{Y}}(u)-\psi_{b^{\prime}}^{\mathrm{Y}}(v)\right|>0 .
$$

But we had assumed that $\omega$ and $\omega^{\prime}$ satisfied the conditions of Lemma 1 , so $\mathrm{E}\left(\omega^{\mathrm{x}}\right)$ and $\mathrm{E}\left(\omega^{\mathbf{X}}\right)$ are in $J_{a}^{\mathbf{Y}}$, and so $\Phi^{\mathbf{Y}}$ and $\Psi_{b}^{\mathbf{Y}}$ agree on these points. Therefore

$$
\theta_{\delta}(\mathrm{Q})=\left|\Phi^{\mathbf{Y}}\left(\mathrm{E}\left(\omega^{\prime \mathbf{X}}\right)\right)-\Phi^{\mathbf{Y}}\left(\mathrm{E}\left(\omega^{\mathrm{X}}\right)\right)\right|>m,
$$

where $m=m_{\mathrm{E}\left(\omega^{\mathrm{X}}\right), \mathrm{E}\left(\omega^{\prime} \mathrm{X}\right)}$ depends only on $\mathrm{Q}=\mathrm{Q}_{a}$ and E .
Q.E.D.

This ends the proof of Lemma 4 and of Proposition 16.

## CHAPTER IV

## One parameter families of maps of degree 2

1. Topological holomorphy. - In this chapter, we will consider an analytic family $f=\left(f_{\lambda}\right)_{\lambda \in \Lambda}$ of polynomial-like mappings of degree 2 , where $\operatorname{dim}(\Lambda)=1$, i. e. $\Lambda$ is a Riemann surface. We will particularly study the straightening map $\chi: \Lambda \rightarrow \mathbb{C}$ (defined using some tubing) and the set $\mathbf{M}_{\mathbf{f}}=\chi^{-1}(\mathbf{M})$.

Recall that $M_{f}$ and the restriction of $\chi$ to $M_{f}$ do not depend on the tubing; we have also shown that $\chi$ is not in general analytic.

[^2]We will show in this chapter that $\chi$ has the same topological properties it would have if it were analytic, and we will give conditions for $\chi$ to induce a homeomorphism, sometimes even quasi-conformal, of $\mathbf{M}_{\mathbf{f}}$ onto $\mathbf{M}$.
The point of these conditions is that they are preserved by small perturbations.
The first two sections are devoted to generalities about "topologically holomorphic" mappings.

Reminder. - Let X and Y be oriented topological surfaces and $\varphi: \mathrm{Y} \rightarrow \mathrm{X}$ a continuous map. If $y \in \mathrm{Y}$ is isolated in its fiber, the local degree $i_{y}(\varphi)$ of $\varphi$ at $y$ is defined as follows:
set $x=\varphi(y)$ and choose neighborhoods U and V of $x$ and $y$ respectively, homeomorphic to D and such that $\varphi(\mathrm{V}) \subset \mathrm{U}$ and $\{y\}=\mathrm{V} \cap \varphi^{-1}(x)$. If $\gamma$ is a loop in $\mathrm{V}-\{y\}$ with winding number 1 around $y$ then $i_{y}(\varphi)$ is the winding number of $\varphi \circ \gamma$ around $x$.
If $\varphi$ is proper and $X$ and $Y$ are connected, then $\varphi$ has a degree. Indeed, the cohomology groups with compact support $\mathrm{H}_{c}^{2}(\mathrm{X})$ and $\mathrm{H}_{c}^{2}(\mathrm{Y})$ are canonically isomorphic to $\mathbb{Z}$ and $\varphi^{*}: \mathrm{H}_{c}^{2}(\mathrm{Y}) \rightarrow \mathrm{H}_{c}^{2}(\mathrm{X})$ is multiplication by the integer deg $\varphi$.
If $\varphi$ is proper, X and Y are connected and $y \in \mathrm{Y}$ has $\varphi^{-1}(y)$ discrete hence finite, then

$$
\operatorname{deg} \varphi=\sum_{x \in \varphi^{-1}(\nu)} i_{x}(\varphi) .
$$

Definition. - Let X and Y be oriented surfaces as above, and $\varphi: \mathrm{Y} \rightarrow \mathrm{X}$ be a continuous map. Let M be closed in X and $\mathrm{P}=\varphi^{-1}(\mathrm{M})$. We will say that $\varphi$ is topologically holomorphic over M if for all $y \in \mathrm{P}, y$ is isolated in its fiber and $i_{y}(\varphi)>0$.

Proposition 17. - Suppose that $\varphi: \mathrm{Y} \rightarrow \mathrm{X}$ is topologically holomorphic over M and let $\mathbf{P}=\varphi^{-1}(\mathrm{M})$.
(a) for all $p \in \mathrm{P}$ there exist open connected neigborhoods U and V of $m=\varphi(p)$ and $p$ respectively, with compact closure, such that $\varphi$ induces a proper map $\mathrm{V} \rightarrow \mathrm{U}$ of degree $d=i_{p} \varphi ;$
(b) if $d=1$ then $\varphi$ induces a homeomorphism of $\mathbf{P} \cap \mathrm{V}$ onto $\mathrm{M} \cap \mathrm{U}$. More generally, $\left.\varphi\right|_{\mathrm{v}}$ can be written $\pi \circ \widetilde{\jmath}$, here $\pi: \tilde{\mathrm{U}} \rightarrow \mathrm{U}$ is the projection of the d-fold cover of U ramified $m$, and $\tilde{f}: \mathrm{V} \rightarrow \widetilde{\mathrm{U}}$ is a proper mapping of degree 1 . The mapping $\tilde{f}$ induces a homeomorphism of $\mathrm{P} \cap \mathrm{V}$ onto $\pi^{-1}(\mathrm{M} \cap \mathrm{U})$.
Proof. - (a) Let B be a compact neighborhood of $p$, containing no other point of $\varphi^{-1}(m)$. Since $m \notin \varphi(\partial \mathrm{~B})$, there is an open neighborhood U of $m$ homeomorphic to D and such that $\mathrm{U} \cap \varphi(\partial \mathrm{B})=\varnothing$. Let V be the connected component of $\varphi^{-1}(\mathrm{U})$ containing $p$; since $\mathrm{V} \subset \mathrm{B}$, clearly $\varphi: \mathrm{V} \rightarrow \mathrm{U}$ is proper. By the reminder above, $\operatorname{deg}\left(\left.\varphi\right|_{\mathrm{v}}\right)=i_{p} \varphi$.
(b) Just apply the lifting criterion of covering space theory. More specifically, we need to know that $\varphi_{*}\left(\pi_{1}(\mathrm{~V}-p)\right.$ ) is contained in (in fact equal to) the subgroup of $\pi_{1}(\mathrm{U}-m)$ generated by $d$, which is the very definition of local degree.
Q.E.D.

Corollary. - With the hypotheses of the above Proposition, the points of P where $i_{p}(\varphi)>1$ form a closed discrete subset of $\mathbf{P}$.

$$
4^{\mathrm{e}} \text { SÉrie }- \text { tome } 18-1985-\mathrm{N}^{\circ} 2
$$

Indeed, if $q \in \mathrm{~V} \cap \mathrm{P}$ and $q \neq p$ then $i_{q}(\varphi)=i_{q}(\tilde{\varphi})$, and since $\operatorname{deg}(\tilde{\varphi})=1$ the Corollary follows.

The next statement can be viewed as a maximum principle for topologically holomorphic mappings.

Proposition 18. - Let X and Y be oriented surfaces, with Y connected and noncompact, $\varphi: \mathrm{Y} \rightarrow \mathrm{X}$ a continuous mapping and $\mathrm{M} \subset \mathrm{X}$ a closed subset, such that $\varphi$ is topologically holomorphic over M . Set $\mathrm{P}=\varphi^{-1}(\mathrm{M})$. If W is a relatively compact component of $\mathrm{Y}-\mathrm{P}$ then $\varphi(\mathrm{W})$ is a relatively compact component of $\mathrm{X}-\mathrm{M}$ and $\varphi$ induces a proper mapping $\mathrm{W} \rightarrow \varphi(\mathrm{W})$ of degree $>0$.

Lemma. - Let $p \in \mathrm{Y}$ satisfy $i_{p}(\varphi)=1$; let $m=\varphi(p)$ and $\mathrm{U}, \mathrm{V}$ be as in Proposition 17. Then $\varphi$ induces a bijection of the set $\pi_{0}(\mathrm{~V}-\mathrm{P})$ of connected components of $\mathrm{V}-\mathrm{P}$ onto $\pi_{0}(\mathrm{U}=\mathrm{M})$, and for each component $\mathrm{V}^{\prime}$ of $\mathrm{V}-\mathrm{P}, \varphi$ induces a proper mapping $\mathrm{V}^{\prime} \rightarrow \varphi\left(\mathrm{V}^{\prime}\right)$ of degree 1 .

Proof. - Consider the diagram

Since $\varphi$ induces a homeomorphism of $P \cap V$ onto $M \cap U$ (Prop. 17,b), $\varphi_{M}^{*}$ is an isomorphism. Since $U$ and $V$ are connected oriented surfaces

$$
\mathrm{H}_{c}^{2}(\mathrm{U})=\mathrm{H}_{c}^{2}(\mathrm{~V})=\mathbb{Z}
$$

and $\varphi_{\mathrm{U}}^{*}$ is multiplication by $i_{p}(\varphi)=1$, so it is also an isomorphism. Finally, $\mathrm{H}_{\mathrm{c}}^{1}(\mathrm{U})=0$ since U is homeomorphic to D .

Therefore $\varphi_{\mathrm{U}-\mathrm{M}}^{*}$ is surjective. But

$$
H_{c}^{2}(\mathrm{U}-\mathrm{M})=\mathbb{Z}^{\pi_{0}(\mathrm{U}-\mathrm{M})} \quad \text { and } \quad \mathrm{H}_{c}^{2}(\mathrm{~V}-\mathrm{P})=\mathbb{Z}^{\pi_{0}(\mathrm{~V}-\mathrm{P})}=\bigoplus_{i \in \pi_{0}(\mathrm{U}-\mathrm{M})} \mathrm{Z}_{i}
$$

where $Z_{i}=\mathbb{Z}^{\pi_{0}\left(V \cap \varphi^{-1}\left(U_{i}\right)\right)}$ and $U_{i}$ ranges over the connected components of $U-M$.
For all $i \in \pi_{0}(\mathrm{U}-\mathrm{M})$ the mapping $\varphi_{i}^{*}: \mathbb{Z}=H_{c}^{2}\left(\mathrm{U}_{i}\right) \rightarrow \mathrm{Z}_{i}$ is therefore surjective. So $\pi^{-1}\left(U_{i}\right)$ has at most one component, and the commutativity of the righthand square of the diagram shows that there is precisely one, and that the degree is 1.
Q.E.D.

Proof of Proposition 18. - Let $W_{1}$ be the component of $X-M$ containing $\varphi(W)$. Since $W$ is relatively compact in $Y, \varphi$ induces a proper mapping $W \rightarrow W_{1}$, which we must show to have degree $>0$.

Clearly $\partial \mathbf{W}$ is compact and infinite; since $\varphi$ has only finitely many ramification points in $\partial \mathrm{W}$, there exists $m \in \varphi(\partial \mathrm{~W})$ with $i_{p} \varphi=1$ for all $p \in \varphi^{-1}(m) \cap \partial \mathrm{W}$. Let $p_{1}, \ldots, p_{k}$ be these points, and let $\mathrm{U}, \mathrm{V}_{1}, \ldots, \mathrm{~V}_{k}$ be as in Proposition 17.

