# 54. On Topological Characterizations of Complex Projective Spaces and Affine Linear Spaces 

By Takao Fujita<br>Department of Mathematics, College of General Education, University of Tokyo<br>(Communicated by Kunihiko Kodaira, m. J. A., May 12, 1980)

In § 1 we present several conjectures. In § 2 we give partial answers to them. In $\S 3$ we discuss remaining problems.
§ 1. Conjectures. Conjecture $\left(A_{n}\right)$. Let $U$ be a complex manifold of dimension $n$ with the homotopy type of a point. Suppose that there is a Kähler smooth compactification $M$ of $U$ such that $D=M-U$ is a smooth divisor on $M$. Then $U$ is isomorphic to an affine linear space $\boldsymbol{A}^{n}$.

Remark 1. The smoothness of $D$ is the essential assumption. Without it, $U$ need not be $A^{n}$ (see [12]).

In § 2 we reduce $\left(A_{n}\right)$ to the following
Conjecture $\left(\boldsymbol{B}_{n}\right)$, Let $M$ be a compact complex manifold with $\operatorname{dim} M=n$ and let $D$ be a smooth ample divisor on $M$. Suppose that the natural homomorphism $H_{p}(D ; \boldsymbol{Z}) \rightarrow H_{p}(M ; Z)$ is bijective for $0 \leqq p$ $\leqq 2 n-2$. Then $M \cong P^{n}$ and $D$ is a hyperplane section on it.

Remark 2. An affirmative answer to ( $B_{n}$ ) would solve the question of [5] (4.15) and give a sharpened form of Proposition V in [13]. See also § 2, Corollary 3.

In § 2 we reduce ( $B_{n}$ ) to the following
Conjecture $\left(C_{n}\right)$. Let $M$ be a projective complex manifold such that the cohomology ring $H^{\cdot}(M ; Z)$ is isomorphic to $H^{\cdot}\left(\boldsymbol{P}^{n} ; \boldsymbol{Z}\right)$ $\cong Z[x] /\left(x^{n+1}\right)$. Suppose further that $c_{1}(M)$ is positive. Then $M \cong \boldsymbol{P}^{n}$.

Remark 3. It is well known that any projective manifold homeomorphic to $\boldsymbol{P}^{n}$ is holomorphically isomorphic to $\boldsymbol{P}^{n}$, provided that $c_{1}$ is positive. Moreover, the positivity assumption on $c_{1}$ is not necessary if $n$ is odd (see [8] and [11]). The proof depends on the theory of Pontrjagin classes.

Remark 4. ( $C_{n}$ ) would not be true without the assumption on the ring structure. Indeed, any odd dimensional hyperquadric has a cohomology group isomorphic to that of $\boldsymbol{P}^{n}$.
§ 2. Partial answers. Theorem 1. Conjecture $C_{n}$ is true for $n \leqq 5$.

We give an outline of our proof for the case $n=5$. In view of the isomorphism $H^{\cdot}(M ; Z) \cong H^{\cdot}\left(\boldsymbol{P}^{n} ; Z\right)$, we regard the Chern classes
$\left\{c_{i}\right\}$ of $M$ as integers. First we have $c_{5}=6 . \quad c_{1}$ is a positive integer by assumption. Moreover, $M \cong P^{5}$ if $c_{1} \geqq 6$ (see [10] or [4]). So we may assume $5 \geqq c_{1} \geqq 1$.

Let $L$ be the ample generator of $\operatorname{Pic}(M) \cong H^{2}(M ; Z) \cong Z$. Write down explicitly the Riemann-Roch-Hirzebruch formulae (see [7]) for $\chi\left(M, \mathcal{O}_{M}[t L]\right), \chi(M, \Omega[t L])$ and $\chi(M, \Theta[t L])$, where $\Omega$ is the sheaf of holomorphic 1-forms and $\Theta$ is the sheaf of holomorphic vector fields on $M$. Since $\chi(M, t L)$ is an integer for any $t \in Z$, we infer that $c_{1}$ is even. Hence we should consider the cases $c_{1}=2$ or 4 .

