ABSTRACT

Background

Oral theophylline has, for many years, been used as a bronchodilator in patients with COPD. Despite the introduction of new drugs, and its narrow therapeutic index, theophylline is still recommended for COPD treatment.

Objectives

To determine the effectiveness of oral theophylline when compared to placebo in patients with stable COPD.

Search methods

We searched the Cochrane Airways Group trial register and Cochrane Central Register of Controlled Trials Cochrane Controlled Clinical Registers were searched.

Selection criteria

All studies were randomised controlled trials (RCTs).

Data collection and analysis

Two reviewers independently abstracted data and assessed the methodological quality.

Main results

Twenty RCTs met the inclusion criteria. Concomitant therapy varied from none to any other bronchodilator plus corticosteroid (oral and inhaled). The following outcomes were significantly different when compared to placebo.

Forced expiratory volume in one second (FEV1) improved with treatment: Weighted Mean Difference (WMD) 100 ml; 95% Confidence Interval (CI) 40 to 160 ml. Similarly for forced vital capacity (FVC): WMD 210 ml 95%CI 100 to 320. Two studies reported an improvement in maximum oxygen consumption (VO2 max); WMD 195 ml/min, 95%CI 113 to 278. At rest, arterial oxygen tension at rest (PaO2) and arterial carbon dioxide tension at rest (PaCO2) both improved with treatment (WMD 3.2 mm Hg; 95%CI 1.2 to 5.1, and WMD -2.4 mm Hg; 95%CI -3.5 to -1.2, respectively). Walking distance tests did not improve (four studies, Standardised Mean Difference 0.30, 95%CI -0.01 to 0.62), neither did Visual Analogue Score for breathlessness in two small studies (WMD 3.6, 95%CI -4.6 to 11.8). The Relative Risk (RR) of nausea

was greater with theophylline (RR 7.7; 95%CI 1.5 to 39.9). However, patients' preference for theophylline was greater than that for placebo (RR 2.27; 95%CI 1.26 to 4.11). Very few participants withdrew from these studies for any reason.

Authors' conclusions

Theophylline has a modest effect on FEV1 and FVC and slightly improves arterial blood gas tensions in moderate to severe COPD. These benefits were seen in participants receiving a variety of different concomitant therapies. Improvement in exercise performance depended on the method of testing. There was a very low dropout rate in the studies that could be included in this review, which suggests that recruited participants may have been known by the investigators to be theophylline tolerant. This may limit the generalisability of these studies.

PLAIN LANGUAGE SUMMARY

Oral theophylline compared to placebo for people with chronic obstructive pulmonary disease (COPD)

Theophylline treatment is commonly used in people with chronic obstructive pulmonary disease (COPD). This systematic review shows that orally administered theophylline improves lung function and levels of oxygen and carbon dioxide in the blood. However, there is limited data on its effect on symptoms, exercise capacity or quality of life. Despite being associated with increased side effects, particularly nausea, participants preferred theophylline over placebo.

BACKGROUND

Chronic obstructive pulmonary disease (COPD), by definition, is characterised by limited reversibility with bronchodilator therapy (Folgering 1994; ATS 1995). Patients often have major limitations of physical activity, especially breathlessness during exercise. Oral theophylline is a bronchodilator that has been used for many years although sympathomimetic and inhaled anticholinergic agents are now used more often (Mulloy 1993). Despite this change in prescribing patterns, there is still a perception that theophylline confers additional benefit over that produced by the newer agents (Raguso 1996). Traditional methods of assessing clinical benefit with theophylline have been based upon physiological measurements of airways function, but some studies have shown improvement in exercise performance, breathlessness and health status (quality of life) with minimal change in lung function (Vereen 1986).

The major therapeutic benefit of theophylline has been attributed to its phosphodiesterase inhibitor activity, which inhibits the degradation of cyclic adenosine monophosphate (cAMP). Other mechanisms of action proposed for the action of theophylline include: inhibition of bronchoconstrictors (prostaglandins) as a result of the increased levels of cellular cAMP (Horrobin 1977); increased cellular calcium uptake and distribution involved in smooth muscle contraction (Aubier 1985); increases in endogenous secretion of cortisol; stimulation of release of endogenous catecholamines (Atuk 1967; Higbee 1982); positive inotropic effect on the heart (Matthay 1986) and theophylline is also known to be a mild diuretic (Johannesson 1985). Increased release of endogenous cortisol and catecholamines by theophylline may have a similar effect to that of the administration of corticosteroids (Mendella 1982).

Theophylline is known to have a central effect on respiration. In COPD, xanthine derivatives can bring about acute and long-term enhancement of the hypoxemic ventilatory response (Aubier 1983) by increasing inspiratory muscle drive, resulting in tidal volume increases (Spinelli 1991).

The role of theophylline in the management of COPD has not been fully defined. Studies have not consistently shown theophylline to be beneficial in the management of stable COPD (Alexander 1980; Eaton 1980; Murciano 1989). The BTS 1997 guidelines on management of COPD recommends use of xanthine derivatives as a last resort and only after all other treatments have failed to show a response. The ATS guidelines on COPD (ATS 1995) makes stronger recommendations for the use of theophylline in both stable and acute management of COPD but due to its narrow therapeutic index (Woodcock 1983) it also recommends cautious use. Due to the increasing numbers of guidelines on COPD management and the lack of evidence-based documentation, the US National Heart Lung and Blood Institute and the World Health Organisation have jointly developed evidence-based guidelines for the management of COPD (Pauwels 2000; Gomez 2002). This project known as the Global Initiative for Chronic Obstructive Lung Disease (GOLD) aims to produce guidelines that are applicable globally and are based on well-controlled clinical studies (where available) and not on consensus. However, the latter would be used where there was insufficient evidence. The current GOLD guideline recommends the use of theophylline as second line option since many studies

have shown its bronchodilator effectiveness in COPD (web address: <http://www.goldcopd.com>).

A major disadvantage with this class of drugs is the incidence of adverse effects, particularly those involving the gastro-intestinal tract, even when the plasma level is within the therapeutic range. The evaluation of efficacy and the assessment of adverse effects are important factors to consider when dose titrating with theophylline preparations (Persson 1986).

Most studies have been performed on small number of patients with short duration. To our knowledge, there is no systematic review regarding theophylline in stable COPD. Owing to the differing recommendations from various COPD guidelines and to the different conclusions from the many clinical studies this systematic review of the literature was performed to assess the effect of theophylline in patients with stable COPD.

OBJECTIVES

To determine the efficacy of oral theophylline compared to placebo in patients with stable COPD.

METHODS

Criteria for considering studies for this review

Types of studies

All studies were randomised controlled trials which involved treatment with theophylline or placebo in patients with COPD. Studies of any duration were considered for inclusion but single dose studies were excluded.

Types of participants

Studies in patients with COPD were considered for inclusion. COPD was defined by internationally accepted criteria (e.g. ATS 1995; ERS 1995; BTS 1997) or defined objectively as a disorder characterised by reduced expiratory flow and slow forced emptying of the lungs and features which do not change markedly over several months (ERS 1995).

Types of interventions

The use of oral theophylline compared to placebo in a randomised fashion.

Types of outcome measures

PRIMARY OUTCOMES MEASURES

- (1) Exercise capacity: timed walking tests, endurance tests and incremental exercise tests on a treadmill or cycle ergometer.
- (2) Lung function measurements (e.g. forced expiratory volume in one second (FEV₁), forced vital capacity (FVC)).
- (3) Health status (quality of life) scores: These include the Chronic Respiratory Disease Questionnaire (CRQ) or the St George's Respiratory Questionnaire (SGRQ).

SECONDARY OUTCOME MEASURES

- (1) Arterial blood gas tensions (partial pressure oxygen (PaO₂), partial pressure carbon dioxide (PaCO₂)) and oxygen saturation (SaO₂) on exercise and rest.

(2) Dyspnoea: measured directly at rest or during exercise, or indirectly by self report on symptom diaries (e.g. visual analogue scale, Borg scale or Likert scale or any other validated measurement).

(3) Participant preference for treatment

(4) Adverse effects: frequency of gastric effects (nausea, diarrhoea, mild abdominal discomfort), insomnia, and arrhythmia's (atrial fibrillation, tachycardia, ventricular extrasystole).