Since $\overline{\mathrm{W}}$ is compact, there exists a neighborhood $U^{*}$ of $m$ in $U$ such that

$$
\varphi^{-1}\left(\mathrm{U}^{*}\right) \cap \overline{\mathrm{W}} \subset \mathrm{~V}_{1} \cup \ldots \cup \mathrm{~V}_{k} .
$$

Let $\mathrm{V}_{1}^{\prime}$ be a connected component of $\mathrm{W} \cap \mathrm{V}_{1}$ which intersects $\varphi^{-1}\left(\mathrm{U}^{*}\right) \cap \mathrm{V}_{1}$ (there is one since $\left.p_{1} \in \partial \mathrm{~W}\right)$.

The open set $\mathrm{V}_{1}^{\prime}$ is a component of $\mathrm{V}_{1}-\mathrm{P}$, and $\mathrm{U}^{\prime}=\varphi\left(\mathrm{V}_{1}^{\prime}\right)$ is a connected component of $U-M$.

By the Lemma there is a unique component $V_{i}^{\prime}$ of $V_{i}-P$ such that $\varphi\left(V_{i}^{\prime}\right)=U^{\prime}$ for each $i=1, \ldots, k$. Let $i_{1}=1, \ldots, i_{\mathrm{I}}$ be the values of $i$ for which $\mathrm{V}_{i}^{\prime} \subset \mathrm{W}$. There may be other components of $\varphi^{-1}\left(\mathrm{U}^{\prime}\right) \cap \mathrm{W}$, but if $\mathrm{V}^{\prime \prime}$ is such a component, then $\varphi\left(\mathrm{V}^{\prime \prime}\right) \neq \mathrm{U}^{\prime}$ since $\varphi\left(V^{\prime \prime}\right) \cap U^{*}=\varnothing$, so the degree of $\varphi: \mathrm{V}^{\prime \prime} \rightarrow \mathrm{U}^{\prime}$ is zero. The degree of $\varphi: W \rightarrow W_{1}$ is equal to the degree of $\varphi: \varphi^{-1}\left(\mathrm{U}^{\prime}\right) \rightarrow \mathrm{U}^{\prime}$, which is $\mathrm{I} \geqq 1$.
Q.E.D.
2. The Riemann-Hurwitz formula. - The results of this paragraph will not be used in an essential way in the remainder of the paper. We have included them to illustrate the strength of topological holomorphy.

For any topological space T we will note $h^{i}(\mathrm{~T})$ the $\mathbb{Z}$-rank of the Čech cohomology group $\mathrm{H}^{i}(\mathrm{~T} ; \mathbb{Z})$, which will be an element of $\mathbb{\mathbb { V }}=\mathbb{N} \cup\{\infty\}$.

For the spaces which we will consider, all subsets of orientable surfaces, $h^{i}(\mathrm{~T})$ is also the dimension of the vector space $\mathrm{H}^{i}(\mathrm{~T} ; k)$ for any field $k$.

Proposition 19. - Let X and Y be oriented connected non-compact surfaces, M a closed connected subset of $\mathrm{X}, \varphi: \mathrm{Y} \rightarrow \mathrm{X}$ a continuous mapping, topologically holomorphic over M and $\mathrm{P}=\varphi^{-1}(\mathrm{M})$. Suppose that $\varphi$ induces a proper map $\mathrm{P} \rightarrow \mathrm{M}$. Then:
(a) For any $m \in \mathbf{M}$ set $d_{m}=\sum_{p \in \varphi^{-1}(m)} i_{p}(\varphi)$. The number $d=d_{m}$ is independant of the choice of $m$ in M .
(b) There exist neighborhoods U of M in X and V of P in Y such that $\varphi$ restricts to a proper mapping $\mathrm{V} \rightarrow \mathrm{U}$ of degree $d$.
(c) The inequalities $h^{0}(\mathrm{P}) \leqq d$ and $h^{1}(\mathrm{P})<d h^{1}(\mathrm{M})+h^{1}(\mathrm{Y})$ are satisfied.
(d) If $h^{1}(\mathrm{M})$ and $h^{1}(\mathrm{Y})$ are finite, then the set C of ramification points of $\varphi$ in P is finite, and

$$
h^{1}(\mathrm{P})-h^{0}(\mathrm{P})=d\left(h^{1}(\mathrm{M})-1\right)+\sum_{p \in \mathrm{C}}\left(i_{p}(\varphi)-1\right) .
$$

Under the hypotheses of this Proposition, the mapping $\varphi: \mathbf{P} \rightarrow \mathrm{M}$ deserves to be called a ramified covering space; part ( $d$ ) is the Riemann-Hurwitz formula in this setting.

Proof. - (b) There exists a closed neighborhood N of P in Y such that $\varphi$ induces a proper mapping of N into X . Indeed, if $h: \mathbf{Y} \rightarrow \mathbb{R}_{+}$is a proper continuous function, then the function $h_{1}: x \mapsto \sup h(y)$ is locally bounded on $M$, and so there is a continuous function $g: X \rightarrow \mathbb{R}_{+}$such that $g(x)>h_{1}(x)$ for all $x \in M$. Then $\mathrm{N}=\{y \in \mathrm{Y} \mid h(y) \leqq g(\varphi(y))\}$ satisfies the requirement.

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

The set $\varphi(\partial \mathbf{N})$ is closed in $\mathbf{X}$, and does not intersect M. Let $U$ be the connected component of $X-\varphi(\partial N)$ containing $M$ and set $V=\varphi^{-1}(U) \cap N=\varphi^{-1}(U) \cap N$. The sets U and V are open and $\varphi$ restricts to a proper mapping $\mathrm{V} \rightarrow \mathrm{U}$.
(a) Let $d$ be the degree of $\varphi: \mathrm{V} \rightarrow \mathrm{U}$. For any $m \in \mathrm{M}$, the sum $\sum_{p \in \varphi^{-1}(m)} i_{p} \varphi$ is equal to $d$ since $\varphi^{-1}(m) \subset \mathrm{P} \subset \mathrm{V}$.
(c) Since $\varphi: P \rightarrow M$ is open and closed, we have that $\varphi(W)=M$ for each connected component W of P . Since a fiber of $\varphi$ has at most $d$ points, there are at most $d$ components, i. e. $h^{0}(\mathrm{P}) \leqq d$.

Consider the diagram

$$
\begin{array}{cc}
\mathrm{H}^{1}(\mathrm{Y}) & \rightarrow \mathrm{H}^{1}(\mathrm{P}) \\
\uparrow & \rightarrow \mathrm{H}^{2}(\mathrm{Y}, \mathrm{P}) \\
\uparrow & \uparrow \\
\mathrm{H}^{1}(\mathrm{X}) & \rightarrow \mathrm{H}^{1}(\mathrm{M})
\end{array} \mathrm{H}^{2}(\mathrm{X}, \mathrm{M}) \rightarrow 0.0 .
$$

Clearly $h^{1}(\mathrm{P}) \leqq h^{1}(\mathrm{Y})+h^{2}(\mathrm{Y}, \mathrm{P})$. But $h^{2}(\mathrm{Y}, \mathrm{P})$ is equal to the number of connected relatively compact components of $\mathrm{Y}-p$. By Proposition $18, h^{2}(\mathrm{Y}, \mathrm{P}) \leqq d h^{2}(\mathrm{X}, \mathrm{M})$. Since $h^{2}(\mathrm{X}, \mathrm{M}) \leqq h^{1}(\mathrm{M})$, we have that $h^{1}(\mathrm{P}) \leqq h^{1}(\mathrm{Y})+d h^{1}(\mathrm{M})$.
(d) We do not known that $\varphi$ is topologically holomorphic over a neighborhood of M. The following Lemma deals with this difficulty.

Lemma. - There exists a neighborhood U of M and a closed surface $\mathrm{Z} \subset \mathrm{Y} \times \mathrm{U}$ such that $\mathrm{Z} \cap(\mathrm{Y} \times \mathrm{M})$ is the graph of $\left.\varphi\right|_{\mathrm{p}}$, and that the projection $\mathrm{pr}_{2}: \mathrm{Y} \times \mathrm{U} \rightarrow \mathrm{U}$ restricts to $q: \mathrm{Z} \rightarrow \mathrm{U}$ which makes Z a ramified covering space of U of degree $d$. Moreover $i_{(p, \varphi(p))} q=i_{p} \varphi$ for all $p \in \mathrm{P}$.

Proof of Lemma. - For any open subset $\mathbf{U}^{\prime}$ of $\mathbf{X}$, let $\mathbf{Z}\left(\mathbf{U}^{\prime}\right)$ be the set of closed surfaces $\mathbf{Z}^{\prime} \subset \mathbf{Y} \times \mathbf{U}^{\prime}$ such that $\mathbf{Z}^{\prime} \cap \mathrm{Y} \times \mathbf{M}$ is the graph of $\left.\varphi\right|_{\mathrm{P}_{\cap \varphi^{-1}\left(U^{\prime}\right)}}$ and that $q_{\mathrm{Z}}: \mathrm{Z}^{\prime} \rightarrow \mathrm{U}^{\prime}$ (induced by $\mathrm{pr}_{2}$ ) is a ramified covering space, and moreover that $i_{(p, \varphi(p))} q_{\mathrm{Z}^{\prime}}=i_{p}(\varphi)$ for $p \in \mathrm{P} \cap \varphi^{-1}\left(\mathrm{U}^{\prime}\right)$.

This defines a sheaf of sets $Z$ on $X$ which induces a sheaf $Z_{M}$ on $M$. The stalk of $Z$ (or of $Z_{M}$ ) at $m \in M$ is $Z_{m}=\underset{\mathrm{U}^{\prime} \ni \mathrm{m}}{\lim } \mathrm{Z}\left(\mathrm{U}^{\prime}\right)$ and for any open set $\mathrm{A} \subset \mathrm{M}$ we have $\mathrm{Z}_{\mathrm{M}}(\mathrm{A})=\lim _{\rightarrow} \mathrm{Z}\left(\mathrm{U}^{\prime}\right)$, with the direct limit taken over open subsets $\mathrm{U}^{\prime}$ of X with $\mathrm{U}^{\prime} \cap \mathrm{M}=\mathrm{A}[\mathrm{G}]$. The problem is to construct an element of $\mathrm{Z}_{\mathrm{M}}(\mathrm{M})$.

First we will show how to construct an element of $Z_{m}$ for $m \in M$. Let $U_{m}$ be a neighborhood of $m$ homeomorphic to D and for each $p \in \varphi^{-1}(m)$ let $\mathrm{V}_{p}$ be a neighborhood of $p$ satisfying the conditions of Proposition 17. For each $p$ choose a continuous mapping $\psi_{p}: \widetilde{\mathrm{U}}_{p} \rightarrow \mathrm{Y}$, where $\tilde{\mathrm{U}}_{p}$ is the covering of $\mathrm{U}_{m}$ of degree $d_{p}=i_{p} \varphi$, and where $\psi_{p}$ is chosen to extend the inverse of the homeomorphism $\mathrm{P} \cap \mathrm{V} \rightarrow \pi_{p}^{-1}\left(\mathrm{M} \cap \mathrm{U}_{m}\right)$ induced by $\varphi$. This is possible by the Tietze extension Theorem, if $V_{p}$ was chosen contained in an open subset homeomorphic to a disc.

Let $\tilde{\mathrm{Z}}_{p}$ be the graph of $\psi_{p}$ and $\mathrm{Z}_{p}$ its image in $\mathrm{Y} \times \mathrm{U}_{m}$ by $\sigma \circ\left(\pi_{p} \times \mathbf{1}_{\mathrm{Y}}\right)$, where $\sigma(x, y)=(y, x)$.

