Blockcipher Based Hashing Examples of DBL Hash Functions

イロト イポト イヨト イヨト

Blockcipher Based Hashing - Why?

- Several attacks on MD4-type functions in recent years (MD4/5, SHA family, RIPEMED, ...)
- Only one primitve for encryption and hashing
- Low cost hardware

Blockcipher Based Hashing Examples of DBL Hash Functions

イロト イポト イヨト イヨト

Blockcipher Based Hashing - Why not?

• Usually slower than dedicated hash function

- Weaknesses not relevant for encryption (e.g. DES weak keys)
- Output length too short (e.g. 128 bits for AES)
- \implies double block length constructions needed (e.g. hash output size of 256 bits for AES)

Blockcipher Based Hashing Examples of DBL Hash Functions

イロト イポト イヨト イヨト

Blockcipher Based Hashing - The Goal

• 'Secure' (ideal cipher model)

- e.g. birthday type collision resistance
- Long hash output (e.g. >> 128 bits = blocksize)

Efficient: efficiency = size of message input number of blockcipher calls needed to process this input

Security Bound

Theorem (Bound for Collision Resistance)

Let *F* be the Tandem-DM compression function and *n*, *q* be natural numbers with $q < 2^n$. Let $N' = 2^n - q$ and let α be any positive number with $eq/N' \leq \alpha$ and $\tau = \alpha N'/q$ (and e^x being the exponential function). Then

$$\mathsf{Adv}_F^{\mathrm{COLL}}(q) \le q 2^n e^{q \tau (1 - \ln \tau)/N'} + 4q \alpha/N' + 6q/(N')^2 + 2q/(N')^3.$$

<ロト <回ト < 回ト < 回

Security Bound

Corollary/Conjecture

For the compression function Tandem-DM, instantiated with AES-256, any adversary asking less than $2^{120.4}$ (backward or forward) oracle queries cannot find a collision with probability greater than 1/2. In this case, $\alpha = 24.0$.

Outline Results on Collision Resistance Introduction Results on Preimage Resistance Security of Tandem-DM Model for the proof Concluding Remarks Proof Details

Theorem (Bound for Preimage Resistance)

Let $F := F^{TDM}$ be the Tandem-DM compression function. For every $N' = 2^n - q$ and q > 1

 $\operatorname{Adv}_{F}^{Inv}(q) \leq 2q/(N')^{2}.$

Main Idea

Main Idea

Upper bound the probability of the adversary making a query that can be used as the *final* query to complete a collision.

Outline	Results on Collision Resistance
Introduction	Results on Preimage Resistance
Security of Tandem-DM	Model for the proof
Concluding Remarks	Proof Details

Analysis Details

- We examine the adversarys queries one at a time as they come in
- 2 The latest query made by the adversary is 'successful' if the adversary can use it to build a collision
- We upper bound the probability of a query being successful, and multiply this probability by q

Example Case: $Win1(\mathcal{Q}) = \neg LUCKY(\mathcal{Q}) \land Fit1(\mathcal{Q})$

Fit1(Q): The last query is used only once in position TL. Note that this is equal to the case where the last query is used only once in position TR.

FIT1a(Q) all queries used in the collision are pairwise different, FIT1b(Q) BL = TR and BR is different to TL, BL, TR, FIT1c(Q) BL = BR and TR is different to TL, BL, BR, FIT1d(Q) TR = BR and BL is different to TL, TR, BR,

Ewan Fleischmann, Michael Gorski, Stefan Lucks On the Security of Tandem-DM

Concluding Remarks

- Only two rate 1/2 DBL compression functions with birthday type collision resistance known: Hirose FSE'06 and Tandem-DM
- Tandem-DM (Eurocrypt'92) took > 15 years for a security proof
- Still missing tight proofs for e.g. MDC-2, MDC-4, ...
- essentially no generic results known in this field
- Ineeds to be a lot more research done