(5) Acute exacerbations

(6) Mortality: proportion of deaths

(7) Dropout rate: number of participants dropping out of the study.

Search methods for identification of studies

We carried out a search of the Cochrane Airways Group trial register and the Cochrane Central Register of Controlled Trials using the following search strategy: obstructive OR bronchitis OR pulmonary emphysema OR bronchial hyperreactivity OR COPD OR COLD OR emphysema AND aminophylline OR theophylline OR theo* OR uniphyl OR nuelin. We also conducted separate and additional searches using MEDLINE (1966 to Feb 2002), EMBASE (1982 to Feb 2002), CINAHL (Feb 2002), and LILACS (1982 to Feb 2002) databases. We considered studies of any duration or in any language. We identified other potential studies by writing to key authors, and examining the bibliographies of included studies and relevant review articles.

Data collection and analysis

LOCATING AND SELECTING STUDIES

Two reviewers (FR, SC) independently assessed the titles and abstracts of all reports of trials identified by electronic searching. The full text copies of all potential trials were obtained. Disagreements between reviewers were resolved with discussion.

STUDY QUALITY

Two reviewers independently assessed the methodological quality. We assessed all included studies using two study quality scales. The Cochrane assessment of allocation concealment was used, Grade A: Adequate concealment, Grade B: Uncertain about the method of allocation concealment, Grade C: Clearly inadequate allocation concealment & Grade D: Allocation concealment not used.

In addition, we also graded studies using the five point [Jadad 1996](#) study quality score:

Was the study described as randomised? Yes = 1; No = 0

Was the study described as double blind? Yes = 1; No = 0

Was there a description of the withdrawals and dropouts? Yes = 1; No = 0

Was the method of randomisation well described and appropriate? Yes = 1; No = 0

Was the method of double blinding well described and appropriate? Yes = 1; No = 0

Deduct one point if methods for randomisation or blinding were inappropriate.

STATISTICAL ANALYSIS

Where possible, we pooled trial outcome data. As planned in the protocol, for continuous variables, we calculated the results

of individual studies as fixed effect weighted mean difference (WMD) or standardised mean difference (SMD) including the 95% confidence interval (CI) for each outcome. Where results were expressed as dichotomous variables, we calculated odds ratio (OR) or relative risks (RR) with 95% CI for individual outcomes.

The intention was to analyse separately trials employing a crossover design from those using a parallel-group design. If first-arm data from crossover trials was reported or if we had been able to obtain this data from the authors, then this would have been combined with data from parallel design trials. In the event, all trials were crossover in design, therefore aggregate means (from both study arms) were entered into RevMan and pooled.

SENSITIVITY ANALYSIS

For pooled effects, we carried out a test for heterogeneity; $p < 0.05$ was considered statistically significant. If there was significant heterogeneity, we would have performed sensitivity tests using study quality, duration of study, dose and type of theophylline preparation and level of concomitant medication usage. When data were missing (in the case of SDs) these were calculated using the average of other trial SDs for that outcome. If range values were reported, SD was computed from the range using the following $[SD = (UR - LR) / (2 \times 1.96)]$, 1.96 is for 95% range but changes to 1.64 and 2.58 for 90% and 99% reference ranges. If only p values were reported, a pooled estimate of SD was computed by converting the p value to a Student's t -value; thereafter calculating SD using the following $[SD = (\text{square-root } \{n1 \times n2\} / \{n1 + n2\}) \times (\text{difference in means} / t\text{-value})]$. Wherever these estimates of SDs were necessary, we conducted a sensitivity analysis of the overall result, excluding the calculated SDs, to test if the treatment effect differed significantly.

RESULTS

Description of studies

Please refer to the table "Characteristics of included studies" for detailed descriptions of each included study. A brief summary is provided below.

SEARCH FOR STUDIES

From 310 abstracts, we retrieved 86 full text papers for closer assessment. We selected twenty-four studies for inclusion. Four studies were multiple publications of the same cohort of participants. [Alexander 1980](#) had one follow-up publication, [Guyatt 1987](#) had two additional publications and the [Iversen 1992](#) study had one duplicate publication. Therefore, there were 20 included studies (excluding four duplicate publications). The 62 excluded studies with their reasons for exclusion are listed in the table "Characteristics of excluded studies".

LOCATION OF STUDIES

Six studies were conducted in USA ([Schmidt 1979](#); [Alexander 1980](#), [Marvin 1983](#); [Mahler 1985](#); [Dullinger 1986](#); [Kongragunta 1988](#)), three in Canada ([Guyatt 1987](#); [Rivington 1988](#); [Thomas 1992](#)), two each in the UK ([Anderson 1982](#); [Chrystyn 1988](#)), Israel ([Fink 1994](#); [Newman 1994](#)), Ireland ([Power 1992](#); [Mulloy 1993](#)) and Japan ([Nishimura 1993](#); [Nishimura 1995](#)) and one each in Denmark ([Iversen 1992](#)), France ([Murciano 1989](#)) and Germany ([Machraoui 1994](#)).

TYPES OF PARTICIPANTS

All studies included adult participants with COPD defined using objective criteria of less than 15% in FEV1 reversibility after inhaling a bronchodilator in six studies (Schmidt 1979; Mahler 1985; Chrystyn 1988; Murciano 1989; Power 1992; Mulloy 1993) or 25% in two studies (Dullinger 1986; Guyatt 1987). The MRC definition of COPD was used in two studies (Anderson 1982; Chrystyn 1988) and the ATS definition in one (Nishimura 1995). One study (Thomas 1992) did not include participants who had a greater than 20% change in either FEV1 or FVC over the previous two years. Most of the studies also used a pre-defined criterion based on predicted FEV1 or FEV1/FVC ratio for including participants in their study, typical values for FEV1 were less than 60 to 70% and for FEV1/FVC ratio it was less than 0.6 to 0.7. One study (Nishimura 1995) included participants with a post-bronchodilator FEV1/FVC ratio of less than 70%. All of the studies included participants who were either ex or current smokers and excluded participants who had asthma. Baseline mean FEV1 for the participants in the 20 studies ranged from 0.96 to 1.15 L. Mean age ranged from 58 to 69 years.

COMMITTANT MEDICATION

Four of the studies did not allow use of bronchodilators during the study period (Alexander 1980; Guyatt 1987; Murciano 1989; Thomas 1992). Twelve studies permitted use of regular bronchodilators and inhaled corticosteroids for the duration of the study (Anderson 1982; Marvin 1983; Mahler 1985; Chrystyn 1988; Kongragunta 1988; Rivington 1988; Mulloy 1993; Nishimura 1993; Fink 1994; Machraoui 1994; Newman 1994; Nishimura 1995). Four studies did not describe concomitant medication use (Schmidt 1979; Dullinger 1986; Iversen 1992; Power 1992).

TYPES OF INTERVENTION

All 20 included studies were of crossover design and used dosing schedules to obtain plasma theophylline levels in the therapeutic range (10 to 20 mg/ml). Five studies used short acting or immediate release theophylline preparations (Schmidt 1979; Alexander 1980; Marvin 1983; Guyatt 1987; Machraoui 1994) while the remaining 15 studies used long acting or sustained release theophylline preparations. Where studies have reported both pre and post-bronchodilator (e.g. salbutamol, terbutaline, ipratropium bromide) study measurements, only the pre-bronchodilator measurements were used (for the meta-analysis) as the purpose of this review was to observe the effects of oral theophylline administration and not to estimate the effects of immediate post-bronchodilator therapy.

The duration of the studies ranged from 7 to 90 days. The duration of each study was entered into RevMan (as days) under user defined category, in order to observe any influence of study duration on effect size.

Nine of the studies reported adequate washout periods between their crossover arms ranging from three days to two weeks (Anderson 1982; Mahler 1985; Guyatt 1987; Kongragunta 1988; Murciano 1989; Mulloy 1993; Fink 1994; Newman 1994; Machraoui 1994). The remaining 11 studies did not report any washout period. This, however, may not mean that no washout period was employed by these 11 studies. To date we have not received any correspondence from the authors to verify this information.

DROPOUT AND WITHDRAWALS

Only one study (Iversen 1992) failed to report dropouts. In the others, with the exception of Guyatt 1987 (eight withdrawals from 27 recruited) the dropout out rate was generally very low. Nine studies reported no dropouts (Marvin 1983; Mahler 1985; Dullinger

1986; Rivington 1988; Murciano 1989; Power 1992; Nishimura 1993; Fink 1994; Newman 1994).