The projection $\mathrm{pr}_{1}: \widetilde{\mathrm{U}}_{p} \times \mathrm{Y} \rightarrow \tilde{\mathrm{U}}_{p}$ induces a homeomorphism of $\tilde{\mathrm{Z}}_{p}$ onto $\tilde{\mathrm{U}}_{p}$, therefore $\mathrm{pr}_{2}$ makes $\mathrm{Z}_{p}$ into a ramified covering space of $\mathrm{U}_{m}$ of degree $d_{p}$, and $\mathrm{Z}_{m}=\underset{p \in \varphi^{-1}(m)}{\cup} \mathrm{Z}_{p}$ defines an element of $\mathbf{Z}_{\boldsymbol{m}}$.

The key point is that the sheaf $Z_{M}$ is soft on $M^{*}=M-\varphi(C)$. This means that if $F \subset A \subset B \subset M^{*}$ with $A$ and $B$ open in $M^{*}$ and $F$ closed, for any $Z^{\prime} \in Z_{M}(A)$ there exists $Z^{\prime \prime} \in Z_{M}(B)$ and a neighborhood $A^{\prime}$ of $F$ in $A$ such that $\left.Z^{\prime \prime}\right|_{A^{\prime}}=\left.Z^{\prime}\right|_{A^{\prime}}$. Indeed, this is a local property, and $\mathrm{Z}_{\mathrm{M}}$ is locally on $\mathrm{M}^{*}$ isomorphic to $\mathscr{I}_{\mathrm{M}}^{\mathrm{d}}$, where $\mathscr{I}$ is the sheaf on X defined by

$$
\mathscr{I}\left(\mathrm{U}^{\prime}\right)=\left\{f \in \mathrm{C}\left(\mathrm{U}^{\prime} ; \mathbb{R}\right)|f|_{\mathbf{U}^{\prime} \cap \mathrm{M}}=0\right\}
$$

and $\mathscr{I}_{M}$ is the sheaf induced by $\mathscr{I}$ on M. It is clear, and classical, that sections of $\mathscr{I}$ and $\mathscr{I}_{\mathrm{M}}$ can be spliced using partitions of unity, and so those sheaves are soft.

Since $\varphi(C)$ is closed and discreet, there exists an open neighborhood A of $\varphi(C)$ in $M$ and a section $Z_{0}$ of $Z_{M}$ over $A$. Let $F$ be a closed neighborhood of $\varphi(C)$ in $M$ contained in $A$ and $Z_{1}$ be an element of $Z_{M}\left(M^{*}\right)$ agreeing with $Z_{0}$ on $A^{\prime}-\varphi(C)$, where $F \subset A^{\prime} \subset A$. We get a section $Z$ of $Z_{M}(M)$ by splicing $\left.Z_{0}\right|_{A^{\prime}}$ and $Z_{1}$.

> Q.E.D.

Proof of Proposition 19 (d). - If $h^{1}(\mathrm{M})$ is finite, there is a basis $\left(\mathrm{U}_{a}\right)$ of open neighborhoods of $M$ in $X$ such that the maps $H^{1}\left(U_{\alpha}\right) \rightarrow H^{1}(M)$ are isomorphisms.

Let $Z$ satisfy the conditions of the Lemma, and set $V_{\alpha}=q^{-1}\left(U_{a}\right)$. The $V_{\alpha}$ form a basis of neighborhoods of P in Z , so for some $\alpha_{0}, \mathrm{~V}_{\alpha_{0}}$ contains no ramification points of $q$ except those in P; we will only consider $\alpha>\alpha_{0}$.

Then, according to the Riemann-Hurwitz formula which is classical for ramified covering maps of surfaces,

$$
h^{1}\left(\mathrm{~V}_{\alpha}\right)-h^{0}\left(\mathrm{~V}_{\boldsymbol{a}}\right)=d\left(h^{1}\left(\mathrm{U}_{\boldsymbol{a}}\right)-1\right)+\sum_{p \in \mathrm{P}}\left(i_{p} \varphi-1\right) .
$$

It is easy to show that $H^{1}\left(V_{a}\right) \rightarrow H^{1}\left(V_{\beta}\right)$ is an isomorphism for $\beta \geqq \alpha$. Since $\mathrm{H}^{1}(\mathrm{P})=\lim _{\rightarrow} \mathrm{H}^{1}\left(\mathrm{~V}_{\alpha}\right)$, we see that $h^{1}(\mathrm{P})=h^{1}\left(\mathrm{~V}_{\alpha}\right)$, so

$$
h^{1}(\mathbf{P})-h^{0}(\mathrm{P})=d\left(h^{1}(\mathbf{M})-1\right)+\sum_{p \in \mathbf{P}}\left(i_{p} \varphi-1\right) .
$$

Since $h^{1}(\mathrm{P})$ is finite, as was shown in $(c)$, we see that $\sum_{p \in \mathrm{P}}\left(i_{p} \varphi-1\right)$ is finite, i. e. C is finite.
Q.E.D.

## 3. Topological holomorphy of $\chi$.

Theorem 4. - Let $\mathbf{f}=\left(f_{\lambda}\right)_{\text {nes }}$ be an analytic family of polynomial-like mappings of degree 2 , with $\Lambda$ connected of complex dimension 1 . Then if the mapping $\chi: \Lambda \rightarrow \mathbb{C}$ defined using some tubing $\mathbf{T}$ of $\mathbf{f}$ is not constant, it is topologically holomorphic over M .

$$
4^{\mathrm{e}} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{0} 2
$$

Proof. - If $\chi$ is not constant, then $\chi^{-1}(c)$ is discreet for all $c \in M$ by Corollary 2 of Proposition 13. So we need to know that $i_{\lambda}(\chi)>0$ for all $\lambda \in \mathbf{M}_{\mathbf{f}}$.

Let $\mathscr{R}$ and $\mathscr{F}$ be the complementary open and closed subsets of $\Lambda$ given by the M-S-S decomposition. We will distinguish three cases.
(a) $\lambda \in \mathscr{R}, c \in \mathbb{M}$. Then $\chi$ is holomorphic on a neighborhood of $\lambda$ by Theorem 2 .
(b) $\lambda \in \mathscr{R}, c \in \partial \mathbf{M}$. According to Proposition $7, f_{\lambda}$, is quasi-conformally equivalent to $f_{\lambda}$ for $\lambda^{\prime}$ sufficiently close to $\lambda$. But by Proposition $4, f_{\lambda^{\prime}}$ is therefore hybrid equivalent to $f_{\lambda}$, and so $\chi$ is constant on a neighborhood of $\lambda$, and so constant.
(c) $\lambda \in \mathscr{F}, c \in \partial$ M. Let $\Delta$ be a disc in $\Lambda$ containing $\lambda$ and no other point of $\chi^{-1}(c)$; set $\gamma=\partial \Delta$ and $i=i_{\lambda}(\chi) . \quad$ By the definition of $\mathscr{F}$ there is $\lambda \in \AA$ such that $\chi(\gamma)$ has winding number $i$ around $c^{\prime}=\chi\left(\lambda^{\prime}\right)$, and that $f_{\lambda^{\prime}}$ has a non-persistent indifferent periodic point.

There then exists $\lambda^{\prime \prime} \in \AA$ so that $\chi(\gamma)$ has winding number $i$ around $c^{\prime \prime}=\chi\left(\lambda^{\prime \prime}\right)$ and $\lambda^{\prime \prime}$ has an attractive periodic point, so $c^{\prime \prime} \in \dot{M}$.

Now $i=\sum_{m \in \Delta \cap \chi^{-1}\left(c^{\prime \prime}\right)} i_{\mu} \chi$; but each term of the sum is $>0$ since $\chi$ is holomorphic at such a $\mu$ (Thm. 3) and there is at least one term in the sum, for $\mu=\lambda^{\prime \prime}$.

> Q.E.D.

Proposition 20. - Under the hypotheses of Theorem 4, if the tubing T is horizontally analytic, then $\chi$ is quasi-conformal on $\Lambda^{\prime}-\mathbf{M}_{\mathbf{f}}$ for any relatively compact open subset $\Lambda^{\prime}$ of $\Lambda$.

Remark. - Here the definition of quasi-conformal is not quite the ordinary one, since $\chi$ may not be injective. Saying that $\chi$ is quasi-conformal on $\mathrm{W} \subset \Lambda-\mathrm{M}_{\mathrm{f}}$ means that $\left.\chi\right|_{\mathrm{w}}$ is in the Sobolev space $\mathrm{H}_{\mathrm{loc}}^{1}(\mathrm{~W})$ and that there exists a Beltrami form $\mu$ on W with $\mathrm{L}^{\infty}$-norm $=k<1$, such that $\bar{\partial} \varphi=\mu \partial \varphi$. In other words, $\chi$ is analytic for the structure defined by $\mu$.

Lemma. - Let V and W be open subsets of $\mathbb{C}, k \in] 0,1\left[,\left(\mathrm{~T}_{\lambda}\right)_{\lambda \in \mathrm{W}}\right.$ a familly of quasiconformal embeddings of V into $\mathbb{C}$, all with dilatation bounded by $k$, and such that $\lambda \mapsto \mathrm{T}_{\lambda}(x)$ is analytic for all $x \in \mathrm{~V}$.

Let $\sigma: \mathrm{W} \rightarrow \mathbb{C}$ be an analytic mapping, and let $\mathrm{W}^{\prime} \subset \mathrm{W}$ be the open subset of all $\lambda$ such that $\sigma(\lambda) \in \mathrm{T}_{\lambda}(\mathrm{W})$. Then the mapping $h: \lambda \mapsto \mathrm{T}_{\lambda}^{-1}(\sigma(\lambda))$ of $\mathrm{W}^{\prime}$ into $\mathbb{C}$ is quasi-conformal with dilatation $\leqq k$.

Proof. - Suppose first that $(\lambda, x) \mapsto \mathrm{T}_{\lambda}(x)$ is of class $\mathrm{C}^{1}$. Then $h$ is also of class $\mathrm{C}^{1}$, and

$$
\begin{aligned}
& \frac{\partial h}{\partial \lambda}(\lambda)=\frac{\partial \mathrm{T}}{\partial x}(\lambda, h(\lambda)) \cdot\left(\sigma^{\prime}(\lambda)-\frac{\partial \mathrm{T}}{\partial \lambda}(\lambda, h(\lambda))\right) \\
& \frac{\partial h}{\partial \bar{\lambda}}(\lambda)=\frac{\partial \mathrm{T}}{\partial \bar{x}}(\lambda, h(\lambda)) \cdot \overline{\left(\sigma^{\prime}(\lambda)-\frac{\partial \mathrm{T}}{\partial \lambda}(\lambda, h(\lambda))\right)}
\end{aligned}
$$

Therefore $h$ is quasi-conformal with dilatation bounded by $k$.

In the general case, the family ( $\mathrm{T}_{\lambda}$ ) can be uniformly approximated by families $\mathrm{T}_{n, \lambda}$ of class $\mathrm{C}^{1}$, still analytic in $\lambda$ and all $k$-quasi-conformal. Then the corresponding $h_{n}$ are $k$ -quasi-conformal, and converge uniformly to $h$. So $h$ is $k$-quasi-conformal.

> Q.E.D.

Proof of Proposition 20. - The tubing $T$ is an embedding of $\Lambda \times\left(\overline{\mathrm{D}}_{\mathrm{R}}-\mathrm{D}_{\mathrm{R}}\right.$ ) into $\mathscr{U} \subset \Lambda \times \mathbb{C}$, with $\mathrm{R}^{\prime}=\mathrm{R}^{1 / 2}$. It can be extended to an embedding $\hat{T}$ of $\bar{\Lambda}\left(\overline{\mathrm{D}}_{\mathrm{R}}-\mathrm{D}_{\mathbf{R}^{\prime}-\varepsilon}\right)$ with $\hat{\mathrm{T}}_{\lambda}(x) \in f_{\lambda}^{-1}\left(x^{2}\right)$ for $\mathrm{R}^{\prime}-\varepsilon \leqq|x| \leqq \mathrm{R}^{\prime}$.