In case $c_{1}=2$, the equations among $\left\{c_{j}\right\}$ derived from $\chi\left(M, \mathcal{O}_{M}\right)=1$ and $\chi(M, \Omega)=-1$ imply that $c_{4}=45$ and $3 c_{2}^{2}-4 c_{2}+2 c_{3}=765$. On the other hand, $\chi(M, L) \in Z$ and $\chi(M, \Theta[-L]) \in Z$ imply $-1 \equiv c_{2} \equiv c_{3}$ $+7 \bmod 12$. This is not consistent with the above equation.

In case $c_{1}=4$, we have $\chi\left(M, \mathcal{O}_{M}[t L]\right)=0$ for $t=-1,-2$ and -3 . Using this, we can derive a contradiction by a similar method as above.

The proofs in the cases $n \leqq 4$ are similar and simpler. Q.E.D.
Remark 5. In case $c_{1}=n-1$, we can also use the theory of Del Pezzo manifolds in order to derive a contradiction (cf. [3] or [6]).

Theorem 2. Suppose that ( $M, D$ ) satisfies the hypothesis of Conjecture $B_{n}$. Then $H^{\cdot}(M ; Z) \cong H^{\cdot}\left(\mathbf{P}^{n} ; Z\right)$ and $H^{\cdot}(D ; Z) \cong H^{\cdot}\left(P^{n-1} ; Z\right)$ as graded rings. Moreover, $[D]$ generates $\operatorname{Pic}(M)$ and both $c_{1}(M)$ and $c_{1}(D)$ are positive.

Proof (mostly due to Sommese [13], Proposition V). Let $f: D \rightarrow M$ be the inclusion. $f^{*}: H^{p}(M ; \boldsymbol{Z}) \rightarrow H^{p}(D ; \boldsymbol{Z})$ is bijective for $0 \leqq p \leqq 2 n-\mathbf{2}$ since $f_{*}: H_{p}(D ; Z) \rightarrow H_{p}(M ; \boldsymbol{Z})$ is so. We have $H_{p}(D ; Z) \cong H^{2 n-2-p}(D ; Z)$ and $H_{p}(M ; \boldsymbol{Z}) \cong H^{2 n-p}(M ; \boldsymbol{Z})$ by the Poincaré duality. Hence $f_{*}$ induces a bijection $f^{\prime}: H^{q}(D ; Z) \rightarrow H^{q+2}(M ; Z)$ for $0 \leqq q \leqq 2 n-2$. Putting $\alpha=c_{1}([D]) \in H^{2}(M ; Z)$, we see $f^{\prime} \circ f^{*}(x)=x \wedge \alpha$ for any $x \in H^{\cdot}(M ; Z)$. So the bijectivity of $f^{\prime}$ and $f^{*}$ implies that $\alpha^{k}$ generates $H^{2 k}(M ; \boldsymbol{Z}) \cong \boldsymbol{Z}$ for any $0 \leqq k \leqq n$. In particular we have $\alpha^{n}=1$ in $H^{2 n}(M)$.

Assume that $b_{1}(M)>0$. Then the Albanese mapping $\pi: M \rightarrow \mathrm{Alb}(M)$ is non-trivial. On the other hand, $H^{2}(M ; Z) \cong Z$ implies that $H^{2,0}(M)$ $=H^{0}\left(M, \Omega^{2}\right)=0$. Hence $\pi(M)$ is a curve, since otherwise $\pi^{*} \psi \neq 0$ for some holomorphic 2-form $\psi$ on $\operatorname{Alb}(M)$ (see [14], p. 116). A fiber of $\pi$ is an effective divisor on $M$ which is not ample. This is impossible since $H^{2}(M ; Z) \cong Z$. This contradiction proves $b_{1}(M)=0$.

Now we have $H^{1}(M ; Z)=0$ since it is torsion free. In view of the bijections $f^{\prime}$ and $f^{*}$, we infer that $H^{p}(M ; \boldsymbol{Z})=0$ for any odd $p$. Thus we obtain a ring isomorphism $H^{\cdot}(M ; Z) \cong H^{\cdot}\left(\boldsymbol{P}^{n} ; Z\right)$. Moreover, Pic (M) $\cong H^{2}(M ; Z)$ because $h^{0,1}(M)=h^{0,2}(M)=0$, and $\operatorname{Pic}(M)$ is generated by $[D]$. Using $f^{*}$, we see $H^{\cdot}(D ; \boldsymbol{Z}) \cong H^{\cdot}\left(\boldsymbol{P}^{n-1} ; \boldsymbol{Z}\right)$.