Risk of bias in included studies

There was total agreement between two reviewers on the inclusion of studies and for the quality scores. Four studies were graded as Cochrane 'A' (adequate allocation concealment) (Schmidt 1979; Marvin 1983; Rivington 1988; Mulloy 1993), and the remaining 16 studies scored a 'B' grade (unclear allocation concealment). The mean (SD) score for Jadad study quality was 2.8 (0.81) and the range was 1 to 5. Most of the included studies (12) received a Jadad score of three, five studies received a score of two, and three studies each received a score of one, four and five. Overall the studies were of adequate quality as none of the studies scored 'C' with the Cochrane grading and the mean Jadad score was 2.8, which is considered of adequate-to-good quality.

Effects of interventions

OUTCOMES REPORTED IN TWO OR MORE INCLUDED STUDIES: STATISTICALLY SIGNIFICANT EFFECT

FEV1 - L [Comparison 01:01:01]

Thirteen studies with 244 patients contributed data towards this outcome which showed a significant improvement of 100 ml with treatment (WMD 100 ml; 95%CI 40 to 160). One of the thirteen studies did not report any SD for FEV1 (Dullinger 1986) so it was estimated from the values reported for range. A sensitivity analysis without the Dullinger 1986 study did not alter the mean overall result (WMD 110 ml; 95%CI 40 to 170) compared to when all 13 studies were included. There was no evidence of heterogeneity in this effect size across the studies.

FVC - L [Comparisons 01:02:01& 01:02:02]

Eleven studies with 196 patients contributed data towards this outcome which showed significant improvement of 210 ml with treatment (WMD 210 ml; 95%CI 100 to 320). Two of the 11 studies did not report any SD's for FVC (Schmidt 1979; Dullinger 1986) so they were estimated from the reported range and p values, respectively. A sensitivity analysis without the Dullinger 1986 and Schmidt 1979 studies did not alter the mean overall result (WMD 200 ml; 95%CI 70 to 320) compared to when all 11 studies were included. FVC reported as percent predicted by three studies was also significant (WMD 3.93; 95%CI 0.22 to 7.65).

VO2 max - ml/min [Comparison 01:09]

Two studies with 32 patients reported this outcome (Fink 1994; Newman 1994) which showed significant improvement with treatment (WMD 195 ml/min; 95%CI 113 to 278).

PaO2 - mm Hg at rest [Comparison 01:10]

Six studies with 156 patients reported this outcome (Alexander 1980; Mahler 1985; Murciano 1989; Mulloy 1993; Fink 1994; Newman 1994) which showed significant improvement with treatment (WMD 3.18 mm Hg; 95%CI 1.23 to 5.13).

PaCO2 - mm Hg at rest [Comparison 01:11]

Six studies with 156 patients reported this outcome (Alexander 1980; Murciano 1989; Mahler 1985; Mulloy 1993; Fink 1994; Newman 1994) which showed significant decrease with treatment (WMD -2.36 mm Hg; 95%CI -3.52 to -1.21).

Patient preference for theophylline or placebo [Comparison 01:21]

Two studies with a total of 50 (cross over) subjects (Alexander 1980; Mulloy 1993) reported that participants preferred theophylline to placebo (RR 2.27; 95%CI 1.26 to 4.11).

Nausea [Comparison 01:23]

Three studies reported data on nausea (Alexander 1980; Mulloy 1993; Newman 1994). The risk of experiencing nausea when on treatment with theophylline was significantly increased (RR 7.67; 95%CI 1.47 to 39.94).

There did not appear to be any influence of study duration on outcome effect size (using user-defined category in Forest plots).

OUTCOMES REPORTED IN TWO OR MORE STUDIES: NO STATISTICALLY SIGNIFICANT EFFECT

Distance walked (m) [Comparison 01:23]

Two studies (58 patients) reported distance walked in six minutes (Guyatt 1987; Chrystyn 1988) and two (22 patients) the distance walked in 12 minutes (Mahler 1985; Dullinger 1986). In neither group of studies was the effect significant and when all four studies were combined using an SMD the effect was still not significant (SMD 0.30; 95%CI -0.01 to 0.62). The mean difference in the six-minute walk studies was 33 m which is not at the threshold of clinical significance.

Visual Analogue Scale (VAS) for breathlessness [Comparison 01:14]

Two studies (32 patients) reported this (Dullinger 1986; Chrystyn 1988), there was no effect.

Symptoms of wheeze and dyspnea [Comparison 01:18]

Two studies (21 patients) reported these (Dullinger 1986; Chrystyn 1988), there was no effect.

Exacerbations [Comparison 01:20]

Two studies (45 patients) reported these (Rivington 1988; Nishimura 1995), there was no effect.

Drop outs

It was possible to compare drop out rates between treatment arms in only three studies totaling 74 patients (Anderson 1982; Fink 1994; Newman 1994). There was no difference.

No data were available for health status and mortality.

DISCUSSION

This review has shown that administering oral theophylline for at least seven days, to patients with moderate to severe COPD improves lung function, ventilatory capacity and arterial blood gas tensions in patients with stable COPD. Participants preference for theophylline was greater than that for placebo. However, the number of adverse effects (nausea) was greater with theophylline treatment.

The magnitudes of the lung function changes are relatively small, but similar to those reported in another Cochrane review of long-acting beta2-agonists (Appleton 2002). Meaningful symptomatic responses from bronchodilators in the presence of only trivial changes in FEV1 and FVC have been reported (Mahler 1985; Wolkove 1989; Hay 1992). Unfortunately, there were very small numbers of studies reporting symptoms in this review. The included studies that attempted to measure improvements in symptoms (e.g. dyspnoea, quality of life, wheeze) all showed improvements, but,

owing to minimal reporting and the use of different methodologies the data could not be collated meaningfully. Individual studies did, however, report benefits. Alexander 1980 used a six point scale which measured dyspnoea, wheezing, cough, sputum, walking and feelings that showed improvements in all categories with the use of theophylline. The study by Guyatt 1987 reported significant improvements in dyspnoea and quality of life scores measures by CRQ. Chrystyn 1988 and Dullinger 1986 reported a modest improvement in dyspnoea with theophylline treatment. Iversen 1992 reported significant improvements in dyspnoea scores during theophylline treatment. Marvin 1983 and Thomas 1992 reported improvements in both wheezing and shortness of breath with theophylline.

Other mechanisms have been proposed to explain how theophylline could improve symptoms or reduce breathlessness in patients with COPD. The Chrystyn 1988 study measured the effects of theophylline on 33 participants with stable COPD. In their study a dose of theophylline that resulted in serum concentrations of 15-20 mg/L, only led to an increase in FEV1 of 13% (130 ml) but there was a significant 64% decrease in trapped gas volume (1.84 L to 0.67 L). Unfortunately, this was the only study to report data on trapped gas volume in this review.

Other workers have shown that inhaled beta 2-agonists and ipratropium bromide reduce exertional breathlessness in subjects with stable COPD and this correlates strongly with decreases in thoracic gas entrapment (Chrystyn 1988; Webb 1990) and dynamic hyperinflation (Belman 1996; O'Donnell 1999). The improvements in lung function seen with theophylline in this review may be due to dilatation of the small airways with a consequent reduction in gas trapping. A fall in trapped gas volume (and thus FRC) is likely to improve the mechanical advantage of the diaphragm and chest wall muscles and may well explain many of the reported effects of theophylline on the respiratory muscles (Murciano 1984).

Theophylline has also been demonstrated to increase the pressure generated by respiratory muscles (Umut 1992) and increase diaphragmatic strength (Kongragunta 1988). Its effect has been shown to be greater in fatigued diaphragm (Murciano 1984) as has been shown in severe COPD. In one study, theophylline increased trans-diaphragmatic pressure by 16% and this increase persisted even after 30 days of treatment with theophylline (Murciano 1984). In therapeutic doses theophylline is also known to increase respiratory drive independent of its effect on lung function (Ashutosh 1997). It is also known to increase respiratory muscle function in normal participants (Sherman 1996) and in COPD (Umut 1992) as measured by increases in maximal inspiratory and expiratory pressures. It has also been suggested that theophylline reduces breathlessness by improving diaphragmatic contractility. The Murciano 1989 trial demonstrated an improvement in respiratory muscle performance as indicated by a decline in the ratio of inspiratory pleural pressure during quiet breathing to the maximal pleural pressure (data not reported in this review as an outcome).