Then $\hat{T}$ is holomorphic in $\lambda$, and $k^{\prime}$-quasi-conformal over $\Lambda^{\prime}$ for some $k^{\prime}<1$.
Call $\omega_{\lambda}$ the critical point of $f_{\lambda}$, and let $W_{n} \subset \Lambda$ be the open set of those $\lambda$ such that $f_{\lambda}^{n}\left(\omega_{\lambda}\right)$ is defined and belongs to $\hat{T}\left(\Lambda \times\left(D_{R}-\bar{D}_{R^{\prime}-\varepsilon}\right)\right.$. On $W_{n} \cap \Lambda^{\prime}$, the mapping $h_{n}: \lambda \mapsto \hat{\mathrm{T}}^{-1}\left(f_{\lambda}^{n}\left(\omega_{\lambda}\right)\right)$ is $k^{\prime}$-quasi-conformal according to the Lemma, but $h_{n}(\lambda)=\Phi(\chi(\lambda))^{2^{n}}$, where $\Phi: \mathbb{C}-\mathbf{M} \xrightarrow{\approx} \mathbb{C}-\overline{\mathrm{D}}$ is the mapping described in [D-H] and [D]. Therefore $\chi$ is $k^{\prime}$-quasi-conformal on $\mathrm{W}_{n} \cap \Lambda^{\prime}$.

For all $\lambda \in \Lambda-\mathrm{M}_{\mathrm{f}}$, the point $f_{\lambda}\left(\omega_{\lambda}\right)$ belongs to the open set $\AA_{\lambda}$ bounded by the curve $T_{\lambda}\left(\partial D_{R}\right)$ since the inverse image of this curve is connected.

For the last $n$ for which $f_{\lambda}^{n}\left(\omega_{\lambda}\right)$ is defined and belongs to $\AA_{\lambda}, \lambda \in \mathrm{W}_{n}$, so $\cup \mathbf{W}_{n}=\Lambda-\mathbf{M}_{\mathbf{f}}$. So $\chi$ is $k^{\prime}$-quasi-conformal on $\Lambda^{\prime}-\mathbf{M}_{\mathbf{f}}$.
Q.E.D.
4. The case $\mathrm{M}_{\mathrm{f}}$ compact. - Suppose that the hypotheses of Theorem 4 are satisfied, and that $\mathbf{M}_{f}$ is compact. Then $\chi: M_{\mathbf{f}} \rightarrow \mathbf{M}$ is a ramified covering space, and since $\mathbf{M}$ is connected $[\mathrm{D}-\mathrm{H}], \chi$ has a degree $\delta$, which we will call the parametric degree of the family f , as opposed to the degree of the family, which is 2 in this case.

If $\delta=0$ then $M_{\mathbf{f}}$ is empty.
If $\delta=1$ then $\chi$ restricts to a homeomorphism $\mathbf{M}_{\mathbf{f}} \rightarrow \mathrm{M}$; in that case we say that $\mathbf{f}$ is Mandelbrot-like.

Call $\omega_{\lambda}$ the critical point of $f_{\lambda}$. A sufficient condition for $\mathrm{M}_{\mathrm{f}}$ to be compact is that there exist $\mathrm{A} \subset \Lambda$ such that $f_{\lambda}\left(\omega_{\lambda}\right) \in \mathrm{U}_{\lambda}-\mathrm{U}_{\lambda}^{\prime}$ for $\lambda \in \Lambda-\mathrm{A}$.

Proposition 21. - Suppose $\lambda$ homeomorphic to D and $\mathrm{M}_{\mathbf{f}}$ compact. Let $\mathrm{A} \subset \Lambda a$ subset homeomorphic to $\overline{\mathrm{D}}$ such that $\mathbf{M}_{\mathbf{f}} \subset \AA$. The parametric degree $\delta$ of $\mathbf{f}$ is equal to the number of times $f_{\lambda}\left(\omega_{\lambda}\right)-\omega_{\lambda}$ turns around 0 as $\lambda$ describes $\partial \mathrm{A}$.

Proof. - Let $\lambda_{0} \in \Lambda$ be a point such that $f_{\lambda_{0}}\left(\omega_{\lambda_{0}}\right)=\omega_{\lambda_{0}}$. Then $\chi\left(\lambda_{0}\right)=0$, and $\chi$ is holomorphic on a neighborhood of $\lambda_{0}$. Moreover, the multiplicity $i_{\lambda_{0}}(\chi)$ of $\lambda_{0}$ as a zero of $\chi$ is equal to its multiplicity as a zero of $\lambda \mapsto f_{\lambda}\left(\omega_{\lambda}\right)-\omega_{\lambda}$.

Indeed, the hybrid equivalence $\varphi_{\lambda}$ of $f_{\lambda}$ with $z \mapsto z^{2}+\chi(\lambda)$ is an analytic function of ( $\lambda, z$ ), and

$$
\chi(\lambda)=\varphi_{\lambda}\left(f_{\lambda}\left(\omega_{\lambda}\right)\right)
$$

with $\varphi_{\lambda}\left(\omega_{\lambda}\right)=0$ and $d \varphi_{\lambda} / d z\left(\omega_{\lambda}\right) \neq 0$.

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{0} 2
$$

Therefore, $\delta=\sum_{\lambda \in \chi^{-1}(0)} i_{\lambda}(\chi)$ is the number of zeroes of $\lambda \mapsto f_{\lambda}\left(\omega_{\lambda}\right)-\omega_{\lambda}$, counted with multiplicities.

> Q.E.D.
5. Further ressemblance of $\mathbf{M}_{\mathbf{f}}$ and M. - Set $\mathrm{I}=[0,1]$, let $\Lambda$ be a Riemann surface and

$$
\mathbf{f}=\left(f_{s, \lambda}: \mathbf{U}_{s, \lambda}^{\prime} \rightarrow \mathbf{U}_{s, \lambda}\right)_{(s, \lambda) \in \mathbf{I} \times \Lambda},
$$

be a family of polynomial-like mappings of degree 2 . We will assume that the conditions (1) and (2) of Definition II, 1,1 are satisfied. We will also assume that $f: \mathscr{U}^{\prime} \rightarrow \mathscr{U}$ is continuous, holomorphic in $(\lambda, z)$, and proper.

Suppose that for each $s \in I$, the analytic family $f_{s}=\left(f_{s, \lambda}\right)_{\lambda \in \Lambda}$ is Mandelbrot-like, and that the $\mathbf{M}_{\mathbf{f}_{s}}$ are all contained in a common compact set $\mathrm{A} \subset \Lambda$.

We will then say that $f_{0}$ and $f_{1}$ are connected by a continuous path of Mandelbrotlike families.

Proposition 22. - Let $\mathbf{f}=\left(f_{\lambda}\right)_{\lambda \in \Lambda}$ and $\mathbf{g}=\left(g_{\lambda}\right)_{\lambda \in \Lambda}$ be two Mandelbrot-like families parametrized by the same Riemann surface $\Lambda$. If $\mathbf{f}$ and $\mathbf{g}$ can be connected by a continuous path of Mandelbrot-like families, then the homeomorphism $\chi_{f, g}=\chi_{\mathrm{g}}^{-1}{ }^{\circ} \chi_{\mathbf{f}}: \mathbf{M}_{\mathbf{f}} \rightarrow \mathbf{M}_{\mathrm{g}}$ is quasi-conformal in the sense of Mañ-Sad-Sullivan.

Proof. - It is enough to prove the property for $g$ sufficiently close to $f$. Set $\eta_{\lambda}=g_{\lambda}-f_{\lambda}$. If $\mathbf{g}$ is sufficiently close to $\mathbf{f}$, there exists $\mathrm{R}>1$ and $\Lambda^{\prime}$ relatively compact in $\Lambda$, containing $\mathrm{M}_{\mathrm{f}}$, such that for any $t \in \mathbb{C}$ with $|t|<\mathrm{R}$, the family $\mathbf{f}_{t}=\left(f_{\lambda}+t . \eta_{\lambda}\right)_{\lambda \in \Lambda^{\prime}}$, appropriately restricted, is Mandelbrot-like.

Then $\left(\chi_{f_{t}}^{-1}\right)_{t \in D_{r}}$ is a complex analytic family of topological embeddings of $M$ into $\Lambda$.
The Proposition follows from the $\lambda$-Lemma [M-S-S] (note that in our case, the parameter is $s$ and the variable is $\lambda$ ).
Q.E.D.

Example 1. -- Let $\Lambda$ and $V$ be open in $\mathbb{C}$, both containing the disc $\overline{\mathrm{D}}_{4}$ of radius 4 , and

$$
(\lambda, z) \mapsto f_{\lambda}(z)=z^{2}+\lambda+\eta_{\lambda}(z)
$$

be a complex analytic mapping of $\Lambda \times V$ into $\mathbb{C}$ with $\eta_{\lambda}^{\prime}(0)=0$ and $\left|\eta_{\lambda}(z)\right| \leqq 1$ for all $(\lambda, z) \in \Lambda \times \mathrm{V}$.

Set $\mathrm{U}_{\lambda}=\mathrm{D}_{10}$ for all $\lambda$, and $\mathrm{U}_{\lambda}^{\prime}=f_{\lambda}^{-1}\left(\mathrm{U}_{\lambda}\right)$. Then $f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}$ is a polynomial-like mapping of degree 2 for $|\lambda| \leqq 4$, and $\mathbf{f}=\left(f_{\lambda}: U_{\lambda}^{\prime} \rightarrow U_{\lambda}\right)_{\lambda \in D_{4}}$ is a Mandelbrot-like family.

Indeed, if $|\lambda| \leqq 4$ and $|z|=4$ then

$$
\left|f_{\lambda}(z)\right| \geqq 16-4-1>10
$$

so the equation $f_{\lambda}(z)=w$ has two solutions $z_{1}, z_{2} \in \mathrm{D}_{4}$ if $|w|<10$, and $f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}$ is proper of degree 2 .

By the maximum principle, $\mathrm{U}_{\lambda}^{\prime}$ is topologically a union of discs, and since there is at least one critical point, namely 0 , the Riemann-Hurwitz formula implies that $U_{\lambda}^{\prime} \approx D$ and $\mathrm{U}_{\lambda}^{\prime} \subset \overline{\mathrm{D}}_{4} \subset \mathrm{D}_{10}$.

Moreover, if $|\lambda|=4$ then $\left|f_{\lambda}(0)\right| \geqq 4-1=3$ and $\left|f_{\lambda}^{2}(0)\right| \geqq 9-4-1=4$, so $f_{\lambda}^{2}(0) \notin \mathrm{U}_{\lambda}^{\prime}$ and $\lambda \notin \mathrm{M}_{\mathbf{f}}$.

Finally, the parametric degree is 1 by Proposition 21.
Remark. - For such a family, the mapping $\chi: \mathbf{M}_{\mathbf{f}} \rightarrow \mathbf{M}$ is quasi-conformal in the sense of M-S-S according to Proposition 22.