Assume that $c_{1}(M) \leqq 0$. Then the canonical bundle $K$ of $M$ is a non-negative multiple of $[D] \in \operatorname{Pic}(M)$. But $h^{0}(M, K)=h^{n, 0}(M)=0$ since
$H^{n}(M ; \boldsymbol{Z}) \cong H^{n}\left(\boldsymbol{P}^{n} ; \boldsymbol{Z}\right)$. This contradiction proves that $c_{1}(M)>0$. Hence $c_{1}(D)=c_{1}(M)-1 \geqq 0 . \quad h^{n-1,0}(D)=0$ implies $c_{1}(D) \neq 0$. So we have $c_{1}(D)>0$.
Q.E.D.

Corollary 1. $\left(C_{n}\right)$ implies $\left(B_{n}\right)$ and $\left(B_{n+1}\right)$.
Corollary 2. Conjecture $B_{n}$ is true for $n \leqq 6$.
Corollary 3. Let $f: M \rightarrow S$ be a surjective holomorphic mapping between compact complex manifolds and let $A$ be a smooth ample divisor on $M$ such that the restriction $f_{A}: A \rightarrow S$ of $f$ is everywhere of maximal rank. Suppose that $\operatorname{dim} M \leqq 2 \operatorname{dim} S+1$ and $\operatorname{dim} M \leqq \operatorname{dim} S$ +6 . Then both $f$ and $f_{A}$ are fiber bundles with fibers being isomorphic to projective spaces.

For a proof, use [13] Proposition V and [5], (4.9).
Theorem 3. Let $U, M$ and $D$ be as in Conjecture $A_{n}$. Then $(M, D)$ satisfies the hypothesis of Conjecture $B_{n}$.

Proof. By the Lefschetz duality we have $H_{p}(M, D ; Z) \cong H^{2 n-p}(U ; Z)$ $=0$ for $p \leqq 2 n-1$. Hence, the long homology exact sequence proves $H_{p}(D ; Z) \cong H_{p}(M ; Z)$ for $p \leqq 2 n-2$. This implies, as in Theorem 2, that $H^{2}(M ; Z)$ is generated by $c_{1}([D])$. On the other hand $M$ is Kähler. Therefore $D$ is ample since any Kähler class of $M$ is a positive multiple of $c_{1}([D])$.

Corollary 4. ( $B_{n}$ ) implies $\left(A_{n}\right)$.
Corollary 5. Conjecture $A_{n}$ is true for $n \leqq 6$.
Remark. Actually, we used only $H^{q}(U ; Z)=0$, and not $\pi_{i}(U)=0$.
§3. Comments. (3.1) It is doubtful if the computational method as in Theorem 1 works in higher dimensional cases. However, this method might work in ( $B_{n}$ ) even though it doesn't in ( $C_{n-1}$ ). So the first non-solved case is $\left(B_{7}\right)$.
(3.2) Without the assumption $c_{1}(M)>0,\left(C_{n}\right)$ might not be true. But, so far as I know, there is no counter-example. I suspect that there will be only few types of such manifolds. In particular, $n$ might be necessarily even.
(3.3) Combining the results of Yau [15] and Kobayashi [9], we infer that $c_{1}(M)>0$ implies $\pi_{1}(M)=0$. So we may assume that $M$ is simply connected in $\left(A_{n}\right)$, $\left(B_{n}\right)$ and $\left(C_{n}\right)$. Hence the rational homotopy type of $M$ is same to that of $P^{n}$ (cf. [2]). Does this imply that $M$ is homeomorphic to $\boldsymbol{P}^{n}$ ? If yes, then our conjectures are solved.
(3.4) In positive characteristic cases we can formulate analogues of $\left(A_{n}\right),\left(B_{n}\right)$ and ( $C_{n}$ ) in terms of Chow rings and some cohomology theory. However, I have no answer except trivial cases. One of the main difficulties is the lack of vanishing theorems of Kodaira type.