Another interpretation is that the improvement in respiratory muscle function is due not to an increase in diaphragmatic contractility but to an improvement in the length-tension relationship of the diaphragm. This is because there is a reduction in gas trapping and a recent study by Hatipoglu 1999 supports this interpretation. It is possible and likely that these effects of

theophylline had a role in slightly but significantly improving lung function as has been shown by this review.

There were small but statistically significant improvements in arterial blood gas tensions in patients treated with theophylline. In severe cases of COPD, respiratory rate is increased, and this may be combined with shallow breathing that is pronounced by carbon dioxide retention. It is known that theophylline improves minute ventilation in humans (Darnall-Jr 1985) and animals (Javaheri 1989) and also alters the ventilatory response in COPD seen as improved ventilatory capacity measured as increased VO₂ max. This ventilatory response results in an increase in tidal volume, which may be responsible for the improvement seen in blood gas tensions. Both these changes (increase in VO₂ max and improved blood gas tensions) could be related to either a direct positive inotropic effect of theophylline on the respiratory muscles (Okubo 1987; Kongragunta 1988; Landsberg 1990; Marsh 1993) or due to its action via a central stimulatory pathway (Cooper 1987; Javaheri 1990) or both. It is known that theophylline is capable of stimulating the medullary respiratory center (Ritchie 1975).

Although only two studies provided data for VO₂ max, this is an important significant finding as greater exercise performance is implied by increases in VO₂ max. Unfortunately there were not enough studies providing data on exercise performance (distance walked, cycle endurance or progressive cycle ergometry) to permit us to relate the increase in VO₂ max to exercise performance. The effect size in the two studies that reported it was approximately 30 metres for a six minute walk which is not clinically significant.

Theophylline has a narrow therapeutic index and adverse effects are common even when the serum concentrations are in the 'therapeutic range' of 10 to 20 mg/L. In this review, nausea was reported by significantly more participants treated with theophylline compared with placebo. Another more serious adverse effect of theophylline in patients with COPD, is supraventricular arrhythmias (Levine 1985; Varriale 1993), however, this was not reported in this review. Nevertheless, the benefits of theophylline in stable COPD have to be weighed against the risk of adverse effects. All of the included studies in this review aimed for theophylline concentrations within the therapeutic range. In patients with asthma theophylline exerts beneficial effects at serum concentrations lower than the traditional therapeutic range of 10 to 20 mg/L (Mitenko 1973; Evans 1997). Lower concentrations of theophylline have the advantage that they are associated with fewer adverse effects. In future studies of theophylline for stable COPD it may be appropriate to have a lower target concentration of theophylline. An alternative approach would be to study specific inhibitors of type IV phosphodiesterases such as Airflo[®] that are reported to be effective in the treatment of asthma but which have fewer adverse effects compared to theophylline (Compton 2000; Barnette 2000; Giembycz 2000).

A possible pitfall of crossover studies, such as those included in this review, is the presence of carry-over effects of the first treatment into the second treatment period, leading to an underestimation of the real difference among treatments (Cleophas 1993). Nine of the studies reported adequate washout periods between their crossover arms ranging from three days to two weeks. The remaining 11 studies did not either have a washout period or failed to report any washout period. To date we have not received any correspondence from the authors to verify this information.

A second possible pitfall associated with crossover designs, is that the software we used (RevMan) forces us to analyse crossover studies as if they were parallel studies. It is known (Cleophas 1996) that the two methods give identical results if the response to the two treatments, in the same individual, is completely unrelated. However, parallel analysis may lead to decreased statistical power when compared to paired analysis, if the response to the two treatments is positively correlated (i.e. if patients improving during bronchodilator are also more likely to improve somewhat during placebo). This possibility cannot be discounted in our review. The results of the statistical analysis from two-period crossover trials make two main assumptions, no period effect and no treatment-period interaction. But none of the authors reported these findings (correlation between the responses to the two treatments) from their studies and the presentation of the data did not permit these types of analysis. Therefore, we cannot exclude that our analysis underestimated the statistical significance of the observed differences, as compared to a paired analysis.

AUTHORS' CONCLUSIONS

Implications for practice

Theophyllines produce a small improvement in FEV₁ that is similar in size to that reported for long acting beta₂-agonists in COPD patients, with and without adjuvant bronchodilator therapy. There also appears to be a small mean improvement in arterial blood gas tensions. The evidence for symptomatic benefit or improved exercise performance is less consistent. There is an increased incidence of nausea, but on average, the patients in the studies reviewed here preferred theophylline. The tolerance of theophylline in the patients recruited to these studies (as reflected by the absence of an increased drop out rate) is a little surprising since clinical experience suggests that a significant number of patients cannot tolerate the gastro-intestinal side-effects. We conclude that, with close monitoring of individual patients and their serum theophylline levels, it appears that beneficial effects may be obtained in those who remain symptomatic from COPD despite first-line bronchodilator therapy.

Implications for research

Larger parallel randomised controlled trials with explicit clinical and diagnostic criteria, sufficient duration of follow-up and description of all relevant clinical outcome measures appear warranted. Many previously conducted studies have relied heavily on the readily available physiological tests (e.g. FEV₁, FVC, PEF_R). As these are not particularly sensitive measures of change in this group of patients (Wolkove 1989; Celli 2000) we suggest that other relevant outcome measures should be used (e.g. symptoms, health status, adverse effects, exercise capacity & endurance, length of hospital stay, incidence of exacerbations, health care utilisation and cost effectiveness). Future studies should also endeavour to define which 'types' of patients are most likely to respond to treatment with theophylline. Studies also need to examine the role of theophylline in comparison, and in conjunction, with newer agents such as long acting bronchodilators. Further investigation of the effect of theophylline on ventilatory mechanics would be helpful to delineate the non-bronchodilator effects of theophylline, which appear important. Because of a lower incidence of adverse effects, it will be interesting to observe the efficacy of specific inhibitors of type IV phosphodiesterases in people with COPD.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]
Alexander 1980

Methods

- 1) Randomisation: not described.
- 2) Allocation concealment: not described.
- 3) Masking: double blind, identical looking placebo theophylline tablets were used.
- 4) Withdrawals / drop-outs: 13 drop-outs. 5 placebo group and 4 theophylline group did not finish both study periods and are not included in the data analysis. 2 from each drug regimen dropped out as a result of acute respiratory distress that was attributed to pulmonary infection.
- 5) Duration of intervention: 4 weeks.
- 6) Design: crossover groups.

Alexander 1980 (Continued)

- 7) Jadad quality score: 3
- 8) Location: Iowa, USA

Participants	<ol style="list-style-type: none"> 1) Inclusion criteria: Outpatients with moderate to severe COPD, stable, FEV1 less than 60 % of predicted, all had smoking histories of greater than 20 pack-years. 2) Definition of COPD: FEV1 at least less than 60% of predicted and a chronic, steadily declining FEV1 and forced expiratory flow during the middle half of the forced vital capacity (FEF 25% to 75%). 3) Type of exercise test: None. 4) Definition of stable COPD: not described. 5) Age: Mean = 59.3. 6) FEV1: not described. 7) Number of patients: 53 men. Drop-out: 13. Final number of patients: 40. 8) Baseline therapy: Bronchodilators and corticosteroids were not allowed during the study, but other maintenance medications were continued. 9) Exclusion criteria: Non-compliant patients (identified by pill counts and by observing serum theophylline concentration during the dose titration period, history of asthma, sputum and peripheral blood eosinophilia or another known cause for pulmonary insufficiency, fluctuation results in pulmonary function tests during a period of several years.
Interventions	<p>THEOPHYLLINE GROUP (n = 40, completed the study)</p> <ol style="list-style-type: none"> 1) Drug: Theophylline. 2) Short or long action: Short-action 3) Dose: 100 mg four times daily 4) Washout period: not mentioned. 5) Theophylline blood level: during titration period to establish steady-state (10 to 20 ug/ml) theophylline serum levels (1.5 to 2.0 hours after the second dose of the day) and on the day of entry into the trial, and on the final day of each treatment period. Mean serum theophylline level during active therapy was 15.1 (SD 4.22) ug/ml. <p>PLACEBO GROUP (n = 40, completed the study).</p>
Outcomes	<ol style="list-style-type: none"> 1) Pulmonary function tests (FVC (L), FVC (% pred), FEV1 (L), FEV1 (% Pred). 2) Resting arterial blood gases 3) Maximal voluntary ventilation. MVV (maximum voluntary ventilation (L), MVV (% pred). 4) Diary questionnaire, about pulmonary symptoms.
Notes	<ol style="list-style-type: none"> 1) Intention-to-treat analyses: No 2) Sample size and statistical power: not reported. 3) Representativity: not described.