Proposition 23. - Choose $\varepsilon<1$, and suppose that the conditions of example 1 above are satisfied. Suppose that $\left|\eta_{\lambda}(z)\right| \leqq \varepsilon$ for $|\lambda|<4,|z|<4$. Then:
(a) $|\chi(\lambda)-\lambda| \leqq 6 \varepsilon$ for all $\lambda \in \mathbf{M}_{\mathbf{f}}$.
(b) If $\lambda_{1}, \lambda_{2} \in \mathrm{M}_{\mathrm{f}}$, then

$$
\frac{1}{k_{-}(\varepsilon)}\left|\lambda_{1}-\lambda_{2}\right|^{1 / \beta(\varepsilon)} \leqq\left|\chi\left(\lambda_{1}\right)-\chi\left(\lambda_{2}\right)\right| \leqq k_{+}(\varepsilon)\left|\lambda_{1}-\lambda_{2}\right|^{\beta(\varepsilon)}
$$

with

$$
k_{-}(\varepsilon)=8^{2 \varepsilon /(1+\varepsilon)}, \quad k_{-}(\varepsilon)=8^{2 \varepsilon /(1-\varepsilon)}
$$

and

$$
\beta(\varepsilon)=(1-\varepsilon) /(1+\varepsilon) .
$$

Proof. - Set $\eta_{\lambda}=\varepsilon h_{\lambda}$, so that $\left|h_{\lambda}(z)\right| \leqq 1$ for $|\lambda|<4, \quad|z|<4$. Set $\mathbf{F}_{s, \lambda}(z)=z^{2}+\lambda+s h_{\lambda}(z)$. For each $s \in D, F_{s}=\left(F_{s, \lambda}\right)_{\lambda \in D_{4}}$ is a Mandelbrot-like family, and if $\chi_{s}$ is defined using $F_{s}$, the mapping $\chi_{s}^{-1}$ is an embedding of $M$ into $D_{4}$. For every $c \in M$, the mapping $\gamma_{c}: s \mapsto \chi_{s}^{-1}(c)$ of $D$ into $D_{4}$ is analytic, since its graph is an analytic subset of $\mathrm{D} \times \mathrm{D}_{4}$ by Proposition 13, Corollary 2.
(a) If $s \in \mathrm{D}$, then $\left|\gamma_{c}(s)\right| \leqq 4$ and $|c| \leqq 2$, so $\left|\gamma_{c}(s)-c\right| \leqq 6$. Since $\gamma_{c}(0)=c$, we see that $\left|\gamma_{c}(s)-c\right| \leqq 6|s|$ by Schwarz's Lemma. If we take $s=\varepsilon$, we find

$$
\left|\chi^{-1}(c)-c\right| \leqq 6 \varepsilon
$$

(b) If $c_{1} \neq c_{2}$, then the mappings $\gamma_{c_{1}}$ and $\gamma_{c_{2}}$ have disjoint graphs. The inequality in the Proposition follows from the following Lemma.

Lemma. - Let $u, v: \mathrm{D} \rightarrow \mathrm{D}_{\mathrm{R}}$ be two holomorphic functions with disjoint graphs. Then

$$
\left|\frac{u(0)-v(0)}{2 \mathrm{R}}\right|^{1 / \beta(z)} \leqq \frac{|u(z)-v(z)|}{2 \mathrm{R}} \leqq\left|\frac{u(0)-v(0)}{2 \mathrm{R}}\right|^{\beta(z)},
$$

with

$$
\beta(z)=\frac{1-|z|}{1+|z|} .
$$

```
4e SÉrie - tome 18-1985 - No 2
```

Proof. - Set $w=\log (u-v) / 2$ R, where some branch of the logarithm is chosen, which is possible since $u-v$ does not vanish and D is simply connected. Let $w_{0}=w(0)$. The function $w$ takes its values in the left half-plane $\operatorname{Re}(w)<0$, and the mapping

$$
w \mapsto \frac{w-w_{0}}{w+w_{0}},
$$

is an isomorphism of that half-plane onto D . Then

$$
\left|\frac{\operatorname{Re}\left(w-w_{0}\right)}{\operatorname{Re}\left(w+w_{0}\right)}\right| \leqq\left|\frac{w-w_{0}}{w+w_{0}}\right| \leqq|z|,
$$

where the first inequality is true because the level curves of

$$
w \mapsto\left|\frac{w-w_{0}}{w+w_{0}}\right|
$$

are circles, and the second follows from Schwarz's Lemma.
So we find that

$$
\beta(z) \leqq \frac{\operatorname{Re}(w)}{\operatorname{Re}\left(w_{0}\right)} \leqq \frac{1}{\beta(z)} .
$$

This finishes the proof of Proposition 23.
Example 2. - Let $\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)_{\lambda \in \Lambda}$ be an analytic family of polynomial-like mappings of degree 2, parametrized by an open subset of $\mathbb{C}$ homeomorphic to D . We will assume that $U_{\lambda}$ is convex for every $\lambda$, and that there is a compact subset $A \subset \Lambda$ such that $f_{\lambda}\left(\omega_{\lambda}\right)$ is not in the convex hull of $U_{\lambda}^{\prime}$ for $\lambda \in \Lambda-A$. This implies that $M_{f}$ is compact. We suppose that the parametric degree $\delta=1$.

Proposition 24. - Under these conditions, the homeomorphism $\chi: \mathbf{M}_{\mathbf{f}} \rightarrow \mathbf{M}$ is quasiconformal in the sense of $M-S-S$.

Proof. - By an affine change of coordinates depending on $\lambda$ we may assume that $\omega_{\lambda}=0$ and $f^{\prime \prime}\left(\omega_{\lambda}\right)=2$ for all $\lambda$, i. e. that

$$
f_{\lambda}(z)=z^{2}+\lambda+O\left(z^{3}\right)
$$

The function $c: \Lambda \rightarrow \mathbb{C}$ has a simple zero at some $\lambda_{0} \in \Lambda$, and we can identify $\Lambda$ with an open subset of $\mathbb{C}$ so that $\lambda_{0}=0$ and $c^{\prime}(0)=1$. Then

$$
f_{\lambda}(z)=z^{2}+\lambda+O\left(|z|^{3}+|\lambda|^{2}\right),
$$

and shrinking $\Lambda$ slightly if necessary, we may assume that the distance of $U^{\prime}$ to the complement of $U$ is bounded below by a number $m>0$ independant of $\lambda$.

Set $\Lambda_{s}=s^{-2} \Lambda$; and for $\lambda \in \Lambda_{s}$ set $U_{s, \lambda}^{\prime}=s^{-1} U_{s^{2} \lambda}^{\prime}$ and $U_{s, \lambda}=s^{-2} U_{s^{2} \lambda}$. Define $f_{s, \lambda}: \mathrm{U}_{s, \lambda}^{\prime} \rightarrow \mathrm{U}_{s, \lambda}$ by $f_{s, \lambda}=s^{-2} f_{s^{2} \lambda}(s z)$, and define $f_{0, \lambda}(z)=z^{2}+\lambda$.

The mapping $(s, \lambda, z) \mapsto f_{s, \lambda}(z)$ gives a continuous path of Mandelbrot-like families connecting ( $f_{\lambda}$ ) to $z \mapsto z^{2}+\lambda$.

We conclude by Proposition 22.
Q.E.D.

Conjecture. - For any complex analytic family $\mathbf{f}=\left(f_{\lambda}\right)_{\lambda \in \Lambda}$ of polynomial-like mappings of degree 2 with $\Lambda \approx \mathrm{D}$, there exists a quasi-conformal mapping $\varphi_{1}: \Lambda \rightarrow \mathrm{D}$ and a holomorphic $\operatorname{map} \varphi_{2}: \mathrm{D} \rightarrow \mathbb{C}$ such that $\chi_{\mathrm{f}}=\varphi_{2}{ }^{\circ} \varphi_{1}$ on $\mathbf{M}_{\mathbf{f}}$.

## CHAPTER V

## Small copies of $M$ in $M$

1. Tunable points of M. - Let $\mathrm{P}_{c}: z \mapsto z^{2}+c$ and let $c \in \mathrm{M}$ be a point for which 0 is periodic of period $k$ for $P_{c}$. We will call $c$ tunable if there is a neighborhood $\Lambda$ of $c$ in $\mathbb{C}$ and a Mandelbrot-like family $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)_{\lambda \in \Lambda}$ such that for every $\lambda \in \Lambda$, the mapping $f_{\lambda}$ is the restriction of $\mathrm{P}_{\lambda}^{k}$ to $\mathrm{U}_{\lambda}^{\prime}$, and $0 \in \mathrm{U}_{\lambda}^{\prime}$.

Call $M_{c}$ the set $M_{f}$, and $x \mapsto c \perp x$ the inverse of the homeomorphism $\chi: M_{c} \rightarrow M$. Then $M_{c} \subset M$ and $\partial M_{c} \subset \partial M$. Indeed, for any $\lambda \in \Lambda$,

$$
\mathbf{K}_{f_{\lambda}} \subset \mathbf{K}_{\mathbf{P}_{\lambda}^{k}}=\mathrm{K}_{\mathbf{P}_{\lambda}}
$$

and if $\mathrm{K}_{f_{\lambda}}$ is connected, the connected components of $\mathrm{K}_{\mathrm{P}_{\lambda}}$ are not points. Any point in $\partial \mathbf{M}_{c}$ can be approximated by $\lambda$ for which $f_{\lambda}$ has an indifferent periodic point; such a point is also an indifferent periodic point of $\mathrm{P}_{\lambda}$.

We will say that $c$ is semi-tunable if there exists an analytic family $\mathbf{f}=\left(f_{\lambda}: \mathrm{U}_{\lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}\right)_{\lambda \in \Lambda}$ of polynomial-like mappings of degree 2 , such that as above $\Lambda$ is a neighborhood of $c$ in $\mathbb{C}$ and each $f_{\lambda}$ is a restriction of $\mathrm{P}_{\lambda}^{k}$, and that $\chi$ restricts to a homeomorphism of $\mathrm{M}_{\mathbf{f}}$ onto $\mathrm{M}-\{1 / 4\}$ whose inverse extends to a continuous map $\mathbf{M} \rightarrow \mathbb{C}$.

In fact, every $c \in M$ for which 0 is periodic under $\mathbf{P}_{c}$ is semi-tunable, and is tunable if and only if the component of $\dot{M}$ of which it is the center is primitive. The proof depends on detailed knowledge of external radii of $M$, and will be part of another publication. Here we will show by more general arguments that there are infinitely many tunable points in M .
2. Construction of a sequence $\left(c_{n}\right)$. - Let $c_{0}$ be a point of $M$ such that 0 is preperiodic. In this paragraph we will approximate $c_{0}$ by a sequence $\left(c_{n}\right)$ such that for each $c_{n}, 0$ is periodic. It is easy, using Picard's Theorem, to show that such a sequence exists, but we will require more specific information about it. Our construction is analogous to that of III,1.

Let $l$ be the smallest integer for which $\zeta_{0}=\mathrm{P}_{c_{0}}^{l}(0)$ is a repulsive periodic point; let $k$ be its period. There exists a neighborhood $\Lambda$ of $c_{0}$ and an analytic function $\zeta: \Lambda \rightarrow \mathbb{C}$ such that $\zeta\left(c_{0}\right)=\zeta_{0}$ and that $\zeta(\lambda)$ is a repusive periodic point of period $k$ for all $P_{\lambda}$ with $\lambda \in \Lambda$.

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{0} 2
$$

Set

$$
\begin{gathered}
\rho(\lambda)=\left(P_{\lambda}^{k}\right)^{\prime}(\zeta(\lambda)), \\
\rho_{0}=\rho\left(c_{0}\right) \quad \text { and } \quad \mu=\inf _{\lambda \in \Lambda}|\rho(\lambda)| .
\end{gathered}
$$

We may assume that $\mu>1$.
Lemma 1. - The function $\lambda \mapsto \mathrm{P}_{\lambda}^{\prime}(0)-\zeta(\lambda)$ has a simple zero at $c_{0}$.
There are several ways of proving this Lemma; we will give an arithmetic one, using an idea of A. Gleason's.