Risk of bias

Bias	Authors' judgement	Support for judgement
Allocation concealment (selection bias)	Unclear risk	B - Unclear

Anderson 1982

Methods	<ol style="list-style-type: none"> 1) Randomisation: not described. 2) Allocation concealment: not described. 3) Masking: Double blind, placebo was used and had the same appearance as theophylline tablets. 4) Withdraw / Drop-out: 4 withdraws, (one because of a confusional state attributed to alcohol withdrawal and 3 because of side effects - nightmares in one, headache in one and nausea and headache in one. (4/17 = 23%). 5) Duration of intervention: 3 periods of 8 days each, with one week washout. 6) Design: Cross-over groups.
---------	--

Anderson 1982 (Continued)

- 7) Jadad quality Score: 3
- 8) Location: Newport, UK

Participants	<ol style="list-style-type: none"> 1) Inclusion criteria: patients that fulfilled the Medical Research Council criteria for chronic bronchitis, all patients were ex-smokers. 2) Definition of COPD: The Medical Research Council criteria for chronic bronchitis (MRC, 1965). 3) Type of exercise test: none. 4) Definition of stable COPD: not described. 5) Age: Mean = 58, (range 34 to 70 years). 6) FEV1: Mean = 1.34, SD 0.122 (L). 7) Number of patients: 21 (17 men and 4 women). 8) Baseline therapy: corticosteroids were not allowed, but other maintenance medications were permitted including inhaled bronchodilators. 9) Exclusion criteria: bronchial asthma.
Interventions	<p>THEOPHYLLINE GROUP (n = 21, completed the study).</p> <ol style="list-style-type: none"> 1) Drug: Theophylline (Nuelin SA) 2) Short or long action: Long-action (Nuelin SA) 3) Dose: 350 mg daily theophylline for 4 days followed by 700 mg daily for four days with matching placebo for 8 days with one week washout period between crossover. 4) Washout period: 1 week. 5) Theophylline blood level: measured on the last day of each study period. The mean daily dose of theophylline for the whole group was 9.2 mg/Kg range 6-13.2 mg/Kg. <p>PLACEBO GROUP: n = 21 completed the study.</p>
Outcomes	<ol style="list-style-type: none"> 1) Pulmonary function tests PEFr, (FVC (L), FVC (% pred), FEV1 (L), FEV1 (% Pred). 2) Symptom scores 3) Side effects: 6 patients had nausea or headache in theophylline group. One patient had insomnia during the placebo week.
Notes	<ol style="list-style-type: none"> 1) Intention-to-treat analyses: No. 2) Sample size and statistical power: not reported. 3) Representativity: not described.

Risk of bias

Bias	Authors' judgement	Support for judgement
Allocation concealment (selection bias)	Unclear risk	B - Unclear

Chrystyn 1988

Methods	<ol style="list-style-type: none"> 1) Randomisation: patients were randomly allocated to the order of treatment by four identical Latin squares. 2) Allocation concealment: Not described. 3) Masking: The dose changes were effected in a single blind manner with matching placebo tablets. 4) Withdraw/Drop-out: 5 drop-out /38 (13,16%). 5) Duration of intervention: 2 months. 4 consecutive two month treatment periods (total = 8 months). Four periods: placebo, low, medium and high theophylline serum concentrations. 6) Design: Crossover groups. 7) Jadad quality score: 2 8) Location: West Yorkshire, UK
Participants	<ol style="list-style-type: none"> 1) Inclusion criteria: COPD, moderate to severe obstruction of airflow. 2) Definition of COPD: Medical Research Council definition.

Chrystyn 1988 (Continued)

- 3) Type of exercise test: Six min waking test
- 4) Definition of stable COPD: not defined. But no patients were recruited who had an acute exacerbation in the previous 2 weeks.
- 5) Age: Mean = 61.2, SD 5.71 years (range 53 to 73)
- 6) FEV1: Mean = 29.1, SD 12.4 (% predc)
- 7) Initial total number of patients: 38. Drop-out: 5. Final patients number: 33 (30 men and 3 women).
- 8) Baseline therapy: Inhalation and oral corticosteroids and other bronchodilators were continued.
- 9) Exclusion criteria: Asthma or allergy, $\geq 15\%$ improvement in FEV1 20 min after inhaling 500 ug terbutaline sulphate, known sensitivity to methylxanthine, severe cardiac disease or other disease that might interfere with exercise testing.

Interventions	<p>THEOPHYLLINE 3 GROUP- low dose (n = 19), medium dose (n = 12), high dose (n = 10), completed the study.</p> <ol style="list-style-type: none"> 1) Drug: Theophylline 2) Short or long action: Long-action 3) Dose: 3 doses used; low (5 to 10 mg/l), medium (10 to 15 mg/l) and high (15 to 20 mg/l). Used the medium dose only for the review as it is clinically the most relevant dose resulting in therapeutic plasma levels. 4) Washout period: not mentioned. 5) Theophylline blood level: measured at the end of each two month period. <p>PLACEBO GROUP (n = 22)</p>
Outcomes	<ol style="list-style-type: none"> 1) Pulmonary function tests (FEV1), (FVC), (SVC) (L), TLC measured by helium dilution (L), FRC measured by helium dilution (L), TLC measured by whole body plethymography (L), FRC measured by whole body plethymography (L) and trapped gas volume (L). 2) Exercise testing : six minute walking test 3) Visual analogue scale for dyspnoea (10 cm) 4) Peak expiratory flow (L/min.) 5) Side effects: nausea, insomnia, dyspepsia, headache, cramp, tremor (theophylline group)
Notes	<ol style="list-style-type: none"> 1) Intention-to-treat analyses: Yes 2) Sample size and statistical power: not reported. 3) Representativity: not specified

Risk of bias

Bias	Authors' judgement	Support for judgement
Allocation concealment (selection bias)	Unclear risk	B - Unclear

Dullinger 1986

Methods	<ol style="list-style-type: none"> 1) Randomisation: not described (block design). 2) Allocation concealment: not described. 3) Masking: Double blind, placebo tablets were identical in appearance to theophylline tablets. 4) Withdraw/Drop-out: none. 5) Duration of intervention: 1 x 4 week as 4 different combinations of treatments were tested. 6) Design: Cross-over group 7) Jadad quality score: 3 8) Location: Minneapolis, USA
Participants	<ol style="list-style-type: none"> 1) Inclusion criteria: COPD, outpatients. 2) Definition of COPD: FEV1 less than 1.5 L and FEV1/FVC of less than 60%. 3) Type of exercise test: 12 minute walk test 4) Definition of stable COPD: not described.

Dullinger 1986 (Continued)

- 5) Age: Mean = 61 years (range 53 to 72 years).
- 6) FEV1: Mean = 2.63 L (range 1.69 to 3.74)
- 7) Number of patients: 10 men. withdraw: 0
- 8) Baseline therapy: Not described.
- 9) Exclusion criteria: presence of significant chest abnormalities on x-ray, asthma, history of atopy, sputum or blood eosinophilia, absence of long-term smoking, frequent episodic attacks of wheeziness, regular use of corticosteroids, FEV1 response to an inhaled beta-agonist greater than 25% of baseline or co-existing disease which might interfere with exercise testing.

Interventions	THEOPHYLLINE GROUP VERSUS PLACEBO (n = 10, completed the study) 1) Drug: Theophylline (Theo-Dur, Key Pharmaceuticals) 2) Short or long action: Long-action 3) Dose: twice daily in amounts to provide average plasma concentrations of 10 to 15 ug/ml. 4) Washout period: not mentioned. 5) Theophylline blood level: measured on the first day of the initial baseline study and at day 6 of each period.
Outcomes	1) Pulmonary function tests: FVC (L), FEV1 (L). 2) Exercise testing (12 minute walking test and Incremental cycle ergometry test) 3) Dyspnea (oxygen cost diagram - OCD and breathlessness rating - BR) 4) Side effects: No reports of adverse effects from any of the treatments.
Notes	1) Intention-to-treat analyses: Yes 2) Sample size and statistical power: not reported. 3) Representativity: not described.

Risk of bias

Bias	Authors' judgement	Support for judgement
Allocation concealment (selection bias)	Unclear risk	B - Unclear

Fink 1994

Methods	1) Randomisation: not described. 2) Allocation concealment: not described. 3) Masking: Double blind, using identical placebo tablets to active treatment. 4) Withdraw/Drop-out: none. 5) Duration of intervention: 1 month. 6) Design: Cross-over groups 7) Jadad quality Score: 2 8) Location: Tel Aviv, Israel
Participants	1) Inclusion criteria: COPD, severe, stable, smokers or former smokers. 2) Definition of COPD: FEV1 less than 50% of predicted. 3) Type of exercise test: Incremental cycle-ergometer. 4) Definition of stable COPD: not described. 5) Age: Mean = 68.5, SD 3.3 years 6) FEV1: Mean = 38.3, SD 8.6 (% pred) and Mean = 1.06, SD 2.8 (L) 7) Number of patients: 22 (17 men and 5 women), withdraw: 0 8) Baseline therapy: Inhalation corticosteroids and other bronchodilators. 9) Exclusion criteria: known cardiac disease or cardiac disorders shown on the baseline incremental exercise test.
Interventions	THEOPHYLLINE GROUP (n = 22, completed the study) 1) Drug: Theophylline (Theotrim, Trima Lab., Israel)

Fink 1994 (Continued)

- 2) Short or long action: Long-action
- 3) Dose: 300 mg theophylline (twice daily). Patients weighing less than 60 Kg took 200 mg twice per day.
- 4) Washout period: 2 weeks.
- 5) Theophylline blood level: measured on the day of the initial baseline study and after the first week of treatment. The dose was adjusted if the level was below 55.5umol/l. This adjustment was repeated until all patients had a blood level above 55.5umol/l.

PLACEBO GROUP (n = 22, completed the study)

Outcomes	<ol style="list-style-type: none"> 1) Pulmonary function tests FVC (L), FVC (% pred), FEV1 (L), FEV1 (% pred). 2) Exercise testing (incremental exercise cycle ergometer test - WR, VO2max, HR, respiratory rate and ventilation, VO2max/HR (maximum oxygen pulse), VEmax/MVV (dyspnoea index), anaerobic threshold (VE/VO2slope). 3) Resting arterial blood gases 4) Maximal voluntary ventilation (MVV) (L), MVV (% pred). 5) Side effects: not described.

Marvin 1983
Methods

1) Randomisation: not described
 2) Allocation concealment: coded in the pharmacy.
 3) Masking: Double blind, placebo controlled. The code was not broken under any circumstances until completion of the entire study.
 4) Withdraw/Drop-out: none.
 5) Duration of intervention: 10 days (four arms to the study therefore 10 days x 4).
 6) Design: Cross-over
 7) Jadad quality score: 3
 8) Location: Little Rock, USA

Participants

1) Inclusion criteria: COPD severe outpatients, clinically stable, smoking history of greater than 20 pack-years.
 2) Definition of COPD: FEV1 less than 50% of predicted.
 3) Type of exercise test: Incremental cycle ergometer and steady-state exercise testing
 4) Definition of stable COPD: not referred.
 5) Age: Mean = (?) range 50 to 69 years
 6) FEV1: Mean = 1.03, SD 0.34 (L)
 7) Number of patients: 15 men. withdraw: 0
 8) Baseline therapy: All medications with cardiopulmonary effect were discontinued for 72 hours.
 9) Exclusion criteria: Asthma, presence of greater than 5% eosinophils on peripheral blood smear, primary cardiovascular disease (angina, systemic hypertension, ventricular arrhythmia), evidence of left ventricular decompensation, other complicating systemic illness.

Interventions

THEOPHYLLINE GROUP (n = 15, completed the study)

1) Drug: Theophylline (Elixophylline)
 2) Short or long action: Short-action
 3) Dose: 200 mg theophylline (four times daily) for 10 days.
 4) Washout: not reported.
 5) Theophylline blood level: measured before and after 10 days of theophylline treatment. The dose was not adjusted.

PLACEBO GROUP (n = 15, completed the study)

Outcomes

1) Compliance with medication
 2) Exercise testing (steady-state exercise (60% of the maximal work load during 6 minutes)
 3) Shortness of breath: using a simple graded scale (absent = 0, mild = 1, moderate = 2, severe = 3).
 4) Wheezing: same simple scale as shortness of breath (above).
 5) Side effects: 'intolerance' in theophylline group (only one patient)
 6) Lung function

6MW: Six minute walk distance
 AT: Anaerobic threshold (mlVO₂/min)
 DLCO: Diffusing capacity of the lung for carbon monoxide (ml/min/mmHg)
 FEV1: Forced expiratory volume in one second (L)
 FVC: Forced Vital Capacity (L)
 FRC: Functional Residual Capacity (L)
 HR: Heart Rate
 MMFER: Maximal mid flow expiratory rate
 MVV: Maximum Voluntary Ventilation (L)
 PaCO₂: Arterial carbon dioxide tension (mmHg or KPa)
 PaO₂: Arterial oxygen tension (mmHg or KPa)
 PC20: concentration of inhaled necessary to produce a 20% fall in FEV1
 PEF: Peak expiratory flow rate
 RV: Residual volume (L)
 SVC: Slow vital capacity (L)
 TGV: Trapped gas volume (L)
 TLC: Total Lung Capacity (L)
 VEmax/MVV: dyspnoea index
 VE/VO₂slope: anaerobic threshold
 VO₂max/HR : maximum oxygen pulse
 VO₂ max: Maximum oxygen consumption
 WR: Work Rate

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Adelroth 1998	Review article.
Arnold 1990	No placebo arm. Study compared enprofylline versus theophylline.
Ashutosh 1997	The objective of this study was to observe the effect theophylline on respiratory drive. The study was also only of single doses of theophylline.
Bachmann 1995	All patients were taking theophylline as study was seeing the effects of cimetidine and famotidine on theophylline.
Berry 1991	Because of the objective of this study is investigate the effect to theophylline on sleep-disordered breathing in patients with COPD.
Beulcke 1995	No placebo arm. Study compared two derivatives of xanthine.
Bleecker 1991	Single dose study lasting 2 hours and probably not an RCT.
Blom 1985	Study did not involve the use of theophylline.
Boos 1989	No placebo arm in study.
Carvalho-Pinto 1991	No placebo arm in study.
Chapman 1990	The population studied had reversible obstructive airway disease (asthma)
Conradson 1987	The population studied have bronchial asthma (23) and/or chronic bronchitis (1).
Crimi 1995	No placebo arm in study. Comparison was between nedocromil sodium and theophylline.
Cusack 1986	No placebo arm in study.
Di Lorenzo 1998	There is no control group, only salmeterol and theophylline intervention groups.
Dini 2001	Not an RCT.
Dorow 1978	Allocation of treatment not randomised, although double-blinding was used.
Dull 1981	This study presents data for post isoproterenol nebulisation response on the final day of 4-wk placebo and theophylline period.
Evans 1984	Single dose study. Patients were given theophylline at 2200hrs on the eve of each study day and all patients were studied 12 hours later. Varying single doses were used (200, 400, 600 and 800 mg) on separate days.
Fitzpatrick 1992	The subjects included in this study are healthy volunteers
Greening 1981	The population is not COPD. They have asthma.
Harkaway 1985	No placebo arm, study comparing 2 preparations of theophylline.
Horiguchi 1999	Not COPD but study done in patients with asthma.
Hudson 1973	No placebo arm in study.