Proof. - It is equivalent to show that

$$
\lambda \mapsto \mathrm{P}_{\lambda}^{l+k}(0)-\mathrm{P}_{\lambda}^{l}(0)
$$

has a simple zero. Set $F_{n}(c)=P_{c}^{n}(0)$; then $F_{n}$ is monic of degree $2^{n-1}$, with integer coefficients, and

$$
F_{n}^{\prime}=2 F_{n-1} F_{n-1}^{\prime}+1
$$

Let $\overline{\mathbb{Q}}$ be the algebraic closure of $\mathbb{Q}$, and let $c$ be a solution of $\mathrm{F}_{l+k}(c)=\mathrm{F}_{l}(c)$ in $\overline{\mathbb{Q}}$. If the smallest $l$ for which $c$ is a solution is $>0$, then

$$
F_{k+l-1}(c)+F_{t-1}(c)=0
$$

and $I \geqq 2$. Set

$$
\mathrm{G}=\mathrm{F}_{k+l-1}+\mathrm{F}_{t-1},
$$

so that $G$ is monic of degree $2^{k+1-2}$, and

$$
\mathrm{G}^{\prime} / 2=\mathrm{F}_{k+l-2} \mathrm{~F}_{k+l-2}^{\prime}+\mathrm{F}_{t-\frac{2}{2}} \mathrm{~F}_{t-2}^{\prime}+1
$$

has integer coefficients.
Extend the 2-adic valuation of $\mathbb{Q}$ to a valuation $v$ on $\overline{\mathbb{Q}}$, and set

$$
\mathrm{A}=\{z \in \mathbb{Q} \mid v(z) \geqq 0\} \quad \text { and } \quad \mathrm{m}=\{z \in \mathbb{Q} \mid v(z)>0\} .
$$

Since $c$ is an algebraic integer, we see that $c \in A$. Moreover,

$$
\left(\mathrm{F}_{k+t-2}(c)\right)^{2}+\left(\mathrm{F}_{t-2}(c)\right)^{2}=-2 c \in \mathbf{m}
$$

so

$$
\mathrm{F}_{k+l^{-2}}(c) \equiv \mathrm{F}_{l^{-2}}(c) \equiv-\mathrm{F}_{l^{-2}}(c) \bmod \mathrm{m}
$$

The computation of $F^{\prime}$ gives

$$
\mathrm{F}_{k+l-2}^{\prime}(c) \equiv \mathrm{F}_{l-2}^{\prime} \equiv 1 \bmod 2 \mathrm{~A} .
$$

so that

$$
\mathrm{G}^{\prime}(c) / 2 \equiv 1 \bmod \mathrm{~m}, \quad \mathrm{G}^{\prime}(c) \neq 0
$$

and

$$
\left(\mathrm{F}_{l+k}-\mathrm{F}_{1}\right)^{\prime}(c)=2 \mathrm{~F}_{l}(c) \mathrm{G}^{\prime}(c) \neq 0
$$

Q.E.D.

By restricting $\Lambda$ if necessary, we may assume that $c_{0}$ is the only zero of $\zeta$ in $\Lambda$, and we can find a neighborhood $\mathscr{V}$ of $\left(c_{0}, \zeta_{0}\right)$ in $\mathbb{C}^{2}$, an $\mathrm{R}>0$ and an isomorphism $(\lambda, z) \mapsto\left(\lambda, v_{\lambda}(z)\right)$ of $\mathscr{V}$ onto $\Lambda \times \mathrm{D}_{\mathrm{R}}$ such that

$$
v_{\lambda}\left(\mathrm{P}_{\lambda}^{k}(z)\right)=\rho(\lambda) \cdot v_{\lambda}(z)
$$

if $v_{\lambda}(z)<\mathrm{R} / \rho(\lambda)$. Set $\mathrm{V}_{\lambda}=\{z \mid(\lambda, z) \in \mathscr{V}\}$ and $g(\lambda)=v_{\lambda}\left(\mathrm{P}_{\boldsymbol{l}}(0)\right)$, so $g^{\prime}\left(c_{0}\right) \neq 0$.
All repulsive periodic points are in the Julia set, so $\zeta_{0} \in \mathrm{~J}_{c_{0}}$; also the inverse images of 0 are dense in $J_{c 0}$. There is therefore a point $\alpha_{0} \in V_{0}$ such that $P_{c_{0}}^{p}\left(\alpha_{0}\right)=0$; then $\left(P_{c_{0}}^{p}\right)^{\prime}\left(\alpha_{0}\right) \neq 0$.

Shrinking $\Lambda$ again if necessary, there exists an analytic mapping $\lambda \mapsto \alpha_{0}(\lambda)$ such that $\alpha_{0}\left(c_{0}\right)=\alpha_{0}$ and that $\mathrm{P}_{\lambda}^{p}(\alpha(\lambda))=0$ for all $\lambda \in \Lambda$. Now shrinking $\mathscr{V}$ and modifying $R$ and the $v_{\lambda}$ appropriately, we may assume that $v_{\lambda}(\alpha(\lambda))=1$ for $\lambda \in \Lambda$.

We define $\alpha_{n}: \Lambda \rightarrow \mathscr{V}$ by $v_{n}\left(\alpha_{n}(\lambda)\right)=\rho(\lambda)^{-n}$, so that $P_{\lambda}^{n k}\left(\alpha_{n}(\lambda)\right)=\alpha_{0}(\lambda)$.
If $n$ is large enough, there exists a unique $\lambda \in \Lambda$ such that $g(\lambda)=\rho(\lambda)^{-n}$, i. e. that $P_{\lambda}^{\prime}(0)=\alpha_{n}(\lambda)$. Let $c_{n}$ denote that value of $\lambda$. Then for $P_{c_{n}}$, the critical point 0 is periodic of period $l+n k+p$.

Proposition 25. - The sequence $\rho_{0}^{n} .\left(c_{n}-c_{0}\right)$ has a finite limit $\mathrm{C}_{1} \neq 0$.
Proof. - Since $\left|g\left(c_{n}\right)\right| \leqq \mu^{-n}$, the sequence $\left(c_{n}\right)$ converges to $c_{0}$ (at least exponentially). Since $f\left(c_{n}\right)=\rho\left(c_{n}\right)^{-n}$, we have that

$$
\rho_{0}^{n}\left(c_{n}\right)=\left(\frac{\rho_{0}}{\rho\left(c_{n}\right)}\right)^{n} \frac{c_{n}-c_{0}}{g\left(c_{n}\right)-g\left(c_{0}\right)}
$$

The first factor tends to 1 ; indeed, $\rho\left(c_{n}\right) \rightarrow \rho_{0}$ at least exponentially, so $n \log \left(\rho\left(c_{n}\right) / \rho_{0}\right) \rightarrow 0$.

The second factor goes to $1 / g^{\prime}\left(c_{0}\right)$, and the Proposition follows with $\mathrm{C}_{1}=1 / g^{\prime}\left(c_{0}\right)$. Q.E.D.
3. Tunability of the $\boldsymbol{c}_{\boldsymbol{n}}$.

Theorem 5. - (a) For $n$ sufficiently large, $c_{n}$ is tunable.
(b) There exists a constant $\mathrm{C}_{2}$ such that the sequence of mappings

$$
\varphi_{n}: \quad x \mapsto \mathrm{C}_{2} \rho_{0}^{2 n}\left(c_{n} \perp x-c_{n}\right)
$$

converge uniformly on M to the canonical injection $\mathrm{M} \rightarrow \mathbb{C}$. The mappings $\varphi_{n}$ are bihölder, with both exponent and coefficient tending to 1 .

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

Proof. - Call $\mathscr{P}$ the mapping $(\lambda, z) \mapsto\left(\lambda, \mathrm{P}_{\lambda}(z)\right)$. By shrinking $\Lambda$, we may find $\mathbf{R}^{\prime}<\mathbf{R}-1$ such that $\mathscr{P}^{p}$ induces an isomorphism of

$$
\mathscr{V}^{\prime}=\left\{(\lambda, z) \in \mathscr{V}| | v_{\lambda}(z)-1 \mid<\mathbf{R}\right\}
$$

onto a neighborhood $\mathscr{U}$ of $\Lambda \times\{0\}$ in $\Lambda \times \mathbb{C}$.
Set $\mathrm{U}_{\lambda}=\{z \mid(\lambda, z) \in \mathscr{U}\}$ and define $u_{\lambda}: \mathrm{U}_{\lambda} \rightarrow \mathrm{D}_{\mathbf{R}^{\prime}}$ by

$$
u_{\lambda}\left(\mathrm{P}_{\lambda}^{p}(z)\right)=v_{\lambda}(z)-1
$$

By decreasing $\mathrm{R}^{\prime}$ and further shrinking $\Lambda$ we may assume that $\mathscr{P}^{\prime}(\mathscr{U}) \subset \mathscr{V}$ and that

$$
\mathscr{P}(\mathscr{U}) \supset\left\{(\lambda, z)\left|\left|v_{\lambda}(z)\right|<m_{1}\right\}\right.
$$

for some $m_{1}$.
Let

$$
\mathscr{V}_{n}^{\prime}=\left\{(\lambda, z) \in \mathscr{V}| | v_{\lambda}(z)-\rho(\lambda)^{-n} \mid<\mathbf{R}^{\prime} \rho(\lambda)^{-n}\right\}
$$

so that $\mathscr{P}^{n k}$ induces an isomorphism of $\mathscr{V}_{n}^{\prime}$ onto $\mathscr{V}$. Let $\mathscr{U}_{n}^{\prime}=\mathscr{U} \cap \mathscr{P}^{-I}\left(\mathscr{V}_{n}^{\prime}\right)$. Choose $n_{0}$ such that $\mathrm{R} / \mu^{n_{0}}<m_{1}$. If $n \geqq n_{0}, \mathscr{P}^{\prime}$ restricts to a proper map $\mathscr{U}_{n}^{\prime} \rightarrow \mathscr{V}_{n}^{\prime}$ of degree 2 , and $\mathscr{P}^{1+n k+p}$ restricts to a proper mapping $\mathscr{U}_{n}^{\prime} \rightarrow \mathscr{U}$.

Let $h_{\lambda}=v_{\lambda} \circ \mathrm{P}_{\lambda}^{\prime} \circ u_{\lambda}^{-1}: \mathrm{D}_{\mathbf{R}^{\prime}} \rightarrow \mathrm{D}_{\mathbf{R}}$ be the map $\mathrm{P}_{\lambda}^{\prime}: \mathrm{U}_{\lambda} \rightarrow \mathrm{V}_{\lambda}$ written in the local coordinates $u_{\lambda}$ and $v_{\lambda}$. The function $(\lambda, u) \Rightarrow h_{\lambda}(u)$ can be written

$$
h_{\lambda}(u)=g(\lambda)+a(\lambda) u^{2}+\eta_{\lambda}(u)
$$

with $a(\lambda) \neq 0$, holomorphic in $\lambda$ and with $\left|\eta_{\lambda}(u)\right| \leqq A_{1}|u|^{3}$, where $A_{1}$ is a constant independant of $(\lambda, u) \in \Lambda \times \mathrm{D}_{\mathrm{R}^{\prime}} . \quad$ Set $m_{2}=\inf |a(\lambda)| ;$ we may assume $m_{2}>0$.