Study	Reason for exclusion
Javaheri 1996	The population studied in this paper have heart failure not COPD
Karpel 1994	There are four groups in this study : ipratropium + theophylline + albuterol vs theophylline + albuterol vs ipratropium vs placebo. But there are no theophylline only group.
Lamont 1982	Study included patients with greater than 20% reversibility in FEV1 after beta2 agonists from pMDI, therefore COPD patients only not included in study.
Lefcoe 1982	Because of the distribution of the groups: P = placebos (2 oral, plus one aerosol), F + T = fenoterol + theophylline, I = Ipratropium bromide + placebo + theophylline, F+ T + I = fenoterol+ theophylline + ipratropium bromide. So, there is not a isolated theophylline study group.
Leitch 1981	Single dose study lasting 3 hours.
Leuenberger 1997	Not an RCT but a review paper.
Lunell 1983	No placebo arm in study.
Mahon 1999	This was not a conventional RCT but an N of 1 trial, therefore it was excluded as only conventional RCT's were included. Patients in this study switched (crossover) to the "other" blinded treatment arm if the first treatment did not appear to work.
Man 1996	No placebo arm in study.
Marlin 1978	Not COPD patients.
Martin 1992	No placebo group in study.
McHardy 1981	Study specifically looked at chronic bronchitis patients only but also included some patients who had COPD. But the data for COPD patients is not presented separately but mentioned in text.
Melani 1994	There is no placebo group in this study.
Melillo 1989	There is no control group.
Morandini 1989	No placebo arm in study.
Oren 1997	This study is not randomised.
Poukkula 1989	Not patients with COPD.
Pulido 1989	Bamyphylline is a theophylline derivate. Our protocol includes only aminophylline and theophylline not their derivates.
Sacco 1995	In this study there was no placebo group. It was doxofylline versus theophylline groups.
Shivaram 1997	Single dose study lasting 120 minutes.
Siemon 1991	Study comparing two different theophylline preparations.
Steen 1980	No placebo arm in study. Tedral versus theophylline only.
Sutton 1981	Not COPD patients.
Svedmyr 1982	Single dose study in patients with asthma. Oral theophylline used in combination with terbutaline.

Study	Reason for exclusion
Taccola 1999	No placebo arm.
Tanzj 1974	Two different theophylline preparations compared with no placebo arm in study.
Tatsis 1988	This study does not a placebo group and includes bronchial asthmatics patients
Taylor 1985	Not COPD patients, mean bronchodilator reversibility in FEV1 of > 26%.
Tsukino 1998	Single dose study.
Umut 1992	Not an RCT.
Van Andel 1999	Not a RCT.
Vereen 1986	Use of iv aminophylline preparation.
Villani 1997	Because doxophylline is a theophylline derivate. Our protocol includes only aminophylline and theophylline.
Vyse 1989	No placebo group.
Wiessmann 1975	Allocation of treatment not randomised, although double-blinding was used.
Winter 1984	No placebo arm. Study only included a comparison between theophylline versus salbutamol.
Yang 2001	Not COPD patients but asthma.
ZuWallack 2001	Study was primarily comparing theophylline plus salmeterol as a combination treatment. Although the study had theophylline only arm it did not have a placebo only arm so the study cannot be included in the review.

DATA AND ANALYSES

Comparison 1. Theophylline versus Placebo - crossover studies

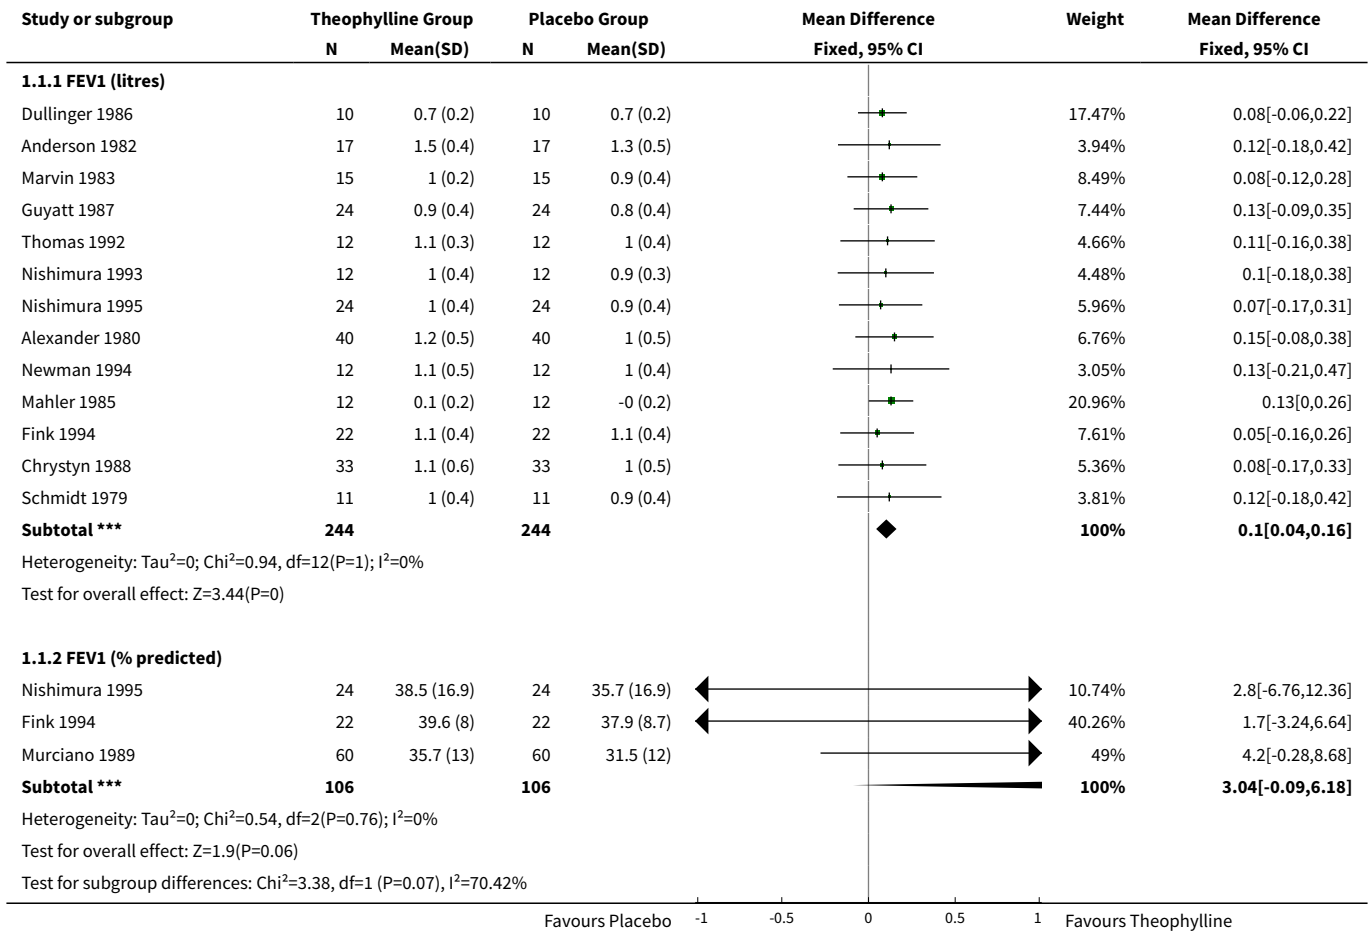

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Forced Expiratory Volume in one second	14		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
1.1 FEV1 (litres)	13	488	Mean Difference (IV, Fixed, 95% CI)	0.10 [0.04, 0.16]
1.2 FEV1 (% predicted)	3	212	Mean Difference (IV, Fixed, 95% CI)	3.04 [-0.09, 6.18]
2 Forced Vital Capacity	13		Mean Difference (IV, Fixed, 95% CI)	Subtotals only