Let $f_{n, \lambda}$ be the mapping

$$
\mathrm{P}_{\lambda}^{++n k+p}: \mathrm{U}_{n, \lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}
$$

written in the local coordinate $u_{\lambda}$ both in the domain and in the range. Then

$$
f_{n, \lambda}: u \mapsto \rho(\lambda)^{n} h_{\lambda(u)-1}=\rho(\lambda)^{n} a(\lambda) u^{2}+\rho(\lambda)^{n} g(\lambda)-1+\rho(\lambda)^{n} \eta_{\lambda}(u) ;
$$

$f_{n, \lambda}$ is defined on

$$
u_{\lambda}\left(\mathrm{U}_{n, \lambda}^{\prime}\right)=\left\{u| | \rho(\lambda)^{n} h_{\lambda}(u)-1 \mid<\mathrm{R}^{\prime}\right\} .
$$

Set

$$
\begin{gathered}
\tilde{u}_{\lambda, n}(z)=\rho(\lambda)^{n} a(\lambda) u_{\lambda}(z), \\
c_{2}=a\left(c_{0}\right) g^{\prime}\left(c_{0}\right) \\
\tilde{\lambda}_{n}=c_{2} \rho_{0}^{2 n}\left(\lambda-c_{n}\right) \quad \text { and } \quad \Lambda_{n}=\left\{\lambda| | \tilde{\lambda}_{n} \mid<4\right\} .
\end{gathered}
$$

Let $\tilde{f}_{n, \lambda}$ be the mapping $\mathrm{P}_{\lambda}^{\mathrm{I}+n k+p}: \mathrm{U}_{n, \lambda}^{\prime} \rightarrow \mathrm{U}_{\lambda}$ written in the local coordinate $\tilde{u}_{\lambda, n}$ and define $\tilde{\eta}_{n, \lambda}$ by

$$
\begin{equation*}
\tilde{f}_{n, \lambda}(\tilde{u})=\tilde{u}^{2}+\tilde{\lambda}+\tilde{\eta}_{n, \lambda}(\tilde{u}) \tag{*}
\end{equation*}
$$

Lemma 2. - (a) If $n$ is sufficiently large, then $\Lambda_{n} \subset \Lambda$ and $\tilde{u}_{\lambda, n}\left(\mathrm{U}_{n, 2}^{\prime}\right) \supset \mathrm{D}_{4}$.
(b) For such an $n$ let

$$
\varepsilon_{n}=\sup _{\substack{\lambda \in \hat{N}_{n}^{n} \\ \tilde{u} \in \mathrm{D}_{4}}} \tilde{\eta}_{n, \mathrm{x}}(\tilde{u}) .
$$

Then the sequence $\left(\varepsilon_{n}\right)$ converges to 0 .
Proof. - Since $\lambda_{n}$ is the open disc centered at $c_{n}$ and of radius $4 /\left(c_{2} \rho_{0}^{2 n}\right)$, the first part of $(a)$ is true.
If $\lambda \in \Lambda$ and

$$
|\tilde{u}|<\frac{4}{|\rho(\lambda)|^{n}|a(\lambda)|},
$$

we can define $\tilde{\eta}_{\lambda, n}(\tilde{u})$ using the formula (*). Then

$$
\tilde{\eta}_{\lambda, n}(\tilde{u})=h-\tilde{\lambda}+\rho(\lambda)^{2 n} a(\lambda) \eta_{\lambda}\left(\tilde{u} /\left(\rho(\lambda)^{n} a(\lambda)\right)\right),
$$

where

$$
\mathrm{H}=\rho(\lambda)^{n} a(\lambda)\left(\rho(\lambda)^{n} g(\lambda)-1\right) .
$$

The modulus of the last term is bounded by

$$
\frac{64 \mathrm{~A}_{1}}{|\rho(\lambda)|^{\mid}|a(\lambda)|^{2}}
$$

if $|\tilde{u}|<4$.
Moreover,

$$
\frac{\mathbf{H}}{\tilde{\lambda}}=\left(\frac{\rho(\lambda)}{\rho_{0}}\right)^{2 n} \frac{a(\lambda)}{a\left(c_{0}\right)} \frac{g(\lambda)-\rho(\lambda)^{-n}}{g^{\prime}\left(c_{0}\right)\left(\lambda-c_{n}\right)} .
$$

When $\lambda \in \Lambda_{n}$ and $n \rightarrow \theta,\left|\lambda-c_{0}\right|$ converges to 0 at least exponentially, so the first two factors tend to 1 .
The last factor can be written

$$
\frac{g(\lambda)-g\left(c_{n}\right)}{g^{\prime}\left(c_{0}\right)\left(\lambda-c_{n}\right)}-\frac{1-\left(\rho(\lambda) / \rho\left(c_{n}\right)\right)^{n}}{g^{\prime}\left(c_{0}\right)\left(\lambda-c_{n}\right) \rho(\lambda)^{n}} .
$$

The first term tends to 1 , and the second is equivalent to

$$
n \frac{\rho^{\prime}\left(c_{n}\right)}{\rho\left(c_{n}\right)} \frac{1}{g^{\prime}\left(c_{0}\right) \rho(\lambda)^{n}}
$$

which tends to 0 .

$$
4^{e} \text { SERIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

Finally, $\mathrm{H} / \tilde{\lambda}$ converges to 1 , and since $|\tilde{\lambda}|<4$, we have that $\mathrm{H}-\tilde{\lambda} \rightarrow 0$. This gives the bound in (b).
Since $\tilde{u} \in \tilde{u}_{\lambda}\left(U^{\prime}\right)$ precisely when $\tilde{f}_{n, \lambda}(\tilde{u})$, as defined by formula (*), satisfies

$$
\left|\tilde{f}_{n, \lambda}(\tilde{u})\right|<\left.\rho(\lambda)\right|^{n}|a(\lambda)| \mathbf{R}^{\prime}
$$

and since whenever $\lambda \in \Lambda_{n},|\tilde{u}|<4$ and $n$ is sufficiently large, the above inequality is satisfied, the second part of $(b)$ is true.
Q.E.D. for the Lemma.

End of proof of Theorem.
We have verified the conditions of Proposition IV,23, which gives the required result. Q.E.D. for Theorem 5.

## CHAPTER VI

## Carrots for dessert

1. A description of Figure 4. - Let

$$
P_{\lambda}(z)=(z-1)(z+1 / 2-\lambda)(z+1 / 2+\lambda)
$$

and let

$$
\mathrm{N}_{\lambda}: \quad z \mapsto z-\mathrm{P}_{\lambda}(z) / \mathrm{P}_{\lambda}^{\prime}(z)
$$

be the associated Newton's method. Since

$$
\mathrm{N}_{\lambda}^{\prime}=\mathrm{P}_{\lambda} \mathrm{P}_{\lambda}^{\prime \prime} / \mathrm{P}_{\lambda}^{\prime 2}
$$

the critical points of $N_{\lambda}$ are the zeroes $1,-1 / 2+\lambda$ and $-1 / 2-\lambda$ of $P_{\lambda}$, and 0 where $P_{\lambda}^{\prime \prime}$ vanishes.
Color $\lambda$ in blue, red, or green if $\mathrm{N}_{\lambda}^{n}(0) \rightarrow 1,-1 / 2+\lambda,-1 / 2-\lambda$, and leave it in white if none of the above.

You obtain (Figs. 14 to 16).
Figure 4 is an enlargement of Figure 16. For $\lambda=\lambda_{0}=-.019134+.296783 i$, the center of the copy of the Mandelbrot set appearing in white, 0 is periodic of period 3 for $\mathrm{N}_{\lambda}$. Set $\mathrm{F}_{\lambda}=\mathrm{N}_{\lambda}^{3}$.

Setting $\Lambda=D\left(\lambda_{0}, .001\right), U_{\lambda}=D(.55)$ and $U_{\lambda}^{\prime}=U_{\lambda} \cap F_{\lambda}^{-1}\left(U_{\lambda}\right)$, one can verify that, after a change of variables, the hypotheses of Proposition 23 are satisfied. Therefore the family

$$
F=\left(F_{\lambda}: U_{\lambda}^{\prime} \rightarrow U_{\lambda}\right)_{\lambda \in \Lambda}
$$

is a Mandelbrot-like family.
For $\lambda \in M_{\mathbf{F}}$, the point 0 is trapped in $U_{\lambda}^{\prime}$ for $F_{\lambda}$, and therefore does not converge to one of the roots of $\mathrm{P}_{\lambda}$ under $\mathrm{N}_{\lambda}$; so such a $\lambda$ will appear in white. This explains the white copy of M in the picture.

Fig. 14

Fig. 15.

Fig. 16

$$
4^{e} \text { SÉRIE - TOME } 18-1985-\mathrm{N}^{\circ} 2
$$

In [1] we studied the standard Mandelbrot set M, and in particular we described the conformal representation $\Phi: \mathbb{C}-\mathrm{M} \rightarrow \mathbb{C}-\overline{\mathrm{D}}$ tangent to the identify at infinity.

Let $\mathscr{R}(\mathrm{M}, \theta)=\{c \mid \arg \Phi(\theta)=\theta\}$ (angles are counted in whole turns, not radians) be the external ray of angle $\theta$. Then each external ray of rational angle $\theta$ ends in a point $\gamma_{M}(\theta)$ of $\mathrm{M}[\mathrm{D}-\mathrm{H}]$; we say that it is the point of external argument $\theta$.

In Figure 2, we see a collection of blue carrots which point precisely to the points of $M_{F}$ which are the inverse images under $\chi_{F}$ of the points of $M$ with argument of the form $p / 2^{k}$. If $k$ is large, the corresponding carrot is small.

If we focus on the red and green region, we see a tree-like structure, on which we can read the dyadic expansion of the external arguments of points of $\partial \mathrm{M}_{\mathbf{F}}$.

In this chapter, we give an interpretation of this phenomenon.
2. Carrots for $z \mapsto z^{2}$. - Fix $\mathrm{R}>1$ and let Q be the closed annulus $\left\{z\left|\mathrm{R}^{\prime} \leqq|z| \leqq \mathrm{R}\right\}\right.$, where $R^{\prime}=R^{1 / 2}$.

Let I be an open arc in $\mathrm{S}_{\mathrm{R}}^{1}$, and let $\mathrm{I}^{\prime}$ be the preimage of I under $f_{0}: z \mapsto z^{2}$. Then $I^{\prime}=I_{0}^{\prime} \cup I_{1}^{\prime}$, where $I_{0}^{\prime}$ and $I_{1}^{\prime}$ are arcs in $S_{R^{\prime}}^{1}$.

Let A be an open set in Q such that

$$
\mathrm{A} \cap \partial \mathrm{Q}=\mathrm{I} \cup \mathrm{I}^{\prime} .
$$

Suppose that A has two connected components $\mathrm{A}_{0}$ and $\mathrm{A}_{1}$, such that

$$
\mathrm{A}_{0} \cap \partial \mathrm{Q}=\mathrm{I} \cup \mathrm{I}_{0}^{\prime} \quad \text { and } \quad \mathrm{A}_{1} \cap \partial \mathrm{Q}=\mathrm{I}_{1}^{\prime}
$$

Suppose moreover that Q-A is connected (Fig. 17).
Consider now the semi-closed annulus

$$
\Omega=\{z|1<|z| \leqq \mathrm{R}\} .
$$

For any $z \in \Omega$, there is an $n$ such that $f_{0}^{n}(z) \in \mathrm{Q}$ [unique unless $f_{0}^{n}(z) \in \mathrm{S}_{\mathbf{R}^{\prime}}^{1}$ and $f_{0}^{n+1}(z) \in \mathrm{S}_{\mathrm{R}}^{1}$ for some $\left.n\right]$. Define $\mathrm{C} \subset \Omega$ as the set of values of $z$ such that $f_{0}^{n}(z) \in \mathrm{A}$ for this $n$. (If there are two values of $n$, they give the same condition.)

Proposition 26 and definition. - The open set C has an infinite number of connected components. For each $\tau \in \mathbb{Q} / \mathbb{Z}$ of the form $p / 2^{k}$, there is a unique connected component $\mathrm{C}_{\tau}$ of C such that $e^{2 \pi i \mathrm{~T}} \in \overline{\mathrm{C}}$. We call it the carrot of argument $\tau$. For $\tau=p / 2^{k}(p$ odd $)$, the carrot $\mathrm{C}_{\boldsymbol{\tau}}$ is contained in $\mathrm{D}_{\mathbf{R}^{1 / 2^{k-1}}}$, and not in $\mathrm{D}_{\mathbf{R}^{1 / 2^{k}}}$.

Proof. - There exists a homeomorphism $\varphi: \Omega \rightarrow \boldsymbol{\Omega}$ such that $\varphi\left(z^{2}\right)=(\varphi(z))^{2}$ and $\varphi\left(\mathrm{A}_{0}\right) \supset \mathrm{Q} \cap \mathrm{R}_{+}$. We can construct such a $\varphi$ by first choosing an arc $\gamma:[0,1] \rightarrow \mathrm{A}_{0}$, connecting $\mathrm{I}_{0}^{\prime}$ to I with $\gamma(1)=\gamma(0)^{2}$, then choosing $\varphi$ on $\mathrm{S}_{\mathrm{R}}^{1} \cup \gamma$, then extending to $\mathrm{S}_{\mathrm{R}}^{1}$, so as to commute with squaring. Now extend to Q as a homeomorphism, and to $\Omega$ by the homotopy lifting property as in chapter 1 .

Clearly such a $\varphi$ extends to a homeomorphism of $\bar{\Omega}$ with $\left.\varphi\right|_{\mathrm{s}^{1}}=$ id. Replacing A by $\varphi(\mathrm{A})$, we may assume that $\mathrm{A} \supset \mathrm{Q} \cap \mathscr{R}_{+}$.

Fig. 17

Let $h_{p, k}$ be the branch of $z \mapsto z^{1 / 2^{k}}$ on $\mathrm{A}_{0}$ such that

$$
h_{p, k}\left(\mathrm{~A}_{0} \cap \mathbb{R}_{+}\right) \subset e^{2 \pi i p / 2^{k}} \mathbb{R}_{+}
$$

Let $\mathrm{C}_{0}=\bigcup_{k} h_{0, k}\left(\varphi\left(\mathrm{~A}_{0}\right)\right)$.
Clearly $\mathrm{C}_{0}$ is a connected component of C , and $\overline{\mathrm{C}}_{0} \cap \mathrm{~S}^{1}=\{1\}$. The other components of C are the $h_{p, k}\left(\mathrm{C}_{0}\right)$, topped with a hat corresponding to the inverse image of $\mathrm{A}_{1}$, so that

$$
\overline{\mathrm{C}}_{\tau} \cap \mathrm{S}^{1}=\left\{e^{2 \pi i \tau}\right\}
$$

Q.E.D.
3. Carrots in a Mandelbrot-like family. - Let $\mathbf{f}=\left(f_{\lambda}: U_{\lambda}^{\prime} \rightarrow U_{\lambda}\right)_{\lambda \in \Lambda}$ be a Man-delbrot-like family of polynomial-like mappings of degree 2 and let $\chi: \mathbf{M}_{\mathrm{f}} \rightarrow \mathrm{M}$ be the straightening homeomorphism.

Set

$$
\begin{aligned}
& \mathscr{U}=\left\{(\lambda, z) \mid z \in \mathrm{U}_{\lambda}\right\}, \\
& \mathscr{K}=\left\{(\lambda, z) \mid z \in \mathrm{~K}_{\lambda}\right\},
\end{aligned}
$$

and let $\mathscr{C} \subset \mathscr{U}-\mathscr{K}$ be an open set such that

$$
\mathbf{f}^{-1}(\mathscr{C})=\mathscr{C} \cap \mathscr{U}^{\prime} .
$$

For each $\lambda \in \Lambda$, denote $\omega_{\lambda}$ the critical point of $f_{\lambda}$, and set

$$
\mathrm{C}_{\Lambda}=\left\{\lambda \in \Lambda \mid\left(\lambda, \omega_{\lambda}\right) \in \mathscr{C}\right\}
$$

$4^{\text {e }}$ SÉRIE - tome $18-1985-\mathrm{N}^{\circ} 2$

Proposition 27. - Suppose that there is a set $\mathrm{A} \subset \mathrm{Q}$ as in section 2, and a tubing

$$
\mathrm{T}: \quad \Lambda \times \mathrm{Q} \rightarrow \mathscr{U}-\mathscr{K}
$$

such that $\mathrm{T}^{-1}(\mathscr{C})=\Lambda \times \mathrm{A}$. Then:
(a) $\mathrm{C}_{\mathrm{A}}$ has an infinity of connected components.
(b) For each $\tau \in \mathbb{Q} / \mathbb{Z}$ of the form $p / 2^{k}$, there is a component $\mathrm{C}_{\Lambda, \tau}$ of $\mathrm{C}_{\Lambda}$ such that

$$
\chi^{-1}\left(\gamma_{\mathbf{M}}(\tau)\right) \in \overline{\mathbf{C}}_{\Lambda, \tau} \cap \partial \mathbf{M}_{\mathbf{r}}
$$

These sets are disjoint.
Lemma 1. - Extend $\chi$ to a map $\chi_{\mathrm{T}}: \Lambda \rightarrow \mathbb{C}$ using T , and define C from A as in section 2. Then

$$
\mathrm{C}_{\Lambda}=\chi_{\mathrm{T}}^{-1}\left(\Phi_{\mathrm{M}}^{-1}(\mathrm{C})\right)
$$

Proof. - For each $\lambda \in \Lambda$, let $\varphi_{\lambda}: \mathrm{U}_{\lambda} \rightarrow \mathbb{C}$ be the map which conjugates $f_{\lambda}$ to $\mathrm{P}_{\lambda}: z \rightarrow z^{2}+\chi(\lambda)$, constructed using $\mathrm{T}_{\lambda}$.

By construction, the map $\varphi_{\lambda} \circ \mathbf{T}_{\lambda}$ is induced by the map $\psi_{\chi(\lambda)}: \mathbb{C}-D_{\mathbb{R}^{\prime}} \rightarrow \mathbb{C}$ which conjugates $z \mapsto z^{2}$ to $\mathrm{P}_{\lambda}$.

For each $c \in \mathbb{C}$, the map $\psi_{c}$ conjugating $z \mapsto z^{2}$ to $z \mapsto z^{2}+c$ in a neighborhood of $\infty$ extends analytically to $\mathbb{C}-\mathrm{D}_{r_{(c)}}$, with $r(c)=1$ if $c \in \mathrm{M}$ and $r(c)>1$ if $c \notin \mathrm{M}$, but still small enough so that $c$ is in the image of $\psi_{c}$. The isomorphism $\Phi: \mathbb{C}-\mathbf{M} \rightarrow \mathbb{C}-\overline{\mathrm{D}}$ is given by $\Phi_{M}(c)=\psi_{c}^{-1}(c)([D-H],[D])$.

For $\lambda \in \Lambda$, and sufficiently close to $\mathbf{M}_{\mathbf{r}}$ to have $\omega(\lambda)$ and $f_{\lambda}\left(\omega_{\lambda}\right)$ in the region enclosed by $T_{\lambda}(Q)$, the following conditions are equivalent:

$$
\begin{gathered}
\lambda \in \mathrm{C}_{\Lambda}, \\
(\exists n) \quad f_{\lambda}^{n}\left(\omega_{\lambda}\right) \in \mathrm{T}_{\lambda}(\mathrm{A}), \\
(\exists n) \quad \mathrm{P}_{\Lambda}^{n}(0) \in \psi_{\lambda}(\mathrm{A}), \\
(\exists m) \quad \mathrm{P}_{\lambda}^{m}(\chi(\lambda)) \in \psi_{\lambda}(\mathrm{A}), \\
(\exists m) \quad\left(\psi_{\chi}^{-1}(\lambda)(\chi(\lambda))\right)^{2 m} \in \mathrm{~A}, \\
\Phi_{\mathrm{M}}(\chi(\lambda)) \in \mathrm{C} .
\end{gathered}
$$

Lemma 2. - Let W and $\mathrm{W}^{\prime}$ be open sets in $\mathbb{C}, \mathrm{M}$ a closed set in W and $\chi: \mathrm{W}^{\prime} \rightarrow \mathrm{W}$ a continuous map which is topologically holomorphic above $\mathbf{M}$. Let $x \in \mathbf{M}$ and $x^{\prime} \in \chi^{-1}(x)$. Let C be a connected open set in W such that $x$ is accessible by an arc in C. Then there is a connected component $\mathrm{C}^{\prime}$ of $\chi^{-1}(\mathrm{C})$ such that $x^{\prime} \in \overline{\mathrm{C}}^{\prime}$.

Proof. - Let $\eta$ be an arc in $C \cup\{x\}$, ending at $x$ and not reduced to $\{x\}$. Let $\Delta^{\prime}$ be a topological closed disc in $\mathbf{W}^{\prime}$, such that

$$
\Delta^{\prime} \cap \chi^{-1}(x)=\left\{x^{\prime}\right\}
$$

and that $\chi\left(\Delta^{\prime}\right) \not \ddagger \eta . \quad$ Set $\gamma^{\prime}=\partial \Delta^{\prime}$.

ANNALES SCIENTIFIQUES DE L'ECOLE NORMALE SUPERIEURE

Let $\eta^{\prime}$ be the connected component of $\chi^{-1}(\eta)$ containing $x^{\prime}$. Then $\eta^{\prime}$ intersects $\gamma^{\prime}$; indeed, if it did not, one could find a loop $\tilde{\gamma}^{\prime}$ enclosing $\eta^{\prime}$ and avoiding $\chi^{-1}(\eta)$. Then $\tilde{\gamma}=\chi \circ \tilde{\gamma}^{\prime}$ would have a positive winding number around $x$ and winding number 0 around some point of $\eta$, without meeting $\eta$ and that is impossible. Then the component $\mathrm{C}^{\prime}$ of $\chi^{-1}(\mathrm{C})$ containing $\eta^{\prime}-\left\{x^{\prime}\right\}$ satisfies the condition.
Q.E.D.

Remark. - The hypothesis of topological holomorphy is necessary to avoid the counter-example shown in Fig. 18.

Fig. 18

Proof of Proposition 27. - Replacing T by $\mathrm{T} \circ \varphi$, where $\varphi$ is constructed as in section 2, we may assume that $\mathbb{R}_{+} \cap \mathrm{Q} \subset \mathrm{A}$. Then $\mathbb{R}_{+} \cap \Omega \subset \mathrm{C}$, and for $\tau=p / 2^{k}$, setting $\Omega_{k}=\bar{D}_{\mathbf{R}^{1 / 2^{k}}}-\overline{\mathrm{D}}$, the segment $e^{2 \pi i \tau} \mathbb{R}_{+} \cap \Omega_{k}$ is contained in a component $\mathrm{C}_{\tau}$ of C .

Now $\gamma_{M}(\tau)$ is accessible by an arc in

$$
C_{M, \tau}=\Phi_{M}^{-1}\left(C_{\tau}\right)
$$

and by Lemma 2 there exists a connected component $C_{\Lambda, \tau}$ of $C_{\Lambda}=\chi^{-1}\left(C_{M, \tau}\right)$ such that

$$
\chi^{-1}\left(\gamma_{M}(\tau)\right) \in \overline{\mathbf{C}}_{\Lambda, \tau}
$$

Q.E.D.

Remarks. - One can prove that $\overline{\mathbf{C}}_{\Lambda, \tau} \cap \mathrm{M}_{\mathrm{f}}$ is reduced to $\chi^{-1}\left(\gamma_{\mathrm{M}}(\tau)\right)$.
(2) If $T$ is horizontally analytic, then $\chi$ is quasi-conformal, and then one can prove that for each $\tau=p / 2^{k}$, the component $\mathrm{C}_{\Lambda, \tau}$ is unique.