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
2.1 FVC (litres)	11	392	Mean Difference (IV, Fixed, 95% CI)	0.21 [0.10, 0.32]
2.2 FVC (% predicted)	3	212	Mean Difference (IV, Fixed, 95% CI)	3.93 [0.22, 7.65]
3 Slow Vital Capacity (liters)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
4 Functional Residual Capacity	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
4.1 FRC - measured by helium dilution (liters)	1	66	Mean Difference (IV, Fixed, 95% CI)	0.15 [-0.54, 0.84]
4.2 FRC - measured by whole body plethysmography (liters)	1	66	Mean Difference (IV, Fixed, 95% CI)	-0.48 [-1.25, 0.29]
4.3 FRC (% predicted)	1	120	Mean Difference (IV, Fixed, 95% CI)	-4.0 [-16.54, 8.54]
5 Peak Expiratory Flow Rate (liters/min)	5	196	Mean Difference (IV, Fixed, 95% CI)	14.82 [-9.39, 39.04]
6 Total Lung Capacity	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
6.1 TLC - measured by helium dilution (liters)	1	66	Mean Difference (IV, Fixed, 95% CI)	0.52 [-0.25, 1.29]
6.2 TLC - measured by whole body plethysmography (liters)	1	66	Mean Difference (IV, Fixed, 95% CI)	-0.26 [-1.03, 0.51]
7 Residual Volume (litres)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
8 Trapped gas volume (liters)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
9 VO2max -maximum oxygen consumption (ml/min)	2	64	Mean Difference (IV, Fixed, 95% CI)	195.27 [112.71, 277.83]
10 PaO2 mmHg (arterial oxygen tension at rest)	6	312	Mean Difference (IV, Fixed, 95% CI)	3.18 [1.23, 5.13]
11 PaCO2 mmHg (arterial carbon dioxide tension at rest)	6	312	Mean Difference (IV, Fixed, 95% CI)	-2.36 [-3.52, -1.21]
12 SaO2 (oxygen saturation at rest %)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
13 Distance walked (m)	4	159	Std. Mean Difference (IV, Fixed, 95% CI)	0.30 [-0.01, 0.62]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
13.1 6MWD	2	115	Std. Mean Difference (IV, Fixed, 95% CI)	0.25 [-0.11, 0.62]
13.2 12MWD	2	44	Std. Mean Difference (IV, Fixed, 95% CI)	0.43 [-0.17, 1.03]
14 VAS (mm) 0 = extremely breathlessness, 100 = not at all breathless	2	54	Mean Difference (IV, Fixed, 95% CI)	3.61 [-4.62, 11.84]
15 Duration of resistive breathing (60% of P _i -max - minutes)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
16 Exercise challenge	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
16.1 Cycle endurance testing (minutes)	1	14	Mean Difference (IV, Fixed, 95% CI)	1.03 [-2.77, 4.83]
16.2 Progressive Cycle Ergometry (PCE) (min)	1	20	Mean Difference (IV, Fixed, 95% CI)	0.0 [-0.82, 0.82]
17 Heart rate (bpm)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
18 Symptoms	2		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
18.1 Wheezing (simple scales)	2	42	Mean Difference (IV, Fixed, 95% CI)	-0.19 [-0.58, 0.19]
18.2 Shortness of breath (simple scales)	2	42	Mean Difference (IV, Fixed, 95% CI)	-0.32 [-0.89, 0.25]
19 PC20 (mg/ml)	1		Mean Difference (IV, Fixed, 95% CI)	Subtotals only
20 Acute exacerbations	2	90	Risk Ratio (M-H, Fixed, 95% CI)	0.33 [0.10, 1.14]
21 Patient preference for theophylline or placebo	2	100	Risk Ratio (M-H, Fixed, 95% CI)	2.27 [1.26, 4.11]
22 Drop-outs	3	148	Risk Ratio (M-H, Fixed, 95% CI)	0.8 [0.23, 2.76]
23 Adverse effects	4		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
23.1 Nausea	3	78	Risk Ratio (M-H, Fixed, 95% CI)	7.67 [1.47, 39.94]
23.2 Insomnia	1	34	Risk Ratio (M-H, Fixed, 95% CI)	0.33 [0.01, 7.65]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
23.3 Dyspepsia	1	66	Risk Ratio (M-H, Fixed, 95% CI)	3.0 [0.33, 27.38]
23.4 Headaches	1	24	Risk Ratio (M-H, Fixed, 95% CI)	3.0 [0.13, 67.06]

Analysis 1.21. Comparison 1 Theophylline versus Placebo - crossover studies, Outcome 21 Patient preference for theophylline or placebo.

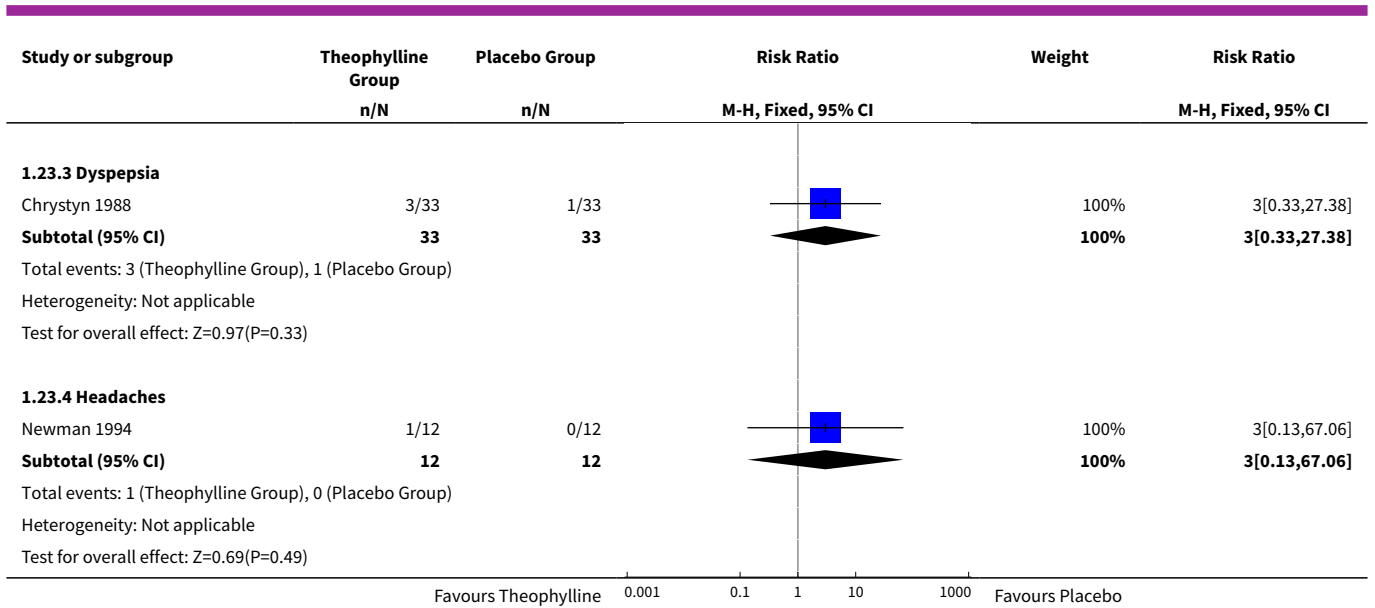

Analysis 1.22. Comparison 1 Theophylline versus Placebo - crossover studies, Outcome 22 Drop-outs.

Analysis 1.23. Comparison 1 Theophylline versus Placebo - crossover studies, Outcome 23 Adverse effects.

FEEDBACK

inconsistent (?) reporting

Summary

Dear Madam or Sir,

I have encountered the difficulty interpreting the results of the review by Ram et al. "Oral theophylline for chronic obstructive pulmonary disease".

1. In Results section it states: "Two studies with a total of 100 subjects (Anderson 1982, Mulloy 1993) reported that subjects preferred theophylline..."

2. In the metaview graph we see 50 patients (cross-over): 40 in Anderson study and 10 in Mulloy study.

3. In "Cachacteristics of the included studies" section, we read:

- Anderson 1982: Number of patients: 21 (I have confirmed that with Medline abstract)

- Mulloy: Number of patients: 10

My problem is the final number of patients that expressed their preference towards theophylline. Is it 100, as the authors say, 50 as appears from the metaview graph, or 31 (10 - Mulloy and 21 - Anderson) as one would expect from the total number of subjects in both trials?

I would appreciate your prompt response.

Sincerely,

Jan Brozek

I certify that I have no affiliations with or involvement in any organisation or entity with a direct financial interest in the subject matter of my criticisms.

Reply

Dear Dr Brozek,

Thank you for your interest in our review. You are correct in pointing out that the patient numbers do not add-up from the two studies for the outcome "preference".

The numbers in the results and meta-view are correct as they stand but unfortunately an incorrect reference was entered for one of the studies. Anderson 1982 should read as Alexander 1980.

In addition, the total number of patients in the results section should read as 50 (cross-over) not 100.

Once again thank you for your interest in our review and we apologise for the incorrect study reference. We will correct this error for the next issue of the Cochrane library.

Sincerely

Felix Ram
